Fathers and grandfathers of children with autism are more likely to work in the field of engineering, compared to fathers and grandfathers of typically developing children (Baron-Cohen et al, 1997, *Autism*). This is in line with higher rates of autism in geographical regions that have higher rates of people working in fields such as information technology, like Eindhoven in the Netherlands (Roelfsema et al, 2012, *JADD*). Such results are also consistent with the hyper-systemizing genetic theory of autism, which suggests that the genetics of autism overlaps with the genetics of strong systemizing talent. Mothers of children with autism in the San Fransisco Bay Area were more likely to work in STEM occupations (Windham et al, 2009, *Autism Research*). Mothers of children with autism also have elevated Systemizing Quotient scores (Grove et al, 2015, *BJP*) and faster/more accurate scores on the Embedded Figures Test of attention to detail (Baron-Cohen and Hammer, 1997, *J Cog Neurosci*). To date, no study has investigated the degrees that mothers of children with autism have studied, prior to having their child.
Objectives:
To test if mothers of children with autism were more likely to have studied (1) a Narrow STEM (science, technology, engineering, or mathematics) degree, and/or (2) a Broad STEM (e.g., linguistics, economics, and other systems-centred) degree, compared to mothers of typically developing children.
Methods:

We recruited 1,961 women, comprising 749 mothers of a child with autism, age 18-75 years old, registered at the online Cambridge Autism Research Database (CARD), and who had provided information about their degree type; and a control group of 1,212 age-matched mothers of a typically developing child who had registered at the online cambridgepsychology database, who had no family history of autism. All women selected their degree type from a drop-down menu of 180 degrees, and these were coded into Narrow STEM, Broad STEM, or Non-STEM, by two independent judges, with 100% agreement.
Results:
Of those women who had also completed the Autism Spectrum Quotient (AQ), mothers of children with autism scored higher than controls (p=0.0045), replicating earlier findings. A Chi Square test of Narrow STEM, Broad STEM, and Non-STEM degrees revealed that mothers of children with autism were more likely to have studied a STEM degree than mothers of typically developing children (Mothers of children with autism: 83%; mothers of typically developing children: 77.5%, Chi Square (1) = 8.84, p=0.003).
Conclusions:
This study is the first to show that mothers of children with autism are over-represented in STEM degrees in their graduate education. This association with risk of autism is likely to reflect both genetic factors (since maternal grandfathers are also over-represented in STEM) and prenatal epigenetic factors (since mothers of children with autism are more likely to have elevated endocrine conditions during pregnancy). Future research should test the genetic and epigenetic basis of this maternal group difference.

192 **166.192** Associations Between Exposure to Ambient Nitrogen Dioxide and Autism Spectrum Disorder in Israel: A Population-Based Nested Case-Control Study

R. Raz[1], *M. Weisskopf*[2], *D. M. Broday*[3], *Yuval*[3], *O. Pinto*[4] *and H. Levine*[1], *(1)Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem - Hadassah, Jerusalem, Israel, (2)Harvard School of Public Health, Boston, MA, (3)Faculty of Civil and Environmental Engineering, Technion, Israel Institute of Technology, Haifa, Israel, (4)Research and Planning Department, National Insurance of Israel, Jerusalem, Israel*

Background: Increasing evidence suggests that environmental exposures may contribute to risk of autism spectrum disorder (ASD). Several studies in the United States have suggested that perinatal air pollution exposure, and in some studies specifically traffic-related pollution, is associated with risk of ASD. Only two studies in Europe have examined this, but they did not see an association. However, those studies looked at autistic traits, or case status based on a traits scale cutoff, rather than clinically diagnosed ASD.
Objectives: To examine associations between various perinatal exposure periods to nitrogen dioxide (NO_2) - a marker of traffic-related pollution - and risk of ASD in the central coastal area of Israel.
Methods: We conducted a case-control study nested within the total population of children born in the central coastal region of Israel between the years 2005-2009. Children with ASD were identified from records of the Israel National Insurance Institute, which provides a service needs-independent financial benefit to families with children with expert physician-confirmed ASD. Our study sample included all children with ASD and a random sample of 20% of the children without ASD in the study area. Exposure was estimated by the new Optimized Dispersion Model (ODM), which takes into account output of a traffic allocation model (traffic volume and average speed per each road segment out of ~12,000 road segments) and half-hourly meteorological and air quality monitoring records from more than 20 monitoring stations distributed across the study area. The model calculates half-hourly NO_2 concentration estimates over the whole study area at 500X500m grid resolution. NO_2exposure was assigned to the children's home addresses based on their census tract at birth. We used generalized additive models with a binary outcome to estimate odds ratios (OR) and 95% confidence intervals (CI), adjusted for year and month of birth, child's sex, population group (Israeli Arabs / ultraorthodox Jews / general population), multiple births, parents immigration, census poverty index, paternal age, paternal wage, maternal age and maternal wage.
Results: The study sample included 2,098 children with ASD and 54,197 children without ASD. The median exposure for NO_2 during pregnancy was 16.8 ppb with an interquartile range (IQR) of 5.85 ppb. There was no indication of a non-linear association with NO_2 during pregnancy. The adjusted OR for ASD in the offspring per IQR NO_2 during pregnancy was 1.07 (95% CI: 0.99-1.17), with the 3rd trimester showing a stronger association (OR=1.10, 95% CI: 1.03-1.18) than the 1st trimester (OR=1.05, 95% CI: 0.98-1.12) and the 2nd trimester (OR=1.03, 95% CI: 0.96-1.10). Associations with exposure during the 1st and the 2nd years of life were slightly stronger (OR=1.10, 95% CI: 1.02-1.19 and OR=1.11, 95% CI: 1.03-1.20, respectively). Further adjustments for prematurity or gestational age at birth did not change the results.
Conclusions: Perinatal exposure to traffic-related air pollution in the central coastal area of Israel is associated with increased risk of autism, with stronger and significant associations observed for exposures beginning at the 3rd trimester.

193 **166.193** Autism Spectrum Disorder Administrative Prevalence in Texas School Children of Immigrant Parents

A. S. Dickerson[1] *and A. S. Dickerson*[2], *(1)Office of Research and Development, Environmental Protection Agency, Durham, NC, (2)Argosy University, Atlanta, GA*

Background: Texas is the second most populated state in the US and has the third highest foreign-born population. Although the etiology of autism spectrum disorder (ASD) is not well understood, migration and ethnicity have been implicated as possible risk factors. However, results from studies on associations between immigration and ASD diagnosis and prevalence have been conflicting.
Objectives: To (1) calculate administrative estimates of children from homes speaking 128 different languages enrolled in Texas schools systems (2) investigate differences in ASD administrative prevalence by comparing estimates for immigrant populations to that of English-speaking children with ASD in Texas school systems.
Methods: We conducted a cross-sectional study using data from educational records of children from pre-K to 12th grade ranging from age 3 to 22 years provided by the Texas Education Agency (TEA). Through a Public Information Request, the total number of children meeting eligibility to receive autism services from TEA was provided in aggregate form from the TEA Special Education Data Book. Additionally, TEA was able to provide cross referenced data on students who met autism eligibility criteria within 128 specific language groups based on reports from Home Language Surveys (HLS). ASD administrative prevalence estimates for Texas students were derived using the total number of children with an educational autism designation stratified by reported home language. Additionally, languages were grouped by primary geographic region and administrative prevalence estimates for geographic regions were calculated. Lastly, using 2 by 2 tables, relative risks and 95% confidence intervals were calculated for administrative estimates of these languages with English language as a reference.
Results: Data for 1225 Local Education Agencies (LAEs), showed that 100% of schools provided services to English-speaking children. Of these 89% also reported serving children whose home language was Spanish. There were approximately 35,555 children of from English-speaking households with an ASD educational designation, accounting for 81% of all children with an ASD designation. Of the 11,524 children from homes speaking Chinese languages, 129 had a TEA autism educational designation, making the estimated risk of ASD 37% higher for these children compared to children from English speaking households (RR=1.37; 95% CI: 1.19, 1.54). Furthermore, although risk of ASD education designation was significantly higher in children of families from West Africa (RR=3.53; 95% CI: 3.26, 3.80), East Africa (RR=2.05; 95% CI: 1.72, 2.37), and South Africa (RR=3.72; 95% CI: 2.76, 4.69), results were not significant for those from Central Africa (RR=1.33; 95% CI: 0.79, 1.87).
Conclusions: Studies of differences based on ethnicity and country of origin could yield results that will contribute to more knowledge on factors associated with receiving an ASD diagnosis. Additionally, social stigma and language barriers may reduce diagnosis and identification of immigrant children with ASD, suggesting that the increased administrative prevalence seen in our study may only be a small indicator of a potentially larger prevalence. The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

194 **166.194** Combined Exposures to Prenatal Pesticides and Folic Acid Intake in Relation to Autism Spectrum Disorders

R. J. Schmidt[1], *V. Kogan*[2], *J. Shelton*[3], *L. Delwiche*[4], *R. Hansen*[5], *S. Ozonoff*[6], *D. J. Tancredi*[7], *I. Hertz-Picciotto*[8] *and H. E. Volk*[9], *(1)Public Health Sciences and the MIND Institute, University of California at Davis, Davis, CA, (2)3Departments of Preventive Medicine and Pediatrics, Zilkha Neurogenetic Institute, Keck School of Medicine, Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)Public Health Sciences, University of California, Davis, Davis, CA, (5)Pediatrics and the MIND Institute, University of California Davis, Davis, CA, (6)UC Davis MIND Institute, Sacramento, CA, (7)Pediatrics, UC Davis School of Medicine, Sacramento, CA, (8)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (9)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background:
Many pesticides are neurotoxic by design and some have been linked to autism spectrum disorder (ASD). Periconceptional folic acid (FA) is associated with reduced ASD risk. In animal studies, maternal FA provides protection from environmental chemicals with developmental toxicity.
Objectives:
We examined combined exposures to maternal FA and selected pesticides, both in-home and agricultural, in relation to ASD risk.
Methods:
California children aged 24-60 months enrolled in the CHARGE case-control study from 2003-2011 were clinically confirmed to have ASD (n=505) or typical development (n= 346). Maternal supplemental FA intake before and during pregnancy and indoor use of products containing pesticides were retrospectively collected by telephone interview. Agricultural pesticide exposure was determined by linking mothers' addresses shortly before, during, and after pregnancy to California's commercial Pesticide Use Reports using 1250 m buffers.
Results:
For all comparisons, the reference group was women with above-median FA intake (800+ µg) during the first pregnancy month and no pesticide exposure. ORs were adjusted for home ownership. Women with <800 µg FA intake and regular exposure (for 6+ pregnancy months) to indoor pesticides had children with elevated ASD risk (OR=5.1, 95% CI: 2.3-11.4). This was over twice that of those with 800+ µg FA and regular pesticide exposure (OR=2.3, 1.3-4.1). ORs for combined low maternal FA intake and any exposure to agricultural pesticides 3 months before or after conception were: 1.6 (0.6-4.4) for chlorpyrifos, 2.1 (1.0-4.4) for organophosphates, 1.9 (0.9-4.1) for

pyrethroids, and 2.1 (0.7-5.9) for carbamates. Except for carbamates, these ORs were larger than those for combinations of pesticide exposure with higher FA intake. All results were consistent with joint multiplicative or additive effects.
Conclusions:
Supplemental FA could potentially reduce the risk of ASD associated with pesticide exposure. Larger studies and research on potential mechanisms are warranted.

195 **166.195** Development and Validation of a Streamlined Autism Case Confirmation Approach for Use in Epidemiologic Risk Factor Research

C. J. Newschaffer[1], *E. Schriver*[1], *L. Berrigan*[2], *R. Landa*[3], *W. L. Stone*[4], *S. L. Bishop*[5], *A. Golden*[6], *L. V. Ibanez*[4], *A. Kuo*[7], *K. D. Lakes*[8], *D. S. Messinger*[9], *S. J. Paterson*[10] *and Z. Warren*[11], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)AJ Drexel Autism Institute, Philadelphia, PA, (3)The Kennedy Krieger Institute, Baltimore, MD, (4)Department of Psychology, University of Washington, Seattle, WA, (5)Department of Psychiatry, University of California San Francisco, San Francisco, CA, (6)Icahn Schol of Medicine at Mount Sinai, New York, NY, (7)Health Care Transitions Research Network for Autism Spectrum Disorders, Los Angeles, CA, (8)Pediatrics, University of California, Irvine, Irvine, CA, (9)Psychology, University of Miami, Coral Gables, FL, (10)Department of psychology, Temple university, Philadelphia, PA, (11)Vanderbilt University, Nashville, TN*

Background: The cost and effort associated with incorporating standardized observational assessments and diagnostic interviews in large-scale epidemiologic studies of autism spectrum disorders (ASD) risk factors can be substantial. More streamlined approaches for confirming ASD case status would benefit the implementation of these studies.
Objectives: To evaluate the performance of three streamlined ASD case confirmation approaches, alone and in combination, for potential application in large epidemiologic studies.
Methods: We conducted a multi-site, cross-sectional criterion validity study in a convenience sample of 388 three-year olds scheduled for neurodevelopmental evaluation that broadly represent children who would fail a stage 1 screen like the M-CHAT. ASD case classification as determined by a battery of three novel assessment instruments (the Early Video-guided Autism Screener E-VAS; the Autism Screening Interview, ASI; the Screening Tool for Autism in Toddlers Extended, STAT-E), each of which designed to be administered in less than 30 minutes by lay staff, was compared to case-classification based on the DSM-based diagnostic assessment from a qualified clinician. Sensitivity and specificity of each instrument alone and in combination were estimated. Order of instrument administration was randomly assigned. Alternative cutpoints were identified under different criteria and two-stage cross validation was used to avoid overfitting. Findings were interpreted in the context of a simulated prospective pregnancy cohort study seeking to estimate relative risks (RRs) of varying strengths for dichotomous exposures of varying prevalences using a two-stage case finding approach where the first stage would be a screener like the M-CHAT and the second stage would be case confirmation based on the instruments tested here. The bias introduced in RR estimation under different case-confirmation approaches was calculated, informed by the sensitivity and specificity estimates for each of the alternative approaches developed here.
Results: Under the instruments' initial recommended cutpoints, sensitivity ranged from 0.63 to 0.94 and specificity from 0.34 to 0.70. Alternative cutpoints that gave equal weight to sensitivity and specificity resulted in sensitivity estimates ranging from 0.56 to 0.84 and specificity ranging from 0.45 to 0.77. Additional sets of alternative cutpoints holding sensitivities at 50% resulted in specificities near 80%. And, while these were lower than the >80% for both sensitivity and specificity that comes with using ADOS and ADI-R in combination (Kim and Lord, 2012), this lower sensitivity and specificity had only modest effect on the extent of bias in dichotomous exposure RR estimates. Several strategies (including use of the direct observation STAT-E alone and the combined administration of the parent interview ASI and parent self-report E-VAS) resulted in performance suitable for application as a second stage case-confirmation tool in an epidemiologic study like that considered here.
Conclusions: Use of more streamlined methods of case-confirmation in large-scale prospective cohort epidemiologic investigations of ASD risk factors appears feasible.

196 **166.196** Development of an Automated Classification Algorithm for the Surveillance of Autism Spectrum Disorder

M. J. Maenner[1], *M. H. Yeargin-Allsopp*[1], *K. Van Naarden Braun*[2], *D. Christensen*[3] *and L. A. Schieve*[2], *(1)Centers for Disease Control and Prevention, Atlanta, GA, (2)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, (3)Centers for Disease Control (CDC), Atlanta, GA*

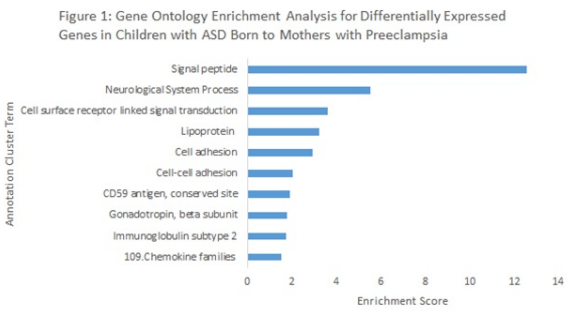
Background: The Autism and Developmental Disabilities Monitoring (ADDM) Network conducts population-based surveillance of autism spectrum disorder (ASD) among 8-year old children in multiple US sites. Each ADDM site collects special education records and/or medical records from providers who evaluate children for developmental problems. Information is abstracted from developmental evaluations that contain descriptions of behaviors consistent with ASD. Trained clinicians then review all abstracted evaluations to determine whether the child meets the ASD surveillance case criteria. The number of abstracted evaluations has dramatically increased since the year 2000, affecting the resources and timeliness of the surveillance system.
Objectives: To develop and evaluate a machine-learning classifier that predicts surveillance ASD case status using the words and phrases contained in children's developmental evaluations.
Methods: We used data from the 2008 metropolitan Atlanta ADDM site to create an algorithm that predicts whether a child meets ADDM ASD case status using words and phrases contained in the child's developmental evaluations. The sample comprised 1,162 children (including 601 meeting ADDM ASD case status) with a total of 5,396 developmental evaluations. Evaluations for each child were concatenated into a single file, and the text was processed to remove punctuation, remove the suffixes of words, and count the occurrence of all words and 2-3-word phrases. A random forest algorithm constructed 10,000 classification trees to identify the words and phrases that were informative for predicting ASD case status. We trained a second, "final", random forest classifier using only the informative words and phrases. We assessed the algorithm's performance by having it predict ASD case status for the records collected by the metropolitan Atlanta ADDM site for the 2010 surveillance year (1,450 children with 9,811 evaluations; 754 children met ADDM ASD case status). We compared the algorithm's predictions to the clinician-assigned case classifications. We also estimated ASD prevalence based on the algorithm's classifications.
Results: The algorithm predicted ASD case statuses that were 86.6% concordant with the clinician-determined case statuses (84.1% sensitivity, 89.4% predictive value positive). The area under the resulting receiver-operating characteristic curve was 0.932. The algorithm was more likely to disagree with the clinician ratings on records where the clinicians indicated greater uncertainty about the case classification. Algorithm-derived ASD "prevalence" for 2010 metropolitan Atlanta study area was 1.46% compared to the published (clinician-determined) estimate of 1.55%.
Conclusions: A machine-learning algorithm was able to discriminate between children that do and do not meet ASD surveillance criteria by using the text contained in developmental evaluations. The 86.6% algorithm-clinician agreement is somewhat lower than the 90.7% inter-clinician agreement observed for the 2010 ADDM Network. While there are many logistical issues to explore (such as whether performance would be similar at other ADDM sites), this approach has the potential to improve the efficiency of ASD surveillance. In addition, classification algorithms trained on the ADDM surveillance data may ultimately be useful to other studies or activities that seek to ascertain ASD from electronic information.

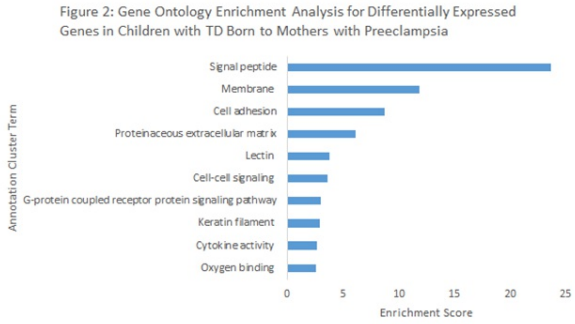
197 **166.197** Differential Gene Expression in Children with Autism Spectrum Disorder Born to Mothers with Preeclampsia

Y. Mukhtar[1], *I. Hertz-Picciotto*[2], *B. Durbin-Johnson*[3], *S. Letovsky*[4] *and C. Walker*[5], *(1)UC Davis MIND Institute, Sacramento, CA, (2)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (3)Public Health Sciences, School of Medicine, University of California, Davis, Davis, CA, (4)SynapDx Corp, Milton, MA, (5)University of California, Davis, Sacramento, CA*

Background:
While autism spectrum disorder (ASD) is one of the most heritable neurobehavioral conditions, the heterogeneity of ASD-concordant twins supports a role for alternative mechanisms in its etiology. Maternal physiology and environmental factors can modify gene expression in-utero independent of the genes inherited and thus can influence neurogenesis and brain development. Preeclampsia is a pregnancy condition associated with poor placentation, progressive maternal inflammation and insulin resistance, and increased odds for ASD. Global gene expression profiling of children with ASD may illuminate underlying metabolic and signaling alterations that may be relevant to the pathobiology of ASD.
Objectives:
1) To identify genes that are differentially expressed in children with ASD born to mothers with preeclampsia, and 2) To determine how preeclampsia expression profiles differ between children with ASD and typical development (TD).
Methods:
This study involved 2-5 year-old children enrolled in the CHildhood Autism Risk from Genetics and the Environment (CHARGE) population-based case-control study. Maternal preeclampsia diagnoses were abstracted from medical records. ASD diagnosis was confirmed with ADI-R and ADOS. Typically-developing controls were assessed using the Mullen Scales of Early Learning, Vineland Adaptive Behavior Scales, and Social Communications Questionnaire. RNA sequencing of peripheral blood obtained from child participants was performed on the Illumina HiSeq 2000 platform. Sequences that failed quality control or had fewer than 30 million reads were discarded, leaving 147 ASD and 70 TD samples. Reads were aligned to hg19 using Bowtie and converted to a counts table using HTSeq. To address differences in sequencing depth between samples, the counts table was normalized using binomial down-sampling. Within child diagnostic categories, we assessed whether presence of a preeclampsia diagnosis versus the absence of PE was associated with child gene expression using a negative binomial generalized linear model in the Bioconductor package edgeR with Benjamini-Hochberg FDR correction with adjustments for maternal education, child gender and ethnicity, and time from previous meal to blood draw. Gene ontological analyses were performed by the DAVID bioinformatics tool.
Results:

Hundreds of genes were differentially expressed in children exposed to preeclampsia in-utero. Ontological analyses performed on genes with a log2 fold change over 1 and under -1 indicated significant enrichment of pathways involved in nervous system development, immune function, and inflammation in children with ASD. While there was some overlap in children with TD exposed to maternal preeclampsia, interesting differences included enhancement of cell-cell signaling and oxygen binding pathways.
Conclusions:
Fetal exposure to maternal preeclampsia is associated with differential expression of many pathways. Heightened maternal systemic inflammation has been suggested as a possible factor influencing ASD susceptibility mediated through an oxidative stress response in the fetus. These processes may be enhanced by genes involved in immunity and inflammation in children with ASD and moderated by pathways involved in oxygen binding in children with TD. Exploration of these biological pathways and potentially-alterable upstream environmental gene influences may elucidate the complex interplay between maternal gestational environment and child gene expression in ASD etiology.





198 **166.198** Do Women with Polycystic Ovary Syndrome (PCOS) and Their Children Have Elevated Rates of Autism? an Electronic Health Records Study in the UK

A. Cherskov[1], *A. L. Pohl*[1], *C. Allison*[1], *R. A. Payne*[2] *and S. Baron-Cohen*[1], *(1)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (2)Primary Care Unit, Institute of Public Health, University of Cambridge, Cambridge, United Kingdom*

Background: Elevated levels of prenatal testosterone may increase the risk for autism spectrum conditions (autism). There is also an association between autism and polycystic ovarian syndrome (PCOS) in women with autism and mothers with a child with autism, although the extent of this association remains obscure. Given that PCOS is also associated with elevated prenatal and circulating testosterone, hyperandrogenism in PCOS may be implicated in the development of autistic traits in women with PCOS and their children.
Objectives: **1.** To examine the prevalence of autism in women with PCOS, and conversely, PCOS in women with autism. **2.** To calculate the odds of developing autism in first-born children of women with PCOS.
Methods: Using electronic health records obtained from the Clinical Practice Research Datalink (CPRD) in the UK, we conducted two matched case-control studies. **1.** We examined the prevalence and risk of PCOS in women with autism and vice versa in a sample of n = 791 and n = 22,263 women, respectively, compared to up to five times as many age and GP practice matched controls. Frequency tables were calculated and differences tested using Chi-Square Test for Proportions. **2.** We examined the risk of autism in first-born children of women with PCOS in a population of n = 8,611 children with mothers with PCOS matched to up to five times as many controls. Cases and controls were linked to mothers using the Mother-Baby Link within the CPRD. Controls were matched on gender, GP practice, and year of birth within ± two years. Two models adjusting for covariates were generated using conditional logistic regression. The first adjusted for maternal age, marital status, and maternal psychiatric diagnoses, while the second also included obstetric complications and metabolic conditions. Autism diagnoses were based on previously validated Read code lists (Fombonne et al., 2004; Smeeth et al., 2004). PCOS was defined according to Read code PCOS diagnoses (polycystic ovarian syndrome, C165.00, and Stein-Leventhal syndrome, C164.12), as well as by phenotypic parameters, where women with a PCO diagnosis, in addition to ovulatory dysfunction and/or hyperandrogenism, according to Rotterdam criteria, were included.
Results: **1.** We found significantly increased rates of PCOS in women with autism (2.3% vs. 1.1%, P = 0.006) and significantly elevated rates of autism in women with PCOS (0.23% compared with 0.09%, P < 0.001). **2.** The odds of having a child with autism for mothers with PCOS was also significantly increased, both in the unadjusted model and following adjustment for marital status, maternal psychiatric diagnoses, obstetric complications, and metabolic conditions (unadj. OR: 1.58, 95% CI: 1.27 – 1.98; adj. OR: 1.35, 95% CI: 1.06 – 1.71).
Conclusions: These two large-scale epidemiological studies present evidence that women with PCOS and their children have a greater prevalence of autism. Prenatal and maternal sex-steroids may be a potential source of this association.

199 **166.199** Does Breastfeeding Protect Against Autism? a Birth Cohort Study

G. Wellby[1], *J. Golding*[2], *A. L. Guyatt*[3], *A. M. Emond*[1] *and* ***D. Rai***[4], *(1)University of Bristol, Bristol, United Kingdom, (2)Centre for Child and Adolescent Health, University of Bristol, Bristol, United Kingdom, (3)University of Bristol, Bristol, United Kingdom of Great Britain and Northern Ireland, (4)University of Bristol, Bristol, England, United Kingdom*

Background: It is suggested that breastfeeding may protect against autism spectrum disorder. However, to date only a handful of epidemiological studies have examined this relationship and have reported inconsistent findings. All previous studies were based on retrospective maternal recall about breastfeeding, sometimes more than ten years after birth, which left them vulnerable to recall bias. In addition most studies did not make attempts to account for potential confounders.
Objectives: To study the associations between prospectively collected information on the intention, initiation and duration of breastfeeding and 1) a diagnosis of autism and 2) symptoms of autism in a large birth cohort study.
Methods: We used data from the Avon Longitudinal Study of Parents and Children (ALSPAC), a birth cohort study in England which recruited 14,541 pregnant women in the Bristol area who had an expected delivery date between April 1991 and December 1992, resulting in 14062 live births. We used prospectively collected data on the intention to breastfeed (collected at 32 weeks of pregnancy), and the initial and duration of breastfeeding (collected post partum at 6 and 15 months). Using these we classified these variables into no intention, less than one month, more than one month and uncertain from the beginning. Another binary variable was created for ever having breastfed versus never. Finally we used the age in months at which any breastfeeding was stopped, whether partial or exclusive, as a continuous measure of duration to test whether any associations might be cumulative. Cohort children with an ASD diagnosis were identified by record linkage with health and education records, or maternal report of having being told the child had autism (n=134). Symptoms suggestive of autism were ascertained by 4 scales that combine optimally within ALSPAC to predict ASD: the Children's Communication Checklist (coherence subscale), the Social and Communication Disorders Checklist, a repetitive behaviour measure, and the Emotionality, Activity and Sociability scale (sociability subscale). These measures were dichotomised, with approximately 10% defined on each scale as having highest autistic traits.
Results: There was no evidence for an association of ever being breastfed in relation to a diagnosis of autism (adjusted OR 1.12 [95% CI 0.64 to 1.95]) but some evidence of a protective effect on impairment in autism related measures of coherence (adjusted OR 0.73 [95% CI 0.51-0.91]) and sociability (adjusted OR 0.83 [95% CI 0.70-1.00]). Similar results were found in analyses on intention to breastfeed and the total duration of breastfeeding.
Conclusions: In this population-based prospective cohort study, we did not find evidence to support the hypothesis that breastfeeding protects against autism spectrum disorders. We did observe some associations between breastfeeding and lower scores on some autistic traits. Whether this is the result of residual confounding or a truly protective effect, and if so, the pathway of this relationship deserves further investigation.

200 **166.200** EU-AIMS Clinical Network: Building a Large Scale European Data Resource

J. E. Tillmann[1], *K. L. Ashwood*[2], *E. Loth*[3], *J. K. Buitelaar*[4], *D. G. Murphy*[5] *and T. Charman*[6], *(1)Institute of Psychiatry Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, London, United Kingdom of Great Britain and Northern Ireland, (3)Institute of Psychiatry, King's College London, London, England, United Kingdom of Great Britain and Northern Ireland, (4)Radboud University Medical Centre, Nijmegen, Netherlands, (5)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: The complexity and heterogeneity of Autism Spectrum Disorder (ASD) makes it necessary to obtain large-scale samples which are difficult to acquire from one site alone. While North American networks such as the IAN (Interactive Autism Network) and ATN (Autism Treatment Network) are increasingly active in pooling data from multiple sites for informative analysis, similar large scale collaborative efforts have been largely neglected in Europe. In response, EU-AIMS (European Autism Interventions -

A Multicentre Study for Developing New Medications), a public-private consortium of leading research centres and industry, set up a unique platform to collaboratively pool European data. This will provide researchers with a resource to answer important questions about the prevalence, causes, and trends in the diagnosis and treatment of ASD, as well as boosting research capacity across Europe.
Objectives: A data sharing platform was set up to collect historical anonymous data from major ASD clinical and research institutions across Europe who are part of the EU-AIMS clinical network. This clinical network now includes 93 sites across 37 countries, giving unique access to a large and heterogeneous cohort of well-characterised ASD patients across different age groups, ability levels, countries and cultures.
Methods: Sites within the EU-AIMS clinical network were contacted to indicate their willingness to share phenotypic, behavioural, and cognitive data for secondary analysis. The pooled data includes information on demographic and clinical characteristics (e.g. sex, age, diagnosis, co-morbidity and ethnicity), as well as core autism symptomatology (e.g. ADI-R, ADOS, SRS, SCQ, AQ), IQ (e.g. WASI, WISC) and behavioural measures (e.g. VABS, CBCL). Item level data for each measure was collected where possible.
Results: Whilst data sharing with sites is still on-going, 20 sites situated in 9 different European countries have already completed the data sharing process. A total of 4118 individuals (males = 3220, females = 898) with a diagnosis of an ASD are currently in the database. Of those, 2226 are children (0-11 years), 1026 are adolescents (11-17 years), and 648 are adults. In addition, 672 individuals across all age groups (males = 344, females = 328) that did not meet a formal diagnosis of ASD are also characterised using these core measures.
Conclusions: Pooling datasets across European clinical and research sites as part of EU-AIMS will help to establish a valuable resource for ASD research in Europe. In the future, this resource will not only boost research capacity, but also improve transparency, openness and research efficiency of autism research in Europe.

201 **166.201** Food Selectivity and Taste/Smell Sensitivity in Children with Autism Spectrum Disorder

L. T. Chistol[1], *A. Must*[2], *S. M. Phillips*[2], *C. Curtin*[3] *and L. G. Bandini*[3,4], *(1)College of Health & Rehabilitation Sciences, Sargent College, Boston University, Boston, MA, (2)Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, (3)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Charlestown, MA, (4)Department of Health Sciences, Boston University, Boston, MA*

Background: Food selectivity is a common feeding problem in children with autism spectrum disorder (ASD) and is associated with increased risk of nutrient deficiencies. Children with ASD exhibit varying degrees of food selectivity, which may reflect differences in sensory processing, specifically taste/smell sensitivity (TSS). Studies on the association between atypical sensory characteristics and food selectivity in children with ASD compared to children without ASD are lacking.
Objectives: We compared the sensory profiles of children with and without ASD. Among children with ASD we further examined the association of TSS and food selectivity, as well as the relationship between TSS and fruit and vegetable repertoire.
Methods: The Children's Activity and Meal Patterns Study, a cross-sectional study conducted in 2007-2008, enrolled 53 children with ASD and 58 children without ASD, ages 3-11 years. Children's TSS scores were determined by parent-report on the Sensory Profile and analyzed as typical/atypical and as a continuous variable. TSS scores were derived from a subset of items from the oral sensitivity score and are equivalent to the TSS subset on the Short Sensory Profile. Food selectivity was operationalized as food refusal and limited food repertoire. Food refusal was assessed using a modified FFQ completed by one parent and expressed as the proportion of indicated foods refused by their child of those offered. Food repertoire, defined as the absolute number of unique foods and beverages the child consumed, was quantified from 3-day food records. Fruit and vegetable repertoire was determined by the number of unique fruits and vegetables consumed on the FFQ, which lists 13 fruits and 20 vegetables.
Results: Compared to children without ASD, children with ASD had significantly lower scores on all nine sensory factors of the Sensory Profile (all $p<0.05$), indicating atypical sensory characteristics. More children with ASD were classified as atypical on TSS compared to children without ASD (66% vs. 6%, $p<0.001$). Among children with ASD, TSS scores were significantly correlated with food refusal ($r=-0.67$, $p<0.001$), food repertoire ($r=0.33$, $p=0.03$), number of unique fruits consumed ($r=0.45$, $p<0.01$), and number of unique vegetables consumed ($r=0.55$, $p<0.001$). Compared to children with ASD classified as typical TSS, those atypical for TSS had significantly higher levels of food refusal (52% vs. 25%, $p<0.001$). In addition, the number of unique fruits (5.3 vs. 8.2, $p<0.01$), unique vegetables (4.2 vs. 8.9, $p<0.001$), and total food repertoire (17.9 vs. 20.7, $p=0.08$) were lower among children with ASD classified as atypical TSS compared to those typical for TSS.
Conclusions: More children with ASD present with atypical sensory characteristics compared to children without ASD. Atypical taste/smell sensitivity is associated with higher rates of food refusal and consumption of fewer unique fruits and vegetables. These findings suggest that children with ASD who have elevated taste/smell sensitivity may benefit from interventions to address their sensory challenges in order to increase food variety, to help ensure that they consume a diet that will meet their nutritional needs for growth and development.

202 **166.202** From Epi to Decisions: Use of Navigation Guide Systematic Review Methodology to Summarize the Evidence for Decision-Making

J. Lam[1], *P. Sutton*[1], *A. Halladay*[2], *A. Kalkbrenner*[3], *G. C. Windham*[4], *L. Davidson*[5], *C. Lawler*[6], *C. J. Newschaffer*[7], *N. Daniels*[1], *S. Sen*[8] *and T. Woodruff*[1], *(1)Program on Reproductive Health and the Environment, University of California, San Francisco, San Francisco, CA, (2)Autism Science Foundation, New York, NY, (3)University of Wisconsin-Milwaukee, Milwaukee, WI, (4)California Department of Public Health, Richmond, CA, (5)University of California at San Francisco, San Francisco, CA, (6)National Institute of Environmental Health Sciences, RTP, NC, (7)A.J. Drexel Autism Institute, Philadelphia, PA, (8)University of California, San Francisco, San Francisco, CA*

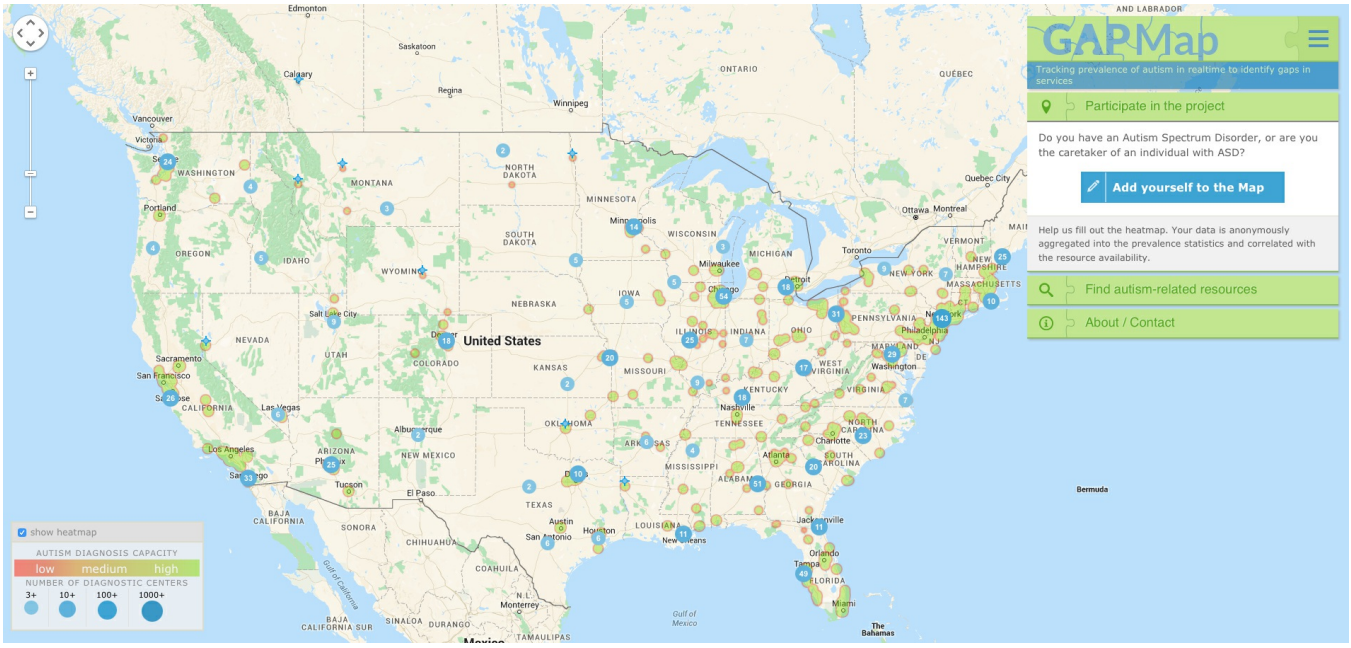
Background: Evaluating the toxicological and epidemiological literature and determining the quality and strength of evidence are critical for informing health and policy recommendations, including risk of air pollution to ASD. The Navigation Guide was developed through a collaboration of 22 clinicians and scientists to improve methods of research synthesis in environmental health. This systematic and transparent approach is modeled after best practices in evidence-based medicine but accounts for the differences in the evidence and decision context of environmental health.
Objectives: To support proof-of-concept of the method, we applied the Navigation Guide methodology to answer the question: Does developmental exposure to air pollution affect diagnosis of Autism Spectrum Disorder (ASD)? Our intent was to identify and evaluate the relevant body of evidence from human studies and come to a final bottom-line conclusion regarding the quality and strength of evidence to support our study question.
Methods: We gathered a panel of experts with expertise relevant to the study question, developed a protocol, conducted a systematic search of the epidemiology literature, and identified relevant studies using pre-specified criteria. Summary effect estimates from studies were synthesized both qualitatively and quantitatively. We adapted empirically-based clinical medicine quality and risk of bias tools to assess individual studies and to rate the quality and strength of the entire body of evidence for toxicity.
Results: We identified 23 relevant human studies. The human body of evidence was rated as "moderate" quality. Through this case study, we identified several challenges hindering the ease of integrating evidence from different sources of information. In particular, evaluating exposure assessment of air pollution was done using various methods and sources of data (for instance, monitoring, modeling, biomarkers, or a combination of several of these) and reliability of these methods may vary by chemical contaminant. As such, current tools available for evaluating the internal validity of individual studies (i.e., risk of bias) are insufficient for addressing these nuances. Therefore, as part of this case study we modified our current risk of bias tool in a novel attempt to address exposure assessment of air pollution. Furthermore, additional study design and reporting challenges were identified and addressed as potential hindrances to the integration of evidence from different epidemiology studies.
Conclusions: We concluded that there was moderate evidence from the human epidemiology evidence to support an association between developmental exposure to air pollution and diagnosis of ASD. This case study demonstrated that the Navigation Guide can be used to apply the rigor of systematic review methodology to reach actionable conclusions in environmental health decision-making. As part of this case study we also developed a novel risk of bias tool for evaluating the air pollution exposure measurement techniques as well as identified further research limitations potentially hindering the incorporation of epidemiology literature to decision making to protect the public.

203 **166.203** Gapmap: Enabling Comprehensive Autism Resource Epidemiology

D. Wall, ***J. Daniels*** *and N. Albert, Stanford University, Palo Alto, CA*

Background:
ASD has been attracting more interest recently as a result of skyrocketing prevalence rates of 1 in 68 children. Comprehensive regional autism prevalence rates would be extremely helpful for determining the true prevalence of autism and correlating genetic and environmental factors with higher standards of significance. In particular, comparing geographic trends in prevalence rates to autism resource epidemiology would be invaluable in invaluable in revealing patient care deficits. Finding these *resource gaps*, regions in which there exist limited diagnostic or treatment resources with respect to the demand, can back up pushes for congressional change with hard data, allocate resources more efficiently, and provide information to emerging organizations and businesses to let them know where their services are most needed. These efforts can help reduce the time to diagnosis and increase the chances that speech and behavioral therapies are started during critical periods when they are maximally impactful.
Objectives:
The specific aims of this study were to: 1) obtain an early approximation of the disconnect between autism resources and diagnosed individuals by determining the average distance between an individual with autism and the nearest diagnostic center, 2) define useful metrics that can be used to determine if a center is overloaded or if a region is underserved, and 3) create an online tool to collect information pertaining to geographic variations of autism prevalence and the geographic resource utilization of autism resources.
Methods:
The Wall Lab created an application, GAPMap, to collect locational, diagnostic, and resource use information from individuals with autism in order to compute accurate prevalence rates and better understand autism resource epidemiology. The metrics *resource load, resource gap,* and *resource availability* were defined to aid in this purpose, and estimates were calculated with limited datasets.

Results:
The average distance from an individual in the United States to the nearest diagnostic center is approximately 182 kilometers (50 miles), with a standard deviation of 235 kilometers (146 miles). The dataset for the United States was comprised of 47,622 individuals with autism and 840 developmental and diagnostic medical centers.
Conclusions:
While these analyses and metrics highlight the lack of resources in much of the United States and the overburdening of many centers, they are not enough. We have built GAPMap as a tool to collect important information and visually display the results. The collected location information, diagnosis, diagnostic tools, and co-morbid conditions will be used obtain both widespread and highly localizable autism prevalence rates. Date of diagnosis and age will be aggregated and used to obtain localizable average age of diagnosis, a measure that correlates with difficulty obtaining a diagnosis and can be used to help approximate geographic differences in resource accessibility. Ratings and local services will be used to estimate resource usage trends with respect to geography and resource density. Prevalence rates and local service usage will also be used to calculate resource load and availability for different resource types, such as behavioral therapy.



204 **166.204** Gestational Age and the Risk of Autism Spectrum Disorders: Findings from the Stockholm Youth Cohort

L. Xie[1], C. Magnusson[2], D. Rai[3], C. Dalman[2] and B. Lee[4], (1)Drexel University School of Public Health, Philadelphia, PA, (2)Karolinska Institutet, Stockholm, Sweden, (3)University of Bristol, Bristol, United Kingdom, (4)Drexel University, Philadelphia, PA

Background: The rising prevalence of autism spectrum disorders (ASD) is mainly driven by the increase in high-functioning ASD (i.e. ASD without intellectual disability (ID)). Gestational age at birth (GA) has been identified as a risk factor of ASD. However, the question of how the specific length of gestation might increase the risk of ASD remains unanswered.
Objectives: We investigated the relationship between GA and high- vs. low-functioning ASD, by quantifying the risk of ASD by each week of gestation in individuals with and without co-occurring ID.
Methods: A sample of 483,843 non-adopted, singleton live births between 1984 and 2007 was derived from the Stockholm Youth Cohort, a register-based cohort in Stockholm County, Sweden. Case status was ascertained using national and regional registers covering all pathways to ASD diagnosis and care in Stockholm County. A total of 9,325 ASD (2,319 ASD with ID, 7,006 ASD without ID) cases were included in the study sample. Splines in generalized additive models were used to model the non-linear relation of GA with ASD, adjusting for sex, birth year, parity, parental ages, gestational diabetes, gestational hypertension, maternal BMI at first antenatal visit, maternal history of depression, family income, maternal educational attainment and maternal country of origin.
Results: The prevalence of both high- and low-functioning ASD was increased in pre- and post-term births. There were approximately 17 individuals with ASD per 1,000 live births at term (GA = 40 weeks). This measure was 43 per 1,000 among very preterm births at 28 weeks of GA, and 25 per 1,000 among post-term births at 43 weeks of GA. The risk of high-functioning ASD monotonically decreased as GA increased. Odds ratios (95% confidence interval) of ASD without ID among those born at 28 and 43 weeks of GA was 2.0 (1.6–2.4) and 0.9 (0.9–1.0), respectively, compared to the risk of ASD in term births. On the other hand, the risk of low-functioning ASD was elevated in both pre- and post-term births. Odds ratios for co-occurring ASD and ID were 4.2 (3.0–5.9) and 1.3 (1.1–1.6) in infants born at 28 and 43 weeks of GA, with respect to the same referent group. Causal mediation analyses are underway to determine what factors may explain these observed associations.
Conclusions: We confirmed previous reports that both shortened and prolonged gestation were associated with higher risk of ASD and demonstrated that this relationship may be more complex than previously thought. In high-functioning ASD, each additional week of gestation lowers the risk incrementally, yet in a non-linear fashion. In low-functioning ASD, the risk associated with gestational length exhibits a U-shaped pattern. Our mediation analyses will elucidate how gestational length may play distinct roles on the causal pathways to ASD in the presence or absence of co-occurring ID.

205 **166.205** Hazardous Air Pollutants in Relation to Autism Diagnosis and Phenotype in a US Family-Based Study

***A. Kalkbrenner**[1], G. C. Windham[2], N. L. Lee[3], R. S. McConnell[4] and H. E. Volk[5], (1)University of Wisconsin-Milwaukee, Milwaukee, WI, (2)California Department of Public Health, Richmond, CA, (3)Drexel University School of Public Health, Philadelphia, PA, (4)Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA, (5)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: Determining modifiable risk factors for Autism Spectrum Disorder (ASD) is important given the well-supported theory that autism results from genetic liability combined with exogenous exposures during brain development. Several studies have reported associations with perinatal exposure to hazardous air pollutants (HAPs), including some metals and volatile organic compounds.
Objectives: To expand the consideration to a larger set of HAPs across the US, and to explore whether prior findings hold in a family-based study design with information on autism phenotype and severity, we examined the association of perinatal HAP exposures with autism in a national study of multiplex families.
Methods: We determined the geographical location of the residence at birth for 1,873 participants (1,435 with ASD and 438 unaffected siblings) from the Autism Genetics Resource Exchange (AGRE) born 1994-2007 across the US, using self-reported residential history or computerized search of historical addresses. We assigned ambient concentrations of HAPs from an annual census-tract emissions-based model, the National-scale Air Toxics Assessment (NATA) from 1996, 1999, 2002, and 2005. We included 124 HAPs meeting our exposure variability criteria, linking to participants using census tract and closest birth year. We included 3 measures of autism: a broad ASD diagnosis based on report of autism, ASD, or PDD-NOS from the Autism Diagnostic Interview- Revised (ADI-R), a calibrated severity score created from individual items from the Autism Diagnostic Observation Schedule (ADOS) (range 1-10), and the total t-score of the Social Responsiveness Scale (SRS) (mean of 50) among all participants. For each HAP, we modeled an association across the interquartile range, using each individual's deviance from the family mean concentration, using hierarchical regression models (SAS hpmixed), including a family term to account for social and family factors and non-independence, family mean HAP concentration and birth year.
Results: Only a few associations between HAPs and autism measures had 95% confidence intervals (CIs) that indicated statistically significant associations: Protective associations with autism diagnosis included ethylene dibromide (odds ratio (OR)=0.5, CI: 0.3, 0.9) and ethylene dichloride (OR=0.4, CI: 0.2, 0.9). Elevated associations with higher SRS score included formaldehyde (+5.1 points, CI: 1.1, 9.0) and methylene chloride (+3.0 points, CI: 0.1, 5.8). Autism severity scores were elevated among children with ASD for chlorobenzene: (+0.3, CI: 0.0, 0.6). Other associations lacked statistical significance but showed consistent patterns across autism measures. For example, 1,1,1-trichloroethane (methyl chloroform) associations were elevated for all 3 measures of autism. Associations with benzene, carbon disulfide, methylene chloride, and propionaldehyde were elevated for the SRS and autism severity score. Protective associations for ethylene dibromide were found for autism diagnoses and the SRS score.
Conclusions: In these models, some HAPs showed associations with autism diagnosis and more severe autism phenotype. Chlorinated solvents were disproportionately represented among the positive associations, consistent with previous studies. Additional statistical approaches to these data, including accounting for the correlation

structure among pollutants, are planned. Although limited in statistical power and by multiple comparisons, this study combining environmental data with genetic repository data adds to the evidence suggesting that some HAPs may be ASD risk factors.

206 **166.206** Homogeneous Subgroups of Autism Spectrum Disorder Based on Behavioral, Developmental, and Medical Phenotypes

L. D. Wiggins[1], *W. Thompson*[2], *L. H. Tian*[2], *L. A. Schieve*[2], *J. L. Daniels*[3], *J. Pandey*[4], *L. C. Lee*[5], *C. E. Rice*[6], *S. Hepburn*[7], *R. Edmondson Pretzel*[8], *L. Blaskey*[4] *and S. E. Levy*[4], *(1)Centers for Disease Control and Prevention, Atlanta, GA, (2)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, (3)University of North Carolina, Chapel Hill, NC, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Emory Autism Center, Decatur, GA, (7)University of Colorado / JFK Partners, Aurora, CO, (8)Carolina Institute for Developmental Disabilities, University of North Carolina Chapel Hill, Carrboro, NC*

Background:
Autism spectrum disorder (ASD) is a complex developmental disorder characterized by deficits in social communication and interaction skills, and the presence of restricted interests and repetitive behaviors that manifest in early childhood. Children with ASD present with remarkable heterogeneity in symptom presentation that ranges from severe impairments that require substantial supports to less noticeable impairments that require fewer supports. Defining the phenotypic complexity among those with ASD may help elucidate distinct etiologies that contribute to symptom development.
Objectives:
The current study explores ASD subgroups based on behavioral, developmental, and medical phenotypes along the ASD continuum.
Methods:
The Study to Explore Early Development (SEED) is a case-control study designed to examine ASD phenotypes and etiologies. Children 2-5 years old were ascertained through birth certificate records and multiple sources that serve children with developmental problems. All children were screened for ASD upon enrollment. After an in-person developmental evaluation, children were classified into one of the following groups based on degree of ASD symptomology noted on the ASD screen and developmental assessments: ASD, developmental delay or disorder (DD) with ASD symptoms, DD without ASD symptoms, and population comparison.
Phenotypic characteristics and behaviors hypothesized to be associated with ASD were obtained via the Autism Diagnostic Observation Schedule, Mullen Scale of Early Learning (MSEL) and child's birth certificate record, and parent report on the Autism Diagnostic Interview – Revised, Child Behavior Checklist, Child Sleep Characteristics Questionnaire, Early Development Questionnaire, Gastrointestinal Questionnaire (created for SEED), Social Responsiveness Scale, and a structured interview that obtained information on demographics and health conditions previously diagnosed by a healthcare provider.
Subgrouping variables were identified via a multi-stage process. Members of the author group first reviewed subgrouping variables used in previous studies and discussed aspects of the ASD phenotype that best characterized children with ASD. Twenty seven variables were selected based on the literature review, clinical and epidemiological expertise, and availability of data in SEED. Subgroups of children with ASD were identified via latent class analysis.
Results:
There were 707 children classified as ASD and 305 children classified as DD with ASD symptoms included in the analyses. The sample was 79.9% male, and 54.8% White, 22.2% Black, 12.3% Multiracial, 5.1% Asian, and 5.6% other or unreported race. Children with ASD had a mean MSEL score of 66.9 whereas children defined as DD with ASD symptoms had a mean MSEL score of 79.0 ($p<.01$).
Data analyses, discussion, and interpretation are underway. Preliminary results reveal a 4-class model distinguished by phenotypic characteristics beyond MSEL scores (e.g., age at first social smile, aggressive and anxious behaviors, developmental regression, diet restrictions, emotional reactivity, repetitive behaviors, restricted interests, self-injurious behaviors, and somatic complaints). Detailed results will be available at the time of presentation.
Conclusions:
Due to its comprehensive data collection and inclusion of children with a range of ASD symptoms, SEED represents a distinct opportunity to explore ASD subgroups based on behavioral, developmental, and medical phenotypes. Consequently, the results of this study will likely inform future studies on the etiology, trajectory, and treatment of ASD.

207 **166.207** Injuries in Children with Autism Spectrum Disorder: Study to Explore Early Development (SEED)

C. G. DiGuiseppi[1], *S. E. Levy*[2], *G. N. Soke*[3], *S. Rosenberg*[4], *K. Sabourin*[5], *L. C. Lee*[6], *E. Moody*[5] *and L. A. Schieve*[7], *(1)University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)University of Colorado Anschutz Medical Campus, Aurroa, CO, (5)University of Colorado Anschutz Medical Campus, Aurora, CO, (6)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA*

Background: Studies examining injury risk among children with autism spectrum disorder (ASD) have shown conflicting results.
Objectives: We examined medically-treated injuries in children with ASD compared to population (POP) controls.
Methods: The Study to Explore Early Development (SEED) is a multi-site ASD case-control study of children aged 30-68 months. ASD cases (n=693) were determined using established ASD-specific diagnostic instruments. POP controls (n=882) were ascertained from birth certificates. Each child's primary caregiver reported if the child ever had a medically-treated injury, and described each such injury. Injuries resulting in an emergency department visit or hospitalization were defined as "serious." We determined the nature and cause of each child's first reported injury. Associations between ASD and having at least one medically-treated injury and at least one serious injury were examined using multivariable logistic regression models adjusted for child sex, age, and IQ; maternal race/ethnicity and education, and family income, with a random intercept for site.
Results: Among children with ASD, 33% ever had a medically-treated injury and 25% ever had a serious injury; the most commonly specified injuries were laceration (41%), fracture (22%) and abrasion/contusion (12%). Among POP children, 30% had a medically-treated injury and 22% a serious injury; the most commonly specified injuries were laceration (46%), fracture (23%) and dislocation/sprain (12%). In both groups, the cause most often specified was a fall (56%). ASD cases and POP controls did not differ in their odds of having a medically-treated injury (crude odds ratio [cOR] = 1.1 [95%CI: 0.9, 1.4]; adjusted OR [aOR] = 1.2 [0.9, 1.7]) or a serious injury (cOR = 1.1 [0.9, 1.4]; aOR = 1.2 [0.9, 1.6]).
Conclusions: Children with ASD and population control children had similar odds of having a medically-treated injury and having a serious injury. Sociodemographic and IQ differences did not influence these results. We plan to further explore and compare specific injury types and causes, and additional injury outcomes, between the two groups.

208 **166.208** Intellectual Disability Risk in Children Born to Women with Perinatal Psychiatric Diagnoses

ABSTRACT WITHDRAWN

Background: Recent studies suggest that up to 20% of women suffer from mood or anxiety disorders during pregnancy. Although there is evidence that psychiatric disorders are more common in mothers of children with intellectual disability (ID), few have assessed maternal mental health diagnosis while pregnant and the possible effect on a fetus.
Objectives: We investigated the extent to which maternal psychiatric diagnoses during pre- and peri-natal hospitalizations were associated with offspring ID in a large, socio-demographically diverse 18-year statewide birth cohort.
Methods: This retrospective cohort study linked hospital discharge records for 8,951,763 California singleton births occurring 1/1/91-12/31/08 from the office of Statewide Health Planning and Development with neurodevelopmental diagnostic and treatment service records from the Department of Developmental Services (DDS). Pre- or perinatal inpatient maternal psychiatric diagnoses - schizophrenia, bipolar disorder, major depressive disorder, dissociative and factitious disorders, somatoform disorder, dysthymic disorder, and depressive disorder-NOS - were culled from delivery discharge diagnoses via ICD-9 codes. DDS diagnosis of ID was the outcome in 53,000 children. Logistic regression models explored the relationship between maternal psychiatric disorders and ID adjusting for maternal education, race, country of birth, and parental age
Results: California children with ID were similar to those in other studies, with inflated risk for males, older parents, lower maternal education and Black race. In adjusted analysis, mothers diagnosed with *any* psychiatric condition during pregnancy – mood and anxiety disorders as well as schizophrenia – were 73% more likely compared to women without psychiatric conditions to have child diagnosed with ID (Figure 1). Mothers diagnosed with *each*specific individual psychiatric condition were 1.48- 2.39 times more likely to have a child with ID (Figure 2), with higher risk in women with psychoses than in those with anxiety and depressive disorders. The correlation between maternal mental health diagnoses and ID varied minimally by severity of ID, with more severe variants less common and confidence intervals widened, and was consistent across all categories of co-morbidity except for seizures (Figure 2). Compared to mothers without mental health issues, those with schizophrenia had a four-fold increased chance that their child's ID would be severe with an IQ of 25-40, and that the child would be diagnosed with cerebral palsy as well.
Conclusions: Women diagnosed with a psychiatric disorder during pregnancy were 73% more likely compared with women without such diagnoses to have a child diagnosed with ID. Mechanisms that may explain these associations involve genetic predisposition, maternal stress, fetal exposure to certain psychiatric medications, and variations in early formal and information support for the child. These findings emphasize the need for routine prenatal screening for psychiatric conditions and timely interventions directed to optimization of maternal wellbeing as well as fetal and early postnatal neurodevelopment. Further, these results underscore the need for targeted developmental monitoring of children born to women with psychiatric conditions to detect early signs of ID and implement early intervention at the earliest possible opportunity.

209 **166.209** Investigating Prenatal Exposure to Groups of Air Toxics and Autism Spectrum Disorder Using Exploratory Factor Analysis

S. L. Stacy[1], *E. Talbott*[2] *and J. Rager*[3], *(1)Epidemiology, Brown University School of Public Health, Providence, RI, (2)University of Pittsburgh, Pittsburgh, PA, (3)University of Pittsburgh GSH, Pittsburgh, PA*

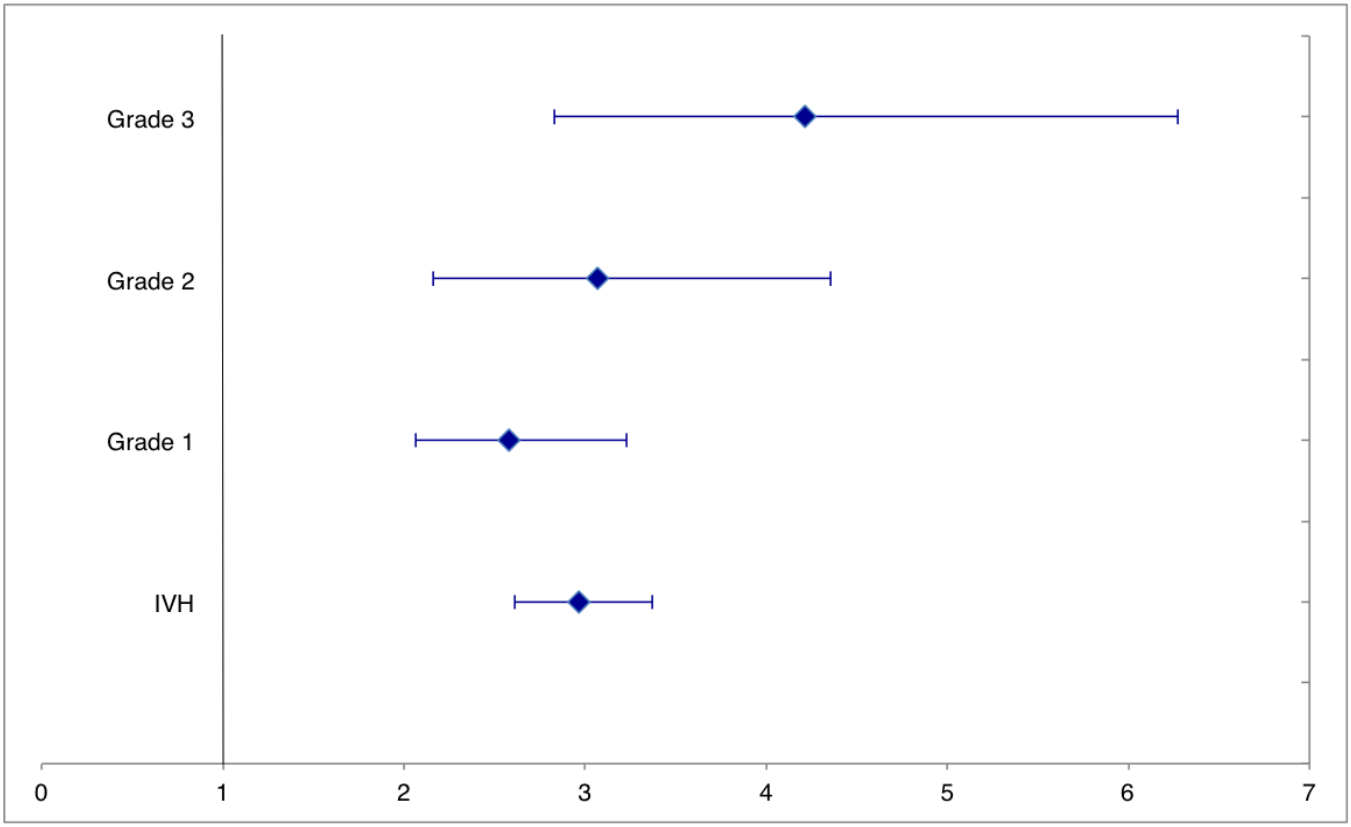
Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by impaired social interaction and rigid behaviors and routines. The prevalence of ASD has increased markedly over the last several decades, motivating investigations into possible causes and risk factors. One area of interest is the role of groups of ambient air pollutants on the development of ASD.
Objectives: N/A
Methods: Estimates of 30 ambient air toxics from the 2005 National Air Toxics Assessment, modeled at the census tract level, were linked to 217 cases of ASD and 224 controls born in southwestern Pennsylvania from 2005 to 2009. An exploratory factor analysis (varimax rotation) was conducted to reduce these 30 pollutants to a set of key predictors. Factor scores were calculated using two methods: index scores based on sums of quartiles of exposure and least squares regression. These scores informed two sets of logistic regression models of ASD risk, adjusted for mother's age, race, education, smoking, child's year of birth and sex. The results of each method for calculating factor scores were compared.
Results: The air toxics loaded onto 7 main factors. Regardless of the method used to calculate the scores, the factors with the most elevated odds ratios appeared to represent traffic, combustion sources, and plastic and rubber manufacturing.
Conclusions: This type of approach can be used in future studies of ASD and environmental risk factors to identify groups of potentially harmful contaminants and pollution sources.

210 **166.210** Is Intraventricular Hemorrhage Associated with Autism?

M. B. Murphrey[1], *C. Walker*[2,3] *and G. Xing*[4], *(1)School of Medicine, Creighton University, Omaha, NE, (2)MIND Institute, University of California, Davis, Sacramento, CA, (3)Department of Obstetrics & Gynecology, University of California, Davis, Sacramento, CA, (4)Center for Healthcare Policy and Research, University of California, Davis, Davis, CA*

Background: Autism has been associated with perinatal cerebral white matter complications; however, many white matter diseases have yet to be studied. We examined the relationship between autism and intraventricular hemorrhage (IVH).
Objectives: To determine whether children whose neonatal course is complicated by IVH are more likely to develop autism, and whether the relationship is influenced by prematurity or gender.

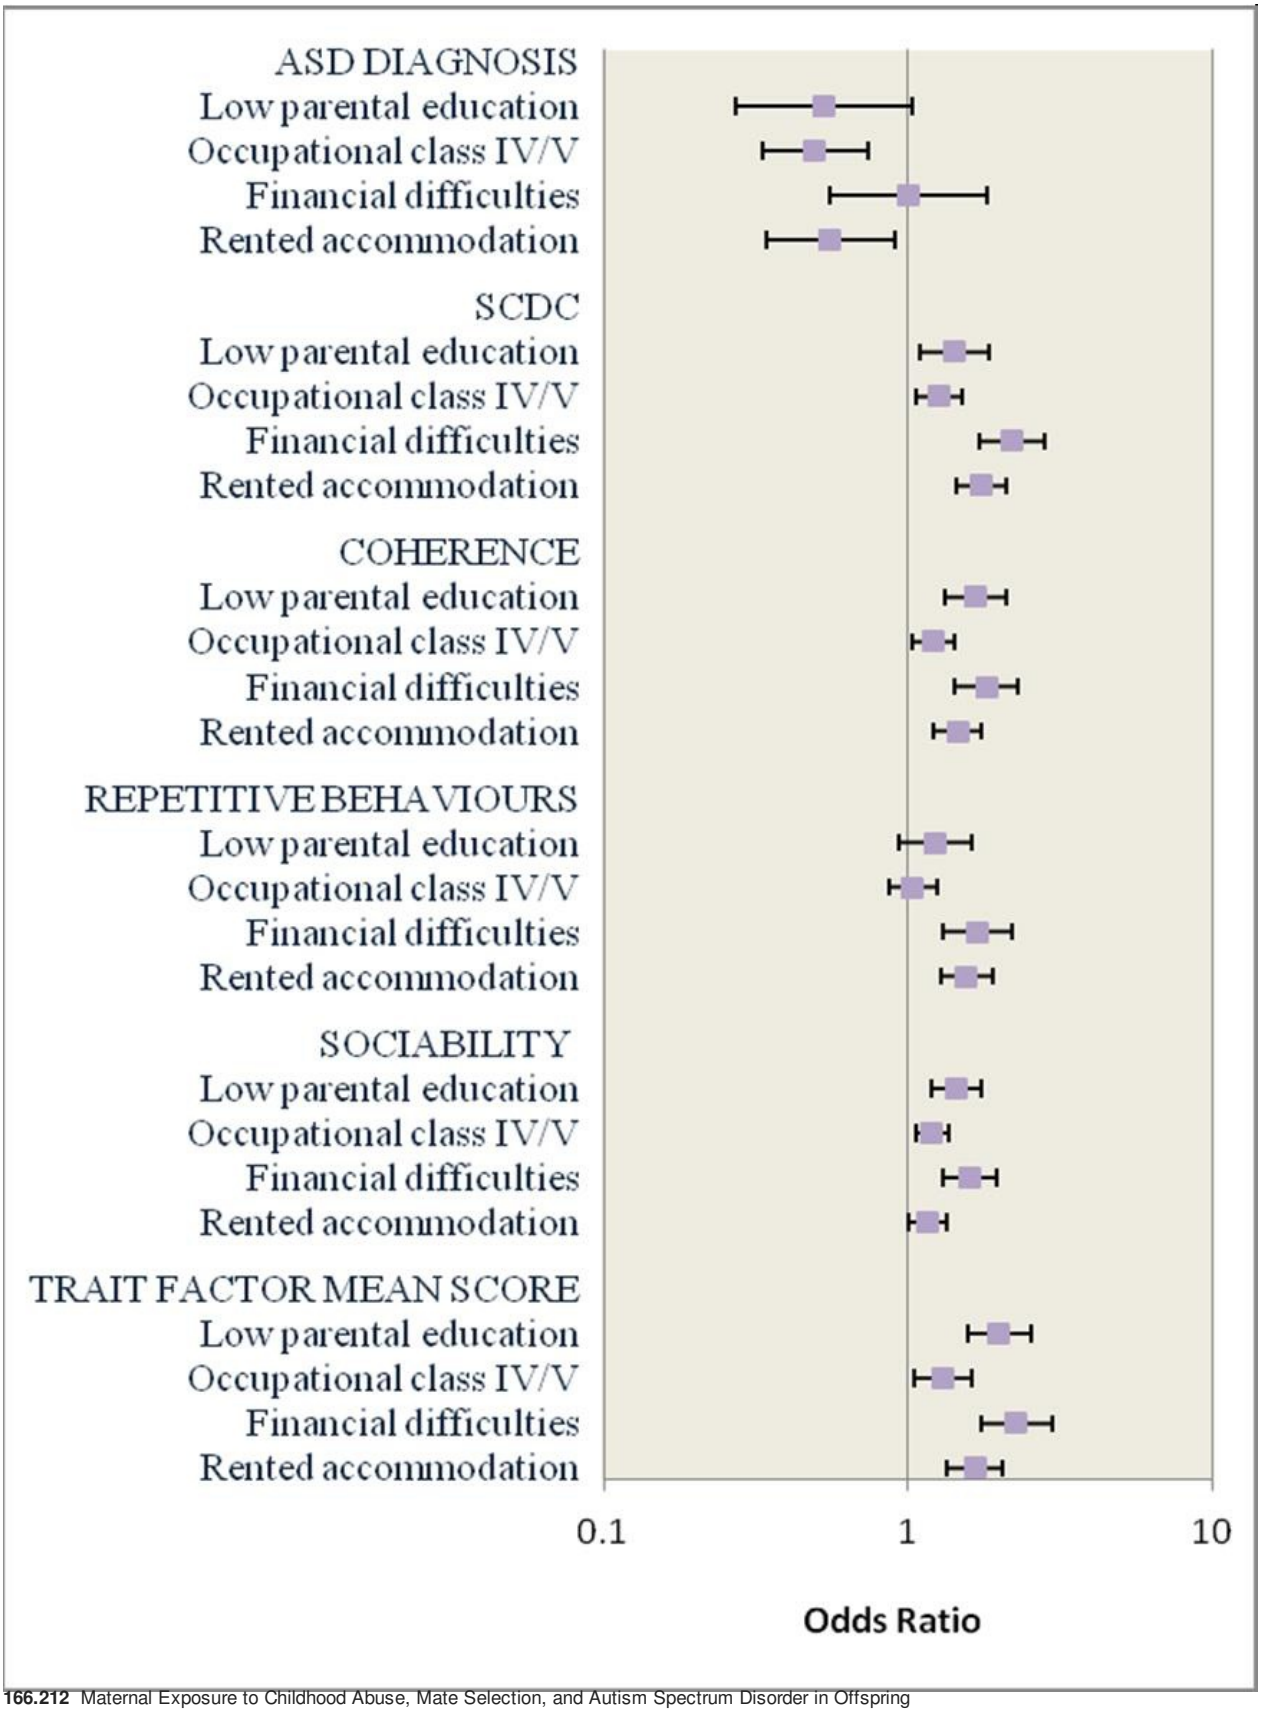
Methods: This retrospective cohort study includes births drawn from the Office of Statewide Health Planning and Development PDD-Birth files from 01/01/1991-12/31/2008 that survived their first year of life. Children diagnosed with autism between 1991 and 2012 by the California Department of Developmental Services (DDS) were identified (n=42,423). The remainder of the birth cohort served as controls (n= 8,909,340). ICD-9-CM codes for IVH were identified with grade sub-categories available from 2001. A step-wise linear regression evaluated the relationship between IVH and autism, controlling for maternal age, race/ethnicity, delivery payer and birth year. Preeclampsia and birth mode did not alter the relationship.
Results: IVH incidence was highest in infants with birthweight <1500 g or gestational age <31 weeks (16% and 20%, respectively). In adjusted analyses, children with IVH who survived their first year of life were 3 times more likely to develop autism (RR 2.97, 95% CI 2.61, 3.37). For those born in 2001-2008, the relative risk of autism increased proportional to severity for grades I-III (Figure 1). Girls with IVH were slightly more likely to develop autism compared with boys (RR 3.5,1, 95% CI 2.62, 4.71 vs RR 2.71, 95% CI 2.35, 3.13) and autism risk rose proportional to gestational age.
Conclusions: The 3-fold increased autism risk in children whose neonatal course was complicated by IVH is concerning, as are the paradoxical findings of increased autism risk in IVH-affected girls and infants born later in gestation. IVH screening in infants born <30 weeks and in others with elevated risk improves early therapeutic potential. Our results underscore the importance of ASD screening in children with IVH and present considerable opportunity for interventions aimed at maximizing neurocognitive development and functional attainment.



211 **166.211** Is 'Autism' a Socioeconomically Biased Diagnostic Label? a Birth Cohort Study

D. Rai[1], *A. M. Emond*[2], *G. Davey Smith*[3], *C. Magnusson*[4], *G. Lewis*[5] *and J. Golding*[6], *(1)University of Bristol, Bristol, England, United Kingdom, (2)University of Bristol, Bristol, United Kingdom, (3)MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, (4)Karolinska Institutet, Stockholm, Sweden, (5)UCL, London, United Kingdom, (6)Centre for Child and Adolescent Health, University of Bristol, Bristol, United Kingdom*

Background: Epidemiologic studies, particularly in USA consistently report autism spectrum disorders (ASD) to be overrepresented in high socioeconomic status (SES) families. It has been argued that such associations are observed because high SES families may have better access to autism services for their child. At least one study also reported biases in the diagnostic labelling of autism by clinicians- with professionals preferring an autism diagnosis in children of high SES families, but preferring other diagnostic labels for children from low SES families with similar symptoms. Whether or not there is a socioeconomic bias in the diagnostic labelling of autism can be directly tested in studies which have information on the receipt of an autism diagnosis as well as symptoms suggestive of autism.
Objectives: To study the associations between measures of parental socioeconomic status (education, financial difficulties, tenure of accommodation and occupational class) and 1) a diagnosis of autism and 2) symptoms of autism
Methods: We used data from the Avon Longitudinal Study of Parents and Children (ALSPAC), a birth cohort study which recruited pregnant women in Bristol, England who had an expected delivery date between April 1991 and December 1992, resulting in 14062 live births. Cohort children with an ASD diagnosis were identified by record linkage with health and education records, or maternal report of having being told the child had autism (n=134). Symptoms suggestive of autism were measured using 4 scales that combine optimally within ALSPAC to predict ASD: the Children's Communication Checklist (coherence subscale), the Social and Communication Disorders Checklist, a repetitive behaviour measure, and the Emotionality, Activity and Sociability scale (sociability subscale). These measures were dichotomised, with approximately 10% defined on each scale as having highest autistic traits. To account for selective attrition, we also used an imputed measure of autistic traits derived from factor analysis, defining scores 2 standard deviations below the mean as having higher autistic symptoms. The measures of lower socioeconomic status we defined included: lowest or no educational qualification, financial difficulties, living in rented accommodation and having a manual occupation. We used logistic regression models to assess the relationship between each measure of low socioeconomic status and a diagnosis of autism and higher traits of autism. Models were mutually adjusted for the SES measures and for sex, parity and parental ages.
Results: Although some associations had wide confidence intervals, a consistent trend was observable in the results (see Figure). Children of parents of lower SES were more likely to have higher symptoms of autism, but appeared less likely to have received a diagnosis of autism.
Conclusions: These findings from a large birth cohort study indicate that there may be a socioeconomic bias in the diagnostic labelling of autism- those who appeared to have higher symptoms appeared least likely to receive a diagnosis. The implications of these findings will be discussed.



212 **166.212** Maternal Exposure to Childhood Abuse, Mate Selection, and Autism Spectrum Disorder in Offspring

A. L. Roberts[1], *K. Lyall*[2] *and M. Weisskopf*[3], *(1)401 Park Drive, Harvard School of Public Health, Boston, MA, (2)California Dept of Public Health, Richmond, CA, (3)Harvard School of Public Health, Boston, MA*

Background: Maternal experience of childhood abuse is associated with offspring ASD, but mechanisms are unknown. Biological effects of abuse are one possibility, and genetics is another. Prior research indicates that girls with autistic traits may be targeted for childhood abuse, inducing an association between maternal genetics and maternal experience of childhood abuse. Additionally, women who experienced abuse in childhood may select as mates men with high levels of autistic traits, and paternal autistic traits predispose to ASD in offspring. Experience of childhood abuse may be an indicator of genetic risk for ASD.
Objectives:
To examine possible reasons for the association between childhood abuse and ASD by addressing three questions: 1) Are women who experienced childhood abuse more likely to select mates with high levels of autistic traits? 2) If so, is this association independent of women's own autistic traits? 3) Is the association of maternal abuse and offspring ASD explained by parents' autistic traits?
Methods: A nested case-control study in the Nurses' Health Study II (N= 222 cases, N=854 controls). ASD based on maternal report, validated with the Autism Diagnostic Interview-Revised in a subset. Parental autistic traits assessed with the Social Responsiveness Scale (SRS). Odds ratios (OR) and 95% confidence intervals (CI) of paternal high autistic traits and ASD estimated with logistic regression.
Results:
Maternal childhood abuse was strongly associated with high paternal autistic traits (severe sexual abuse, OR=3.98, 95% CI=1.29, 12.27; severe physical/emotional abuse, OR=2.24, 95% CI=1.30, 3.88). Maternal childhood abuse predicted offspring ASD (severe combined abuse, RR=3.62, 95% CI=1.80, 7.28). Paternal autistic traits accounted

for 21% of the association between maternal childhood abuse and offspring risk of ASD (adjusted RR=2.97, 95% CI=1.45, 6.09).
Conclusions:
Childhood abuse may affect women's mate selection. At the same time, parental autistic traits alone do not account for the association of maternal childhood abuse with offspring ASD, as these explained only a small portion of the association of maternal abuse with offspring ASD.

213 **166.213** Maternal Metabolic Determinants of Neurodevelopmental Compromise

P. Krakowiak[1], *D. J. Tancredi*[2], *G. Xing*[3] *and C. Walker*[4], *(1)UC Davis, Sacramento, CA, (2)Pediatrics, UC Davis School of Medicine, Sacramento, CA, (3)Center for Healthcare Policy and Research, University of California, Davis, Davis, CA, (4)University of California, Davis, Sacramento, CA*

Background: A growing number of studies have shown associations between autism and intellectual disability (ID) and several conditions characterized by metabolic dysfunction, including obesity, gestational diabetes, and preeclampsia. Although these conditions often co-occur, few studies have explored combinations of metabolic conditions in relation to autism or ID risk.
Objectives: We studied the relationships between clusters of maternal metabolic risk factors to identify women whose metabolic dysfunction places them at greatest risk for autism and ID.
Methods: We used a large population-based cohort of California births from 1991 to 2008 with linked information on ASD and ID diagnosis from the California Department of Developmental Services. Diabetes (type 2, gestational) and hypertensive disorders (chronic and gestational hypertension, preeclampsia, eclampsia) were identified by ICD-9-CM codes. Prepregnancy body mass index (BMI) was calculated using maternal weight and height information from birth files (available for birth years 2007 and 2008 only) and then categorized into obese (BMI ≥30), overweight (BMI 25-29.9), and healthy weight (BMI <25). Combinations of MCs were based on the presumed level of metabolic disruption, with the highest level of disruption expected for T2DM with any hypertensive disorders (HTN/PE). We conducted log-binomial regression models adjusted for birth year, maternal age, race, delivery payer, and parity to estimate risk ratios (RR) and 95% confidence intervals (CI) using the entire cohort of 1991-2008 births and a subset of 2007-2008 births with BMI data.
Results: Women whose pregnancies were complicated by diabetes or hypertension were at highest risk for ASD relative to GP in the full cohort. Specifically, T2DM with HTN/PE was associated with a 52% increase in risk for ASD, followed by a 40% increase for T2DM without HTN/PE, and 37% increase for GDM with HTN/PE. Similarly, in our subset of 2007-2008 births, we observed varying magnitudes of association across combinations of MCs that included BMI categories compared to healthy weight without MCs. Mothers with T2DM irrespective of other MCs were at the highest risk for ASD, followed by GDM with either HTN/PE or obesity, and then PE with obesity. We did not find significant differences in risk for autism vs. ID in children born to mothers with diabetes or hypertension in the full cohort or our subset.
Conclusions: Our findings suggest that greater levels of metabolic disruption as evidenced by combinations of clinical diagnoses increase the risk of having a child with autism. Given that we did not observe differences in risk for autism relative to ID, the detrimental neurodevelopmental effects of metabolic disruption are not specific to autism alone.

214 **166.214** Maternal Pre-Pregnancy BMI and Pregnancy Weight Gain in Relation to Autism Spectrum Disorder (ASD) in Offspring

G. C. Windham[1], *M. Anderson*[2], *K. Lyall*[3], *J. L. Daniels*[4], *T. V. Kral*[5], *L. A. Croen*[6], *S. E. Levy*[7], *C. B. Bradley*[8], *L. Young*[9] *and L. A. Schieve*[10], *(1)California Department of Public Health, Richmond, CA, (2)Impact Assessment, Inc., Richmond, CA, (3)A.J. Drexel Autism Institute, Philadelphia, PA, (4)University of North Carolina, Chapel Hill, NC, (5)Biobehavioral Health Sciences, University of Pennsylvania School of Nursing, Philadelphia, PA, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)Children's Hospital of Philadelphia, Philadelphia, PA, (8)Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, (9)School of Nursing, PA-SEED, CADDRE, Philadelphia, PA, (10)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA*

Background: A handful of studies have examined the relationship of maternal pre-pregnancy weight or body mass index (BMI) and weight gain during pregnancy to ASD in offspring, producing inconsistent results. Further examination is important for distinguishing associations and teasing apart potential mechanisms.
Objectives: Examine the relationship of maternal pre-pregnancy BMI and weight gain during pregnancy, as well as their combination, with a diagnosis of ASD in the offspring.
Methods: The Study to Explore Early Development (SEED) is a multi-site, case-control study of children born in 2003-2006 designed to characterize ASD and examine a variety of risk factors. Children were enrolled at ages 2-5 and classified based on pre-study diagnosis, a maternal screening questionnaire (SCQ), and in-person developmental evaluations of the child, into three study groups; 1) children with ASD (n=696), 2) children with other developmental delays (DD) (n=987), and 3) a population-based control group selected from birth certificates (POP) (n=887). Maternal height, pre-pregnancy weight, and gestational weight gain were obtained from maternal interview conducted 2-5 years post-partum, as measured weights were not available. Three primary weight "exposures" were examined: 1) Pre-pregnancy BMI classified as

underweight (<18.5 kg/m^2), normal weight (18.5-24.9 kg/m^2), overweight (25.0-29.9 kg/m^2), and obese (≥30 kg/m^2). Weight gain assessed by 2) comparing upper and lower deciles to the middle 60%, and by 3) a combined variable using IOM/ACOG weight-gain-by-initial BMI recommendations, which are categorized as "Below", "Meets" or "Exceeds" recommendations. Chi-square values were used to assess the distributions across the study groups. Odds ratios adjusting (AOR) for maternal age, race/ethnicity, education, and parity were calculated by multivariable logistic regression models for these weight variables separately, comparing the ASD or DD groups to the POP group.
Results: The distribution of all three maternal weight variables varied significantly across study groups; about 19% of mothers of children with ASD or DD were obese pre-pregnancy, compared to 13% of POP mothers (p<0.001), and more mothers of children with ASD exceeded IOM weight gain recommendations (47%) than DD or POP mothers (42%), while more mothers of DD children gained below recommendations (21% vs. 16% of ASD or POP) (p=0.006). After adjustment, associations for ASD vs. POP were not significant for maternal obesity (AOR 1.29, 95%CI 0.95-1.74), but were for weight gain in the upper decile (≥55 lbs.; AOR=1.57, 95%CI 1.10-2.24) and in the Exceeds IOM-recommended weight gain (AOR=1.27, 95%CI=1.01-1.61). Examining DD (vs. POP), maternal overweight and obesity were significantly associated after adjustment (AORs =1.37, 95%CI 1.08-1.73 and 1.50, 95%CI 1.14-1.98, respectively), but neither weight gain variable was significantly associated.
Conclusions: To our knowledge, ours is the first study of ASD to examine pregnancy weight gain categories taking pre-pregnancy BMI into account. Results indicate ASD was associated with such weight gain measures, but only marginally associated with maternal obesity, while DD was associated with both maternal obesity and overweight but not weight gain. Additional sensitivity analyses will determine whether differences persist. They might yield clues to the influence of timing of excess weight, which may affect neurodevelopment via metabolic/hormonal or immunologic pathways.

215 **166.215** Oral Health and Dental Needs in Adolescents with ASD: An Italian Study

E. Grossi[1], *M. Gangale*[2], *C. Sciessere*[2], *D. R. Dunca*[1] *and L. Levrini*[3], *(1)Autism Unit, Villa Santa Maria Institute Neuropsychiatric Rehabilitation Center, Tavernerio, Italy, (2)Research Centre Cranio Facial Disease and Medicine, School Dental Hygiene, University of Insubria, Como, Italy, (3)Research Centre Cranio Facial Disease and Medicine, School Dental Hygiene,University of Insubria, Como, Italy*

Background: There are few studies that investigate oral health and dental needs of children with autism. Many ASD subjects experience great difficulties in performing oral hygiene due to their limited manual dexterity, sensory and intellectual disabilities and thus are prone to poor oral health. Different studies conducted on caries prevalence and oral inflammation in ASDs have shown contradictory results. Some studies report lower caries prevalence in autistic children, however this finding seems somewhat surprising. To date, there are no studies addressing this phenomenon in Italy
Objectives:
The aim of this study is to determine the prevalence of caries and overall oral hygiene in ASD adolescents and compare them to adolescents belonging to the general population in Italy.
Methods:
Thirty one (26 male-5 female) adolescents with ASD with a mean age of 15. 35 years diagnosed according to DSM V and ADOS-2 criteria and treated at our Institute as permanent residents were selected for the study. . All subjects were checked by one examiner for oral hygiene status and dental caries while seated in a standard dental chair. The examiner used a standard dental mirror, an explorer and periodontal probe with William's markings. The examination of the soft and hard tissues was done under both a flash light and regular room light. The DMFT index was used, with codes and criteria established by the WHO. The gingival status, evaluated according to the gingival index of Loe and Silness, was then recorded as generalized or localized gingival inflammation, depending on the amount of gingival redness and bleeding during the examination.
Results:
Both teeth-brushing time and technique were incorrect in 31/31 and in 28/31 cases respectively. Gingival status was assessable in 30/31 cases and the DMFT index in 23/31 cases due to insufficient cooperation. Mean age and mean ADOS total score of cooperative and un-cooperative subjects was not statistically different (8.36 vs 8.28; 14.95 vs 16.5). In this subset, the overall prevalence of dental caries was 34.7% and the mean DMFT index was 1.43. The corresponding values in the general population control group (made up of 805 adolescents from the surrounding area) was 54.5% and 2.04 respectively. The difference in the carious prevalence and DFMT index was significant (p<0.05) between the two groups. The prevalence of moderate/severe gingivitis was 78.2%, with the corresponding value in the control group being 60%. In this case the difference was also statistically significant (p>0.05). However, there was no significant correlation between the ADOS severity total score and gingivitis degree (r = 0.10; NS)
Conclusions:
The oral hygiene status in autistic adolescents observed in this study is indeed poor, but does not appear to be directly correlated to autism severity. The prevalence of caries is in fact lower in ASD adolescents than in the general population. Further investigation is required to explain this rather counterintuitive finding.

216 **166.216** Population-Based Registries in Autism Research

D. E. Schendel*, Aarhus University, Aarhus, Denmark*

Background:
Understanding of the epidemiology of autism spectrum disorder (ASD) is benefited by eclectic approaches, study designs and data sources. Contributions to the ASD epidemiologic literature from studies based on Nordic and other population-based registries have increased in recent years, but the strengths and limitations of the registry approach is best understood in the broader context of epidemiologic studies over all.
Objectives:
Describe the population-based registry approach in the broader context of ASD registries overall and illustrate the kinds of epidemiologic research gaps they can and cannot fill, with reference to published and ongoing studies.
Methods:
The objectives are achieved in three steps: 1) a general overview of registries, with specific ASD examples, and including a description of key epidemiologic features that distinguish the research utility of individual registries; 2) a description of epidemiologic characteristics of Nordic and other population-based registry systems; and 3) a description of select studies based on the Nordic and other population-based registry-system approach that have contributed to ASD epidemiologic questions, including geographic and temporal prevalence variation, quantitative studies of sources of variation in prevalence, mortality, perinatal risk, medical contact patterns during the years of transition from adolescent to adult care settings and multi-generation family morbidity patterns in association with ASD. Each example is described in terms of its registry-based design, results, strengths and limitations, highlighting both published findings and new findings in ongoing studies.
Results:
Registries are widely used in ASD research and service provision but their research utility varies depending on the source of new cases, mechanism of inclusion of new cases and data collection. The limitations of individual registries have been mitigated, in part, in the Nordic and other countries by the creation of registry systems. Multiple, single data bases containing limited individual data are linked together using stable unique identifiers to create research data sets that greatly expand the available data per individual. Rigorous data harmonization and data federation approaches have been applied to further expand the research utility of individual national- or state-level registry systems. Registry-system studies have documented geographic and temporal ASD prevalence trends based on harmonized data analyses; quantified effects of systematic registry data collection changes on observed ASD prevalence trends; and elucidated ASD mortality risks considering comorbidity, fine-grained patterns of common perinatal risks, medical contact perturbations during the transition years, and family-wide morbidity patterns that may reflect heritable ASD risk from underlying liability across other morbidities.
Conclusions:
Registry-systems have limited data breadth and complexity, however, their robust sample sizes, population representativeness and time depth make them well suited to derive reliable patterns of risk from routinely collected factors, against which results from smaller studies with more in depth, sophisticated data collection can be calibrated.

217 **166.217** Prebiotic and Probiotic Consumption during Pregnancy and Autism Observational Scale for Infants (AOSI) Score at 12-Months in the Early Autism Risk Longitudinal Investigation (EARLI)

C. Holingue[1], *L. A. Croen*[2], *I. Hertz-Picciotto*[3], *J. Pandey*[4], *C. J. Newschaffer*[5] *and M. D. Fallin*[6], *(1)Wendy Klag Center for Autism and Developmental Disabilities and Center on Early Life Origins of Disease, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Division of Research, Kaiser Permanente, Oakland, CA, (3)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)A.J. Drexel Autism Institute, Philadelphia, PA, (6)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background:
Children with Autism Spectrum Disorder often have co-occurring gastrointestinal symptoms and abnormalities. The microbiome has been suggested as an important driver or mediator of this co-morbidity. Research suggests that dysregulation of the microbiome can lead to behavioral changes as well as gastrointestinal symptoms. Probiotics are live bacteria and yeasts that are beneficial to the gut and overall health. Prebiotics are compounds that probiotics use for nutrition. In the framework of a dysregulated microbiome, a prebiotic and probiotic rich diet is theorized to improve gastrointestinal and behavioral symptoms. There is limited evidence that prebiotic/probiotic supplementation during pregnancy and the postnatal period may be beneficial for physical and mental health. However, little research has yet examined the association between prebiotic and probiotic consumption and development of behavioral symptoms in an autism cohort.
Objectives:
Our objective was to test the association between maternal prebiotic and probiotic consumption during pregnancy and child development performance at 12 months.

Methods:
In an ASD-enriched birth cohort, the Early Autism Risk Longitudinal Investigation (EARLI), pregnant mothers were interviewed about the frequency and amounts of eating/ingesting/consuming certain foods during the first half of pregnancy (weeks 1-20) and the second half of pregnancy (weeks 21 - birth+). Dietary questions regarding the following prebiotic or probiotic-rich foods were extracted from the data: oatmeal, bran, bananas, strawberries, cooked and raw greens, cabbage, beans, asparagus, onions, fresh tomatoes, rice or other cooked grains, whole-wheat bread, sourdough bread, tofu, tempeh and other soy products, yogurt, kefir, miso soup, pickles and pickled vegetables or fruit. For each of the 214 mothers, a score was created by taking the product of the frequency and amount of each food and summing across all foods (possible range: 0-2448). Child development was measured at 12 months via the Autism Observational Scale for Infants (AOSI), a measure shown to be correlated with later diagnosis of ASD. Linear regression was used to predict the effect of the maternal prebiotic/probiotic score on child 12-month AOSI score on the natural log scale.
Results:
Maternal pregnancy prebiotic/probiotic scores were available for 214 women, and ranged from 0 to 488 with a median of 139. The 12-month AOSI score ranged from 0 to 20 with a median of 4. The prebiotic/probiotic score was not significantly associated with child 12-month log AOSI score (effect estimate= 0.0006 for a 1 unit increase in the prebiotic/probiotic score, p-value=0.15, n=214).
Conclusions:
Maternal prebiotic/probiotic consumption during pregnancy was not significantly associated with 12-month AOSI performance in the child. However, further research is needed to further explore this question. Future analyses would benefit from a larger sample size and a more refined variable representing prebiotic and probiotic consumption.

218 **166.218** Predictors of Emergency Department Usage Among Children Ever Diagnosed with Autism Spectrum Disorder

L. I. Black *and B. Zablotsky, National Center for Health Statistics, Hyattsville, MD*

Background: Children with autism spectrum disorder (ASD) have high rates of healthcare utilization (Kogan et al., 2008), potentially a product of the high co-occurrence of ASD and other medical and psychiatric conditions (Levy et al., 2010). Many families of children with ASD have difficulty accessing specialty medical and related services (Warfield & Gulley, 2006) and may depend on emergency department services. Previous research has indicated an increased use of the emergency department for psychiatric crises (Kalb et al., 2012) and injury (McDermott, Zhou, & Mann, 2008) among children with ASD, but little is known about predictors of emergency department services. This study explores predictors and parent-reported reasons of emergency room (ER) visits among a national population of children with ASD.
Objectives: Compare the likelihood of any ER visits in the last year between children with and without ASD. Examine reported reasons for last ER visit.
Methods: Data come from the 2011-2014 National Health Interview Survey (NHIS). NHIS is a nationally representative household survey that collects data continuously throughout the year of the noninstitutionalized US population. Respondents (usually the parent) answer on behalf of one randomly selected child in the family. Children aged 2-17 years were included in this analysis (n=46,316), which included children ever diagnosed with ASD (n=689) and children never diagnosed with ASD (n=45,602). Estimates were calculated using SUDAAN to account for the NHIS complex sample design. Logistic regressions were used to examine the association between ASD and any ER visits in the past year. Model 0 was an unadjusted model, Model 1 adjusted for survey year, child and family demographics, and Model 2 additionally adjusted for co-occurring child conditions (seizures, food/digestive allergies, asthma, attention-deficit/hyperactivity disorder, frequent diarrhea/colitis), as well as survey year and demographics.
Among those who had any ER visits in the past year, parents endorsed multiple reasons (up to eight) for the child's most recent ER visit. Children were assigned to mutually exclusive categories summarizing their reason for their last ER visit; seriousness of the medical problem or access to healthcare. If a parent endorsed both a seriousness and access reason, the reason was coded as being due to the seriousness of the medical problem.
Results: Children ever diagnosed with ASD (23%) were significantly more likely than children without ASD (17%) to have had an ER visit in the past year ($p<0.05$) (Model 0). This association remained significant after adjusting for survey year and demographics (Model 1). However, after adjusting for co-occurring child conditions (Model 2) this association was no longer significant. Approximately 70% of parents of children ever diagnosed with ASD reported that the most recent ER visit was due to the seriousness of the medical problem and approximately 27% of parents reported reasons only related to healthcare access.
Conclusions: Differences between ER use of children with and without ASD may be explained by differences in the presence of co-occurring medical and psychiatric conditions. Parents of children with ASD were most likely to report their child's most recent ER visit was due to the seriousness of the medical problem.

219 **166.219** Prenatal Exposures As Measured By Routine Placental Histopathology in a Community Cohort of ASD

ABSTRACT WITHDRAWN

Background:
Autism Spectrum Disorder (ASD) is a set of neurodevelopmental disorders expressed in early life as stereotypic behaviors and language and social-emotional deficits. Exposure to inflammation and oxidative stress have each emerged as prenatal risk factors. These processes can be identified at birth in the baby's placenta by routine histologic methods.
Objectives: We will study a unique contemporary population based birth cohort for which placental examination was performed at birth for all newborns. Does histologic evidence of prenatal exposure to acute, chronic or both acute and chronic inflammation and evidence of maternal underperfusion of the placenta, a condition that may involve oxidative stress, correlate with subsequent ASD diagnosis?
Methods: Our case-control sample was drawn from a broad population based sample of nearly all births occurring at a large urban community based hospital (New York Methodist Hospital, NYMH) from 2007 to 2013, during which time there was universal placental examination of births at NYMH. Coupled with access to links to billing data for children who remain in the system for pediatric care has yielded a unique population based cohort with (currently) 55 population based cases (42 males, 13 females) and 199 controls (150 males, 49 females). Pathology diagnostic reports reviewed by a single observer at birth were extracted for coding of markers of AI, CI and maternal underperfusion as "present/absent". Conditional logistic regression accounted for our matched case-control design.
Results: As expected with matched data, there were no significant differences in genders or gestational ages between ASD cases and controls. There were substantial significant differences in several measures of inflammation between cases and controls. Placentas of cases were much more likely to have acute fetal chorionic vessel inflammation (23.6% cases vs. 6.5% controls; conditional logistic regression odds ratio (COR), 95% CI: 4.88, 1.99, 11.96). There was a higher risk of chronic inflammation as measured by uteroplacental chronic vasculitis in the placentas of cases (7.3% cases vs. 1.5% controls; COR, 95% CI: 6.36, 1.13, 35.90). There was also a higher risk of chronic choriodeciduitis but this difference was not statistically significant (p=0.14). Finally, the finding of histologic evidence of poor maternal perfusion (villous fibrosis, hypovascularity and Tenney-Parker changes of trophoblast (considered to reflect local hypoxia) was also much more likely in cases (7.3% cases vs. 0.5% controls; COR, 95% CI: 13.54, 1.51, 121.6).
Conclusions: Children who eventually are diagnosed with ASD have significantly more histologic placental evidence of prenatal exposures to both acute and chronic inflammation, and features that are typically attributed to chronic maternal perfusion pathology and oxidative stress. These diagnoses are gleaned from routine histopathology slide preparations that can be performed in any hospital laboratory. These findings may point to a universally available and inexpensive screen for ASD risk at birth.

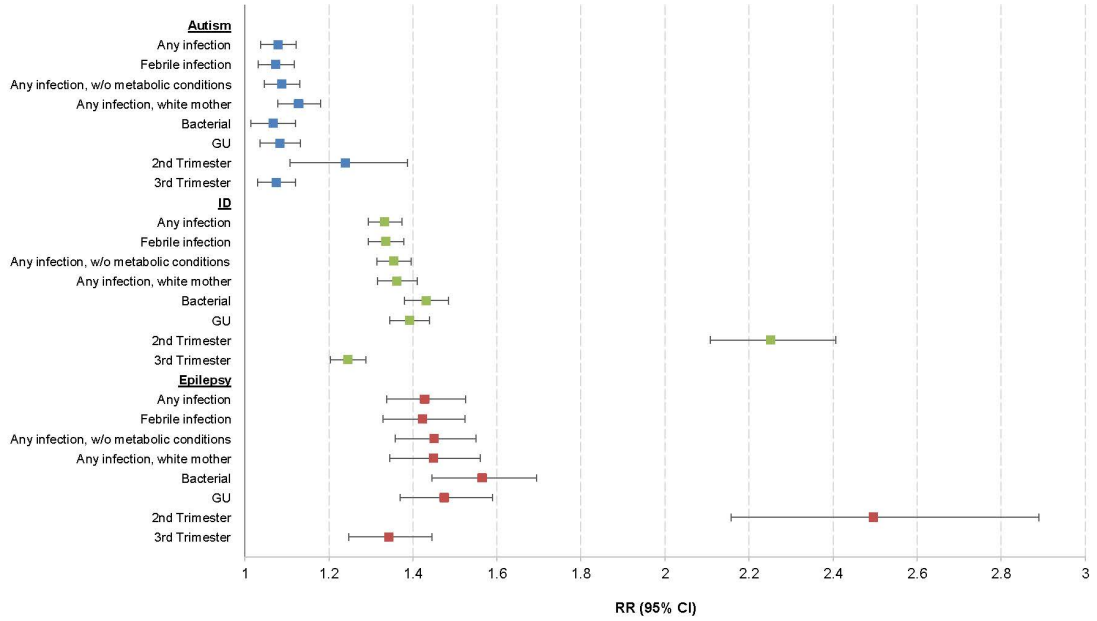
220 **166.220** Prenatal Infections and Risk of Autism, Intellectual Disability and/or Epilepsy

H. R. Haber[1]*, G. Xing*[2] *and C. Walker*[3]*, (1)School of Medicine, University of California, Davis, Sacramento, CA, (2)Center for Healthcare Policy and Research, University of California, Davis, Davis, CA, (3)University of California, Davis, Sacramento, CA*

Background: Although epidemiologic studies have reported associations between infections and febrile episodes during gestation and offspring autism and co-morbid intellectual disability (ID), results are mixed and limited to specific populations.
Objectives: In a demographically-heterogeneous population-based retrospective birth cohort, we examined the association between maternal inpatient diagnosis of infection and offspring risk of autism, ID and epilepsy. Specifically, we studied whether type of infection (by anatomic site, microbe category, fever propensity, or timing) was associated with autism, ID, or epilepsy risk.
Methods: We included births in California from 1/1/1991-12/31/2008 and limited our analysis to singletons born at gestational ages 23-43 weeks with birthweights 500-6000 grams who survived the first year of life (n=8,618,171). Infection during pregnancy was defined using ICD-9-CM codes from any maternal hospitalization; codes with fewer than 50 observations were excluded. Birth files were merged with records from the California Department of Developmental Services (DDS) for children receiving care between 1/1/1991-12/31/2012, including 42,998 with autism, 45,546 with ID, and 2,507 with epilepsy. Outcomes were defined by standardized assessments and ICD-9-CM codes, and were not mutually exclusive. Multinomial logistic regression models controlling for maternal age, race/ethnicity, educational attainment, payer, parity, and birth year – with or without gestational and pregestational forms of diabetes and hypertension – examined relative risks (RRs) and 95% confidence intervals (CIs) for pregnancies complicated by infection for offspring autism, ID, or epilepsy. Additional models using sub-categories of the predictor explored the effect of type, site, fever propensity, and timing of infection on outcomes of interest.
Results: Demographic features of mothers and children with autism resembled published data, including predilection for white race, higher maternal age and educational attainment, and lower parity. Parous women were more likely to have children with ID and/or epilepsy than their nulliparous counterparts. Maternal infection was associated with an 8-43% increased risk for autism, ID, and/or epilepsy in adjusted analyses (Figure 1). Effects did not differ by infection febrile potential. Although women with metabolic conditions were more likely to have children with adverse neurodevelopmental outcomes, correlations between infection and adverse outcomes persisted when

metabolic conditions were removed from statistical models. While increased risk of ID or epilepsy was sustained across all racial and ethnic groups, increased risk for autism was seen solely among white women with infections. Stronger associations were observed between sub-categories of infection and ID and epilepsy, including bacterial etiology (increased by 43% and 57%, respectively), and GU site (39% and 48%, respectively). Outcome risk differed by timing of infection, with second trimester infections conferring a 24% increased risk for autism and a greater than two-fold risk for ID and epilepsy, and third trimester timing elevating risk to a lesser degree.
Conclusions: This study adds to the growing body of evidence implicating immune-mediated exposures during fetal development, particularly second trimester infections, in the etiology of autism, ID, and epilepsy. Our findings highlight the need for targeted investigation into the mechanisms underlying these fetal exposures and immunologic responses resulting in distinct patterns of neurodevelopmental compromise.

Figure 1. Maternal Inpatient Diagnosis for Infection and Risk of Autism, ID or Epilepsy



221 **166.221** Prenatal Organophosphate Pesticide Exposure and Social Cognition Among Adolescents in an Agricultural Community

S. K. Sagiv[1], *M. H. Harris*[1], *K. G. Harley*[2], *K. Kogut*[3], *J. Deardorff*[3], *K. Parra*[3], *A. Bradman*[4] *and B. Eskenazi*[3], *(1)Epidemiology, University of California, Berkeley, Berkeley, CA, (2)School of Public Health, University of California, Berkeley, Berkeley, CA, (3)University of California, Berkeley, Berkeley, CA, (4)university of California, Berkeley, Berkeley, CA*

Background: Organophosphate (OP) pesticides are cholinesterase-inhibiting insecticides used primarily in agriculture. Low-dose exposure to OPs could adversely impact human neurodevelopment, particularly if exposure occurs during the prenatal period when the fetal brain is undergoing rapid development and the ability to detoxify OPs is not yet mature. The CHAMACOS (Center for Health Assessment of Mothers and Children of Salinas) longitudinal birth cohort study, designed to investigate pesticide exposure and the health of pregnant women and their children living in a predominantly Mexican-American agricultural community, has previously reported associations of prenatal OPs with lower IQ, poorer attention and parental report of behaviors at 24 months related to pervasive developmental disorder (PDD), which includes symptoms consistent with ASD. Social cognition, a measure of how individuals perceive and respond to social interaction, is a central trait impaired in individuals with an autism spectrum disorder (ASD).
Objectives: To investigate the association of prenatal exposure to OP pesticides with social cognition among adolescents in CHAMACOS.
Methods: We estimated exposure to OPs using measures of dialkyl phosphate (DAP) metabolites in maternal urine collected during the first and second half of pregnancy. When the CHAMACOS children were age 14 years parents were asked to assess their children using the Social Responsiveness Scale (SRS), a rating scale quantifying the frequency of traits related to social behavior and stereotypic behavior/restricted interests. We estimated associations of maternal DAP concentrations (average of the 2 pregnancy measures) with SRS scores using linear regression models, adjusting for maternal age, education, country of birth, years in the United States, marital status, depression, child's age at assessment, sex and quality of the home environment.
Results: For the 247 children with prenatal DAPs and a completed SRS, the median (25%ile, 75%ile) DAP concentration was 130.5 (61.9, 279.7) nmol/L. Prenatal DAPs were associated with poorer 14-year SRS scores, represented by a higher score (β=7.3; 95% Confidence Interval (CI): 2.6, 12.1 per 10-fold increase in average maternal DAP concentration). We found a linear, monotonic dose-response relationship between DAPs and SRS score, confirmed by splines and by categorical analysis, where we detected a 10.8 point increase (95% CI: 4.6, 17.1) in SRS score for the 4^{th} vs. 1^{st} quartile of DAP concentration. Associations were consistent across males and females and across the 5 subscales of the SRS (social awareness, cognition, communication, motivation and restricted interests and repetitive behaviors).
Conclusions: We found that prenatal exposure to OP pesticides was associated with poorer parent-reported social cognition among adolescents in the CHAMACOS cohort. Prenatal DAP concentrations in CHAMACOS mothers were high, though in range with concentrations in the general U.S. population. Associations are consistent with CHAMACOS findings at earlier ages as well as with other epidemiologic studies showing associations of OPs with poorer neurodevelopment. Examination of continuously distributed traits, such as social cognition, offers a statistically powerful approach to studying modifiable environmental risk factors for ASDs.

222 **166.222** Prenatal Triclosan or Triclocarban Product Use and Autism Observational Scale for Infants at 12 Months

B. Park[1], *B. Lee*[2], *L. Tabb*[3], *I. Burstyn*[2], *M. D. Fallin*[4], *I. Hertz-Picciotto*[5], *L. A. Croen*[6] *and C. J. Newschaffer*[7], *(1)Mental Health Department, 1. Department of Mental Health, Johns Hopkins Bloomberg School of Public Health,, Baltimore,, MD, (2)Drexel University, Philadelphia, PA, (3)Department of Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (4)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (5)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)A.J. Drexel Autism Institute, Philadelphia, PA*

Background:
The antimicrobial agents triclosan (TCS) and triclocarban (TCC) have androgen disrupting potential and are widely used in household and personal care products. An increase in prenatal testosterone level has been associated with autistic traits. However, the roles of prenatal TCS and TCC exposures in this context have not been

explored.
Objectives:
The goal of this analysis is to examine whether triclosan and triclocarban containing antimicrobial use during pregnancy is associated with early autistic traits.
Methods:
The EARLI (Early Autism Risk Longitudinal Investigation) cohort follows mothers of a child with autism spectrum disorders (ASD) at the start of a subsequent pregnancy through to ASD assessment in the subsequent child. Home walk-through surveys conducted during pregnancy and postpartum were used to estimate dichotomized "early prenatal" and "late prenatal/early postpartum" TCS or TCC product use among 170 pregnancies in the EARLI study. Linear regression models were used to determine the association between dichotomized exposures during early prenatal and late prenatal/early postpartum period and autistic traits at 12 months using AOSI (Autism Observational Scales in Infants) scores.
Results:
During the early prenatal period, 89% of mothers reported using at least one personal care product potentially containing TCS/TCC. In the late prenatal/early postpartum period, 73% of mothers reported using personal care products potentially containing TCS/TCC. Among the four categories of personal care products examined, the largest proportion of mothers (67%) reported using TCC/TCS-containing dish soap, followed by antibacterial soap (49%), toothpaste (45%) and body/face soap (19%) during the early prenatal period. The total AOSI scores did not differ by TCS or TCC product use and the results did not differ by sex of the child.
Conclusions:
Findings from this study do not support an association between use of TCS or TCC-containing products during pregnancy and total AOSI scores. Product use based TCS/TCC exposure estimate and small sample size may have affected our results and should be considered in future investigations of TCS/TCC exposure and ASD.

223 **166.223** Prevalence of Autism Spectrum Disorder in a Japanese Community-Based Population Sample of Five-Year-Old Children

M. Saito[1], *N. Takayanagi*[2], *M. Adachi*[2], *A. Osato*[3], *S. Yasuda*[2], *T. Masuda*[4], *M. Tanaka*[4], *S. Yoshida*[2], *M. Kuribayashi*[2] *and K. Nakamura*[5], *(1)Hirosaki University, Hirosaki, Aomori, Japan, (2)Research Center for Child Mental Development, Hirosaki University, Hirosaki, Japan, (3)Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (4)Faculty of Education, Hirosaki University, Hirosaki, Japan, (5)Hirosaki University Graduate School of Medicine, Aomori, Japan*

Background: In Japan, local governments perform pregnant women and infants' health check-up as a fundamental maternal-and-child-health service. However, it cannot completely pick up developmental disabilities, especially ASD. A further problem is that the children with ASD who were undetected by the checkup tend to show secondary problems because of maladjustment after entering a school. Psychiatric disorders are common and frequently multiple in children with ASDs (Simonoff, 2008). Therefore, we conducted five-year-olds developmental health check-up on about 1,300 children per a year in a local city, where the number of citizens is approximately 180,000, and directly diagnosed developmental disorders. It allows investigating the prevalence of ASD, and proposing early identification and intervention.
Objectives: The purpose of this study is to investigate the prevalence of Autism Spectrum Disorder (ASD) in a community-based population sample of five-year-old children. We also clarify the difference of clinical data between children with ASD or other developmental disorders and healthy controls.
Methods: This study was conducted as Hirosaki Five years check-up (HFC) study-assessing mental health among children in Hirosaki. Subjects are 1919/2571 children who become 5 year old between April 2013 and March 2015 in Hirosaki city. After primary screening was performed, 405 children were selected to undergo secondly developmental health examination. Finally 282 children and their parents visited to the developmental health check-up. Pediatricians and psychiatrists diagnosed neurodevelopmental disorder directly using DSM-5 criteria, ASD, ADHD, DCD (Developmental coordination disorder), and ID/BID (Borderline Intellectual Disability). We calculated the prevalence and comorbidities. In addition, clinical data were statistically analyzed by multiple comparisons with Bonferroni correlation between groups of ASD (comorbid with other disorders), other developmental disorders and healthy control.
Results: 59 children were diagnosed as ASD. The prevalence of ASD was 3.31% (95% CI: 2.48 –4.14). The comorbidities of ASD were ADHD (55.9%), DCD (59.3%) and ID/BID (44.1%). 46/88 ADHDs were ADHD without any comorbidity. 43/59 ASDs (73%) had not been diagnosed with ASD until this health checkup. Mean birth weight of ASDs was significantly lower than other developmental disorders and control groups. In mean CSHQ (Children's Sleep Habit Questions) scores, Bedtime Resistance of ASDs was significantly higher than other groups. In mean Conners3 scores, 'Anxiety' of ASDs was significantly higher than other groups. In mean the child side scores of PSI (Parenting Stress Index) , ASD group was significantly higher than other groups.
Conclusions: This is the first epidemiological study of a community-based population sample in Japan. These findings suggest that ASD children and their caregivers have more difficulties than other developmental disorders and healthy children and 40% of them have not yet received any support.

224 **166.224** Prevalence of Autism in China: A Mainstream-School Population National Study in 3 Cities

X. Sun[1], *C. Allison*[2], *L. Wei*[3,4], *F. E. Matthews*[5], *B. Auyeung*[6], *Y. Y. Wu*[7], *M. Jia*[8], *S. Baron-Cohen*[2] *and C. Brayne*[9], *(1)ä¸å›½åŒ—äº¬å¸‚æœé˜³åŒºïz½ïz½ æˆé¦¨å›å°åŒº104æ¥¼äºŒå•å…ƒ501, University of Cambridge, Beijing 100023, China, (2)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (3)Center for Bioinformatics, School of Life Sciences, Peking University, Beijing, China, (4)National Institute of Biological Sciences, Beijing, Beijing, China, (5)MRC Biostatistics Unit, Cambridge, United Kingdom, (6)University of Edinburgh, Edinburgh, United Kingdom, (7)YuNing Psychiatry Clinic, Taiwan, Taiwan, (8)Peking University 6th Hospital, Beijing, China, (9)University of Cambridge, Cambridge, United Kingdom*

Background:
Our previous study utilising a Mandarin Chinese translation of the Childhood Autism Spectrum Test (CAST) in mainstream schools reported a prevalence of Autism Spectrum Conditions (ASC) in Beijing of 119 per 10,000 (95%CI: 53, 265). The results from the Beijing study suggested an under-diagnosis of autism in a mainstream-school population, which laid the groundwork for the current large population-based prevalence study of ASC in mainland China.
Objectives:
(1) To conduct a pilot study in one city in China to test the feasibility of the measures for the main study. (2) To compare these results to two other cities in China.
Methods:
Pilot Study: We sampled one school district in the urban area of Jilin city. All students in Grades 1 to 4 (6-10 years old) in 13 mainstream primary schools and two special schools in the district were invited to participate. Each screening package included the Mandarin CAST and questions on parents' background. After screening, the children were divided into 3 groups according to their CAST score: 1) the high-score group, also known as screen-positive group: CAST score≥15; 2) the borderline group: CAST score 12-14; and 3) the low-score group: CAST score ≤11. *Study in Two Cities*: We repeated the same process in Shenzhen city, Guangdong province, in the south of China, and Jiamusi city, Heilongjiang Province, in the north of China. Children were given diagnosis of ASC after clinical assessments and research diagnostic assessments using the ADOS and the ADI-R.
Results:
Pilot Study: Seventy-seven cases were identified among a total study population of 7,258 in the district in the urban area of Jilin City, resulting in a prevalence estimate for autism of 108 per 10,000 (95% CI: 89, 130). *Study in Two Cities*: Shenzhen city: Of 21,420 children screened in mainstream primary schools (age 6-10), 122 children were given a clinical diagnosis of "ASC" or "suspected ASC". After research diagnosis, the direct raw prevalence estimate for the population was 42.3 per 10,000 children (95% CI 20.1-88.6). Jiamusi city: 16,358 questionnaires were distributed to 27 mainstream primary schools, with 100% response. 24 children were given a clinical diagnosis of "ASC" or "suspected ASC". The direct raw prevalence estimate for the population was 19.0 per 10,000 children age 6-10 (95% CI 9.7-37.5). The differences between the two regions were not significant either as a crude effect (OR=0.45 95% CI 0.16-1.23, p=0.12) or after adjusting for age, sex, income and education differences between the two regions (OR=0.39, 95% CI 0.12-1.30, p=0.13).
Conclusions:
This study shows that screening and diagnostic instruments developed in the West can be adapted for use in non-Western countries. In particular, the CAST can be used for a national prevalence study in China. Our results confirmed the under-diagnosis of ASC in the mainstream-school population in China. The current results will be compared to results from ongoing screening studies in seven other provinces. This type of epidemiological survey is essential for the assessment of service needs and the choice of the best model of service delivery.

225 **166.225** Prospective Vs. Retrospective Report of Indoor Pesticide Use during the Perinatal Period

J. Barkoski[1], *R. J. Schmidt*[2], *P. C. Chen*[1], *D. J. Tancredi*[3], *C. Walker*[4], *I. Hertz-Picciotto*[5] *and D. Bennett*[1], *(1)Public Health Sciences, University of California, Davis, Davis, CA, (2)University of California at Davis, Davis, CA, (3)Pediatrics, UC Davis School of Medicine, Sacramento, CA, (4)MIND Institute, University of California, Davis, Sacramento, CA, (5)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA*

Background: Questionnaires can help advance research when biomarker sample collection and analyses are too expensive or invasive, but only for exposures that can be reliably reported.
Objectives: Compare the reliability of maternal report of product use in and around her home on the ELEAT (Early Life Exposure Assessment Tool) administered retrospectively with her responses regarding the same products reported prospectively during pregnancy.
Methods: Participants (n=130) from the MARBLES (Markers of Autism Risk in Babies-Learning Early Signs)prospective study underwent structured interviews during pregnancy and then again with the ELEAT, a shorter instrument derived from the one utilized longitudinally, 2 or more years postpartum. The ELEAT environment module has questions about interior paint, pet flea and tick treatments, personal care products, and indoor/outdoor pesticide use. Agreement was assessed with Cohen's Kappa statistic (K), sensitivity, specificity and Youden's index (YI=Sensitivity+Specificity – 1).

Results: We found excellent agreement (K= 0.61, YI=0.59) for mothers reporting professional outdoor pesticide use during the index time (3 months before pregnancy through the child's 1st year). Questions about freshly painted walls, pet flea and tick pouch products, antibacterial soap, and indoor pesticide foggers had moderate agreement (K=0.41-0.60,YI=0.42-0.63). Other pesticide questions, professional indoor applications and, indoor and outdoor sprays, had fair agreement (K=0.21-0.40, YI=0.19-0.38). Report of pet flea treatments; such as, soap, collars, and skin products showed fair agreement. Differences in wording of the questions may have contributed to these findings of only fair agreement. Responses to specific time points over the index period did not perform as well and generally had fair agreement.
Conclusions: In this study population, responses on environmental questions at 2 years postpartum or later had very good to fair agreement when compared to answers given prospectively during the perinatal period. Studies relying on retrospective reporting need to take misclassification into account.

226 **166.226** Reliability of Self-Reported Lifestyle Exposures before, during, and after Pregnancy in Autism Studies

R. J. Schmidt[1], *P. C. Chen*[2], *C. Walker*[3], *I. Hertz-Picciotto*[4] *and D. J. Tancredi*[5], *(1)Public Health Sciences and MIND Institute, University of California at Davis, Davis, CA, (2)Public Health Sciences, University of California, Davis, Davis, CA, (3)MIND Institute, University of California, Davis, Sacramento, CA, (4)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (5)Pediatrics, UC Davis School of Medicine, Sacramento, CA*

Background:
Questionnaires can help advance research on environmental risk factors for autism when biomarker sample collection and analyses are too expensive or invasive, but only when exposures can be reported reliably.
Objectives:
To compare agreement of maternal retrospective report of lifestyle exposures in and around pregnancy on the ELEAT (Early Life Exposure Assessment Tool) with prospectively collected responses regarding the same exposures.
Methods:
Participants (n=130) from the MARBLES (Markers of Autism Risk in Babies-Learning Early Signs) prospective cohort study of high-risk siblings of children with autism completed structured telephone interviews during pregnancy and then again with the ELEAT, a shorter instrument administered 2 or more years postpartum. Agreement was assessed with Cohen's Kappa statistic (K), sensitivity (Se), specificity (Sp) and Youden's index (Y=Se+Sp-1) for each exposure ever during the index period (3 months before pregnancy until the end of breastfeeding) and during six time periods: 3 months before pregnancy, pregnancy, each trimester of pregnancy, and during breastfeeding (if a maternal exposure) or the child's first year of life (if an exposure to the child).
Results:
Retrospective reporting of maternal cigarette smoking (K=0.60, Y=0.54), other smokers within the home (K=1, Y=1), coffee drinking (K=0.64, Y=0.67), energy drinks (K=0.55, Y=0.75), alcohol (K=0.54, Y=0.63), illicit drugs (K=0.72, Y=0.57), and teeth clenching (K=0.87, Y=0.92) agreed substantially with prospective reports for the index period, but weakly to modestly agreed when taking into account timing (K/Y=0.05-0.60). Caffeinated soda (K=0.24, Y=0.42) and tea (K=0.32, Y=0.40), and sunscreen use (K=0.25, Y=0.26) during the index period had fair to moderate agreement. Sauna, hot tub and Jacuzzi use (K=0.04, Y=0.03) and maternal dental amalgam fillings (K=-0.08, Y=0.24) did not agree. Several exposures were rarely reported during pregnancy.
Conclusions:
Retrospective reports of most lifestyle exposures were reliable; future studies need to assess validity.

227 **166.227** Socioeconomic, Racial and Ethnic Disparities in the Prevalence of Autism Spectrum Disorder Among US Children

M. S. Durkin[1], *M. J. Maenner*[2], *D. Christensen*[3], *L. C. Lee*[4], *R. Fitzgerald*[5], *M. Wingate*[6], *J. L. Daniels*[7], *C. L. Arneson*[1], *K. Van Naarden Braun*[8] *and M. H. Yeargin-Allsopp*[2], *(1)University of Wisconsin-Madison, Madison, WI, (2)Centers for Disease Control and Prevention, Atlanta, GA, (3)Centers for Disease Control (CDC), Atlanta, GA, (4)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Washington University School of Medicine, St. Louis, MO, (6)University of Alabama, Birmingham, AL, (7)University of North Carolina, Chapel Hill, NC, (8)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA*

Background: Population-based studies in the US published during the past decade have reported persisting racial and ethnic differences in the prevalence of autism spectrum disorder (ASD), with prevalence estimates being significantly higher for white non-Hispanic relative to both black non-Hispanic and Hispanic children. Some US studies have also found a socioeconomic status (SES) gradient in ASD prevalence, with prevalence increasing with increasing SES. These findings point to potential under-ascertainment of ASD in disadvantaged groups, and raise the question of whether the racial and ethnic disparities in ASD prevalence are due to confounding by SES.
Objectives: Using data from the Autism and Developmental Disabilities Monitoring (ADDM) Network for surveillance year 2010, the objectives of this study were to: (1) replicate findings from a previous study based on data for surveillance years 2002 and 2004, which showed a SES gradient in ASD prevalence and prevalence nearly 70% higher in children of high versus low SES (prevalence ratio 1.69, 95% confidence interval [CI] 1.55, 1.83); and (2) evaluate whether racial and ethnic differences in ASD prevalence persist after controlling for SES.
Methods: A cross-sectional study was implemented combining data from the 11 2010 ADDM Network sites. The ADDM Network is a multiple source surveillance system that incorporates abstracted data from health and/or school records to determine the number of 8-year-old children meeting diagnostic criteria for ASD (for 2010, this included *Diagnostic and Statistical Manual of Mental Disorders, fourth edition, text revision* criteria for autistic disorder or pervasive developmental disorder). The population base included 363,749 8-year-old children, of whom 5,338 met criteria for ASD in 2010. Census tract-level measures of poverty from the 2006-2010 American Community Survey were used to create SES tertiles of the population.
Results: The prevalence of ASD in the combined study area in 2010 was 14.7 per 1,000 children (95% CI 14.3, 15.1) and was higher in white non-Hispanic than both black non-Hispanic (prevalence ratio 1.22 [95% CI 1.13, 1.30]) and Hispanic children (prevalence ratio 1.47 [95% CI 1.35, 1.59]). Prevalence increased stepwise with increasing SES, from a low of 10.9 (95% CI 10.3, 11.5) per 1,000 children in the lowest SES tertile to a high of 19.7 (95% CI 18.9, 20.5) in the highest SES tertile (high to low SES prevalence ratio 1.81 (95% CI 1.69, 1.94). In stratified analyses, the SES gradient and significantly elevated SES prevalence ratios were present among all sub-groups examined. Racial and ethnic differences in ASD prevalence were also present in children of low SES, among whom the white non-Hispanic to black non-Hispanic and white non-Hispanic to Hispanic prevalence ratios (95% CI) were 1.34 (1.17, 1.53) and 1.46 (1.28, 1.68), respectively.
Conclusions: The SES disparity in ASD prevalence based on US surveillance data persisted between 2002 and 2010, and this disparity, according to SES measures available for this study, does not appear to fully explain the observed racial and ethnic disparities in ASD prevalence in the US.

228 **166.228** Stressful Life Events during Pregnancies Related to Children with ASD, Their Siblings and Typically Developing Children

E. Grossi[1], *F. Veggo*[1,2], *A. Narzisi*[3], *F. Muratori*[3], *I. Rolla*[4] *and L. Migliore*[4], *(1)Autism Unit, Villa Santa Maria Institute Neuropsychiatric Rehabilitation Center, Tavernerio, Italy, (2)Child and Adolescent Neuropsychiatry, University of Milan- Bicocca, Monza, Italy, (3)IRCCS Stella Maris Institute, Pisa, Italy, (4)Human Genetics, Pisa University, Pisa, Italy*

Background: The role of stressful events in contributing to increased autism risk deserves special attention since very few studies have attempted to collect this kind of information. Adverse experiences during the prenatal period (a time of rapid growth and of heightened brain plasticity) have been demonstrated to induce significant effects on neurobiology, metabolism, and physiology that can persist across the lifespan. Generally, the more variable the stressor and the earlier the stressors occur in the pregnancy, the more profound the effect on offspring development. A number of basic science studies indicate that a family history of stress may program central and peripheral pathways regulating gestational length and newborn health outcomes in the maternal lineage. Epigenomic programming related to hypothalamic-pituitary-adrenal (HPA) axis responses to chronic stress may be an important mechanism involved in autism development.
Objectives: The aim of this study was to assess the frequency and impact of different stressful life events. Data was collected from careful interviewing during pregnancies of the following three groups: mothers of children with ASD, of their typically developing siblings (internal controls) and of only typically developing children (external controls) in two Italian provinces, Como and Pisa.
Methods:
The clinical sample included a cases group of 73 ASD children and adolescents – group 1 (mean age 8.2; S.D. 6.35) compared to an internal control group formed by 45 healthy siblings – group 2 (mean age 8.9 years; S.D. 6.66) and to an external control group formed by 96 typically developing children – group 3 (mean age 7.8; S.D 5.67). It is important to note that the second group represented all the siblings available. Mothers of ASD children who met the inclusion criteria were invited to an individual structured interview about stressful life events after having signed an informed consent form. Stressful events considered in the survey were: death or severe disease of a relative, divorce, separation or conjugal conflict, loss of house or eviction or relocation, abuse or violence and job strain.
Results:
A statistically higher prevalence of the mean number of stressful events per pregnancy was recorded in the ASD group when compared to the internal and external control groups. The mean number stressful events (range) was = 0.45(0-5), 0.29(0-3) and 0.11(0-2) in the three groups respectively. Group 1 vs group 2: $p < 0.05$; Group 1 vs group 3: $p < 0.001$; Group 2 vs group 3 $p < 0.01$.
Conclusions: Stressful life events during pregnancy are more frequent in mothers of children with autism than mothers of typically developing children. The rate observed in sibling pregnancies lies exactly in the middle, pointing out a possible threshold effect in women predisposed to suboptimal pregnancies.

229 **166.229** The Association Between Prenatal Exposure to Maternal Infection and Autism Spectrum Disorder in the Boston Birth Cohort

M. Brucato[1], *C. Ladd-Acosta*[2], *M. Li*[3], *D. M. Caruso*[4], *X. Hong*[5], *X. Wang*[6] *and M. D. Fallin*[7], *(1)Epidemiology, Johns Hopkins University School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Johns Hopkins School of Public Health, Baltimore, MD, (4)Center on the Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD, (5)Johns Hopkins University School of Public Health, Baltimore, MD, (6)Center on Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD, (7)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: ASD is phenotypically and etiologically heterogeneous, with evidence for genetic and environmental contributions to disease risk. Research has focused on the prenatal period as a time where environmental exposures are likely to influence ASD development. There is evidence from animal models and human epidemiologic studies that prenatal exposure to maternal infection may lead to an increased risk of neurodevelopmental disabilities, including autism, in the offspring.
Objectives: We aim to estimate the association between prenatal exposure to maternal infections, including influenza and genitourinary infections, and ASD in a prospective birth cohort of an understudied urban minority population in the United States.
Methods: We used data from the Boston Birth Cohort (BBC), a prospective birth cohort with pregnancy exposure, early life factors, and phenotypic data available for over 8,000 mother-child dyads recruited at the Boston Medical Center. The BBC enrolls predominantly urban, low-income minority mothers and their children (approximately 38% self-identify as black/African American, 22% Hispanic, 19% Haitian, 8.5% white). We performed a nested case-control analysis including 109 children with ASD and 833 children with typical development. ASD information was obtained from electronic medical record data, based on the presence of relevant ICD-9-CM hospital diagnosis codes from pediatric outpatient, inpatient, and emergency room visits. Information on maternal history of infection during a child's gestation was obtained from postpartum maternal questionnaires, given 24-72 hours after delivery, years prior to any ASD diagnosis. Analyses were adjusted for socioeconomic status as represented by educational attainment, marital status, and race. Sensitivity analyses further included adjustment for child sex, maternal age, birth year, parity, and maternal smoking during pregnancy.
Results: No association was found between self-reported maternal history of influenza, fever, or genitourinary (GU) infections and risk of ASD development in the offspring in either unadjusted (flu, OR of 1.03 [95% CI 0.60-1.68]; fever, 1.38 [0.71-2.52]; GU infection, 0.63 [0.39-1.00]) or adjusted analyses (flu, 1.05 [0.62-1.73]; fever, 1.39 [0.71 - 2.54]; GU infection, 0.67 [0.41-1.06]). Further adjustment for child sex, maternal age, birth year, parity, and maternal smoking during pregnancy did not alter these null associations.
Conclusions: In contrast to the results from several large studies of European registries or predominantly white American populations, the Boston Birth Cohort, a large urban, minority prospective birth cohort does not provide evidence for an association between history of exposure to infection during gestation and later development of Autism Spectrum Disorder.

230 **166.230** The Association Between Trimester Specific Daily Average PM2.5 and Autism Spectrum Disorder: A Large-Scale Multi-Source Linked Analysis

N. Connolly and ***K. A. Bowers****, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Data integration allows one to take advantage of the vast amounts of data available in various sources in order to gleam new insights into the etiology of ASD. This presentation presents the results of a large-scale data integration analysis, combining electronic medical records (EMR) from a premier ASD diagnosis and treatment center with Ohio state birth records, as well as with an environmental toxin exposure dataset released by the Environmental Protection Agency (EPA).
Objectives: Our objective was to assess the applicability of big data analytics to integrate multiple data streams and conduct epidemiologic analyses using multiple environmental exposures as a model.
Methods: In order to produce our integrated dataset, we first queried the EPIC-hosted EMR of Cincinnati Children's Hospital Medical Center (CCHMC) to identify all patients with a diagnosis of ASD. We included all patients with a 299.* ICD9 diagnostic code in their EMR from 2009-2014 that was recorded by CCHMC's Division of Developmental Disabilities and Behavioral Pediatrics (DDBP). In addition, we employed natural language processing (NLP) techniques to gleam clinical concepts (including diagnoses) from free-text office visit notes. We manually reviewed approximately 100 clinical notes to ascertain the agreement between the NLP-extracted assessment of ASD status in the clinical notes, and the presence or absence of the corresponding ICD9 code in the encounter diagnosis list.
We then matched the EMR data with Ohio state birth records in order to 1) identify the pre-birth residence of mothers who gave birth to offspring with ASD; and 2) have access to a large number of locale- and age- matched controls unaffected by ASD. To link the data sources, we wrote custom software (based on the PERL scripting language) that matched patients by birthdate, and first and last names, allowing for minor misspellings.
Having geocoded the addresses where mothers of ASD cases and controls resided immediately prior to giving birth, we estimated prenatal exposure to environmental factors by linking addresses with two public datasets released by the EPA. The first dataset estimates green scape coverage within 400 m of an address; the second uses a Bayesian space-time fusion model [1-3] to estimate daily $PM_{2.5}$ (daily average) and O_3(daily 8-hr maximum) on a 12km x 12km grid for the conterminous United States, for years 2001-2008.
Using logistic regression to control for birth year and additional covariates, we will determine the association between ASD and green space, as well as trimester-specific association with $PM_{2.5}$ and O_3.
Results: We have found that NLP techniques successfully abstract clinical concepts from free text. We found integration of Ohio state birth records with EMR can be conducted with high accuracy. However, due to sparsity of environmental monitors in our geographical area, extrapolation of environmental data to a wide range of geocoded location is associated with uncertainty.
Conclusions: Using novel EMR data extraction methods and data linkage with multiple source/databases, we will efficiently evaluate the association between prenatal exposure to $PM_{2.5}$, O_3 and access to green space, and ASD.

231 **166.231** The Effects of in Vitro and In Vivo Exposure of Persistent Organic Pollutants on Immune Function in Children with ASD

J. Van de Water[1], *M. E. Akintunde*[2], *Y. Lin*[3], *B. Puschner*[3], *P. Ashwood*[4], *I. Hertz-Picciotto*[5] *and P. Krakowiak*[4], *(1)University of California at Davis MIND Institute, Davis, CA, (2)University of California Davis, Davis, CA, (3)University of California, Davis, Davis, CA, (4)UC Davis, Sacramento, CA, (5)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA*

Background: It has been previously demonstrated that some children with autism (AU) have a dysregulated immune profile that often correlates with behavioral deficits. We postulate that such dysregulation might be the result of an increased susceptibility to environmental toxicants, such as the congener polybrominated diphenyl ether-49 (BDE-49).
Objectives: We sought to examine the relationship between blood levels of PBDE and the differential sensitivity of the immune cells following *ex vivo*PBDE exposure using banked plasma and activated peripheral blood mononuclear cell (PBMC) supernatants from children with ASD, and age- and geographically- matched typically developing control (TD) children enrolled through the CHARGE (CHildhood Autism Risks from Genetics and the Environment) study.
Methods: Using banked plasma from children with ASD, and age- and geographically-matched typically developing control (TD) children enrolled through the CHARGE (CHildhood Autism Risks from Genetics and the Environment) study, we determined blood levels of 11 major PBDE congeners using mass spectrometry. We analyzed cytokine/chemokine levels in activated peripheral blood mononuclear cell (PBMC) supernatants with and without ex vivo BDE-49. We then correlated total body burden as well as individual congener levels with T cell cytokine/chemokine production.
Results: We found that despite no difference in overall body burden between the two subject populations, increased body burden of PBDE correlates with a suppressed immune response, especially in children with ASD. There was a differential effect of total PBDE body burden on baseline (no activation) immune function between ASD and TD children whereby T cell function was more negatively affected in ASD than in TD, as measured by lower levels of IL-2, IL-13 and IFN-gamma**.** Higher plasma levels of PBDE were also negatively correlated with production of the adaptive T-cell cytokines IL-2 and IL-13 after activation of PBMCs. Further, higher plasma levels of PBDE negatively correlated with the production of inflammatory (IL-17) and regulatory (IL-10) T-cell cytokines after PBMC activation. Finally, baseline production levels of T cell cytokines IL-2 and IFN-gamma are significantly negatively impacted by several individual BDE congeners in children with ASD compared to TD controls at baseline; this was highly significant for the congener BDE-49 ($p=0.001$). Further, when PBMC from children with ASD and TD controls were exposed *ex vivo* 50nM BDE-49 without stimulation (media control), we noted a significant increase in the production of the inflammatory cytokines IL-6, TNF-alpha, IL-1, and the chemokines MIP-1a and MCIP-1 in ASD cases compared to the TD controls ($p<0.05$). Finally, an increase in IL-6 ($p=0.01$) and GM-CSF ($p=0.03$) was noted following pre-treatment with 250nm of BDE49, and this was significantly positively correlated with higher body burden of BDE-49, but not BDE-47 or BDE-95.
Conclusions: We have found that despite a nearly identical body burdens of the flame-retardant PBDE in ASD and TD children, there is a differential impact of PBDE exposure on immune system function in children with ASD compared to little or no impact on the TD control children. This suggests an underlying susceptibility to environmental toxicant exposure in children with ASD that could relate to immune anomalies reported in these children.

Baseline production levels of T cell cytokines IL-2 and IFN-gamma are significantly negatively impacted by several BDE congeners in children with ASD compared to TD controls at baseline

232 **166.232** The Hidden Disorder: Undiagnosed Autism Spectrum Disorder in Women

H. L. Belcher[1], *S. D. Stagg*[2] *and R. M. Ford*[2], *(1)Anglia Ruskin University, Cambridge, England, United Kingdom, (2)Psychology, Anglia Ruskin University, Cambridge, United Kingdom*

Background:
Autism Spectrum Disorder (ASD) is thought to be more prevalent in males than females, and this is especially true at the higher end of the spectrum. However, females are often diagnosed later than males, suggesting that rather than females being less likely to have the disorder, it is possible they are more likely to be missed; either going undiagnosed or being misdiagnosed with a mental health condition.
Objectives:
The current study aimed to determine the rate of undiagnosed autism in males and females in a large sample of individuals responding to an online survey. The study also aimed to evaluate the number of mental health diagnoses among participants who met the cut-off on an ASD screening tool as a function of gender and diagnostic status.
Methods:
A screening survey was distributed to all UK universities and advertised to the general public via radio and TV. Participants were not informed about the nature of the survey until after completion. Amongst other measures, the survey consisted of the Autism Quotient (AQ) and a simple self-report mental health checklist. The survey received 7,537 respondents (mean age = 32 years, SD 13.77, range 16 - 88). Responses were grouped according to their AQ scores and current diagnostic status (e.g., meets the AQ cut off for concern/diagnosed, meets cut off/undiagnosed, does not meet cut off).
Results:
A significantly higher number of female respondents met the AQ cut off without a diagnosis than male respondents fulfilling the same criteria (22% of females v. 17% of males). These women had significantly fewer mental health conditions (M = 1.20) than women who met the cut off and were diagnosed (M = 1.70), but a similar number to males who met the cut off and had a diagnosis (M =0.90).
Conclusions:
Our findings suggest that there is a large proportion of women who may meet the criteria for autism but do not have a diagnosis. Our findings further suggest that women may require more mental health problems prior to a diagnosis of ASD. This would support the Female Masking Effect theory of ASD, which suggests that females need to reach a higher threshold of difficulties before being noticed or diagnosed. Females with ASD may only arouse suspicion after seeing numerous professionals and presenting with a complex symptom history.

233 **166.233** The New Jersey Autism Registry: Development and Impact

S. Howell[1] *and N. Scotto Rosato*[2], *(1)NEW JERSEY DEPT OF HEALTH, Milford, NJ, (2)New Jersey Dept of Health, trenton, NJ*

Background: The rise in the prevalence of Autism Spectrum Disorders (ASD) rates over the past 15 years has spurred a number of national endeavors by the CDC, NIH, and other organizations to better understand the increase, what causes autism, and what services are needed. In 2007, New Jersey enacted a mandated an Autism Registry for all children (0-21) in response to its CDC prevalence rate of 1:94. Today, over 18, 000 children have been registered and referred for case management services. The data has provided a wealth of information on demographic differences, risk factors, and Early Intervention (EI) service use.
Objectives: This presentation provides an overview of how a mandated state-based autism registry was developed and can yield information regarding age of diagnosis, symptoms, demographics, and other vital information for policy makers and service planners.
Methods: A descriptive overview is provided regarding the development and key components of the Registry. Data were analyzed in terms of race/ethnicity, age of diagnosis, comorbidities, difference in subtypes, maternal and paternal age, birthweight, and plurality. Data were matched to Birth Certificate and EI data.
Results: Over 3000 children per year have been registered since 2009. 60.8% of children were classified with Autistic Disorder, 23.3% Pervasive Developmental Disorder (PDD)-NOS, and 15.3 Asperger Syndrome. The mean and median age of first diagnosis was significantly different by subtype: Autistic Disorder=4.25 and 3.2; PDD-NOS=4.6 and 3.6; and Asperger Syndrome=8.2 and 7.8. The race/ethnicity analysis (see Table 1) shows Hispanics represented 24.5% of the children in the Registry, while 18.9% of all children in NJ and 17.1% in the US are Hispanic. Black Non-Hispanics and Asians were less likely to be in the Registry. Age of diagnosis by race shows that Hispanics are more likely to be diagnosed earlier (38.6% by age 3) than Whites (32.8%) and Blacks (35.2%). While most children were diagnosed after the age of 3, the EI data showed that about 60% of children registered had been enrolled in EI (see Table 2). As expected, children in the Registry are more likely to born to older mothers, born prematurely and have lower birth weights. Interestingly, the percent of mothers over 35 is much higher in New Jersey (22.1%) than the US (15.3%) which may help explain why the rates of autism appears to be higher in NJ than the other states in the CDC surveillance studies.
Conclusions: Using a state-law to mandate the reporting of Autism, NJ designed a registry with three main goals: link individuals to services and resources; plan services; provide prevalence and epidemiological information. The system was designed to include newly and previously diagnosed children, collect maternal, birth, and diagnosis-

specific information, and refer all children to case management services. The Autism Registry has also produced important information for policy makers about the age of diagnosis, the impact of race on the age of diagnosis, and the population risk factors that may exist in New Jersey.

234 **166.234** The Relationship Between Use of Maternal Anesthesia during Delivery and Child Development at 12 Months in the Enriched Risk EARLI Pregnancy Cohort

S. C. Brown[1], *M. D. Fallin*[2], *C. J. Newschaffer*[3], *L. A. Croen*[4], *M. Stacy*[5], *M. Landrum*[6], *C. Walker*[7], *M. L. Massolo*[4], *R. Landa*[8], *J. Feinberg*[9], *K. M. Bakulski*[6], *I. Hertz-Picciotto*[10], *D. M. Caruso*[11], *X. Hong*[12] *and X. Wang*[13], *(1)Mental Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (3)A.J. Drexel Autism Institute, Philadelphia, PA, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)Southern Illinois University- Carbondale, Carbondale, IL, (6)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)MIND Institute, University of California, Davis, Sacramento, CA, (8)The Kennedy Krieger Institute, Baltimore, MD, (9)Johns Hopkins University, Baltimore, MD, (10)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (11)Center on the Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD, (12)Johns Hopkins University School of Public Health, Baltimore, MD, (13)Center on Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD*

Background: Many pre- and perinatal risk factors have been reported to increase the risk of ASD, including obstetric complications, antidepressant and anti-seizure medications, maternal infection, and pre-pregnancy BMI. The rate of maternal anesthesia use has tripled over the past 35 years and it is estimated that approximately 60% of US women receive some form of anesthesia during labor. Many of the anesthetics have been shown to move rapidly through the placenta, but research on the effects has focused mainly on short term outcomes.

Objectives: To evaluate the relationship between maternal anesthesia use during delivery and child development at 12 months based on the AOSI (Autism Observation Scale for Infants), in an ASD high-risk pregnancy cohort. To also evaluate the relationship between the specific types and doses of anesthetics used during delivery and child development and ASD diagnosis in an urban medical system.

Methods: Data are from the Early Autism Risk Longitudinal Investigation (EARLI) study and the Boston Birth Cohort (BBC). EARLI is an ASD high-risk pregnancy cohort that follows mothers of children with ASD from the start of a subsequent pregnancy through age 3 of the child. Available data include self-reported maternal medical, dietary, and health behaviors histories; labor and delivery; biological samples; and autism and other behavioral assessments. The AOSI is a play-based observational evaluation for children aged 6-18 months that has been correlated with later diagnosis of ASD. Of 259 live births in the EARLI cohort, 176 had both maternal labor and delivery records and AOSI scores available. The association between maternal use of anesthesia (all, epidural, spinal) and AOSI score parameterized as continuous and dichotomous (total AOSI>7) outcomes was estimated using multiple linear and logistic regression, respectively, while adjusting for potential confounders. The BBC is a prospective birth cohort of approximately 8,500 mother infant pairs. Available data include labor and delivery records, hospital and medical records. At this time there are approximately 107 children in the BBC with an ICD9 code indicating ASD. As a replication, BBC data will be analyzed to evaluate the relationship between specific anesthetics and the doses used during delivery and an ASD diagnosis.

Results: Twelve month AOSI score was significantly associated with the use of epidural (β = 2.3., p =0.005) and spinal (β = 2.6., p =0.002) anesthesia in the EARLI cohort with adjustment for gender, gestational age and father's ethnicity. After adjusting for cesarean delivery only epidural anesthesia (β = 2.5., p =0.002) was significantly associated with AOSI score. Similar results were seen whether AOSI was parameterized as dichotomous (top quartile) or continuous. No significant associations were found with AOSI score and other labor and delivery or maternal medical history risk factors examined. Replication analyses in the BBC sample are underway.
Conclusions: The use of maternal epidural anesthesia during delivery was associated with an increase in the 12 month AOSI score in 176 children in the EARLI cohort. BBC data will be analyzed to assess the drug and dose specific relationships between maternal anesthesia and a diagnosis of ASD.

236 **166.236** The Utility of Traditional Epidemiologic Designs in ASD Research

***M. D. Fallin**, Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: Autism epidemiology can be informed through many design choices. For example, registry-based data have very large samples sizes and increased precision. However, they often lack detailed information about presentation, subtypes, exposures, and biosamples. More traditional case-control and cohort designs sacrifice precision given the typically much smaller sample sizes, but can capture deep phenotype and biomarker information.
Objectives: To describe the advantages and disadvantages of traditional case-control and cohort designs that include direct enrollment and participation, and to show the utility of such designs in ASD research.
Methods: We work primarily with three epidemiology studies of autism: a national population-based case-control study, an enriched risk pregnancy cohort, and a hospital system-based birth cohort. The Study to Explore Early Development (SEED) is a 6-site case-control study that recruits ASD cases, non-ASD developmentally disabled children (DD), and typical children (POP) aged 3-5 years via medical and education service providers (ASD and DD), and vital records (POP). The Early Autism Longitudinal Risk Longitudinal Investigation (EARLI) recruits pregnant women from 4 sites who already have a child with ASD and follow them through the pregnancy and the baby's first 3 years. The Boston Birth Cohort (BBC) recruits women 1-3 days post-delivery and follows the babies through childhood via direct contacts at routine clinic visits and via electronic medical records.
Results: SEED includes extensive interview-based information on peri-natal risk factors, maternal and child medical records, extensive clinical assessment, and biosamples of children and parents, enabling examination of environmental, genetic, epigenetic, and gene-environment hypotheses. While the case-control design allows relatively large sample sizes, it precludes biosample and exposure assessment in the perinatal risk period and is subject to recall bias. The EARLI study collects home environmental samples, parental, ASD case, and new sibling biosamples longitudinally beginning in pregnancy, extensive prospective questionnaire/interview data, and developmental phenotypes from 6 – 36 months. This allows very detailed analysis of exposures, genetics, and epigenetics at relevant time windows in different tissue types, as well as examination of ASD and related quantitative and longitudinal phenotypes. It is necessarily enriched risk to enable enough accumulated cases for study, but nevertheless is limited in total sample size. Finally, the BBC collects birth biosamples on mothers and babies, as well as later childhood biosamples, in addition to access to complete medical record information combined with prospective questionnaire data and neurodevelopmental screening. It has the advantage of large sample size and nearly exhaustive medical record access.
Conclusions: Studies that involve direct contact offer advantages to registry and HMO-based research that passively use data collected for other purposes. These include deep phenotyping data, biomarker availability, and a diversity of biosamples from relevant time windows. However, such studies are limited by design challenges and sample size. All design choices inform ASD epidemiology, services, and policy research in complementary ways and cross-collaboration between them can help to maximize that complement.

237 **166.237** Title: Investigation of Parental Priorities for Research in Children with Neurodevelopmental and Genetic Disorders: A National Irish Study

***N. Mc Devitt**[1], L. Gallagher[2] and R. B. Reilly[3], (1)Trinity College Dublin, Dublin, Ireland, (2)Psychiatry, Trinity College Dublin, Dublin, Ireland, (3)Department of Engineering, Trinity College Dublin, Dublin, Ireland*

Background: Very little research exists that investigates the opinions of people affected by neurodevelopmental disorders on a daily basis. The current research investigates what parents consider most important in terms of research for their children. This information my help to inform how funding is allocated and what areas need funding. Collaboration between families and the scientific community will create a research environment that is more structured and patient based.
Objectives: To conduct a consultation with the community of individuals impacted by neurodevelopmental disorders particularly Autism Spectrum Disorders (ASD) to better understand critical issues that the community might identify as priorities for research.
Methods: This research consisted of a 30 question survey, the aim was to collect both quantitative and qualitative responses from a significant number of parents. The survey was divided into several categories including; background, research priorities and motivations and barriers to research. A number of question types were utilised e.g Likert scale, multiple choice and answer boxes. The survey was distributed via www.surveymonkey.com, to parent advocacy groups and parent groups all over Ireland.
Results: 260 parents successfully completed the survey. 80% of Participants were parents of people with ASDs. Of all participants 33% said they had been approached to take part in research before and 22% of this group had taken part. The types of research that these participants took part in were mostly surveys (56%) and Interview Assessments (33%), with only one participant having taken part in a drug trial. The main research priorities for participants are development of services for adults and development of therapies/programs that aid day to day life (>90% Very Important). Development of methods for earlier/easier diagnosis was also deemed to a priority for research with (83% Very Important). Development of medicines is showing to be of least priority for parents. Parents indicated that if a therapeutic intervention was offered as part of the research" they would be more motivated to participate. Parents also reported that factors such as the location of the research centre and likelihood of causing distress to their child as reasons for them not to participate.
Conclusions: This research is particularly novel and timely due to the fact that there is very little research, which involves investigating research priorities for people who are affected by intellectual and developmental disabilities day to day. It was notable that only 22% of the people approached to take part in research ultimately participated. At a minimum this illustrates that researchers are challenged to communicate adequately regarding research methods to alleviate these concerns where these are unfounded. The survey clearly illustrated that parents prioritised clinical services research and interventions over basic scientific questions. Development of medicines was consistently reported to be of least importance to parents. Utilising the information gained from this research correctly may help to create a more friendly research environment which could increase research participation, develop research studies that aim to meet the needs of affected individuals and create more balanced allocation of research funding.

238 **166.238** Validation of the Spanish Version of the M-CHAT-R/F within the Public Health System

***M. Magan Maganto**[1], A. Aranz-Hernandez[1], M. Martinez-Velarte[1], S. Manso[1], A. De Pablos De La Morena[1], P. Garcia Primo[2], M. Posada[3], A. B. Sanchez-Garcia[1] and R. Canal-Bedia[1], (1)University of Salamanca, Salamanca, Spain, (2)Institute of Rare Diseases Research, IIIER, Carlos III National Health Institute, Madrid, Spain, (3)Carlos III National Health Institute, Madrid, Spain*

Background:
Different studies have shown that the M-CHAT is among the best screening tools for ASD in general populations studied so far (McPheeters et al., 2015), while the proportion of recognizing that identified ASD cases in the studies remains lower than the prevalence estimated by the CDC. Besides the M-CHAT can have a high rate of cases with suspected ASD initially requiring subsequent telephone follow-up.
A new version of the M-CHAT questionnaire, the M-CHAT-R / F is available (Robins et al., 2014) which includes a structured monitoring and referral and to apply a risk-based algorithm system levels, reducing the number of cases that require follow-up phone call. The M-CHAT-R / F seems to have better psychometric properties, but information about the feasibility and validity of this tool in a general population-based study is still necessary.
Objectives:
The main objective of this work is to validate the Spanish version of the M-CHAT-R/F. Furthermore, to describe the possibility of integrating the ASD screening practice, that has up till now been focused on research, into the national health system, as a standard practice for pediatricians who are responsible for well-child visits.
Methods:
The M-CHAT-R/F was translated into Spanish and a cross-cultural adaptation was performed. A population-based ASD screening programme using MCHAT-R/F Spanish version was established in two Spanish regions. Parents of 18 months and/or 24 months aged children were asked to fill in this questionnaire at the outpatient public health services (compulsory vaccination programme and well-child check-up programme respectively). The original MCHAT-R/F criteria and a refining procedure for the phone call were adopted after agreement with the MCHAT authors. The identification of false negatives is coordinated with the ASD early intervention centres, and the Hospital diagnosis units in both regions.
Results:
A total of 2970 questionnaires were administered to 2560 children from April 2014 to October 2015. Of the positive screening cases, 7 children have been diagnosed with ASD; 8 with non ASD disorders following the DSM-5 criteria; 3 with typical development; and 13 children that have not yet been evaluated. Only 10 families of the 62 positive cases from the questionnaire were unreachable during the item verification stage. The sensitivity and specificity obtained were 0.857 and 0.997, respectively. Positive predictive value was 0.429 and negative 0.999. Updated results will be presented in May 2016.
Conclusions:
The M-CHAT-R/F shows promise as a screening tool for developmental disorders in the general population. This work is an important contribution to ongoing research into identification of ASD at a young age. Although there have been many advances in the screening process, the tools used, and strategies to detect false negatives and reduce

false positive rates, ongoing study is needed to continue improving the early detection of autism.

239 **166.239** Variance in Autism Prevalence Across States: Links with Insurance Policy, Availability of Clinical Resources, Proximity to Research Institutions, and Presence of Awareness-Raising Organizations

*J. S. Kester[1], **T. L. Hill**[1], L. B. Swineford[2] and C. N. Baker[1], (1)Department of Psychology, Tulane University, New Orleans, LA, (2)Department of Speech and Hearing Sciences, Washington State University, Spokane, WA*

Background:
Not only are prevalence estimates of autism spectrum disorders (ASD) increasing, but marked variability in prevalence rates also exists across US states. While specific reasons for this variability remain unknown, previous studies have highlighted the influence of sociodemographic characteristics (e.g., maternal education), availability of educational and medical records, and variation in service models. However, variables related to state infrastructure such as healthcare and insurance policy, availability of clinical resources, location of federally-funded research institutions, and the presence of advocates and non-profit organizations dedicated to raising awareness about ASD have not yet been examined. Given that prevalence rates underlie policy, research, and practice decisions, understanding state infrastructure differences that impact ASD prevalence has important implications.
Objectives:
To determine if variation in ASD prevalence estimates across US states can be linked to between-state differences in policy, clinical resources, research institutions, and awareness.
Methods:
Data for independent variables were abstracted per standardized coding schemes from publically available databases such as those on the Autism Speaks and NIH RePORTER websites. States received a 0-6 score for healthcare and insurance policy based on number of insurance mandates providing coverage for ASD. States received a clinical resource score based on the total number of diagnostic resources, intervention resources, and board certified behavior analysts present in the state. Research institution scores were based on the number of institutions with active federal funding for autism research. Finally, states received an awareness summary score based on the number of advocates and non-profit organizations dedicated to raising awareness about ASD. The dependent variables were the published CDC/ADDM Network and IDEA Part B Child Count prevalence rates for ASD.
Results:
States had on average 3.18 (*SD*=1.42) of the attributes of comprehensive healthcare and insurance policy. Clinical resources (*M*=519.42, *SD*=774.84), the number of research institutions performing autism research (*M*=5.58, *SD*=6.87), and the number of groups that aim to raise awareness (*M*=51.34, *SD*=61.03) varied considerably across states. Policy, clinical, research, and awareness composites were not related to CDC/ADDM prevalence rates of autism (*rho*s=.26-.44, all *p*s>.10). States with and without CDC/ADDM data were also compared. States that provided CDC/ADDM prevalence rates had better policy than those that did not (*U*=86.5, *p*=.002); no significant differences were found for clinical, research, and awareness scores between states that did and did not provide CDC/ADDM estimates (*U*s=151.5-192.5, all *p*s>.10), In contrast to the CDC/ADDM prevalence rates, higher scores on policy (*rho*=.28, *p*=.05), clinical resources (*rho*=.90, *p*<.001), research institutions (*rho*=.76, *p*<.001), and awareness (*rho*=.88, *p*<.001) were all strongly related to higher IDEA prevalence rates. See Table 1 for descriptive statistics of resource summaries by state subgroup.
Conclusions:
Prevalence rates vary by state depending on the number of resources within that state focused on ASD. However, the relationship between prevalence estimates and resources also vary between the two main sources of prevalence estimates of ASD. Study implications for policy, research, and practice will be discussed.

Table 1

Descriptive Statistics of Resource Summaries by State Subgroup

	States with CDC/ADDM Prevalence Data (n = 11)			All States (n = 50)		
Variable	*M*	*SD*	Range	*M*	*SD*	Range
Policy	4.27	1.27	[1,6]	3.18	1.42	[1,6]
Insurance Mandate	.91	.30	[0,1]	.82	.39	[0,1]
Age Limit	.73	.47	[0,1]	.44	.50	[0,1]

173 - "Moving the Needle" with Life Course Research on Autism
9:00 AM - 10:00 AM - Hall B

Speaker: P. Shattuck, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

There have been many calls to “move the needle” on adult outcomes. What kinds of research might influence population-level outcomes and build the “gauges” that will let us see if the adult outcomes needle is moving over time? A life course perspective on autism has roots in sociology, public health and ecological models of human development. I will selectively describe some major tenets from this perspective. Then I will illustrate ways the AJ Drexel Autism Institute’s Life Course Outcomes research team has sought to examine specific topics and our attempts to connect research to policy and practice. Poor young adult outcomes are occurring despite historic record-setting levels of expenditures on research and interventions. My talk aims to stimulate discussion about how our field can tighten the linkage between research and improved outcomes that are observable at a population level.

9:00 “Moving the Needle” with Life Course Research on Autism

***P. Shattuck**, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

There have been many calls to “move the needle” on adult outcomes. What kinds of research might influence population-level outcomes and build the “gauges” that will let us see if the adult outcomes needle is moving over time? A life course perspective on autism has roots in sociology, public health and ecological models of human development. I will selectively describe some major tenets from this perspective. Then I will illustrate ways the AJ Drexel Autism Institute’s Life Course Outcomes research team has sought to examine specific topics and our attempts to connect research to policy and practice. Poor young adult outcomes are occurring despite historic record-setting levels of expenditures on research and interventions. My talk aims to stimulate discussion about how our field can tighten the linkage between research and improved outcomes that are observable at a population level.

Panel Session
174 - Life Course and Ecological Perspectives on Autism
10:30 AM - 12:30 PM - Hall B

Panel Chair: Paul Shattuck, *Suite 560, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

This panel’s purpose is to illustrate a range of types of questions and methods informed by life course and ecological perspectives. In general, these perspectives emphasize the social context of development and interventions, how social role attainment and performance intersect with social institutions, and a longitudinal perspective on individual development that pays particular attention to transitions and turning points. How life turns out is not solely a function of one’s behaviors, symptoms and individual abilities. Studies reported as part of this panel will examine topics including social networks and the social dynamics of intervention, barriers to positive outcomes during the transition to adulthood, stigma, and advocacy preparedness as a target of intervention.

10:30 **174.001** Out in the Cold: Adults with Autism Spectrum Disorders Post High School

***C. Anderson**[1] and A. Lupfer[2], (1)Department of Interprofessional Health Studies, Towson University, Towson, MD, (2)Towson University, Towson, MD*

Background: National data have revealed that adults with autism spectrum disorder (ASD) are not faring well as a group in the years post high school. Few live independently, many are disengaged from services, and participation in post-secondary education and the world of work is often restricted.
Objectives: To move beyond national statistics and determine why so many young adults with ASD are disengaged from services and educational or vocational opportunities in the years post high school.
Methods: Utilizing a qualitative, grounded theory approach, 90 minute interviews were conducted with twenty parents of young adults with ASD who were 1-15 years post high school. These young adults had been either “certificate-bound,” exiting high school around age 21 (n=7), or “diploma-bound,” exiting around age 18 (n=13). Inclusion of both groups yielded experiences from across the autism spectrum. Parents shared information about their young adult’s experiences surrounding transition. Interviews were transcribed and de-identified. We used Atlas.ti to apply the *constant comparative method*. First, key themes based on participants’ experiences and beliefs were identified (e.g. a number of families described how services provided to their adult child were inappropriate and did not meet the adult child’s needs). Second, material associated with each theme was divided into meaningful categories (e.g. “inappropriate services” was subdivided into access, program, and staffing issues). Finally, statements of relationship were developed to link key themes, categories, and outcomes. An example would be the linking of one theme – the fact that ASD is misunderstood by people in many institutions and settings – to another – services that don’t meet the needs of people with ASD.
Results:
You walk outside the public school system, you hear the doors slam behind you. They are iron, steel doors. They are not letting you in. That money’s over. And you’re in a world of like what just happened? – mother of a 30 year old man with autism.
School transition processes were frequently judged inadequate. Youth crises surrounding transition were common and sometimes severe. Families often found adult services inaccessible or inappropriate, forcing the “round peg” of ASD into the “square hole” of a program developed for people with other disabilities. Social-emotional delay and lack of independent living skills hindered success at college while the interview process and social complexity of the workplace presented barriers to those seeking employment. When other systems failed to meet young adults’ needs, families struggled to do so with substantial emotional and financial consequences. Success stories and imagined solutions provided insight into programs and approaches that may yield more encouraging outcomes.
Conclusions: This qualitative study takes the initial steps necessary to generate insight into the mechanisms and experiences behind dismal national statistics on outcomes for young adults with ASD. It identifies major challenges and successes, and begins to categorize these based on individual, family and community characteristics. It therefore provides a preliminary conceptual model of disengagement that illustrates what is going wrong (or right), and for whom – a necessary precursor to developing effective strategies to improve outcomes.

11:00 **174.002** Toward Social Acceptance of Autism: Listening to Autistic People

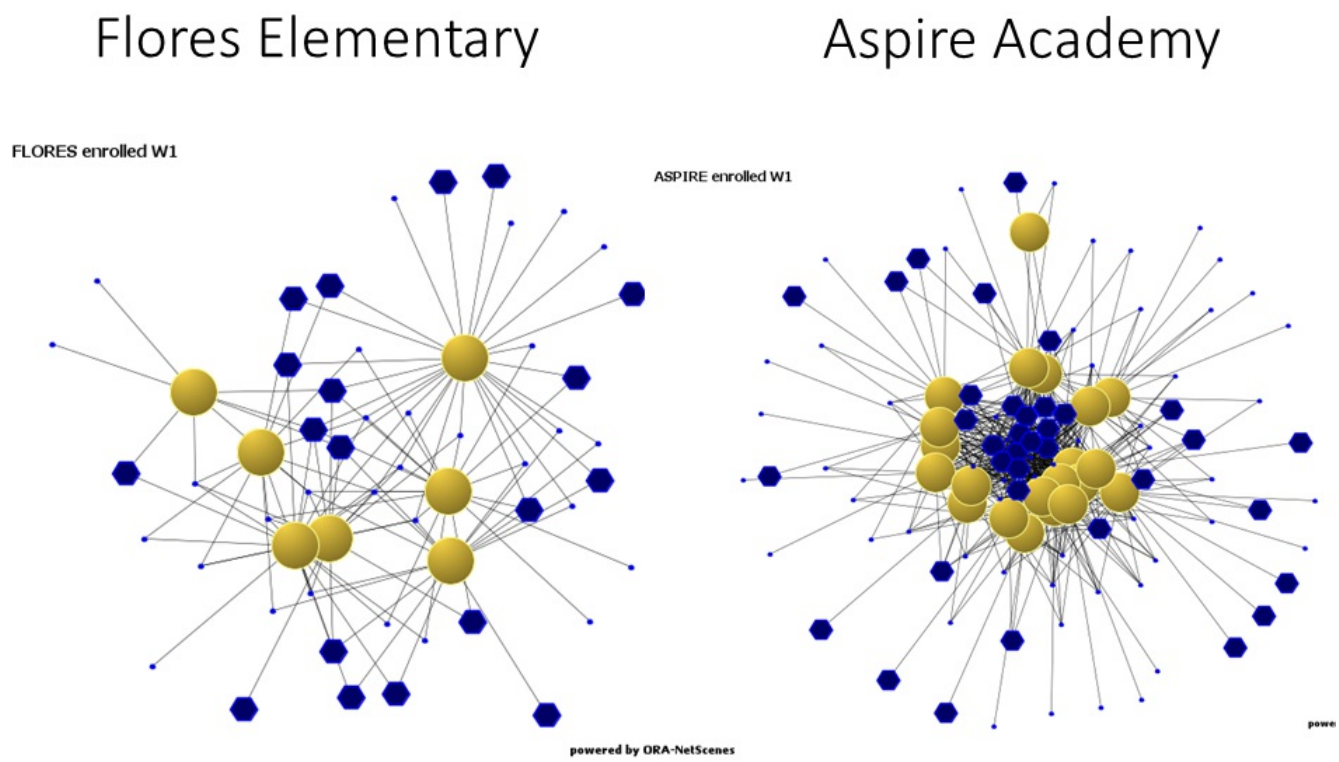
***S. K. Kapp**[1] and K. Gillespie-Lynch[2], (1)University of California, Los Angeles, Los Angeles, CA, (2)City University of New York, College of Staten Island, Staten Island, NY*

Background: In the first study to compare knowledge and stigma toward autism among autistic adults, family members, and the public, we found that autistic adults exhibited significantly more knowledge of autism than the public, especially in terms of strengths (Gillespie-Lynch, Kapp et al., 2015). Autistic adults reported the least autism stigma and defined autism in the least medical terms; stigma was inversely related with knowledge. Findings challenge the clinical notion that autistic people lack perspective on autism, and suggest the need for more nuanced inquiry into possible inaccuracy and harm arising from the medical emphasis on changing autistic people rather than their environments.
Objectives:
1) Examine associations between normalization-related attitudes and autism knowledge/stigma in an online sample of autistic adults, nuclear family members, and the public.
2) Evaluate critiques of scientific knowledge about autism (an autism training and associated measures) by survey participants.
3) Compare in-person discussions of the training by autistic high school and college students to findings from the online sample.
Methods: An online survey of autistic adults ($N = 309$), nuclear relatives of autistic people ($N = 188$), and the public ($N = 139$) assessed autism knowledge, autism stigma, and related attitudes (Gillespie-Lynch et al., 2015). Participants could provide open-ended elaborations to responses. We qualitatively coded open-ended elaborations to the item from each category of questions about autism (e.g., importance of a cure/cause/normalcy, stigma, and knowledge) that yielded the highest effect size when comparing across groups. Sixteen autistic high school and college students discussed the training as part of a summer program. Their perspectives will be coded and compared to the online sample. Only $p <= .001$ are reported as significant.
Results:
Greater endorsement of the importance of normalizing autistic individuals, curing autism, and finding the cause of autism were associated with more stigma across groups. Greater endorsement of normalizing/curing autism was associated with less knowledge across groups (the association between cure and knowledge was a trend for the public; $p = .006$).
Recognition that autistic people have empathy was associated with the largest group difference for knowledge items. In elaborations, autistic adults exhibited a trend toward reporting an excess of empathy relative to family members ($p < .008$).
The stigma item yielding the largest effect size difference assessed willingness to marry an autistic person. Autistic participants more often elaborated that they would prefer an autistic romantic partner than family and the public, although the latter was a trend ($p = .002$).
The largest effect size difference in normalization-related attitudes reflected autistic adults endorsing the least interest in curing autism. In their elaborations, they most opposed the medical model and the view that autism is a disease.
Conclusions: Society may stigmatize autistic people and disadvantage their development by overlooking their perspectives and overpathologizing differences. Disinterest in normalizing autistic individuals had the most consistent relationship with knowledge of and lack of stigma toward autism. Findings question whether losing an autism diagnosis constitutes an “optimal outcome”. Individuals’ manifestations of autism may decline despite persistent adaptive impairments as they seek acceptance in an often unaccepting society.

11:30 **174.003** Measuring Changes in Collaborative Networks Among Parents and Autism Intervention Providers

E. McGhee Hassrick[1] *and K. Carley*[2]*, (1)Weill Cornell Medical College, Ossining, NY, (2)Carnegie Mellon University, Pittsburgh, PA*

Background: To manage a child's autism treatment effectively, parents need to learn specialized knowledge, skills and scientific information about autism and its treatment; master particular teaching skills; obtain information about where to find services; gain familiarity with special education laws; negotiate on behalf of their children with many different types of clinical providers and coordinate interventions with school providers, where children with autism receive many of their services. Who do parents collaborate with as they manage their child's interventions, over their child's life course? We do not currently have a systematic way of mapping the emergence and subsequent changes in collaborative networks among parents, community providers and teachers, around individual children with ASD, to examine how these emergent networks influence intervention selection and implementation and a parent's knowledge or monitoring capacity for their child.
Objectives: This research study used innovative dynamic social networks techniques to measure changes over time in the collaborative networks that emerged around 45 individual children with ASD, situated in two different urban, public schools, named "Aspire" and "Flores". For each child's collaborative network, we analyzed changes over the course of one school year in the implementation and alignment of interventions; the use of autism resources; and the completion of autism trainings. We concurrently tracked changes in the coordination, problem solving and trust networks that provided interventions for each child. Examining the social network processes that emerge around the child help us to identify interactional mechanisms that inform the ongoing treatment of children diagnosed with autism, as they develop across the life course.
Methods: We conducted 90 network surveys with school teachers, aides, clinicians and parents, at the fall, spring and summer of one school year, wherein they reported coordination, resource, training and intervention implementation for forty five children diagnosed with autism spectrum disorder. Parent and autism provider network survey data was analyzed using ORA for dynamic, multi-modal networks and network visualizations.
Results: Findings confirmed that problem solving and collaboration between parents and school staff varied across children and across schools, with most parents at Aspire frequently connected to multiple staff throughout the school year, compared with few parents at Flores. Child treatments at Aspire were more often shared among providers, with low exclusivity scores (0.2 to 4.0), while at Flores, they were idiosyncratic, with higher exclusivity scores (2.0 to 8.0). See Figure 1. Autism resource and training networks were also clustered among parents and staff at Aspire as compared with Flores. Parents and staff at both schools accessed far more general autism resources, than specific, and was more robust in fall.
Conclusions: Findings suggest that dynamic networks of children at Aspire were aligned around a particular group of treatments with related resources and trainings, making each child's map more similar, over time, at Aspire. Dynamic networks at Flores were more idiosyncratic, with lower overall levels of frequent problem solving between parents and school providers, suggesting a more individualized, less aligned approach to management.



12:00 **174.004** Ecological Approaches to Transition Interventions in ASD: Training Parents to More Effectively Navigate the Adult Service System

J. L. Taylor[1]*, R. Hodapp*[2]*, M. Burke*[3] *and C. Rabideau*[2]*, (1)Vanderbilt Kennedy Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN, (3)University of Illinois, Urbana-Champaign, Urbana, IL*

Background: Although there is an increasing body of descriptive and intervention work that aims to improve the transition to adulthood for youth with autism spectrum disorders (ASD), most studies focus on characteristics of the youth themselves. Yet, the ecological contexts in which these youth are found also play critical roles in transition outcomes. In this study, we report initial findings from a small randomized-controlled trial (RCT) that intervenes at the level of the family, by training parents how to more effectively interface with the adult service system.
Objectives: The study's goal was to test whether, for parents of transition-aged youth with ASD, participating in a parent advocacy intervention led to increased knowledge about the adult service system; greater feelings of empowerment; increased advocacy skills; and increased connectedness with the disability community.
Methods: This study has two phases. In Phase 1, we recruited seven families of transition-aged youth with ASD, who participated in a pre-pilot of the 12-week parent advocacy intervention. In Phase 2, we examined the intervention using an RCT, waiting-list control design with 45 families of transition-aged youth with ASD. Families were randomly assigned to either the intervention group (Fall 2015) or a wait-list control (who will receive the intervention in Spring 2017). Participant characteristics are presented in Table 1. In Phase 2, the intervention was delivered in three locations: in person in Nashville, TN, and via webcast in Chattanooga and in Memphis. All youth had ASD diagnoses confirmed using the Autism Diagnostic Observation Schedule-2 administered by research-reliable clinicians.
The intervention group met weekly for 12 weeks; each session lasted 2.5 hours. Sessions covered aspects of the adult service system (e.g., Vocational Rehabilitation, post-secondary education programs, SSI, SSDI) and advocacy skills. Primary outcomes, measured before and after the intervention, included knowledge about the adult service system; advocacy skills and comfort, family empowerment, and connectedness to the disability community.
Results: In Phase 1, six of seven families provided data. After taking the intervention, parents reported increased advocacy skills/knowledge, paired $t(5)=-6.52$, $p<.001$, connectedness to the disability community, paired $t(5)=-3.05$, $p<.05$, and knowledge of the adult disability service system, paired $t(5)=-2.08$, $p=.09$. No significant changes

occurred in family empowerment.
For Phase 2, pre-test data collection has now been completed, with post-test data collected in December 2015/January 2016. Beyond examining changes in primary outcomes for the treatment vs. control group, we will also explore potential moderators of treatment response, including characteristics of offspring (intellectual disability vs. no intellectual disability), training (in person vs. via webcast), and family (high vs. low parent stress).
Conclusions: From initial findings, it appears that participating in the parent advocacy training can improve parents' ability to advocate for adult services for their son/daughter with ASD. In future analyses, we will examine whether improving parents' capacity to advocate also changes "broader" transition outcomes (e.g., employment, community integration) – and, if not, which barriers might be in place. More generally, discussion will highlight the continued role of the family in the lives of individuals with ASD across the lifespan.

Panel Session
175 - Towards Big Data Approaches in Eye Tracking
10:30 AM - 12:30 PM - Room 307

Panel Chair: Frederick Shic, *Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Discussant: Ami Klin, *Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Eye tracking has become a core research methodology for understanding human development, social cognition, and neuropsychiatric conditions. In this panel, we follow the next logical evolution of eye tracking in autism research towards large scale studies that begin to blur the line between research technique and practical tool. The thematically-linked presentations in this panel report on new eye tracking findings involving four institutions and 1,808 unique participants including 696 individuals with ASD. Weaving between the science enabled by eye tracking and the eye tracking enabled by methodological advances, the goal of this panel is to provide perspectives on (1) what eye tracking across large samples tells us about autism, (2) the potential of eye tracking as a practical tool for discovery, therapeutics, and phenotyping, and (3) the methodological issues that must be addressed to enable the next generation of big data studies using eye tracking in autism research.

10:30 **175.001** The Search for Biomarkers and Clinically Meaningful Subtypes of ASD Based on Eye Tracking Data

K. Pierce[1], *A. Moore*[2], *S. Pence*[1], *C. Carter*[1], *D. Cha*[1] *and E. Courchesne*[1], *(1)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA, (2)University of California, San Diego, La Jolla, CA*

Background: Our understanding of autism as a heterogeneous disorder and the pressing need to discover and understand potential subtypes has emerged as a high research priority. Markers that precede diagnosis or indicate ASD subtypes are extremely valuable because of their potential implications about causes, mechanisms, prognosis, and treatments. However, discovering and understanding such subtypes requires large sample sizes. In 2011 we published an eye tracking study that included 110 toddlers (Sample 1) and in 2015 examined an additional sample of 334 children (Sample 2) and raised the possibility that markers based on eye tracking, if robust, could be considered biomarkers of ASD (Pierce et al., 2011, 2015). In both studies we discovered that a percentage (~20%) of ASD toddlers showed unusually high fixation levels on geometric rather than social images, a profile not often seen in typically developing or non-ASD contrast groups (Specificity 98%, PPV 89%). Since that time we have collected data on another independent sample (Sample 3) of 387 toddlers that has not yet been published. Presumably if experience dependent mechanisms play an important role in how a child develops, the degree to which abnormal visual attention persists during early development may have some power to predict later outcome. Moreover, if a true "biological subtype" is discovered, persistent visual attention traits within an individual toddler might be in evidence across different eye tracking paradigms.
Objectives: As part of an education motivated panel, the primary objective is to discuss the ways in which such a large dataset could be examined. Topics relating to disentangling heterogeneity and the value of eye tracking indices as diagnostic and prognostic biomarkers will be considered. Other topics include examination of state and trait markers and stability of responding across time and different paradigm types to discover a true biotype.
Methods: Combining Samples 1-3, a total of 837 toddlers participated and included 242 ASD and 595 contrast toddlers (LD, DD, Typical, Typical Sibling and "Other") ranging in age from 12-48 months. Using a Tobii wireless eye tracker, all toddlers participated in the "GeoPref Test", a 1-minute movie containing both dynamic geometric and social images. Fixation duration within each area of interest and number of saccades were recorded. Toddlers were diagnostically and psychometrically evaluated at time points both proximal and distal to the eye tracking session. In order to examine stability of responding across paradigms, toddlers participated in several different eye tracking tests beyond the GeoPref Test, such as one containing complex social interactions.
Results: Data from the new unpublished sample (Sample 3), replicates the finding that overall ASD toddlers fixate more on geometric images than other diagnostic groups (e.g., ASD vs TD, $t_{212} = 8.37$, $p<.0001$, CI of the difference = 17.6%-28.5%). Other analyses will be performed to understand subtypes, examine visual attention across time and consider how a child's visual fixation patterns at ages 1-2 years might predict his outcome at ages 3-4 years.
Conclusions: Eye tracking is a powerful tool for discovering subtypes of ASD and for understanding its early course.

10:55 **175.002** Large Scale Eye Tracking in EU-AIMS Longitudinal Autism Research Project (LEAP): Methods and Preliminary Findings from a Biological Motion Task

L. Mason[1], *F. Shic*[2], *E. Loth*[3], *T. Banaschewski*[4], *S. Baron-Cohen*[5], *S. Bolte*[6], *T. Bourgeron*[7], *T. Charman*[8], *S. Durston*[9], *M. H. Johnson*[10], *A. M. M. Persico*[11], *J. K. Buitelaar*[12], *D. G. Murphy*[13] *and W. Spooren*[14], *(1)European Autism Interventions - A Multicentre Study for Developing New Medications, Basel, Switzerland, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Institute of Psychiatry, King's College London, London, England, United Kingdom of Great Britain and Northern Ireland, (4)University of Heidelberg, Heidelberg, Germany, (5)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (6)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden, (7)Institute Pasteur, Paris, France, (8)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Rudolf Magnus Institute of Neuroscience, University Medical Center Utrecht, Utrecht, Netherlands, (10)Birkbeck, University of London, London, United Kingdom of Great Britain and Northern Ireland, (11)Child and Adolescent Neuropsychiatry Unit, Lab of Molecular Psychiatry and Neurogenics, University Campus Bio-Medico, Rome, Italy, (12)Radboud University Medical Centre, Nijmegen, Netherlands, (13)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (14)Roche, Basel, Switzerland*

Background: There are no effective treatments for the core symptoms of ASD because the underlying pathophysiology(ies) remain(s) poorly understood. Clinical trials are hampered by the profound clinical and etiological heterogeneity among individuals with ASD, as any treatment is likely only effective in some biological sub-groups. Large-scale multi-disciplinary studies and new biomarker stratification approaches are needed to identify more biologically homogeneous ASD subgroups. The EU-AIMS Longitudinal European Autism Project (LEAP) is conducted in seven European centres and will include approximately 400 individuals with ASD from 6-30 years, and 250 controls with typical development or diverse intellectual disabilities.
We present here preliminary data from a subsample (N = 197) of the LEAP dataset, focusing on one of our eye tracking tasks which measures differences in preference for biological and non-biological motion. From birth both humans and animals exhibit such a preference, suggesting that attention to biological stimuli is important for the development of effective social interaction and nonverbal communication.
Objectives: To assess preference for biological motion across adolescence and adulthood in a large international sample. We use this data to illustrate some of the processes we developed to manage the acquisition, quality control and analysis of large volumes of multi-site eye tracking data, and to discuss some of the challenges and promises of a big data approach to clinical and developmental research. We also touch on the potential for concurrent multimodal approaches to clinical and developmental research by combining behavioural, video, eye tracking, EEG and physiological (GSR, ECG) data types.
Methods: As part of a 40-minute battery of eye tracking tasks, adults (38 ASD, 51 TD) and adolescents (54 ASD, 34 TD) viewed point light displays of biological motion, paired on a trial-by-trial basis with either scrambled or rotating non-biological motion. Gaze behaviour was recorded by eye trackers and was stored, subjected to quality control, and analysed using custom-written Matlab scripts. Datasets were batch processed without manual intervention.
Results: Compared to neurotypical controls, individuals with ASD looked less at the biological motion than the control stimuli ($F=6.931$, $p=.009$, $d=.309$). The distribution of scores in the ASD group compared to the neurotypical group mean showed that 26.5% performed below 1SD (TD = 16.7%), and 2% performed below 2SD (TD = 1%). All participants looked longer at biological motion when it was paired with a rotating than a scrambled control stimulus ($F=108.895$, $p<.001$, $d=.513$) but this did not differ by diagnosis.
Conclusions: The preliminary results from the biological motion task suggest it has the potential to function as a stable biomarker in individuals with an ASD across the ages of 13-30 years. Further analyses once data collection is complete will allow us to extend this to children aged 6-12 years, and to relate these findings to ASD symptomatology and quality of life measures, in order to understand whether individuals can be stratified on this measure. The data processing pipelines developed for LEAP enabled large quantities of data to be stored and analysed efficiently in a structured and highly accessible manner.

11:20 **175.003** Children with ASD Look Less at Faces When It Really Matters

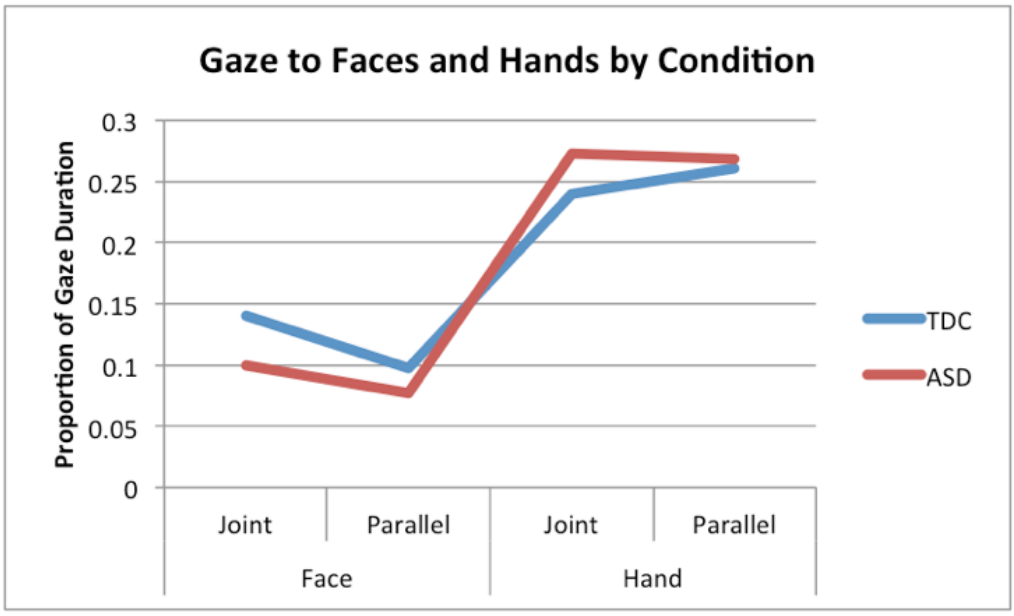
J. Parish-Morris[1], *C. Chevallier*[2], *B. E. Yerys*[3], *J. Herrington*[4], *E. S. Brodkin*[5] *and R. T. Schultz*[6], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Laboratoire de Neurosciences Cognitives, INSERM, Paris, France, (3)The Center for Autism Research, Philadelphia, PA, (4)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)University of Pennsylvania, Philadelphia, PA, (6)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Attention to social stimuli is often evident from birth. All social stimuli are not created equal, however, nor should they be weighted the same regardless of context. Sometimes it is important to look at gestures or posture, and other times (as in the case of nonverbal communication between two people) it is especially important to look at faces. In this study, we test the hypothesis that typically developing individuals look more at faces than at other interesting stimuli (hands playing with toys) when they watch videos of children playing together versus separately. We further hypothesize that contextual modulation of social attention is diminished in individuals with Autism Spectrum Disorder (ASD), which is characterized by social impairment. Acquiring a large, heterogeneous sample aged 3-18 years allowed us to probe for subgroups within ASD that demonstrate distinct gaze patterns, and to correlate eye gaze data with diverse clinical phenotypes.
Objectives: Compare rates of looking to faces versus hands in the context of joint play and parallel play in children with ASD and typical controls, and assess whether looking patterns correlate with clinical ratings of autism severity.
Methods: Participants (ASD: N=154; TDC: N=66; Table 1) watched videos of children engaged in either joint interactive play or parallel play. A Tobii X120 infrared eye tracker recorded the direction and duration of participants' gaze to dynamic areas of interest (AOI) that were drawn around the faces and hands of actors while they played with toys. We calculated the proportion of participants' gaze to each AOI type relative to their total attention on the full screen. We used calibrated severity scores from the ADOS-2 for correlations. Groups differed on IQ and age, so we entered these variables as covariates.
Results: An analysis of covariance with condition (joint, parallel) and stimulus type (face, hands) as within-subjects factors and diagnosis (ASD, TDC) as a between-subjects factor revealed a significant 3-way interaction, $F(1,213)=14.15$, $p<.001$, $\eta_p^2=.06$. Both groups increased looking to faces in the joint vs. parallel condition ($ps<.05$), but the ASD group looked less at faces and more at hands than the TDC group in the joint condition ($ps<.001$ and .02; no differences in the parallel condition; Figure 1). Total proportion of gaze to faces in the joint condition was negatively correlated with ADOS-2 severity scores in the ASD group (*Pearson*=-.18, $p=.03$).
Conclusions: Children with ASD and control participants looked more at faces during nonverbal communication, but this effect was dampened in ASD. Reduced gaze to faces in a communicative context was associated with increased ASD symptoms. Between now and May 2016, we will assess test-retest reliability of this paradigm in 90 participants that provided 2 time points, analyze existing data from an additional 60 participants (including 30 adults with ASD), and recruit 30 typical participants to match our ASD adults, thus extending our analysis into adulthood to examine effects of age on visual attention to faces. We will discuss special challenges and rewards associated with collecting gaze data across multiple years in a heterogeneous population.

Table 1. Participant information. IQ scores are missing for 3 participants in the ASD group, and ADOS severity scores are missing for 9 participants.

	ASD	TDC	Difference
Males (females)	145 (9)	60 (6)	Chi square = .77, p = .39
Age Mean (SD)	11.79 (3.33)	12.84 (2.97)	$t = 2.22$, $p = .03$
IQ (DAS-II) Mean (SD)	93.11 (25.67)	112.15(18.03)	$t = 5.46$, $p < .001$
ADOS severity Mean (SD)	7.14 (2.15)	.	.

Figure 1. A three-way interaction between diagnosis, stimulus type, and condition emerged from the gaze data. Children with ASD looked more at hands and less at faces in the joint condition than TDC participants.



11:45 **175.004** Eye Tracking in Between: Gaze Behaviors on Structural Trial Components in Toddlers with ASD

F. Shic[1], *Q. Wang*[1], *C. A. Wall*[1], *A. Naples*[2], *S. Macari*[1] *and K. Chawarska*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT*

Background:
Individuals with ASD look at social information atypically in multiple contexts and across their lifespan. These atypicalities have been quantified through eye tracking, typically

through repeated presentation of experimental stimuli. Trials in these paradigms often begin with (1) a central fixation (CF) simultaneously displayed with salient sound to orient participants to a consistent visual starting point, (2) followed by the stimulus of interest, (3) followed by an interstimulus interval (ISI; e.g. blank screen) to disrupt visual processing. Little is known about the behaviors of individuals with ASD during these structural components of experimental trials.

Objectives:

To examine eye tracking data metrics collected from CFs and blank screen ISIs across several years of studies on young children with ASD in order to gain insights into attentional processes associated with developmental heterogeneity. More broadly, to discuss strategies for large-scale aggregation of eye tracking data, techniques to enable long-term consistency in data acquisition, and unique opportunities for studying early typical and atypical human development.

Methods:

Data were collected from toddlers (N=554) 1 to 3 years of age with confirmatory diagnoses of ASD (N=208, age=23.3months), developmental delay (DD, N=59, 23.5m), or typically development with or without a sibling with ASD (TDHR, N=57, 24.1m, and TDLR, N=230, 24.2m, for High Risk and Low Risk for ASD, respectively). CFs were analyzed for valid data retention (%Valid) and looking time at the CF (%CF) in 200ms bins up to 1s of total presentation time. Blank ISIs were examined for blinks and fixation counts as defined by a 1 degree 80ms distance dispersion algorithm. Linear mixed model analyses on over 2.5 million sifted rows of data with group x age x bin + Mullen nonverbal developmental quotient (NVDQ) fixed and intercept with bin slopes by subject nested in protocol random effects for CFs and group x age + NVDQ with subject intercept random effects nested within protocol for ISIs.

Results:

Toddlers with ASD looked longer at screens with CFs (%Valid) than DD (p<.05, d=.39), TDHR (p<.01, d=.31), and TDLR (p<.01, d=.20) toddlers, though they showed less looking with age compared to other groups (all p<.01). Similar results were found for %CF for age-related changes (p<.01), though only ASD-TDHR contrasts were significant (p<.01). For blank ISIs, toddlers with ASD also showed more Valid data and fewer blinks than TDHR (p<.001,p<.01) and TDLR (p<.001,p<.001) but not DD (p=.11,p=.37) groups, and more fixations than the TDHR group (p<.001). Higher NVDQ was associated with more %Valid, fewer blinks, and more fixations.

Conclusions:

Toddlers with ASD show increased looking towards scenes with salient non-social perceptual cues, as evident in CFs, but also during periods of visual inactivity. They also show greater exploratory activity during these blank trials as evident by more fixations, and may show decreased disengagement from the computer monitor in general, as evidenced by decreased blink rates and. These results contrast to opposing effects observed for social events (Shultz, Klin, & Jones, 2011; Chawarska, Macari, & Shic, 2012). Applications of explored approaches will be discussed.

Panel Session
176 - Recent Advances in Statistical Methods for Autism Research
10:30 AM - 12:30 PM - Room 308

Panel Chair: Elizabeth Stuart, *Johns Hopkins School of Public Health, Baltimore, MD*

Discussant: Elizabeth Stuart, *Johns Hopkins School of Public Health, Baltimore, MD*

Many complexities arise when studying individuals with Autism Spectrum Disorders (ASD), including challenges in measuring key constructs as well as in estimating the effects of exposures or interventions. This panel will highlight recent advances in statistical methods that are relevant for autism research. The first talk will discuss measurement challenges and specifically how to use Item Response Theory to equate ADOS modules 1 and 2, allowing longitudinal analysis across time. The other three talks will discuss various advances in estimating causal effects: innovative randomized designs for studying adaptive interventions (with three examples of using these designs to study interventions for children with ASD), clever use of non-experimental data to estimate the effects of non-randomized exposures (applied to examining the effects of antidepressant use during pregnancy), and the use of propensity scores to equate two groups (applied to examining the associations between prenatal nutritional supplementation and ASD). Attendees will come away with a better understanding of advanced statistical methods and how new methods can help them obtain better answers to more nuanced questions of relevance to autism research.

10:30 **176.001** Development and Validation of a Harmonized Scale of Autism Symptom Severity Across ADOS Modules 1 and 2: A Bsrc Study

A. Gross[1], *L. Kalb*[2], *G. S. Young*[3], *E. Stuart*[2], *R. Landa*[4], *T. Charman*[5], *K. Chawarska*[6], *T. Hutman*[7], *D. S. Messinger*[8], *S. Ozonoff*[9], *W. L. Stone*[10], *H. Tager-Flusberg*[11] *and L. Zwaigenbaum*[12], *(1)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Johns Hopkins School of Public Health, Baltimore, MD, (3)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (4)The Kennedy Krieger Institute, Baltimore, MD, (5)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (7)University of California Los Angeles, Los Angeles, CA, (8)Psychology, University of Miami, Coral Gables, FL, (9)UC Davis MIND Institute, Sacramento, CA, (10)Department of Psychology, University of Washington, Seattle, WA, (11)Boston University, Boston, MA, (12)University of Alberta, Edmonton, AB, Canada*

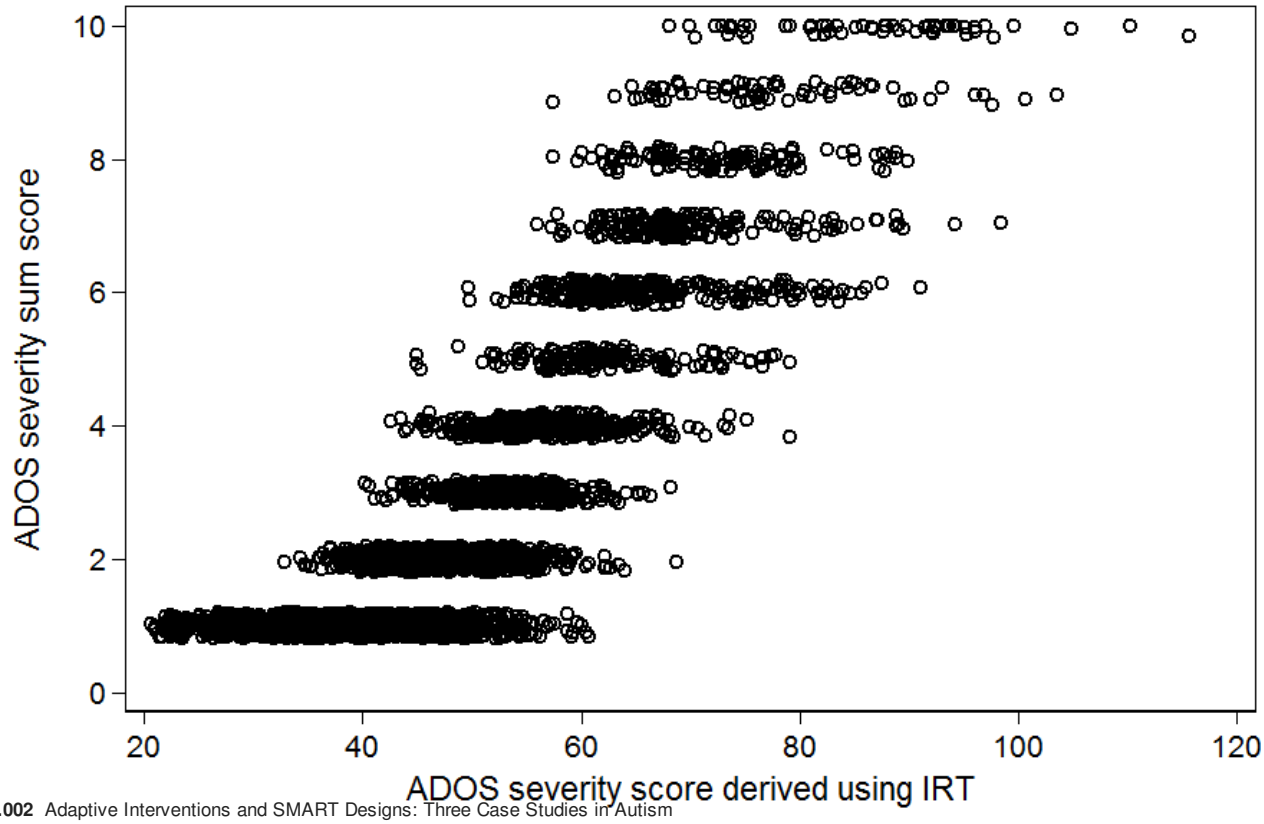
Background: The Autism Diagnostic Observation Schedule-Generic (ADOS-G) is a gold standard diagnostic assessment for autism spectrum disorders (ASD). The ADOS-G overall calibrated severity score (CSS), which provides a 10-point common metric across all ADOS modules, has several measurement limitations, including ceiling/floor effects, limited scoring range, collapsing of symptom domains, and questionable measurement invariance across modules. Failure of the overall CSS to capture heterogeneity in children with ASD led to research that culminated in defining separate CSS scores for social affect (SA-CSS) and restricted and repetitive behavior (RRB-CSS) domains. However, there is substantial overlap in distributions of domain calibrated scores of children with and without ASD. An alternate metric of ASD severity with expanded range may be more sensitive to differences in ASD behavioral phenotype and to changes in ASD severity over time.

Objectives: The goal of this study was to derive an alternative to the overall CSS that could be used across ADOS-G modules 1 and 2 for use in longitudinal research. Despite the introduction of the ADOS-2, many sites and consortia have substantial longitudinal ADOS-G data. We used item response theory (IRT) to provide a finer, more precise score on a metric common across modules 1 and 2.

Methods: Using data from the Autism Speaks Baby Sibs Research Consortium (N=2191 with 6237 observations, age range 24 - 48 months) with a broad range of autism severity (N=755 low-risk siblings, N=1436 high-risk), we applied graded response IRT models to equate the 21 items of the ADOS that were highly consistent in the nature of the behavior being scored and scoring criteria across ADOS modules 1 and 2. Data analyses were conducted on participants having 36-month diagnostic confirmation assessments. Measurement invariance by module, reliability, and convergent as well as criterion validity of the IRT-based autism severity score was assessed.

Results: A total of 21 items, representing items across each of the ADOS domains (Social, Communication, and Restricted/Repetitive Behavior), were used to develop the harmonized IRT ASD severity score (mean 50, SD 10, range 21.9 to115.6, 2716 distinct values). This IRT-derived severity score was highly correlated (r=0.86, p<.001) with the classic 10-point ADOS severity score, and was highly internally consistent (Cronbach's α=0.88). The IRT-derived score demonstrated strong criterion validity against clinical best estimates of ASD (sensitivity=0.84, specificity=0.82, AUC=0.93), which was marginally superior to the CSS (AUC=0.90). Whereas 46% (2023/4396) of CSS scores were at the ceiling or floor, 0.2% of IRT-derived scores (15/6237) fell at the ceiling or floor (see Figure). The IRT-derived score could be scored in 30% of records (1841/6237) that the CSS could not be scored due to item missingness.

Conclusions: The IRT-derived ASD severity measure demonstrated strong psychometric characteristics, compared to the classic 10-point severity score, in terms of reduced ceiling and floor effects, finer differentiation particularly in the non-ASD range of severity, and facilitates a linkage across ADOS modules. This measure may provide important advantages when characterizing trajectories and treatment responses during early, critical stages of development.



10:55 **176.002** Adaptive Interventions and SMART Designs: Three Case Studies in Autism

D. Almirall[1] *and C. Kasari*[2]*, (1)University of Michigan, Ann Arbor, MI, (2)University of California Los Angeles, Los Angeles, CA*

Background: Due to the great heterogeneity of children with autism spectrum disorders (ASDs), effective treatment often requires individualized, sequential decision-making. To do this, each child's treatment is dynamically tailored over time based on the child's changing state, including response to prior treatment. *Adaptive interventions* (also known as dynamic treatment regimens) operationalize such individualized decision making using a sequence of decision rules that specify which intervention option to offer, for whom, and when. Intervention options correspond to varying doses, types or delivery modes of pharmacological or behavioral treatments. The sequential, multiple-assignment, randomized trial (SMART) is a type of multi-stage randomized trial research design used to build high-quality adaptive interventions.
Objectives: The objectives of this talk are to (i) provide a brief introduction to adaptive interventions, and (ii) present case studies of three SMART designs in autism.
Methods: The first SMART study was designed to develop an adaptive intervention for children with ASD who are minimally verbal using a speech-generating device in the context of a naturalistic intervention involving joint attention, symbolic play, engagement and regulation (JASPER) plus enhanced milieu training (EMT). The second study, again among children with ASD who are minimally verbal, was designed to develop an adaptive intervention involving JASPER+EMT, discrete trials training (DTT), parent training, combined JASPER+EMT+DTT and a clinician-rated clinical global impressions measure to monitor child's progress. The third is a SMART pilot study, which aims to develop an adaptive intervention to improve social engagement outcomes in children with ASD in inclusive school settings. This novel study examines the feasibility and acceptability of adaptive interventions involving Remaking Recess (a school-level intervention), Classroom Supports (a classroom-level intervention), Parent- and Peer-mediated social skills interventions, and the use of paraprofessionals to monitor child progress on the playground and inform subsequent treatment decision-making. For each study, we present the SMART design, its rationale, and the scientific questions.
Results: Three SMART studies have been designed to develop adaptive interventions in children with autism. Each is designed to answer novel questions concerning how best to individualize treatment in children with ASD. The first study is completed; the second and third studies are in the field.
Conclusions: Adaptive interventions are intended to serve as a guide for sequential treatment decision-making in actual clinical practice. They hold the promise of improving outcomes for greater numbers of children with autism by providing the right treatment to children who need it, when they need it. Currently, there is great interest in the use of SMART designs to build high-quality adaptive interventions in autism.

11:20 **176.003** Prenatal Nutritional Supplementation and ASD: Causal Inference Analyses

E. A. DeVilbiss[1]*, C. Magnusson*[2]*, R. M. Gardner*[2]*, D. Rai*[3]*, C. J. Newschaffer*[4]*, K. Lyall*[4]*, C. Dalman*[2] *and B. Lee*[1]*, (1)Drexel University, Philadelphia, PA, (2)Karolinska Institutet, Stockholm, Sweden, (3)University of Bristol, Bristol, United Kingdom, (4)A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Studies have suggested that early prenatal supplementation with folic acid, iron, or multivitamins may be protective against ASD, although other studies have not found evidence of this
Objectives: Using a large population-based study with high case ascertainment, we investigated relationships between early maternal nutritional supplementation (folic acid, iron, and/or multivitamins) and ASD, stratified by intellectual disability (ID).
Methods: The Stockholm Youth Cohort, a prospective cohort study, was examined using Swedish national and regional health registers. The exposure of interest was nutritional supplementation at the first antenatal visit, recorded in the Medical Birth Register. Children born between 1996 and 2005 were followed up for a diagnosis of ASD until December 31, 2011.
Results: Of 206,771 participants in this sample, 4317 cases (2.1%) of ASD were identified, consisting of 984 (0.5%) low-functioning autism cases (LFA; defined as the presence of comorbid ID) and 3333 (1.6%) high-functioning autism cases (HFA; defined as the absence of comorbid ID). Supplement users were different from non-users across multiple medical and social characteristics.
Our primary analysis indicated that overall, taking multivitamins or multiple vitamins (MV) by the first antenatal visit (median 10.1 weeks gestation) was associated with a lower likelihood of LFA relative to mothers who did not take nutritional supplements (adjusted odds ratio: 0.70 [95% confidence interval: 0.56-0.87]), whereas taking folic acid or iron alone was not associated with reduced risks of LFA (adjusted odds ratios: 1.24 [95% confidence interval: 0.91-1.70] and 1.04 [95% confidence interval: 0.89, 1.20], respectively). Supplement use was not associated with overall risk of HFA.
To inform interpretation of our LFA results, we will present results from causal inference analyses including a matched sibling analysis and propensity score (PS) matching. Since siblings share the same mother, a matched sibling analysis reduces the potential for residual confounding by maternal health status and behaviors. PS matching is a technique that matches supplement users and non-users based on the estimated probability of taking specific nutritional supplements prenatally. Matching on the PS can also reduce the potential for residual confounding since there is less reliance on model-based assumptions.
Conclusions: Early maternal vitamin supplementation, especially multivitamins or iron and folic acid used in combination, may be protective against low functioning autism. However, there was no evidence that either iron or folic acid supplements used individually was associated with either high or low functioning ASD. Results from sibling analyses and propensity score matching will aid in interpretation of potential causality.

11:45 **176.004** Clever Analysis of Nonheritable Risk Factors: Maternal Use of Antidepressants during Pregnancy and Risk of ASD

B. Lee[1] *and C. J. Newschaffer*[2]*, (1)Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Few nonheritable risk factors for ASD have been concretely established, in part due to methodological challenges of conducting observational epidemiology studies. Observational studies are subject to multiple biases and limitations that hinder causal inference. The alternative of randomized controlled trials is often not feasible for various reasons, such as ethical problems in studying randomized exposures in pregnant women. Thus, scientists attempting to identify nonheritable risk factors of ASD

must extract as much insight as possible from observational studies.
Objectives: The objective of this presentation is to discuss and critique three recent epidemiology studies in Denmark that performed clever analytic techniques to examine whether maternal use of antidepressants during pregnancy increases risk of child ASD, or if the increased risk is actually due to confounding by indication.
Methods: We examine three published studies by Sorensen et al. (2013), Hviid et al. (2014), and Gidaya et al. (2014) drawn from the same Danish register data. The different strategies used by the studies included: stratification on the indication; sibling analyses; negative controls; and simulation approaches for measurement error correction.
Results: Using traditional analytic approaches, all three studies found that maternal use of antidepressants during pregnancy increased risk of child ASD. However, after application of clever analytic approaches, only one study suggested an increased risk of ASD. All analytic approaches had their own difficulties, and such difficulties likely influenced to varying degrees the utility of these approaches. We offer insight as to what further studies on this topic can do to improve the state of science.
Conclusions: While clever analyses are often good ideas in theory, they are challenging to carry out in practice, and may yield flawed conclusions.

Panel Session
177 - Understanding Cultural Differences in Diagnostic and Treatment Services for Children with ASD
10:30 AM - 12:30 PM - Room 309

Panel Chair: Jennifer Singh, *School of History and Sociology, Georgia Institute of Technology, Atlanta, GA*

Discussant: Diana L. Robins, *Drexel University, Philadelphia, PA*

Despite the growing prevalence of ASD worldwide, there are disparities to diagnosis and treatment services especially for racial and ethnic minorities in the U.S. and low and middle-income countries (LMIC). The purpose of this panel is to share research on the utility of diagnostic and screening tools for culturally diverse communities and examine cultural differences in diagnosis and services in U.S. Latino populations and two LMIC countries, Bangladesh and South Africa. The panel will consist of four papers and Dr. Diana Robins will serve as the discussant. The first paper examines the processes of culturally adapting the ADOS-2 and ADI-R in rural Bangladesh and the use of the Social Communication Questionnaire. The second paper qualitatively analyzes contextual factors and acceptability of a caregiver-mediated early ASD intervention in South Africa. The third paper evaluates the utility of the Spanish ADI-R in distinguishing between ASD and DD in a U.S. based Latino population. The final paper surveys whether there are ethnic disparities between Latino and White children with ASD in specialty autism-related services, and whether condition severity moderate the relationship between ethnicity and receipt of autism services.

10:30 **177.001** Cultural Adaptations in ASD Diagnostic Assessments and Case Determination in a Rural Region of Bangladesh

L. C. Lee[1], *S. Risi*[2], *H. Rahman*[3], *A. Hasmot*[3], *A. A. M. Hanif*[3], *S. Shaikh*[3], *S. Mehra*[4], *M. Mitra*[5], *L. S. F. Wu*[6], *N. Z. Khan*[7], *K. West*[5] *and P. Christian*[6], *(1)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)University of Michigan, Ann Arbor, MI, (3)Johns Hopkins University Bangladesh, Gaibandha, Bangladesh, (4)Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)Pediatric Neuroscience, Dhaka Shishu Children's Hospital, Dhaka, Bangladesh*

Background:
Cultural influence on the perception of autism-related behaviors has drawn much attention, yet data are scant on this subject. Because Autism Spectrum Disorder (ASD) diagnosis is solely based on observed behaviors, cultural norm and perception of these behaviors play a crucial role on modification of diagnostic assessment tools and threshold of diagnostic cut-offs. Taking advantage of a community-based ASD epidemiologic study recently conducted in rural Bangladesh, we aim to propose a way to modify criteria used in Western countries for the study population.
Objectives:
First, to describe the procedures of conducting the Autism Diagnostic Observation Schedule-2 (ADOS-2) and the Autism Diagnostic Interview – Revised (ADI-R) research training for local clinicians. Second, to discuss modifications on the diagnostic tools and case determination criteria. Third, to report screening process using Social Communication Questionnaire (SCQ). Fourth, to determine ASD case status based on ADOS-2 and ADI-R in children aged 8-10 years who were SCQ positive from this community-based epidemiologic study.
Methods:
Building on the infrastructure of JiVitA, a large maternal and child health project aims to evaluate interventions to improve reproductive and child health in Bangladesh, the present study adapted and culturally modified SCQ, ADOS-2, and ADI-R in order to estimate prevalence rate in the defined population. The A three-week long workshop was conducted in Bangladesh by an ADOS-2 and ADI-R expert from the US (Dr. Risi), followed with weekly conference calls to discuss practice administrations, standard practice videos and respond to questions, modification and cultural adaptations. SCQ was administered by research staff via an at-home interview. The ADOS-2 and the ADI-R were administered by a local developmental psychologist after achieving research-level reliability.
Results:
A total of 8211 mother's completed the SCQ screener on 4109 boys and 4102 girls aged 8-10 years. Children with SCQ>=15 and a selected group of SCQ<15 were invited for ADOS-2 and ADI-R evaluations. As a result, 107 ADOS-2 and 121 ADI-R were conducted.
Conclusions:
ADOS-2 and ADI-R research training in Bangladesh is a challenge for many reasons including language barriers and unknown cultural applicability of these instruments. Required research reliability can be reached; however, enormous effort and time are needed. Cultural adaptation may not be a one-time task occurring during translation, as the need for more adaption may be recognized and recommended after more experience is gained from ADOS-2 and ADI-R administration.
We substituted ADOS-2 standard materials with more culturally relevant materials when necessary (e.g., Description of a Picture materials on the ADOS). The ADI-R questions about more general behaviors such as toileting, aggression, family routine, as well as some items 'use of a body as a tool' were not as informative in this cultural context; however, specific social-communication items and RRB questions are more pertinent.
Because of reporting of specific behaviors related to ASD on the ADI-R was lower overall, standard cut-offs were reduced in an effort to capture children who may be exhibiting some ASD related behaviors and to assess these behaviors directly using the ADOS-2.

10:55 **177.002** Adapting Caregiver-Mediated Early Autism Interventions in South Africa: Contextual Factors and Acceptability of Caregiver Involvement

L. Franz[1], *J. Guler*[2], *N. Seris*[3], *N. Shabalala*[4] *and P. J. de Vries*[5], *(1)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (2)Duke University, Durham, NC, (3)Psychology, University of Cape Town, Cape Town, South Africa, (4)University of Cape Town, Cape Town, South Africa, (5)Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background:
A significant global challenge is to develop scalable, feasible, early interventions for ASD that can be implemented in diverse and low resource communities. Caregiver-mediated early ASD interventions could provide the necessary avenue to address the capacity barrier globally. However, important questions remain about contextual factors of importance in intervention adaptation and the acceptability of intervention techniques that utilize caregivers in a service delivery model.
Objectives:
This qualitative, South African study explored: (1) contextual factors relevant to the adaptation of a caregiver-mediated early ASD intervention, and (2) the acceptability of utilizing caregivers in the delivery of an early ASD intervention from the perspective of caregivers and providers.
Methods:
Focus groups and in-depth interviews were conducted in Cape Town, South Africa, with 28 caregivers of children with ASD and 12 local autism service providers. The caregivers included mothers (n=20), fathers (n=5), and grandmothers (n=3) of children with ASD who were under the age of 7 years. The local ASD service providers, who worked in the public health (n=7) or education (n=5) sector, included psychologists, educators, speech therapists, occupational therapists, and a parent advocate. This sample included participants from a number of African countries, representing the cultural diversity and typical migration patterns seen in South Africa. Participants spoke in English, isiZulu, isiXhosa, and Afrikaans in the interviews and focus groups. All data was translated, transcribed, and then coded for emerging themes using the NVivo qualitative data analysis software package.
Results:
Contextual factors reported by both caregivers and service providers included: (1) the importance of matching provider to family by spoken language, (2) cultural sensitivity to traditional parenting practices and family customs, (3) affordability of treatment, (4) the importance of immediate and extended family acceptance and support, and (5) the effects of community-based stigma. Specific caregiver contextual factors included: (1) the importance of religion and faith as a form of support and (2) feeling financially exploited by ASD service providers. Specific provider contextual factors that emerged included: (1) lack of parental psychoeducation, and (2) difficulty contacting or communicating with caregivers. Caregivers and service providers reported acceptability of the concept of training caregivers to deliver an early ASD intervention. Caregivers noted that they would experience this education and training as empowering and reported interaction styles with their children which suggest they may be able to be trained to implement early ASD interventions. Specifically, caregivers: (1) were aware of their child's affective state, (2) regularly engaged in child-directed play activities that

included both object-based play and sensory-social routines, and (3) utilized locally available, child-selected play materials.
Conclusions:
Common themes around important contextual factors and acceptability of utilizing caregivers in the service delivery model emerged from a culturally and geographically diverse group of participants. This study had the unintended positive consequence of providing a shared platform for parents and caregivers to seek support and gather information from one another, highlighting the paucity of available social support in this environment.

11:20 **177.003** Assessing Differences in Lifetime Item Scores of the Spanish ADI-R in Latino Children with ASD and Children with DD

S. B. Vanegas[1] *and S. Magana*[2]*, (1)Disability and Human Development, University of Illinois at Chicago, Chicago, IL, (2)University of Illinois at Chicago, Chicago, IL*

Background:
There is a growing body of research that has identified significant disparities in ASD diagnoses among racial/ethnic minority children (e.g., Daniels & Mandell, 2014). Thus, it is critical that research addresses possible issues in the diagnostic tools used with diverse populations. The Autism Diagnostic Interview-Revised (ADI-R; Lord et al. 1994) is a 'gold-standard' parent interview that provides a composite of past and current behaviors as it pertains to ASD. Select items from the extensive interview are then used to determine whether the individual demonstrates sufficient symptoms that would merit an ASD diagnosis. However, little is known whether the selected algorithm items from the ADI-R are adequate in identifying children with ASD in a Latino population.
Objectives:
The objective of this paper is to evaluate the utility of all lifetime items from the Spanish ADI-R in distinguishing between children with ASD and children with DD in a U.S. based Latino population.
Methods:
The current study included 50 Spanish-speaking Latino parents of children and adolescents who were between 4 and 16 years of age and received a clinical diagnosis of ASD (n = 29) or a Developmental Delay (DD; n= 21). Clinical diagnoses were confirmed by review of the medical records. The official Spanish version of the ADI-R was administered by trained interviewers. All lifetime item scores were converted based on the recommended guidelines (e.g., Rutter et al. 2003).
Results:
Analyses were first conducted on the lifetime algorithm items to determine which items distinguished children with ASD from children with DD. In the social reciprocity domain, the following items were significantly different between children with ASD and children with DD: social smiling, range of facial expressions, showing/directing attention, seeking to share enjoyment, use of other's body, offering comfort, and quality of social overtures. All restricted and repetitive behavior items, with the exception of unusual preoccupations and verbal rituals, distinguished the ASD and DD groups. The communication domain had the fewest items that were significantly different between children with ASD and children with DD. Additional analyses were then run on additional lifetime non-algorithm items. These analyses showed that children with ASD had higher levels of impairment on comprehension of simple language, social disinhibition, difficulties with changes to routines/environment, and self-injury (all p's < .05). These additional non-algorithm items demonstrated the largest differences observed between children with ASD and children with DD.
Conclusions:
The results of this study demonstrate that the communication domain had the lowest proportion of items that distinguished between ASD and DD, whereas the restricted and repetitive behavior items had the highest proportion of items. The results also find that additional items not included in the diagnostic algorithms of the ADI-R may enhance the validity of the parent interview among Latino families. This can be attributed distinct ways that ASD manifests or is perceived by Latino parents. With the publication of the DSM-5 and its updated diagnostic criteria for ASD, it is important to evaluate how existing diagnostic tools can be used to inform new diagnoses.

Table 1

Impairments on Lifetime Algorithm Items

	ASD ($n = 29$)		DD ($n = 21$)		F	Partial η^2

11:45 **177.004** Severity and Latino Ethnicity in Specialty Services for Children with Autism Spectrum Disorder

S. Magana[1], *S. Parish*[2] *and E. Son*[3], *(1)University of Illinois at Chicago, Chicago, IL, (2)Brandies University, Waltham, MA, (3)Social Work, College of Staten Island, Staten Island, NY*

Background:
Children with autism spectrum disorder (ASD) experience a range of severity levels characterized as levels of support they need for everyday functioning. By this definition, greater levels of severity should warrant greater use of services and supports among children with ASD. In previous studies, Latino children with ASD in the USA have been shown to have lower access to diagnosis and treatment services than White children. However, none have examined service use in relation to severity.
Objectives:
In this study, our objective was to examine whether there are ethnic disparities between Latino and White children with ASD in specialty autism-related services, and whether condition severity moderate the relationship between ethnicity and receipt of autism services.
Methods:
We used data from the Survey of Pathways to Diagnosis and Services, a supplement to the National Survey of Children with Special Health Care Needs and analyzed current use of four specialty services commonly used by children with ASD: behavioral interventions, occupational therapy, social skills training, and sensory integration. The analytic sample included non-Latino White (n=1,063) and Latino (n=120) children with any ASD. When weighted, the sample represented 431,525 White children and 85,154 Latino children with any ASD. Logistic and Linear and logistic regressions were used to determine the relationships of ethnicity and severity to the outcome service variables, adjusting for demographic variables. An interaction term of ethnicity and severity was created to test for interaction effects.
Results:
We found that children whose conditions were more severe were twice as likely to receive each of the services as children who were less severe. Being Latino was significantly related to lower total service use. Furthermore, Latino children with ASD who had severe conditions received fewer specialty autism-related services than White children with similarly severe conditions. These disparities were evident despite the fact that the sample of Latino children in this data were more privileged than the general US Latino population given that it was an English speaking and relatively high income sample.
Conclusions:
Future research is needed to investigate factors that contribute to Latino children who have greater severity receiving fewer services than White children. Also, data sets are needed that are more representative of the US Latino population. Assertive policy initiatives are needed to address these disparities and ensure that these highly vulnerable children with severe conditions receive appropriate services and supports.

Panel Session

178 - Efforts Towards a More Cohesive Understanding of Anxiety in ASD: Correlates and Underlying Mechanisms

10:30 AM - 12:30 PM - Room 310

Panel Chair: Nicole Kreiser, *1750 East Fairmount Ave, Kennedy Krieger Institute, Baltimore, MD*

Discussant: Mikle South, *Brigham Young University, Provo, UT, Brigham Young University, Provo, UT*

Anxiety is a common co-occurring problem among individuals with ASD. However, the phenomenology, correlates and mechanisms of anxiety in this population remain poorly understood. The existing research has identified executive functioning (Lawson et al., 2015; Lopez, Lincoln, Ozonoff, & Lai, 2005), emotion regulation (White et al., 2014), and dispositional traits (i.e., Intolerance of Uncertainty; Boulter et al., 2014; Chamberlain et al., 2013) as potential correlates of anxiety in ASD. Physiological and fear conditioning processes (e.g., Chamberlain et al., 2013; South et al., 2011; Kleinhans et al., 2010) as well as brain circuitry related to anxiety in ASD have also been explored, though findings have been inconsistent. This panel attempts to explore several identified contributors to anxiety in ASD in an effort to move towards a more integrated understanding of neurobiological and psychological processes underlying anxiety in ASD. Panel presentations explore co-occurring anxiety in ASD in relationship to the following constructs: dimensions of emotion regulation impairment, profiles of executive functioning difficulties, brain circuitry (i.e., role of prefrontal cortex regions), dispositional traits (i.e., intolerance of uncertainty), and core ASD deficits. Integration of study findings, conceptual and methodological limitations and considerations, and future research directions will be discussed.

10:30 **178.001** The Underlying Structure of Emotion Regulation Impairment in ASD

C. A. Mazefsky[1], *L. Yu*[2], *S. W. White*[3] *and M. Siegel*[4], *(1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Virginia Polytechnic Institute and State University, Blacksburg, VA, (4)Maine Medical Center Research Institute - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME*

Background:
Impaired emotion regulation (ER) is strongly associated with a range of psychopathology and poor functioning. Studies of verbal individuals with ASD indicate reliance on maladaptive ER strategies. Understanding of the phenomenology of ER in severely affected and less verbal individuals with ASD is limited given the dependence of most measures on verbal indicators or self-report. Further, despite substantial variability in emotional presentation in ASD, empirically-based dimensions of emotion dysregulation have not been identified.
Objectives:
To identify empirically-derived dimensions of emotion dysregulation in an ASD sample with a wide range of verbal and cognitive functioning, and explore how they are associated with psychiatric and cognitive factors.
Methods:
The *Emotion Dysregulation Inventory* (EDI) was developed to capture the full presentation of affective experiences and emotional control in individuals with ASD of any verbal ability. PROMIS® guidelines for item development and piloting were followed to create the 66-item EDI with a 5-point intensity scale ("not at all" to "very severe"). The EDI was completed by the parents/guardians of 190 children (mean age 13, range 4-20; 77% male) with ADOS-confirmed ASD who were admitted to one of six specialized psychiatric inpatient units for ASD. The mean non-verbal IQ based on the *Leiter-3* was 74 with a wide range (SD = 30, Range = 30-145) and 53% were non- or minimally-verbal. Parents completed a battery of questionnaires including the *Child and Adolescent Symptom Inventory*(CASI) as a measure of psychiatric symptoms. A maximum likelihood factor analysis with oblique rotation was conducted with EDI items and the association between the resultant factor scores and other participant characteristics was explored.
Results:
The EDI total score was normally distributed, not correlated with IQ or age, and did not differ based on verbal ability level, suggesting lack of IQ and verbal ability biases. Factor analysis of EDI items justified a 2-factor model, based on a higher eigenvalues for the first two factors (17.4; 4.8), scree plot inflexions, and factor loading patterns. The factors were moderately correlated (r = .34) but no items had a rotated factor loading above .4 on both factors. Factor one accounted for the most variance and included indicators of poor ER (e.g., rapidly escalating, intense, and labile reactions, difficulty calming down once upset) and negative mood (e.g., angry/irritable, agitated behavior, etc.). Factor 2 included symptoms characteristic of anxiety and depressive disorders (e.g., nervousness, decreased positive affect and vitality). Different patterns of correlations with CASI and Leiter subscale scores and administrator ratings also supported a distinction between the two factors.
Conclusions:
Two distinct dimensions of emotion dysregulation were identified. The results support theories arguing that the experience of negative emotion and its regulation are difficult to separate, as the primary factor included indicators of poor ER as well as heightened reactivity and more negative affect. However, specific manifestations of negative affect, namely anxiety and depression symptoms, loaded onto a separate factor. Identifying dimensions of emotion dysregulation in ASD will aid in the development of targeted intervention efforts and support the detection of underlying biological mechanisms.

10:55 **178.002** Differentiating Profiles of Anxiety and Executive Function in ASD without ID

C. E. Pugliese[1], *L. G. Anthony*[1], *X. You*[2], *A. C. Armour*[3], *Y. Granader*[1] *and L. Kenworthy*[4], *(1)Children's National Medical Center, Rockville, MD, (2)Children's National Health System, Washington, DC, (3)Children's National Medical Center, Arlington, VA, (4)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Youth with ASD experience high rates of co-morbid anxiety, which has been linked to rumination and inflexibility in typically developing (TD) youth and those with developmental disorders. Inflexibility is a near ubiquitous problem in ASD, which is also associated with a range of other EF problems. Given the fact that not all youth with ASD develop anxiety, it is important to explore whether anxiety in ASD is driven by inflexibility and/or other specific EF deficits. A further question is whether the heterogeneity of ASD anxiety symptomatology can be parsed with specific profiles of EF.
Objectives: To examine whether (1) specific domains of parent-reported EF, particularly flexibility, was predictive of greater parent-reported anxiety symptoms, and (2) specific profiles of EF and anxiety cluster together in subgroups of youth with ASD.
Methods: 220 youth (44 females) with a DSM diagnosis of ASD between the ages of 8 and 13 (M=10.46, SD=1.69) were evaluated on the Behavior Rating Scale of Executive Function (BRIEF) and Child Behavior Checklist (CBCL). Participants possessed average IQ (M=106.13, SD=19.17) and met CPEA criteria for 'broad ASD' on the ADI-R and/or ADOS. To determine whether specific EF domains were predictive of anxiety, we regressed CBCL Anxiety Problems DSM-oriented scale scores onto BRIEF subscales (predictors), age, and IQ (covariates). We also used a data driven, model free community-detection approach to parse heterogeneity in EF and anxiety profiles in ASD. This approach is an optimization clustering method, which identifies subgroups that share similar behavioral phenotypic features. It reveals profiles-based dimensions to detect how EF and anxiety cluster together in terms of relative strengths and weaknesses.
Results: When all predictors and covariates were entered into the regression model, the only significant predictor was the BRIEF shift scale (t=3.56, p<.001) with the overall model explaining 22.6% of the variance in Anxiety scores (F=8.43, p<.001). The community detection analyses revealed three subgroups: 1) a high anxiety group (n=88) clustered with high shifting and emotional control issues, 2) a low anxiety group (n=60) clustered with high disinhibition and working memory problems but fewer issues with flexibility and emotional control, and 3) a medium anxiety group (n=77) clustered with metacognitive impairments and fewer inhibition, shifting, and emotional control problems. See attached image for group profiles. Approximately 64%, 17%, and 53% of participants in each group, respectively, received Anxiety scores above the borderline cut-off on the CBCL.
Conclusions: Both regression and cluster analyses revealed positive associations between anxiety and inflexibility. In addition, the cluster analysis revealed that two other EF profiles were associated with anxiety: group 1 was characterized by relatively high anxiety, inflexibility, and emotion dysregulation; group 2 was associated by relatively high inhibition problems and relatively low anxiety. As such, clinical treatment may differ for each of these profiles; the highest anxiety group may need behavioral intervention for cognitive flexibility and emotion regulation along with effective, direct treatments for anxiety.

11:20 **178.003** The Relationship Between Intolerance of Uncertainty, Core ASD Deficits, and Anxiety

N. L. Kreiser[1], *A. Keefer*[1,2], *V. Singh*[1], *S. H. Mostofsky*[3] *and R. A. Vasa*[1], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)School of Medicine, Johns Hopkins University, Baltimore, MD, (3)Johns Hopkins School of Medicine, Baltimore, MD*

Background: Intolerance of uncertainty (IU) is a dispositional trait involving maladaptive responding under conditions of uncertainty that has been linked to anxiety in typically developing (TD) individuals. Recently, there has been interest in examining how IU relates to ASD given high levels of anxiety and difficulty tolerating uncertain situations in this population. Several studies have examined the construct of IU in ASD. The findings indicate higher levels of IU and a positive relationship between anxiety and IU (Boulter et al., 2014; Chamberlain et al., 2013; Wigham et al., 2014). No studies to date have examined whether IU is exclusively a feature of anxiety in ASD or whether it is related to ASD characteristics irrespective of anxiety.
Objectives: The objectives of this study were to: 1) Replicate the finding of higher IU levels in youth with ASD compared to TD children (Aim 1), 2) Confirm the relationship between IU and anxiety (Aim 2), and 3) Examine whether IU was associated with core and related ASD characteristics (i.e., repetitive behaviors, executive dysfunction) when controlling for anxiety (Aim 3).
Methods: Fifty-seven children with ASD and 32 TD control participants (IQ > 80), ages 7- 16 years, participated in this study. Participants were a subset of a larger community sample of youth with ASD who were recruited for behavioral and neuroimaging research. ASD diagnosis was established by clinical evaluation and supported by the ADOS. Participants also completed measures of IU (Intolerance of Uncertainty Scale: IUSC), anxiety (SCARED), ASD behaviors (SRS), repetitive behaviors (RBS-R), and executive functioning (EF) (BRIEF). Due to a skewed distribution, non-parametric tests were utilized for all analyses. Aims 1 and 2 were pursued using Wilcoxon Mann-Whitney U tests and Spearman's Rho correlations. Aim 3 was examined using hierarchal linear regressions with bootstrapping.

Results: Children with ASD had significantly higher parent (z = -5.04, p < .001) and child (z = -3.69, p < .001) reports of IU compared to the TD group (Aim 1). For the ASD group, significant relationships between IU and anxiety were present based upon parent (r = .37, p = 01) and child (r = .50, p < .001) report (Aim 2). Regressions using both parent and child report showed that ASD diagnosis was associated with IU over and above the effects of anxiety (Table 1). Similarly, the relationship between IU and SRS, when controlling for anxiety, approached significance (p = .07). Neither repetitive behaviors nor EF difficulties were associated with IU when controlling for anxiety.
Conclusions: Findings from this study confirm that IU is elevated in youth with ASD and is associated with anxiety. The novel finding of this study is that core ASD deficits were related to IU in this study beyond the contributions of anxiety. This raises questions about whether IU might be an inherent or heritable feature of ASD or related to a unique presentation of anxiety in ASD. Heritability and longitudinal studies of IU as well as research with clinically anxious ASD samples are necessary to better understand these relationships.

11:45 **178.004** The Neurobiology of Emotion Regulation Problems and Co-Occurring Anxiety in ASD

J. Herrington[1], *A. McVey*[2], *J. C. Bush*[3], *K. Rump*[4], *J. Worley*[5], *L. R. Guy*[6], *J. Pandey*[7], *J. Miller*[8] *and R. T. Schultz*[9], *(1)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Marquette University, Milwaukee, WI, (3)Indiana University, Bloomington, IN, (4)The Center for Autism Research, Philadelphia, PA, (5)CHOP, Blue Bell, PA, (6)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (7)Children's Hospital of Philadelphia, Philadelphia, PA, (8)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (9)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:
There is a growing recognition that emotion regulation difficulties are common in ASD, resulting in increased symptoms of anxiety. However, the neurobiology of emotion regulation problems in ASD has yet to be fully examined. Data from non-ASD samples suggest that this examination will point to brain systems that we already know function differently in ASD, but are seldom interpreted in terms of emotion regulation. This is particularly true of prefrontal cortex (PFC), where decades of affective neuroscience research have implicated cognitive control structures in the regulation of emotion. This presentation examines data from two functional MRI studies that associate anxiety deficits with abnormal PFC function in ASD.
Objectives: To examine the role of cognitive control (PFC) regions in youth diagnosed with co-occurring anxiety and ASD.
Methods: Both fMRI studies used face-processing tasks that are known to elicit activity in emotion and emotion regulation structures. The first study (N = 81 ASD, 67 control, mean age = 12.5 years) follows a dimensional approach, examining the relationship between anxiety symptoms (measured via the Screen for Child Anxiety Related Emotional Disorders) and PFC function in ASD. The second study follows a categorical approach, including ASD samples with formal anxiety disorder diagnoses (established via the Anxiety Disorder Interview Schedule; n = 15), and without (n = 13). ASD diagnoses were made following a developmental interview with parents and administration of the Autism Diagnostic Observation Schedule.
Results: Both dimensional and categorical approaches strongly associated increased anxiety in ASD with increased activation in multiple portions of PFC, including both dorsal and ventral medial PFC, superior frontal gyrus, and the frontal poles (see Fig. 1 for an illustration of the frontal pole activation). Although ASD studies often interpret activation in many of these regions in terms of mentalizing abilities, they also have known relationships with cognitive control. Given the direction of the results (i.e., increased PFC activity in ASD with anxiety), interpretations of findings in terms of anxiety and emotion regulation seem more parsimonious than those related to mentalizing. Post hoc analyses indicated that the findings from these studies cannot be attributed to differences in core ASD symptoms or intellectual level.
Conclusions:
Findings of altered PFC function in ASD may be best accounted for by models of emotion regulation that integrate cognitive control processes. The direction of effects (increased PFC activation) suggests that individuals with ASD and increased anxiety symptoms are over-engaging brain systems involved in cognitive control and emotion regulation. Future research should explore whether this increase is a compensatory response for increased levels of negative affect, or possibly inefficient communication between PFC and other emotion structures (i.e., amygdala).

The IBIS Network*[1], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Minnesota, Minneapolis, MN, (3)Psychiatry and Radiology, Washington University School of Medicine, St. Louis, MO, (4)University of Washington School of Medicine, Seattle, WA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of Alberta, Edmonton, AB, Canada, (7)University of Washington Autism Center, Seattle, WA, (8)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Previous research has shown that the caudate is enlarged in preschool-aged children with fragile X syndrome (FXS) (Hazlett, 2009; 2012). The amygdala is enlarged in young children with ASD (Hazlett, 2009; Mosconi, 2009; Nordahl, 2012; Schumann, 2009; Sparks, 2002) and exhibits neuronal abnormalities (Amaral, 2008; Schumann, 2006). However, it is unknown whether altered growth trajectories of the caudate and amygdala can be detected prior to age 2.
Objectives: We conducted a longitudinal MRI study and hypothesized that infants with FXS would show caudate enlargement, while infants who develop ASD would show amygdala enlargement, compared to age-matched control infants.
Methods: Longitudinal MRIs were collected at 6, 12, and 24 months in N=21 infants with FXS, N=50 high-risk infants who were later diagnosed with idiopathic ASD, N=227 high-risk infants who were not diagnosed with ASD (HR-neg), and N=134 low-risk control infants (LR-neg). Between 6-24 months, 50 scans were acquired in the FXS group, 153 in the ASD group, 611 in the HR-neg group, and 330 in the LR-neg group. Multi-atlas subcortical segmentation generated volumes for left and right caudate, amygdala, globus pallidus, putamen, thalamus, and hippocampus. A repeated-measures mixed-effects model tested main effects and interactions with group, while controlling for age, sex, and total cerebral volume (TCV).
Results: For the caudate, there was a significant main effect of group ($F_{3,456}$=16.33, p<.0001), as well as TCV, age and sex, but no group interactions. Pairwise comparisons revealed that the FXS group had larger caudate volume at 6, 12, and 24 months, compared to all other groups (p<.0001). The FXS group had 16% larger caudate volume at 6 months (vs. all other groups), 20% larger at 12 months, and 17% larger at 24 months (Fig. 1). For the amygdala, there was a significant group x age interaction ($F_{3,494}$=6.35, p<.05) with the ASD group having a steeper trajectory, such that by 12 months the ASD group had significantly larger amygdala volume (5% larger vs. HR-neg and LR-neg) and the FXS group had significantly smaller amygdala (5% smaller vs. HR-neg and LR-neg), after controlling for TCV, age and sex (Fig. 2). The globus pallidus showed a significant main effect of group ($F_{3,494}$=4.45, p<.05) with the FXS group having larger volume at 6-24 months. There were no significant group differences in the thalamus, putamen, or hippocampus. No group x laterality interactions were observed in any structure. Behavioral analyses revealed that caudate enlargement in the FXS group was significantly associated with greater motor stereotypies (r=.55, p<.05).
Conclusions: Infants with FXS have a striking enlargement of the caudate present by 6 months of age, whereas infants who develop ASD have amygdala enlargement that emerges between 6 and 24 months. While FXS shares some behavioral characteristics with idiopathic ASD, it appears that longitudinal brain imaging can delineate distinct brain trajectories early in life. Caudate enlargement has a pathological effect on motor behavior, consistent with findings in preschoolers (Wolff, 2013). We will examine the association between amygdala size and behaviors regulated by this brain region, including sensory function and social ability.

2 **179.002** Age, Verbal IQ and Autism Severity Information Improves ASD Classification Based on Brain Morphometry

*G. J. Katuwal[1,2], N. D. Cahill[3], S. A. Baum[4] and **A. M. Michael**[1], (1)Autism and Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA, (2)Center for Imaging Science, Rochester Institute of Technology, Rochester, NY, (3)School of Mathematical Sciences, Rochester Institute of Technology, Rochester, NY, (4)Faculty of Science, University of Manitoba, Winnipeg, MB, Canada*

Background:
Previous findings of brain morphometry abnormalities in autism spectrum disorder (ASD) have been inconsistent (Chen 2011). In addition, previous large multi-site studies that use brain morphometry to classify ASD from typically developing controls (TDC) report low classification accuracies (<60 %) (Haar 2014; Katuwal 2015; Sabuncu & Konukoglu 2014). The variability of the reported findings and the low accuracies can be mainly attributed to the heterogeneity of ASD.
Objectives:
In this study we investigate if the challenges posed by the heterogeneity of ASD brain morphometry for ASD classification can be improved by utilizing autism severity (AS), verbal IQ (VIQ) and age information.
Methods:
Structural MRIs of 373 ASD and 361 TDC male subjects (age range: 6-40years) from the ABIDE were preprocessed using FreeSurfer. For each image, 538 brain morphometric features were derived. ASD vs. TDC classification was performed using the Random Forest classifier on morphometric features. Classification success was measured using the area under the curve (AUC) metric estimated by 10-fold cross validation. AS, VIQ and age information were utilized in two ways. First, VIQ and age information were used in conjunction with morphometric features. Second, subjects were divided into 3 sub-groups each for AS, VIQ and age (Figure 1). In this scheme,

subject numbers of ASDs and TDCs were matched either by 'up-sampling' the smaller class in each training fold or by 'down-sampling' the larger class to match demographics of the smaller class.

Results:

A moderate AUC of 0.61, similar to the best of previous work, was achieved when only brain morphometric features were used for classification. Adding age and VIQ to brain morphometry features improved the AUC to 0.68. When subjects were divided into sub-groups, classification performance improved significantly and AUC patterns of both the up-sampling and down-sampling schemes matched (Figure 1). The highest AUC of 0.92 was achieved in the down-sampling scheme for the low AS group (Figure 1B). The most important features for classification varied across sub-groups (Figure 2), however, they were predominantly from the left amygdala, right hippocampal, ventricular, insular, frontal and temporal regions. Further, the mean of Cohen's d metric of the important features followed the AUC patterns. In both schemes, AUC was high for low AS (4 to 5) but decreased for moderate AS (6 to 7) and high AS (8 to 10). AUC decreased with VIQ. AUC was moderate for age groups of 6-13years and 18-40years but low for 13-18years age group. See Figure 1 for AUC values.

Conclusions:

The variability of the important features for classification across the sub-groups indicates that brain anatomical abnormalities in ASD are dependent on factors such as AS, VIQ and age. The increase in classification performance with the utilization of the above information demonstrates that the challenges posed by ASD heterogeneity can be mitigated by sub-grouping ASD. This study shows that the search for brain markers for sub-groups of ASD may be more fruitful than searching for markers across the whole spectrum of autism.

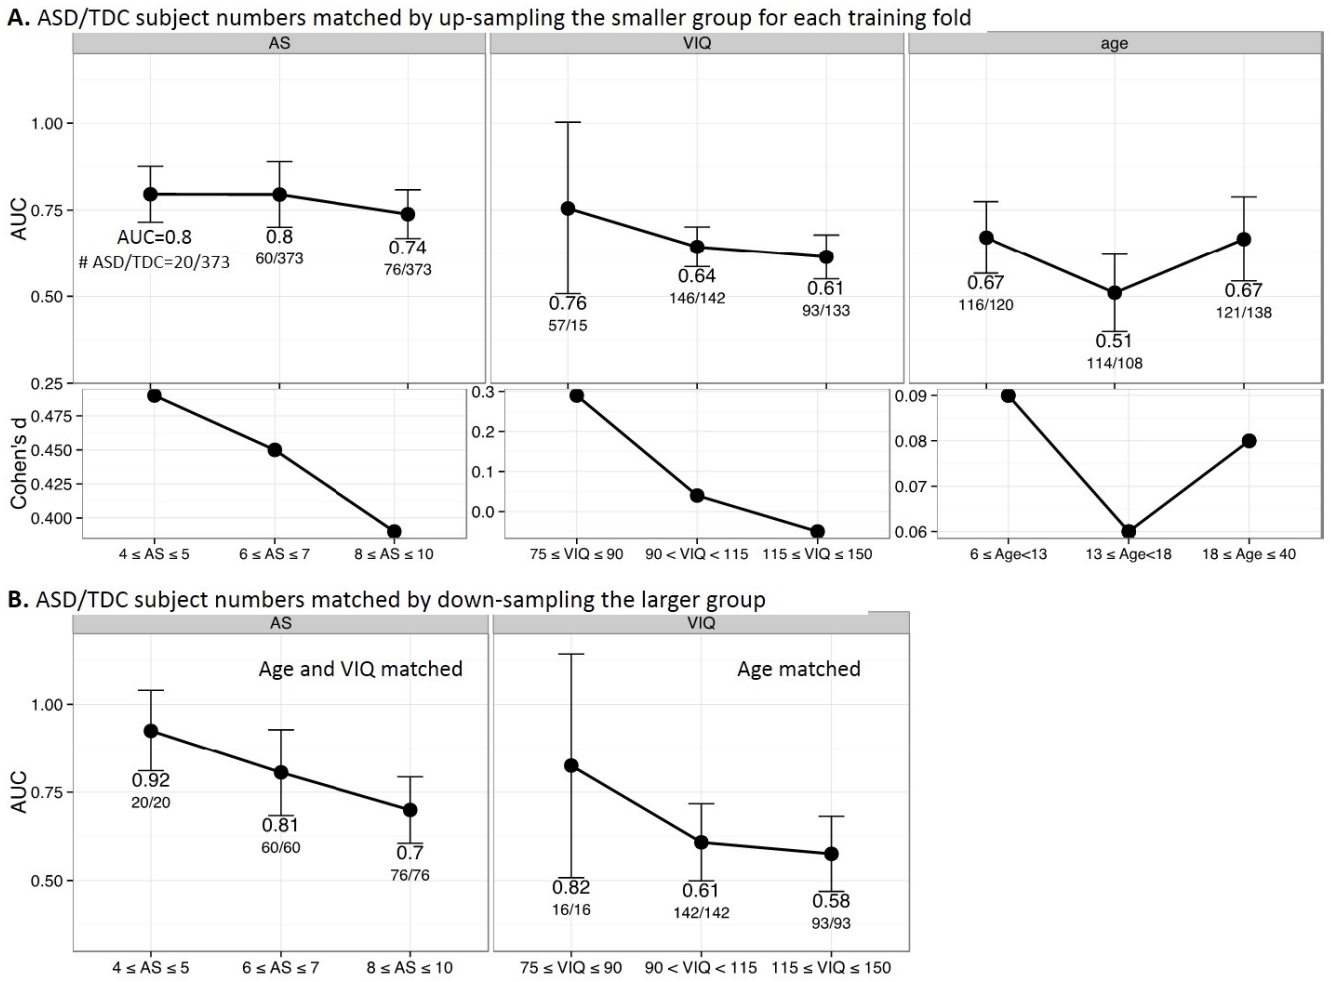

Figure 1: Improvement in classification when subjects are sub-grouped by autism severity (AS), verbal IQ (VIQ) and age. Mean and standard deviation of area under the curve (AUC) across 10 test folds are presented. The Cohen's d which is proportional to the separation of features follows the AUC.

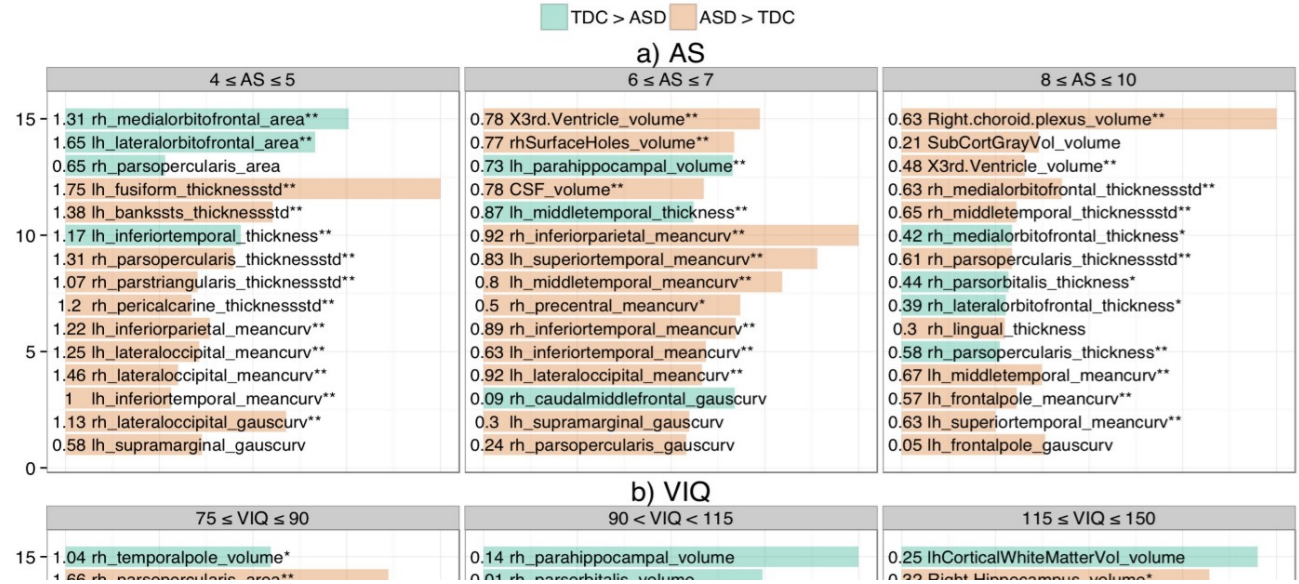

Figure 2: Most Important Features for Classification. Top 15 important features for ASD vs. TDC classification in each sub-group are presented. Each feature is represented by a bar. The length of the bar represents the relative % importance for classification (with respect to the top feature). The color of the bar represents the directionality of ASD vs. TDC group difference. The features have been grouped by volume, area, thickness, thickness standard deviation, folding index, mean curvature and Gaussian curvature. Before and after each feature we present the Cohen's d value and two sample t-test significance (P<0.005** and P<0.05*).

3 **179.003** Altered Organization of the Connectome in Pre-School Aged Children with Autism Spectrum Disorder

D. Grayson[1], *D. D. Li*[2], *S. J. Rogers*[2], *D. Fair*[3], *C. W. Nordahl*[2] *and D. G. Amaral*[4], *(1)UC Davis Mind Institute, Davis, CA, (2)University of California at Davis, Sacramento, CA, (3)Oregon Health & Science University, Portland, OR, (4)UC Davis The M.I.N.D. Institute, Sacramento, CA*

Background: It is now largely recognized that Autism Spectrum Disorder (ASD) is a syndrome that involves alterations in brain connectivity. Previous diffusion-weighted imaging (DWI) research in late childhood has emphasized microstructural alterations of white matter pathways in Autism by using voxel-wise statistics. However, thorough analyses of whole-brain network properties of the structural connectome in early childhood are, thus far, limited.
Objectives: In the current study, we expand on the literature by using probabilistic tractography along with a graph theoretical measurement, termed communicability, to determine what aspects of brain communication might be altered in children with Autism.
Methods: T1-weighted structural images and DWI were acquired in a sample of 55 children with ASD (age range: 3-5 years) and 13 typically developing (TD) children matched on age and gender. Scanning was performed while children were sleeping and images were visually inspected to exclude subjects with motion or other noticeable

artifact. Voxelwise diffusion was modeled using constrained spherical deconvolution (Tournier et al., 2008) and probabilistic tractography was performed throughout all voxels of white matter. The Freesurfer cortical gray matter parcellation of 83 regions was then used to generate a whole-brain structural connectivity matrix (the connectome) for each subject. In order to understand how alterations in the structural connectome might relate to altered functional brain communication, we applied a measure termed communicability. Communicability measures the ease with which information can travel between two nodes (Crofts and Higham, 2009) by calculating a weighted sum of all paths between them. Comparisons of communicability across all node pairs was conducted between ASD and TD subjects using the Network-Based Statistic (Zalesky et al., 2010). In addition, multi-dimensional scaling was applied to child matrices to examine the variability of brain-wide communicability profiles within the TD and ASD populations.
Results: Structural networks of children with ASD showed remarkable agreement with their TD counterparts across much of the region set when comparing node strength (i.e. the sum of a node's connection strengths) and node communicability (the sum of a node's communicabilities). However, results indicated reduced communicability in ASD between a subset of nodes including regions of the frontal cortex and the caudate (T-statistics>3, FWE-corrected P<.04). Results implicate the lateral orbitofronal cortex most heavily, although the frontal operculum and superior frontal cortex also had reduced communicabilities. Our multi-dimensional scaling analysis identified a small number of subjects with ASD (n=6) whose pattern of brain-wide communicability differed markedly from the central tendency of the TD group and the remainder of the ASD sample.
Conclusions: Consistent with previous work, our findings suggest that from an early age ASD may be linked with alterations in brain communicability. In particular, connections throughout the integrative systems of the frontal cortex appear most atypical. Importantly, while our findings were robust across the group, not all children shared the same brain phenotype - highlighting sample heterogeneity. Future work will focus on characterizing this heterogeneity, and identifying the behavioral, genetic, and immunological correlates of these connectome phenomena.

4 **179.004** Association Between Microstructural Properties of the Uncinate Fasiculus and Emotion Recognition in Women with and without Autism Spectrum Conditions

Background: Autism spectrum conditions (ASC) are a heterogeneous set of neurodevelopmental conditions. Difficulties with communication and social interactions are some of the main characteristics of ASC. Previous studies have noted potential sex/gender differences in the behavior and brain structural characteristics in individuals ASC, based on studies in which females are frequently outnumbered.
Objectives: This study aims to investigate interactions between neuropsychological tasks measuring emotion recognition and mentalizing and microstructural properties of the uncinate fasciculus (UF; which connects the frontal and temporal lobes) in women with and without ASC.
Methods: 42 age- and IQ-matched women with (n=21) and without ASC were scanned (3T GE) using a cardiac-gated 32-direction diffusion-weighted sequence. ExploreDTI was used for preprocessing (Leemans, et al., 2009) and UF deterministic tractography was performed according to guidelines given by Catani & Thiebaut de Schotten (2008) using TrackVis software (http://trackvis.org). Participants completed the "Reading the Mind in the Eyes" (RMET) and the Karolinska Directed Emotional Faces (KDEF) tasks. Number of correct responses was used to test for group differences in performance on the RMET, and log-transformed accuracy-adjusted reaction times (aaRT; mean reaction time divided by accuracy) were used for each individual emotion on the KDEF. A multivariate repeated-measures analysis of covariance (MANCOVA) was performed on fractional anisotropy (FA), mean diffusivity (MD), radial diffusivity (RD), axial diffusivity (AD) and tract volume respectively, with 'hemisphere' as within-subjects factor, 'diagnosis' as between-subject factor, and 'IQ' as a covariate. Any significant interaction effects were followed up by post-hoc ANCOVAs.
Results: On average, typically developing (TD) females performed better on the RMET (TD, 28.5; ASC, 23.0; $F(1,38) = 10.1$, $p = 0.003$) and identified "happy" KDEF expressions faster (TD, 1561ms; ASC, 1925ms; $F(1,38) = 9.82$, $p = 0.003$). No group differences were found for other emotional KDEF expressions. There were no group differences in FA, MD, number of streamlines or volume of the UF. Significant hemispheric asymmetries were found across groups for FA and MD, with higher FA ($F(1,40) = 31.6$, $p < 0.001$) and lower MD ($F(1,40) = 14.9$, $p < 0.001$) in the right UF. In women with ASC, higher FA in the right UF was related to better identification of the "happy" facial expression (TD: $r = -0.36$, $p = 0.12$, ASC: $r = -0.44$, $p = 0.05$) and higher MD of the right UF was associated with better performance on the RMET (TD: $r = -.03$, $p = 0.89$, ASC: $r = 0.45$, $p = 0.04$). Fisher's Z-test was used to compare the correlation coefficients and showed that there were no significant group differences.
Conclusions: This is the first study that investigates if and how microstructural properties of WM in TD and ASC females relate to socio-emotional task performance. Two significant correlations were found between microstructural properties of the right UF and performance on mentalizing tasks. However, post-hoc Fisher's Z-test determined that the effect sizes were not significantly different between groups. Future research should investigate if socio-emotional task performance in autism can be predicted by any other WM tracts.

5 **179.005** Associations Between Cortical Thickness and Social Cognition in Autism Spectrum Disorders

K. A. R. Doyle-Thomas[1], *N. E. Foster*[2], *A. Kushki*[3], *C. Horlin*[4], *A. Tryfon*[5], *K. L. Hyde*[6], *A. C. Evans*[6], *J. D. Lewis*[6], *L. Zwaigenbaum*[7] *and E. Anagnostou*[8], *(1)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Montreal, Montreal, QC, Canada, (3)Bloorview Research Institute, Toronto, ON, Canada, (4)Holland Bloorview, Toronto, ON, Canada, (5)McGill University, Montreal, QC, Canada, (6)Montreal Neurological Institute, Montreal, QC, Canada, (7)University of Alberta, Edmonton, AB, Canada, (8)University of Toronto, Toronto, ON, Canada*

Background: Cortical thickness atypicalities in individuals with autism spectrum disorders (ASD) have been reported in several brain regions. Normative studies have shown that cortical thickness is associated with socio-emotional capacities such as theory of mind. Recent studies with individuals with ASD have explored the relationship between cortical thickness and socio-communicative abilities using scores from diagnostic measures such as the Autism Diagnostic Interview–Revised. The use of these assessments however precludes a comparison with typically developing (TD) peers.
Objectives: The present study examined emotion recognition in individuals with and without ASD using the Reading the Mind in the Eyes task (RMET), and explored whether overall performance, specific valances, and the level of difficulty were associated with differences in cortical thickness.
Methods: 51 youth with ASD and 15 TD controls (7-17 years of age) were included in these analyses. Participants were part of a multi-site imaging study (NeuroDevNet) at two Canadian sites, the Hospital for Sick Children, and the Montreal Neurological Institute. Participants were imaged using a Siemens Allegra 3T MRI system. A T1-weighted high-resolution automatic scan was obtained at the following parameters: TR=2300 ms, TE=2.96 ms, flip angle=90, FoV=256 x 192 x 240, slice thickness=1mm. Total imaging time was approximately 5 minutes. The CIVET automated analysis pipeline was using for preprocessing analysis. SurfStat and SAS were used for statistical analysis. We explored (1) baseline differences in age and IQ, (2) performance differences in RMET total scores, valence scores (positive, negative and neutral) and difficulty scores (easy and difficult), (3) the relation between RMET total, valence and difficulty scores, and cortical thickness between groups and (4) the effect of site.
Results: Groups were similar on age (ASD = 13.03±2.78, TD = 12.91±2.60, p=0.58), but significantly different on IQ (ASD = 95.55±18.88, TD = 116.06±7.97, p<0.001). RMET total scores were significantly poorer in individuals with ASD compared to TD youth (ASD = 16.41±0.61, TD = 20.29±1.16, p=0.004). After controlling for IQ, scores were no longer significantly different (ASD = 16.96±0.54, TD = 18.29±1.09, p=0.29). IQ was not controlled for in subsequent analyses. A significant interaction was observed between accuracy and cortical thickness between groups in the inferior frontal gyrus (Brodmann area; BA 45, p=0.05) and the cingulate gyrus (BA 32, p=0.003) for overall performance; the superior frontal gyrus (BA 11, p<0.001) and the medial prefrontal gyrus (BA 10, p<0.001) for negative emotions; and the middle frontal gyrus (BA 11, P=0.003), the inferior frontal gyrus (BA 44, p=0.008), and the cingulate gyrus (BA 24, p=0.016) for difficult emotions, after controlling for age and correcting for multiple comparisons. The results did not change significantly when controlling for site. In all cases, TD individuals showed increased cortical thickness related to improved accuracy, whereas no such relation was observed in individuals with ASD. No significant interactions were found between performance and cortical thickness for positive or neutral emotions, and easy items (all p>0.05).
Conclusions: These findings suggest that cortical thickness across the brain may relate to social perception in different ways in individuals with and without ASD.

6 **179.006** Asymmetry of Fusiform Structure in ASD and Its Association with Symptom Severity

C. C. Dougherty[1], *D. W. Evans*[2], *G. J. Katuwal*[1,3] *and A. M. Michael*[1], *(1)Autism and Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA, (2)Department of Psychology, Bucknell University, Lewisburg, PA, (3)Center for Imaging Science, Rochester Institute of Technology, Rochester, NY*

Background:
Deviations from typical brain asymmetry have been implicated in neurodevelopmental disorders (Renteria 2012). Of the brain regions implicated in autism spectrum disorder (ASD), the fusiform gyrus, is associated with abnormalities in face processing (Schultz 2003). Although the fusiform may underlie ASD symptoms, only a few studies have examined its structural asymmetry (Herbert 2002; 2005). The asymmetry of the fusiform in terms of volume, surface area (SA), cortical thickness (CT), or developmental

trajectory are not well characterized. Furthermore, the relationship between fusiform asymmetry and ASD symptom severity is unclear.

Objectives:

We examine the following: 1) Left-Right (L-R) asymmetry of volume, SA, and CT of the fusiform gyrus in ASD compared to typically developing controls (TDC); 2) developmental differences in fusiform asymmetry between ASD and TDC; 3) correlation between fusiform asymmetry and symptom severity as measured by Gotham Autism Severity Scores (Gotham 2009).

Methods:

Structural MRIs and demographics of 128 ASDs (average age ± std: 15.5 ± 4.1 years) and 127 TDCs (15.6 ± 3.8 years) from the ABIDE dataset were used in this study. All subjects were right handed males between the ages of 6 to 25 years. We processed the MRIs with FreeSurfer and derived the volumes, SAs and CTs of the fusiform gyri. Symmetry index (SI) (Galaburda 1987) of the above measures was calculated as the difference between the left and right hemispheric measures as a percentage of the average of the left and right measures.

A generalized linear model was fitted for SI with the following regressors: age, ASD/TDC status, verbal IQ (VIQ), performance IQ (PIQ), and age status interaction. For correlations between SI and symptom severity, SIs from 69 ASDs were fitted with the following regressors: age, VIQ, PIQ, and ADOS. The aforementioned model was repeated with autism symptom severity scores from 28 ASDs. ADOS and severity score analyses were limited to a subset of subjects for whom these data were available.

Results:

Significant group differences in volume (*p = 0.031)* and SA (*p = 0.031)* asymmetries emerged between ASD and TDC. ASD subjects exhibited greater leftward asymmetry for both measures (Figure 1A). Although significant overall group differences are evident, asymmetries for ASDs were spread both leftward and rightward (see distribution in Figure 1A). A significant interaction with age (*p = 0.049)* emerged in SA for ASD and TDC with decreasing leftward asymmetry in ASD with increasing age (Figure 1B). ADOS scores and fusiform volume asymmetry were negatively correlated (*p = 0.047)*. A stronger correlation (*p = 0.0097)* was observed between autism symptom severity and fusiform volume asymmetry. See Figure 2A, B.

Conclusions:

We provide evidence for abnormal patterns of asymmetry in fusiform gyrus volume and SA in ASD compared to TDC. The wide distribution of asymmetry in ASD may indicate the presence of ASD subtypes, and closer evaluation is needed. Furthermore, the development of asymmetry in fusiform SA may differ in ASD. Finally, we provide evidence that asymmetry in fusiform volume may be related to autism symptom expression using both ADOS and autism severity scores.

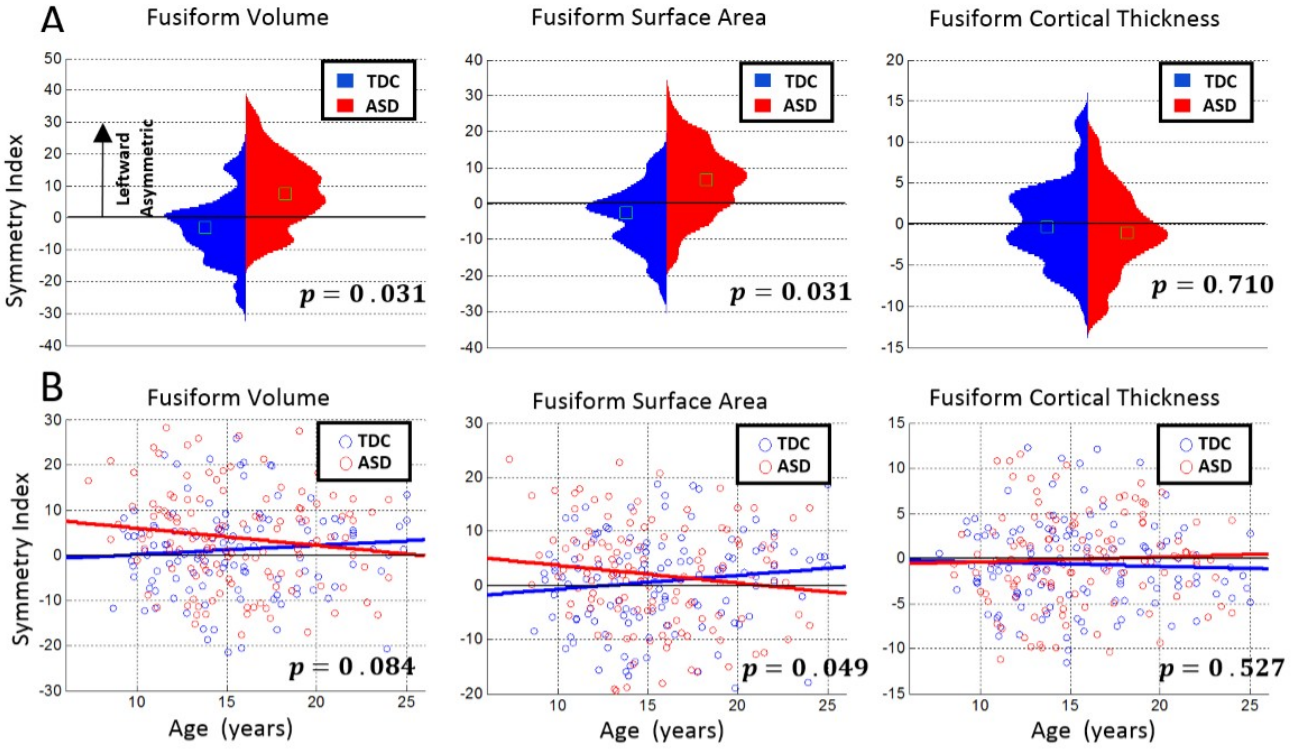

Figure 1: Distribution of Symmetry Index and Age x Diagnosis Interaction Plots: A depicts distribution of symmetry index (adjusted for age and IQs) for ASD (red) and TDC (blue) for fusiform volume, surface area, and cortical thickness. Group means are presented in the green box. Group mean differences were significant for volume ($p = 0.031$) and surface area ($p = 0.031$). **B** depicts symmetry Index across age range for cross-sectional data (adjusted for IQs). Age x diagnosis interaction was significant for surface area ($p = 0.049$). Linear fit indicates a trend of decreasing leftward asymmetry with age for ASD and decreasing rightward asymmetry for TDC.

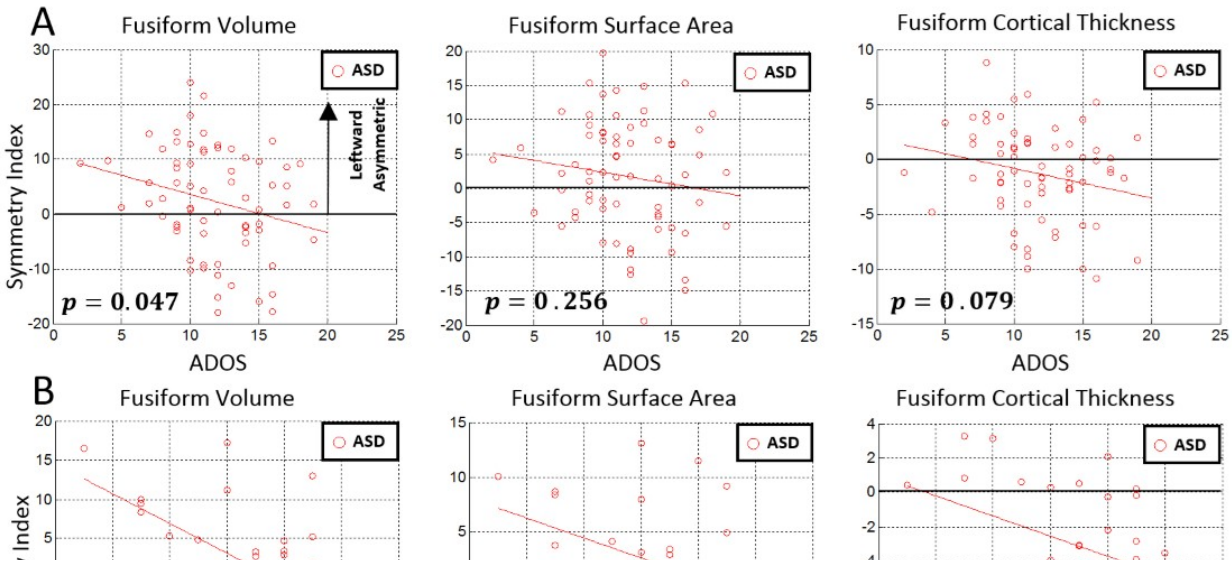

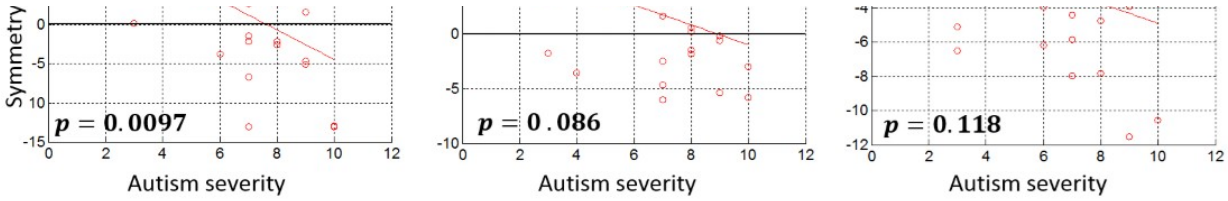

Figure 2: Symmetry index vs. ADOS and Autism Severity plots: A depicts relationships between symmetry index and ADOS for fusiform volume, surface area, and cortical thickness in ASD. Results indicate a significant negative relationship between volume symmetry index and ADOS score ($p = 0.047$). **B** depicts relationships between symmetry index and autism severity scores as measured by Gotham autism severity scores. A significant relationship between volume symmetry index and autism severity emerged ($p = 0.0097$). Data were adjusted for age and IQs.

Background:
Handedness and language are the most lateralized functions in the brain. Individuals with autism exhibit core deficits in language and auditory functions and show increased rates of non-right-handedness and atypical language specialization. Based on these observations, the prediction is that language-related measures of asymmetry should be sensitive to different developmental language profiles in individuals with autism.
Objectives:
No previous studies have examined lateralized differences in cortical language-related structures between language-delayed and non-language-delayed individuals with autism. Only one has looked at differences in handedness between these subgroups. Thus, we aimed to compare individuals with autism with and without language delay (LD) on language-related asymmetry measures including handedness and auditory and language cortical asymmetry.
Methods:
Sample 1: Participants were recruited online from the Cambridge Autism Research Database. The sample comprised 445 males with autism (LD=52, no LD=393) and 2,372 control male adults without autism (18-60 years). Handedness was categorically classified as 'right-handed' or 'non-right-handed'. A Chi-square-test compared the handedness categories across groups.
Sample 2: Participants comprised 67 right-handed, high-functioning adult males with autism (LD: 26; no LD: 41) and 69 male adults aged 18-43 years. Autistic symptoms were assessed by the ADI-R and ADOS. Language was assessed by a phonological memory and a word-generativity task.
T1-weighted images were segmented, rigid-body registered and reflected across the midline using SPM8. All images were mapped onto a symmetrical study-specific DARTEL template. Laterality indices (LI) were defined as: 2*(right–left)/(right+left). Spatially-restricted voxel-wise analysis of LIs was conducted using two co-activation maps for the terms 'language' and 'auditory' from the online database NeuroSynth. To test the effect of LD, univariate ANCOVAs were conducted for the interaction between diagnosis and any significant cluster and language and symptom measures as dependent variables.
Results:
Sample1: A significant between-group difference in handedness was observed across the three groups of autism with LD, without LD, and controls (p<0.001). Individuals with autism with LD were more strongly non-right-handed than controls (Cohen's d=0.404) and individuals with autism without LD showed an intermediate position (Cohen's d=0.198).
Sample2: Voxel-wise analysis of LIs within the auditory ROI revealed significant reductions from typical leftward asymmetry in adults with autism with LD (cluster-level FDR-corrected q=0.015), but not in individuals with autism without LD who had a significant intermediate position based on a polynomial trend analysis (p<0.001). There were no significant differences for the language ROI. There was a trending interaction between diagnosis and the significant auditory cluster for social reciprocity symptoms (ADI-A) (p=0.066). Follow-up correlational analyses showed significance within individuals with autism with LD (r=0.373, p=0.036), but not in individuals with autism without LD (r=-

0.092, p=0.289).
Conclusions:
Increased non-right-handedness and reductions in leftward asymmetry of perisylvian regions were found in male adults with autism. These potentially constitute behavioural markers and biological underpinnings of LD associated with autism, and represent a putative cardinal neurophenotype of LD in autism. It still has to be established whether handedness also differentiates between different developmental language profiles in females with autism and whether atypical cortical asymmetries are more pronounced in language-delayed females with autism.

8 **179.008** Atypical Patterns of Gyrification in Preschool-Aged Boys with Autism Spectrum Disorder

L. Libero[1], *M. Schaer*[2], *H. Ohta*[3], *S. J. Rogers*[4], *D. G. Amaral*[5] *and C. W. Nordahl*[4], *(1)UC Davis MIND Institute, Sacramento, CA, (2)Stanford University, Palo Alto, CA, (3)Showa University, Tokyo, Japan, (4)University of California at Davis, Sacramento, CA, (5)UC Davis The M.I.N.D. Institute, Sacramento, CA*

Background: Gyrification is a measure that describes the convolution or cortical folding of the brain. It is a feature of human cortex that develops prenatally and very early in life. Early adverse events affecting cerebral development are known to result in cortical folding alterations that can be quantified later on in the brains of children. Given that gyrification develops early in life, investigating this neural feature in a young population of children with autism spectrum disorder (ASD), close in time to the age of diagnosis, may provide insight into the earliest neuropathological manifestations of ASD.
Objectives: To examine local gyrification index in a large sample of young children with ASD and age-matched typically developing (TD) children.
Methods: Participants included 105 male children with ASD and 48 typically developing boys between 2 and 3.5 years of age enrolled in the Autism Phenome Project. T1-weighted structural MRIs were collected for each child and local gyrification index (LGI) was quantified based on these images. Retrospective measures including birth head circumference, birth length, birth weight, and gestational age at birth were acquired retrospectively from medical records. A subgroup of boys with ASD (n = 19) were classified as having disproportionate megalencephaly (ASD-DM; based on having a standardized ratio of total cerebral volume to height that was 1.5 SD above the mean for the TD group), while the remaining 86 boys with ASD had brain volume to height ratios within the normal range. Group comparisons included all children with ASD relative to TD, followed by comparisons of each ASD subgroup relative to TD.
Results: There were no significant differences between groups for age, gestational age, birth weight, birth length, or birth head circumference. However, the children with ASD had significantly reduced LGI in left and right fusiform gyrus, compared to TD boys. Additional comparisons of ASD subgroups revealed a different pattern of gyrification alterations in the ASD-DM group. Compared to TD boys and controlling for differences in brain volume, the ASD-DM group had significantly increased LGI in right superior frontal, left isthmus cingulate, and left posterior cingulate, suggesting that the ASD-DM group has a different neural phenotype from boys with ASD without megalencephaly. An examination of the relationships between global gyrification and measures from birth records revealed the children with ASD had a significant positive correlation between head circumference at birth and global gyrification, while the TD group had no such relationship.
Conclusions: Significant alterations in LGI in right and left fusiform in boys with ASD holds strong implications for social and emotional processing. But importantly, not all children with ASD exhibited this pattern of alterations; our results suggest that boys with ASD and disproportionate megalencephaly may have a different neural phenotype. Associations between global gyrification at 2-3.5 years of age with birth head circumference in the ASD group suggest that alterations in gyrification patterns may be determined prenatally and already present at birth.

9 **179.009** Autism Spectrum Disorder Is Characterized By Structural Under-Connectivity in Reward Circuitry

B. Tunc[1], *D. Parker*[1], *R. T. Schultz*[2,3] *and R. Verma*[1], *(1)Center for Biomedical Image Computing and Analytics, University of Pennsylvania, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Departments of Pediatrics and Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: The idea that the reward system dysfunctions play a central role in etiology of autism spectrum disorder (ASD) has gained increased interest over the last decade due to the potential of unifying currently disjoint characteristics of ASD such as social deficits and repetitive behaviors under a single theory. The brain regions associated with the reward circuitry have been repeatedly reported as being affected in ASD. However, the literature still lacks a systematic connectivity analysis of the reward circuitry in ASD, as well as changes in its integration with other circuitries corresponding to distinct neuropsychological mechanisms.
Objectives: The aim of this work is to provide a systematic connectivity analysis of the reward system in ASD, by studying diffusion imaging based structural connectivity changes within the reward circuitry, as well as between the reward circuitry and several other circuitries.
Methods: A dataset of 97 male participants with ADOS/expert clinician confirmed ASD (age: 12.6 2.9 years) and age-matched 75 male TDCs with diffusion tensor imaging (DTI) data were studied. Data processing entailed generating connectivity maps (connectomes) of the entire brain, using a parcellation scheme of 82 cortical and subcortical gray matter regions (*i.e.* nodes of connectome). Network measures encoding connectivity changes at multiple levels including individual regions, clusters of regions, and specific functional subnetworks were calculated and compared between the groups using univariate parametric statistical tests.
Results: Our results suggested significant structural connectivity differences related to subcortical and several cortical regions traditionally associated with the reward system. Almost all regions of the reward circuitry including caudate, putamen, pallidum, hippocampus, accumbens area, amygdala, and orbitofrontal cortex showed local connectivity differences. Connectivity was significantly weaker in the ASD group in the reward circuitry as a whole, and in its integration with circuitries associated with other neuropsychological systems, including those composing the *social brain*.
Conclusions: Regions of reward circuitry were, both individually and as a whole, affected by ASD induced changes. Overall, our findings were in line with the social motivation theory of ASD, which suggests that ASD phenomenology is significantly associated with deficiencies in social reward mechanisms. These results strengthen speculation that developmental trajectories in ASD may be altered in those who develop ASD by early appearing reward deficiencies, such that social interactions are not reinforced typically. This may impact cognitive and social development. If Social motivation deficits precede fully syndrome ontogeny, interventions that boost social motivation, rather than aiming at the improvement of specific social skills, might be the most effective strategy.

10 **179.010** Autism Spectrum Disorder Liability Is Modulated Along a Gender Continuum from the Female to Male Neuroanatomical Brain Phenotype

D. Andrews[1], *M. Gudbrandsen*[1], *A. Marquand*[2,3], *E. Daly*[1], *C. M. Murphy*[1], *S. Baron-Cohen*[4], *M. C. Lai*[4,5,6], *M. V. Lombardo*[4,7], *A. N. Ruigrok*[4], *E. Bullmore*[4,8], *J. Suckling*[4], *S. C. Williams*[2], *M. Craig*[1], *D. G. Murphy*[1] *and C. Ecker*[1], *(1)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Centre for Neuroimaging Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (3)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (4)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (5)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (6)Centre for Addiction and Mental Health, The Hospital for Sick Children, and Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (7)Department of Psychology and Center for Applied Neuroscience, University of Cyprus, Nikosia, Cyprus, (8)Department of Psychiatry, Brain Mapping Unit, University of Cambridge, Cambridge, United Kingdom*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition more commonly observed among males, with an estimated male:female prevalence ratio around 2-5:1 (Fombonne 2005, Lai 2015). Findings of a greater familial etiological load of ASD in females relative to males suggest the existence of male-specific risk, and female-specific protective factors for ASD (Robinson, 2013). However, while the existence of gender-related risk and protective factors for ASD are supported by genetic and demographic studies, little research has been conducted to establish whether having a female or male brain phenotype mediates ASD liability.
Objectives: Here, we aimed to (1) identify neuroanatomical patterns that are characteristic of the male and female brain phenotype, and (2) test the hypothesis that having a male or female brain phenotype represents a risk or protective factor for ASD, respectively.
Methods: 98 right-handed adults with ASD (49 males, 49 females) and 98 matched neurotypical controls (51 males, 47 females) aged 18-42 years were recruited and assessed at the IoPPN, London, and the ARC, Cambridge. A Gaussian Process classifier (GPC) (Rassmussen 2006, Marquand 2010) was initially trained to make probabilistic predictions for each control participant based on binary classes of biological sex using eight surfaced based measures of cortical neuroanatomy (cortical thickness, grey & white matter surface areas, cortical volume, grey:white matter signal intensity ratio, curvature, sulcal depth, and metric distortion). This approach allowed us to derive a probabilistic prediction for each individual based on the binary categories dictated by biological sex, and to represent each brain along a gender continuum with individuals being most confidently classified representing the prototypical male or female brain phenotype. The performance accuracy of each model was estimated using leave-one-out cross validation and tested for significance via permutation of class labels (n=1000). Subsequently, we applied each predictive model to the males and females with ASD in order to estimate probabilistic predictions for individuals with ASD along a gender continuum. ASD liability for each model as a function of neuroanatomical gender phenotype was estimated as the ratio of males (females) with ASD to the total number of males (females) in eight bins along the axis of predictive probabilities of gender.
Results: Across all eight vertex based cortical features, GPC was able to separate male from female controls at accuracies ranging from 68% for metric distortion to 84% for G:W intensity ratio (p<=.001). When predicting individuals with ASD we found that female ASD cases were allocated more frequently to the male category across all eight models (as opposed to the female category), significantly above chance level (p-values ranging from <.001-<.002). When examining the proportion of ASD cases as a function of predictive probability for the male phenotype, we found that increased probabilities for the male brain phenotype were associated with an increased prevalence ratio for ASD within our sample.
Conclusions: Our results support the hypothesis that having a male brain phenotype constitutes greater risk for the development of ASD regardless of biological sex, hence implying that a female brain phenotype may provide a protective effect for ASD.

11 **179.011** Autism and Early Exposure to the Extrauterine Enviroment

ABSTRACT WITHDRAWN

Background: Children born extremely preterm (EPT) have an elevated risk for autism spectrum disorder (ASD). In this condition, MRI studies have suggested volumetric brain abnormalities. We hypothesized that such volumetric changes are present already in the neonatal brain
Objectives: To explore regional grey matter (GM) and white matter (WM) volume differences in EPT infants at termequivalent age (TEA) with a positive screen of ASD and/or a clinical diagnosis of ASD compared to a group of unaffected EPT infants.
Methods: We included 87 children born in Stockholm between January 2004 and March 2007 with a gestational age (GA) of <27 weeks + 0 days. Infants underwent MRI at TEA. 23 children had scores above cut-off on the Social Responsiveness Scale (SRS) and/or a clinical diagnosis of ASD at 6,5 years, and out of them 11 infants had high-quality 3D MRI and no focal lesion. Comparisons were made with 22 EPT infants with a negative ASD screening. Global (atlas-based segmentation) and regional (voxel-based morphometry (VBM)) analyses were applied. Significant clusters at the corrected ($p<0.05$) and uncorrected ($p<0.001$) level are reported for VBM.
Results: Out of 87children, 26% of EPT children either screened positive for ASD and/or had a clinical diagnosis of ASD. The ASD positive group showed significantly smaller total volumes of temporal, occipital, insular and limbic cortices in the global analysis. They also had grey matter reductions, predominantly involving the left parietal and lateral occipital cortices according to the regional analysis. After including birth weight as a covariate only the regional differences remained.
Conclusions: EPT birth resulted in high positive screens for ASD at 6,5 years. Altered brain volumes and different maturational trajectories in regions involving social communication and behavior domains were detectable already in the neonatal period.

12 **179.012** Brain Morphometry of Dimensional Autism: A Twin Study

E. Cauvet[1]*, A. Van't Westeinde*[1]*, K. Mevel*[1,2]*, R. Toro*[3] *and S. Bolte*[4]*, (1)Karolinska Institutet, Stockholm, Sweden, (2)LaPsyDÉ UMR CNRS 8240, Universités Paris Descartes et Caen Normandie - Sorbonne Paris Cité -GIP Cyceron, Paris, France, (3)Institut Pasteur, Paris, France, (4)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden*

Background:
Structural morphology related to Autism Spectrum Disorder (ASD) might give valuable insights into its etiology and contribute to the identification of biomarkers for diagnostic and treatment purposes. However, though many studies do report abnormal brain morphology, the structural imaging literature on ASD has shown inconsistent results. The latter is probably due in part to the small sample sizes but also to the complex interaction between brain structure and age, gender, IQ and phenotypic heterogeneity in ASD (Haar et al., 2014; Lefebvre et al., 2015). Moreover, most previous research used a volume-based approach, which only partly characterizes brain morphology, and being less sensitive to subtle alterations in anatomy (Raznahan et al., 2013). Twin design is one way to overcome some of these issues, but to date there have been few twin-based imaging studies, of which most have used limited sample sizes (Mevel et al., 2014).
Objectives:
Our aim was to investigate the relation between both volume- and surface-based brain morphology and a continuous estimate of autistic traits in a population-based sample enriched of broader phenotypic autism and clinical ASD.
Methods:
T1 weighted anatomical images of 116 subjects aged 8-23 years, both mono- and dizygotic twins, were acquired within the Roots of Autism and ADHD Twin Study Sweden (RATSS) (Bölte et al., 2014). Within twin-pair differences in estimates of lobar volume (FSL, N=116) and gyral volume, surface area and cortical thickness (Freesurfer, N=48) of regions previously implicated in ASD were correlated to within twin-pair differences in total scores on the parent-report Social Responsiveness Scale (SRS). The results from the within twin-pair conditional regression model were compared to a regular linear regression model across all subjects, which is more sensitive to differences in age and gender.
Results:
Higher SRS scores were associated with an increase in white matter volume in the Right Occipital lobe ($z=2.1$, $p=0.04$), and Bilateral Parietal lobes (left: $z=-2.3$, $p=0.02$ and right: $z=-3.4$, $p=<0,001$), using within twin pair differences on volume-based morphometry. Surface-based analysis confirmed these findings: higher SRS scores were related to 1) an increase in gray matter volume and surface areas in the right Lateral Occipital gyrus (respectively $z=2.3$, $p=0.02$ and $z=1.8$, $p=0.066$), and 2) a decrease of gray matter volume and surface areas in the left Inferior Parietal gyrus (respectively $z=-2.4$, $p=0.02$ and $z=-3.8$, $p<0.001$). No differences in cortical thickness were related to SRS score in these regions. Only the associations with the Right Occipital lobe white matter volume were repeated using the linear regression model.
Conclusions:
A higher score on the SRS, indicating increasing autism traits, seems to be related to altered volume and surface area in sensory regions namely Occipital and Parietal, when using a within twin-pair design, but not when using a conventional linear regression model. Crucially, twin models allowed us to detect brain structure alterations related to ASD that are sensitive to differences in age, gender and IQ. Our results further add evidence that alterations in cortical thickness and surface area may independently contribute to changes in brain volume and ASD pathology.

13 **179.013** Cortical Correlates of Gustatory and Olfactory Avoidance in Autism

G. Wallace[1]*, H. S. Popal*[2]*, E. I. White*[2]*, K. Simmons*[3]*, L. Kenworthy*[4] *and A. Martin*[2]*, (1)The George Washington University, Washington, DC, (2)NIMH, Bethesda, MD, (3)Laureate Institute for Brain Research, Tulsa, OK, (4)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Autism spectrum disorder (ASD) has been linked with sensory related atypicalities dating back to seminal descriptions by Leo Kanner and Hans Asperger. This sensory dysfunction is thought to contribute to, if not drive feeding-related problems in ASD. These problems, including food selectivity and food refusal, are considerable mealtime stressors for families and interfere with daily functioning during adolescence and adulthood. Nevertheless, to date, investigations into sensory-related phenomena in ASD have concentrated on vision and audition to the relative exclusion of gustation and olfaction. Moreover, the neural underpinnings of taste and smell remain largely unexplored in ASD. Therefore, in the present study we investigated structural neural correlates of gustatory and olfactory sensory atypicalities in ASD.
Objectives: Examine structural brain correlates of gustatory and olfactory avoidance in ASD.
Methods: 40 adolescent and young adult males with ASD (M age=16.60, SD=2.78; M IQ=113.28, SD=15.08), diagnosed using the Autism Diagnostic Interview, Autism Diagnostic Observation Schedule, and DSM criteria, completed self-ratings of items from the olfactory portion of the Sensory Avoidance quadrant of the Adolescent/Adult Sensory Profile. Each participant also provided a high-resolution 3 Tesla anatomic magnetic resonance imaging scan. The FreeSurfer image analysis suite (version 5.1) was used to derive vertex-level cortical thickness and to complete data analysis.
Results: In the ASD group, increasing gustatory/olfactory avoidance was associated with increasing cortical thickness (cluster corrected *p*s<.05) in several regions, including the primary (insula and frontal operculum) and secondary (portions of the orbitofrontal cortex) gustatory cortex of the right hemisphere and both inferior and medial temporal cortices bilaterally. See Figure 1.
Conclusions: This is the first study to examine neural correlates of gustatory and olfactory avoidance in ASD. Strikingly, self-ratings of these behaviors in ASD were correlated with thickness in distinct cortical regions (e.g., insula/frontal operculum and orbitofrontal cortex) that are crucial to gustatory and olfactory function more broadly. These findings complement existing literature linking these sensory-related behaviors with these brain regions using structural brain imaging in non-ASD populations. For example, one prior study found increased cortical thickness in the orbitofrontal cortices and increased gray matter volume in medial temporal cortices in congenital anosmia (i.e., the loss of smell) (Frasnelli et al., 2013; NeuroImage). Another study found that individual differences in laboratory tests of olfactory function were positively associated with cortical thickness in the insula and orbitofrontal cortices of the right hemisphere in neurotypical adults (Frasnelli et al., 2010; Exp Brain Res). The present study extends this work to ASD, which is characterized by both gustatory and olfactory sensory avoidance. However, it remains unclear whether these brain correlates are the result of a history of these sensory-related avoidant behaviors or their cause. Future work in earlier developmental periods and longitudinal studies are needed to answer this question.

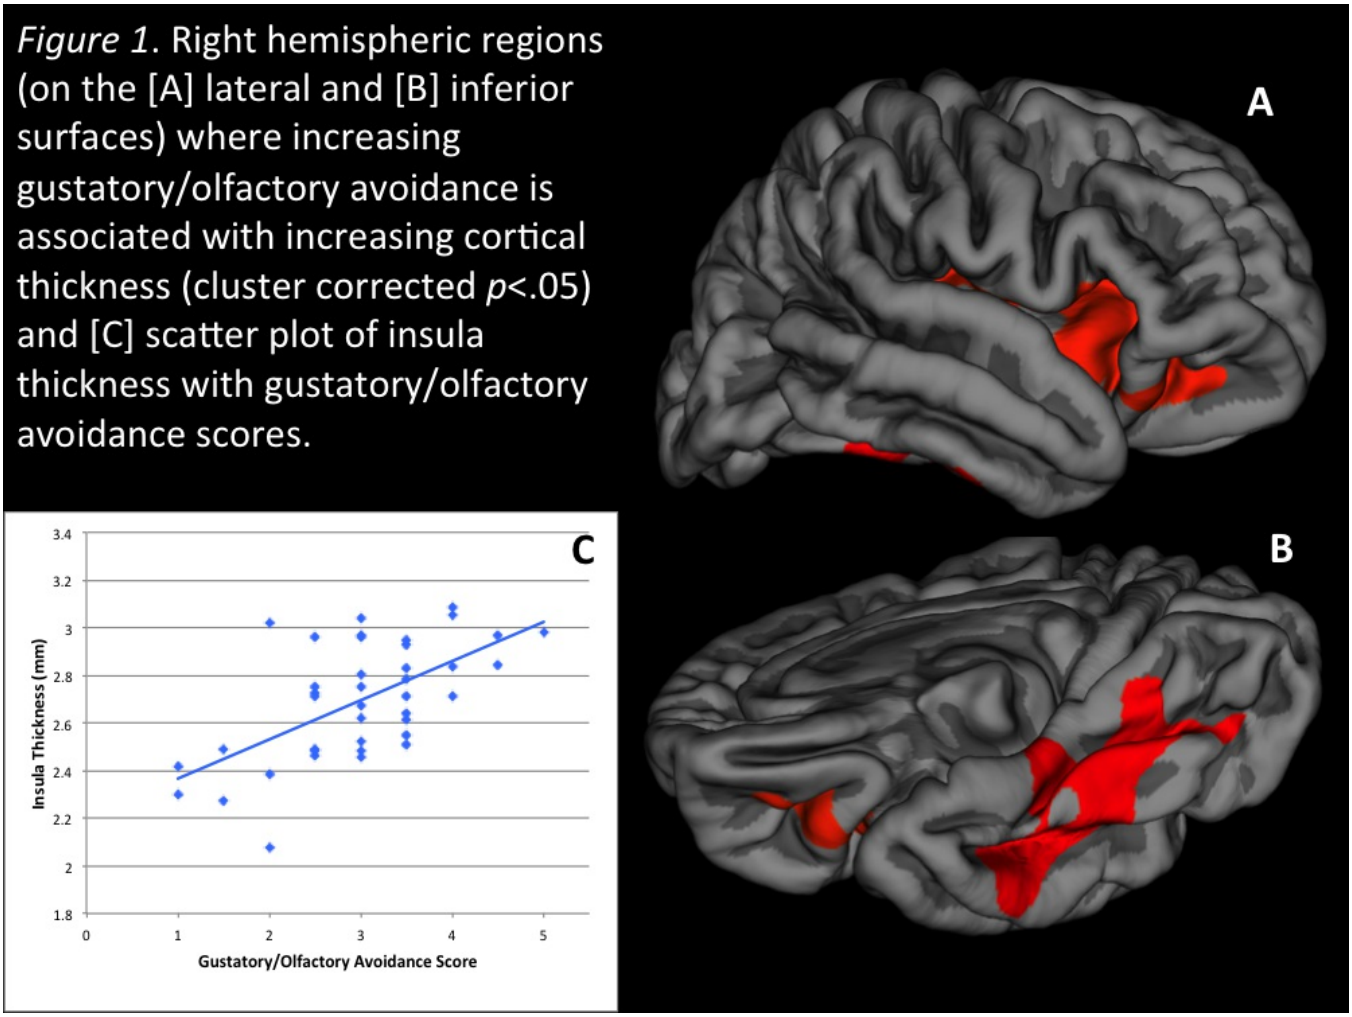

Figure 1. Right hemispheric regions (on the [A] lateral and [B] inferior surfaces) where increasing gustatory/olfactory avoidance is associated with increasing cortical thickness (cluster corrected $p<.05$) and [C] scatter plot of insula thickness with gustatory/olfactory avoidance scores.

14 **179.014** Coupling Between Global and Regional Brain Structural Variation in Autism Is Modulated By Symptom Severity

N. E. Foster[1,2], *M. Sharda*[1], *K. A. R. Doyle-Thomas*[3], *A. Tryfon*[1,2], *E. Anagnostou*[3,4], *A. C. Evans*[2], *L. Zwaigenbaum*[5], *J. D. Lewis*[2], *J. P. Lerch*[6], *K. L. Hyde*[1,2] *and .. NeuroDevNet ASD Imaging Group*[7], *(1)International Laboratory of Brain, Music and Sound Research, University of Montreal, Montreal, QC, Canada, (2)Montreal Neurological Institute, Montreal, QC, Canada, (3)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)University of Toronto, Toronto, ON, Canada, (5)University of Alberta, Edmonton, AB, Canada, (6)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (7)NeuroDevNet, Vancouver, BC, Canada*

Background: Brain imaging has revealed differences between individuals with Autism Spectrum Disorders (ASD) and Typical Development (TD), both in global (e.g., mean cortical thickness; CT) and regional structure. Global differences may reflect genetic or environmental influences acting across the brain in neurodevelopment, whereas local differences presumably reflect region-specific influences. However, global and regional factors in ASD have so far been studied separately, even though they act in concert to affect brain structure.
Objectives: 1) Examine how global CT drives regional CT differently in ASD, and 2) Test whether local uncoupling of CT in ASD is explained by symptom severity.
Methods: Participants were 48 ASD and 50 TD males from the NeuroDevNet project. Groups were age-matched (mean=12.8 years, SD=3.0) and had IQ>70. ASD participants were diagnosed using ADI-R and ADOS. CT was calculated from T1 MR images using CIVET software. Effects of age, IQ, site and brain volume were removed. Coupling between global mean CT and regional CT was assessed at two regional spatial levels: in 58 AAL regions (mean value), and by vertex (20mm smoothing). In both cases, the correlation of each region's CT with global CT was calculated across subjects, separately by group. Group differences in correlation were assessed via Fisher transformation. For the AAL analysis, P values were corrected via false discovery rate. For vertex analysis, clusters were calculated using permutation testing to control familywise error (FWE) rate to P<0.05. Developmental effects were examined by splitting the sample at median age and repeating the analysis in both age cohorts. After identifying regions where global-regional correlation differed between groups, the contribution of each ASD subject to the correlation difference was quantified by factoring out the baseline TD relationship. The resulting residuals represented CT variation in ASD unaccounted for by the baseline global influence. Linear interaction analyses then tested modulation by symptom severity (SRS, ADI-R, ADOS) of the correlation between residual CT and global mean CT.
Results: A strong influence of global CT upon regional structure was evident in the global-regional CT correlations in both groups. Regional correlations were generally diminished in ASD vs TD. After FWE correction, a correlation decrease was found in right inferior frontal gyrus (IFG) in both AAL and vertex analyses. Younger and older participants showed similar effects. Interaction analyses showed that global-regional coupling in ASD was modulated by symptom severity (SRS) in the right IFG.
Conclusions: Variability in regional cortical structure is strongly driven by a global component in both TD and ASD, but there is a greater degree of variance unexplained by global CT in ASD. The more localized nature of structural variability in ASD is consistent with the idea that brain differences in ASD result from a complex interaction of genetic factors. These results are important from a functional perspective because of IFG's role in social cognition and theory of mind, core features of ASD. This work offers a new approach to examine brain structural variability in special populations, and highlights the importance of accounting for global and local factors in brain structure.

15 **179.015** Diffusivity Measures Detect Changes in Cellular Organisation in the Cortex Associated with Elevated Glutamate in ASD: A 7T MRS and Ex Vivo DTI Study

S. A. Chance[1], *M. Torso*[1], *R. McKavanagh*[1], *K. Miller*[1] *and M. Jenkinson*[2], *(1)University of Oxford, Oxford, United Kingdom, (2)NDCN (FMRIB), University of Oxford, Oxford, United Kingdom*

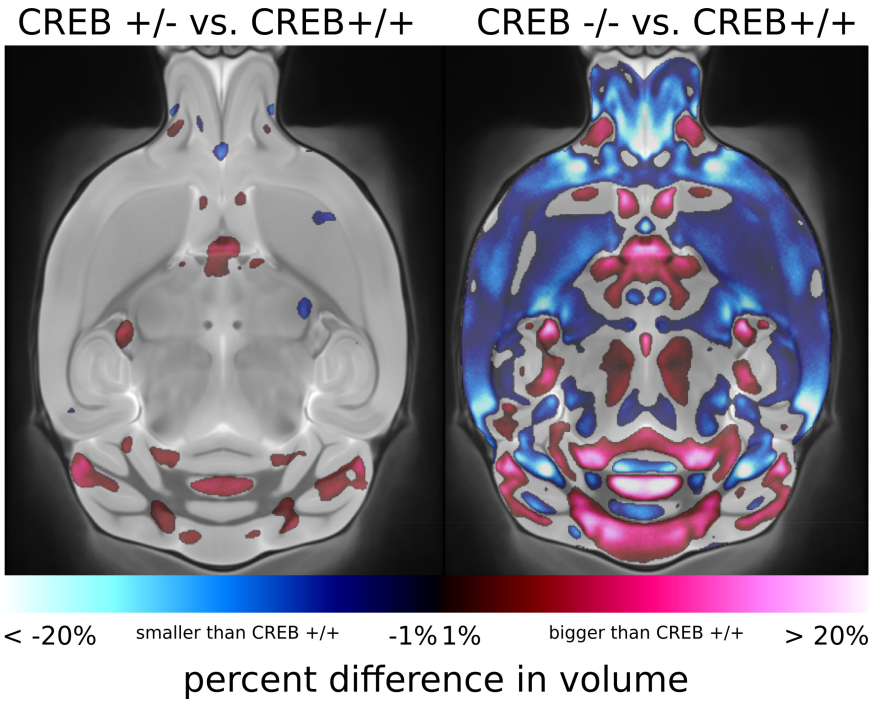
Background:
Minicolumns of cells are altered in cortical regions in ASD. Minicolumns have been found to be wider in primary and associative cortex. New MR imaging measurements derived from analysis of high resolution DTI of cerebral cortex show promise as an index of minicolumn alterations.
Objectives:
The present study sought to confirm these DTI measures as potential biomarkers for ASD by investigating: (i) the correspondence between histology and DTI in selected cortical regions and in the arcuate fasciculus that connects them; (ii) their diagnostic sensitivity for detection of ASD in vivo.
Methods:
2 experiments were conducted to confirm the utility of these biomarkers. The newly developed 'CHIPS' (Cortical High-Intensity Profile Segmentation) software was used to calculate several unique measures by comparing diffusivity data with the predicted minicolumn vertical axis derived from structural MRI of cortical grey matter.
i) **Post-mortem** MRI was conducted to validate the DTI signal as an index of minicolumn alteration by comparison of histological measurements from the identical brain regions. The 3T MRI acquisition protocol on formalin-fixed tissue included: Modified spin-echo sequence with 3D segmented-EPI, and Structural 3D balanced steady state free precession (BSSFP) sequence. Data processing used the FMRIB software library (FSL). ROIs were Brodmann areas 9, 40, 41, 42 . Fiber tracts were estimated via

Bayesian Estimation of Diffusion Parameters (Bedpostx). The arcuate fasciculus was obtained and thresholded. The mean FA, MD, Drad and Dax were extracted from the tracts.
ii) **In vivo** 7T DTI and magnetic resonance spectroscopy (MRS) were conducted to investigate the relationship of the DTI signal to neurochemical markers of elevated excitation in ASD. A sample of 11 ASD and 10 TD individuals were MRI scanned and MRS was used to measure brain metabolites in primary visual and medial prefrontal cortex. Data were collected with the semi-LASER sequence and the LCModel. A VBM analysis was also performed on these structural scans.
Results:
i) The post-mortem DTI confirmed the model's predictions indicating a clear correlation between the mean diffusivity and minicolumn width and significant differences in the components of the principal diffusion direction between TD and ASD in brain regions with wider minicolumns.
ii) The high resolution in vivo DTI and MRS found significantly elevated glutamate in ASD and correlations between increased prefrontal glutamate and a diffusion marker of wider minicolumns.
The inferior frontal gyrus also had significantly reduced grey matter density in ASD compared to TD individuals. The relationship between glutamate and the diffusion signal in this region was different from other brain regions and contrasted with TD controls.
Conclusions:
Diffusivity parameters in the cerebral cortex correspond to variation in the minicolumnar organisation of neurons. Minicolumns are more widely spaced in several cortical regions in ASD and this can be detected using novel diffusivity measures.
There is a link between elevated excitation (glutamate level) and these microstructural changes in ASD, consistent with the excitation/inhibition imbalance hypothesis. Greater excitation appears to be associated with wider minicolumns in ASD which may have a toxic effect causing reduced grey matter in some regions.

16 **179.016** Disruption of Creb-Dependent Transcription Alters Brain Anatomy

***D. A. Vousden**, M. C. van Eede, L. Spencer Noakes, B. J. Nieman and J. P. Lerch, Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada*

Background: In the nervous system, many signaling cascades converge upon and activate the CREB family of transcription factors. Subsequent CREB-dependent gene expression has been implicated in many complex processes, including cell growth/survival, synaptic plasticity, and memory formation. Mutations of genes in the CREB signaling pathway are associated with neurodevelopmental disorders, including Rubinstein-Taybi syndrome, Coffin-Lowry syndrome, and other "Rasopathies".
Objectives: To use whole-brain MRI to characterize whether loss of CREB affects mouse brain anatomy, and whether these effects depend on CREB gene dosage.
Methods: We used male and female mice with targeted deletions of two CREB isoforms (CREBαδ mutants). All 3 genotypes (CREB+/+, CREB+/-, and CREB-/-, n=12-16/genotype/sex, total N=82) were used. At 2-4 months of age, mice were perfusion-fixed for high-resolution (40 µm isotropic) ex-vivo MRI. Automated algorithms were used to align the images and compute the volumes of 62 segmented structures for each brain. The Jacobian determinant of the deformation field was used to measure expansion/contraction at each voxel. For each structure or voxel, ANOVAs were performed to determine whether that structure/voxel volume differed by genotype. Gene dosage effects were modeled by treating genotype as an ordered factor and testing for linear versus quadratic genotype effects. Multiple comparisons were controlled using a False Discovery Rate of 5%.
Results: Total brain volume was reduced by 2.5% in CREB-/- mice versus CREB+/+ mice ($p<0.001$) but did not differ significantly between CREB+/- and CREB+/+ mice. The loss of brain volume in CREB-/- mice was driven by a significant decrease in volume throughout the cerebral cortex, olfactory bulbs, basal ganglia, amygdala, hippocampus, and major white matter tracts, including the corpus callosum and anterior commissure. These areas remained significantly smaller in CREB-/- mice versus CREB+/+ mice even after normalizing for brain volume. In general, the absolute volume of these areas did not differ between CREB+/+ and CREB+/- mice. Notable exceptions include some white matter tracts including the lateral olfactory tract and internal capsule. As in CREB-/- mice, these were significantly smaller in CREB+/- versus CREB+/+ animals. Intriguingly, the arbor vita and cerebellum were significantly larger in CREB+/- versus CREB+/+ mice, and were larger still in CREB-/- animals, indicating a gene-dose effect.
Conclusions: Loss of CREB produces a substantial volume loss throughout the brain, including cortical and subcortical areas, and white matter tracts. Even after accounting for differences in total brain volume, most of these regions were smaller in CREB-/- versus CREB+/+ mice. This suggests these areas either fail to develop fully or undergo degeneration. CREB+/- mice were overall phenotypically similar to CREB+/+ mice. The exceptions included white matter tracts, suggesting they may be more sensitive to disruption of CREB-dependent transcription. Overall, disrupting CREB has widespread effects on brain anatomy which may underlie the intellectual impairments observed in related neurodevelopmental disorders.



Effect of CREB genotype on brain anatomy as assessed by MRI. The percent difference in volume between CREB +/- (*left*) or CREB -/- (*right*) and wildtype CREB +/+ mice was computed at each voxel. Then ANOVAs and t-tests were performed to assess the effect of genotype on the volume of each voxel. Multiple comparisons were accounted for using the false discovery rate (FDR). Transverse brain slices depict areas where there was a significant (5% FDR) main effect of genotype and a significant difference in volume between that genotype and the CREB +/+ mice. Increases in volume compared to CREB +/+ mice are displayed in red, and decreases are displayed in blue.

17 **179.017** Dysgenesis of the Corpus Callosum As Evidence of Developmental Defects of Long Distance Connectivity in Autism

***J. Wegiel**[1], W. Kaczmarski[2], T. Wisniewski[3], W. T. Brown[4], K. K. Chadman[5], E. London[6], K. Nowicki[3], I. Kuchna[6], S. Y. Ma[3] and J. Wegiel[5], (1)Developmental Neurobiology, New York State IBR, Staten Island, NY, (2)Developmental Neurobiology, New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (3)New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (4)Human Genetics, Institute for Basic Research in DD, Staten Island, NY, (5)Developmental Neurobiology, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (6)NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY*

Background: The corpus callosum (CC) is the largest white matter tract containing 138 to 195 million axons (Riise 2006, Tomasch 1954) that connect homologous brain cortical areas. Neuroimaging studies reveal a reduced size of the CC in individuals diagnosed with autism (Minshew 2007, Frazier 2009) whereas postmortem studies of control subjects reveal a correlation between the area of CC and the number of axons (Riise and Pakkenberg 2006). Despite strong neuroimaging evidence of CC pathology, the microscopic characteristics of axonal CC abnormalities in autism are lacking.
Objectives: The aim of this postmortem study of the brain of autistic subjects is (a) to characterize the type and topography of structural CC defects and (b) expand the concept of CC pathology by detection of markers of focal CC midline axonal misguidance.
Methods: The brain hemispheres used in this study were preserved for several parallel studies designated to detect the global pattern of developmental abnormalities in autism. Brain hemispheres of 10 autistic individuals from 4 to 56 years old and 10 age matched control subjects were fixed with formalin, dehydrated, embedded in celloidin, and cut into serial 200-µm thick sections that were stained with cresyl violet. Every 6th section was used to establish the midsaggital area of the corpus callosum. Postmortem MRI and serial coronal sections were used to characterize CC developmental abnormalities. Segmentation of the CC applied in this study was based on diffusion tensor

imaging and fiber tractography distinguishing five CC regions reflecting the position of cortical neurons contributing to CC connectivity (Hofer 2006).
Results: This postmortem study revealed (a) more CC shape differences, (b) significant reductions of the midline CC area ($p<0.05$) associated with significant area deficits in regions II, IV and V ($p<0.05$), and (c) partial agenesis of the corpus callosum in autistic subjects. A consistent feature in three cases was the lack of axonal connections in region IV (primary sensory cortical connections), lack in one case and a severe (50% and 66%) deficit in the other two cases of axonal connections in region III (primary motor cortex connections). In addition in an 11 year old female, a 60% deficit was detected in region I (prefrontal cortex projections) and a 42% deficit in region V (connections of parietal, temporal and occipital cortex). CC dysplasia detected in autistic subjects, a several millimeter-wide gap between truncated arms of the left and right corpus callosum, appears to be a marker of axonal misguidance in the CC midline. Studies of animal models and human fetal brain suggest that the axonal misguidance detected in examined autistic subjects reflects a developmental failure of guidepost cells including glial wedge, indusium griseum, midline zipper glia, and subcallosal sling cells (Richards 2004, Sanchez-Camacho 2011).
Conclusions: Regional reduction of CC area and midline CC dysgenesis reflect deficits of axonal interhemispheric connections and defects of long distance connectivity in autism. Our study demonstrates the presence of cortical neurons interhemispheric connectivity deficit in the majority of postmortem examined autistic subjects and focal CC midline axonal misguidance in 30% of cases.

18 **179.018** Electron Microscopic Analysis of Myelin Thickness and Oligodendrocytes in Autism

T. A. Avino[1] *and C. M. Schumann*[2]*, (1)University of California at Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA*

Background: Structural and functional brain imaging studies support the prevailing hypothesis that autism involves disruptions to cortical network connectivity. Specifically, diffusion tensor imaging (DTI) studies of white matter in autism have reported reductions to the integrity of fiber tracts throughout the cerebrum and combined functional imaging studies demonstrate reduced cortical synchrony among brain areas. One potential explanation for this deficient communication in autism is alterations to the myelin sheathing these axons, which has been reported in the frontal lobe (Zikopoulos & Barbas, 2010). In the present study, we further examine these ultrastructural changes to the myelination of axons within the temporal lobe white matter in autism and explore the characteristics of oligodendrocytes from the same subjects as a potential mediator of these abnormal myelin findings. Our results have implications for the observed physiological disruptions in the disorder as well as informing how these ultrastructural changes may occur.
Objectives: The goal of the present study was to assess the degree of myelination of axons occupying the temporal lobe white matter in individuals with autism relative to their age-matched typically developing counterparts. Furthermore, we examine these myelin thickness findings with regard to oligodendrocyte characteristics, such as their overall number, in the same subjects.
Methods: Data regarding the overall number of oligodendrocytes were acquired stereologically using an optical fractionator method from the amygdala in frozen 50µm sections of the temporal lobe (Morgan et al., 2015). From adjacent 50µm sections, white matter dissections were made from the superior temporal gyrus and fusiform gyrus within 4mm of the gray-white matter boundary and prepared for electron microscopic processing. Myelinated axons of varying sizes were randomly selected for myelin thickness measures (g-ratio) and imaged at 8,400x magnification.
Results: For all subjects, data from the g-ratio measures indicates proportionally thinner myelin with increasing axon diameter, which is consistent with previous reports. However, individuals with autism demonstrate thinner myelin in both cortical regions and across all axon sizes compared to their age-matched typically developing counterparts. Furthermore, these results show an age x diagnosis interaction wherein ASD subjects regress towards thinner myelin with increasing age whereas the typically developing subjects show a slow and gradual thickening of myelin with age. Lastly, correlation analysis reveals a strong positive relationship between the number of oligodendrocytes and myelin thickness in both ASD and typically developing subjects ($r = .85$, $p < .01$).
Conclusions: Our data demonstrate a reduction of myelin thickness in autism affecting at least 2 cortical locations across all axon size classes potentially providing a substrate for which altered cortical communication and/or increased diffusivity is occurring in the disorder. These data are consistent with similar reports of alterations to myelinated axons in areas of the frontal lobe in autism (Zikopolous & Barbas, 2010) and also demonstrate abnormal myelination patterns with increasing age in autism. Our data also show a strong relationship between the number of oligodendrocytes and myelin thickness in both subject groups, potentially providing a mechanism for which hypomyelination and/or altered myelinated axon density is occurring in autism.

19 **179.019** Finding Individual Developmental Brain Circuitry and Brain-Behavior Associations in Autism By a New Multivariate Crossmatch Method

N. Lange[1]*, D. C. Dean*[2]*, B. G. Travers*[3]*, B. A. Zielinski*[4]*, A. L. Alexander*[2] *and J. E. Lainhart*[2]*, (1)Psychiatry, Harvard Medical School, Boston, MA, (2)Waisman Center, University of Wisconsin-Madison, Madison, WI, (3)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI, (4)Pediatrics and Neurology, University of Utah, Salt Lake City, UT*

Background:
There is an ongoing worldwide search for clinically meaningful associations between an individual's cognitive-behavioral functioning and brain structure and function in autism. For this pursuit, we developed a new case-by-case method, being a longitudinal extension of an existing crossmatch method, to compare one individual's longitudinal Mahalanobis distances from another's based on any type and number of individual brain and/or other measurements.
Objectives: To employ the new method to identify individual associations between circuitry network distances and scores on ADOS, SRS, and VABSII Receptive and Expressive Language assessments, if any.
Methods: Our sample consisted of repeated and co-temporal brain image measurements and cognitive-behavioral assessments contributed by 92 male participants with autism ages 3-35 years followed for 12 years, and 56 age-matched typically developing male participants also followed for 12 years. Study design and scanner settings have been described elsewhere. Based on current literature on the corpus callosum (CC) and arcuate fasciculus (AF) in autism, we examined means and growth rates of fractional anisotropy (FA) in the CC genu, CC body, CC splenium, right AF, left AF, right AF longitudinal segment, and left AF longitudinal segment in order to find the best DTI brain measurements that separate the participants with autism from typically developing participants, if any.
Results: The new multivariate method found that the best subset of the regional FA measures in the corpus callosum and arcuate fasciculus included the body, splenium, left AF, right AF, right AF longitudinal segment, left AF longitudinal segment, and the growth rate of the genu (distribution separation p-value < 0.000000005). Two other measurement subsets performed equally well, having identical distribution separation p-value. These included, separately and in addition, the genu, splenium, left AF longitudinal segment, and the growth rates of the body, splenium, left AF, and the left AF longitudinal segment. The single measurement included in all three measurement subsets was the growth rate of the genu. These aggregated FA means and growth rates showed significant associations with the selected cognitive-behavioral measures.
Conclusions: Developmental circuitry differences in autism, as measured in the corpus callosum and arcuate fasciculus, are complex. Our findings suggest that the growth rates of the brain circuitry structures examined may play a more salient role than the mean sizes of regional DTI coefficients in distinguishing differences in the brains and cognitive-behaviors of individuals with autism.

20 **179.020** Gray Matter Volume Deficit and Neuropsychological Performance in First Degree Relatives of Children with Autism Spectrum Disorder

S. Srinath*, J. V. Kommu, G. Venkatasubramanian, K. Kumar, S. C. Girimaji, S. P. Seshadri, C. Prasad, S. M. Kaku and T. Kandavel, National Institute of Mental Health and Neurosciences, Bangalore, India*

Background:
Neurobiological studies evaluating for potential endophenotypic markers in First Degree Relatives (FDRs) of children with Autism Spectrum Disorder (ASD) are sparse in India because a) very few centers in the country are involved in research of this kind, b) challenges of obtaining consent from participating parents. Search for endophenotypic markers in ASD, a known to be a heritable disorder, is a logical way forward. Among several neurocognitive parameters, facial emotion recognition deficit is one such marker. However, concurrent assessment involving both neuropsychological tests and gray matter volumes in FDRs of ASD has received little attention.
Objectives:
To study the gray matter volume and the neuropsychological profile of FDRs of children with ASD
Methods:
36 parent/s of 19 children with ASD and 11 matched controls were recruited for the study in a university teaching hospital in southern India. The index children aged 30 months to 14 years were diagnosed by experienced child psychiatrists as per DSM IV guidelines. The index children were rated on Childhood Autism Rating Scale (CARS). Parents were assessed using a) MINI-Plus, b) neuropsychological assessment that comprised tests from the NIMHANS Neuropsychological battery, subtests of Wechsler's memory scale III and the Embedded figure test, c) Magnetic Resonance Imaging (3-Tesla):T1-weighted images were processed using SPM (http://www.fil.ion.ucl.ac.uk/spm), implemented through the Voxel Based Morphometry (VBM) Toolbox 8. Statistical parametric maps were examined for group differences as well as correlation between Gray Matter Volumes (GMV) of FDRs and CARS scores of the index child / neuropsychological test scores of FDRs.
Results:
There was a significant negative correlation between the CARS score of the index child and left superior parietal lobule [T=5.76] and right insula [T=5.58] GMV of the FDRs (N=36). The FDRs had significantly deficient volume of right fusiform gyrus in comparison with healthy controls [T=3.45]. FDRs (N=31) demonstrated a significant negative correlation between a) the embedded figure test score and bilateral superior temporal gyri [Left: T=5.71; Right: T=5.31], b) finger-tapping test score and left inferior frontal gyrus [T=5.89] c) Controlled Word Association Task score and the left middle frontal gyrus [N=29; T=4.22]. All these findings were significant at p (uncorrected) ≤ 0.001 and small volume correction ($p<0.05$).
Conclusions:

Certain brain regions implicated in the study findings are relevant for neurocognitive aberrations seen in ASD, namely, fusiform gyrus in face processing and fronto-temporal network in working memory. Significant negative correlation between neuropsychological test performance and frontal/temporal brain regions in this study adds support to what is already stated in literature. The findings of the Superior Parietal Lobule (which has been implicated in mediating motor learning and repetitive behavior) and the Insula (implicated in emotion processing) having a negative correlation with the CARS score needs further confirmation. Larger sample of FDRs, improved methods and addition of oculomotor tests of sensorimotor responses and diffusion tensor imaging studies may give us more robust support for these findings and potentially reveal additional endophenotypic markers for ASD.

21 **179.021** Increased Sensorimotor U-Fiber Connections in Autism: Localization and Association with Symptom Severity

C. Buckless[1], *E. Bordbar*[1,2], *S. H. Mostofsky*[2] *and D. Crocetti*[1], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins School of Medicine, Baltimore, MD*

Background: Autism spectrum disorder (ASD) is commonly associated with deficits with motor skills and tactile sensory processing. Multiple DTI studies have revealed abnormalities in the white matter connectivity in individuals with ASD, including in fronto-parietal regions crucial for motor and sensory control; however, U-fibers connecting primary somatosensory cortex and the primary motor cortex ("sensorimotor U-fibers") have not been examined in detail. Mapping sensorimotor U-fibers to clusters associated with three functionally distinct regions: foot, hand, face and mouth, could help characterizing microstructure in underlying white matter tracts in children with ASD.
Objectives: To examine the sensorimotor U-fibers in order to reveal differences between children with ASD and typically developing (TD) white matter fiber integrity and symptom severity.
Methods: Diffusion weighted imaging was acquired on 20 boys with ASD and 20 typically developing (TD) boys aged 8-12 years. Groups were balanced for age and IQ. All children were right handed. MRIStudio was used to perform deterministic fiber tracking in the left sensorimotor cortex. The fibers were further segmented into face/mouth, foot, and hand regions using spherical fMRI-based seeds. Total number of streamlines (white matter connections), Fractional Anisotropy (FA) and mean diffusivity (MD), FA were calculated for the whole sensorimotor fiber map and for each region separately. ANOVA was used to examine the effect of diagnosis on number of streamlines, FA, and MD. Pearson's correlations were used to examine associations between the number of streamlines, FA, and MD and symptom severity. Symptom severity was assessed using the Autism Diagnostic Observation Schedule (ADOS).
Results: Preliminary analysis suggests boys with ASD showed increased total number of sensorimotor U-fiber streamlines (p=0.031); this appeared to be particularly localized to the foot (p=0.032). Pearson's correlation further revealed a positive correlation between the increased number of streamlines and increased symptom severity (ADOS total score; r=0.50, p=0.025). Interestingly, while we observed an association between increasing age and total number of streamlines for face/mouth (r=0.554, p=0.011), foot (r=0.457, p=0.043), and for all regions collapsed (r=0.443, p=0.051) in TD boys, this was not observed in boys with ASD. MD was significantly higher in ASD boys for foot (p=0.013) and hand region (p=0.042) sensorimotor U-fibers, but not for face/mouth. FA was not significantly different in any of the three regions or the overall fiber map.
Conclusions: Consistent with prior findings suggesting disorganized overgrowth of early developing white matter connections, we found children with ASD show increased volume (number of streamlines) and decreased organization of sensorimotor U-fiber connections. The findings were localized to foot and hand regions, and there was a positive association with symptom severity, such that increase volume was associated with increased symptom severity. In addition, children with ASD showed an anomalous association of sensorimotor U-fiber volume with age: whereas the number of streamlines increased with age in the TD children, this relationship was not seen in children with ASD.

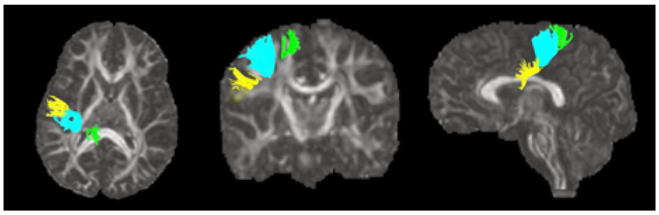


Figure 1: 3D rendering of sensorimotor U-fibers corresponding to foot (green), hand (blue) and face/mouth (yellow) regions.

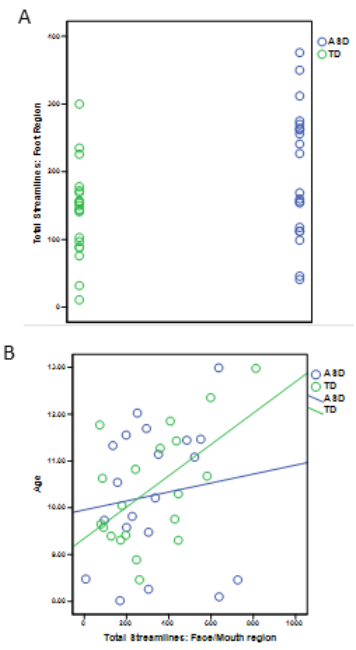

Figure 2: (A) effect of diagnosis in which total number of streamlines in foot region is significantly increased in ASD (p=0.032). (B) the positive association between age and total streamlines in face/mouth region (r=-.554, p=0.011). (C) the positive association between symptom severity demonstrated with ADOS total score and total streamlines collapsed across regions (r=0.50, p=0.025)

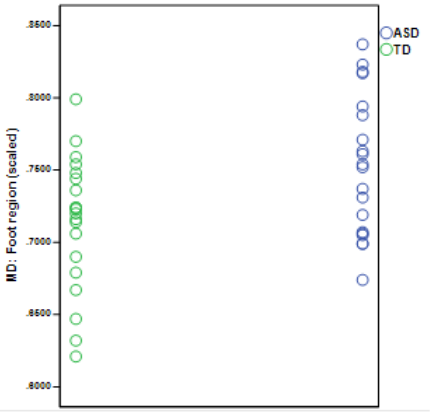

Figure 3: Effect of diagnosis is shown in which MD in foot region is significantly increased in ASD (p=0.013).

22 **179.022** Longitudinal Microstructure of the Thalamus and Anterior Limb of the Internal Capsule in Individuals with Autism Spectrum Disorder

K. McLaughlin[1], *B. G. Travers*[2], *D. C. Dean*[1], *D. Tromp*[1], *N. Adluru*[1], *D. Destiche*[1], *D. P. Samsin*[1], *M. D. Prigge*[3], *A. Froehlich*[4], *E. D. Bigler*[5], *N. Lange*[6], *A. L. Alexander*[1] *and J. E. Lainhart*[1], *(1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI, (3)Pediatrics, University of Utah, Salt Lake City, UT, (4)University of Utah, Salt Lake City, UT, (5)Psychology/Neuroscience Center, Brigham Young University, Provo, UT, (6)McLean Hospital, Cambridge, MA*

Background: The thalamus is a highly connected brain area, and white matter connections related to the thalamus have been shown to be atypical in adolescents with autism spectrum disorder (ASD) and related to motor impairments in this population (Nair et al., 2013). What is not known is how thalamic white and gray matter microstructure develops and changes from childhood through adulthood in ASD. In other populations, gray matter microstructure has been shown to be a sensitive marker of age-related changes (Manna et al., 2015). Given that the thalamus is a key sensorimotor relay area, it is essential to examine microstructural changes in thalamic gray and white matter and surrounding white matter tracts as a function of age and motor ability in ASD.
Objectives: (1) To compare the longitudinal development of white and gray matter microstructure of the bilateral thalamus and the anterior limb of the internal capsule (ALIC)

between the ASD and typically developing groups. (2) To examine if microstructure in these areas are related to finger tapping speed.
Methods: Fifty-six males with typical development and 100 males with ASD (ages 3.3 to 41 years old) underwent longitudinal DTI scanning on Siemens 3T scanner at four points across a 10-year period of time (DW, single-shot, spin-echo EPI, b=1000, 12 non-collinear directions, 4 averages). At the time of each scan, participants completed a neuropsychological battery of tasks, including finger tapping speed. Groups were matched on age (p= .46). Anatomical regions of interest were defined, including the left and right thalamus and left and right ALIC, a white matter tract connecting thalamus to frontal cortices. Linear mixed-effects analyses examined age-related changes in thalamic microstructure as a function of group, accounting for repeated measures over time. For aim 2, linear mixed-effects analyses examined finger tapping speed changes as a function of thalamic microstructure and age.
Results: In the ALIC, the group with ASD had significantly lower fractional anisotropy (FA) and higher radial diffusivity (RD) (p < .05). However, developmental trajectories in the ASD and typically developing groups did not differ. In the thalamus, the group with ASD had significantly different developmental trajectories from the group with typical development in FA, RD, and mean diffusivity (MD) (all p's < .02) but not axial diffusivity. After accounting for age, the thalamus predicted finger tapping speed (p = .009), but the anterior limb of the internal capsule did not (p > .28).
Conclusions: DTI studies in ASD have traditionally focused on white matter tracts. However, DTI in gray matter has been used to examine aging and learning-related brain changes (Sagi et al., 2012) in non-ASD populations. In applying DTI to the thalamus and ALIC, we found that the microstructure of the thalamus demonstrated a different pattern of results than the microstructure of the ALIC. Specifically, the thalamic metrics had distinct developmental trajectories in ASD compared to the ALIC metrics. Further, the thalamic microstructure related to finger tapping speed, whereas the ALIC microstructure did not.

23 **179.023** Longitudinal Trajectories of Large-Scale Brain Network Architecture in Autism

B. A. Zielinski[1], *M. D. Prigge*[2], *M. White*[2], *D. C. Dean*[3], *B. G. Travers*[4], *A. L. Alexander*[3], *N. Lange*[5], *E. D. Bigler*[6] *and J. E. Lainhart*[3], *(1)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (2)Pediatrics, University of Utah, Salt Lake City, UT, (3)Waisman Center, University of Wisconsin-Madison, Madison, WI, (4)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI, (5)McLean Hospital, Cambridge, MA, (6)Psychology/Neuroscience Center, Brigham Young University, Provo, UT*

Background:
Background: Autism spectrum disorders (ASD) comprise complex neurological conditions characterized by childhood onset of dysfunction in multiple cognitive domains. Accumulating evidence suggests that autism is a network-based disease, and that abnormalities in brain network structure underlie the abnormal brain function at the core of the disorder[1]. However, developmental timing and topology of brain network development in autism remains unclear. Here we utilize longitudinal structural MRI data to evaluate developmental trajectories of large-scale brain networks in autism.
Objectives: Using an emerging technique known as structural covariance MRI (scMRI)[2], in tandem with correlated cortical thickness change, this study sought to characterize autism-related longitudinal growth trajectories of network-level brain architecture. Specifically, we sought to determine whether specific developmental abnormalities in large-scale brain network organization are associated with autism, and whether network trajectories and correlated inter-regional change are associated with behavioral measures.
Methods: We used scMRI and cortical thickness correlation (MACACC)[3] to determine longitudinal trajectories of large-scale brain networks in autism. Using scMRI, we first identified canonical large-scale 'structural covariance networks' (SCNs) strongly implicated in autism, namely the socioemotional salience network (SN), the speech network, and the default mode network (DMN). Three hundred and forty-five MRI scans were examined from 97 males with autism (mean age = 16.8 years; range 3–36 years) and 60 age-matched males with typical development (mean age = 18 years; range 4–39 years), with an average of 2.2 scans and interscan interval of 2.6 years. FreeSurfer was used to parcellate the cortex into 34 regions of interest per hemisphere and to calculate mean cortical thickness for each region using methods reported previously[4]. Partial correlation (controlling for age at date of scan) was used to characterize region-wise relationships in cortical thickness change across time using scMRI-derived network hubs as reference regions. We then determined patterns of regional change that correlated with a broad array of behavioral scores.
Results: Region-based cortical thickness correlation revealed specific perturbations in longitudinal brain network architecture within distinct SCNs, consistent with phenotypic manifestations of autism. Thickness correlation maps in controls were consistent with canonical SCN topologies[2]. Extent and topology of the salience network (SN), involved in social- emotional regulation of environmental stimuli, demonstrated weaker average correlation in autism, corroborating earlier findings[1]. The speech network in ASD lacked right temporal regions that were highly correlated with left pars opercularis in the TDC group. The DMN in ASD showed stronger correlations posteriorly and weaker frontal correlations, which were stable across time. Behavioral data also demonstrated distinct differences between ASD and TDC. For example, thickness of the left pars opercularis was negatively correlated with social responsiveness scale (SRS) score in TDC, whereas right pars opercularis was positively correlated with (SRS) in ASD.
Conclusions: Abnormal longitudinal trajectories of large-scale brain network structure characterize autism, and these abnormalities are consistent with phenotype. Moreover, specific patterns of structural coherence in ASD are correlated with behavioral measures. Our findings are consistent with a network vulnerability model of autism, and provide a plausible approach to MRI-based subphenotyping.

24 **179.024** Longitudinal, Voxel-Based Analysis of White Matter Contributions to Processing Speed in Individuals with Autism Spectrum Disorder

B. G. Travers[1], *D. C. Dean*[2], *D. Tromp*[2], *N. Adluru*[2], *D. Destiche*[2], *B. A. Zielinski*[3], *M. D. Prigge*[4], *A. Froehlich*[5], *J. S. Anderson*[5], *P. T. Fletcher*[5], *E. D. Bigler*[6], *N. Lange*[7], *A. L. Alexander*[2] *and J. E. Lainhart*[2], *(1)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI, (2)Waisman Center, University of Wisconsin-Madison, Madison, WI, (3)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (4)Pediatrics, University of Utah, Salt Lake City, UT, (5)University of Utah, Salt Lake City, UT, (6)Psychology/Neuroscience Center, Brigham Young University, Provo, UT, (7)McLean Hospital, Cambridge, MA*

Background: Slowed processing speed has been commonly reported in autism spectrum disorder (ASD) and has major implications for social and cognitive functioning. A recent longitudinal investigation found that processing speed was substantially slower across the life span in individuals with ASD compared to individuals with typical development, and processing speed was correlated with whole-brain fractional anisotropy (a diffusion tensor imaging measure of circuit integrity) (Travers et al., 2014). However, until recently, it has not been possible to examine which white matter tracts within the whole brain are longitudinally related to processing speed in ASD and in typical development. Given that processing speed is a difficulty for many people with ASD, understanding the specific white matter tracts that underlie processing speed difficulties is essential.
Objectives: The objective of this study is to use a voxel-based, longitudinal approach to examine the white matter tracts in the brain that are related to processing speed in individuals with autism and individuals with typical development.
Methods: Fifty-one males with typical development and 70 males with ASD (ages 6.4 to 40.6 years old) underwent longitudinal processing speed assessments and longitudinal DTI scanning on Siemens 3T scanner at four points across a 10-year period of time (DW, single-shot, spin-echo EPI, b=1000, 12 non-collinear directions, 4 averages). Groups were matched on age (p = .48). Voxel-based, linear mixed-effects analyses examined fractional anisotropy as a function of group and processing speed, controlling for age, head motion, and a head coil replacement (between Times 1 and 2).
Results: In both the ASD and typically developing groups, the results suggested that processing speed was significantly related with a number of white matter areas, including the bilateral posterior medial parietal cortex, the tip of the anterior genu/cingulate, left temporal parietal junction, and the right prefrontal white matter (p< .05, FDR corrected). However, a group x processing speed interaction demonstrated that the group with ASD had weaker correlations between these areas and processing speed than the group with typical development (See Figure 1, p< .05, FDR corrected).
Conclusions: We found that processing speed in both groups was related to the white matter microstructure of areas previously reported to be implicated in processing speed (i.e., the bilateral posterior medial parietal cortices, the tip of the genu of the corpus callosum/anterior cingulate, the temporal white matter, and prefrontal white matter) (Turken et al., 2008). However, there were significantly weaker correlations in the ASD group between these white matter areas and processing speed, suggesting that these areas may not contribute as much to processing speed in the ASD group as in the typically developing group. At the group level, these data imply that white matter contributions to processing speed are similar in both groups, albeit these relations were weaker in ASD, suggesting compensatory mechanisms more inter-individual variability in ASD.

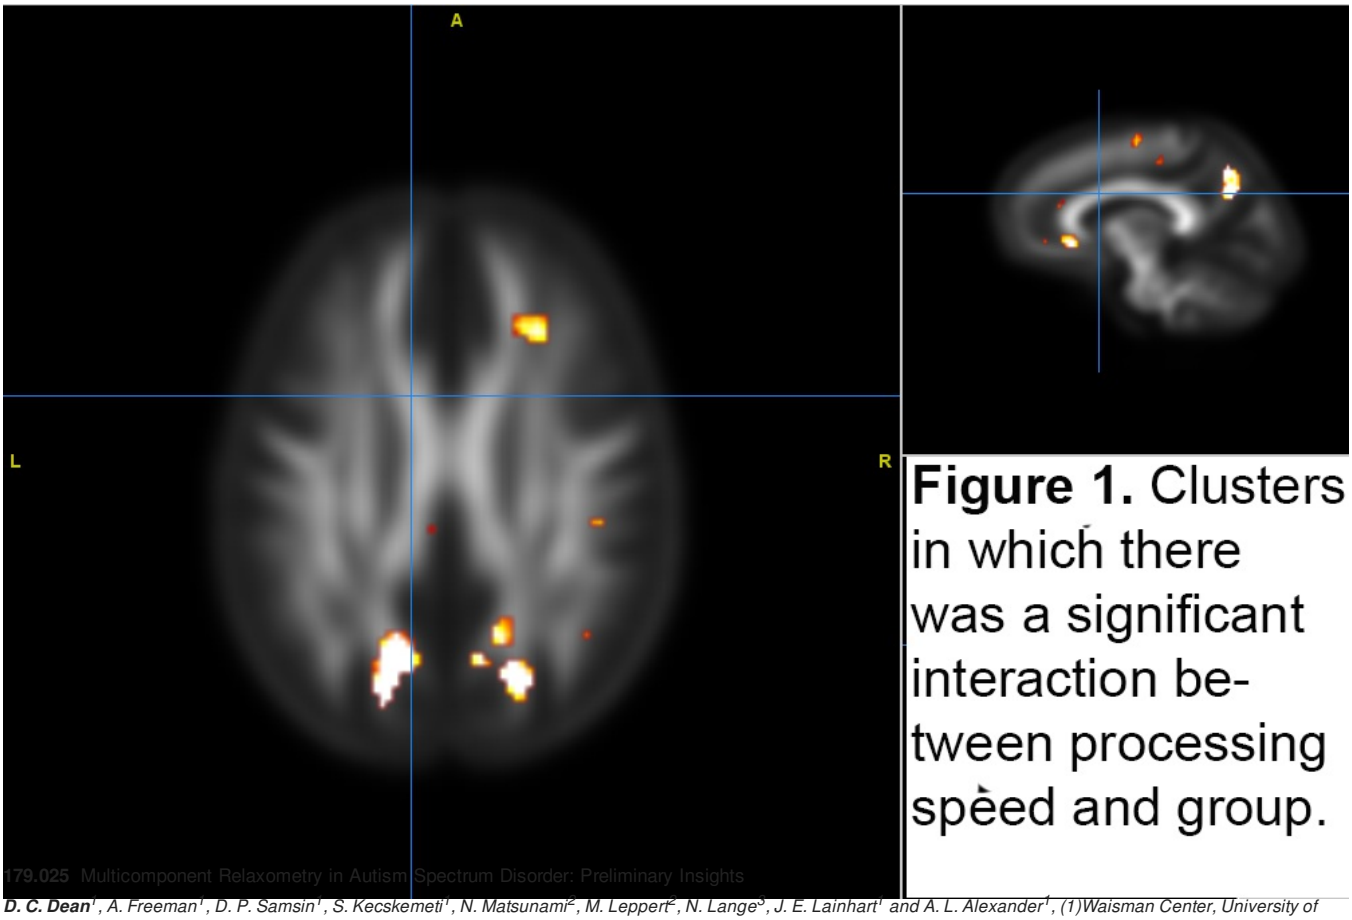

Figure 1. Clusters in which there was a significant interaction between processing speed and group.

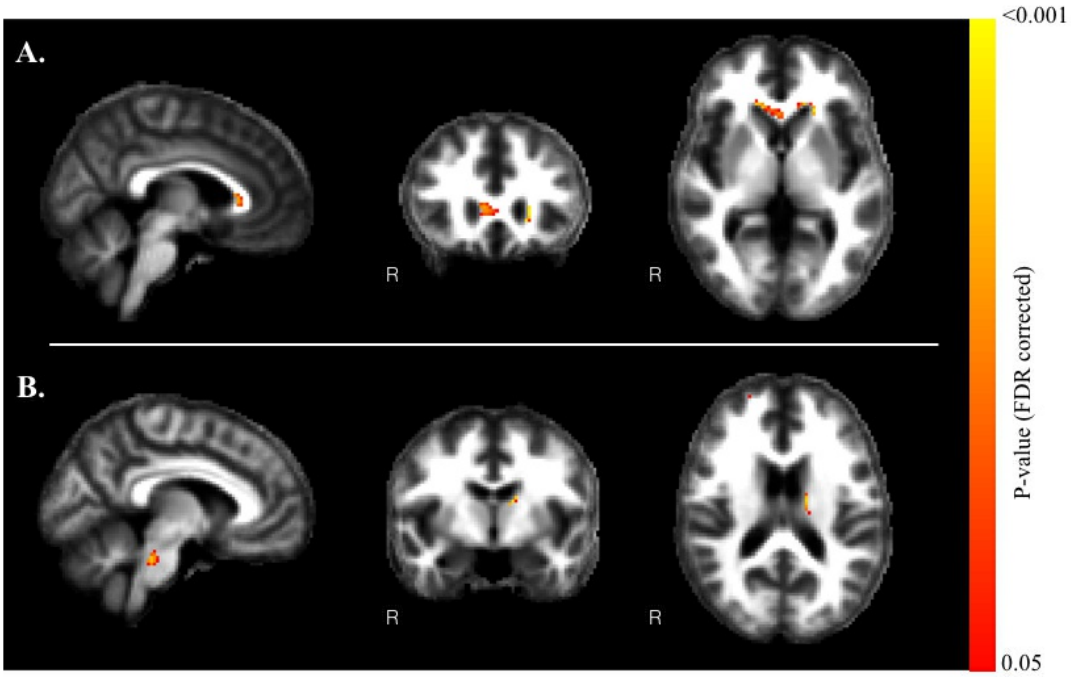
25 **179.025** Multicomponent Relaxometry in Autism Spectrum Disorder: Preliminary Insights

D. C. Dean[1], *A. Freeman*[1], *D. P. Samsin*[1], *S. Kecskemeti*[1], *N. Matsunami*[2], *M. Leppert*[2], *N. Lange*[3], *J. E. Lainhart*[1] *and A. L. Alexander*[1], *(1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)University of Utah, Salt Lake City, UT, (3)McLean Hospital, Cambridge, MA*

Background: Important to white matter and the establishment of brain connectivity is myelin. It is accepted that normal brain function relies on rapid and coordinated brain messaging afforded by myelinated axons, while recent studies have suggested that autism spectrum disorder (ASD) is associated with alterations to white matter (for review, see Travers et al., 2012). While several neuroimaging techniques that are sensitive to changes in myelin have been used to study white matter in ASD, these neuroimaging techniques are inherently non-specific to changes in myelin content. Multi-component analysis of relaxation time data, also termed multi-component relaxometry, may provide a more sensitive measure of myelin content through measurement of myelin water fraction (MWF; Alexander et al. 2011). The study of brain's myleoarchitecture using MCR may thus provide important new insights into the neurological substrates of ASD and illuminate key brain regions involved in the development and onset of ASD.
Objectives: We examined the extent to which the underlying white matter microstructure, as measured by relaxometry and multicomponent relaxometry measures, compared in a small sample of ASD and typically developing (TD) individuals. Specifically, we compared quantitative R_1 relaxation rates, R_2 relaxation rates, and MWF in these individuals.
Methods: *MRI Acquisition*: Participants for this study consisted of 22 individuals between 10 and 42 years of age, 14 of which were diagnosed with ASD. Magnetic resonance imaging (MRI) data were acquired from each participant using a 32 channel head RF coil on a 3.0 Tesla GE MR750 scanner. Multiple flip-angle spoiled gradient echo (SPGR) and balanced steady-state free precession (bSSFP) images were acquired and mcDESPOT post-processing (Deoni et al. 2013) was used to calculate R_1 ($1/T_1$), R_2 ($1/T_2$), and MWF parameter maps. Images were subsequently non-linearly registered to the MNI template using the Advanced Normalization Tools (ANTS) software.
Voxelwise linear regressions, corrected for multiple comparisons using the FDR, examined differences between ASD and TD groups, while co-varying for age.
Results: No significant age differences were observed between the two groups ($p=0.67$). MWF was found to be significantly ($p<0.05$, FDR corrected) reduced in the genu of the corpus callosum in the ASD group compared to the TD group (**Fig. 1A**). R_2 was also observed to be reduced in smaller clusters near the thalamus and pontine crossing tract of the brain stem (**Fig. 1B**). R_1 was not observed to significantly differ between the groups.
Conclusions: Our preliminary findings suggest that, within this small sample, the ASD group has reduced MWF in genu of the corpus callosum, compared to the TD group, while also having reduced R_2 near the thalamus and brain stem. These findings agree well with the current literature that describes alterations of white matter microstructure associated with ASD while also suggesting the possibility of that these white matter alterations may result from atypical myelin content. While these findings are promising, it is important to note that the small sample size of the current study limits our ability to interpret these findings. Future analyses will extend these characteristics in a larger sample of individuals.



26 **179.026** Orbitofrontal Cortex Sulcogyral Anatomy and Value Signals: An Interaction of Structure and Function

M. A. Patti[1], *C. Hyde*[1], *K. M. Adamson*[1], *H. Zhang*[2], *S. Deitrick*[1] *and V. Troiani*[1], *(1)Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA, (2)Temple University, Philadelphia, PA*

Background:
The orbitofrontal cortex (OFC) has an important function in codifying individual social and motivational behaviors. Atypical organization of the OFC architecture has been linked to psychiatric disorders including schizophrenia and Autism Spectrum Disorder (ASD) (Watanabe et al, 2014). Little is known about the influence of atypical cortical organization on functional organization of the OFC. Here we characterized two types of motivational brain responses, food and social, as well as their underlying sulcogyral anatomy.
Objectives:
This study localizes face-selective and food-selective value signals in OFC for each individual by contrasting faces or food with all other objects. We also characterize subject's OFC sulcogyral pattern type bilaterally, in order to determine if a pattern exists between variation in OFC sulci and OFC peak signal location for faces and food. We predict that value signals for faces are located in medial OFC and value signals for food are located in lateral OFC. We anticipate individuals with more consistent sulcogyral anatomy will have greater spatial consistency in the location of their face- and food-selective value signals.
Methods:
In this experiment, 28 healthy adults (mean age: 21; 14 females) were scanned using a 3T Siemens MRI and completed the Broader Autism Phenotype Questionnaire (BAP-Q). Value signals were determined for each individual by contrasting faces or food with all other objects using a variant of a standard fMRI face localizer task that included faces, food, scenes, and objects. OFC structure was determined by classifying each hemisphere as Type I, II, or III, based on the continuity of the medial and lateral orbital sulcus.
Results:
Consistent with our hypothesis, we found that medial value signals were more often associated with faces (27/28 subjects), while only 14 subjects had medial food value signals. While lateral value signals were consistently present for both faces and food (27/28 for food; 26/28 for faces, these were found in distinct sulcogyral locations within lateral OFC. Frequency of OFC sulcogyral patterns was consistent with previously published work, with Type I the most prevalent, followed by Type II and Type III. We found that subjects with a Type II pattern (known to increase risk for schizophrenia; Lavoie et al. 2014) were more likely to have atypical value signal locations. We also found that individuals with a Type II pattern present in at least one hemisphere scored significantly higher on the Aloof subscale of the BAP-Q ($p<0.05$). Ongoing analysis and additional data collection to increase sample size will validate these findings and combine the functional and structural characterizations to test for an anatomo-functional relationship.
Conclusions:
Future studies will attempt to identify the developmental trajectory and stability of object-selective patches in OFC. Understanding predictable developmental patterns of sulcogyral anatomy in typically developing healthy controls will allow us to better characterize and assess deviations that may occur in an ASD population. Observable structural and functional differences in sulcogyral pattern and value signal location may assist as predictive biomarkers of cross-diagnostic social or motivational behavior.

27 **179.027** Post-Mortem Analysis of Amygdala Neuron Morphology in ASD

R. K. Weir, *M. D. Bauman and C. M. Schumann, UC Davis MIND Institute, Sacramento, CA*

Background:
The amygdala is a medial temporal lobe structure posited to function as a danger, salience and value detector. It evaluates the emotional significance of environmental stimuli and coordinates appropriate responses. This has highly significant implications for the development of social interactions and thus makes it an ideal target for study in terms of autism spectrum disorders (ASD). Previous MRI and post-mortem studies from our lab have determined that the amygdala is larger in children diagnosed with ASD compared to typically developing (TD) controls, a difference that resolves by adulthood (Schumann et al., 2004; Schumann & Amaral, 2006).
Objectives:
The neurobiological underpinnings responsible for the differences in amygdala volume remain unknown. Our laboratory has been exploring two conceivable hypotheses: 1) Are there a greater number of neurons or 2) are the neurons physically larger in the amygdala of young children with ASD? This latter hypothesis is addressed here in a study of lateral nucleus neuron morphology across a range of ages from 4-46 years.
Methods:
Tissue from 17 TD and 16 ASD cases was assembled from a combination of samples from the NIH NeuroBioBank (previously NICHD brain and tissue bank) and the brain repository at UC Davis MIND Institute. Blocks of amygdala tissue approximately 1.5x1.5x0.5cm were excised from the temporal lobe and neurons were visualized using a modified Golgi-Kopsch staining technique. After dehydration and embedding in parlodion, 150µm sections were cut on a sliding microtome. 10 lateral nucleus neurons per

case were selected (fully impregnated, central within the slice and free from obscurities) to be traced using Neurolucida software (MBF Biosciences). Measures of dendrite morphology such as total dendritic length, segment count and spine density were analyzed using Neurolucida Explorer (MBF Biosciences) and statistical analyses conducted in SPSS v22 (IBM).
Results:
In an early analysis of a small subset (6 TD and 5 ASD cases) of the full case list, we have found a trend for a linear decrease in spine density across age ($F_{(1,9)}$=2.98, P=0.11), however this did not differ between the ASD and the TD group. Similarly with this small subset, no significant group differences were found in total dendritic length or spine density.
Conclusions:
This is the largest post-mortem analysis comparing neuron morphology in ASD vs. typically developing controls and the first study of its kind in the amygdala. The findings help to resolve our understanding of why the amygdala grows larger in children with autism spectrum disorders.

28 **179.028** Premature Aging in Autism: The Double Jeopardy Hypothesis of White Matter Integrity

H. M. Geurts[1], *P. C. M. Koolschijn*[2], *M. W. Caan*[3], *S. D. Olabarriaga*[3] *and J. Teeuw*[3], *(1)University of Amsterdam, Amsterdam, NH, Netherlands, (2)University of Amsterdam, Amsterdam, Netherlands, (3)Academic Medical Center, Amsterdam, Netherlands*

Background: Typical development of brain white matter (WM) microstructure across the lifespan shows a curvilinear pattern with a plateau around mid-adulthood and a rapid decrease in old age. Autism spectrum disorder (ASD) is typified as a brain connectivity disorder in which WM abnormalities are already present early on in life. However, it is unknown whether older adults with ASD show similar age-related WM deterioration as observed in typical aging.
Objectives: The aim of this first cross-sectional study in mid and late adulthood in ASD was to characterize WM integrity and its relationship with age.
Methods: We utilized diffusion tensor imaging with head motion control in 48 adults with ASD and 48 age-matched controls (30-75 years, IQ>80), who completed a Flanker task. We focused on fractional anisotropy, and mean, axial, and radial diffusivity of 18 major fiber tracts. Intra-individual variability (IIV) measures based on performance on the Flanker interference task were used to assess IIV-WM integrity associations between groups.
Results: We observed widespread reductions in white matter integrity in ASD, which persisted after taking head motion into account. These alterations were generally found in long-range association and projection tracts. Importantly, group-by-age interactions revealed increased age-related white matter deterioration in ASD, again for major association and projection fibers in the brain. We also observed different IIV-white matter integrity relations between groups. For example, reduced fiber coherence in callosal fibers was associated with higher IIV (when controlling for differences in MRT) in ASD, but not in controls.
Conclusions: The observed white matter integrity reductions lend support to the structural under connectivity hypothesis in ASD. These reductions seem to have behavioral repercussions given an atypical relationship with IIV. Taken together, the current results may suggest a premature aging pattern in adults with ASD.

29 **179.029** Reduced Age-Related Trajectories of Fractional Anisotropy and Volume for the Left Arcuate Fasciculus in Autism

K. A. Kellett[1], *P. T. Fletcher*[2], *M. D. Prigge*[3], *N. Lange*[4], *E. D. Bigler*[5], *A. L. Alexander*[6] *and J. E. Lainhart*[6], *(1)Department of Psychology, University of Wisconsin-Madison, Madison, WI, (2)University of Utah, Salt Lake City, UT, (3)Pediatrics, University of Utah, Salt Lake City, UT, (4)McLean Hospital, Cambridge, MA, (5)Psychology/Neuroscience Center, Brigham Young University, Provo, UT, (6)Waisman Center, University of Wisconsin-Madison, Madison, WI*

Background: The arcuate fasciculus is a white matter fiber bundle connecting canonical language regions in the brain. Previous diffusion tensor imaging studies comparing metrics of white matter microstructure integrity of the arcuate fasciculus between individuals with autism and typical development have been cross-sectional with regard to age and have produced inconsistent results.
Objectives: To compare age-related trajectories of arcuate fasciculus development between individuals with autism spectrum disorder (ASD) and typically developing controls (TDC) by examining longitudinal changes in mean fractional anisotropy (FA) and total volume for both left and right arcuate fasciculi.
Methods: Three-hundred and seventy-six diffusion-weighted imaging scans were collected from 94 males with autism (mean age of 15.1 years at first scan with age range of 3.0 – 45.4; nonverbal IQ > 60) and 43 males with typical development (mean age of 16.0 years at first scan with age range of 4.0 – 29.5). One to four scans were acquired per participant, at an average interscan interval of 2.5 years. Diffusion tensor image processing involved implementing a previously used volumetric segmentation approach to extract arcuate fasciculus white matter tracts, from which mean FA and total volume of tracts were measured. Using age mean-centered at time of first scan (15.4 years), longitudinal mixed effects models were used to identify group differences in longitudinal age-related trajectories for left arcuate mean FA, left arcuate total volume, right arcuate mean FA, and right arcuate total volume.
Results: For the left arcuate fasciculus, the ASD group showed a reduced age-related increase in mean FA compared to the TDC (group by age interaction: $t(232) = 2.84$, $p = 0.02$, Bonferroni corrected); the ASD group had significantly lower FA than the TDC (group effect: $t(135) = 3.5$, $p = 0.002$, Bonferroni corrected). Additionally, the ASD group showed a smaller age-related increase in left arcuate volume compared to the TDC (group by age interaction: $t(237) = 2.68$, $p = .03$, Bonferroni corrected), but ASD and TDC groups did not significantly differ in left arcuate volume. For the right arcuate fasciculus, no significant group or age-related group differences were found for mean FA or total volume.
Conclusions: Our results suggest that development of the left arcuate fasciculus occurs more slowly in individuals with autism. The ASD group compared to TDC group showed a reduced age-related increase in FA, indicative of a slower increase in axonal organization and density, as well as a reduced age-related increase in volume for the left arcuate fasciculus tract. Given that language functioning is typically left lateralized, future study will examine relationships between development of language ability and white matter microstructure in the arcuate fasciculus in autism.

30 **179.030** Rescue of Neuroanatomical Impairments Following Mecp2 Reactivation in Adult Mice

R. A. Allemang-Grand[1], *J. P. Lerch*[2], *L. Spencer-Noakes*[2] *and B. J. Nieman*[2], *(1)Hospital for Sick Children, Toronto, ON, Canada, (2)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada*

Background: Rett syndrome is a neurodevelopment disorder caused by sporadic mutations in the X-linked gene, Mecp2[1]. Interestingly, reactivation of Mecp2 leads to a rescue of the neuronal and behaviour impairments in adult mice[2,3]. Although these findings are exciting, these studies quantified rescue in a limited number of brain regions and restricted their analyses to a few time points. However, to fully understand the dynamics, a non-invasive, high-throughput method is required that can quantify where the remodelling of the cellular structure occurs across the entire brain and the time course of these changes. Magnetic Resonance Imaging (MRI) is an imaging modality that has the ability to longitudinally acquire high-resolution neuroanatomical information from the mouse brain.
Objectives: We scanned mice longitudinally with MRI to determine: a) the brain regions affected by Mecp2 silencing and b) the spatial and temporal changes that occur in the brain following Mecp2 reactivation.
Methods: At P50, male Mecp2-STOP/Cre and Cre littermates were scanned in vivo with a Manganese-enhanced MRI protocol (MEMRI), followed by 4 weeks of treatment with oil or tamoxifen to reactivate Mecp2. At P80, a follow up MEMRI scan was conducted. The acquired images were aligned using a series of iterative linear and nonlinear registrations steps[4]. This process generates a consensus average representing each individual brain and the deformations of each image from this average. The Jacobian-determinants, which represents local volume changes, were then extracted from the deformations fields and used as the dependent variable in the statistical analyses to assess volumetric changes.
Results: At P50, Mecp2/Cre mice began to show reduced mobility and breathing impairments. At this age, total brain volume of Mecp2/Cre (n=9) mice was 14% smaller than Cre (n=5) controls (t-statistic=4.07, $p < 0.001$). Following normalization for brain volume, volumetric decreases were found across the cortex, striatum, hippocampus, while volumetric increases were found in the cerebellum and medulla. Following the baseline scan, Mecp2/Cre mice treated with oil showed a steady increase in body weight (beta=0.33, $p < 0.05$) and phenotypes reaching a score of 5 around 80 days of age. Conversely, tamoxifen treatment reduced the increase in body weight of Mecp2/Cre mice (beta=0.07, p=0.42) and reversed the increase in phenotype score from 2 at 60 days, to 0 by 80 days. At P80, the brain of Mecp2/Cre mice treated with tamoxifen (n=4) was 30% larger than Mecp2/Cre treated with oil (n=2) (t-statistic=8.71, $p < 0.001$). Interestingly, the tamoxifen treated Mecp2/Cre brain grew at a rate of 1.73mm^3 per day (beta=1.73, $p < 0.05$), eventually reaching Cre control volumes at 80 days (t-statistic=0.32, p=0.76). A regional-based analysis demonstrated a lack of regional specificity, with all brain regions increasing in volume following Mecp2 reactivation.
Conclusions: Our results demonstrate that Mecp2 mice have volumetric differences across many brains networks early in adult life. However, following Mecp2 reactivation, a substantial neuroanatomical rescue occurs across the brain eventually normalizing with controls.

31 **179.031** Selective Impairments in White Matter Integrity of Right Inferior Longitudinal Fasciculus in ASD

B. Boets[1,2,3], *L. Van Eylen*[4], *K. Sitek*[3], *I. Noens*[4], *J. Steyaert*[1], *S. Sunaert*[5] *and J. Wagemans*[6], *(1)Child and Adolescent Psychiatry, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research consortium (LAuRes), KU Leuven, Leuven, Belgium, (3)McGovern Institute for Brain Research, Massachusetts Institute of Technology, Cambridge, MA, (4)Parenting and Special Education Research Unit, KU Leuven, Leuven, Belgium, (5)Translational MRI, KU Leuven, Leuven, Belgium, (6)Laboratory of Experimental Psychology, KU Leuven, Leuven, Belgium*

Background: One of the most widely established features of the neural phenotype of ASD is the reduced integrity of long-range white matter fiber tracts as assessed by diffusion-weighted imaging, leading to the conceptualization of ASD as a "disconnection" syndrome. Recent methodological studies, however, have shown that this same pattern of aberrant connectivity may artifactually result from excessive head motion and poorer data quality. A recent study comparing white matter integrity in children with ASD and TD controls while carefully controlling for head motion and data quality, revealed that the classical effect of reduced fractional anisotropy (FA) in multiple and widespread white matter tracts in ASD disappears (Koldewyn et al., 2014, PNAS). Instead, reduced white matter integrity was present in only one tract, the right inferior longitudinal fasciculus (ILF). This same tract has also been identified as particularly affected based on a recent quantitative meta-analysis of diffusion-weighted imaging studies in ASD (Hoppenbrouwers et al., 2014, RASD).
Objectives: We aimed to replicate these findings in an independent sample of adolescents with ASD and TD, using an identical methodological approach. Moreover, given the evidence of atypical visual processing in ASD and given the involvement of the ILF in ventral visual stream processing, we also assessed the association between ILF integrity and a series of visual processing measures.
Methods: Diffusion MRI data were obtained in 19 12-to-18-year-old boys with ASD and 19 age-matched TD boys. Anatomically constrained probabilistic diffusion tractography was carried out using TRACULA to extract integrity measures of 18 major white-matter pathways. Application of a strict head motion criterion resulted in a sample of 18 ASD and 17 TD participants, well-matched in terms of data quality. In addition to the structural connectivity data, a series of questionnaires and experiments were administered to assess ASD characteristics, attention to detail, perceptual grouping, visual processing style, motion coherence sensitivity and visual search.
Results: Comparing ASD vs. TD on each of the 18 tracts revealed similar FA values for both groups on every tract (all p>.10), with the exception of significantly reduced integrity of the right ILF in ASD (p=.022). FA values of left ILF (p=.057) and right SLFt (p=.058) were marginally significantly reduced in ASD . Apart from both questionnaires, no group differences were observed on any of the visual processing tasks. Concerning associations of white matter integrity with visual processing measures and ASD characteristics, we observed that poorer integrity of right ILF showed a (statistically insignificant) association with a more fragmented processing style (r_s=-.31, =.07), slower perceptual grouping and detection of Gabor patterns (r_s=-.29, p=.10),slower visual search (r_s=-.32, p=.06), more attention to detail (r_s=-.33, p=.06) and more ASD characteristics (r_s=-.31, p=.06). As expected no association was observed between ILF integrity and coherent motion sensitivity (p>.28), a traditional measure of dorsal visual stream functioning.
Conclusions: Our findings support the growing evidence for a specific and selective impairment of the right ILF in ASD. Suggestive evidence for a modest association between white matter integrity of this ventral visual pathway and behavioral visual processing performance was found.

32 **179.032** Structural Connectivity of the Accumbofrontal Tract in Youth with and without Autism: Associations with Behavioral Phenotypes

L. M. Hernandez[1], *J. Liu*[1], *C. Ponting*[2], *K. E. Lawrence*[1], *S. Y. Bookheimer*[1] *and M. Dapretto*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: Human neuroimaging work suggests that reward processing is affected in individuals with autism spectrum disorder (ASD); compared to neurotypical controls, individuals with ASD show altered brain activity to rewarding stimuli in nodes of reward circuitry including the ventral striatum, anterior cingulate, and prefrontal cortex (e.g., Scott-Van Zeeland 2010; Dichter 2012; Kohls 2013). The inferior portion of the VS encompasses the nucleus accumbens (NAcc), a region that animal studies indicate is critical for the formation of positive associations with social rewards (Dolen 2013) and attachment behavior (Keebaugh 2015). Importantly, the presence of an accumbofrontal white matter tract has recently been reported using diffusion tensor imaging (DTI) in humans (Karlsgodt 2015). This tract connects the NAcc and orbitofrontal cortex, two areas that display altered activity during reward processing in ASD. Here, we used DTI to detect and compare accumbofrontal fractional anisotropy (FA; a measure of white matter integrity) in youth with and without ASD, and relate FA to behavioral measures associated with the ASD phenotype.
Objectives: 1) Compare accumbofrontal structural connectivity in youth with and without ASD. 2) Investigate how accumbofrontal connectivity relates to measures of ASD symptomatology.
Methods: DTI data was acquired in high functioning youth with ASD (N=44) and typically developing youth (N=44) ages 8-17. Data analysis consisted of quality control and removal of volumes with artifacts using DTIPrep (Oguz 2015), eddy current correction, brain extraction, calculation of diffusion parameters (BEDPOSTX), registration to standard space, and probabilistic tractography (PROBTRACKX; Behrens 2007). Binary masks of the left and right NAcc (defined using the Havard-Oxford Atlas) were used as seed regions for probabilistic tractography. For each subject, 5,000 streamlines were initiated from the seed voxels using the contralateral hemisphere as an exclusionary mask; a minimum threshold of 50 streamlines was applied for inclusion in subsequent analyses. The resulting map was binarized and used as a mask to extract FA values for the left and right accumbofrontal tract for each subject, which were compared between diagnostic groups and correlated with behavioral measures of intelligence and social functioning.
Results: In both TD and ASD participants, the left and right NAcc showed structural connectivity with the ipsilateral orbital frontal cortex. There were no significant differences in FA for either the left or right accumbofrontal track when comparing TD and ASD participants (p>0.05). In ASD youth, left (r=0.40, p=0.007) and right (r=0.50, p=0.0005) accumbofrontal FA was associated with higher scores of verbal intelligence. Higher right accumbofrontal connectivity was also associated with less severe scores on the Autism Diagnostic Observation Schedule (ADOS; Lord 2000) social (r=-0.36, p=0.02) and social/communication (r=-0.32, p=0.03) subscales in youth with ASD. There were no significant behavioral correlations in TD youth.
Conclusions: These findings indicate that structural connectivity between the NAcc and orbital frontal cortex is intact in youth with ASD, and that higher levels of FA is associated with less severe verbal and social/communication impairment. This work suggests that structural connectivity of the reward network may be an important biomarker, helping to explain variability of symptomatology in youth with ASD.

33 **179.033** Structural Features of the Mid Fusiform Sulcus in Autism Spectrum Disorders

C. Ammons, *M. E. Winslett, J. Bice, P. Patel and R. K. Kana, University of Alabama at Birmingham, Birmingham, AL*

Background: A landmark paper published recently identified a minor sulcus bisecting the fusiform gyrus (FG) into lateral and medial subdivisions (Weiner et al., 2014). The "mid-fusiform sulcus" (MFS) was shown to be a stable characteristic in healthy individuals, present across ages and identifiable in right and left hemispheres of the brain. Furthermore, this macroanatomical feature was related to a microanatomical division between cytoarchitectonic regions FG1 and FG2 occurring at the fundus of the MFS in 90% of cases (Weiner et al., 2014). Despite the importance of the FG in face processing and social cognition as well as the considerable literature demonstrating abnormal FG activation in ASD (Nomi & Uddin, 2015), no systematic investigation of MFS structure has been undertaken in an ASD population.
Objectives: To characterize the anatomical organization of the MFS in children and adults with ASD and compare and contrast it with that in TD participants.
Methods: Structural MRI data from 49 subjects (23 ASD; 26 TD) collected on a Siemens 3T scanner were analyzed for this study. The sample consisted of 41 males and 8 females (4 ASD, 4 TD). Participant ages ranged from 9 to 40 years (ASD mean=21.13, TD mean=19.62) with no significant group differences [t(47)=.67, p=.51]. IQ ranged from 80 to 140 (ASD mean=113, TD mean=113) with no significant group differences [t(47)=.17, p=.68]. Each hemisphere was analyzed independently resulting in a total sample size of 98 hemispheres. Identification and classification of MFS in each hemisphere was performed using criteria established in Weiner et al. (2014). Criteria included 1) an "omega" shape on T1 coronal slices created by the deeper Collateral sulcus medially and Occipital-Temporal sulcus laterally; and 2) visible sulcus representation on the inflated brain surface. Identifiable MFS were classified into one of four surface patterns using *Freesurfer* 2D rendering and rough correspondence with an *fsaverage* brain MFS label created for this project. These patterns reflect a combination of fractionation and contiguity with surrounding sulci.
Results: The MFS was identifiable through inspection of the inflated surface and T1 image in 97% of hemispheres. ASD or TD group membership was not associated with unidentifiable MFS. Of the 95 hemispheres with identifiable MFS the following classification patterns emerged: 1) In both TD and ASD groups, unfractionated MFS patterns were slightly more common across hemispheres (56% ASD; 59% TD); 2) MFS which are independent of neighboring sulci are slightly more common across groups and hemispheres (53% ASD, 55% TD); 3) Classification of MFS gross anatomy was similar between ASD and TD groups (ASD: IA-14, IB-11, IIA-11, IIB-9; TD: IA-17, IB-10, IIA-13, IIB-10).
Conclusions: The MFS can be reliably identified in the ASD population. Its macroanatomical structure appears to follow largely similar patterns seen in TD individuals. Planned follow-up analyses include addition of another 65 subjects to increase power as well as quantitative indices of sulcal length and depth measurement. Further elaboration of structural features of the MFS in ASD will be important for future investigations into structure-function relationships in this critical region of the social brain.

34 **179.034** Structural Language Abilities Are Related to Cortical Structure and Covariance in Autism Spectrum Disorders

M. Sharda[1], *N. E. Foster*[1,2], *A. Tryfon*[1,2], *K. A. R. Doyle-Thomas*[3], *E. Anagnostou*[3,4], *A. C. Evans*[2], *L. Zwaigenbaum*[5], *J. D. Lewis*[2], *J. P. Lerch*[6], *K. L. Hyde*[1,2] *and .. NeuroDevNet ASD Imaging Group*[7], *(1)International Laboratory of Brain, Music and Sound Research, University of Montreal, Montreal, QC, Canada, (2)Montreal Neurological Institute, Montreal, QC, Canada, (3)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)University of Toronto, Toronto, ON, Canada, (5)University of Alberta, Edmonton, AB, Canada, (6)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (7)NeuroDevNet, Vancouver, BC, Canada*

Background: Autism spectrum disorders (ASD) are characterized by significant difficulties in language and communication. Recent changes in diagnostic criteria define language difficulties as distinct from core communication symptoms. Neuroimaging evidence suggests that language impairments in ASD may be related to atypical connectivity between fronto-temporal brain areas (Courchesne et al, 2007). However, the relationship of language and communication abilities to brain structure remains unknown.
Objectives: The objectives of the current study were to measure cortical thickness and anatomical covariance associated with language and communication in ASD

compared with typically developing (TD) controls.
Methods: Participants were 46 ASD and 50 TD males, matched on age (mean=12.8 years, SD=3.06), with IQ>75. ASD group was diagnosed using ADI-R and ADOS. Structural language and communication abilities in ASD were assessed using CELF-4 (Clinical Evaluation of Language fundamentals, Semel et al, 1996) and CCC-2 (Children's Communication Checklist-2, Bishop, 1998), respectively. High-resolution T1-weighted images obtained for all participants were analyzed using the CIVET pipeline (Ad'dabagh et al, 2006) to calculate cortical thickness (20mm smoothing). Seed-based analysis of anatomical covariance was performed to measure the Pearson correlation coefficient, across subjects, between cortical thickness at a seed vertex and all other vertices to generate a group map of covariance (Evans, 2013). Seed loci known to recruit the language structural covariance network (SCN) were selected in left inferior frontal gyrus (IFG), left superior temporal pole (STP) and their right hemisphere homologues. Statistical analyses were performed using vertex-wise general linear interaction models with age, site, full-scale IQ and brain volume as nuisance variables and vertex-wise seed thickness as variable of interest. Modulation of SCN strength by language and communication ability in ASD was measured by adding terms for CELF-4 and CCC-2 scores in the models respectively. All results were corrected for multiple comparisons at $p<0.05$ using random field theory.
Results: Results showed increased cortical thickness in ASD versus TD in left fronto-temporal regions. SCNs for both groups were mapped from 4 seed loci. While SCNs for controls reflected intrinsic connectivity networks described in earlier studies, SCNs for ASD showed widespread disruption, especially for the left STP seed. A direct comparison of the SCNs between TD and ASD revealed reduced covariance of the left STP seed with a region in the right frontal loci in ASD, suggesting decreased bilateral interactions of the left hemisphere language network. Furthermore, alterations in both cortical thickness and covariance were modulated by structural language ability as measured by CELF-4 of the ASD group but not communicative function (as measured by CCC-2).
Conclusions: Our findings reflect distinct differences in cortical structure and covariance of fronto-temporal regions in ASD, which are best explained by their structural language abilities but not communicative abilities. These differences further indicate the importance of structural language abilities in the study of altered fronto-temporal cortical structure and covariance in ASD. They also suggest that diagnostic specifiers, such as language, can be useful tools for understanding heterogeneity while maintaining the generalizability of findings in brain structural differences, much more than either symptom severity or cognitive ability.

35 **179.035** The Basal Ganglia Has Altered Inhibitory Receptor Expression in Autism

K. Ganapathy Subramanian[1], *C. Brandenburg*[2] *and G. J. Blatt*[2], *(1)Hussman Institute for Autism, Baltimore, MD, (2)Hussman Institute for Autism, Inc., Baltimore, MD*

Background:
The basal ganglia (BG) is a collection of sub-cortical nuclei that contain mainly inhibitory GABAergic medium spiny neurons (MSN's). The BG projects to the thalamus and has reciprocal connections with multiple cortical regions and the cerebellum. Parts of the BG are implicated in OCD, habit formation, motor, speech and language disorders. Thus, the BG is an ideal region of interest to examine the neurochemical basis of repetitive, stereotyped behavior and social communication difficulties observed in autism. This is the first study to examine changes in inhibitory circuits and receptors in specific regions of the BG in individuals with autism. Previously, Wegiel et al. 2014 reported volumetric and neuronal density changes in BG regions.
Objectives:
Determine levels of expression of inhibitory $GABA_A$ receptors in functional subdivisions of the BG in autism. Specifically, the dorsal striatum consisting of caudate and putamen, and the ventral striatum including the core and shell territories of nucleus accumbens (NAcc) were quantified.
Methods:
Sixteen post-mortem cases (8 autism and 8 control) were examined in select regions of the BG in age-matched control (mean=22.6±2.9 years) and autism (mean=22.9±3.0 years) cases. Sampled regions in the dorsal striatum included projection fields from the anterior cingulate cortex (ACC) and dorsolateral pre-frontal cortex (dlPFC) in caudate and putamen. Sampled regions in the ventral striatum included projection fields from ventromedial pre-frontal cortex vmPFC and orbitofrontal cortex (OFC) to the NAcc core and shell, areas that play a critical role in reward related behaviors. Cryostat cut 20 µm sections from these regions of interest were mounted on gelatin coated glass slides and incubated with tritiated flunitrazepam ([^{3}H]-flunitrazepam 5 nM, specific activity = 79.8 Ci/mmol, Perkin Elmer) before they were loaded into X-ray cassettes with tritium standards and apposed to tritium-sensitive film ([^{3}H]-hyperfilm) for four weeks at room temperature. Two sections per case were used for determining total binding with the tritiated ligand and one section was used for non-specific binding with a competitive displacer (Ro-15-451, 15 nM). After exposure, the films were developed and digitized to quantify measurements of binding in femtomoles per milligram of tissue for the ligand. Analysis was performed using student's t-test.
Results:
Tritiated flunitrazepam binding was found to be significantly increased in the caudate region of the dorsal striatum in subjects with autism compared to controls ($p=0.015$). Additionally, significantly increased benzodiazepine binding site density was found in the region of caudate that receives putative projections from the ACC ($p=0.03$).
Conclusions:
The results from this initial study suggest that there are significant increases in the expression of inhibitory $GABA_A$ receptors in the striatum of subjects with autism. Normally, the limbic ACC input that specifically targets the striatal interneurons plays an important role in BG efferent projections. In autism cases, increased $GABA_A$ receptors in the ACC recipient region of the caudate may be compensatory to an increase in excitatory input(s) and/or may represent an overexpression of receptors due to decreased GABA availability in this region. In either case, there is likely a disturbance of inhibitory/excitatory balance within BG circuitry in autism.

36 **179.036** The Number of Parvalbumin-Expressing Chandellier and Basket Cells Are Differentially Decreased in Medial Prefrontal Cortex in Autism

V. MartiÂnez Cerdeno, *J. Ariza Torres, E. Hashemi and H. Rogers, UC Davis, Sacramento, CA*

Background:
Cortical interneurons have been linked with the altered balance of excitation / inhibition in the cerebral cortex that is present in autism. However, a specific subtype of interneuron had not been correlated with autism until we discovered that the number of parvalbumin (PV) expressing interneurons was decreased in the prefrontal cortex in autism. PV+ interneurons are the primary cortical interneuron that directly innervates the pyramidal neuron soma or axon initial segment. There are two PV+ interneuron subtypes: Basket (Bsk) cells and Chandellier (Ch) cells. Bsk cells innervate the soma and proximal dendrites of pyramidal neurons, while Ch cells innervate the initial segment of pyramidal neuron axon. Both Bsk and Ch cells are fast-spiking neurons that innervate a large number of pyramidal neurons, and therefore even a small decrease in Ch or Bsk cell number could critically impair pyramidal neuron output and regional cortical function. These cells account for only 1% of total neurons in the cerebral cortex, with Bsk cells more numerous than Ch cells.
Objectives:
We investigated whether one subtype of the PV+ cells, the Bsk or Ch cell, or both, was decreased in the medial prefrontal cortex (Brodmann areas (BA) 46, 47, and 9) in autism.
Methods:
A specific marker that differentiates Bsk from Ch cells has not been devised. However, we have designed a method that allows us to discern between these two cell types. Our method is based on the differential expression of *Vicia villosa* lectin (VVA) by Bsk and Ch cells. VVA lectin belongs to a family of tetrameric glycoproteins that binds to N-acetylgalactosamine, which is present in the perineuronal net surrounding Bsk cells. While the vast majority of Bsk cells can be labeled using VVA, Ch cells do not express VVA. We used PV and VVA double labeling, and based on exclusion distinguished Ch cells from Bsk cells in cortical slices of prefrontal cortex in autism and control groups. We then quantified the number of each cell type (PV+/VVA+; PV+AVV-) present in each Brodmann area in our tissue samples and compared data between autism and control groups.
Results:
We found that PV+ Ch cells (VVA-) but not PV+ Bsk cells (VVA+) are decreased in prefrontal BA46 and BA47, while both PV+ Chk and PV+ Bs cells are decreased in prefrontal BA9.
Conclusions:
The changes in PV+ Ch and PV+ Bsk cells reported here may reflect altered information processing within the PFC and could contribute to the cognitive impairments seen in autism.

37 **179.037** The Rates of Incidental Perivascular Space (PVS) Findings on MRI Among Infants at High- and Low-Risk for ASD: Preliminary Results from the IBIS Study

R. F. Slomowitz[1], *J. Pandey*[2], *M. D. Shen*[3], *S. Das*[4], *L. MacIntyre*[4], *J. Wood*[5], *J. E. Maldarelli*[6], *K. Botteron*[7], *S. Dager*[8], *A. M. Estes*[9], *L. Zwaigenbaum*[10], *H. C. Hazlett*[11], *M. Styner*[3], *D. Shaw*[12], *R. T. Schultz*[6], *J. Piven*[3], *R. McKinstry*[13] *and .. The IBIS Network*[3], *(1)Psychology, The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)McGill Centre for Integrative Neuroscience, Montreal Neurological Institute, Montreal, QC, Canada, (5)The Children's Hospital of Philadelphia, Philadelphia, PA, (6)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (7)Psychiatry and Radiology, Washington University School of Medicine, St. Louis, MO, (8)University of Washington School of Medicine, Seattle, WA, (9)University of Washington Autism Center, Seattle, WA, (10)University of Alberta, Edmonton, AB, Canada, (11)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (12)Seattle Children's Hospital, Seattle, WA, (13)Washington University School of Medicine, St. Louis, MO*

Background: Prior research has highlighted an increased frequency of incidental findings in the MRI scans of children diagnosed with ASD. However, little research has

explored the frequency of incidental MRI findings in infants who are at high familial risk for autism. While no differences in the frequency of incidental MRI findings have been reported in infants at high (HR) and low risk (LR) for ASD at 6 months of age, it is possible that differences in the frequency of incidental MRI findings between these groups become apparent later in infancy.
Objectives: We examined the frequency with which incidental findings occur in HR and LR infants at 6, 12, and 24 months of age. We examined how findings at different ages relate to subsequent diagnostic outcomes.
Methods: Participants are part of an ongoing multi-site study (The Infant Brain Imaging Study) and underwent MRI scans at 6, 12, and 24 months (Total N=324; 239 HR, 85 LR). Diagnostic outcome of ASD was determined at 24 months of age by expert clinicians. The final sample was composed of three groups: N=49 HR infants who were diagnosed with ASD (HR-ASD); N=190 HR infants who were not diagnosed with ASD (HR-neg); and N=85 LR control infants (LR-neg). A neuroradiologist at each site (blind to risk status and diagnosis) reviewed and classified each scan, and each scan classification was confirmed by a second neuroradiologist. For the purposes of this study, each scan was classified as being either Abnormal or Typical by the presence and degree of perivascular spaces (PVS). The degree of PVS was rated on a five-point scale: none, minimal, mild, moderate, and marked. The rate of Abnormal vs. Typical scans at 24 months was compared between groups using Chi-squared tests.
Results: The rate of abnormal scans at 24 months was higher in the HR-ASD compared to the HR-neg and LR-neg groups: 63.27% of scans in the HR-ASD group were classified as abnormal, compared to less than 40% of scans in the HR-neg and LR-neg groups. The ratio of abnormal vs. normal scans in the HR-ASD group was significantly higher compared to both the HR-neg group ($\chi^2 = 11.15$, $p < .001$) and LR-neg group ($\chi^2 = 7.44$, $p < .01$). PVS were found in >60% of abnormal scans at 24 months across all groups.
Conclusions: The examination of MRI scans across diagnostic outcomes demonstrated that abnormal findings at 24 months were significantly more common in HR-ASD children, compared to HR-neg and LR-neg children. Interestingly, for all three diagnostic groups, PVS were the most frequent findings across all abnormal scans. Analyses of other incidental findings and correlations between MRI findings and clinical characteristics are currently underway and will be presented.

Table 1

	Radiology Review Result	
Time Point & Risk Status	Normal	Abnormal
HR+		
6 HR+	42.11% (16)	57.89% (22)
12 HR+	52.27% (23)	47.73% (21)
24 HR+	36.73% (18)	63.27% (31)
HR-		
6 HR-	55% (77)	45% (63)
12 HR-	54.55% (96)	44.55% (80)
24 HR-	63.16% (120)	36.84% (70)
LR-		
6 LR-	43.59% (34)	56.41% (44)
12 LR-	59.74% (46)	40.26% (31)
24 LR-	61.18% (52)	38.82% (33)

38 **179.038** The Relationship Between Temperament and Brain Development in Infant Siblings with Autism Spectrum Disorder

S. J. Paterson[1], *J. J. Wolff*[2], *M. R. Swanson*[3], *J. T. Elison*[2], *L. Zwaigenbaum*[4], *A. M. Estes*[5], *K. Botteron*[6], *H. C. Hazlett*[7], *J. Pandey*[8], *R. T. Schultz*[9], *J. Piven*[3] *and .. The IBIS Network*[3], *(1)Department of psychology, Temple university, Philadelphia, PA, (2)University of Minnesota, Minneapolis, MN, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of Alberta, Edmonton, AB, Canada, (5)University of Washington Autism Center, Seattle, WA, (6)Psychiatry and Radiology, Washington University School of Medicine, St. Louis, MO, (7)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (8)Children's Hospital of Philadelphia, Philadelphia, PA, (9)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:
Differences in temperament profiles are already present at 6 months in infants who develop autism spectrum disorder (ASD) and are some of the disorder's earliest behavioral signs (Zwaigenbaum et al., 2005; del Rosario et al., 2013; Paterson et al., 2014). Brain imaging in these same infants has revealed that differences in white matter development are also present by 6 months (Wolff et al., 2012). However, the relationship between brain development and temperament in infants at risk for ASD has yet to be examined.
Objectives:
Given the correspondence of timing of these atypical brain and behavioral phenomena, we aimed to characterize the association between white matter structural connectivity and individual differences in temperament at 6 and 12 months in infant siblings who received a diagnosis of ASD at age two years.
Methods:
Thirty-seven infants who developed ASD (HRPos) and eighty-three infants with typically developing siblings (LR) were assessed longitudinally in a larger, multi-site study of brain and behavioral development in ASD. Temperament was assessed at 6 and 12 months using the IBQ-R (Gartstein & Rothbart, 2003). Diffusion tensor imaging data were collected during natural sleep. Five white matter pathways were selected and deterministically segmented in common atlas space (see Verde et al. 2014). These were the: genu of the corpus callosum, uncinate fasciculus, cingulum, superior cerebellar peduncle (SCP) and the anterior limb of the internal capsule (ALIC). Microstructure was characterized by fractional anisotropy (FA). The relationships between three aspects of temperament: Surgency, Regulatory Control, and Negative Affect, and FA in five white matter fiber pathways at 6 and 12 months were examined using Pearson correlations.
Results:
Preliminary analyses found no correlations between white matter pathways and temperament concurrently at 6 months. However, significant concurrent correlations between white matter and temperament were found at 12 months in both groups. In addition, correlations were found between 6-month white matter microstructure and 12-month temperament data, between higher FA in the genu and higher negative affect,($r = .044$, $p<.05$), FA in the SCP at 6 mo and decreased surgency at 12 mo in the HRPos group ($r = -.047$, $p<.01$), and between FA in the cingulum at 6 months and Negative Affect at 12 month in the low risk group ($r =.033$, $p<.01$).

Conclusions:
These data suggest that there are indeed relationships between neurobiology and temperament in infants at high risk for ASD. Brain differences at 6 months correlate with behavior at 12 months, but concurrent relationships are not yet present at 6 months, probably because there is not yet enough variability in temperament. Tracts such as the uncinate, which links the anterior temporal lobe with the orbito-frontal cortex, are likely to play a role in self-control and orienting behavior. These are important for aspects of temperament such as regulatory capacity. These findings of differences in neurobiology and temperament appear before many of the major symptoms of ASD and are likely to have important implications for the development of the disorder. Further examination of a larger dataset is underway and will include trajectory analysis.

39 **179.039** Understimulation in Autism: A Preliminary Diffusion Tensor Study Using Tract-Based Spatial Statistics

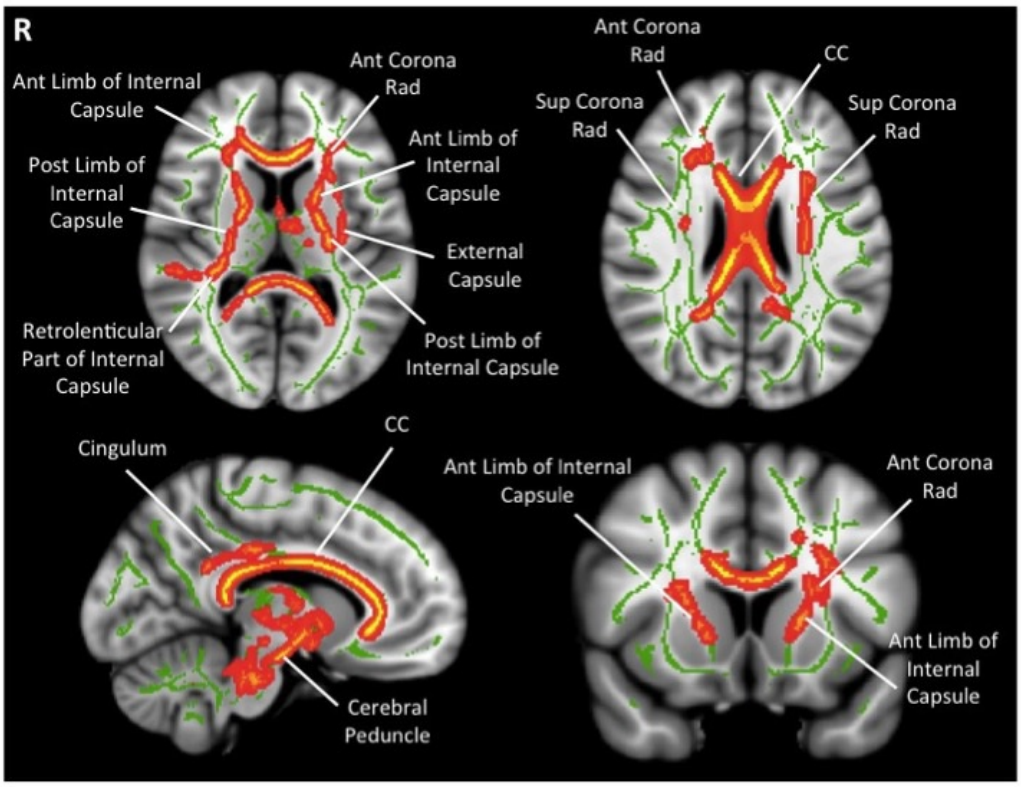
S. M. Kaku, *R. D. Bharath, G. Venkatasubramanian, S. Bansal, S. C. Girimaji and S. Srinath, National Institute of Mental Health and Neurosciences, Bangalore, India*

Background:
Autism is known to be influenced by a plethora of environmental influences. Among the many environmental factors, understimulation in the early stages of brain growth is also known to contribute. There is evidence suggesting widespread aberrations in neural connectivity implicating underconnectivity as a theory explaining the underlying neurobiology of autism.
Objectives:
In this study we tried to explore the possible connectome differences between those with autism and understimulation as we have frequently observed a spurt of initial improvement once the intervention starts, thus having better short term outcome as compared to those who develop autism even though adequately stimulated.
Methods:
22 subjects with autism aged 3-8 years were recruited for the study from the Child and Adolescent Psychiatry services at a tertiary care centre in India. They were divided into 2 groups with 11 children in each group, depending on whether they had understimulation as a major environmental factor. The case group were those with understimulation who were clinically classified as those with >4 hours/day television time, social isolation, precious child, etc. Those with adequate stimulation were classified as controls. Subjects were group-matched on age, cognitive functioning, sex, and handedness. DTI data were acquired using a 3T scanner. FSL, including TBSS, was used to process and analyse DTI data where FA was chosen as the primary measure of fiber tract integrity.
Results:
Clinical data established no significant differences between the two groups of children with autism even with respect to comorbidities, medication prescribed, family history etc. Connectivity differences, similar to previous studies demonstrating long range connectivity dysfunction, though not at significance levels, were observed between the two groups. Aberrant connectivity was mainly noticed in areas related to the fronto-parietal and fronto-temporal networks and few areas in the occipital cortex.
Conclusions:
At the preliminary level, this study validates the established evidence of long range cortical connectivity dysfunction in autism. We hypothesize that autism which is known to exhibit a heterogeneous symptom profile also possibly demonstrates specific neural correlates for sub categories of the disease population like those with understimulation. It also could be possible for these correlates to act as neuroanatomical indicators of short term outcome. The results of this study though small, indicate possible differences in brain connectivity patterns across the autism group which need further evaluation with larger groups of children with autism with differing symptom profiles.

40 **179.040** What's the (white) Matter in Autism Spectrum Disorder

V. M. Vogan[1], *B. R. Morgan*[1], *R. Leung*[2], *E. Anagnostou*[3] *and M. J. Taylor*[4], *(1)The Hospital for Sick Children, Toronto, ON, Canada, (2)Psychology, University of Toronto, Toronto, ON, Canada, (3)University of Toronto, Toronto, ON, Canada, (4)Diagnostic Imaging, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Autism Spectrum Disorder (ASD) is characterized by complex underlying neuropathology that is not fully understood. There is evidence of early dysregulated brain growth in children with ASD, which may have profound effects on neural connectivity. A large body of research has pointed to atypical functional and structural networks in ASD, with evidence for both functional underconnectivity and overconnectivity. Diffusion tensor imaging (DTI) studies have shown widespread white matter abnormalities in children with ASD, which may disrupt neural circuitry, impacting crucial cognitive processes, such as working memory. However, previous studies have been limited by sample size and comprehensive diffusion analyses.
Objectives: To explore white matter development in a large sample of children with and without ASD using DTI, and the relations between various DTI metrics and cognitive processes, such as working memory.
Methods: 60-direction diffusion data was acquired on a 3T Siemens Trio MRI scanner with a 12-channel head coil. Subjects included 61 children with ASD (51 male) and 69 age- and sex-matched healthy control (51 male) children (ages 7-15). Values for fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD) and radial diffusivity (RD) were calculated. Tract based spatial statistics (TBSS) was used to define subject-specific FA skeletons, which were used as masks to examine differences in FA, MD, AD and RD. FSL Randomise was used to statistically evaluate these differences. Associations (Pearson's) between FA in select tracts and working memory, as measured by the Working Memory Test Battery, were examined in a subgroup of children with (n= 39) and without ASD (n = 34).
Results: Compared to controls, children and adolescents with ASD showed widely distributed reduced FA and AD, with no group differences in MD or RD values. Both groups showed age-related changes, but there was no interaction between age and group. Regions of reduced FA included the corpus collosum, cerebral peduncle and projection fibres (corona radiata, internal capsule, posterior thalamic radiation). Similarly, regions of reduced AD included the corpus collosum, cingulum, cerebral peduncle, corona radiata, internal capsule and external capsule. In control children only, FA of the bilateral superior fronto-occipital fasciculus showed a positive association with working memory ($p<0.05$, uncorrected).
Conclusions: In one of the largest samples studied with DTI and ASD, our findings highlight widespread atypical white matter in children with ASD that persists well into adolescence. Altered white matter structure was not limited to specific networks, and was observed primarily in the corpus callosum and thalamocortical fibres—tracts crucial for interhemispheric exchange and higher order information processing. Widespread white matter impairment in ASD is consistent with the view that ASD is a disorder of generalized complex information processing. The relation between patterns of white matter integrity and specific aspects of cognition in ASD remains elusive.



Regions of reduced FA in children with ASD relative to control children. Red/yellow= significant voxels at p <0.01 TFCE-corrected. Mean FA skeleton overlaid in green.

41 **179.041** White Matter Microstructure Is Associated with Auditory and Tactile Processing in Children with and without Sensory Processing Disorder

***Y. S. Chang**, M. Gratiot, J. Owen, A. Brandes-Aitken, S. Desai, S. S. Hill, E. J. Marco and P. Mukherjee, University of California in San Francisco, San Francisco, CA*

Background: Sensory processing disorders (SPD) affect 5-16% of school-aged children, and can cause downstream deficits of intellectual and social development. While sensory processing differences are now widely recognized in children with autism, children with sensory deficits who do not meet autism criteria for language and social deficits remain virtually unstudied. In a previous, small-scale diffusion tensor imaging (DTI) study, we demonstrated that children with SPD have altered white matter microstructure primarily affecting the posterior cerebral tracts, which subserve basic sensory processing and integration. This altered microstructural integrity was further shown to correlate with parent report measures of atypical sensory processing.

Objectives: In this present study, we seek to investigate prior findings in a larger, mixed-gender cohort, and to further explore auditory and tactile in depth.

Methods: Whole-brain diffusion tensor imaging (DTI) with 64 directions and b=2000 s/mm^2 were acquired in 41 children with SPD (33M/8F), and 41 typically developing children (TDC) (28M/13F), all aged 8-12 years and matched for IQ and handedness. Maps of fractional anisotropy (FA), mean diffusivity (MD), and radial diffusivity (RD) were derived for each subject. Each map was then skeletonized and registered to the same space using tract-based spatial statistics, allowing for the calculation of voxel-wise statistics along the white matter skeleton. All voxel-wise statistics were performed with regression of motion. Group differences were assessed with nonparametric permutation testing, and corrected for multiple comparisons using threshold-free cluster enhancement. Sensory correlations with FA along the white matter skeleton were assessed using the parent report metrics of the Sensory Profile auditory and tactile scores, along with direct behavioral measurements of auditory and tactile processing, derived respectively from the Acoustic Index of the Differential Screening Test for Processing (DSTP) and the Graphesthesia subtest of the Sensory Integration Praxis Tests. In post-hoc analyses, general linear models were constructed to assess the confounding effects of group (TDC vs SPD), age, and gender for each of these sensory correlations.

Results: As in our prior work, significant posteriorly biased decreases of FA, and elevations of MD and RD, were found in the SPD cohort relative to TDC. There were robust correlations of FA with both parent report and direct measurements of tactile and auditory processing. However, for the parent report metrics, these correlations were heavily driven by group differences (TDC vs SPD), and regression lines of the metrics vs FA differed between TDC and SPD. In contrast, the DSTP and Graphesthesia correlations were most strongly driven by FA, with TDC and SPD mapping along similar regression lines. These results suggest that direct measurements of sensory processing map more closely to the underlying biology, as revealed by DTI, than their corresponding subjective report metrics.

Conclusions: To our knowledge, this work is the first to demonstrate a relationship between direct measurements of tactile and non-linguistic auditory function with white matter microstructural integrity -- not just in SPD, but also in typically developing children. We also confirm our prior DTI results demonstrating altered white matter microstructure in children with SPD in a larger mixed-gender cohort.

42 **179.042** White Matter Microstructure in ASD and ADHD: A DTI Study

ABSTRACT WITHDRAWN

Background:
Autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) are neurodevelopmental disorders. Previous researches have shown high rate of ADHD comorbidity (30-50%) in individuals with ASD. According to the Diagnostic and Statistical Manual of Mental Disorders—5th edition (DSM-5), ASD and ADHD can be diagnosed together.

Structural and functional magnetic resonance imaging (MRI) has shown brain abnormalities in ASD and ADHD. Recent neuroimaging technique makes it possible to investigate white matter fiber structure using Diffusion Tenor Imaging (DTI). Not only the localized brain abnormality, but impaired structural brain connectivity are considered to be related the core feature of ASD and ADHD. However, there has been no neuroimaging research that investigated the white matter microstructure in ASD with ADHD.

Objectives:
The aim of the present study is to reveal the commonality and difference of white matter microstructure between ASD with and without ADHD.

Methods:
A total of 89 participated in this study; 41 ASD without ADHD (ASD-), 20 ASD with ADHD (ASD+), 28 Normal Controls (NC). Two medical specialists diagnosed ASD and ADHD according to DSM-5 criteria. All participants do not have mental retardation. All participants are adults (age > 20 years old). The three groups did not differ statistically in their chronological age and estimated IQ.

MRI scans were conducted using a 3.0 Tesla Siemens scanner. DTI data were processed using programs in the FMRIB Software Library (FSL) version 5.0. The FA map of each subject was calculated using the DTIFIT program implemented in FSL. TBSS (Tract-Based Spatial Statistics) was used for voxelwise statistical analysis. All FA data were normalized into a common space and averaged to create a mean FA image. FSL Randomise performed group comparison of FA maps. The statistical threshold was defined at $p < 0.0000001$ (uncorrected for multiple comparisons).

Results: The two disorder groups showed reduction of FA extensively in anterior corpus callosum (CC) compared to NC group. Several previous studies have found the lower FA of CC in both ASD and ADHD. This finding suggested reduced FA of CC in ASD regardless of ADHD comorbidity. Lower FA of bilateral superior longitudinal fasciculus (SLF) in ASD+ compared to ASD-. The SLF is a part of attentional network. Several previous studies have found lower FA of SLF in both ASD and ADHD. The finding suggested that the lower FA of SLF in ASD is contributed by ASD+, not by ASD-. The FA of right sagittal stratum including inferior longitudinal fasciculus (ILF) and inferior fronto-occipital fasciculus is lower in ASD- compared to ASD+. The ILF is considered to play important role in recognition of facial expressions. The finding suggested that there is some difference in the neural substrate of social disability between ASD- and ASD+.

Conclusions: Compared to NC, ASD+ and ASD- had lower FA in anterior CC. Between ASD+ and ASD-, FA value is different in some regions such as SLF and ILF. The present study suggested that the neural substrate of ASD- and ASD+ has some commonality and difference in the white matter microstructure.

Poster Session
180 - Early Development (<48 months)
11:30 AM - 1:30 PM - Hall A

43 **180.043** A New "Geopref Test" with Complex Social Stimuli

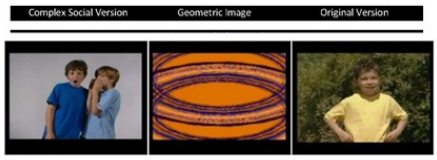
A. Moore[1], *C. Carter*[2], *D. Cha*[2], *S. Pence*[2], *A. Yousef*[3], *M. Wozniak*[3], *E. Courchesne*[2] *and K. Pierce*[2], *(1)University of California, San Diego, La Jolla, CA, (2)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA, (3)Neuroscience, University of California San Diego, La Jolla, CA*

Background:
There is increasing appreciation of autism as a highly heterogeneous disorder in terms of symptom profiles, outcomes, and most likely etiologies. Using eye-tracking technology we recently showed that a subset of ASD toddlers exhibit heightened visual fixation toward geometric, rather than social, images (Pierce et al. (2011, 2015)). It is unclear, however, if the effect identified in previous studies using the "GeoPref Test" was specific to the stimuli used, or would generalize across different stimuli. The current study evaluated the robustness of the Geometric Preference phenomenon identified previously by creating a new test, the "Complex-Social GeoPref Test" that varied the stimulus presentation total length, scene length, and complexity of social images. In this way we will be able to determine if eye-tracking technology can identify a specific ASD subtype that persists regardless of stimulus type.
Objectives:

1. To determine if our previously described phenomenon of increased fixation towards geometric images in a subset of ASD toddlers persists using a new stimulus set.
2. Examine the degree to which percent fixation on geometric images is related to ASD symptom severity.

Methods:
243 toddlers (71 ASD, 72 TD, 100 Non-ASD contrast) ranging in age from 12-48 months participated. Children were recruited primarily through the One-Year Well-Baby Check-Up (see Pierce et al., 2011). Once enrolled, children are evaluated periodically until they receive a final diagnosis at age 3. Each evaluation included the ADOS and Mullen, as well as eye-tracking. Eye-tracking data were collected while children viewed a 90-second video from 60cm distance on a 17" computer monitor using the Tobii T-120Hz system.
Results:
Differences were found in percent fixation on geometric images using an ANOVA across 6 diagnostic groups (F=12.88, P<.001), see Figure 1. Pairwise follow-up comparisons with Bonferroni correction revealed that the ASD group showed significantly greater fixation towards geometric images than other contrast groups (ASD vs TD and DD, p<.001; ASD vs other contrast groups, p<.05).
As we demonstrated in our previous studies, increased fixation on the Complex-Social GeoPref Test's geometric images as defined by > 69% fixation towards geometric images is associated with increased symptom severity, see Table 1.
Conclusions:
Debate and controversy regarding the replication of findings from the biological sciences and psychology have been common in recent years (Paschler & Wagenmakers (2012)). In contrast, the Geometric Preference effect has now been replicated multiple times in both direct, identical replication and in this conceptual replication with varied social stimuli, suggesting that toddlers with unusual visual attention profiles may represent a biologically stable, unique subtype. Future analyses will examine data from ASD children receiving multiple GeoPref tests that suggests that those with a consistent Geometric Preference may differ in clinical symptom severity compared to those with a consistent Social Preference. Experience dependent mechanisms play an important role during early development, and therefore toddlers with a persistently abnormal visual attention profile who prefer geometric images may potentially have a poorer prognosis than those who prefer social images.

Figure 1. (A) Sample images from each Geometric Preference Test. The geometric image is common to both versions.



(B) Scatterplot of 6 diagnostic groups showing individual and mean scores.

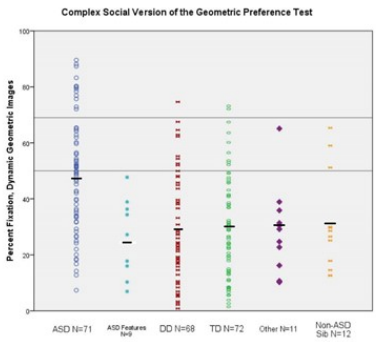


Table 1.

	ASD Geometric Responder (N=13), Mean (Std.Dev.)	ASD Social Responder (N=14), Mean (Std. Dev.)	Independent Samples T-test, P-value
Mullen Visual Reception T-score	36.2 (10.1)	37.0 (14.0)	NS
Mullen Fine Motor T-score	36.6 (12.6)	35.9 (12.6)	NS
Mullen Receptive Language T-score	20.8 (11.8)	31.6 (14.5)	P<.05
Mullen Expressive Language T-score	21.2 (12.1)	29.9 (14.3)	P=.1 (NS)
ADOS Social Affect score	15.9 (3.3)	12.3 (4.4)	P<.05
ADOS Restricted Repetitive score	3.8 (2.5)	3.3 (1.6)	NS
ADOS Total score	19.6 (4.5)	15.6 (4.1)	P<.05

44 **180.044** A Novel Method for Quantifying Eye-to-Eye Gaze during Naturalistic Social Interactions Finds Preliminary Differences Between ASD and TD Toddlers

S. R. Edmunds[1], *A. Rozga*[2], *Y. Li*[2], *L. V. Ibanez*[1], *E. A. Karp*[1], *J. M. Rehg*[2] *and W. L. Stone*[1], *(1)Department of Psychology, University of Washington, Seattle, WA, (2)Georgia Institute of Technology, Atlanta, GA*

Background: Monitor-based eye tracking studies indicate that young children with ASD show atypical patterns of attention to internal features of the face, particularly the eyes. These findings have not been replicated in the context of more ecologically valid live social interactions, owing largely to a reliance on coding gaze behavior from videos recorded by stationary room camcorders and use of "gaze to face" as a proxy for "gaze to eyes." Children's eye contact during social interactions was measured that by instrumenting their social partner with a pair of glasses that contain an outward facing (point of view, PoV) camera (Pivothead Kudu Black) in the nose bridge (Figure 1). Coding gaze based on the PoV video produces more reliable estimates of toddlers' looks to the partner's eyes (vs. the face in general) than coding based on videos from stationary camcorders (Edmunds et al., 2014).
Objectives: To compare patterns of gaze to and away from a social partner's eyes and face during a live play interaction in toddlers with ASD and typically developing (TD) toddlers. We hypothesized that toddlers with ASD would look less frequently to the adult's eyes and face and look away longer compared to TD children, and that more instances of gaze to eyes would be detectible using the PoV camera than the camcorders, as the PoV camera will more likely capture the toddlers' entire face and support more accurate gaze coding.

Methods: Seven toddlers with ASD (*M*=33.5 mos; *SD*=3.5 mos) and eight TD toddlers (*M*=34.6 mos; *SD*=6.0 mos) participated in a 5-minute structured interaction routine with an examiner wearing a PoV camera. Interactions were also recorded simultaneously by three tripod-mounted camcorders that captured different angles. Onsets and offsets of three categories of eye gaze—to eyes, face (not eyes), and away—were coded for the PoV and camcorder videos by separate pairs of coders who were blind to the toddlers' diagnostic status. Overall Kappas for frame-level agreement were *k*=.67 for the PoV camera and *k*=.49 for the camcorders (Figure 2a).
Results: Multivariate ANOVAS examined the effect of diagnosis on looks to eyes, face, and away as correlated dependent variables. As measured by the PoV camera, toddlers' rate of looks varied by diagnosis, $F(4,10)=4.55$, $p=.02$. ASD toddlers looked at the examiner's eyes and face less frequently than did TD toddlers, $F(1,14)=6.11$, $p=.03$ and $F(1,14)=16.44$, $p<.00$ respectively. Toddlers' average duration of looks away varied by diagnosis, $F(4,10)=4.70$, $p=.02$. ASD toddlers had longer average looks away from the examiner, $F(1,14)=22.21$, $p<.001$. In contrast, as measured by the camcorders, ASD and TD toddlers did not differ in their overall rate of looks or average duration of looks to the examiner's eyes (Figure 2b), face, or away.
Conclusions: The PoV camera, but not the camcorders, found differences in TD and ASD toddlers' eye-to-eye gaze during social interactions. This approach is unobtrusive, easily deployed in multiple settings, and cost-effective compared to monitor-based eye tracking. Future directions include replication with larger samples, examining use in natural settings, and developing automated coding of toddlers' gaze from PoV videos.

45 **180.045** Accuracy of Parental Report As Compared to Standardized Assessment: A Comparison of the Ages and Stages to the Mullen and ADOS

T. Hamner[1], *C. Klaiman*[2] *and S. Richardson*[1], *(1)Marcus Autism Center, Atlanta, GA, (2)Emory University, Atlanta, GA*

Background: The need for early detection of developmental delays in young children is critical. Early intervention is key for children with ASD where it has been shown to alter developmental trajectories and improve lifetime outcomes (Orinstein et al., 2014; Zwaigenbaum et al., 2015). There is a push for effective, parental self-report screening measures to help identify developmental delays and ASD. One of the more commonly used measures is the Ages and Stages Questionnaire (ASQ). However, previous research has revealed mixed findings regarding the ASQ as a developmental screener with some studies showing poor agreement with the Bayley Developmental Scales (Veldhuizen et al., 2014) and others, especially across cultures, finding the ASQ to be a strong predictor of developmental delays (Juneja et al., 2011). Additionally, there is a need to evaluate the use of this measure for children with ASD.
Objectives: The goal of this study is to assess the relationship between the ASQ and standardized assessments for children with ASD.
Methods: 51 children (47 males) who received an initial ASD diagnosis following evaluations conducted as part of a research study. All children were between the ages of 16-43 months (mean = 29.71) and referred based on parent concerns and/or recommendation from pediatrician or early interventionist. Parents completed the ASQ and children were evaluated with the Mullen Scales of Early Learning and the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2).
Results: ASQ scales were significantly correlated with T-scores from the Mullen, with significant associations between the ASQ problem solving scale and Mullen visual reception, fine motor, expressive, and receptive language domains (*r's*=.53, .49, .46, and .64 respectively, all p's<.01). The ASQ fine motor scale was associated with Mullen visual reception, fine motor, and expressive language domains (*r's*=.29, .28, and .35 respectively, all p's<.05). The ASQ communication scale was associated with Mullen visual reception, fine motor, receptive, and expressive language domains (*r*=.54, .32, .68 and.70 respectively, all p's<.05). ASQ social-emotional scale was associated with Mullen visual reception, fine motor, receptive and expressive language domains (*r*=.42, .33, .36, .45 respectively, all p's<.01). The ASQ communication scale was negatively correlated with the ADOS social affect score (r=-0.39, p<.05) and ADOS total score (r=-.83, p<.05).
Conclusions: Findings reveal that the ASQ is a good predictor of delays in development for children with ASD. Results provide support for the use of parent-report measures in identifying children requiring referrals for evaluations and parent perceptions regarding their children's skill level in the specific domains of nonverbal problem solving, fine motor, and communication skills. The social-emotional scale was also associated with Mullen performance; however, this scale did not predict specific autism symptomatology on the ADOS. Instead, the communication scale of the ASQ is indicative of social and communication ASD red flags. Practitioners are encouraged to pay close attention to the communication scale when considering whether a referral for an ASD specific evaluation is necessary. Overall, the ASQ appears useful to identify developmental delays but an autism specific screener is also indicated given the more limited associations with the ADOS.

46 **180.046** Action Prediction in Infants at-Risk for Autism: Neural and Behavioral Findings

R. Braukmann[1,2], *C. van den Boomen*[3,4], *N. M. Munsters*[3,4], *H. Bekkering*[2], *J. K. Buitelaar*[1] *and S. Hunnius*[2], *(1)Radboud University Medical Centre, Nijmegen, Netherlands, (2)Radboud University Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (3)Utrecht University, Utrecht, UT, Netherlands, (4)University Medical Centre Utrecht, Utrecht, Netherlands*

Background:

Recently, theoretical approaches on the underlying mechanisms of ASD suggest that abnormalities in forming and updating predictions about the environment might underlie several of the diverse deficits (van der Cruys et al.,2014; Pellicano & Burr,2012). The ability to predict others' behavior is important for social functioning, and research has indeed demonstrated prediction difficulties in ASD. Not only do children with ASD show behavioral impairments in action prediction (Zalla et al.,2010; Fabbri-Destro et al.,2009), abnormalities of the neural representation of others' actions in the motor system involved in forming predictions have also been reported (Cattaneo et al.,2007; Obermann et al.,2005).
Objectives:
Difficulties in predicting complex action sequences in older individuals with ASD might arise through abnormalities during the early development of action processing. In this study, we investigated whether deficits in processing and prediction can be observed already in infants at risk for ASD, by assessing action prediction abilities longitudinally in infants at high (HR) and low (LR) familial risk. From six months onwards, typically developing (TD) infants show more predictive eye movements towards the goal of usual compared to unusual everyday actions (Hunnius & Bekkering,2010). In addition, differential activation of the neural motor system during observation of usual compared to unusual actions in 12-month-old TD infants indicates that the infant motor system is already involved in action processing and forming predictions about observed actions (Stapel et al.,2010). In this study, we implement comparable experimental designs to study potential prediction abnormalities in HR infants.
Methods:
Action prediction was studied using eye-tracking at 10 months and EEG at 14 months. In both experiments, infants were presented with videos displaying an actor using everyday objects either in usual or unusual ways (Figure 1). In Experiment1, we used eye-tracking to assess the participants' ability to predict the action goal. In Experiment2, we investigated the infants' motor system response to the observed actions using EEG.
Results:
Preliminary eye-tracking data from 20 participants (15HR, Experiment1) suggests that HR infants perform similar to controls (Figure 2A). Both groups show predictive eye movements, anticipating more frequently to the correct goal location. Preliminary EEG data from 6 HR participants (Experiment2) suggests motor system activation during both action observation conditions (Figure 2B). Whereas previous research in TD infants suggests enhanced activation for unusual compared to usual actions (Stapel et al.,2010), in the HR group of the current study a conditional difference seems to be small or absent. Data collection is ongoing and results from a complete sample will be presented at the conference.
Conclusions:
Our preliminary data suggest that HR infants show similar behavioral signatures of predicting goal-directed actions as controls. In addition, their motor system is activated during action observation, but differential activation for the unusual compared to usual actions currently seems to be small or absent. If these observations hold in the complete sample, the dissociation of behavior and neural processing implies that while HR infants are able to predict simple goal-directed actions behaviorally, the neural processes associated with the formation of predictions are impaired.

Figure 1. Illustration of the experimental stimuli. Participants were presented with videos of a female actor manipulating everyday objects (a phone or a cup) either in a usual (i.e. moving the phone to the ear/ the cup to the mouth; top) or in an unusual way (i.e. moving the cup to the ear/ the phone to the mouth; bottom).

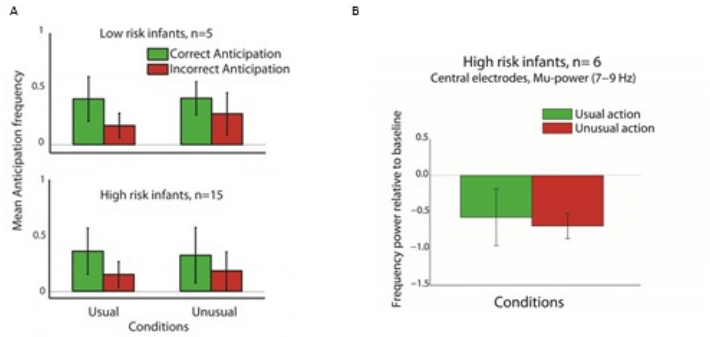

Figure 2. Preliminary data suggest that the groups of HR and LR infants performed similar in Experiment 1 (A). All infants seem to predict the correct goal location more frequently in both conditions. In Experiment 2 (B), HR infants show motor system activation during action observation, indicated by a suppression of central mu-frequency power for both conditions compared to baseline (see Marshall & Meltzoff, 2011). Differences between the two conditions seem to be small or absent.

47 **180.047** Adaptive Functioning in High-Functioning and Low-Functioning Preschool Children with Autism Spectrum Disorders

I. C. Chen *and C. C. Wu, Department of Psychology, Kaohsiung Medical University, Kaohsiung City, Taiwan*

Background:
In past studies, few studies examined the adaptive functioning in high-functioning and low-functioning preschool children with autism spectrum disorders (ASDs).
Objectives:
This study examined adaptive functioning of children with ASDs using the Adaptive Behavior Assessment System-II (ABAS-II) which is based on Taiwanese norm. Specific purposes included examination of (1) the difference of adaptive functioning between children with high-functioning autism spectrum disorders (HFASDs), with low-functioning autism spectrum disorders (LFASDs) and with developmental delay (DD); (2) the patterns of adaptive functioning in children with HFASDs, with LFASDs, and with DD.
Methods:
The participants, aged 2-5, were assigned into three groups according to Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR) and Mullen Scale of Early Learning. The ABAS-II was used to assess each child's adaptive functioning, including Conceptual, Socialization, and Practical domains. Children were diagnosed with ASDs according to DSM-IV-TR, whose developmental quotient (DQ), mental age (MA) divided by chronological age (CA), was above .70, belong to HFASDs group (n = 70) in contrast to DQ below .70 were in LFASDs group (n = 54). And, children whose DQ was below .70, but weren't diagnosed with ASDs were assigned to DD group (n = 39). Children in LFASDs group and DD group were matched on CA, MA, and DQ.
Results:
Results indicate that, first, in Socialization and Practical, children with LFASDs had significant deficits compared to children with DD and with HFASDs; In Conceptual, children with LFASDs and with DD were rated significantly lower than children with HFASDs, but no difference between children with LFASDs and with DD whose DQ were

matched. Second, there were interaction effects between the three groups and the three adaptive domains. Socialization is the relative weakness in children with HFASDs in contrast to all three adaptive domains has significant deficits in children with LFASDs. In addition, Conceptual was the relative weakness in children with DD.
Conclusions:
The results of this study provide us more details of adaptive functioning of preschool children with ASDs or DD, including both within-subject and between-subject profiles by using culture-appropriate scales. It's not surprising that children with ASDs had lower scores on Socialization domain, considering social interaction is the core deficit of ASDs. Besides, we found that caregivers had tended to give the relatively lower scores on ABAS-II if their children had a poor cognitive ability. The results showed on LFASDs and DD groups. However, children with LFASDs got poor adaptive behavior scores on all of the three domains, but DD group got a significant lower score on Conceptual. It reflects that the main deficit of children with DD is cognitive ability, so that caregivers scored lower on Conceptual domain which is more relevant to cognitive ability. These results would be helpful for classifying ASDs in a more precise way. Furthermore, it provides more information to early diagnosis and designing early interventions.

48 **180.048** Agreement Between Early Intervention Staff Impressions and Screening Tools for Autism Spectrum Disorder

N. Rasuratnam[1], *M. Penner*[2], *C. L. Saul*[3], *J. A. Brian*[4] *and W. Roberts*[5], *(1)ISAND, Scarborough, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Community and Health Services, York Region Early Intervention Services, Newmarket, ON, Canada, (4)Bloorview Research Institute, Toronto, ON, Canada, (5)University of Toronto, toronto, ON, Canada*

Background:
Early diagnosis of autism spectrum disorder (ASD) is important so that early intervention (EI) can begin as soon as possible. Early identification of ASD allows for earlier access to EI, during a time when neural plasticity is at its peak. Further research is needed to optimize identification of children with possible ASD through EI systems, including evaluating the role of standardized screening tools.
Objectives:
The objective of this study was to determine the agreement between ASD-targeted screening tools and the clinical impressions of EI clinicians.
Methods:
This study was carried out through York Region Early Intervention Services (YREIS), in Ontario, Canada. The screening tools used were the Modified Checklist for Autism in Toddlers – Revised with Follow-Up Interview (M-CHAT-R/F) and the CSBS DP Infant-Toddler Checklist (ITC). 235 packages containing the ASD-specific screening tools were distributed to families through YREIS' intake staff according to three age groupings: children 9-15 months received the ITC, children 16-24 months received the ITC and MCHAT-R/F, and children 25-30 months received the MCHAT-R/F. The MCHAT-R/F questionnaires were scored and those over the cut-off (score of 3 or higher) underwent the follow-up interview. During the intake process, the EI clinician (blinded to the results of the questionnaire) also filled a clinical opinion sheet indicating whether they suspected the child had ASD. The consistency between the EIS clinical opinions and the screening tools were measured using a kappa statistic.
Results:
Of the 235 distributed packages, 57 were returned back to YREIS (24% response rate). Of the 57 packages, 51 were completed. YREIS clinicians identified concerns about ASD in 25 of the 51 participants (49%). Of the completed MCHAT-R/F's, 11 of 39 (28%) were positive (indicating concern), compared with 14 of 26 ITC questionnaires (54%). In the comparison between clinical opinion and the ITC in 26 participants, kappa was calculated to be 0.429, demonstrating fair agreement. Agreement was calculated for the MCHAT-R only and clinical opinion in 46 participants, which showed a kappa of 0.136 (slight agreement). The kappa for the full M-CHAT-R/F (39 participants) and clinical opinion was 0.238 (fair agreement). The agreement between one positive screening tool and clinical opinion (51 participants) was 0.280, demonstrating fair agreement.
Conclusions:
The results of this study show a disappointing level of agreement between EI staff and ASD-targeted questionnaires. There was a higher rate of concern in the EI staff when compared with the M-CHAT-R/F. The ITC has lower specificity for ASD, which may explain the higher proportion of identified concerning cases when compared with the M-CHAT-R/F. These results suggest that combined use of clinical opinion and screening tools is likely to maximize the proportion of cases of suspected ASD identified through EI intake processes, with a trade-off of lower specificity.

49 **180.049** Analysis of Alpha Power in 9-Month Old Infants at High-Risk of ASD

A. Miquelajauregui*, C. Ponting, A. Marin, J. Frohlich and S. S. Jeste, Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: Previous studies found differences in frontal alpha waves characterizing infants at high-risk (HR) for ASD when compared to low-risk (LR) age-matched groups. In particular, decreased frontal alpha power and altered hemispheric asymmetry have been described during the first year of life (Tierney et al., 2012; Gabard-Durnam et al., 2015). Interestingly, the developmental trajectories of alpha asymmetry proceeded in opposite directions between groups: whereas LR infants showed an initial relative right frontal power at 6 months, HR infants presented left frontal asymmetry initially, decreasing with age at 12 and 18 months (Gabard-Durnam et al., 2015).
Objectives:
Given the differences described for alpha bandwidth between HR and LR infants, we aimed to examine alpha power at 9 months, around the time when alpha asymmetry shift is predicted to take place. We thus asked whether alpha power differed between HR and LR groups in frontal and posterior regions.
Methods:
Resting EEG data at 9 months of age were collected from HR infants (n=25; F: 37.5%; M: 62.5%; including 4 ultra high-risk subjects, defined as having more than one sibling with ASD), and LR infants (n=16; F/M: 50%) using high-density 128-hydrogel nets (EGI inc). In NetStation, data were filtered at 1–50 Hz, divided into 1 sec. segments and re-referenced using an average reference. Segments containing artifacts were visually inspected and removed from the analysis. Regions of interest (ROIs) were defined as

described before (McEvoy et al. 2015). We calculated absolute alpha power at 6-9 Hz, a well-defined band for infant alpha EEG (Stroganova et al., 1999; Marshall et al., 2002).
Results:
Absolute alpha power was analyzed at frontal and posterior locations. Independent samples t-test revealed a slight trend towards decreased frontal alpha in HR compared to LR (mean ± SEM: 11.14 ± 1.3 vs.12.96 ± 2.0, respectively; p=0.43, t=0.80), with no significant differences at posterior sites (HR: 14.12 ± 1.4, LR:13.60 ± 1.9; p=0.72, t=0.36). Although frontal hemispheric asymmetry scores (right-left) were similar (HR: -0.25 ± 0.73; LR: -0.75 ± 1.6; p=0.92, t=0.11); posterior-frontal asymmetry scores showed highly significant differences (HR: 2.97 ± 0.56; LR: 0.65 ± 0.66; p=0.013, t=2.60). In spite of being limited by our sample size, UHR infants generally followed the trend of their assigned group (HR).
Conclusions:
Overall, our data suggest that alpha power is a useful indicator of ASD risk in infancy. The significant reduction in posterior-frontal scores, together with the trend towards reduced frontal alpha, indicate that relevant rearrangements in the distribution of alpha occur at this critical developmental age.

50 **180.050** Assessment of Intelligence: A Comparison of Intellectual and Adaptive Functioning in Preschool Autistic Children

D. Girard[1], *V. Courchesne*[2], *E. Danis*[1], *M. Descamps*[1] *and I. Soulières*[1], *(1)University of Quebec in Montreal, Montreal, QC, Canada, (2)University of Montreal, Montréal, QC, Canada*

Background: DSM-5 autism diagnosis must specify whether there is an accompanying intellectual deficiency, but few intellectual tests are available for children under age 3. Available tests to assess cognitive development mostly consist of developmental scales that may not accurately represent the potential of young autistic children, whose developmental paths are highly atypical. Indeed, school-aged autistic children perform differently depending on the test used to assess their intelligence (Dawson et al., 2007) and present a discrepancy between intelligence and adaptive level (Charman et al., 2011). Typically used tests in preschool years are Vineland Adaptive Behavior Scales (VABS) and Mullen Scales of Early Learning (MSEL). The differences and resemblances in the performance of ASD preschoolers on those two tests is not well documented.
Objectives: 1) To compare performance of young autistic (ASD), developmentally delayed (DD) and typically developing (TD) children on MSEL and VABS, respectively used as indicators of IQ and adaptive level in young autistic children. 2) To examine the difference between the similar subscales in VABS and MSEL in each group (e.g. receptive language, expressive language and fine motor subscales). 3) To explore the MSEL subscale profile in each group.
Methods: Recruitment is ongoing, and the goal is to reach groups of 40 ASD, 40 DD and 40 TD. To date, the sample includes 29 ASD, 12 DD and 31 TD children aged 18 months to 5 years old. No exclusion criteria were applied in the clinical groups.
Results: MSEL global score was significantly higher than VABS global score in autistic (p<.001) and DD (p<.01) children, but not in TD children (p=.211). As expected, ASD and DD children performed significantly lower than typical children on both tests (p<.001). On expressive language subscales, performance on MSEL was significantly lower than performance on VABS in ASD (p<.001) and DD children (p<.05), but not in TD children (p=.573). On receptive language subscales, there was a main effect of Test (p<.01), VABS score being significantly higher than MSEL score. There was also a main effect of the group, ASD and DD children scoring lower in receptive language than typical children (p< .001). Finally, ASD (p<.001) and DD (p<.05) children performed significantly lower on MSEL subscale assessing fine motor abilities than on the corresponding VABS subscale. In MSEL, visual reception scores were significantly higher than the three others in the ASD group, while there was no significant difference among subscales in the TD group.
Conclusions: These preliminary results indicate that intellectual potential can be judged very differently depending on the type of test used in preschool children with developmental delays and/or ASD. Clinical groups performed better on MSEL compared to VABS global scores, but the reverse when comparing similar subscales from the two tests (receptive and expressive language, and fine motor abilities). This suggests that the information reported by the caregiver may differ substantially from performance in a formal evaluation setting. Hence, the two assessment methods (self-reported vs. observed) are both important and should be interpreted with prudence, especially in preschool children with atypical development.

51 **180.051** Atypical Relationship Between Anxiety and Approach-Withdrawal Behavior in Young Children with Autism

H. J. Nuske[1,2], *D. Hedley*[2] *and C. Dissanayake*[2], *(1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background:
Prevalence rates of anxiety disorders in children with autism are much higher than in typically developing children. There is also significant symptom overlap between the anxiety and autism disorders, for example, in social withdrawal and avoidant behavior.
Objectives:
Here we attempt to disentangle the unique contribution of anxiety to behavioral response to threat by examining approach and avoidance/withdrawal behavior in the context of mildly aversive social and non-social stimuli, in children with and without autism. We hypothesized that children with autism would exhibit more avoidant behavior in response to social, but not non-social aversive stimuli, compared to typically developing children. We also hypothesized an interaction between anxiety symptoms and stimulus, such that children with higher levels of anxiety would respond similarly to both social and non-social stimuli.
Methods:
A total of 70 children aged 2-4 years participated in our study, with 41 children with autism (32 M) and 29 typically developing controls (22 M). Results are from the first videos coded (by coders blind to diagnostic group): 12 children with autism and 15 typically developing children (presentation will include analyses of entire group). Social and non-social approach-withdrawal was assessed using the Stranger task of the Laboratory – Temperament Assessment Battery (LabTAB) (a 'stranger' enters the room and interacts with the child) and the Unpredictable Mechanical Toy task of the LabTAB (battery-operated toys are presented to the child). Total time (in seconds) that children were engaged in proximity-related behavior (time spent approaching vs. avoiding the stranger and toys) was coded, as was the total time (in seconds) that children attended to vs. away from the stimuli. We created two approach-avoidance indices by determining the ratio of time (seconds) spent approaching vs. avoiding the stimulus and looking at vs. away from the stimulus (i.e., we calculated separate proximity and attention indices). A low index value (less than 50) indicated a relatively greater proportion of time engaged in withdrawal behavior/gaze aversion and a high index value (greater than 50) indicating a relatively greater proportion of time engaged in approach behavior/stimulus attention. Anxiety symptoms were assessed with the Early Childhood Inventory-5.
Results:
Proximity Index. As predicted, children with autism exhibited similar patterns of approach vs. avoidant behavior as did the control children in the non-social condition (p=0.19, η^2=0.07), and increased avoidance in the social condition (p<0.01, η^2=0.40) (see Figure 1).
Attention Index. Children with autism looked less to the stimuli than the typically developing group overall, $F(1, 26)= 7.47$, p =.01, η^2 =.23 and showed more gaze avoidance with social than non-social stimuli (p< .001, η^2= .62) (Figure 2). Interestingly however, higher symptoms of Generalized Anxiety Disorder in the autism group were marginally related to *increased* attention in the social condition (r= .55, p= .07) a pattern not seen in the typical developing children (r= -.48, p= .17).
Conclusions:
These preliminary results suggest an atypical relationship between anxiety and socially-directed attention in autism, indicating a pattern of vigilance in this group not seen in the typical children (pending final analyses).

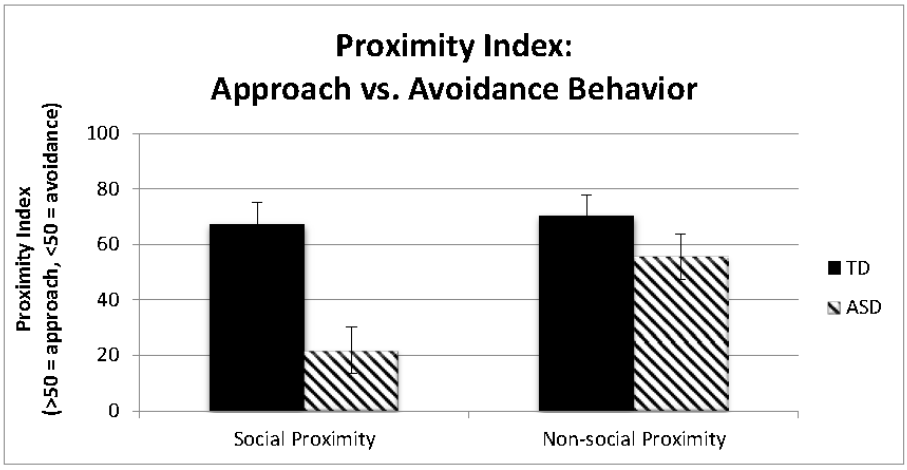

Figure 1. Proximity towards or away from social and non-social anxiety provoking stimuli for children with and without autism (higher scores signify increased proximity to the stimulus). Error bars = standard error.

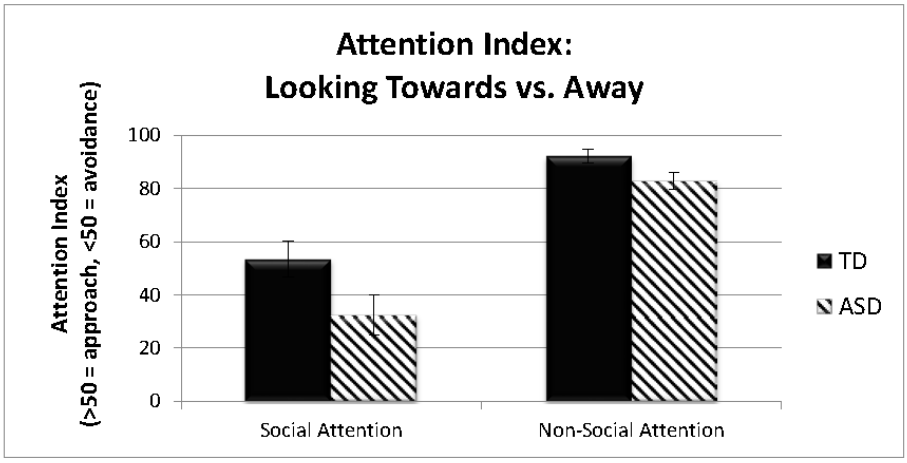

Figure 2. Attention towards or away from social and non-social anxiety provoking stimuli for children with and without autism (higher scores signify increased attention to the stimulus). Error bars = standard error.

52 **180.052** Atypical Visual Attention and Autism Severity in Infants at High Risk for Autism Spectrum Disorders

***D. Reisinger**, A. Brewe and J. E. Roberts, Psychology, University of South Carolina, Columbia, SC*

Background: Early visual attention control is a foundational developmental skill important for social engagement in infancy across typical and clinical populations. Evidence suggests that individuals with Autism Spectrum Disorders (ASD) have a primary impairment in social functioning shown to manifest in early infancy with reduced eye contact, atypical gaze behaviors, and atypical attention disengagement (Elsabbagh, 2013). Furthermore, developmental changes between the ages of 6 to 12 months in their disengagement of visual attention may cause longer attention shifts that has been shown to predict later ASD diagnoses (Ibanez et al., 2008). Infants with fragile X syndrome (FXS) and infants with an older sibling diagnosed with ASD (ASIBs) are at high risk for developing ASD; thus, investigating early deficits in visual attention can help characterize the infant phenotype of FXS and ASIBs and serve as a potential prognostic indicator of ASD risk.
Objectives: Characterize the relationship of initial latency to disengage from a non-social stimulus and frequency in attention shifts across FXS and ASIBs at 12 months of age and the potential predictive value of these attention patterns to ASD severity at 24 months.
Methods: Participants included infant males with FXS (n=13), ASIBs; n=26), and a typically developing group (TD; n=18) assessed at 12 and 24 months of age. A toy play epoch from the Laboratory Temperament Assessment Battery (LabTAB; Goldsmith & Rothbart, 1996) reflected duration of attention to a social stimulus (mother/examiner), initial latency to disengage attention from the toy, and frequency of visual shifts in attention to the non-social stimuli (e.g., shifts away and to the toy). Behaviors were coded

offline with a kappa of > 0.80. The Mullen controlled for developmental level, and the autism severity score from the Autism Diagnostic Observation Schedule-2 at the 24-month assessment represented autistic behavior.
Results: Developmental level was included in all models. No group differences were found in the duration of gaze to the social stimuli, $F(2,53)=2.48$, $p=0.09$, partial $\eta^2= 0.09$, or in their latency to disengage from the non-social stimulus, $F(2,53)=1.84$, $p=0.17$, partial $\eta^2= 0.06$. Group differences were found in attentional shifts, $F(2,53)=5.88$, $p=0.005$, partial $\eta^2= 0.20$, indicating infants with FXS had less attentional shifts ($M=8.52$, $SD=2.06$) than infant ASIBs ($M=16.81$, $SD=1.35$) and TD infants ($M=16.79$, $SD=1.56$). No differences were found between ASIB and TD infants ($p>0.05$). Regression analyses indicated that attention to the social stimuli predicted later ASD severity, $F(2,23)=3.46$, $p=0.04$, $R^2 = 0.16$ while latency to disengage did not predict later ASD severity, $F(2,23)=2.23$, $p=0.13$, $R^2=0.09$. A trend was evident for attentional shifts predicting ASD severity, $F(2,23)=3.18$, $p=0.06$, $R^2=0.15$. No group effects emerged for these regressions.
Conclusions: Results suggest that infants with FXS had less attention shifts than both ASIB and TD infants. Furthermore, our results support that decreased attention to social stimuli at 12 months was associated with autism symptoms at 24-months-of-age across groups. These findings suggest that atypical visual attention may be a phenotypic feature for infants with FXS and ASIBs and highlight the potential value of visual attention as a prognostic indicator of autism risk in these populations.

53 **180.053** Autism Symptoms Profiles in Toddlers with Tuberous Sclerosis Complex

S. S. Jeste[1], *K. J. Varcin*[2], *G. Hellemann*[3], *A. Gulsrud*[4], *C. Kasari*[5], *M. Sahin*[6], *J. Y. Wu*[7] *and C. A. Nelson*[8], *(1)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (2)Harvard Medical School, Boston Children's Hospital, Cambridge, MA, (3)Psychiatry and Biobehavioral Sciences, UCLA Center for Autism Research and Treatment, Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (5)University of California Los Angeles, Los Angeles, CA, (6)Department of Neurology, Boston Children's Hospital, Boston, MA, (7)UCLA, Los Angeles, CA, (8)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: TSC is one of the most commonly occurring single-gene disorders associated with ASD, with rates of ASD in TSC approaching 60% (Bolton, 2002; Jeste, 2008). Given the high rate of ASD in TSC and the fact that TSC is often diagnosed in utero or in early infancy (Datta, 2008) prior to the onset of social communication delays, TSC has been considered a model system for understanding mechanisms underlying ASD (Tsai, 2012; Tye, 2013; Davis, 2015). However, the specific phenotypic profile of ASD in TSC and the extent to which it converges with non-syndromic ASD has not been well established (Moss, 2009; Van Eeghen, 2013). Moreover, given our findings of non-verbal cognitive function predicting ASD in infants with TSC (Jeste et al, 2014), we hypothesized that a distinctive autism symptom profile would emerge in TSC characterized by non-verbal communication impairments and global developmental delay.
Objectives: To determine the extent to which deficits associated with ASD in TSC overlap with those in toddlers with non-syndromic ASD by examining item-level symptom profiles from a play-based diagnostic measure of ASD (the Autism Diagnostic Observation Schedule [ADOS]) and, second, to examine the clinical characteristics of toddlers with TSC and ASD by comparing cognitive function and epilepsy severity between toddlers with and without an ASD diagnosis.
Methods: This is the endpoint analysis from the first longitudinal investigation of autism risk factors in infants with TSC. Measures included the Autism Diagnostic Observation Schedule (ADOS), the Mullen Scales of Early Learning (MSEL), and for the TSC group, clinical epilepsy variables. Four groups were compared for the primary analysis: TD, TSC/no ASD, TSC/ASD, nonsyndromic ASD. A repeated measures analysis of variance (ANOVA) was performed with the between subjects factor of group and within subjects factors of each ADOS item in the social communication and repetitive behavior/restricted interest domains. Within TSC group comparisons on epilepsy characteristics and cognitive domains were performed using independent samples t tests.
Results: Children with TSC and ASD demonstrate a profile of social communication impairment that, at the behavioral level, has almost complete convergence to that of children with non-syndromic ASD. There were no individual markers that distinguished the two groups. This convergence was observed despite the high comorbidity between ASD and cognitive impairment in the TSC group. Within the TSC group, although there were trends towards greater seizure severity in those children with TSC/ASD, there were no statistically significant differences in epilepsy characteristics between those with and without ASD.
Conclusions: This study supports the clinical diagnosis of ASD in young children with TSC and demonstrates remarkable convergence of autism symptoms between TSC/ASD and non-syndromic ASD, despite greater cognitive impairment in children with TSC. Our results necessitate a study of early intervention in toddlers with TSC, with treatment strategies targeting social communication function as well as broader developmental domains, before the onset of autism symptoms.

(E) TSC/ASD (with SD)

54 **180.054** Behavioral Indicators of Social Fear in Preschool-Aged Children with ASD and Siblings of Children with ASD

A. L. Hogan-Brown*, J. Scherr and J. Roberts, Psychology, University of South Carolina, Columbia, SC*

Background: Social anxiety is one of the most common comorbidities of autism spectrum disorder (ASD), with at least 20% of children with ASD meeting diagnostic criteria for social anxiety disorder (for review, see White et al., 2009). Though there is some evidence that social anxiety develops in early childhood in both typically developing children and children with ASD (Davis et al., 2011), very few studies have sought to characterize early behavioral indicators of social anxiety in young children with ASD. Because elevated symptoms of social anxiety are associated with poorer social and academic outcomes in ASD as well as typical populations, identifying early behavioral indicators of social anxiety (e.g., social fear) is of critical importance for early treatment of anxiety symptoms and optimization of outcomes. This study examined social fear in preschool-aged children with ASD and typically developing controls.
Objectives: To examine social fear in preschool-aged children with ASD and younger siblings of individuals with ASD, contrasted with typically developing controls.
Methods: The study included 75 children (24 ASD, 10 siblings without ASD, and 41 TD), aged 23 to 70 months. The Stranger Approach epoch of the Laboratory Temperament Assessment Battery (Lab-TAB; Goldsmith & Rothbart, 1996) was used to elicit behavioral indicators of social fear (e.g., gaze). ASD symptoms were assessed concurrently using the Autism Diagnostic Observation Scale - 2 (ADOS-2) and/or the Childhood Autism Rating Scale (CARS). Results include the first videos coded (24 ASD and 41 TD).
Results: Preliminary results indicated that groups differed on avoidant gaze (i.e., averting gaze away from the stranger), $p < .05$. More specifically, children with ASD

demonstrated more avoidant gaze relative to TD controls. ASD symptom severity, as measured by the CARS, was correlated with proportion of time looking away from the stranger, $r = .33$, $p < .01$. In sum, findings suggest that early behavioral signs of social anxiety are present at elevated levels in children with ASD by the time they reach preschool age. These data are being extended by inclusion of additional participants, a high-risk sibling group, and integration of the ADOS-2.
Conclusions: Findings suggest that early behavioral signs of social anxiety (e.g. avoidant gaze behavior when approached by a stranger) are present at elevated levels in children with ASD by the time they reach preschool age.

55 **180.055** Behavioral Intervention Improves Social Communication Skills in Infants with Tuberous Sclerosis Complex

A. Gulsrud[1], *S. S. Jeste*[2], *N. Tu*[3], *S. Huberty*[4], *C. K. McCracken*[5] *and C. Kasari*[3], *(1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)Psychiatry and Biobehavioral Sciences, UCLA Center for Autism Research and Treatment, Los Angeles, CA, (5)University of California, Los Angeles, El Segundo, CA*

Background: Tuberous Sclerosis Complex (TSC) is an autosomal dominant disorder strongly associated with cognitive impairment, behavioral disturbances, and autism spectrum disorders (ASD), with rates of ASD ranging from 30-60% (Jeste, 2008). Young children with TSC demonstrate specific delays in nonverbal cognition, visual attention and social communication, making these important targets for intervention (Jeste, 2014). Despite this developmental profile, no studies have investigated the efficacy of behavioral interventions in this population. The current pilot study integrates infants and toddlers with TSC ages 12-36 months into an existing early intervention study of the Joint Attention, Symbolic Play, Engagement and Regulation (JASPER), which targets social communication function in infants and toddlers at high risk for ASD (NIMH 2P50HD055784-06 PI: Kasari). The JASPER intervention (a) targets the foundations of social-communication (joint attention, imitation, play), (b) uses naturalistic strategies to increase the rate and complexity of social-communication and (c) includes parents as implementers of the intervention to promote generalization across settings and activities and to ensure maintenance over time.
Objectives: To examine the effects of the experimental intervention (JASPER) on the primary outcome of joint engagement and secondary outcome of parental strategy use in TSC infant-toddlers compared to IQ matched non-TSC infant-toddlers at risk for ASD.
Methods: Participants included five infant-toddlers with TSC and five IQ matched non-TSC infant-toddlers at-risk for ASD. Infant-toddlers were approximately 19 months old, with the TSC group consisting of slightly older children. Average IQ was 75.4 (sd=24.1) and 70.2 (sd=17.1), respectively for TSC and non-TSC children; $t(8) = -.39$, $p = .70$. All children received the experimental JASPER intervention. Parents and children came to UCLA twice per week for 2.5 hours per session across the 8 weeks. A 10 minute parent- child play interaction was videotaped prior to and immediately following an 8 week intervention. The total time in mutually shared play routines and parent use of JASPER strategies were coded.
Results: A paired samples t-test revealed that the TSC group increased in total time spent in jointly engaged play routines ($t(4) = -3.5$, $p = .03$) from pre to post treatment. Similarly parents improved in their implementation of the JASPER intervention by increasing their use of joint attention gesturing ($t(4) = -3.6$, $p = .02$) and the quality of their play routines ($t(4) = -4.3$, $p = .01$) across the intervention period. The non-TSC group showed similar findings in increased time in play routines ($t(4) = -2.6$, $p = .06$), and parents use of joint attention ($t(4) = -5.0$, $p = .01$), and overall quality of play routine ($t(4) = -9.5$, $p = .001$). The pre to post intervention change was in the same order magnitude for the TSC group compared to the non-TSC group at-risk for ASD.
Conclusions: This study provides preliminary evidence for the effectiveness of a targeted social-communication intervention for young children with TSC. Similar to children at-risk for ASD, children with TSC increased their time spent jointly engaged in play with their parents and parents were able to improve their use of social communication strategies. Replication with a larger sample sizes is underway that investigates both behavioral and biological markers of treatment outcome.

56 **180.056** Can Joint Attention Skills be Measured Reliably? Dutch Effect Study of Jasper-Training

M. E. Buruma[1] *and* ***E. M. Blijd-Hoogewys***[2], *(1)Infant team, INTER-PSY, Groningen, Netherlands, (2)Autism Team, INTER-PSY, Groningen, Netherlands*

Background:
Infants with autism spectrum disorders (ASD) have problems with social interaction, communication and play (Zwaigenbaum et al., 2013). Early intervention can lead to better long-term outcomes (Dawson et al., 2010). Early stimulation of joint attention (JA) skills, in particular, is associated with better language, communication and social outcomes (Warreyn et al., 2014; White et al., 2011).
The JASPER training (Kasari et al., 2006) focuses on Joint Attention Symbolic Play Engagement and Regulation in young children. During play sessions, parents learn how they can encourage JA and play skills in their child. They learn how to recognize, model, connect and expand these skills. If applicable, parents also learn how they can support their child in regulating its emotions.
Objectives:
Is the Dutch version of the JASPER training effective in infants with ASD?
Can we develop an observation standard to reliably assess JA amelioration?
Methods:
Infants with ASD, developmental delays and limited spoken language (2-4 years old, ADOS-2, BSID-II) participated in the JASPER training. There were 15 weekly sessions: 10 play sessions (30-45 minutes, with child & parent(s)) and 5 evaluation sessions (60 minutes, with parent(s) only). All JASPER play sessions were videotaped and later used during the evaluation sessions with parents.
There were two control groups: a clinical non-JASPER group (infants with ASD who did not receive the JASPER training) and a typically developing group (TD).
Pre- and post-treatment, parents filled in the ESCBQ (Early Social Communicative Behavior Questionnaire) and the PICS (Pictorial Infant Communication Scale), as measurements for JA and other early social communicative behaviors.
Results:
The data collection is ongoing (N = 20 have been collected).
Preliminary results of a small group of infants with ASD (n = 4) show that specific skills improved significantly at post-treatment, in comparison with the clinical non-JASPER group, as measured by 4 ESCBQ subscales (Mann Whitney: z(-2.081), z(-1.875), (z(-1.979), z(-1.732); $p < .05$; eye contact, emotion, gaze following and showing respectively) and all 3 PICS subscales (Mann Whitney: z(-1.955), z(-1.949), z(-2.453); $p < .05$; initiating JA, initiating behavior request, and responding to JA respectively). Though, their skills are still at a significant lower level than that of TD children (ESCBQ total score; z (-1.874), $p < 0.05$; no data available concerning BICS).
In order to really capture the amelioration of early social communicative behaviors through parent child interactions, a qualitative coding system needed to be developed. Originally, 46 categories were formulated in MediaCoder, based on literature study and clinical experience. The statistical analyzes proved multiple categories to be unreliable, difficult to operationalize and/or poor on inter- and intra-variability. Therefore, the subsequent qualitative coding system consists of 15 child and 5 parent categories. Currently, all JASPER videotapes of another small group of infants with ASD (n=4) are being coded with this new coding system.
Conclusions:
The first results concerning the JASPER intervention study are promising and in line with former findings (Kasari et al., 2006, 2008, 2010, 2012, 2014; Stickles-Goods et al., 2013). A qualitative coding system is being developed. Further research is warranted.

57 **180.057** Capturing the Moment: Using the Autism Observational Scale for Infants (AOSI) to Assess the Developing Phenotype in a Prospective Sample of High Risk Children for ASD

J. Pandey[1], *E. Schriver*[2], *S. Ozonoff*[3], *R. Landa*[4], *S. E. Levy*[1], *A. T. Pomykacz*[5], *C. R. Hess*[6], *M. V. Hsu*[7], *M. D. Fallin*[8], *I. Hertz-Picciotto*[9], *L. A. Croen*[10] *and C. J. Newschaffer*[2], *(1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)UC Davis MIND Institute, Sacramento, CA, (4)The Kennedy Krieger Institute, Baltimore, MD, (5)Center for Autism Research, Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (6)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (7)Kaiser Permanente ASD Center, San Jose, CA, (8)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (9)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (10)Division of Research, Kaiser Permanente, Oakland, CA*

Background: Following the development of high-risk (HR) sibling cohorts allows for the identification of earlier differences in those who later develop ASD, and can serve as an indicator of early life development. While certain markers have been documented, the cascade of symptom development with environmental influences is not reported and is important for early intervention. The Autism Observational Scale for Infants (AOSI) is an experimenter-led assessment that measures early behavioral markers of ASD between 6 -18 months. The measure captures atypical social communication, non-social behaviors, temperament and repetitive behavior markers, yielding a Total Score (TS).
Objectives: To assess the predictive accuracy of AOSI scores for ASD classification at 36 months in a HR infant cohort and to examine accuracy across variable AOSI cutoff scores.
Methods: Participants represented a subset of HR children in the Early Autism Risk Longitudinal Investigation (EARLI). Infants (n=132) were given the AOSI at 6 and/or 12 months of age and an ASD diagnostic evaluation at 36 months. Diagnostic outcomes were determined by two clinicians using clinical best estimate, utilizing information from the Mullen Scales of Early Learning and Autism Diagnostic Observation Schedule (ADOS-2). ANOVAs were conducted to assess the difference in AOSI TS at 6 and 12 months, receiver operatic characteristic (ROC) analyses examined how well AOSI TS predicted diagnostic outcome when comparing ASD/NON-ASD samples combined, and then comparing NTD/TD separately. Spearman Correlations compared 36 month ADOS Comparison Scores to the AOSI TS at both 6 and 12 months.

Results: At 36 months, 30 children (23%; 26 males) met DSM-5 ASD criteria; 38 had other delays (non-typically developing; NTD); and 64 were developing typically (TD).Twelve month AOSI TS predicted 36 month ASD status better than 6 month AOSI TS. There was a difference in AOSI TS across the three outcome groups at 12 months (Kruskal-Wallis, p=0.004), but not at 6 months (ANOVA, p=0.12). AOSI 12 month scores (cutoff point = 6 using distance closest to (0,1) and Youden criteria) had a sensitivity of 0.63 and specificity of 0.68 (Area under Curve (AUC) =0.68; PPV=0.37, NPV=0.83) when comparing children with ASD to Non-ASD samples overall. At 12 months, when comparing ASD vs. TD and ASD vs. NTD, the AOSI had a higher sensitivity (vs. TD=0.61, vs. NTD= 0.57) and specificity (vs. TD=0.77, vs. NTD=0.62). The AOSI score had little predictability at 6 months when comparing ASD to Non-ASD (AUC=0.59). 36 month ADOS Comparison Scores were significantly correlated to the AOSI TS at 12 months (r=0.24; p=0.008), but not 6 months (r=0.08; p=0.33).
Conclusions: Our findings are consistent with previous reports of emergence of behavioral symptoms over time as the AOSI differentiated children with ASD from NTD/TD better at 12 months than 6 months. Additionally, the 12-month AOSI better differentiated ASD from TD than NTD, which is not surprising given the overlap in behavioral presentation between ASD and NTD groups. Along with overall diagnostic classification, the 36-month ADOS was significantly correlated with the AOSI at 12 months, supporting the emergence of the ASD behavioral phenotype over time.

EARLI Sample Characteristics – 6, 12, and 36 months			
	6 months*	12 months*	36 months*
Age at Visit (6mo N=128, 12mo N=132, 36mo N=123)	6.2 (1.5)	12.3 (0.74)	36.6 (0.99)
Gender			
Males	74 (57.8%)	75 (56.8%)	68 (55.3%)
Female	54 (42.2%)	57 (43.2%)	55 (44.7%)
AOSI Total Score (6mo N=128, 12mo N=132)	10.6 (4.3)	5.3 (4.1)	--

58 **180.058** Children with Persistent, Idiopathic Feeding Difficulties: An at Risk Group for Developing Autism Spectrum Disorder?

P. Warreyn[1], *E. Van de Sijpe*[1] *and I. De Groote*[2], *(1)Ghent University, Ghent, Belgium, (2)Ghent University Hospital, Ghent, Belgium*

Background:
Feeding and eating problems, e.g., food selectivity associated with taste or texture, are often reported in children with autism spectrum disorder (ASD; Field et al., 2003; Sharp et al., 2013). These feeding problems have also been linked to autism severity (Aponte et al., 2015) and are often among the first concerns reported by parents (Olsson et al. 2013). Following up infants with persistent feeding difficulties may therefore be an additional strategy to learn about early markers of and developmental trajectories into ASD. However, to our knowledge, no such studies have been conducted yet.
Objectives:
The aim of the current study was to assess ASD risk in a group of young children referred for persistent, idiopathic feeding difficulties.
Methods:
In a period of 4 years, 32 young children (20 boys) between 12 and 73 months old, were referred to the University infant and child psychiatric unit (ICPU) with persistent feeding difficulties after medical (e.g., reflux) or organic (e.g., swallowing problems) causes were excluded by a specialised paediatric unit. Demographic characteristics (gender, age), history of the feeding problems (age and type), medical history (pregnancy and birth complications, developmental problems), details of the current feeding problems and contextual factors were linked with infant- and child psychiatric diagnosis of the children.
Results:
For 4 children, the parents refused a full assessment at the ICPU. Of the 28 remaining children, 4 (14%) were diagnosed with ASD (all boys), and an additional 7 (25%; 4 girls) received a working diagnosis of ASD (and will be followed up further). There were no differences between the children with (working diagnosis of) ASD and those without ASD in age of first concern, age at first consultation in the ICPU, complications during pregnancy or birth and contextual factors. Children with (working diagnosis of) ASD were less likely to have had problems with liquid food or with food intake before the age of 4 months ($\chi^2 = 8.866$, $p < .05$ and $\chi^2 = 4.196$, $p < .05$, respectively), but problems at other ages with other types of food were equally likely in both groups. At the moment of assessment at the ICPU, however, children with (working diagnosis of) ASD were more likely to still have problems with solid food, with or without lumps ($\chi^2 = 5.916$, $p < .05$ and $\chi^2 = 3.962$, $p < .05$, respectively). They were also more likely to have a language delay ($\chi^2 = 11.733$) or to be sensory overreactive ($\chi^2 = 5.051$, $p < .05$).
Conclusions:
Children with persistent, idiopathic feeding difficulties are at increased risk for ASD. In the children with ASD, the feeding difficulties usually started when solid food was introduced, and these problems with solid food were more persistent than in children without ASD. The current pilot study has implications for the early detection of ASD risk, and for the treatment of a subgroup of children with feeding difficulties.

59 **180.059** Circadian Profiles of Infants from Families with a History of Autism

G. L. Glickman[1], *E. M. Harrison*[1] *and K. R. Dobkins*[2], *(1)Center for Circadian Biology, University of California, San Diego, La Jolla, CA, (2)Department of Psychology, University of California, San Diego, La Jolla, CA*

Background: Sleep problems and irregular hormone profiles are extremely common in children with Autism Spectrum Disorder (ASD), suggesting impairments in the circadian timing system. While sleep and circadian disturbances have also been observed in adolescents and adults with ASD, early development of these physiological functions has not yet been examined. Since ASD is only diagnosed reliably after 2-3 years of age, we are taking the innovative approach of examining sleep and hormone rhythms in infants at greater risk for developing ASD because they have an older sibling with the disorder.
Objectives: Sleep and circadian rhythms are being rigorously characterized in these high-risk infants as well as in infant siblings of typical children at three different ages that represent important milestones in the early development of the circadian system: 3, 9 and 12 months.
Methods: At each age, sleep-wake patterns are examined with actigraphy, sleep diary and a modified version of the Sleep Habits Questionnaire, and fluctuations in melatonin and cortisol are examined across one mid-week day via assessment of saliva at 5 time points (8 AM, 9 AM, 10 AM, 6 PM and 9 PM). Patterns of light exposure, an important environmental factor that regulates both sleep and circadian rhythms, are also being measured, using both diary information and photosensors embedded within the actigraph devices.
Results: Thus far, seven consecutive days of sleep diaries and actigraphy as well as one day of serial salivary sampling have been collected for each infant (N=14, n=3 high-risk at mean±SD age=94.5±6.4 days; n=11 low-risk, mean±SD age= 95.3±10.5 days). Actigraphy data to date shows statistical differences between high- and low-risk infants

in terms of mean sleep latency, with high-risk infants taking significantly longer to fall asleep (t=2.63, p<0.05). In addition, preliminary analysis of diary measures indicates that sleep is more asymmetrically distributed across the 24 h day in high-risk infants, with more sleep during morning hours, as compared with low-risk infants (t=4.24, p <0.01). Though still underpowered, the patterns of results also reveal greater light exposure and poorer sleep efficiency in high- versus low-risk infants. Salivary melatonin and cortisol assays are currently underway, providing data that will allow for the determination of phase angle relationships between sleep and hormone rhythms.
Conclusions: Sleep and circadian rhythm abnormalities may be observed at even the earliest stages of development in infants with a family history of ASD. Ultimately, a better understanding of the sleep and circadian dysfunction that often co-occur with ASD may help guide treatment strategies and minimize the negative impact of these disturbances on both the children and their families.

60 **180.060** Comparison of Children with ASD at 3 Years of Age Ascertained from Community Screening in Primary Care Versus from a Prospective Infant Sibling Cohort

T. N. Day[1], *A. M. Wetherby*[2], *C. Nottke*[2], *A. Delehanty*[3], *A. M. Iosif*[4] *and S. Ozonoff*[5], *(1)Clinical Psychology, Florida State University, Tallahassee, FL, (2)Florida State University Autism Institute, Tallahassee, FL, (3)Communication Science & Disorders, Florida State University, Tallahassee, FL, (4)Public Health Sciences, University of California Davis, Davis, CA, (5)UC Davis MIND Institute, Sacramento, CA*

Background: Prospective research of infants at high-risk (HR) for ASD due to having an older sibling with ASD has provided critical information about early signs and developmental characteristics of ASD. HR infant sibling studies have shown that early signs are distinguishable at 12-18 months in infants later diagnosed with ASD suggesting that early detection is possible. However, the developmental level of infant sibling cohorts (Ozonoff et al., 2015) appears to be substantially higher than community samples ascertained from primary care using current autism-specific screening tools (Eaves et al., 2006; Robins et al., 2014; Stenberg et al., 2014), demonstrating a possible sampling bias toward missing higher-functioning toddlers with ASD. In a review of current evidence for ASD screening, priorities for future research included examining how broadband and autism-specific screening tools can be used together to improve screening accuracy and the need for large representative HR and low-risk (LR) samples to strengthen generalizability of findings (Zwaigenbaum et al., 2015).
Objectives: To compare phenotypic presentations of children diagnosed with ASD at 3 years of age from two large prospective samples, one ascertained from community screening (CS) in primary care using a broadband screen for communication delay followed by autism-specific screening and the other ascertained from HR and LR infant siblings (IS).
Methods: Children in the CS sample were recruited from over 10,000 children screened at 9-18 months in primary care settings using the Infant-Toddler Checklist (ITC; Wetherby & Prizant, 2002), a broadband screen of communication delay, followed by inviting positive screens and randomly selected negative screens for an ASD screening using the Systematic Observation for Red Flags (SORF; Wetherby et al., 2004). Children in the IS sample were recruited at 6-9 months of age and comprised of 175 HR and 111 LR infants. Children from both the CS (*n*=464) and IS (*n*=286) samples were invited for an evaluation to make a best-estimate clinical diagnosis using the ADOS, Mullen, and Vineland around 3 years of age; 204 CS and 32 IS children (30 HR, 2 LR) were diagnosed with ASD.
Results: No significant differences were found between children with ASD ascertained from the CS (*n*=204) and IS (*n*=32) samples on any scale of the ADOS or Mullen. On the ADOS, the mean Social Affect total for both groups was 10.9 and the Restricted Repetitive Behavior total 4.2 and 4.0 for the CS and IS groups, respectively. The Mullen Early Learning Composite had a mean of 74.8 (*SD*=23.8) for the CS group and 76.4 (*SD*=18.9) for the IS group. T-scores on the four Mullen subscales were also equivalent.
Conclusions: These findings demonstrate similar autism severity and developmental level in two large prospective samples, one ascertained from CS using a broadband screen for communication delay followed by ASD screening, and the other ascertained from an IS sample. The similar phenotypic expression on the ADOS and Mullen around 3 years of age provides initial support for the use of broadband and autism-specific screening tools together to improve screening accuracy and the generalizability of HR infant sibling research.

61 **180.061** Determining Predictors of Improved Cognitive Function in Children with ASD Between 3 and 6 Years of Age. Which Toddlers Improve?

ABSTRACT WITHDRAWN

Background: Longitudinal Investigation of the cognitive development of children with ASD offers a promising way to identify clinically significant subgroups. Here, we focus on cognitive phenotypes, defined by IQ, which constitutes one of the greatest sources of heterogeneity within ASD and is among the strongest predictors of outcome. By leveraging the extensive behavioral data in the APP, we seek to extend past cross-sectional outcome studies that suggest associations between early social motivation, adaptive language functioning, psychopathology and repetitive behaviors, and later cognitive functioning.
Objectives: To: (1) present descriptive information about the ASD symptoms, adaptive functioning, and psychopathology measurements in the APP cohort; (2) explore an ASD phenotype derived from IQ-based developmental trajectories during the formative 3 to 6 year period; and (3) examine the association between measurements of social reciprocity, language functioning, attention dysregulation, and repetitive behaviors at 3 years of age and IQ trajectory.
Methods: Participants were 93 individuals with ASD. To identify cognitive developmental trajectories, the PROC TRAJ macro in SAS was used on an adjusted DQ score derived from the Mullen Scales and the DAS-II. Univariate and multivariate nomial logistic regression models were then employed to investigate unique and composite predictors of trajectory membership using measurements from the ADOS-2, Vineland Adaptive Behavior Scales, Achenbach System of Empirically Based Assessment, and the Repetitive Behavioral Scales-Revised.
Results: Three distinct trajectories of intellectual development were identified. The first consisted of individuals with IQs ≤ 75 at both times (**Greater challenges**: n=34; 37%). The second was comprised of individuals with IQs ≥ 80 at both times (**Lesser challenges**: n=23; 25%). A third group exhibited IQs < 80 at T1, and had scores of ≥ 80 at T3 with increases of ≥ 1 standard deviation (**Changers**: n=36; 38%). Univariate logistic regression showed that more severe ADOS-2 social reciprocity symptoms at T1 predicted membership in the **Greater Challenges** vs. both **Lesser Challenges** (odds ratio = 2.00, 95% CI: 1.48 – 2.69) and **Changers** (odds ratio = 1.44, 95% CI: 1.16 – 1.80) groups (both p <.001). Similarly, children with better language functioning on the T1 Vineland were more likely to be in the **Changers** (odds ratio = 1.06, 95% CI: 1.02 – 1.11, p <.01) or the **Lesser Challenges** (odds ratio = 1.15, 95% CI: 1.08 – 1.22, p <.001) versus the **Greater Challenges** group. Findings remained significant when social reciprocity and language functioning were entered in a multivariate logistic regression model (all p <.03). No associations were found with attention, hyperactivity, and repetitive behaviors.
Conclusions: The high proportion of young children experiencing robust early cognitive development provides is hopeful for families. It also suggests that low early social reciprocity and adaptive language are risk markers and treatment targets for intensive early intervention. Analyses of the mechanisms of intervention are ongoing. We are also conducting a middle childhood follow-up using behavioral and neuroimaging assays of memory, executive control, language, academic performance, and anxiety to extend the investigation of ASD phenotypes into the understudied, middle childhood period.

62 **180.062** Differences in EEG Power at 3 Months Distinguish Infants at High-Versus Low Risk for ASD

K. J. Varcin[1], *A. R. Levin*[2], *H. M. O'Leary*[3], *H. Tager-Flusberg*[4] *and C. A. Nelson*[5], *(1)Harvard Medical School, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Neurology, Boston Children's Hospital, Boston, MA, (4)Boston University, Boston, MA, (5)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background:
In the context of increasing evidence for the efficacy of early intervention in improving developmental outcomes, there is both significant interest and a need to delineate early risk markers of atypical development that may facilitate earlier intervention. An emerging body of evidence from prospective studies of infants at high familial risk for ASD suggests that alterations in brain development are present from 6 months of age, prior to the emergence of the first behavioral signs of ASD (Jones et al., 2014). To date, early neural markers *within* the first six months of life have been scarcely explored.
Objectives:
In an effort to guide the identification of early risk markers in ASD, we aimed to (1) identify whether infants at high-risk for ASD show altered intrinsic oscillatory patterns by 3 months of age compared to infants at low-risk and (2) explore whether early neural activity is associated with behavioral, cognitive, and social communicative outcomes across early development.
Methods:
Participants in the current study were part of an ongoing, prospective study examining infant siblings at high (HRA) versus low (LRC) familial risk for ASD. At 3 months of age, we collected continuous, high-density baseline electroencephalographic (EEG) recordings (HRA n = 25; LRC n = 14). Average frontal EEG power was calculated within the delta, theta, alpha, beta and gamma bands (as defined previously by Tierney et al., 2012). Cognitive development was assessed at 6 and 12 months using the Mullen Scales of Early Learning (MSEL) and early ASD markers were assessed at 9 and 12 months using the Autism Observation Scale for Infants (AOSI).
Results:
The HRA group had significantly lower power in the high-alpha (U = 78.00, z = -2.840, p = .004) and beta (U = 67.00, z = -3.162, p = .001) bands, with a trend in the low-alpha (U = 93.00, z = -2.401, p = .016) and gamma bands (U = 88.00, z = -2.547, p = .010). A Kruskal-Wallis H test revealed significant differences in frontal power between outcome groups (LRC no-ASD [n = 8], HRA-ASD [n = 7], HRA no-ASD [n = 15]) in the beta band (H(2) = 6.31, p = .043) and a trend in the gamma band (H(2) = 5.60, p = .061). This effect was driven by significant differences between the LRC no-ASD and HRA-ASD groups. Frontal EEG power at 3-months, for all infants, was positively correlated with gross motor and expressive language skills across the first year of life (ps < .05) and inversely correlated with AOSI total score at 9 months (i.e., higher 3mo EEG power was associated with fewer ASD risk markers).
Conclusions:

Our findings suggest that frontal EEG power, as early as 3 months of age, offers potential to predict ASD risk as well as the development of gross motor and expressive language skills. On a broader scale, this finding is consistent with the well-established concept that across neurologic disorders brain-based changes may be detectable on imaging well before behavioral changes become manifest.

63 **180.063** Differential Habituation to Social Scenes in Toddlers with ASD, Non-ASD Developmental Delays, and No Delays

N. Ludwig[1], *R. A. Williamson*[2], *R. K. Ramsey*[2], *L. B. Adamson*[2] *and D. L. Robins*[3], *(1)Georgia State Univeristy, Atlanta, GA, (2)Psychology, Georgia State University, Atlanta, GA, (3)Drexel University, Philadelphia, PA*

Background: Studies have shown slowed rates of behavioral and neural-based habituation to static facial stimuli in individuals with autism spectrum disorder (ASD) across the lifespan. Slowed rates of habituation to faces in toddlers is associated with more symptoms; however, little is known about habituation to other kinds of social stimuli and how habituation rates compare to toddlers with non-ASD delays. Such data may be useful in identifying early behavioral markers of ASD and informing targeted interventions.
Objectives: The current study examines whether differences emerge in behavioral habituation during a dynamic social attribution task between children with ASD, non-ASD developmental delays (DD), and those without developmental delays (TD). This study also aims to examine whether these differences are moderated by modality of task presentation (i.e., puppet show vs. computerized cartoon) given studies suggesting that computerized learning may be more effective for children with ASD than live-based learning.
Methods: This preliminary sample included 18 toddlers (16 male, m_{age}=22.7mo, *SD*=3.7), six with ASD, seven with DD (i.e., language disorder or global developmental delay), and five typically developing (TD).
Toddlers were presented with both a live puppet show and computerized cartoon (order counterbalanced) of alternating helping and hindering social scenes featuring geometric shapes (10s each) on separate days. Scenes were presented until habituation criterion was reached (i.e., the sum of looking time on three consecutive presentations is less than half of the sum of the looking time on the first three presentations, with a maximum of twelve presentations).
Results: The pattern of findings suggest that children in the ASD and DD groups require additional habituation trials in the puppet version (ASDm_{trials}=10.5, *SD*=2.5; DDm_{trials}=9.9, *SD*=2.8) compared to the TD group (m_{trials}=7.8, *SD*=1.6) whereas all groups require a similar number of trials in the computerized version (ASDm_{trials}=8.5, *SD*=2.3; DDm_{trials}=9.0, *SD*=2.4; TDm_{trials}=9.0, *SD*$_{trials}$=3.0). Additionally, data suggest that children with ASD look longer at the puppet scene during habituation (m_{time}=82.9, *SD*=2.3), compared to the DD and TD groups (DDm_{time}=67.6, *SD*=42.9; TDm_{time}=56.8, *SD*=36.3), but that this difference is absent during the computerized version (ASDm_{trials}=62.9, *SD*=28.5; DDm_{trials}=68.0, *SD*=30.8; TDm_{trials}=81.7, *SD*=58.4). Effect sizes for the interaction between diagnosis and modality (puppet vs. cartoon) for the number of habituation trials and total looking time were medium (η_p^2=.12) and large (η_p^2=.94), respectively. Not surprisingly in this small sample, conventional levels of statistical significance were not reached; however, medium to large effects suggest that significant differences will emerge as additional children are recruited.
Conclusions: Preliminary findings suggest that there may be differential behavioral habituation rates to non-facial social stimuli, and that this may be moderated by the modality in which stimuli are presented. More data are needed to examine whether these medium to large effects become significant. Future research should compare habituation rates of social vs. nonsocial stimuli in these groups and modalities and explore the utility of behavioral habituation as an early behavioral marker of ASD.

64 **180.064** Diminished Autonomic Response to Social Partners in Infants Later Diagnosed with Autism Spectrum Disorder

C. McCormick*, S. J. Sheinkopf, T. P. Levine, L. L. LaGasse and B. M. Lester, Brown Center for the Study of Children at Risk, Women & Infants Hospital The Warren Alpert Medical School of Brown University, Providence, RI*

Background: The core behavioral symptoms of autism spectrum disorder (ASD) emerge developmentally and are not reliably observed within the first year of life (Jones et al., 2014). Even sensitive measures, like those generated from eye-tracking techniques, have not yet identified consistent reliable differences between children with and without ASD until the second year of life. Biological measures, such as respiratory sinus arrhythmia (RSA), hold great potential for detecting predictors of an ASD outcome before behavioral differences emerge. RSA is a measure of heart rate variability that indicates the body's readiness to engage with environmental stimuli (Grossman & Taylor, 2007). RSA response patterns have been linked to social functioning in children with ASD (Sheinkopf et al., 2009). Differential patterns of RSA response may be part of the underlying biology of ASD and, therefore, be detectable within early infancy.
Objectives: To identify early patterns of behavioral and RSA responses in infants later diagnosed with ASD.
Methods: Two groups of infants were compared: infants with an ASD outcome (N = 8) and matched controls (N = 186). Infants were seen as part of their participation in the Maternal Lifestyle Study (MLS), a longitudinal study of the effects of drug exposures on long term developmental outcomes. At four months infants completed the face-to-face still-face (FFSF) protocol with their mother. The FFSF begins with the caregiver and infant in face to face interaction (play), followed by a period when the caregiver is instructed to face the infant relatively expressionless (still face), and ending with a reunion episode of normal face to face interaction (reunion). Infants were also observed in a face to face play interaction with a novel female examiner immediately following the caregiver interaction (stranger). ECG was collected to measure RSA. ECG post-processing incorporated automated artifact detection and correction routines. RSA was calculated from the resulting "cleaned" time series data using Porges' method. Infant behaviors (passive-withdrawn, protest, object-environment, social monitor, and social positive engagement) were coded from video.
Results: A general linear mixed model of the FFSF paradigm revealed no significant group differences on RSA during interactions with the mothers between infants with an ASD outcome and controls. Both groups of infants demonstrated a decrease in RSA during the still face phase compared to the play phase ($p < .05$). No significant behavioral differences were detected. However, in response to play with a stranger, an ANOVA revealed that the infants with an ASD outcome had lower RSA than controls ($p < .05$). During the interaction with a stranger, lower RSA response was associated with more protesting behaviors ($p < .01$), whereas higher RSA response was associated with more social monitoring ($p = .001$).
Conclusions: Infants later diagnosed with ASD exhibited greater autonomic reactivity during interactions with an unfamiliar adult than did comparison infants. There were no differences between groups during interactions with mothers. Physiological dysregulation, as indicated here by a lower RSA response, may function as an early biological marker of difficulties with social interactions before differences in behavioral responses are detectable.

65 **180.065** Does Infant Temperament Predict Autistic Traits in Toddlers? Findings from a Prospective Longitudinal Study of Singaporean Toddlers

A. Chew[1], *C. S. Chee*[2], *D. A. Goh*[3], *D. Gan*[3], *S. B. Lim*[4], *P. Agarwal*[5], *B. Broekman*[6,7], *A. Rifkin-Grabol*[6], *S. M. Saw*[8], *Y. S. Chong*[9], *K. Kwek*[10], *P. D. Gluckman*[6,11], *M. Meaney*[6,12] *and* ***I. Magiati***[1], *(1)Department of Psychology, National University of Singapore, Singapore, Singapore, (2)Child Development Unit, Department of Pediatrics, National University Health System, Singapore, Singapore, Singapore, (3)Department of Psychology, National University of Singapore , now at the Ministry of Social and Family Development, Singapore, Singapore, Singapore, (4)Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore, (5)Department of Neonatology,, KK Women's and Children's Hospital, Singapore, Singapore, (6)Singapore Institute for Clinical Sciences, Agency for Science, Technology and Research (A* STAR), Singapore, Singapore, (7)Department of Psychological Medicine, National University Health System, NATIONAL UNIVERSITY OF SINGAPORE, Singapore, Singapore, (8)Saw Swee Hock School of Public Health, National University of Singapore, National University Health System, Singapore, Singapore, (9)Singapore Institute for Clinical Sciences, Agency for Science, Technology and Research (A* STAR), Singapore; Department of Obstetrics and Gynaecology, Yong Loo Lin School of Medicine, National University of Singapore, National University Health System, Singapore, Singapore, (10)Department of Maternal Fetal Medicine, KK Women's and Children's Hospital, Singapore, Singapore, (11)Liggins Institute, University of Auckland, Auckland, New Zealand, (12)Ludmer Centre for Neuroinformatics and Mental Health and Department of Psychiatry, McGill University, Montreal, Canada*

Background:
Limited but emerging evidence suggests that early temperament or temperament trajectories may be different in children who are later diagnosed with ASD. However, most existing research is methodologically limited by cross-sectional studies and small sample sizes and to our knowledge, no study has yet examined temperament in relation to ASD symptoms in infants younger than 6 months. Conceptualizing ASD as the extreme of a normal distribution of autistic traits in the general population allows us to investigate variation in autistic traits and their relationship to infant temperament within larger prospective longitudinal studies.
Objectives:
The current study examined infant temperament as a predictor of autistic traits in a large community sample of unselected toddlers, using a prospective longitudinal design with multiple time-points. Differences in temperament characteristics were examined both cross-sectionally at each time point and longitudinally in terms of changes in temperament trajectories over time.
Methods: 649 infants were recruited from two major public hospitals in Singapore and followed up at regular intervals from approximately 12 weeks gestation to 3 years of age as part of a large longitudinal study of growth and development (GUSTO; Growing Up in Singapore Towards healthy Outcomes). Caregivers completed the Carey Temperament Scales at 3 (N=645), 9 (N=539), and 18 (N=445) months; and the Quantitative Checklist for Autism in Toddlers (Q-CHAT) at 18 (N=368) and 24 months (N=365). 174 caregivers completed all temperament and autistic trait measures at all timepoints.
Results:
Correlational analyses showed that rhythmicity, distractibility and adaptability at most earlier time-points were positively associated with later autistic traits, with small to medium effect sizes. In regression analyses, infants' low distractibility and high threshold were the strongest unique predictors of autistic traits. Low persistence and high threshold were the strongest unique predictors of social autistic traits, as compared to greater persistence which predicted non-social/ behavioral autistic traits. Toddlers with higher autistic traits at 24 months showed a developmental pattern of consistently lower rhythmicity between 3 and 18 months, consistently decreasing persistence and

increasing threshold to stimulation from 3 months to 18 months, as compared to their peers with low autistic traits at 24 months who displayed more stable levels of persistence and threshold from 9 to 18 months.
Conclusions:
This study provides preliminary evidence that at least some temperament differences as early as 3 months are associated with later sub-clinical autistic traits in the general population. Studying infant temperament in the context of autistic traits may provide further insight into how early developmental pathways of those who later go on to have high rates of autistic-like behaviors may deviate from those observed in toddlers with fewer autistic traits. Such knowledge may further and inform our understanding of early development in the extreme end of the continuum of autistic traits.

66 **180.066** Early Behavioral Fear in Infants and Preschoolers at High Risk for Autism: Fragile X Syndrome Versus Autism

J. Roberts[1], *J. Scherr*[1], *A. L. Hogan-Brown*[1], *D. Reisinger*[2] *and S. L. O'Connor*[1], *(1)Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC*

Background: Young males with fragile X syndrome (FXS) are at high risk for both autism spectrum disorders (ASD) and anxiety disorders with up to 70% and 80% meeting diagnostic criteria, respectively. Likewise, infants with an older sibling with ASD of unknown etiology are at high risk for ASD and anxiety with nearly 20% meeting criteria for ASD and 40% of those with ASD diagnosed with an anxiety disorder. Despite the high association of anxiety with FXS and infants with siblings, few studies have examined early indicators of anxiety in either group, and no work has examined the specificity of early anxiety indicators in FXS to those in infant siblings. Given that features of ASD and anxiety overlap considerably, disentangling the association of ASD and anxiety features in FXS and infant siblings is important to address the latent heterogeneity in ASD and to direct targeted treatments in both high risk groups.
Objectives: To investigate social and non-social fear in infants and young children with FXS, contrasted with infant siblings of children with ASD and typically developing controls.
Methods: 76 boys (2-5 years) participated in our initial preschool study representing 29 with FXS, 11 with idiopathic ASD, and 36 typical controls. An additional 68 infants (12–24 months) completed our infant extension, representing 25 with FXS, 22 infant siblings, and 29 typical controls with 20 having data coded at this time and coding scheduled to be completed by 12/2015. Social and non-social fear were measured using gaze from the Stranger and Scary Spider epochs of the Laboratory – Temperament Assessment Battery at 12 and 24 months and at preschool age (stranger only). Autism symptoms were assessed using the severity score from the Autism Diagnostic Observation Schedule 2 and Childhood Autism Rating Scale -2 with anxiety symptoms estimated using the anxiety subscale of the Child Behavior Checklist. We anticipate increased sample sizes for the presentation.
Results: Data indicate that preschool males with FXS display a similar proportion of gaze towards the stranger as the ASD group (32% and 25% of time, respectively) with both being lower than typical controls (45%; p=.01). There were nonsignificant relationships between stranger gaze and autism symptom severity or parent rated anxiety symptoms in the preschoolers (p>.05). For infants, no differences were found between FXS (48%), autism siblings (58%), and typical infants (83%) on the proportion of time spent looking at the spider (p>.05). In contrast, results approached significance for the FXS group to gaze longer to the stranger (52%) than the autism siblings (32%; p=0.07); FXS and autism siblings were both similar to typical controls (p>.05).
Conclusions: Results from this study suggest that children with FXS and siblings of children with ASD may demonstrate different developmental trajectories of social and non-social fear. Though non-social fear does not appear to discriminate children with FXS from other children in infancy, children with FXS and children with ASD do demonstrate elevated social fear later in development, at preschool age.

67 **180.067** Early Play Behaviors in Infants at Risk for Autism

J. E. Flanagan[1], *B. B. Demchick*[2], *R. J. Parente*[3], *J. Delany*[2], *L. A. Crabtree*[4], *P. D. LaVesser*[5] *and R. Landa*[6], *(1)SPD Foundation, Centennial, CO, (2)Towson University, Towson, MD, (3)Psychology, Towson University, Towson, MD, (4)Towson University, Lutherville, MD, (5)University of Colorado, Denver, CO, (6)The Kennedy Krieger Institute, Baltimore, MD*

Background: Few studies have found early markers of autism that are associated with later diagnosis. Various studies examined early play behaviors after nine months of age but none have looked at early play behaviors during mid-infancy. Early play behaviors include the ability to move and explore one's environment, play with objects, and attend and interact with a caregiver. These play abilities may provide valuable information about sensory, motor, cognitive, and social functioning that may predict risk factors for ASD.
Objectives: This study examined the relation between early play behaviors at age 6 to 7 months and 36-month outcome classification of ASD in high and low risk infants.
Methods: A retrospective analysis of longitudinal data was collected from a cohort of 58 infant participants by coders blinded to child's diagnostic category. Play skills were rated from videotapes of administration of the Mullen Early Learning Scale and a Peek a boo task. The Revised Knox Preschool Play Scale was used to code these dimensions of play: gross motor skills, fine motor skills, early imitation and early social and communication behaviors (e.g. participation) during interactions (Knox, 1997, 2008). Researchers operationally defined play categories and established reliability in their scoring. Social and communication behaviors associated with a diagnosis of ASD were determined at age 3 by expert clinical researchers using the DSM IV TR criteria (2000) for autistic disorder and pervasive developmental disorder not otherwise specified along with performance on the following diagnositic assessments: The Autism Diagnostic Observation Schedule, Mullen Scales of Early Learning Receptive and Expressive Language Scales, and Preschool Language Scale.
Results: A Mann-Whitney U test was run to determine if there were differences in play scores between the infants with ASD and infants without an ASD diagnosis. Distributions of the scores were not similar, assessed by visual inspection. Play score for infants later diagnosed with ASD at age 3 had lower play abilities at 6 months compared to infants without an ASD diagnosis (U = 130, z = -2.29, p < 0.05, r = 0.31). Analysis of the play dimensions revealed that infants with ASD had a lower imitation score (U = 145.5, z = -2.26, p < 0.05, r = 0.31) and participation score (U = 138, z = -2.30, p < 0.05, r = 0.31) compared to the NonASD group.
Limitations: Play skills were observed retrospectively during the administration of a standardized assessment rather than in a naturalistic play context. In addition, there were only a small number of infants diagnosed with ASD in the sample.
Conclusions: Play behaviors may be early indicators of developmental disruption in infants later diagnosed with ASD. Findings suggest the need to move beyond standard assessments that focus on the accomplishment of gross or fine motor tasks to look also at the quality of interaction with a caregiver during early play, which may serve as potential indicators of ASD.

68 **180.068** Early Predictors of Restricted and Repetitive Behaviors in Toddlers at-Risk for ASD

S. F. Fontenelle, *D. Macris, K. K. Powell, S. Macari and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Developmental theory suggests that RRBs in children with Autism Spectrum Disorder (ASD) may function to occupy and soothe oneself, which may interfere with new experiences and learning (Leekam, Prior, & Uljarevic, 2011). Previous findings also suggest that severity of RRB symptoms might be linked with limited communicative skills. Specifically, increases in language levels were associated prospectively with decreases in RRBs in 2 to 3-year-olds with ASD (Subramanian and Weismer, 2012). Despite potential clinical and theoretical importance of the relationship between communication skills and RRBs, evidence in this area remains scant. The current study seeks to extend the literature by examining the association between language acquisition and RRBs in the second year of life, a critical developmental period for communication skills and emergence of RRBs.
Objectives: Examine the association between early language skills and RRBs in younger siblings of children diagnosed with ASD. We hypothesize that RRBs and dynamic language acquisition will predict later levels of RRBs in high-risk siblings.
Methods: Participants were 98 high-risk infants followed prospectively at 12, 18, 24, and 36 months. The sample consisted of toddlers with ASD (n = 16), developmental delays (n = 36), and no clinical features (n= 46). Comprehensive evaluations were conducted at each time point. Language skills were assessed with the MSEL (e.g., age equivalent (AE) scores). RRBs were assessed through clinical observations with the ADOS (e.g., RRB total scores). Rate of skill acquisition was calculated by determining the change in AE scores between visits divided by the time that passed between visits (Klintwall, Macari, Eikeseth, & Chawarska, 2015). The hypothesis was evaluated using multiple regression analysis with RRB at 24 months as the predicted variable, and EL rate acquisition and RRB levels at 12 and 18 months as predictors. Analyses were conducted on the combined HR sample to evaluate associations between RRB and language development across the spectrum of risk.
Results: The dependent variable for the high-risk cohort was a measure of clinically-observed RRBs at 24 months (M=1.21; SD = 1.36; Min = 0; Max = 7). Mean RRBs at 12 and 18 months were .96 and 1.29, respectively. Rates of EL growth between 12 and 18 months and 18 and 24 months were 1.05 and 1.59, respectively. Multivariate regression analysis revealed the model significantly accounted for 26% of the variance in 24-month RRB scores ($F(9, 84) = 4.612$, p = .000; adjusted R^2 = .259), with 12-month RRB scores (β = .247, p = .034) and 18-24 month EL Acquisition Rate scores (β= -.423, p = .007) making significant contributions.
Conclusions: The results suggest that higher level of RRBs at 12 months and lower rates of language acquisition between 18 and 24 months predict higher levels of RRBs at 24 months in high-risk siblings. These results highlight the role of expressive language development in the emergence of RRBs in high-risk toddlers and underscore the importance of intervention targeting language development in high-risk toddlers between 18 and 24 months of age.

69 **180.069** Evidence for Language Phenotypes in Children with ASD Based on Varied, Longitudinal Assessment Measures

L. Naigles[1], *A. M. Mastergeorge*[2], *R. T. Johnson*[3], *C. W. Nordahl*[4] *and D. G. Amaral*[5], *(1)University of Connecticut, Storrs, CT, (2)University of Arizona, Tucson, AZ, (3)UC Davis M.I.N.D. Institute, Sacramento, CA, (4)University of California at Davis, Sacramento, CA, (5)UC Davis The M.I.N.D. Institute, Sacramento, CA*

Background: Language assessment is challenging in young children with ASD, yet is crucially important for designing interventions and predicting outcomes. Standard scores situate children with ASD in relation to their TD peers, yet specifics of which aspects of language are known vs. unknown are lacking. Moreover, language-brain comparisons may suffer because children of comparable standard scores may be at different stages of language development; specifics of language growth also become hard to document. We hypothesize that scrutiny of *raw* scores from standardized assessments might be revealing concerning children with ASD's actual levels of language knowledge, plus relationships among their early language, brain development, and language growth.
Objectives: 1) To examine how raw Mullen (MSEL) scores might distinguish language knowledge in a large group of 3-year-olds with ASD, and 2) to investigate relationships among these scores, acquired MRI data and subsequent language levels.
Methods: 239 families of children with ASD participated in the APP study of autism phenotypes at three years old (M_{age} = 35.06 months; $M_{MullenVR\text{-}T}$=28.88, *SD*=12.97); 98 of these provided additional data at 5 years (M_{age}=68.63 months; $M_{DAS\ NV\ SS\text{-}score}$=81.39, *SD*=27.51). Three-year-olds were administered the MSEL and CDI; five-year-olds were administered the ADOS, DAS Verbal-Comprehension, EOWPVT and PPVT. 104 of the 3-year-olds underwent structural MRI imaging, enabling DTI analyses.
Results:
Based on the MSEL receptive and expressive language, the 3-year-olds were divided into three language subgroups based on raw scores: *Nonverbal*, *WordLearner*; *Words&Grammar*. Subgroups' language scores differed (p<.05); however, *Nonverbal* and *WordLearner* subgroups differed only marginally on MSEL VR (p<.10) and *WordLearner* and *Words&Grammar* groups did not differ on ADOS scores. Fractional anisotrophy (FA) in the DTI analyses varied in several tracts according to these subgroups; that is children in the *Nonverbal* group manifested the lowest FAs in the left inferior longitudinal fasciculus (ILF).
The 5-year-olds were divided into four subgroups based on standard scores: *Low Verbal* , *High Verbal*, *Low Normal*; and *Possible SpecificLanguage Impai*ment . Comparison of the children at T1 vs. T2 revealed stability: *Words&Grammar* children at T1 predominantly scored as *HighVerbal* at T2. However, 28 children who were *Nonverbal* at T1 scored in one of the three higher subgroups at T2.
Conclusions: 3-year-olds' raw MSEL language scores revealed subgroups that implicated graded vocabulary development. The DTI findings supported this interpretation, as children at lower vocabulary levels manifested less mature white matter tracts, particularly tracts connecting visual and auditory cortex. These children may exhibit impaired word-object mappings. Many of the 5-year-olds remained at similar verbal levels relative to their chronological age. However, a significant minority demonstrated marked improvement. Ongoing analyses consider the children's actual speech, comparing lexical with grammatical functioning and potential neural correlates thereof.
Understanding language profiles of young children with ASD provides important information about stability and variability in language symptomatology and furthers our understanding of emergent language phenotypes.

70 **180.070** Evidence for Metabolomic Phenotypes Based on Analysis of Plasma from the APP Cohort

A. Smith[1], *R. Alexandridis*[1], *R. Burrier*[1], *P. West*[2], *L. A. Egnash*[3], *J. King*[1], *D. D. Li*[4], *D. G. Amaral*[5] *and E. Donley*[1], *(1)Stemina Biomarker Discovery, Madison, WI, (2)BioAnalytical Chemistry, Stemina Biomarker Discovery, Madison, WI, (3)Client Services and Operations, Stemina Biomarker Discovery, Madison, WI, (4)University of California at Davis, Sacramento, CA, (5)UC Davis The M.I.N.D. Institute, Sacramento, CA*

Background: Metabolomics has the potential to identify predictive and actionable biomarker profiles from a child's inherited biochemistry as well as capture the interactions of the gut microbiome with dietary and environmental factors that contribute to ASD. Identification of common metabolic profiles in children with ASD creates an opportunity to develop metabolic based diagnostics that enable early diagnosis and identification of metabolic subtypes that can facilitate intervention and lead to a better understanding of the biochemical changes associated with ASD.
Objectives: 1) To identify predictive metabolic signatures which distinguish ASD from typically developing (TD) children enrolled in the Autism Phenome Project. 2) To discover metabolic subtypes of ASD as defined by differentially abundant metabolic features that can identify a subset of ASD individuals with a high positive predictive value and specificity.
Methods: Plasma was obtained from 180 children with ASD at the time 1 assessment time point and from 93 age-matched TD children. Samples were analyzed using 4 orthogonal HILIC and C8 LC/HRMS-based methods as well as GC/MS. Data from the patient samples were split into a training set, utilized for identification of biomarkers, and an independent validation test set used for evaluation of the diagnostic signatures. Univariate, multivariate, machine learning and heuristic methods were applied to the training set to identify predictive metabolic features. The predictive molecular signatures were evaluated in the validation test set to determine their classification performance.
Results: Computational models were created that classified the ASD and TD samples in the validation set with a maximum accuracy of 79% and AUC of 0.80. Differentially abundant features (p value < 0.05) from the models were identified as metabolites derived from multiple biochemical processes which included lysophospholipids, hormone sulfates, and amino acids. Two metabolites, 3-Carboxy-4-methyl-5-propyl-2-furanpropionic (CMPF) and an unknown metabolite related to CMPF exhibited a large differential abundance (> 6 fold, p val < 1e-6) in a subset of subjects with ASD. These metabolites discriminates 14% of the ASD population in the APP study and may describe a metabolic subtype of ASD.
Conclusions:
Non-Targeted metabolomic profiling of children with ASD revealed predictive metabolic signatures able to discriminate individuals with ASD from TD individuals and suggests the presence of metabolic subtypes. Applying this paradigm to identify metabolic signatures associated with ASD and elucidating their biochemical implications may be useful in directing therapy on a personalized basis. Work is currently under way to compare these metabolic phenotypes with behavioral and neuroimaging data acquired in the APP. These results form the basis for additional work with the goals of 1) developing diagnostic tests to detect ASD in children to improve their outcomes through personalized treatment, 2) gaining new knowledge of biochemical mechanisms involved in ASD and 3) identifying biomolecular targets for new modes of therapy.

71 **180.071** Examining the Relation Between Walking and Receptive Language in Infants at Heightened Risk for Autism Spectrum Disorder

K. L. West, *N. B. Leezenbaum, J. B. Northrup and J. M. Iverson, University of Pittsburgh, Pittsburgh, PA*

Background: The onset of walking appears to be a point of inflection for communicative development in typically developing infants (e.g. Clearfield, 2011). Notably, research shows the acquisition of this milestone is accompanied by an increase in receptive language, independent of age (e.g. Walle & Campos, 2013). The present study examined whether this relation may be disrupted in the infant siblings of children with autism spectrum disorder (ASD; High Risk; HR)—particularly among infants who go on to receive an ASD diagnosis—given that there is ample evidence of substantial variability in language and motor development in HR infants (e.g. Gamliel, Yirmiya & Sigman, 2007; Iverson & Wozniak, 2007).
Objectives: To examine changes in the *Words Understood* measure of the MacArthur-Bates Communicative Development Inventory (CDI; Fenson et al., 1993) longitudinally across the transition to walking in infants with no family history of ASD (Low Risk; LR) and three groups of HR infants: No Diagnosis, Language Delay, and ASD.
Methods: Participants included 81 HR infants who were visited at home monthly from 5-14 months and a comparison group of 25 LR infants. This study focused on CDI data beginning 4 months prior to infants' walk onset and ending 3 months after walk onset. To establish walk onset, parents recorded infants' motor milestones, and an experimenter confirmed them at each visit. At 36 months, 15 HR infants received an ASD diagnosis (HR-ASD). Twenty-six HR infants with language delays were identified (HR-LD). Forty HR infants did not meet ASD or LD criteria (No Diagnosis; HR-ND).
Results: A two-level piecewise Hierarchical Linear Model was used to examine change in receptive language (RL) over time within individuals, and change across individuals within outcome classifications. The piecewise model allowed us to estimate growth in RL over the entire trajectory (piece 1; all time points) as well as change in growth from the final crawling visit forward (piece 2). Results revealed that the slope of growth following walk onset significantly explained variance in receptive language, even when variance explained by the overall slope (piece 1) was accounted for. This replicates previous findings that walk onset marks an inflection point in receptive language.
To examine group differences, dummy variables for outcome classification were included on the intercept and slopes for HR-ND, HR-LD, and HR-ASD infants, with a LR reference group. To control for age, age at walk onset was included in the model. Results revealed that HR-ASD infants displayed marginally slower growth than the LR group overall (piece 1), and significantly less change in growth following walk onset (piece 2). While the HR-ND group did not differ from the LR group, the HR-LD group demonstrated marginally reduced change in growth following walk onset compared to their LR peers.
Conclusions: For infants with no diagnosis—regardless of risk status— walk onset corresponded to increased RL growth. However, this pattern was significantly attenuated for HR-ASD infants. One possible explanation is that in typical development, the ability to walk influences underlying mechanisms of language acquisition, but this relation may diverge in ASD.

Table 1. Fixed Effects	Coefficient	s.e.
For INTRCPT1, π_0		
Mean LR intercept, β_{00}	44.76***	8.72
HR-ND, β_{01}	14.59	10.82
HR-LD, β_{02}	-9.35	12.2
HR-ASD, β_{03}	-16.23	14.76
For Piece 1 slope, π_1		
Mean LR slope, β_{10}	9.50***	2.10
Age at walk onset, β_{11}	-0.40	0.48
HRND, β_{12}	1.09	2.60
LD, β_{13}	-2.35	2.97
ASD, β_{14}	-6.81~	3.63
For Piece 2 slope, π_2		
Mean LR slope, β_{20}	16.25***	3.19
Age at walk onset, β_{21}	-1.90~	1.13

72 **180.072** Examining the Role of Inhibitory Control in the Emotion Regulation Strategies Employed By Toddlers with and without ASD

L. DiNicola[1], *S. Macari*[1], *L. Flink*[2], *S. F. Fontenelle*[1], *G. Greco*[3], *P. Heymann*[1], *E. Hilton*[1], *S. S. Lansiquot*[4], *A. Milgramm*[1], *K. K. Powell*[1] *and K. Chawarska*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, (3)Boston Children's Hospital, Harvard Medical School, Boston, MA, (4)School of Nursing, Columbia University, New York, NY*

Background: Emotion regulation (ER) involves the modification of emotional expressions and behaviors (Fuster et al., 2008). Children with autism spectrum disorder (ASD) exhibit marked ER difficulties, particularly in frustrating contexts (Jahromi et al., 2012), but the mechanisms underlying these ER problems are unclear (Mazefsky et al., 2013). Within typically developing (TD) preschool-aged children, executive functioning (EF) skills, particularly those involved in inhibitory control, appear to influence ER abilities (Carlson & Wang, 2007). The potential relationship between ER and inhibitory control in young children with ASD has yet to be explored.
Objectives: (1) Determine if differences in inhibitory control appear during toddlerhood between children with and without ASD. (2) Examine the relationship between inhibitory control skills and ER strategies employed within frustrating contexts.
Methods: 24 toddlers aged 18-24 months, 14 with ASD (M_{age} = 21.42 months) and 10 TD (M_{age}= 20.28 months) completed the Laboratory Temperament Assessment Battery, Locomotor Version (LabTAB; Goldsmith et al., 1999). LabTAB includes three frustrating tasks: (1) restraint within a car seat, (2) removal of a toy from reach, and (3) blocked access to a toy through a parent's physical restraint. During each task, behavioral measures of negative affect (ratings of facial, bodily and vocal anger) and ER strategies (occurrence of disengagement, self-soothing, self-stimulating, social overtures, undirected bids for attention, and physical comfort-seeking) were coded by blind

raters. ER scores indicating the proportion of trials in which each strategy was employed were derived, excluding trials in which no negative affect was observed. Inhibitory control skills were reported by parents through the Early Childhood Behavior Questionnaire (ECBQ; Putnam, Gartstein, & Rothbart, 2006).
Results: Toddlers with ASD had significantly lower inhibitory control scores ($M = 2.67$) than TD toddlers ($M = 3.69$), $F(1, 22) = 8.469$, $p < 0.01$. For each ER strategy, between-group comparisons indicated no significant differences in occurrence scores. Pearson's r correlations were performed between the ECBQ inhibitory control scores and each ER score within each diagnostic group. No significant correlations were found for toddlers with ASD. However, within the TD group, inhibitory control scores were significantly correlated with both disengagement ($r = 0.65$, $p < 0.05$) and physical comfort seeking ($r = 0.62$, $p = 0.056$).
Conclusions: Differences in inhibitory control skills between individuals with ASD and TD emerge as young as toddlerhood. Toddlers in both diagnostic groups appear to employ similar ER strategies within frustrating contexts; however, the mechanisms underlying the use of these strategies may diverge between groups early in development. Within our sample, TD toddlers with higher inhibitory control scores were more likely than intragroup peers to disengage from the source of frustration and seek physical comfort from a parent. This suggests an early-emerging link between the ability to control behavior in everyday situations and the coping strategies chosen within frustrating contexts for TD toddlers but not those with ASD. Elucidating these differences may provide clues pertaining to ER impairments associated with ASD and may inform pathways to treatment. Full-sample analyses of 50 toddlers will be presented at IMFAR.

73 **180.073** Fear Reactivity in Toddlers with ASD: Diminished Response and Atypical Associations with Visual Attention

S. Macari[1], *L. DiNicola*[1], *G. Greco*[2], *F. Shic*[1], *L. Flink*[3], *S. S. Lansiquot*[4], *K. K. Powell*[1], *S. F. Fontenelle*[1] *and K. Chawarska*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Boston Children's Hospital, Harvard Medical School, Boston, MA, (3)Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, (4)School of Nursing, Columbia University, New York, NY*

Background:
Among children with autism spectrum disorders (ASD), comorbid anxiety is common, affecting up to 80% of children. Anxiety symptoms are already more prevalent in 3-5-year-olds with ASD compared to preschoolers with other psychiatric disorders. In typically-developing children, individual differences in attention and proximity to a threatening stimulus are associated with social inhibition and anxiety. Little is known about these putative anxiety precursors in toddlers with ASD or relationships with fearful temperament.
Objectives:
To examine emotional reactivity, attention, and approach/escape in toddlers with ASD compared to their non-ASD peers in response to behavioral probes aimed at eliciting fear, and to examine parent-reported fearful temperament and its relationship with in-vivo responses.
Methods:
Participants were 50 age-matched toddlers (M=20 months; SD=2.6) with ASD (n=19), other developmental delays (DD; n=16), or typical development (TD; n=15). We adapted the Laboratory Temperament Assessment Battery/Locomotor version (Lab-TAB; Goldsmith & Rothbart, 1999) for use with toddlers with developmental disabilities. A Fear episode (Scary Spider) was administered; sessions were coded offline by blinded coders for intensity of emotional responses. Composite scores were computed for Fear (facial fear, distress vocalizations, bodily fear, and escape). Parents completed the Early Childhood Behavior Questionnaire (ECBQ; Putnam et al., 2006), including the Fear scale, capturing reactivity and distress to novelty. Duration of attention and approach/escape behavior was also coded for a subset of toddlers (18 ASD, 13 TD).
Results:
There was a significant group difference in the behavioral fear response ($F(2,47)=4.65$, $p=.01$; **Fig1**). Planned contrasts indicated that the ASD group exhibited less intense fearful affect than the TD group ($p<.01$) and the DD group ($p=.04$). There were no group differences on the Fear subscale of the ECBQ ($p=.80$). The ASD and TD groups did not differ in terms of time spent looking at the spider (M=91.1%, SD=6.4 and M=93.8%, SD=4.0, respectively; $p=.37$), and toddlers with ASD spent more time physically approaching the spider than did children with TD ($p=.006$). Visual attention to the spider appears to serve a different function for children with ASD: while TD toddlers with more pronounced *in-vivo* fear responses were more likely to attend to the spider ($r=.60$, $p=.01$), looking was more randomly associated with fear for the children with ASD ($r=-.18$; **Fig2**). Similar patterns of associations between attention to spider and fearfulness were found when considering parent-reported fear (ECBQ, $r=.59$, $p=.05$ in the TD group; $r=.04$ in the ASD group).
Conclusions:
This study suggests a divergent response to threat in toddlers with ASD compared to TD and DD at the level of behavioral fear responsivity and proximity seeking, one that is not evident via parent report of fear. Although the overall duration of looking at a threatening stimulus was similar across diagnostic groups, the patterns of associations with fearful temperament appeared different in the two groups. This study suggests a potential decoupling of affective responses to threat and voluntary attentional strategies for handling such threat in young children with ASD. The factors underlying atypical emotional reactivity in ASD, including attentional, physiological, affective, and cognitive processes require further examination.

74 **180.074** Fetal Head Growth in Children with Autistic Traits and Autism Spectrum Disorder

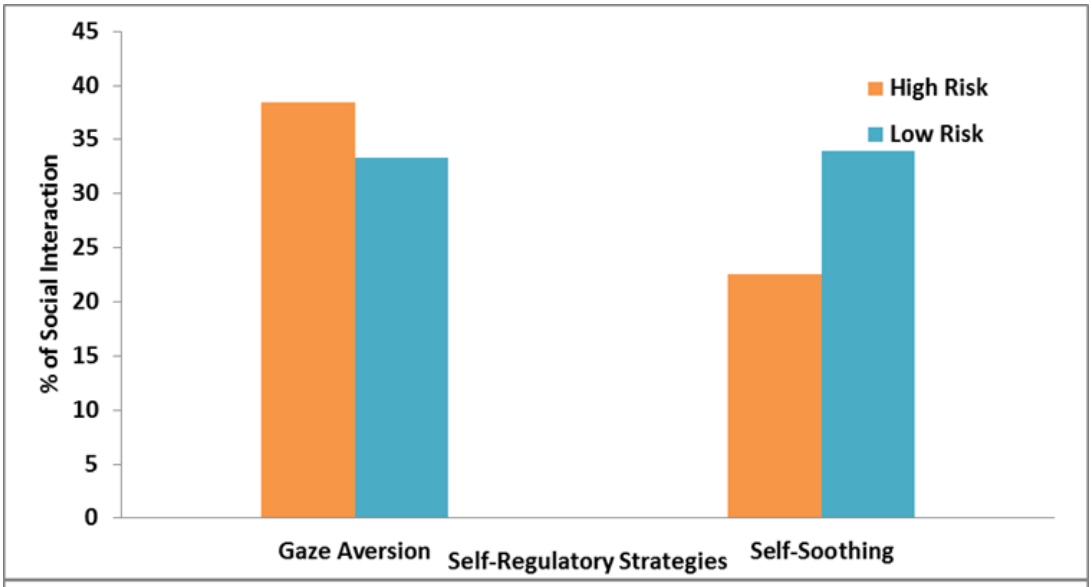
L. M. Blanken[1], *A. Dass*[2], *G. Alvares*[2], *J. van der Ende*[3], *M. Maybery*[4], *C. Dissanayake*[5], *C. Pennel*[6], *M. Hickey*[7], *F. Verhulst*[3], *H. Tiemeier*[3], *A. Whitehouse*[8] *and T. J. White*[9], *(1)Erasmus Medical Center - Sophia Children's Hospital, Leiden, Netherlands, (2)Telethon Kids Institute, West Perth, Australia, (3)Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC-Sophia, Rotterdam, Netherlands, (4)University of Western Australia, Perth, Australia, (5)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (6)The University of Western Australia, Crawley, Australia, (7)Department of Obstetrics of Gynaecology and Obstetrics, University of Melbourne, Melbourne, Australia, (8)University of Western Australia, West Perth, WA, Australia, (9)Erasmus University Medical Centre, Rotterdam, Netherlands*

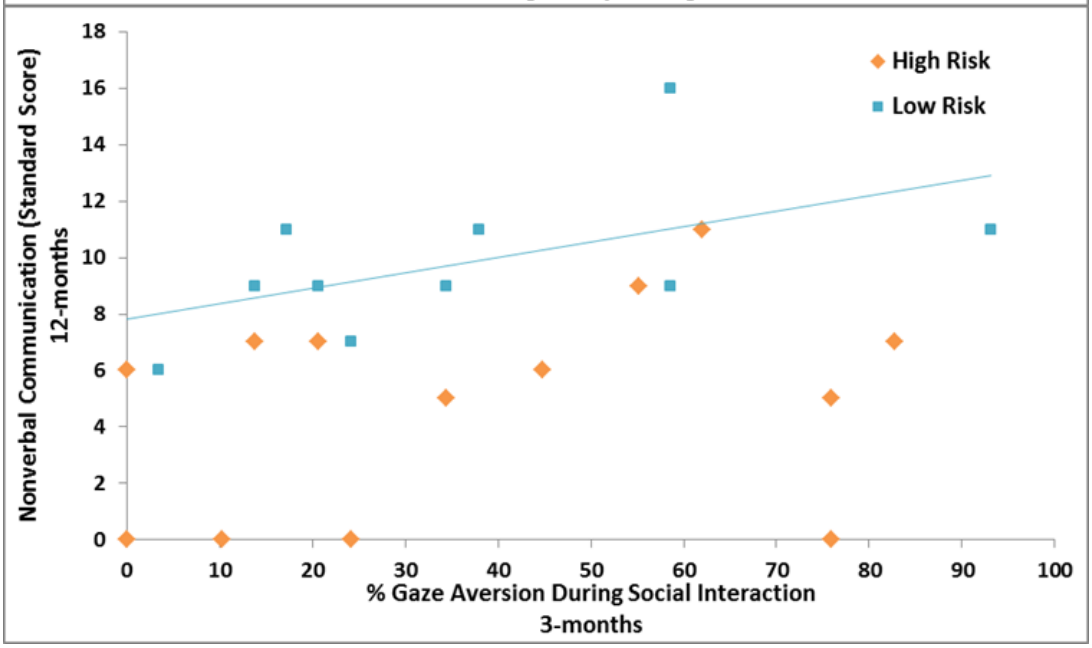
Background: Altered trajectories of brain development are often reported in Autism Spectrum Disorder (ASD), particularly early brain overgrowth in the first year of life (Hazlett, Poe et al. 2011). However, less is known about prenatal head growth trajectories. The few studies available have small sample sizes, typically depend on retrospectively collected ultrasound data and do not include repeated measurements of growth (Whitehouse, Hickey et al. 2011). While there is increasing support for the notion that ASD lies at the extreme end of a continuum of autistic traits, and that characteristics of the neurobiology may form a continuum as well (Blanken, Mous et al. 2015), there are no studies that investigate growth characteristics of the full spectrum of symptom severity (Constantino and Todd 2003).
Objectives: The objective of the current study is to prospectively evaluate prenatal head growth in children from the general population that later develop autistic traits. A second objective is to compare prenatal head growth between children with clinically diagnosed ASD and typically developing children.
Methods: This study included over 5,700 children participating in two large longitudinal prenatal cohorts, including more than 80 children with a confirmed diagnosis of ASD. Fetal head circumference (HC) was measured repeatedly during pregnancy using ultrasound. Autistic traits were measured with the Social Responsiveness Scale and the Autism Quotient. A diagnosis of ASD was based on mother report and confirmed with medical records. Additionally, ultrasounds were retrospectively collected for 45 children with ASD at a clinical research center. Longitudinal HC measurements at three time points were analyzed using a Latent Growth curve model approach to assess the relation of prenatal growth on autistic traits measured later in life.
Results: Preliminary analyses suggested an inverse relationship between prenatal head growth and autistic traits later in life. Children with more autistic traits showed HC growth curves that were characterized by smaller slopes and intercepts.
Conclusions: To our knowledge, this is the first large population-based study looking into prenatal brain growth and autistic traits. Preliminary results suggest that atypical brain growth in ASD may start in utero. Additional analyses comparing prenatal head growth between children with clinically diagnosed ASD and typically developing children will be conducted.

75 **180.075** Gaze Aversion and Self-Soothing at 3-Months and Social-Communicative Outcome at 12-Months for Infants at High- and Low-Risk for ASD: An Exploration of Differences in Self-Regulatory Capacities

J. Bradshaw[1], *S. Shultz*[2], *C. A. Saulnier*[3], *W. Jones*[2] *and A. Klin*[2], *(1)Marcus Autism Center, Children's Healthcare of Atlanta & School of Medicine, Emory University, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (3)Department of Pediatrics, Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Self-regulation in the face of highly stimulating or distressing events is the primary developmental task for 2-6-months-old infants. Effective self-regulation and self-soothing during social interactions allows for sustained alertness, enhanced learning opportunities, and the development of fluid, coordinated parent-infant interactions. 3-month-old infants primarily use two methods of behavioral regulation: self-regulation through gaze aversion and self-soothing through bringing the hand to the mouth ("hand-to-mouth"). Some studies have suggested that the use of gaze aversion to self-regulate during social interaction is disrupted in 6-month-old high-risk infant siblings (e.g., Ibanez et al., 2008). However little is known about how these regulatory capacities at 3-months may promote later social-communicative abilities for high-risk or even low-risk infants. Understanding the form of self-regulatory capacities in early infancy and the function they serve for later social development will illuminate novel developmental pathways for the emergence of social-communication and development of ASD.
Objectives: The goal of the current study is to investigate self-regulatory strategies used by infants at high- and low-risk for ASD during parent-infant interactions and to associate these patterns with later developing social-communication skills
Methods: Participants included infants at high-risk (HR, N=13) and low-risk (LR, N=12) for ASD followed from 3-months through 12-months of age. At 3-months infants participated in a 30-second parent-infant interaction; parents were not touching or holding their infant to ensure the absence of potential external regulatory mechanisms. Parent-infant interactions were coded for the occurrence of self-regulatory gaze aversion (looking away from the caregiver) and self-soothing ("hand-to-mouth"). At 12-months, the Communication and Symbolic Behavior Scales (CSBS) was administered and the Social subscales were included as a measure of social-communicative ability.
Results: Results revealed no significant differences between groups in the amount of time spent using either self-regulatory strategy. There was a significant association between the use of gaze aversion during parent-infant interactions at 3-months and nonverbal communication at 12-months for LR infants ($r=.71, p<.05$), but not HR infants ($r=-.06$, *ns*). A trend was observed for both HR and LR infants that suggested a negative association between self-soothing and nonverbal communication at 12-months (HR:$r=-.45$, LR:$r=-.53$, *ns*). That is, high rates of self-soothing at 3-months were associated with lower rates of nonverbal communication at 12-months.
Conclusions: This study provides initial results indicating comparable use of self-regulatory strategies for high-risk and low-risk infants and unique relationships to social-communicative outcome. First, results suggest that using gaze aversion to self-regulate during social interactions promotes later social-communicative development for LR infants, but not HR infants. In contrast, self-soothing was marginally, negatively associated with nonverbal social-communication for both groups. Perhaps increased self-soothing is indicative of increased distress in response to social interaction, and thus these infants are less likely to communicate with an unfamiliar examiner in an unstructured setting at 12-months. Future analyses with additional participants will strengthen findings and further elucidate these patterns. Overall, this study highlights a novel approach for exploration of the unfolding of social behavior in very young infants and suggests that early self-regulatory strategies could provide a foundational context for the emergence of social-communication.





77 **180.077** Gaze-Contingent Event Triggering in the Social and Nonsocial Conditions

ABSTRACT WITHDRAWN

Background: Eye movement is more than passive viewing of the world and retrieval of visual input. Particularly in social scenarios, eye movements are important social cues that communicate emotion and shared attention. Most eye-tracking experiments in studies of autism spectrum disorder (ASD) are designed to explore the looking behavior of participants, but fail to consider eye movements as an interactive way for a participant to communicate shared attention.
Objectives: To create a gaze-contingent (GC) paradigm to provide opportunities for participants to trigger an event with their eye movement. To explore the differences in triggering time and looking duration in Social and Nonsocial conditions for children with ASD and typical development (TD).
Methods: Participants included TD children (n = 12 , Age = 38.3 ± 17.34 months) and children with ASD (n = 6, Age = 33.5 ± 8.55 months). Both groups completed 16 trials of Social and 16 trials of Nonsocial GC trials. In the Social condition, an actress sat in the center of the screen with an empty circular area on either side of her. Each condition started with a greeting, after which the trial began. Within each trial, the actress used escalating directional cues consisting of a Gaze Shift, Head Turn, Finger Point to one of the areas, with the last escalation involving a Flashing Red strobe in the target area. Once the participant looked at the target after one of the cues, the appearance of an animated toy in the target area was triggered as a visual reward. If the participant did not respond to any of the cues, the animated toy would appear after a delay. Each of the five steps took 2 seconds, for a maximum of 10 seconds per trial. The Nonsocial condition was constructed by scrambling the image of the actress in the Social condition, controlling for movement duration, motion, and size of moving area. We compared time required for the toddlers to follow the cue and move their gaze to the target area (Triggering time) and total looking duration on the screen (Looking duration).
Results: A Diagnosis x Condition linear mixed model on Triggering time revealed a significant effect of condition ($p < .001$) and diagnosis ($p = 0.02$). Triggering time was shorter in the Social (M = 2.9 s, SD = 0.44) versus the Nonsocial condition (M = 5.1 s, SD = 0.45) and TD children responded faster to the cues than children with ASD. Analysis of looking duration indicated a significant interaction effect ($p < 0.05$). Toddlers with ASD looked significantly longer at the Nonsocial cues compared to the Social cues ($p < 0.001$), but this was not the case for TD toddlers ($p = .502$).
Conclusions: Our preliminary results indicate that children with ASD have a preference for looking at nonsocial compared to social information. Children with ASD evidenced slower responses to directional cues in both conditions compared to typical peers, suggesting that they may need more cueing steps in both the social and nonsocial conditions.

78 **180.078** General Gross and Fine Motor Impairment Vs Specific Deficits in Prospective Control in Three-Year-Olds with Autism Spectrum Disorder

E. Nilsson Jobs[1], *G. Gredebäck*[2], *S. Bolte*[3] *and T. Falck-Ytter*[2], *(1)Psychology, Uppsala University, Uppsala, Sweden, (2)Uppsala University, Uppsala, Sweden, (3)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden*

Background: Motor impairments are very common in children with Autism Spectrum Disorder (ASD). Whether some aspects of motor control should be seen as core features of the disorder is currently debated Research point to the possibility that atypicalities in prospective control, – i. e. to anticipate future events and adjust ones actions to these events before they occur – are particularly difficult for many people with ASD.
Objectives: The aim of the study was to compare prospective control as well as general gross and fine motor ability in 3-year-olds with and without ASD. We expected that group differences would be particularly pronounced in the prospective control task.
Methods: The general motor tasks consisted of the gross and fine motor subscales of the Mullen Scales of Early Learning (MSEL). The prospective control task was to draw a line from one point to another within an outlined curve-shaped path on paper (named the Way Home Task). In order to succeed on this task, the child has to anticipate the upcoming curves and proactively adjust his/her actions to avoid crossing the lines defining the path boundaries. The number of crosses was used as our measure of (failure) of prospective control. Twenty-eight children, 9 boys and 19 girls between 36-48 months (M= 39,9 months) from a longitudinal study of 'high risk' infant siblings participated

(all children were at high risk for ASD due to having an older sibling with the disorder). Diagnosis according to DSM 5 was decided upon in a professional team according to best practice, based on clinical assessment in a clinical research setting with the Mullen Scales of early learning, ADOS-2, ADI-R, Vineland and clinical observations. Twelve children were diagnosed with ASD and 16 got no diagnosis.
Results: Independent sample t-test showed that there was a significant difference between the groups on the two MSEL motor scales as well as the specific prospective control task (all *P*s < .05, one tailed). Grip type and visual reception subscale on the MSEL did not differ between the groups. However, logistic regression showed that gross motor ability was the only unique statistically significant predictor of diagnostic group, recording an odds ratio of 1.80.
Conclusions: In line with our hypothesis, the groups differed in their performance on the prospective control task. However, the groups also differed on more general fine motor as well as gross motor scales, and only the latter explained a unique portion of the variance in diagnostic status. This study indicates substantial differences in motor development in young children with ASD relative to other at risk children who did not fulfil criteria for diagnosis. With more participants reaching 3 years in our ongoing study, we will be able to more reliably assess the role of specific motor abilities, such as prospective motor control in ASD.

79 **180.079** Identifying Attentional Differences in Children with and without ASD: A Human-Robot Interaction Study

E. C. Barney[1], *L. Boccanfuso*[1], *C. Foster*[1], *C. A. Wall*[1], *B. Scassellati*[2], *K. Chawarska*[1] *and F. Shic*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale University, New Haven, CT*

Background: The ability to share one's focus of attention with another person is essential for social learning during early development (Carpenter et al., 1998). Children with autism spectrum disorder (ASD) show impairments in joint attention, specifically its initiation (Mundy & Newell, 2007). Typically, the presence or absence of such impairments in children is ascertained by trained clinicians in carefully planned play sessions during the diagnostic decision-making process (Dawson et al., 1998). Although robots are more commonly viewed as an interventional tool for children with ASD (Scassellati et al., 2012), they also have the potential to provide clinically relevant markers to aid in behavioral phenotyping (Scassellati, 2005).
Objectives: To examine behaviors related to the initiation of joint attention (IJA) in toddlers with ASD and with no clinical diagnosis (typical development; TD) during a short, unstructured interaction with a robot.
Methods: This study involved 22 toddlers (n_{ASD} = 11; n_{TD} = 11) matched on chronological age. Participants ranged in age from 20 to 42 months (M= 30.8 months). The human-robot interaction lasted approximately ten minutes and took place in an assessment room with a research assistant and typically a caregiver present. The spherical robot used light, sound, and movement to emulate the emotions of joy, fear, anger, and sadness in a fixed pattern that was at times contingent upon child interaction (Boccanfuso et al., 2015). No restrictions on physical contact were placed. The research assistant engaged the child by asking questions about the robot, but refrained from attributing emotions to it. Percentage of the total interaction time was calculated to assess duration of gaze behaviors and physical contact, while frequency counts were used to measure gesturing behaviors, instances of cooperative play, and gaze alternation between the robot and an adult.
Results: A series of one-way ANOVAs revealed differences between IJA behaviors in the two groups during the robot interaction. The group of children with ASD spent significantly less time looking at others' faces during the interaction than the TD group (F(1,20) = 13.13, p < .01, d = -1.55). Similarly, attempts to share attention by alternating gaze from the robot to an adult and vice versa were significantly lower for toddlers with ASD than TD toddlers (F(1, 20) = 6.61, p < .05, d = -1.10). There was a marginally significant difference between the cooperative play behaviors of the two groups (ASD < TD; F(1, 20) = 6.61, p = .058, d = -.86). No significant between group differences were found for the percent of total interaction time spent looking at the robot, time spent in physical contact with an adult, frequency of pointing behaviors at the robot, or frequency of gestures toward other items in the assessment room.
Conclusions: Our results highlight the differences between children with and without ASD during a brief, unstructured play session with a robot and adult supervisors. The findings are consistent with previous research on IJA, and they suggest a potential auxiliary role for robotics in the early identification of ASD.

80 **180.080** Incongruous Emotions during Fear-Eliciting Tasks in Children with Autism Spectrum Disorder

P. Heymann, *S. Macari, A. Milgramm, L. DiNicola, E. Hilton, K. K. Powell, S. F. Fontenelle and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Many school-aged children with Autism Spectrum Disorder (ASD) are reported to have unusual fears (e.g., toilets, elevators) and are significantly less likely to be afraid of animals and harm (e.g., knives) than typically-developing (TD) and developmentally-delayed (DD) peers (Mayes et. al., 2013; Evans et al., 2005). Fear of animals, specifically spiders, is one of the most common and biologically-preprogrammed fears in the general population (Davey, 1992). Lacking such fears is both unusual and potentially maladaptive. It is unclear if atypical fear responses are present during the early stages of ASD.
Objectives: To examine emotional reactivity in TD, DD and ASD toddlers in response to potentially frightening stimuli.
Methods: 50 Toddlers (20 ASD, 15 DD, 15 TD) between the ages of 15 and 26 months (M = 20 months) were administered three fear-eliciting tasks from the Laboratory Temperament Assessment Battery, Locomotor Version (LabTAB; Goldsmith & Rothbart, 1999): (1) Spider: a remote-controlled spider crawled toward participants, (2) Masks: an experimenter entered a room wearing masks, and (3) Dinosaur: a mechanical dinosaur emerged from a box. Each task consisted of three to four trials lasting 10 seconds each. Videotaped sessions were coded offline by blind coders for intensity of emotional responses during each trial using four-to-six-point Likert scales. Responses were averaged across trials, and composites were computed for Negative Affect (facial, bodily and vocal distress and escape behaviors) and Joy (facial, bodily and vocal joy). Emotions were then labeled as congruous with the task (e.g., Negative Affect) or incongruous (e.g., Joy). Proportions of congruent and incongruent emotions were computed by dividing each composite score by the sum of negative and joy composite scores during each task. All participants received the Autism Diagnostic Observation Schedule 2-Toddler Module (ADOS2-T: Lord et. al., 2012) to evaluate severity of autism symptoms.
Results: A linear mixed model revealed a significant Diagnostic Group*Task interaction (F(4,75.67) = 2.9, p = 0.027) for incongruous emotions. Pairwise comparisons revealed that the ASD group produced significantly more joy and less negative affect during Spider compared to the DD (p = .004) and TD groups (p = .02); however, there were no significant differences between groups for the Masks or Dinosaur tasks. While the majority of the TD (73%) and DD (80%) groups expressed fear during the Spider task, many toddlers with ASD (n = 11, 55%) expressed joy instead. For children with ASD, there was a significant positive correlation between the proportion of joy expressed during Spider and ADOS2-T total scores (r=.405, p=.006).
Conclusions: Preliminary findings suggest that toddlers with ASD are more likely to exhibit an incongruous emotion (joy) in response to a novel and potentially frightening stimulus compared to DD and TD peers. Their expression of joy did not generalize to other stimuli (Masks, Dinosaur). Incongruous emotion expression was associated with higher autism symptom severity in the ASD group. The presence of incongruous emotions in response to frightening stimuli in toddlers with ASD may have implications for later idiosyncratic fear expression, comorbidities, safety concerns, and challenging behaviors.

81 **180.081** Infant Neuroconnectivity Is a Predictor of Social Responsiveness Deficits at Age Four

A. Ross[1], *D. Swain*[2], *A. Scarpa*[1] *and M. A. Bell*[3], *(1)Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Psychology, Virignia Tech, Blacksburg, VA*

Background:
The ability to identify infants who are at increased risk of developing Autism Spectrum Disorder (ASD) would facilitate referral to early intervention, which has been shown to lead to improved outcomes. Biomarkers offer one method to attain that possibility. Hyperconnectivity between brain regions is seen in animal models of ASD and in human neuroimaging studies. A noninvasive way to assess neuroconnectivity in very young populations is via the electroencephalogram (EEG), a measure of neuroelectrical activity. EEG coherence is the squared cross-correlation between two electrodes and is conceptualized as a measure of functional connectivity between underlying neural networks.
Objectives:
The association between hyperconnectivity and social deficits in the literature led to our *a priori* hypothesis that early frontotemporal connectivity would predict later levels of poor social responsiveness and engagement (positive *beta* weights) in typically developing children.
Methods:
At five-months of age, 58 infant-parent dyads participated in a research study; baseline EEG was recorded while the infant watched multicolored balls spin in a toy. When the children were four years old, parents completed the Social Responsiveness Scale (SRS) about their child's social impairments. The SRS produces a total score, as well as five subscales: social awareness, social cognition, social communication, social motivation, and restricted and repetitive behaviors, with a higher score indicating increased impairment in each domain. All children were born full term with no complications, representing a typically developing sample.
Results:
Five-month EEG coherence at baseline between bilateral frontal and temporal scalp locations predicted SRS total score at four years (p=.03, F=3.64), with right hemisphere electrodes (F4-T8) providing unique variance (p=.012, b=.332). This measure of connectivity at five-months accounted for 12% of the variance in SRS total seen at four years. Based on this finding, we conducted *post hoc* analyses to determine which of the subscales may be driving the effect. Social communication (p=.028, F=3.835) and social motivation (p=.038, F=3.477) were the only two subscales predicted by five-month frontotemporal EEG coherence. Again, the right hemisphere electrodes (F4-T8) contributed unique variance for social communication (p=.011, b=.337) and social motivation (p=.039, b=.271)
Conclusions:
These findings suggest that right frontotemporal hyperconnectivity is associated with later social behaviors that may contribute to the social deficits seen in disorders like ASD. This hyperconnectivity seems to result in diminished social motivation and communication, but not in restricted and repetitive behaviors or social cognition and

awareness. Currently, there are no empirically supported methods to diagnose children with ASD as young as five-months of age; however, this measure of hyperconnectivity could serve as a predictor for reduced social responsiveness at age four. This could lead to early screening techniques and allow for targeted interventions for children who are at risk for developing ASD or other difficulties with social engagement.

82 **180.082** Initiating the 1-Year Well-Baby Check-up Approach in Early-Detection Challenged Areas: Survey Results and Initial Feasibility Findings

S. James[1], *E. C. Bacon*[2], *C. J. Smith*[1] *and K. Pierce*[3], *(1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)University of California San Diego, La Jolla, CA, (3)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA*

Background: A recent study in San Diego centered on creating a large-scale pediatrician network and utilization of the CSBS to screen all babies at the 1-year check-up as standard of care resulted in a mean age of 12 months for screening, 14 for evaluation, and 18 for treatment participation. These are far younger ages than is common in the U.S. It is unclear, however, if this model could be easily adopted in other cities. According to the CDC, Phoenix Arizona has one of the latest ages of diagnosis in the country at 4.7 years, and thus would be an ideal location to examine feasibility of implementing the 1-Year Well-Baby Check-Up Approach.
Objectives: The objective of this study was to first survey existing screening practices between San Diego, a long time 1-Year Well Baby Check-Up Approach city and Phoenix, a city without existing standardized screening programs. Next, the study sought to determine if following the steps of the 1-Year Well-Baby Check-Up Approach, which included building a pediatrician network and providing pediatricians with screening tools that contain clear cut-off scores and guidelines for referral, is an effective way to promote autism screenings at 12-month well-baby checkups and subsequent developmental evaluations.
Methods: First, 62 physicians in San Diego already engaged in active screening, and 85 physicians in Phoenix who were not part of an active screening program were surveyed to compare screening practices and beliefs. Second, the 1-Year Well-Baby Check-Up Approach was initiated in Phoenix, and initial indices of program development such as time required to create a pediatrician network and monthly rates of screening and referral was tracked.
Results: Survey responses indicated that the majority of pediatricians in Phoenix (64.29%) and San Diego (76.27%) agreed that autism can be detected at 12 months, but significantly fewer pediatricians in Phoenix (37.50%) than in San Diego (85.96%) reported that they frequently screen for autism at 12-month well-baby checkups, X^2 (1, N = 129) = 30.87, p < .001. Similarly, significantly more physicians in San Diego (77.59%) than in Phoenix (16.66%) reported using standardized screening tools as part of 12-month well-baby checkups, X^2 (1, N = 136) = 50.47, p < .001. A network of 108 pediatricians in Phoenix was created in 8 months and has resulted in a mean rate of 591 screens per month, and 84 referrals per month. Currently, 119 developmental evaluations have been completed as a result of the pediatrician network.
Conclusions: Results from this study suggest that rates of autism screenings conducted at 12-month well-baby checkups can be increased when pediatricians are provided simple tools that link screening and evaluation referrals. Indeed, results from this study found that the odds of screening for autism and using standardized screening tools at 12-month well-baby checkups is more than 10 times greater when pediatricians are provided simple screening tools with referral guidelines. Initial feasibility indices suggest that initiating the 1-Year Well-Baby Check-Up Approach to detect ASD around the 1st birthday may be a realistic option for many cities.

83 **180.083** Insights Gained from Electrophysiological Investigation of High-Risk Infants: Early Markers of ASD in Infants with Tuberous Sclerosis Complex

ABSTRACT WITHDRAWN

Background: Early identification and intervention research has traditionally relied on behavioral markers to predict outcomes and measure change across development. While valuable, this approach is limited by the restricted behavioral repertoire of infants and young children, particularly those with developmental delays. The integration of quantifiable brain-based measures in developmental research provides a means to capture subtle and covert processes, both within and across individuals, which may not be detected at the behavioral level. In this context, non-invasive brain-based measures that can be used from early in life, such as electroencephalography (EEG), hold promise as biomarkers of risk, prediction, stratification and treatment monitoring. Importantly, as EEG reflects the synchronous activation of large populations of neurons, it serves as a "bridge" between genes and behavior that holds considerable promise in mechanistic discovery in neurodevelopmental disorders.
Objectives: Here, we draw upon our prospective, longitudinal study of infants with TSC to demonstrate (1) how we have used EEG to explore whether impairments in higher-order visually mediated behaviors in TSC are grounded in alterations in low-level visual processing, (2) the ability of EEG to facilitate the deeper characterization of early development in this rare population, (3) the promise of EEG methods to guide the search for early, predictive biomarkers that uniquely sensitive to ASD and Intellectual Disability in this high-risk population.
Methods: High-density EEG recordings were conducted with infants with TSC and typically-developing control infants at 6, 12, 18, 24 and 36 months using 128-channel HydroCel Geodesic Sensor Nets (EGI Inc.). Based on evidence from animal models of TSC for alterations in the retinogeniculate pathway, we used a visual evoked potential (VEP) paradigm to determine whether alterations in low-level visual processing in TSC may be a potential mechanism for deficits in higher-order visually mediated behaviors (as indexed on behavioral measures). We also assayed more complex visual processing in TSC by recording event-related potentials (ERPs) to faces versus objects.
Results: To date, we have identified intact low-level visual processing in TSC (as demonstrated by remarkably intact VEPs; Varcin et al., in press) albeit with alterations in more complex visual processing emerging between 12 and 24 months. These findings suggest that atypical face processing does not appear to be a consequence of early visual processing alterations, and instead, point toward aberrations in circuits associated with the processing of more complex visual stimuli.
Conclusions: Impairments in the non-verbal, visually-mediated behaviors in TSC do not appear to be rooted in disturbances in low-level visual processing and, instead, may stem from higher-level alterations in information processing. Our EEG findings are also capturing changes in the processing of complex visual stimuli between 12 and 24 months, complementing our behavioral findings in highlighting this period as an important target for early intervention and guiding further investigation into potential mechanisms accounting for this change.

84 **180.084** Lateralization to Speech Stimuli and Handedness in Early Development of Autism Spectrum Disorder

K. H. Finch[1], *A. Seery*[2], *M. R. Talbott*[3], *H. Tager-Flusberg*[1] *and C. A. Nelson*[4], *(1)Boston University, Boston, MA, (2)New York University School of Medicine, New York, NY, (3)University of California, Davis, Sacramento, CA, (4)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background:
Numerous studies have investigated the patterns of asymmetry in individuals with autism spectrum disorder (ASD). Atypical lateralization of language has been found in individuals at risk for ASD as young as 12-months-old. Seery et al. (2013) found distinct patterns of lateralization in the late slow wave (LSW) in response to speech, and in follow-up studies, 12-month-olds later diagnosed with ASD showed reversed lateralization. Atypical behavioral asymmetry has been observed as left and mixed handedness occur more frequently in children with ASD (Dane & Balci, 2007). To date, no study has investigated the relationship between early patterns of cerebral lateralization and behavioral asymmetry in infants later diagnosed with ASD.
Objectives:
The current study aims to explore the relationship between neural responses to language stimuli at 12 months and handedness at 36 months.
Methods:
Participants
79 monolingual, English-speaking infants were divided into three groups: Low-risk controls (LRC; N=40), high-risk for ASD (HRA) infants (older sibling with ASD) without ASD (HRA-; N=31), and HRA infants with ASD (HRA+; N=8)
Language Lateralization
Event-related potentials to speech sounds were recorded at 12 months. A later sustained negativity (LSW; 300-700ms) was observed over the central regions. A laterality index was calculated by subtracting the mean amplitude of the LSW of the right hemisphere from the mean amplitude of LSW of the left hemisphere (LSW_{left}-LSW_{right}).
Handedness
Utilizing a novel observational approach, hand preference was measured on a variety of behavioral observations during the Autism Diagnostic Observation Schedule and the Mullen Scales of Early Learning at 36 months. Factor analysis with principle axis factoring extraction technique indicated a one-factor model with medium to high factor loadings (Table 1). Using these measures, a composite handedness score ([RH-LH]/[RH+LH]*100) was calculated for each individual.
Results:
At 12 months, LSW laterality index was significantly different across groups ($F(2,76)=3.86$, $p<.05$) with LRC and HRA+ infants showing opposite patterns ($p<.05$); handedness scores at 36 months did not differ across groups ($H(2)=3.934$, $p=.140$) (Table 2).
Across all participants, there was no significant relationship between LSW asymmetry at 12 months and handedness at 36 months (r_s=-0.09, p=0.43). Within each of the groups, 12 month LSW asymmetry did not significantly predict 36 month handedness in LRC infants (r_s=-0.22, p=0.17) or HRA- infants (r_s=-0.05, p=0.78). Conversely, for HRA+ infants, there was a significant relationship (r_s=0.78, $p<0.05$) such that infants with a laterality index more similar to the LRC group at 12 months were stronger right handers at 36 months.
Conclusions:
This study is the first to investigate the relationship between early asymmetry patterns in infants with and without ASD. We did not find a relationship between language lateralization at 12 months and handedness at 36 months in children without ASD. However, infants with ASD exhibit such a relationship in that HRA+ infants with a more typical response to speech at 12 months have more typical handedness at 36 months. This suggests that these individuals might have an underlying protective factor in the early development of cortical lateralization which later manifests into more typical language lateralization and handedness.

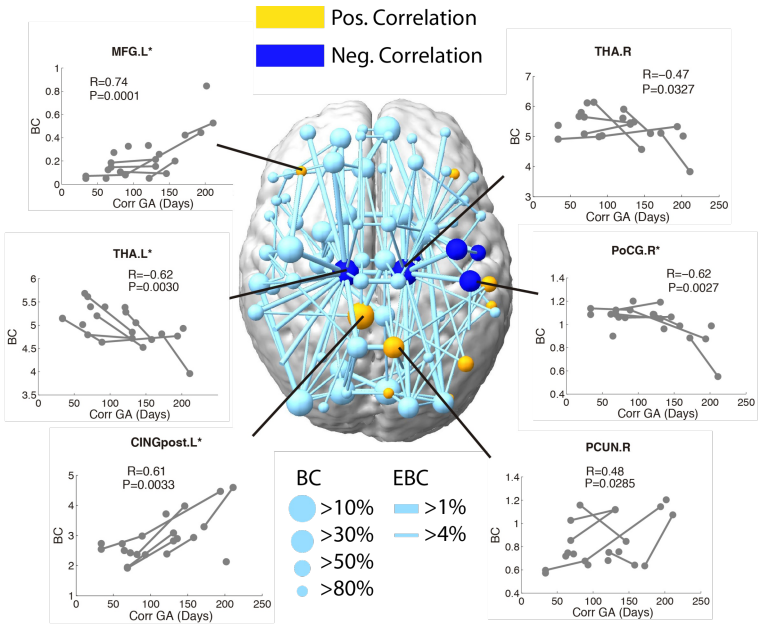
85 **180.085** Longitudinal Charting of Infant Brain Connectomes in the First 6 Months of Life

L. Li[1], *S. Shultz*[2], *X. P. Hu*[3], *A. Klin*[2] *and W. Jones*[2], *(1)Department of Pediatrics, Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (3)Department of Biomedical Engineering, Emory University, Atlanta, GA*

Background:
Recent advances in graph theory and its application in brain imaging science (i.e., brain connectomes) have shed tremendous light on organizational principles of brain structure and function[1]. However, Research utilizing the technique to longitudinally follow the development of brain networks in infants is still rare. Such work will reveal new information with regard to the architecture of brain structure and function in brain development and has direct translational significance in many neurodevelopmental disorders, including autism spectrum disorder (ASD).
Objectives: To chart spatial and temporal details of brain networks of infants in their first 6 month of life using diffusion MRI and graph theory
Methods:
14 typically developing infants (corrected gestational age: 34-211 days, 4 females) were imaged up to 3 times under natural sleep in the first 6 months of life, resulting in 21 scans in total. The diffusion data were collected on Siemens Trio TIM system with a 32-channel head coil and multiband technique. The imaging parameters include: MB factor of 2, TR/TE=6200/74ms, FOV=184×184, matrix size of 92×92, diffusion directions of 61 with 6 b=0 images and a b-value of 700. Streamline probabilistic tractography based on the outputs of FSL was implemented in Camino, achieving approximately 7 million streamlines per subject. We assume that patterns of macro-scale region-to-region connections (i.e., brain connectivity pattern) of the brain in infants with different ages will be largely constant. It is the brain connectivity efficacy (defined as the inverse of the mean radial diffusivity (RD)) along the pathway linking the two regions that alters over time[3]. Thus, we first derived connectional matrices of 90 brain regions in 14 typical infant brains and then thresholded the averaged connectivity matrix at the network density of 10%. The weights of brain networks were quantified by the mean of 1/RD in each pathway. We then examined the relationship between a graph-theoretic metric, betweenness centrality(BC), and the corrected gestational age for changes of brain network maturation over time.
Results:
The global efficiency of whole brain networks is positively correlated with age(R=0.94, P<1.8e-10). The topological roles of each brain region in structural brain networks of infants vary with time and have divergent trends: quantified by BC, bilateral thalamus and right pre- and post- central gyri have decreasing centrality over time (Fig.1), even though the averaged connectivity efficacy (as measured by 1/RD) in these regions increases over time (THA.L: R=0.88, P<1.99e-7; PoCG.R: R=0.91, P<8.1e-9). In contrast, several cortical regions, such as left posterior cingulate gyrus (CINGpost), left middle frontal gyrus (MFG), right angular gyrus (ANGU) and right inferior occipital lobe (IOC) have increased BC over time, indicating their increasingly important roles in infant brain networks (Fig.1).
Conclusions:
Our study also seems to fit the two-process theory of early brain development[4], which proposes that early reflexive behaviors in young infants are mainly mediated by subcortical structures. Such experience-expectant subcortical control will gradually decline and be replaced by experience-dependent, cortical control. Recent work by our group suggests disruptions in this neurodevelopmental transition in infants subsequently diagnosed with ASD[5].



86 **180.086** Neural Precursors of Language in Infants at High Risk for Autism Spectrum Disorder

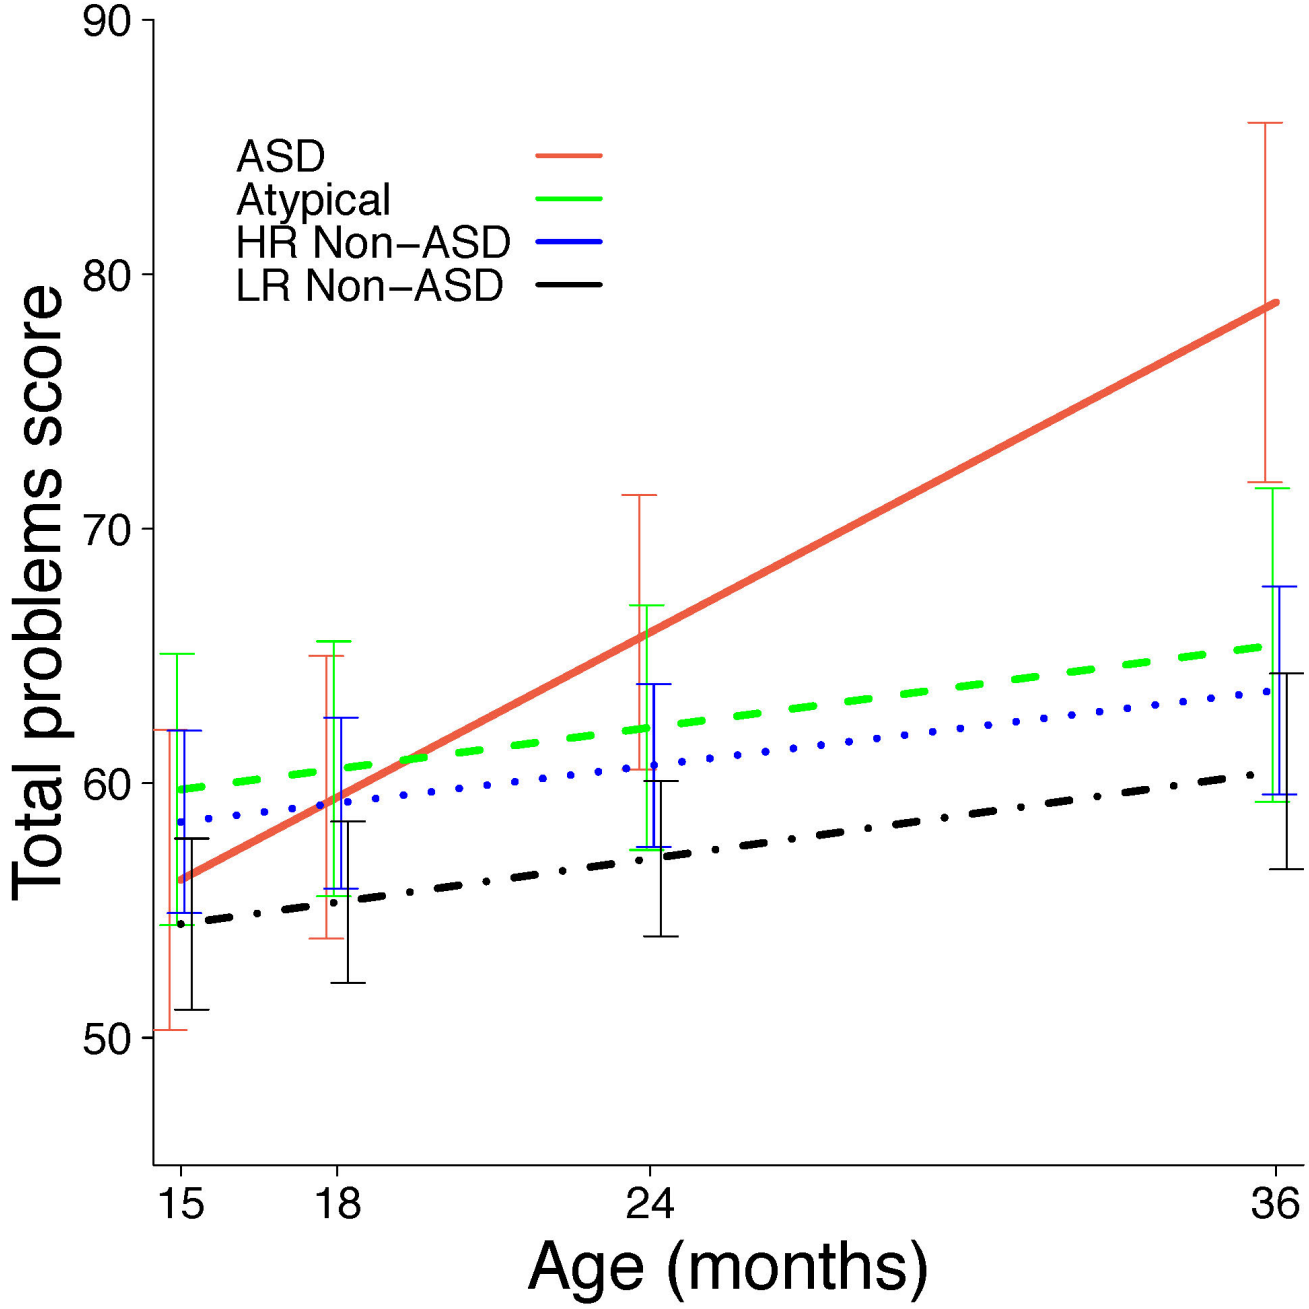
L. A. Edwards[1], *H. Tager-Flusberg*[2] *and C. A. Nelson*[3], *(1)Boston Children's Hospital, Boston, MA, (2)Boston University, Boston, MA, (3)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Autism spectrum disorder (ASD) is a developmental disorder characterized by difficulties in social interaction and communication. One in 5 infants with an older sibling with ASD will develop this disorder, compared to the rate of 1 in 68 in the general population. However, a subset of siblings who do not develop ASD may also exhibit a variety of developmental delays/problems, including language impairments. Research on children with ASD and their siblings has repeatedly shown that those who develop stronger language abilities have more positive outcomes. One strategy for improving language is to get children at risk for ASD into effective and appropriately targeted educational interventions in the very earliest stages of life, when precursors of language and other social behaviors are developing. However, ASD is currently not diagnosed until children have reached 2 or 3 years of age.
Objectives: In this study, we first investigate neural precursors of language acquisition as potential biomarkers of atypical development in 3-month-old infants at high risk for ASD. We then examine whether these biomarkers predict children's language and communicative outcomes at 18 months of age.
Methods: Participants were drawn from a larger sample of infants enrolled in an ongoing, longitudinal, prospective study of early development in siblings of children with ASD. Three month olds with high (HRA; *n*=21) and low (LRC; *n*=17) familial ASD risk were imaged using functional near-infrared spectroscopy while they listened to speech-like stimuli containing syllable repetitions or control syllable sequences (see Gervain et al., 2008). We analyzed their neural responses to these stimuli over left and right temporal regions to determine whether biomarkers of atypical language development are present the first few months of life. We then used multiple and ordinal linear regression techniques to investigate whether 3-month-old neural activity predicts children's 18-month expressive and receptive language (measured by the Mullen Scales of Early Learning [MSEL] and the MacArthur-Bates Communicative Development Inventory: Words and Sentences Module [MCDI]), and autism symptomatology (measured by Autism Diagnostic Observation Schedule severity scores) outcomes.
Results: While LRC infants showed initial neural activation that decreased over exposure to repetition-based language stimuli, potentially indicating a habituation response to repetition in speech, HRA infants showed no changes in their neural activity to these stimuli over exposure ($F(1,33) = 6.77$, p[*sequence*exposure*risk*gender*]=0.014). This 3-month-old neural activity predicted 18-month MSEL expressive language ($0.001<p<0.045$) and MCDI early gesture scores ($0.004<p<0.041$) in both LRC and HRA groups; in some cases, these associations also differed for males and females.
Conclusions: Putative precursors of language acquisition are disrupted in children at high risk for ASD from as young as 3 months of age. The current research thus identifies neural biomarkers that may be specific to language development, and which, with future research and educational application, may aid in determining which children are most likely to benefit from placement into language-based educational intervention programs from the very first months of life.

87 **180.087** Onset, Trajectory and Pattern of Feeding Difficulties in Infants Later Diagnosed with ASD

M. B. Steinfeld[1], *G. S. Young*[2] *and S. Ozonoff*[1], *(1)UC Davis MIND Institute, Sacramento, CA, (2)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background:
Restrictive, rigid and extremely narrow food preferences, difficulties managing advanced or mixed textures, and negative mealtime behaviors are commonly described in children with Autism Spectrum Disorder (ASD).
Objectives:
To identify the onset, trajectory and pattern of feeding difficulties in infants later diagnosed with ASD.
Methods:
A new autism-specific factor structure (Allen et al 2015) for the Behavioral Pediatrics Feeding Assessment Scale (BPFAS), a validated and commonly used parent report measure of feeding problems (Crist & Napier-Phillips 2001), was applied to prospectively collected BPFAS's in a sample of 93 infants with an older sibling with ASD -- the high-risk (HR) group -- and 62 infants with no known familial ASD -- the low-risk (LR) group, as part of a larger funded infant sibling study. Infants enrolled at 6 or 9 months and were assessed prospectively at 6, 9, 12, 15, 18, 24 months. At 36 months comprehensive diagnostic assessments were conducted using ADOS, Mullen and observational data. The BPFAS was completed by parents at 15, 18, 24, and 36 months.
4 outcome groups were formed based on the 36 month clinical assessments: ASD, Atypical (defined as mild-moderate cognitive, language, or social impairment), high-risk typically developing (HR-TD) and low-risk typically developing (LR-TD).
Results:
As can be seen in Fig 1, longitudinal trajectories across groups revealed that the ASD group exhibited a significantly increasing number of feeding problems between 15-36 months compared to all other groups. By 36 months, the ASD group exhibited significantly more problems than all other groups. No differences were found between any of the other groups in change over time or at any age point.
The analysis of the 3 factor score described by Allen et al (2015) revealed a similar pattern for the food acceptance and mealtime behavior domains, with significant age by group interaction effects. The ASD group exhibited greater problems in terms of food acceptance and mealtime behavior domains over time compared to the other groups.
The medical/oral-motor domain did not show main effects for either age or group and no significant interaction between age and group.
Conclusions:
Children developing ASD showed a rapid increase in parent-identified feeding problems starting between 15-18 months of age, with significantly more feeding problems by 36 months of age compared to the other 3 groups. Food acceptance problems and mealtime behavior problems were significantly more common whereas medical/oral motor problems were not more frequent than in the other groups.



88 **180.088** Orienting Response to Social Versus Physical Audiovisual Synchrony Does Not Differ in Toddlers with ASD

R. D. Sifre, *W. Jones, A. Klin and S. Shultz, Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

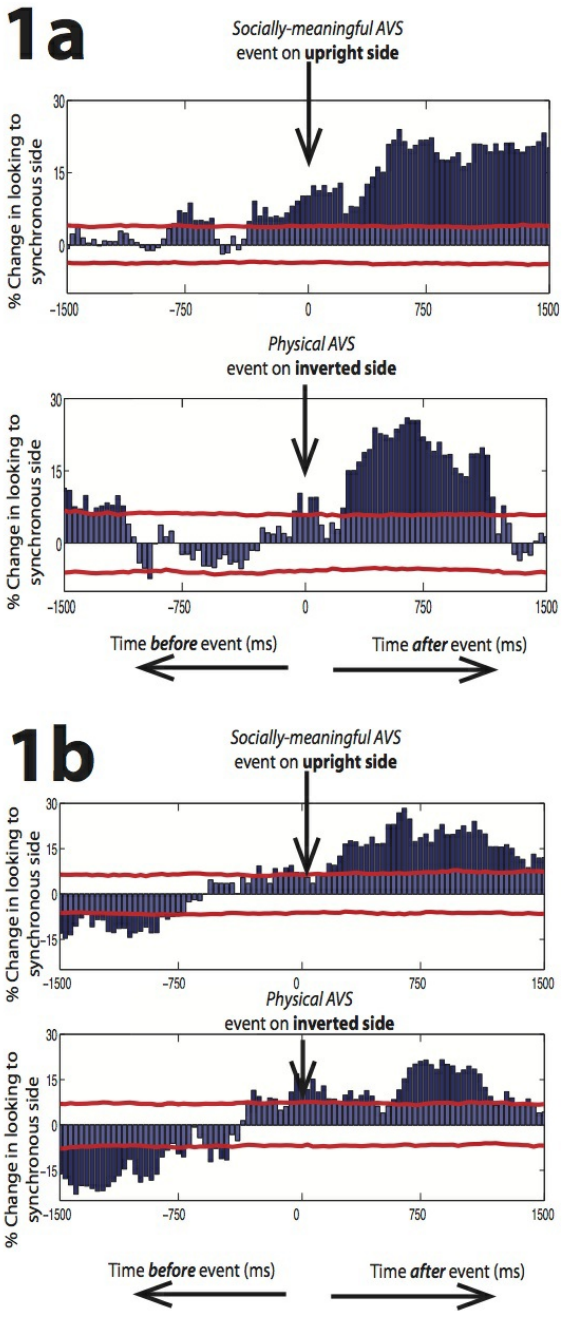
Background: Preferential orienting to biological motion, a skill thought to be critical for early social development, is disrupted in 24-month-old toddlers with autism (Klin et al., 2009). Instead of orienting to biological motion, toddlers with ASD attend to audio-visual synchrony (AVS), suggesting that their attention is guided by physical rather than social contingencies. Despite this apparent dichotomy, it should be noted that while AVS is indeed characterized by physical contingencies (the simultaneous presentation of light and sound), high AVS signals can also contain critical social information, as in the case of speech or co-speech gestures. This raises important questions about the adaptive value of orienting to AVS in typical development, and whether attention to AVS observed in ASD is driven primarily by preferences for physical or socially-meaningful contingencies.

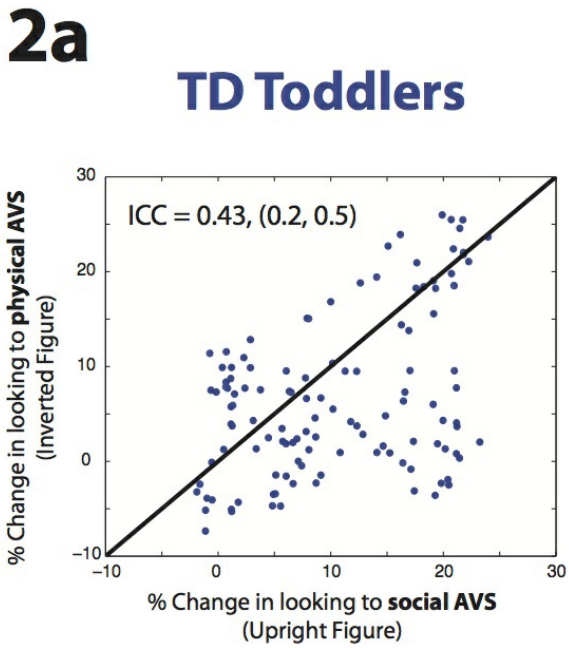
Objectives: Investigate whether toddlers with and without ASD attend differently to high-AVS signals generated by *socially-meaningful* versus *physical* contingencies.

Methods: 58 toddlers (21 ASD, 37 TD) were shown point-light biological motion animations. An upright animation was presented on one half of the screen with the soundtrack of the actor's vocalizations. On the other screen half, the inverted version of the same animation played in *reverse order.* Levels of AVS were quantified for the upright and inverted figure by measuring synchronous change in motion and sound at each frame. High-AVS moments were defined *a priori* as frames with AVS values exceeding the 90th percentile threshold. High-AVS moments generated by the *upright figure* were classified as *socially-meaningful AVS* in that they were generated by the movements and vocalizations of a biological figure. Conversely, high-AVS moments generated by the *inverted figure* were classified as *physical AVS* in that they were generated by the coincident alignment of two disparate signals of light and sound. Peristimulus time histograms were created to assess the probability of looking at the upright/inverted figure, 1500ms before and after a high-AVS event. If toddlers orient to both socially-meaningful and physical AVS, then they should show similar orienting towards high-AVS moments generated by the upright and inverted figure. If toddlers distinguish between socially meaningful and physical AVS, then they should orient differently to AVS generated by the upright versus inverted figure.

Results: Intra-class correlations revealed that while ASD toddlers showed remarkably similar orienting to AVS on the upright and inverted side at all time-points ($r=0.89$, $p<10^{-13}$), this relationship was weaker for TD toddlers ($r=0.14$, $p<10^{-6}$) (Figure 2a). TD toddlers' orienting to AVS on the upright and inverted side differed in two ways: They showed anticipatory looking towards the upright figure *before* socially meaningful high-AVS events, and demonstrated sustained looking *after* socially meaningful high-AVS events. Anticipatory and sustained looking were not observed for physical high-AVS events (Figure 2b).

Conclusions: While TD toddlers differentially orient to socially-meaningful and physical AVS, ASD toddlers' attention is indiscriminately biased by these two synchrony types. These findings support and expand on findings that ASD toddlers' preferentially attend to physical rather than social contingencies, while highlighting the important role that orienting to socially-meaningful AVS may play in typical development.





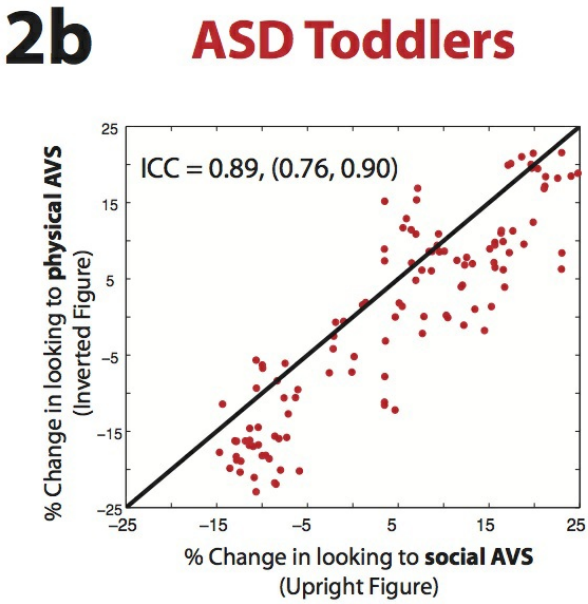


Figure 1. Peristimulus time histograms demonstrating % change in fixation 1500 ms before and after the onset of high-AVS events. Red lines indicate significance thresholds obtained via permutation testing (1000 permuted resamplings); shading indicates when the change in fixation reaches statistical significance ($p<0.05$). **a)** TD results. *Upright figure.* TD viewers show a prolonged increase in fixation beginning 333 ms *before* onset of a high-AVS event and sustained looking *after* event onset for 1500 ms. *Inverted figure.* There is a significant increase in fixation after the event onset that peaks at 25.9% and lasts for 1000 ms. **b)** ASD results. *Upright figure.* ASD viewers increase looking *after* the high-AVS event, peaking at ~700ms, but reducing to chance levels by 1500ms. *Inverted figure.* A similar profile is observed for the inverted figure, with increased looking peaking at ~750ms and reducing to chance levels by 1250ms.

Figure 2. To quantify similarity in response when looking at either socially-meaningful or non-social physical contingencies, we created scatterplots of change in looking to AVS events on the upright versus the inverted side. Intra-class correlation values quantify the relationship for **a)** TD and **b)** ASD results. ICC values reveals a significantly stronger degree of similarity in response patterns for the ASD (r=0.89, 95% CI: 0.76 – 0.90) than for TD toddlers (ICC = 0.43, 95% CI: 0.2–0.5).

89 **180.089** Otitis Media and Expressive Language Outcomes Across Toddlers with ASDs, Language Delays, and Typical Development

E. L. Fisher[1] *and D. L. Robins*[2]*, (1)Georgia State University, Atlanta, GA, (2)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Research indicates that children with autism spectrum disorders (ASDs) experience otitis media at higher rates than typically developing children (Niehus &

Lord, 2006). This is particularly concerning given that children with ASDs are already at heightened risk for long-term language impairments, and recurrent otitis media is associated with poorer speech and language outcomes among typically developing children (Teele et al., 1984). Additionally, the presence of temporary hearing impairment due to fluid obstruction in the middle ear may complicate the diagnostic evaluations by negatively impacting a child's social engagement. A deeper understanding of the incidence of recurrent otitis media (ROM) across different populations and correlates ROM within those populations would be informative for both physicians selecting medical treatments and early intervention specialists attempting to evaluate children and recommend interventions.
Objectives: 1. To compare the incidence of ROM across children with ASDs, language delays, and typical development 2. To examine the relationship between ROM and expressive language outcomes within each group.
Methods: Toddlers (n=197) screened positive on the Modified Checklist for Autism in Toddlers (-Revised) (M-CHAT(-R); Robins et al., 1999, 2009) or were flagged by their pediatrician for possible ASD. Evaluations included ADOS, Vineland Adaptive Behavior Scales-II (VABS-II), and Mullen Scales of Early Learning (MSEL) and a developmental history. Children were classified as having ROM if parents reported ≥ 3 ear infections OR if children received myringotomy tubes.
Results: Fifty-six (20%) children were determined to have ROM. A chi-square test of independence was performed to examine the relationship between child diagnosis following a developmental evaluation and history of ROM. The results indicated no differences in rates of ROM among children with ASD, language delays and typical development, X^2 (2, N = 197) = .35, *Cramer's V* =.02, p = .84. Independent samples t-tests were performed to compare the expressive language development of children with ASD with and without a history of otitis media. The results indicated no significant differences on either the MSEL Expressive Language subscale or the VABS Expressive Communication subdomain, t = -.52, eta^2 = .002, $p > .05$. Higher socio-economic status (SES) was associated with presence of ROM, r = .27, $p < .01$.
Conclusions: Our sample did not show significant differences in the rate of ROM by diagnosis. Additionally, our finding that ROM did not relate to language differs from the current literature on typically developing children. It suggests that the influence of otitis media on language development may be reduced in children with ASD, perhaps due to the relatively larger contribution of social development. Our findings could also indicate the close monitoring of middle ear health leading to prompt treatments for infections may reduce the overall impact of ROM. This monitoring may relate to access to healthcare and information, which is affected by SES. Limitations of this study include the parent report of ROM design rather than standardized monitoring in a healthcare setting, which introduces the possible confound of parent ability to detect otitis media.

90 **180.090** Parent Concerns and Early Detection of Autism Spectrum Disorder

S. Saleem[1], *B. G. Davidson*[2], *A. C. Dowd*[2], *M. A. Lecheler*[3] *and A. R. Neal-Beevers*[2], *(1)The University of Texas Health Science Center at Houston, Houston, TX, (2)Psychology, University of Texas at Austin, Austin, TX, (3)School Psychology, Texas State University, Austin, TX*

Background: Early intervention significantly improves later outcomes of children with autism spectrum disorder (ASD) (Green et al., 2013). Parent-reported concerns about children prompt pediatricians to screen for ASD (Dosreis, Weiner, Johnson, & Newschaffer, 2006). However, oftentimes, clinicians respond to parent concerns with a watch-and-see stance (Landa, 2007). This may be particularly true of parents of high-risk siblings, for whom there is a concern that they will overreport symptoms due to overestimating the recurrence risk of ASD (Whitelaw, Flett, & Amor, 2007).
Objectives: This study compared parent concerns of high (HR) versus low-risk (LR) siblings and examined the association between parent concerns and standardized clinician ratings of ASD symptoms and language development.
Methods: Participants were enrolled in a longitudinal study tracking the emergence of ASD symptoms in HR siblings. The final sample consisted of 21 LR infants, 18 HR infants, and their mothers. The presence or absence of ASD in older siblings was determined via the ADOS-2 (Lord et. al, 2012) for HR older siblings and the Social Communication Questionnaire (Rutter, Bailey, & Lord, 2003) for LR older siblings. Infants were assessed at 12-, 15-, 18-, and 24-months-of-age. The Parent Concerns Questionnaire (PCQ; Ozonoff et al., 2010) was used to classify concerns into two categories: PCQ-Total (speech/language/communication, social, stereotyped behaviors, motor, medical/regulatory, behavior/temperament, general developmental, and unspecified ASD) and PCQ-ASD (speech/language/communication, social, stereotyped behaviors, and unspecified ASD; Ozonoff et al., 2010). Infant ASD symptoms were directly assessed at 12-, 15-, 18-, and 24-months using the Autism Observation Scale for Infants (AOSI; Bryson, Zwaigenbaum, McDermott, Rombough, & Brian, 2008). Language development was directly assessed using the Bayley Scales of Infant Development, Third Edition at 12-, 15-, and 24-months (Bayley-III; Bayley, 2006).

Results: Separate one-way ANOVAs revealed that, compared to LR parents, HR parents (1) reported significantly more PCQ-Total concerns at 12, 15, 18, and 24 months and (2) reported significantly more PCQ-ASD concerns at 12, 15, and 24 months (see Table 1). To examine potential associations between parent (PCQ-ASD) and clinician reports (AOSI), a pairwise correlation was conducted at each age. The findings revealed that parents and clinicians observed similar ASD-related symptoms at 12 ($r(26)=0.64$, $p<.05$) and 15 months ($r(33)=0.560$, $p<.01$). Lastly, we analyzed language concerns by conducting a one-way ANOVA between PCQ-Language and Bayley-III language scores at each age. Parents who reported a language concern had infants with significantly lower Bayley-III language scores at 12, 15, and 24 months (see Table 2).
Conclusions: The findings in this study highlight that HR parents report increased concern about their infant's development beginning at 12 months, especially with regard to symptoms relevant to ASD. It should be noted, however, that greater parent ASD concerns were associated with higher scores on the AOSI. Furthermore, parents who report concerns about delayed language development, have infants who score lower on a standardized measure of language development beginning at 12 months of age. Thus, these findings indicate convergent validity, suggesting that parent concerns regarding ASD symptoms and language development are credible and warrant referral for further developmental evaluation.

91 **180.091** Parent-Reported Social Interaction and Race, but Not Observed Social Impairments, Predict Intervention Enrollment in Toddlers Diagnosed with ASD

D. N. Abrams[1], *L. B. Adamson*[1], *D. A. Fein*[2] *and D. L. Robins*[3], *(1)Psychology, Georgia State University, Atlanta, GA, (2)Psychology, University of Connecticut, Storrs, CT, (3)Drexel University, Philadelphia, PA*

Background: It is widely accepted that early intervention following early diagnosis leads to the best prognosis for children with autism spectrum disorder (ASD; MacDonald, Parry-Cruwys, Dupere, & Ahearn, 2014; Orinstein et al., 2014). However, some children who are diagnosed as early as age 2 do not enroll in intervention targeting their ASD symptoms, despite this recommendation from clinicians. It is unclear what factors may contribute to a parent's ability or decision to enroll their child in intervention. It is possible that race, socioeconomic status, severity of their child's symptoms, the parent's perception of the child's difficulties, or other factors may contribute to enrollment (Thomas et al., 2007). It is important to identify factors contributing to intervention access in order to increase participation in relevant services.
Objectives: To identify predictors of enrollment in ASD-specific intervention following initial ASD diagnosis at age 2.
Methods: Toddlers (n=110) were diagnosed with ASD at around age 2 after screening positive on the Modified Checklist for Autism in Toddlers (-Revised) (M-CHAT(-R); Robins et al., 1999, 2009) and Follow-Up, or being flagged by their pediatrician for possible ASD. Evaluations included ADOS, Vineland Adaptive Behavior Scales (-II; VABS), Mullen Scales of Early Learning (MSEL), and a developmental history. Information regarding enrollment in intervention was collected at a follow-up evaluation at age 4.
Results: Of the 110 toddlers diagnosed with ASD at age 2, 71 (64.5%) enrolled in ASD-specific intervention whereas 39 (35.5%) did not; all but 8 toddlers participated in some type of early intervention (e.g., speech therapy). Logistic regression revealed that VABS(-II) Social Domain was predictive of enrollment, *OR*=.91, *p*<.001, whereas the ADOS Social Affect Calibrated Severity Score (ADOS SA CSS) was not predictive, *OR*=1.05, *p*=.68. Race was also predictive, as Black families (n=18) had 91% lower odds of enrolling in ASD-specific intervention than White families, *OR*=.09, *p*<.001, and other races (Hispanic n=8, Asian n=5, Multiracial n=8) had 82% lower odds of enrolling compared to White families, *OR*=.18, *p*=.001. Furthermore, in a multivariable model, VABS(-II) Social Domain scores, *OR*=.92, *p*=.001, and race (Black *OR*=.13, *p*=.001, other *OR*=.20, *p*=.004), independently predicted seeking intervention. Maternal education and child sex, age, cognitive, language, and symptom domain variables were not predictive, *p*s>.05.
Conclusions: Although all children received an ASD diagnosis at age 2, 35.5% did not enroll in ASD-specific intervention as recommended. Parent-reported social interaction (VABS Social Domain) was predictive of enrollment, but directly-observed social symptom severity (ADOS SA CSS) was not predictive. Therefore, parents who were more aware of, and possibly more concerned about, their children's social functioning were more likely to seek ASD-specific intervention regardless of actual symptom severity. Furthermore, racial minority families were much less likely to enroll in intervention than White families. This has clinical implications for working with parents to address barriers to enrollment in intervention. Future research should examine barriers, such as cultural beliefs, mismatch of race between the family and intervention provider, and stressors on the family related to socioeconomic or racial status. Research should also work to identify strategies to overcome these barriers.

92 **180.092** Parental Stress and Proband Mental Health As Predictors of Mental Health in Toddlers at High-Risk for Autism Spectrum Disorders

K. Hudry[1], *K. Crea*[2] *and C. Dissanayake*[3], *(1)Olga Tennison Autism Research Centre, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, Bundoora, VIC, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background:
Autism Spectrum Disorders (ASD) are diagnosable from toddlerhood and have a significant and pervasive impact on development and wellbeing across the lifespan. Furthermore, where a family includes one child with an ASD diagnosis, various risk factors present for adverse outcomes among later-born children, including both the genetic susceptibility for also developing ASD. However, temperamental characteristics are also heritable and unique environmental influences may present as a result of the ASD diagnosis in the older child (*proband*). While most 'high-risk' sibling research to date has focused on development of core ASD symptoms, there has been little consideration of broader factors such as emotional wellbeing and early indicators of mental health.
Objectives:
Using a variant on a high-risk sibling design, we investigated early emotional wellbeing and mental health indicators among the toddler-aged siblings of children with ASD, including a comparison group of low-risk controls with no family history of ASD. Specifically, we sought to identify the relative predictive value of environmental factors – parent stress and proband mental health difficulties – for toddler mental health, across the period of 2- to 3-years of age, beyond other factors such as risk status, temperament and core symptom presentation.
Methods:
A sample of 30 high-risk and 28 low-risk control toddlers was followed from 2- to 3-years of age. At the first visit, parents completed the self-report Depression Anxiety Stress Scales and the Behaviour Assessment System for Children (BASC) regarding their older child, and they also completed the BASC and the Short Temperament Scale for Toddlers (STST) for their younger child at each of the 2- and 3-year visits. A comprehensive assessment was conducted with high-risk toddlers at the 3-year visit to identify subgroups with and without ASD outcome.
Results:
As anticipated, the probands of high-risk toddlers (i.e., older children with ASD) had greater parent-reported mental health difficulties – internalising and externalising

problems, and broad behaviour symptoms – than did the older siblings of low-risk toddlers (i.e., those with no family history of ASD). Further, parents of high-risk toddlers had greater self-reported depression and stress than parents of low-risk controls. Across the sample as a whole, parent stress and proband mental health difficulties were significant predictors of concurrent mental health difficulties among toddlers (i.e., at the 2-year visit), and substantial continuity in these was then observed one year later (i.e., to the 3-year visit). Risk status (i.e., high- vs. low-risk group) and diagnostic outcome (i.e., ASD vs. no-ASD outcome, among the high-risk group) were not observed to confer additional risk for toddler mental health difficulties, beyond these parent and proband factors.
Conclusions:
Environmental risk factors may play an important role in determining mental health outcomes for young children – with effects apparent already by 2 years of age and showing continuity to 3 years – in the context of family history of ASD. It seems important therefore to monitor early social-emotional development and intervene early to support emotional wellbeing among toddlers at high-risk of ASD to support optimal developmental outcomes.

93 **180.093** Pupillary Light Responses in Infants at Low and High Risk for ASD

J. B. Wagner[1], *S. R. Scarano*[1], *H. Tager-Flusberg*[2] *and C. A. Nelson*[3], *(1)Department of Psychology, College of Staten Island, CUNY, Staten Island, NY, (2)Boston University, Boston, MA, (3)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Research has identified atypical physiological responses in individuals with ASD (e.g., Bal et al., 2008; Joseph et al., 2008), including an abnormal pupillary light reflex (PLR) that discriminated children with ASD from controls with 92.5% accuracy (Fan et al., 2009). The PLR is a well-studied index of the cholinergic system (for discussion, see Fotiou et al., 2009), and recently, Nyström et al. (2015) examined the PLR in infant siblings of children with ASD, a group with as high as a 1 in 5 chance of developing the disorder (Ozonoff et al., 2011). This work found increased sensitivity in the PLR in 10-month-old infants at high risk for ASD (HRA), marked by stronger and faster responses in comparison to low-risk controls (LRC; Nyström et al., 2015).
Objectives: The present study extends the findings of Nyström et al. (2015) to examine sensitivity in the PLR in HRA and LRC infants at 6 and 12 months, in hopes of gaining a richer picture of the trajectory of this response across the first year of life.
Methods: Participants included 32 infants, 12 6-month-olds (HRA: n=5; LRC: n=7) and 20 12-month-olds (HRA: n=5; LRC: n=15). As part of a paradigm examining attention to faces, a Tobii x120 eye-tracker was used to present infants with up to 14 trials of a black fixation screen followed by 32-s videos with white backgrounds showing familiar and unfamiliar faces. On trials where infants were attending to the screen during the shift from dark to light, the maximum absolute acceleration during the PLR and the relative pupil constriction were obtained. Pupil diameter was sampled at 60 Hz and Gaussian-smoothed with a standard deviation of 5 samples (83 ms). Velocity and acceleration were similarly smoothed prior to further processing. Relative pupil constriction was calculated from D_0 (baseline diameter) and D_m (minimum diameter) as $(D_0\text{-}D_m)^2/D_0{}^2$. Infants with at least three valid trials were included.
Results: Univariate ANOVAs were used to examine the influences of age (6, 12) and group (HRA, LRC) on constriction and acceleration during the PLR. For constriction, a marginal age*group interaction was found (p=.06), with LRC showing decreased constriction across age while HRA show increased constriction (Figure 1). For acceleration, a significant age*group interaction was found (p=.046), with HRA showing marginally increased acceleration in their PLR across age (p=.058) and LRC showing no change (p=.63; Figure 2).
Conclusions: Despite the modest sample size, this study extends the work of Nyström et al. (2015) to illustrate changes in the PLR between 6 and 12 months in HRA and LRC. Their work found stronger and faster responses in HRA as compared to LRC at 10 months, but the present findings suggest this is not yet the case at 6 months. Further analyses are underway with an extended sample, and future work will examine how individual differences in this physiological response might relate to developmental outcomes.

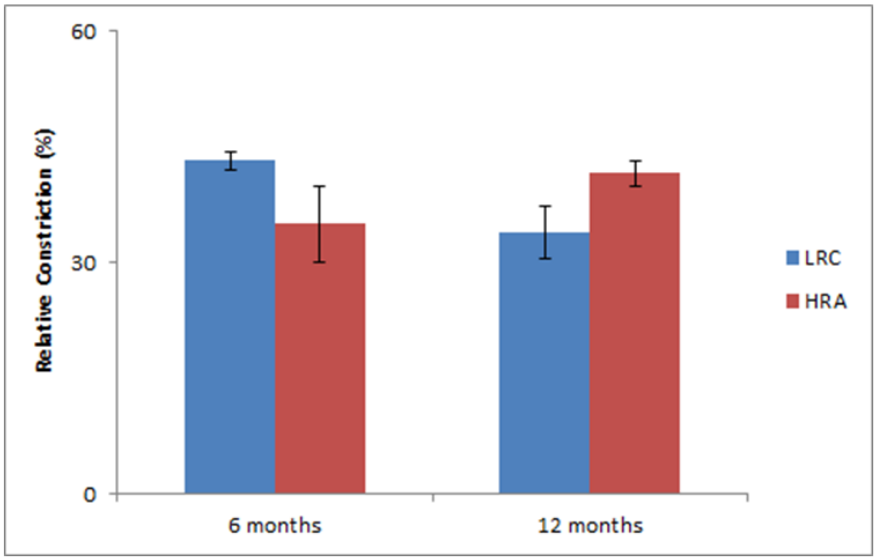

Figure 1: Relative pupil constriction in LRC and HRA at 6 and 12 months. A marginal interaction between age and group was found (p = .06). Error bars +/- SE.

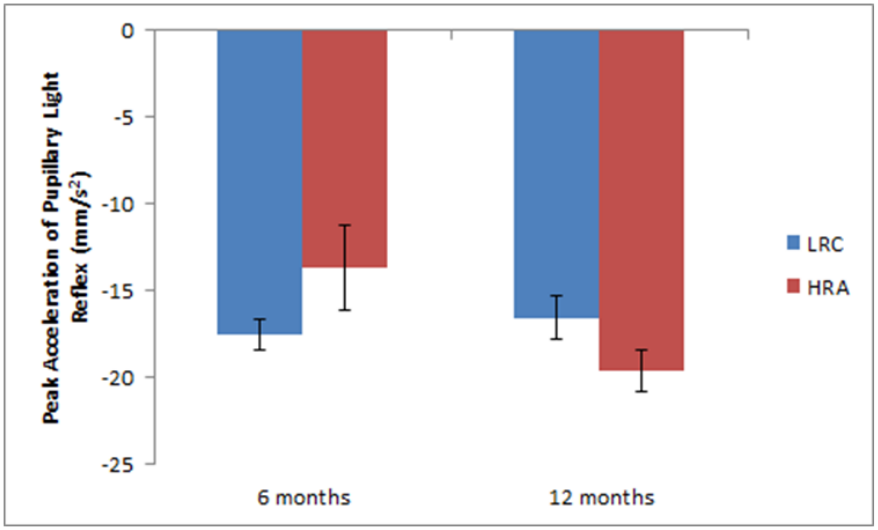

Figure 2: Peak acceleration of the pupillary light reflex in LRC and HRA at 6 and 12 months. A significant interaction between age and group was found (p = .046), with HRA showing marginally faster acceleration in the older age group and LRC showing no difference across age. Error bars +/- SE.

94 **180.094** Reliability of the Toddler Temperament Scale and Differences in Early Temperament Between High Risk Baby Siblings with and without Autism

***J. Chen**, M. Barton and D. A. Fein, Psychology, University of Connecticut, Storrs, CT*

Background: Research has shown that baby siblings of children diagnosed with autism who go on to receive an ASD diagnosis at 36 months demonstrate unique early temperament trajectories in the first two years (Garon et al., 2009). This study builds upon this literature by looking at early temperament differences between high risk baby siblings with and without a diagnosis of ASD at age 2, using the Toddler Temperament Scale (TTS).
Objectives: To assess the internal reliability of the TTS subscales, and test for group differences in parent-rated temperament between baby siblings with and without an ASD diagnosis at age 2.
Methods: Baby siblings were screened for autism using the M-CHAT or M-CHAT-R. Parents of children who screened positive completed the TTS when their child received a diagnostic evaluation including the ADOS, Mullen, Vineland, and parent interview (n=149, mean age of child = 22.6 months). Cronbach's alphas were calculated for each of the nine subscales of the TTS. Chi-square tests were used to compare demographics between children with an ASD diagnosis (n=80) and those with a non-ASD diagnosis (n=69; includes developmental delay, language disorder, and no diagnosis). Subscale scores (average score across items within a subscale), as well as parent responses to general impression items on the TTS were compared between groups using t-tests.
Results: Several subscales of the TTS were found to have acceptable to good internal reliability: Activity (α=.748), Rhythmicity (α=.758), Approach (α=.849), and Distractibility (α=.873). Other subscales were found to be less reliable: Mood (α=.693), Adaptability (α=.654), Persistence (α=.607), Intensity (α=.559), and Threshold (α=.573). ASD and non-ASD groups did not differ significantly in terms of gender or ethnicity. Parents of children in the ASD group tended to rate their child's behavioral style as significantly less distractible (p<.001, d= 1.00), less rhythmic (p=.004, d= .48), slower to adapt (p=.011, d= .43), more withdrawn (p=.009, d= .44), and having more negative mood (p=.004, d= .48), compared to parents with children in the non-ASD group. When asked directly for general impressions of their child's temperament, parents in the ASD group described their child as being more irregular in bodily functioning (p=.037, d= .35), slower to adapt to socially acceptable behavior (p<.001, d= .87), and less manageable (p=.002, d= .52).
Conclusions: Certain subscales of the TTS appear to be reliable when used with a sample of children at high risk for autism. Within this high risk group, baby siblings who receive an ASD diagnosis around age 2 may demonstrate different temperament profiles than their peers without autism. In particular, these children may be less able to remove themselves from ongoing behavior; less consistent in their eating, sleeping, and elimination routines; slower to change their behavior in response to novel people, events, and instructions; less likely to approach novel people or experiences; and present with more negative and less positive mood. Parents of these children may also describe their child as significantly harder to manage. Temperament assessments may provide important information about parents' experience of their child's behavioral tendencies in this high-risk group.

95 **180.095** Restricted and Repetitve Behaviors (RRBs) in Simplex and Multiplex ASD

***K. R. Bradbury**[1], M. Barton[2] and D. A. Fein[2], (1)University of Connecticut, Storrs, CT, (2)Psychology, University of Connecticut, Storrs, CT*

Background: Limited research has been conducted to explore the extent to which affected infant siblings of children with ASD are representative of the general population of children with ASD. Previous research from our lab suggests that affected infant siblings in multiplex families may be higher functioning than children with ASD in simplex families with respect to language and cognitive ability. While overall ASD severity did not differ, prior analyses suggested that children with ASD from multiplex families might

display more restricted and repetitive behaviors (RRBs) than those from simplex families. The current study proposes to further explore the profile of RRBs in simplex and multiplex ASD using a four-factor model.
Objectives: To examine differences in RRBs in toddlers with ASD from simplex and multiplex families.
Methods: A sample of 39 younger siblings with ASD (M_{age} = 24.2 months) from multiplex families (M-ASD) was compared to a matched sample of 39 children with ASD (M_{age} = 24.4 months) from simplex families (S-ASD). Samples were matched pairwise on age, gender, maternal education, and ethnicity. Presence and type of RRBs was assessed using parent report (ADI/parent interview) and clinician-rated measures (CARS, ADOS, and DSM-IV-TR). Based on previous research on the ADI, RRBs were divided into three factors - Insistence on Sameness (IS), Restricted Motor Behaviors (RMBs), and Circumscribed Interests (CI). A fourth factor, Unusual Sensory Responses (SE), was added. All RRB items were coded as present or absent. RRB factor scores and an ADI RRB total score were calculated and compared between groups. Relevant CARS items, ADOS items, and DSM-IV-TR criteria were selected based on these factors and compared between groups.
Results: Samples were well matched on age, gender, maternal education, and ethnicity (*p's* > .5). Based on parent-report, the M-ASD group exhibited more RRBs than the S-ASD group (p = .01, d = .76). Significant differences between M-ASD and S-ASD groups were observed in the Insistence on Sameness (p =.045, r = .25) and Unusual Sensory Responses (p =.039, r = .28) factors. More parents of M-ASD children endorsed the ADI *Compulsions/Rituals* item (M-ASD 29% vs. S-ASD 11%) and ADI *Unusual Sensory Interests* item (M-ASD 69% vs. S-ASD 27%) than parents of S-ASD children. Similarly, more M-ASD children meet DSM-IV-TR diagnostic criteria for adherence to routines than S-ASD children (M-ASD 26% vs. S-ASD 11%). No significant differences were observed on clinician-rated measures of behavior (ADOS and CARS).
Conclusions: Based on parent report, M-ASD children display more RRBs than S-ASD children, specifically in the areas of Insistence on Sameness and Unusual Sensory Responses. Scores on clinician-rated measures failed to corroborate these findings, potentially due to the small window in which a child is observed during an evaluation. This study builds upon previous research suggesting the heterogeneity of RRB presentation within the ASD population. Further research is needed to determine whether the presence of an older sibling with ASD sensitizes parents to the presence of RRBs and leads to more accurate reporting or perhaps even an over-reporting of symptoms.

96 **180.096** Retrospective Video Analysis of Grasp Types and Functional Actions in Infants at Heightened Risk for Autism Spectrum Disorders

L. Sparaci[1], *J. B. Northrup*[2], *O. Capirci*[1] *and J. M. Iverson*[2], *(1)Institute of Cognitive Sciences and Technologies (ISTC), National Research Council of Italy (CNR), Rome, Italy, (2)University of Pittsburgh, Pittsburgh, PA*

Background: Research shows delays in fine motor skills and object exploration, with cascading effects on later communication in infants at heightened risk for Autism Spectrum Disorders (ASD; LeBarton & Iverson, 2013). Studies on typical development highlight that infants' ability to grasp and use tools in accordance to function, supports later non-verbal and verbal communication skills (Capirci, Contaldo, Caselli & Volterra, 2005; Caselli, Rinaldi, Stefanini & Volterra, 2012). However, only a few studies have analyzed grasping behavior in infants at heightened risk for ASD and they have considered presence/absence of grasping rather than grasp types and functional actions (Libertus, Sheperd, Ross & Landa, 2014).
Objectives: To analyze functional grasps and functional actions with a standard object in a group of infants at heightened risk for ASD.
Methods: Participants were 42 infants at heightened risk for ASD: 15 with typical development (TD), 15 with language delay (LD) and 12 with ASD (ASD). As part of a larger longitudinal study, infants were videotaped at home for 45 min sessions at 10, 12, 18 and 24 months of age and administered the Early Social Communication Scales (ESCS; Mundy et al., 2003). During the ESCS, infants sat at a table and were given the opportunity to grasp and use a spoon positioned in front of them together with a small bowl for 1 min. Spontaneous behavior was retrospectively video coded analyzing: (1) whether infants produced at least one spoon grasp (grasp production); (2) in all cases in which the spoon was grasped at least once, whether the first grasp produced was functional or non-fuctional (grasp types); (3) in all cases in which at least one spoon grasp was produced, the number of infants that produced a functional action. Grasps were classified as 'functional' if they allowed to easily perform an eating action and 'non-functional' if the grasp rendered eating actions difficult (Connolly & Dalgleish, 1989). Actions were classified as 'functional' if the spoon was either dipped in the bowl or placed in the bowl and brought to the mouth as in feeding. Analyses focused on group differences in grasp production, grasp types, and numbers of infants producing a functional action.
Results: Analyses indicated: (1) no differences in numbers of infants who grasped the spoon (all ps >.05); (2) a significant difference at 24 months in the number of functional vs. non-functional grasps between ASD and TD (p=.03), but not between TD and LD infants (p=.10); (3) a significant difference at 10 months in the numbers of infants producing a functional action between ASD and TD (p=.005), but not between TD and LD infants (p=.23). This difference was no longer present by 18 months.
Conclusions: Data indicate later onset of functional grasps and actions in infants subsequently diagnosed with ASD. None of the infants in the ASD group produced a functional action at 10 months. Late onset of functional grasps and actions may hinder their role in supporting infant-caregiver interactions, leading to cascading effects on later communication skills in ASD.

97 **180.097** Revisiting Fixation Toward Eye and Mouth Region in ASD Toddlers from the General Population: Cross Sectional and Longitudinal Analyses

M. K. Kwon[1], *A. Moore*[2] *and K. Pierce*[3], *(1)Neuroscience, University of California, San Diego, La Jolla, CA, (2)University of California San Diego, San Diego, CA, (3)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA*

Background: Atypical eye contact is a well-known characteristic of children with Autism Spectrum Disorder (ASD), (APA, DSM-5, 2013), and it is thus not surprising that eye tracking studies have reported reduced fixation towards the eye region in ASD (Jones, Carr, & Klin, 2008; Jones & Klin 2013) . However, several studies have not replicated this effect (e.g., Chawarska et al., 2013; Young et al., 2009). One possible explanation for these inconsistent findings is different ages of participants. In Jones and Klin's (2013) study, ASD children showed similar rates of fixation as TD children on eye regions at 2 months and ASD children's rates of fixation on eyes declined to half the rate of TD children's at 24 months. Therefore, comparing fixation times across multiple time points may influence differences detected between groups (Klin, Shultz, & Jones, 2015).
Objectives: The present study examined the developmental changes in fixation time toward the eye, mouth and body region in ASD and TD children between 1 to 3 years of age.
Methods: Participants were 125 ASD and 110 TD toddlers ranging in age from 1 and 3 years. All toddlers participated in standard psychometric testing and were followed longitudinally until a diagnosis was confirmed at age three. Toddlers watched a 44 second movie showing a close-up image of a female speaking short common phrases coupled with familiar hand gestures (e.g., peekaboo). Fixation duration within 3 AOIs (eyes, mouth, and body) was measured using a Tobii T120 eye-tracker and was subsequently compared between three age cohorts (ages 1, 2 & 3 years). Ninety seven children (47 ASD, 50 TD) also had eye-tracking data available for a subsequent evaluation, approximately one year later, and changes in looking times were examined (T1 vs T2).
Results: Three two-way ANOVAs with Age (3) and Group (2) as between-subjects factors and proportion of fixation time of each AOI as a dependent variable revealed that only fixation time on body differed between ASD and TD children (F(1,229)= 5.342, p=.022, η^2=.023), and the amount of this group difference did not differ across ages (p=.445, η^2 = .007). Change in fixation times across two visits also revealed that ASD children looked at body regions longer than TD children (F(1, 95) = 10.228, p=.002, η^2 = .097), and no differences were found in looking times at eye or mouth regions, *p's* >. 465. The amount of group differences in fixation times on each of the 3 AOIs did not differ across time, *p's*>. 129.
Conclusions: Neither fixation times nor change in fixation times on eyes were different between ASD and TD groups. The ASD group did show slightly longer fixation to the body region (3-4 % difference at Ages 1 and 2) when compared to TD children. This result was consistent across one and two year old samples, but was not evident in three year olds. Overall the fixation patterns between ASD and TD toddlers were strikingly similar.

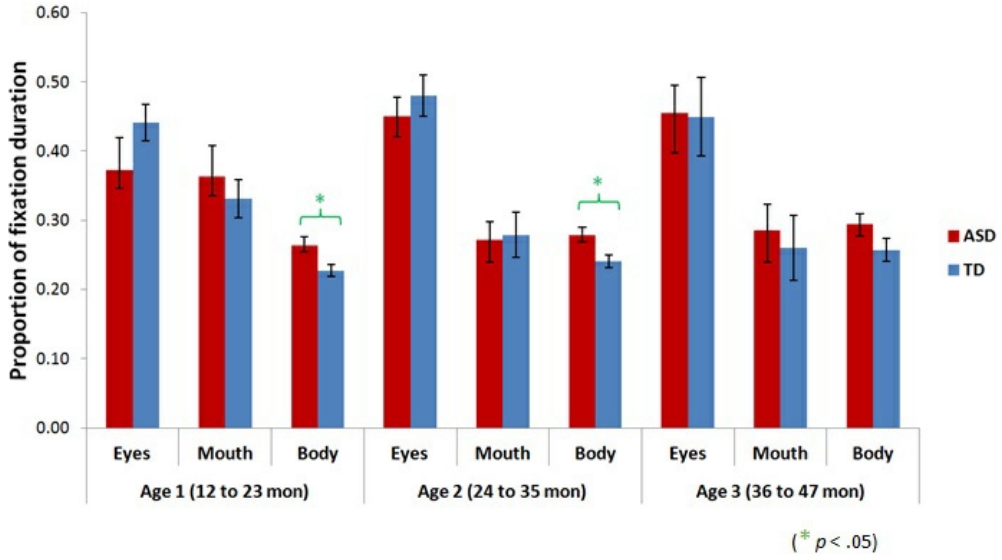

Figure 1. Mean proportions of total fixation durations from one-time visit samples (total *N*= 235). Error bars represent standard errors of the mean.

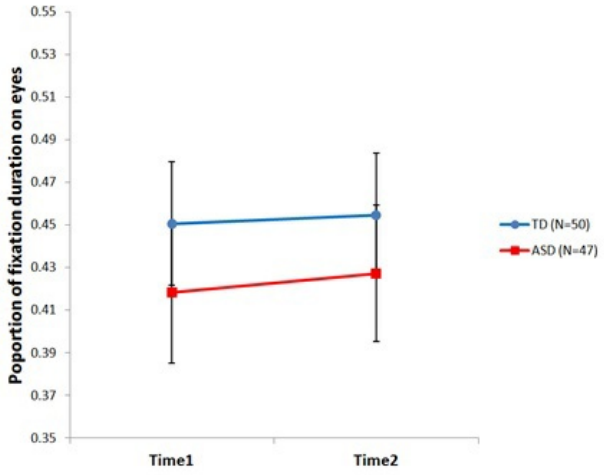

Figure2. Mean proportions of total fixation durations on eyes in ASD and TD groups. Error bars represent standard errors of the mean.

98 **180.098** Sex-Differences in 17-30 Months Old Toddlers: An Analysis of the M-CHAT

R. A. Oien[1,2], *L. Hart*[2], *S. Schjolberg*[3], *C. A. Wall*[2], *E. S. Kim*[2], *M. R. Eisemann*[1], *K. Chawarska*[2], *F. R. Volkmar*[2] *and F. Shic*[2], *(1)Psychology, UiT - The Arctic University of Norway, Tromsø, Norway, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Mental Health, Norwegian Institute of Public Health, Oslo, Norway*

Background: Research suggests that in general population males tend to be more prone to developmental delay (Boyle et al 2011) and have a higher activity level (Riddoch et al., 2007), while females have better social orientation (MacCoby et al., 1979), gaze responses (Conellan et al., 2003, Lutchmaya et al., 2002), as well as strengths in imitation (Hittelmann & Dickens 1979). Studies in ASD population also reveal marked sex differences in behavioral presentation. Females are four times less likely to be diagnosed with ASD than males (Baio, 2012) and, when diagnosed are more likely to exhibit co-occurring anxiety and other internalizing symptoms than males with ASD (Hartley & Sikora, 2009; Solomon et al., 2012). They also exhibit higher symptom severity than males (Dworozynski et al., 2012). These differences are apparent already in preschoolers with ASD (Hartley & Sikora, 2009; Zwaigenbaum et al., 2012).
Objectives: To evaluate sex differences in parent-reported autism-related behaviors in a large epidemiologic Norwegian sample of 17 to 30-months-old toddlers with and without ASD.
Methods: Data were drawn from the Norwegian Mother and Child Cohort Study (MoBa) and its sub-study the Autism Birth Cohort (ABC). The total sample comprised of 53,728 children, including 185 children later diagnosed with ASD. There were 153 (83%) of males and 32 (17%) of females in the ASD sample. Diagnoses were obtained from the ABC clinic or from the National Patient Register. Questionnaires were completed between 17 and 30 months. We conducted ANOVA to compare the proportion of failures on the M-CHAT between males and females in the non-ASD and in the ASD samples. Chi-square risk analyses were conducted to compare which items were most frequently failed by males and females in the non-ASD stratified samples matched on mean to ASD males and females. Logistic regression was used to analyze which items most frequently failed by males and females in the ASD sample, controlling for sex and total number of failed items.
Results: Non-ASD males (M=.85, SD=1.22) failed more (P<.001) than females (M=.74, SD=1.11). ASD males (M=2.68, SD=3.54) failed less (P<.001) than females (M=5.16, SD=5.34) on mean number of failed items. Risk analyses showed that non-ASD sample females presents strengths on *imitation* and *pretend play*. Males showed strengths on *enjoy climbing on things* and *functional play with objects*. Logistic regression revealed that ASD females were more likely to fail the *imitation* item, but less likely to fail the *follow to point* item compared to ASD males.
Conclusions: In this epidemiologically ascertained Norwegian sample, mothers reported a higher degree of symptom severity in female than male toddlers later diagnosed with ASD. Females in the non-ASD samples show strengths related to imitation compared to males, a strength that ASD females have lost compared to ASD males. They do however preserve the strength of response to joint attention over males. The study suggests that females later diagnosed, already during the very early stages, may show strengths in joint attention compared to ASD males, but show selective impairments in imitation.

99 **180.099** Sex-Specific Differences in Infant Visual Attention and Early Word Production: Potential for Female Protective Factors

R. Burger-Caplan[1,2], *A. Klin*[3], *J. N. Constantino*[4] *and W. Jones*[3], *(1)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (2)Department of Psychology, Emory University, Atlanta, GA, (3)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (4)Washington University School of Medicine, Saint Louis, MO*

Background: Autism Spectrum Disorder (ASD) is among the most highly heritable of all psychiatric disorders, with a large body of research supporting a multifaceted genetic etiology. One well-documented but still poorly understood feature of that etiology is a highly skewed sex ratio, with only one affected female with ASD for approximately every 4 males (Werling & Geschwind, 2013). It has been suggested that there may exist some mechanism of “resilience” in females such that risk factors are less potent. We hypothesize that sex-specific differences in processes of typical development (TD)—i.e. female precociousness in acquisition of communicative milestones—could serve as such a protective factor and could support female resilience to ASD. Previous research from our laboratory suggested sex-specific differences in visual attention to the mouth in the first 18 months of life, temporally and developmentally aligned with language acquisition.

Objectives: We studied sex-specific differences in both visual attention to the mouth and in language acquisition, from 2 until 40 months of life, in order to better understand their potential role as protective factors for females at risk for ASD.
Methods: Eye-tracking data were collected in TD infants longitudinally from 2 until 40 months of life (146 male, 131 female). The MacArthur-Bates Communicative Development Inventory (CDI) was administered longitudinally at 9, 12, 18, and 36 months, assessing vocabulary acquisition. Z-scores were calculated from raw CDI scores.
Results: A marked sex difference exists in visual attention to the mouth (figure 1a) between 2 and 20 months of life, and is most pronounced in early infancy through the first year, with females demonstrating an increase in mouth-looking that is greater in magnitude and steeper in slope than the parallel phenomenon in males. Sex-differences in visual attention to the mouth disappear, however, by 36 months. A concurrent difference in vocabulary production between females (M=0.25, SD=1.05) and males (M= -0.22, SD=0.89) at 18 months (t=4.02, p<0.001) converges by 36 months, at which point females (M=0.12, SD=0.86) no longer differ from males (M= -0.09, SD=1.09; t=1.14, p=0.256; figure 1b).
Conclusions: Results indicate strong sex-specific differences in preferential visual attention beginning in very early infancy. When seen as an index of engagement with the social-communicative task of early language learning, female precociousness (increasing visual attention to the mouth more quickly than males in the first year) suggests an opportunity by which an existing sex difference of typical development might serve as a protective factor against developmental processes disrupted in ASD. Coupled together, the previously reported alignment of sex difference in mouth-fixation with sex difference in language acquisition, and the present study's report of the disappearance of sex difference in mouth-fixation concurrent with the disappearance of sex difference in language indicate a role for female precociousness in communicative development (particularly in its earliest stages) as protective against insults to the typical trajectory of normative social development.

100 **180.100** Sleep and Developmental Progress in Infants at High-Risk for Autism

*A. J. Schwichtenberg[1], **E. Abel**[2], J. Amstutz[1], S. L. Christ[1], M. Miller[3], S. Ozonoff[3] and T. F. Anders[4], (1)Purdue University, West Lafayette, IN, (2)Purdue University, Lafayette, IN, IN, (3)UC Davis MIND Institute, Sacramento, CA, (4)UC Davis M.I.N.D. Institute, South Dartmouth, MA*

Background: Sleep dysregulation in families raising children with autism spectrum disorder (ASD) is common. Parents of children with ASD report more sleep problems in themselves, their children with ASD, and in younger siblings. Although several studies have documented elevated rates of sleep problems, few studies have assessed the

developmental correlates of these problems. The impact of sleep on development is a growing research area with studies of typically developing children noting deficits in language learning, memory, and social competence when sleep is restricted or dysregulated. Each of these developmental domains are also known areas of difficulty for children at elevated risk for ASD.
Objectives: This study aimed to assess the associations between sleep regulation and language, social, and visual reception skills within young children at elevated risk for ASD (i.e., infant siblings of children with ASD) across two independent samples.
Methods: In two samples child actigraph-derived sleep/activity patterns were classified as regulated or dysregulated. Infant/toddler developmental progress was indexed with the Mullen Scales of Early Learning (MSEL) and the Vineland Adaptive Behavior Scales. The first sample included 55 toddlers at 24 or 36 months of age (Sample C). Within this sample, 27 toddlers were younger siblings of children with ASD (high-risk group) and 28 had siblings with no known diagnosis (low-risk group). The second sample (Sample P) included 118 assessments between 6 and 30 months for 80 children (high-risk group = 41, low-risk group = 39).
Results: Using sleep time series and multivariate general linear models, children with regulated sleep had higher average MSEL visual reception (VR) and expressive language (EL) scores (β = 1.91, p < .05 and β = 2.03, p = .01, respectively) relative to children with dysregulated sleep (Sample P). Sleep explained 5% of the variance in VR and 6% of the variance in EL. In Sample C, there was a statistically significant interaction for sleep with ASD risk status for the MSEL VR scale. This interaction showed a modest but positive effect of regulated sleep for children in the low risk group (β = 4.38, p = .07) and no significant effect of sleep regulation for children in high risk (β = -1.78, p =.40). Sleep also interacted with both ASD risk status and child gender for MSEL receptive language (RL) scale. Sleep was associated with receptive language for children in the low-risk group but not the high-risk group. Additionally, boys with dysregulated sleep performed on average 7 months lower than their chronological age on the MSEL RL scale (β = 6.88, p < .01).
Conclusions: In the first three years of life, the present study demonstrated a modest but significant association between sleep regulation and concurrent language and visual reception development. However, this influence was not robust for infants developing at high risk for ASD. This may reflect the relative magnitude of the influence sleep has on development. Infants at elevated risk for ASD face both genetic and environmental risk factors which may have a stronger developmental impact when compared to sleep regulation.

101 **180.101** Social Emotion Regulation Strategies in Toddlers with ASD

A. Milgramm, *S. Macari, L. DiNicola, P. Heymann, E. Hilton, K. K. Powell, S. F. Fontenelle and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Emotion regulation (ER) encompasses the processes involved in initiating, maintaining, and modulating emotional responsiveness (Bridges & Grolnick, 1995). Toddlers often use social interaction to assist in the regulation of their emotions. Children with Autism Spectrum Disorder (ASD) often exhibit atypical emotional responses and also experience difficulties in social interactions. It is not clear if children with ASD differ from their non-ASD peers in their use of proximal (ProxER; i.e., physical contact with an adult) and distal (DistER; e.g., looking, vocalizing, smiling) social ER strategies.
Objectives: (1) To compare frequency of ProxER and DistER strategy use in toddlers with and without ASD. (2) To investigate whether the use of these strategies is modulated by the emotional context of the situation. We hypothesized that toddlers with ASD exhibit fewer proximal and distal social ER strategies compared to the Non-ASD group across all emotional probes.
Methods: Participants included 50 toddlers (ASD, n=20; Non-ASD, n=30) between 15 and 26 months of age (M=20 months) who completed the Laboratory Temperament Assessment Battery (LabTAB; Goldsmith & Rothbart, 1999). The Non-ASD group consisted of typically developing and developmentally delayed toddlers. Nine tasks were presented in order to elicit three emotions: Frustration, Joy, and Fear. Videotaped sessions were coded offline by blinded coders. DistER strategies included pointing, vocalizing, talking, and making eye contact with the examiner or parent. ProxER strategies consisted of physical comfort seeking behaviors such as touching the parent or moving into the parent's lap. Generalized linear mixed model (GLMM) analyses were used to examine the fixed effects of diagnostic group, emotion type, and their interactions on frequencies of DistER and ProxER.
Results: Preliminary analyses indicated that both groups used more DistER than ProxER overall. Analysis of DistER revealed a main effect of diagnosis (F(1,144)=6.19, p<.05; Non-ASD>ASD), no effect of emotion, (p=.357), and a marginally significant interaction effect (F(2,144)=2.37, p=.097). Planned contrasts revealed that the groups differed in frequency of DistER strategies only in the Joy condition, such that ASD<NonASD (p=.003). Analysis of ProxER revealed a significant main effect of diagnosis (F(1,144)=5.0, p<.05; ASD>Non-ASD) and emotion type (F(2,144)=24.8, p<.05, Fear>Frustration=Joy), and a significant group x emotion interaction (F(2,144)=3.26, p<.05). Planned comparisons indicated that the groups differed only in the Joy condition, such that ASD>NonASD (p=.049; see Figure 1a&b).
Conclusions: Overall, toddlers exhibited more distal than proximal social ER strategies, with toddlers seeking proximity to parents most frequently during Fear tasks. Both groups of toddlers used similar ER strategies in response to Fear and Frustration probes. However, while experiencing joy, toddlers with ASD were less likely to use ER strategies involving eye contact, pointing, or socially directed vocalizations and more likely to initiate physical contact. This increased use of proximal ER strategies may represent a lower level of social referencing by toddlers with ASD within contexts that encourage sharing emotions (e.g., joy) as opposed to seeking comfort (e.g., frustration, fear). Given that interventions for children with ASD often target social behaviors, these findings may help inform current approaches and lead to more effective outcomes.

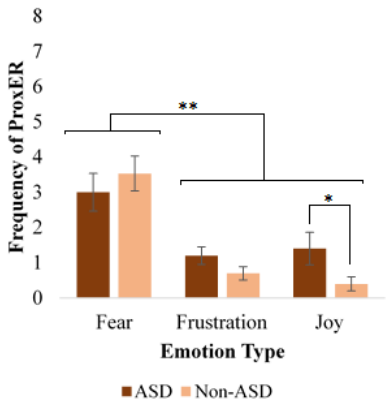

Figure 1a. ProxER across diagnoses and emotion types. *p < .05; **p < .01

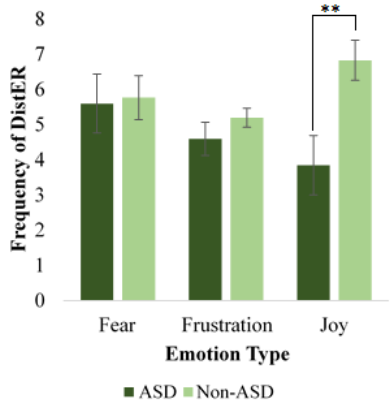

Figure 1b. DistER across diagnoses and emotion types.

102 **180.102** Social Orienting, Joint Attention, and Empathy: Impacts of Early Impairments on Subsequent Social Development

A. C. Dowd, *B. G. Davidson and A. R. Neal-Beevers, Psychology, University of Texas at Austin, Austin, TX*

Background:
Autism Spectrum Disorder (ASD) is characterized by deficits in social skills that develop early in infancy, including impairments in social orienting, joint attention, and empathy (Dawson et al., 2004). Early impairments in attending to social situations are posited to deprive children of social information that subsequently limits the development of other social skills (Mundy & Neal, 2001). Understanding how these early social skills build incrementally upon each other is crucial for building a developmental model of ASD, identifying target areas for intervention, and establishing a timeframe for beginning early interventions.
Objectives:
Identify the extent to which concurrent social orienting and joint attention skills predict infants' empathic responses at 12 and 15 months.

Methods:
Eighteen high-risk and 15 low-risk infant siblings were assessed longitudinally at 12- and 15-months-of-age for: 1) Attention and Affect responses to a standard empathy paradigm (Hutman et al., 2010); 2) Responding to and Initiating Joint Attention (RJA and IJA, respectively; Early Social Communication Scales; Mundy et al., 2003); 3) deficits in social orienting (FailToOrient) based on 'Orients to Name' (Autism Observation Scale for Infants; Bryson et al., 2008) and 'Responds to Name' (Bayley, 2006). Linear mixed-effects models were conducted separately for Attention and Affect as outcome variables, with RJA, IJA, FailToOrient, Age, and all possible two-way interactions as predictors. Models were optimized by removing non-significant interactions and main effects when their removal reduced the Akaike Information Criterion.
Results:
Attention: Significant RJA-by-Age and FailToOrient-by-Age interactions suggest that Attention at 12 months did not vary by RJA or FailToOrient. However, Attention at 15 months was lower for infants with low RJA scores or who failed to orient to their name. Furthermore, a significant RJA-by-FailToOrient interaction suggests that failing to orient to name did not affect Attention in infants with strong RJA skills; however, for infants with low RJA scores, Attention was even lower for infants who also failed to orient to name.
Affect: A significant RJA-by-Age interaction and marginally significant FailToOrient-by-Age interaction suggest that Affect at 12 months did not vary by RJA or FailToOrient. By 15 months, however, Affect was higher in infants with stronger RJA skills and marginally stronger for infants who oriented to their name.
Conclusions:
As empathy develops between 12 and 15 months, infants with deficits in RJA or social orienting also attend less and display less affect to another's distress. Attention was even lower when infants had deficits in both RJA and social orienting. However, infants attended more when they exhibited the more advanced skill (RJA) regardless of whether or not they failed the developmentally easier skill (social orienting). Together these findings help us understand how these social skills develop in relation to each other and may inform early intervention strategies.

103 **180.103** Social Scene Manipulation through Gaze-Contingent Interfaces: Towards Automated Gaze Strategy Instruction for Young Children with ASD

***Q. Wang**, E. S. Kim, C. A. Wall, E. C. Barney, Y. A. Ahn, C. Foster, M. Mademtzi, M. G. Perlmutter, S. Macari, K. Chawarska and F. Shic, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Eye tracking has been used to examine gaze patterns in studies of autism spectrum disorder (ASD). However most of these studies only recorded participants' eye movement during passive viewing, used static images, and manually defined boundaries of areas of interest (AOIs). In the present study, we investigate how typically developing (TD) children and children with ASD attend to dynamic social scenes in an interactive gaze paradigm.
Objectives: 1) To construct normative gaze models of dynamic social scene viewing by translating gaze patterns from TD controls into probability heatmaps and applying this model as an implicit AOI map for each video frame of dynamic stimuli. 2) To evaluate whether the looking behavior of children with ASD can be modified to resemble the normative gaze pattern.
Methods: Each toddler viewed four categories of dynamic video stimuli: Dyadic Speech (Motherese), Body Movements, Activity with Objects, and Singing Songs. These video stimuli were separated into 5 blocks with all categories of videos represented in each block. Participants included TD children (n = 31, Mage = 37.4 ± 14.29 months) and children with ASD (n = 9, Mage = 33.4 ± 7.07 months). All TDs were assigned to the regular, non-Gaze Contingent (non-GC) viewing condition, and their data was used for normative gaze pattern. Among ASD children, five were assigned to the Gaze Contingent (GC) condition and four were assigned to the non-GC condition. Subsequently dynamic heatmaps of the normative gaze pattern were applied to construct a corresponding set of attention-redirecting videos which darkened and blurred areas where the TD children were not looking. If the participants in the GC condition looked away from normative attention areas, the next video frame switched to the attention-redirecting video with bright and sharp regions corresponding to TD's heatmap distribution. This GC adaptive training method was designed to automatically attract the visual attention of children with ASD while they viewed the videos.
Results: In all four categories of videos children with ASD had significantly shorter looking times compared with TD children ($p < 0.001$). Furthermore, a linear mixed model analysis showed that children with ASD looked significantly less at Motherese dyadic speech videos compared to the other three categories of social scenes ($p < 0.001$); no significant difference was found in the TD group ($p > 0.4$). With GC adaptive training, children with ASD maintained their attention better than in the non-GC condition ($p < .05$). There were no significant contributions of Verbal ($p = .605$) or Nonverbal DQ ($p = .163$) to the model.
Conclusions: The preliminary data provide support for the application of GC training as a viable option for modifying gaze behaviors in children with ASD. Given that visual attention gates learning, this paradigm offers a highly promising avenue for developing new therapeutic interventions. By improving looking strategies of children with ASD, we hope to broaden their future access to social learning opportunities during this period of great neuroplasticity.

104 **180.104** Socio-Communicative Difficulties in Severely Visually Impaired (VI) Children WHO ARE at Risk of Autism As Measured By the Social Communication Schedule (SCS) and Parental Report

***N. J. Dale**[1], E. Sakkalou[2], M. O'Reilly[2], R. MacKechnie[3], C. Springall[3] and A. Salt[2], (1)UCL Institute of Child Health/ Great Ormond Street Hospital for Children, London, United Kingdom, (2)Clinical Neurosciences, UCL Institute of Child Health, London, United Kingdom, (3)Great Ormond Street Hospital for Children, London, United Kingdom*

Background:
Young children with congenital profound or severe visual impairment (VI) have a high risk of developing difficulties in social communication and interaction and behaviour problems. Children with profound VI (PVI) children, with light perception at best, are at greater risk for autism than children with basic 'form' vision (SVI) with difficulties becoming evident around the 2nd year of life (Dale & Sonksen, 2002). Existing tools used to measure early social communicative development are highly vision-dependent and not valid for children with VI. The Visual Impairment and Social Communication Schedule (VISS - Absoud et al., 2010) has had preliminary validation with children with VI and was highly reliable in predicting a later diagnosis of ASD; we are now developing this further to include standard behavioural items and social 'presses' (Social Communication Schedule -SCS).
Objectives:
To examine socio-communicative skills and difficulties in a sample of 2-year-old children with PVI and SVI using the SCS and Negative Behaviour Screener (NBS), and further examine relations with parent report of infant socio-communicative skills and pervasive developmental problems.
Methods:
Preliminary data from 51 children (M=26 months; 11 PVI, 40 SVI), with 'simple' congenital disorders of the peripheral visual system were rated using the SCS (high scores indicated better social communicative abilities) and the NBS (higher scores indicated more negative behaviours), whilst engaging in social and independent play tasks. Functional vision was assessed with the Near Detection Scale (Sonksen et al., 1983) to establish lower PVI and higher SVI. Parents rated the Vineland Adaptive Behaviour Scales (VABS) and the Child Behavior Checklist (CBCL). The subscales Communication and Social Skills from the VABS and the subscale Pervasive Developmental

Problems (PDP) from the CBCL were utilised. These subscales have shown predictive relations with ASD in previous studies (Volker et al, 1987; Sikora et al, 2007).
Results:
Strong negative relations found between SCS scores and NBS scores (r= -.74, *p*<.001) showed that children who scored higher on socio-communicative abilities on SCS had lower negative behaviour scores on NBS. A correlational analysis of the effect of vision level showed higher SCS scores and lower negative behaviours with higher level of functional vision (r= .48, *p*<.001; r= -.35, *p*<.01). Positive correlations were found between the SCS and VABS Communication (r=.53, *p*<.001) and Social Skills (r= .60, *p*<.001) and negative correlations between the NBS and VABS Communication, r= -.36, *p*<.01 and Social Skills, r= -.50, *p*<.001. Children with lower SCS scores and higher NBS scores were rated higher on the PDP by parents (r= -.37, *p*<.01, r= .33, *p*<.05 respectively).
Conclusions:
Children with VI with higher social communicative abilities at 2 years showed lower negative behaviours. Lack of functional vision was a risk factor with children with lowest functional vision (PVI) demonstrating weaker socio-communicative behaviours and higher negative behaviours. Together with promising validation with the parent report measures, the findings suggest that this 'early stage' tool may provide a useful means of differentiating behaviours which may be early signs of autism in this at risk population.

105 **180.105** Temperament Differences Across the First Three Years in High-Risk Younger Siblings of Children with ASD Compared to Low-Risk Controls

C. R. Hess[1] *and R. Landa*[2]*, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)The Kennedy Krieger Institute, Baltimore, MD*

Background:
Temperament differences between high-risk children who do and do not develop ASD have been noted during the first few years of life (Clifford et al., 2013; del Rosario et al., 2014).
Objectives:
To examine differences in child temperament characteristics in the first three years in a high-risk group of children who have an older sibling with ASD compared to a low-risk control group using a prospective, longitudinal design.
Methods:
Parents rated child temperament characteristics on the *Carey Temperament Scales (*Carey & McDevitt, 1995*)* for younger siblings of a child with ASD (N=157, 90 males) and low risk control children (N=23, 12 males) with no family history of ASD at 6-, 14-, 24-, and 36-months. The *Autism Diagnostic Observation Schedule* (*ADOS*; Lord et al., 2002; 2012) and *Mullen Scales of Early Learning* (*MSEL*; Mullen, 1995) were administered at each visit. At 36-months, children were categorized as high risk ASD (HR-ASD, n=32), high risk non-ASD (HR non-ASD, n=125) or low risk typically developing (LR, n=23) based on results of the *ADOS* and clinical best estimate.
Results:
Nonparametric Kruskal-Wallis tests, followed by Mann-Whitney U tests for comparisons, were used to analyze temperament differences between the three diagnostic groups from 6-36 months. Results were considered significant with p-values<.01 or lower. At 6 months, there was a trend for group differences for Intensity (*p*=.037). After removing an outlier, group differences were significant (*p*=.01). HR-ASD group was rated as lower in Intensity (i.e., more passive) than the HR non-ASD and LR groups (*p*s<.01), but the latter two groups did not differ. At 14 months, there were differences between groups for Distractability, Rhythmicity, and Threshold for Noticing New Stimuli (*p*s<.01). HR-ASD group was harder to distract from what they were interested in compared to the HR non-ASD and LR groups, and more arrhythmic than the LR group (*p*s<.01). The HR non-ASD group needed a higher threshold before noticing new stimuli compared to the LR group but not the HR-ASD group; the latter two groups did not differ. At 24 months, there were group differences for Adaptability, Rhythmicity, and Distractability (*p*s<.01). The HR-ASD group had greater difficulties with Adaptability and Rhythmicity than LR group, and were harder to distract from what they were interested in and more arrhythmic compared to the HR non-ASD group (*p*s<.01). At 36 months, there were group differences for Adaptability, Distractability, Mood, Persistence, and Threshold for Noticing New Stimuli. HR-ASD group had greater difficulties with Adaptability and more Negative Mood compared to LR group, and had greater difficulty with Adaptability, Distractability, Persistence, and Threshold for Noticing New Stimuli compared to HR non-ASD group (*p*s<.01).
Conclusions: In this prospective, longitudinal study, temperament differences between high-risk children who developed ASD and typically developing controls were noted as early as 6 months of age and continued through 36 months. This is consistent with findings that children with ASD tend to be more passive in infancy compared to infants without ASD, with notable difficulties in self-regulation of temperament in the second and third years.

106 **180.106** Temperament and Adaptive Functioning in a High-Risk Infant Sib Cohort

N. Garon[1]*, L. Zwaigenbaum*[2]*, S. E. Bryson*[3]*, I. M. Smith*[4]*, J. A. Brian*[5]*, C. Roncadin*[6]*, T. Vaillancourt*[7]*, V. L. Armstrong*[8]*, L. A. Sacrey*[9] *and W. Roberts*[10]*, (1)Mount Allison University, Sackville, NB, Canada, (2)University of Alberta, Edmonton, AB, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (5)Bloorview Research Institute, Toronto, ON, Canada, (6)Kinark Child & Family Services, Markham, ON, Canada, (7)University of Ottawa, Ottawa, ON, Canada, (8)IWK Health Centre / Dalhousie University, Halifax, NS, Canada, (9)Department of Pediatrics, University of Alberta, Edmonton, Alberta, Canada, Edmonton, AB, Canada, (10)University of Toronto, toronto, ON, Canada*

Background:
Siblings of children with Autistic Spectrum Disorder (ASD) have been found to be at higher risk of developing the disorder. As such this population provides a unique opportunity to investigate early mechanisms that influence the trajectory of individuals who develop ASD. Recent findings indicate that temperament may provide insight into the heterogeneous nature of ASD. Research supports a pattern of low positive affect, high negative affect and low regulation in prospective studies of high-risk infants subsequently diagnosed with ASD (Bryson et al., 2007; Garon et al., 2009). Notably, two studies have indicated that infants who are subsequently diagnosed with ASD show distinctive temperament trajectories in the first year of life (Clifford et al., 2013; del Rosario et al., 2014). Of interest for the current study, Evans and Rothbart (2009) have found evidence for two higher order temperament factors, which involve an integration of regulation and reactivity. Recently, Garon et al. (2015) have found differences in how these two main aspects of temperament were structured in a high risk population. In particular, Positive and Negative Affect factors at 24 months were positively associated with one another in the high risk population while the association was non-significant for the low risk population.
Objectives:
The current study had two main objectives. The first was to determine the higher order factor structure of temperament in a high risk population. The second was to determine whether these high order temperament factors at 12 and 24 months predicted adaptive functioning at 5 years.
Methods:
Infant siblings of children with ASD were assessed prospectively at 12 months on the Infant Behavior Questionnaire (IBQ) and at 24 months on the Toddler Behavior Assessment Questionnaire (TBAQ), both completed by parents. At 36 months, an independent 'gold-standard' diagnostic assessment for ASD was conducted including the Autism Diagnostic Observation Schedule (ADOS). At 5 years, parents completed the Vineland Adaptive Behavior Scale II (VABS-II). A confirmatory factor analysis (CFA) was used to derive two higher order temperament factors. A multivariate analysis of variance (MANOVA) was used to explore whether the temperament factors predicted different aspects of adaptive functioning. The dependent variables were VABS-II subscale scores while the independent variables were the two temperament factors and ASD symptoms as measured by the ADOS severity score at 36 months.
Results:
The hierarchical CFA resulted in two higher order temperament factors. The first factor labelled Regulation included significant loadings from the Positive Affect at 12 months, Positive Affect at 24 months, and Effortful Control at 24 months. The second factor, labelled Reactivity, included loadings from Negative Affect at 12 months, Negative Affect at 24 months and Positive Affect at 24 months. The MANOVA indicated that both Reactivity and Regulation made significant contributions to the prediction of adaptive function. Furthermore, these temperament factors remained significant predictors even when ASD symptoms at 36 months were included in the analysis.
Conclusions:
The present findings highlight the importance of early temperament. Further, these results suggest that temperament provides additional information beyond that provided by early ASD symptoms.

107 **180.107** The Clinical Utility of the Chinese Version Modified Checklist for Detecting Children with Autism Spectrum Disorders before Age 4 in Taiwan

Y. S. Wong*, C. C. Wu and C. C. Yang, Department of Psychology, Kaohsiung Medical University, Kaohsiung City, Taiwan*

Background: Autism spectrum disorders (ASDs) are characterized by impairment in social interaction, communication and restricted and repetitive patterns of behaviors (APA, 2000). However, the DSM-5 defined a single autism spectrum disorder (ASD), which changed the corresponding symptom structures from three to two dimensions, including deficits in social interaction/ communication, and repetitive interests/ stereotyped behaviors (APA, 2013).Children with ASDs will show symptoms before age 3 (APA, 2000) or early childhood (APA, 2013). Recently, the prevalence of ASDs increases significantly since 2007(CDC, 2014). However, the diagnosis of children with ASDs is usually delayed. Hence, the screening measures are very crucial to identify individual who has high risk for ASDs. Earlier detection usually promises a better prognosis. Among the numerous screening tools, the Modified Checklist for Autism in Toddlers (M-CHAT; Robins et al., 2001) is one of the most widely-used and well-researched, it consists of 23 yes/no items and can be finished in a short time by the caregivers.
Objectives: Therefore, this study aims to examine clinical utility of the M-CHAT for detecting children with ASDs before age 4 years in low-socioeconomic area of Southern Taiwan. Chia-Yi area was chosen because it belongs to one of the low-socioeconomic area in Taiwan and there are much indigenous people who is relatively disadvantage.

Methods: The Autism Diagnostic Observation Schedule (ADOS; Lord et al., 1999) was used to divide the children into ASDs and non-ASDs group, and M-CHAT was filled in by their caregiver. We would later see whether the classification of M-CHAT consistent with the result of ADOS. There were 236 children aged from 18 to 47 months old, including 113 children with ASDs and 123 children with developmental delay.
Results: The cutoff score of failing any 4 of the 23 M-CHAT items showed sensitivity of .77 and specificity of .72. Using cutoff score of failing any 3 of the 14 new critical items, which is called Brief 14 and was selected by using discriminant analysis, yielded the sensitivity of .71 and specificity of .82.
Conclusions: Inconsistence with previous studies, there is no item that children with ASDs showed failure rate beyond 50%.It might be due to the cultural issue in Chinese parents, they might underreported or deny their kids' symptoms as they want to save their face. Being unfamiliar with ASDs symptoms, they might normalize and misinterpret their kids' abnormal behavior. Even so, the validity of using the M-CHAT to screen clinical samples less than age of 4 years seemed acceptable in low-socioeconomic area of Southern Taiwan. This study also showed that there is cultural universality for children with ASDs in the domain of joint attention and imitation. Furthermore, this study replicated previous findings which children with ASDs showed impairments in social-communicative skill. Results suggest the need for increased education and detail information about childhood development. Furthermore, Brief 14 is suggested to use in the population in Taiwan to gain a better validity.

108 **180.108** The Development of Joint Attention and Vocalizations in Infants at Heightened Risk for Autism Spectrum Disorder

P. Heymann[1], *J. B. Northrup*[2], *M. V. Parladé*[3], *N. B. Leezenbaum*[2], *K. L. West*[2] *and J. M. Iverson*[2], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)University of Pittsburgh, Pittsburgh, PA, (3)University of Miami, Coral Gables, FL*

Background: Infants at heightened risk (HR) for Autism Spectrum Disorder (ASD) who later receive an ASD diagnosis exhibit delays in both joint attention (JA) and pre-linguistic vocalization development (Morales et. al., 2000; Paul et. al., 2011). In typically developing infants, vocalizations are used early on to establish JA between infants and caregivers (Wu & Gros-Louis, 2014), demonstrating an early-emerging link between these behaviors. Previous studies have focused on JA and vocalizations separately (Toth et. al., 2006), but the simultaneous development of these behaviors, as well as their collective impact on early skill acquisition, remains to be explored.
Objectives: This study was designed to examine the development of JA, vocalizations, and their co-occurrence in three groups of HR infants.
Methods: 50 HR infants (30 males) were observed during the Early Social Communication Scale (ESCS; Mundy et. al., 2003) at 14, 18 and 24 months as part of a larger longitudinal study. At 36 months, each infant was classified into one of three outcome groups: Autism Spectrum Disorder (ASD; n = 9); Language Delay (LD; n = 15), or No Diagnosis (ND; n = 25). Videotaped sessions were coded offline by blind coders. Initiating joint attention (IJA: e.g., eye contact between a toy and experimenter, showing) and initiating behavioral requests (IBR: e.g., reaching, giving, pointing) were coded according to the ESCS manual (Mundy et. al., 2003). Each vocalization was identified and coded as vowel only (VO), syllabic (i.e. containing a consonant), or word.
Results: Repeated measures ANOVAs were utilized for all analyses. For JA, a significant main effect of outcome was found only for higher level IJA behaviors (e.g., shows: $F(2,47)=14.43$, $p=.00$). For vocalizations, a 3 (age) x 3 (outcome group) x 3 (vocalization type) repeated measures ANOVA revealed a significant 3-way interaction ($F(8,188)=8.613$, $p=.000$; see Figure 1). Follow-up ANOVAs indicated an age by vocalization type interaction for the ND ($F(4,100)=71.71$, $p=.000$) and LD ($F(4,56)=10.611$, $p=.000$) groups, but not for the ASD group. The ASD group consistently produced fewer and lower quality vocalizations at all three ages, showing no increases in production of any vocalization type at any age. Examining the co-occurrence of JA behaviors and vocalizations, a main effect of outcome was revealed for both IJA + vocalization and IBR + vocalization (p's < .05). Infants later diagnosed with ASD paired vocalizations with JA behaviors significantly less frequently than their ND and LD peers.
Conclusions: Infants who later receive an ASD diagnosis produced fewer higher level IJA behaviors, vocalized less, and produced more vowel-only vocalizations then their ND and LD peers. They further demonstrated a specific difficulty coordinating these behaviors. Coordinating JA behaviors with a vocalization likely enhances communicative quality and engages partners in a way that a simple reach or shift in eye gaze may not. These findings highlight the importance of observing how these two types of communicative behaviors develop together in a HR population.

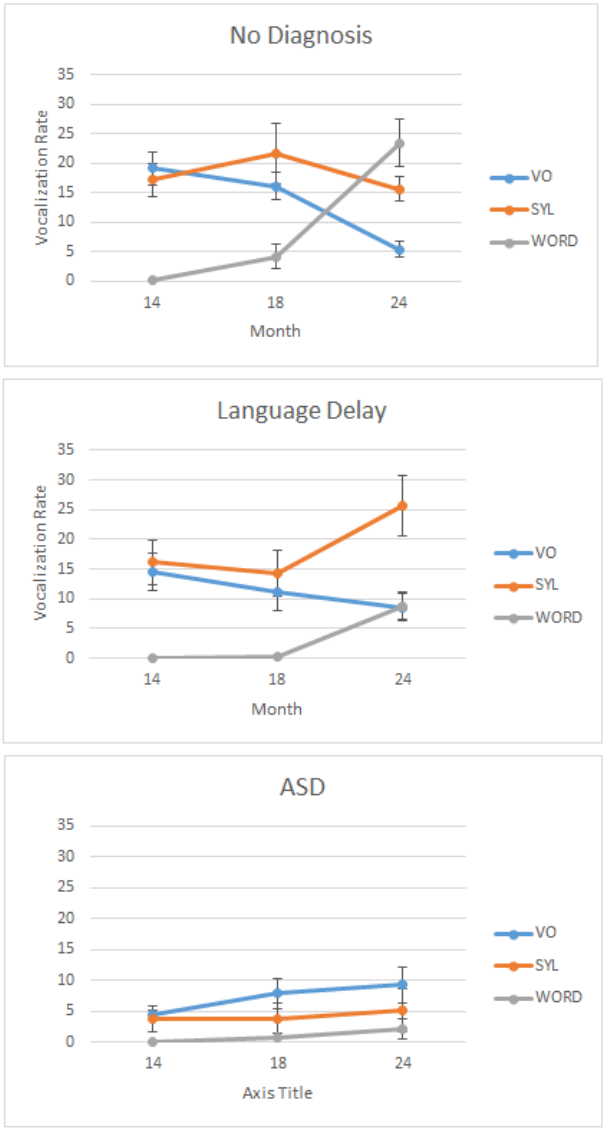

Figure 1: Rate per 10 Minutes of Vocalizations at 14, 18 and 24 months between the three outcome groups.

109 **180.109** The Effects of Others' Speech during Activity Monitoring on Attention Patterns in Toddlers with and without ASD

***Y. A. Ahn**, Q. Wang, C. A. Wall and F. Shic, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Previous research on activity monitoring eye-tracking tasks suggests that toddlers with Autism Spectrum Disorder (ASD) attend less to people and their activities than developmentally delayed and typically developing toddlers (Shic, Bradshaw, Klin, Scassellati, & Chawarska, 2011). Toddlers with ASD divert their attention more towards non-social stimuli (Shic et al., 2014). However, it is unclear whether the presence or absence of others' speech influences attention allocations in toddlers with ASD.

Objectives: To examine the impact of others' speech during activity monitoring in toddlers with and without ASD.

Methods: Thirty-two toddlers with ASD (M_{age} = 30 months, *SD* = 7 months) and 42 toddlers without ASD (M_{age} = 27 months, *SD*= 9 months) viewed 16 20s video clips of two female adults interacting and engaging in a shared activity. Participants without ASD consisted of toddlers with typical development and those with developmental delays not classified as ASD. The video clips varied by the actress pair, type of activity, background, gaze behavior of the actresses, and presence of distractors. Participants' gaze patterns were examined with eye-tracking method. Analyses were conducted to investigate between-group differences in the percentage of time participants spent looking at the scene (%Scene), the actresses' heads (%Head), bodies (%Body), both actresses' heads and bodies (%People), shared activity (%Activity), and background (%Background) during times when actresses were speaking vs. when actresses were silent.

Results: Compared to non-ASD toddlers, the ASD group demonstrated significantly less looking towards people ($p < .01$) and activity ($p < .001$), and significantly more looking at the background ($p < .001$) throughout the experiment. For both diagnostic groups, %People increased with the presence of speech ($p < .05$). There was a trend towards decreased looking at activities when speech was present ($p = .08$). Non-ASD toddlers looked more at heads than bodies when speech was present ($p < .05$). ASD participants looked more at people when actresses were speaking than when they were not speaking ($p < .05$), but %Head and %Body within the ASD group did not differ. Univariate ANOVA analysis did not yield any significant interaction between speech and diagnostic groups for any outcome measure ($p > .05$).

Conclusions: These results support previous findings that toddlers with ASD demonstrate decreased attention towards people and activities and increased attention towards the background as compared to their peers without ASD. The current analyses further highlight that the presence of speech may play a role in directing toddlers' attention to social components of the scene. Non-ASD toddlers attended significantly more to heads, whereas toddlers with ASD attended to heads and bodies equally, even in the presence of speech. This may suggest that the speech is not salient enough to direct attention to heads for toddlers with ASD, which is generally the focus of typically developing and developmentally delayed toddlers. Future research should explore the effects of non-speech sounds or movement on the monitoring of social activities.

110 **180.110** The Onset of Restricted, Repetitive and Stereotyped Patterns of Behavior in 18 Month Olds with Suspected Language Delay

***A. Thurm**[1], S. S. Manwaring[2], L. B. Swineford[3], A. Stevens[2] and C. Farmer[4], (1)National Institutes of Health - National Institute of Mental Health, Bethesda, MD, (2)University of Utah, Salt Lake City, UT, (3)Pediatrics and Developmental Neuroscience Branch, National Institute of Mental Health, Bethesda, MD, (4)National Institutes of Health, Bethesda, MD*

Background: The study of the ontogeny of ASD symptom development has begun to include exploration of the early presence of Restricted, Repetitive and Stereotyped Patterns of Behavior (RRBs) in children at risk but not yet diagnosed with ASD (Elison et al. 2014). With significantly more studies devoted to the differentation of delay versus deviance in social-communicative skills, it is important to also explore the presence and timing of RRB's in children at risk for autism because they show specific delays (e..g language delay).

Objectives: The aim of the present study was to examine the frequency and timing of RRB onset in 18 month olds evaluated due to referral for language delays.

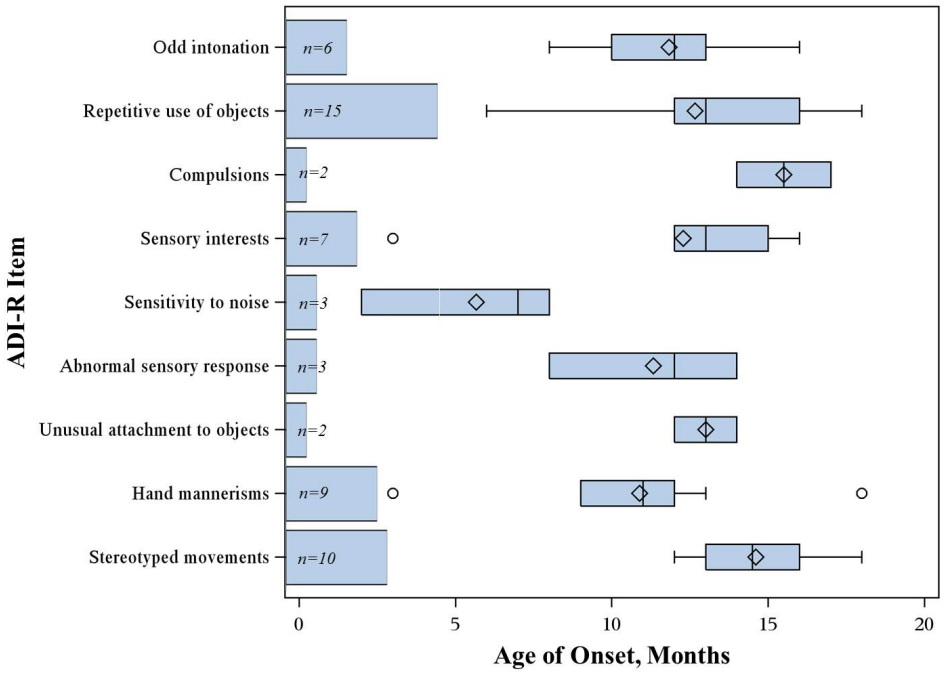
Methods: Participants (n=37) were recruited based on suspicion of language delay, with only one child diagnosed with ASD before study participation. Data were collected during an initial screening at approximately 18 months of age (mean = 18.6, SD = 1.4, range 16-21 months). The assessment battery included the Mullen Scales of Early

Learning, the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2) Toddler module and the Autism Diagnostic Interview-Revised (ADI-R) Toddler version- four restricted and repetitive behavior domain items (RRB), in which a score of 0 indicates absence of a symptom, 1 indicates mild presentation, and 2 indicates symptoms with interference. The Repetitive Behavior Questionnaire (RBQ) was also administered to a parent.

Results: The mean nonverbal ratio IQ in this sample was 94.2±17.1, with a mean verbal ratio IQ of 61.0±22.8. Of 33 participants with ADI-R administrations, 42% (n=14) had a score of zero on the RRB domain. Eleven toddlers (33%) had scores of 1 or 2, and the remainder (n=8, 24%) had scores of 3 to 8. All RRBs were reported to emerge by 18 months of age, with specific behaviors noted as early as 2 months of age (*Sensitivity to Noise*) (Figure 1). Two behaviors, *Difficulties with minor changes in routine and Resistance to trivial changes in environment* were not reported for any participant. The ADI-R RRB algorithm score was strongly correlated with the ADOS RRB severity score and the Social Affect severity score, and was more moderately correlated with the RBQ Total Score (Table 1). Both the ADI-R and ADOS RRB scores were negatively correlated with Mullen nonverbal and verbal ratio IQs. The RBQ Total Score was not correlated with the Mullen scores. The earliest reported age of onset for any repetitive behavior was calculated from the ADI-R, but this did not correlate with any other variable.

Conclusions: This study found significant rates of RRBs in 18 month olds referred for language delay, with sensory related symptoms starting earliest. Validating previous findings, insistence on sameness was minimal in this young sample, but the presence of motor movement abnormalities and repetitive use of objects was frequent. Repetitive behaviors, both reported and observed, were strongly related to each other and to both nonverbal and verbal development. Further studies with larger sample sizes and diagnostic outcome groupings should explore the stability of RRB's in children referred for language delays.

Figure 1. Rate of endorsement (left bar) and age of onset (boxplot) for repetitive behaviors in toddlers with language delays



Note: N=33. Two items were not endorsed for any participant (*Difficulties with minor changes in routine, Resistance to trivial changes in environment*).

Table 1. Spearman correlations among repetitive behavior measures in toddlers with language delays

	ADI RRB Score	Earliest age of onset for RRB	ADOS RRB CSS	RBQ Total Score
ADI-R RRB Algorithm Score	N=33			
ADI-R Earliest Age of Onset	-.06	N=22		
ADOS RRB Calibrated Severity Score	.71**	-.21	N=35	
RBQ Total Repetitive Behavior Score	.41*	-.40	.30	N=35
ADOS Social Affect Calibrated Severity Score	.84*	.27	.59**	.39*
Mullen Nonverbal Ratio IQ	-.49**	-.05	-.43**	-.20
Mullen Verbal Ratio IQ	-.69**	-.06	-.66**	-.30

Note: **p<.01, *p<.05. n=31 for correlations with ADI; n=33 for correlations between ADOS and RBQ.

D. Oosting *and A. S. Carter, Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background: Joint attention (JA) skills, and particularly the ability to initiate joint attention (IJA), have been shown to predict receptive and expressive language development in young children with ASD (Charman et al., 2003; Mundy, Sigman, & Kasari, 1990). Fewer studies have focused specifically on JA indices as predictors of language and social interaction skill development in very young (<3 years) minimally verbal children with ASD.
Objectives: We explored whether one-year gains in language and social interaction skills were associated with the following baseline joint attention indices in toddlers with ASD who were minimally verbal: initiation of, and response to, joint attention, behavioral requests, and reciprocal social interactions.
Methods: Participants were 62 children with ASD assessed first at 18 to 33 months (Time 1, T1; M=28±4) and again approximately one year later (T2). All participants were minimally verbal at time 1, defined by Mullen Scales of Early Learning expressive language t-scores of 20. Social interaction skills were assessed with the ADOS Reciprocal Social Interaction scores and mother-reported Vineland Adaptive Behavior Scales (VABS-I) Socialization standard scores. Language abilities were assessed with the Mullen Scales of Early Learning Expressive and Receptive Language t-scores, and JA indices assessed with the Early Social Communication Scales. Regression analyses examined whether T1 JA indices independently predicted improvements in receptive and expressive language and social interaction skills, represented by T1-T2 difference scores. T1 Mullen nonverbal developmental quotient (NVDQ) and/or T1 age were covaried in regression models when correlated with the dependent variable.
Results: Prior to examining regression models, pairwise comparisons established significant improvements from T1 to T2 on all outcome measures (ts > |3.5|, ps < .001). Younger age at T1 and higher T1 NVDQ scores were associated with greater gains in receptive language. Children who were younger at time 1 showed greater improvement in ADOS Reciprocal Social Interaction score, whereas the reverse was true for the VABS-I Socialization scores. T1 IJA and response to JA (RJA) significantly predicted gains in receptive language skills (β = .29, p = .02; β = .47, p < .001). JA indices were unrelated to gains in expressive language. T1 response to social interaction significantly predicted greater social interaction symptom reduction on the ADOS and larger gains in VABS-I Socialization score (β = .26, p = .04; β = .33, p = .01).
Conclusions: Previous literature highlighted early initiation of, and response to, joint attention as predictors of both receptive and expressive language gains. Our results show that for these young minimally verbal children, early IJA and RJA skills were associated with gains in receptive language and were unrelated to gains in expressive language. Improvements in social interaction skills and reductions in social interaction symptoms were associated with responsiveness to other social situations (e.g., reciprocal social games).

112 **180.112** The Role of Temperament and Broader Autism Phenotype in the Prediction of Toddlerhood Externalising and Internalising Symptoms

M. Uljarevic[1]*, K. Crea*[2]*, C. Dissanayake*[3] *and K. Hudry*[4]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia, (2)Olga Tennison Autism Research Centre, Bundoora, VIC, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (4)Olga Tennison Autism Research Centre, Melbourne, Australia*

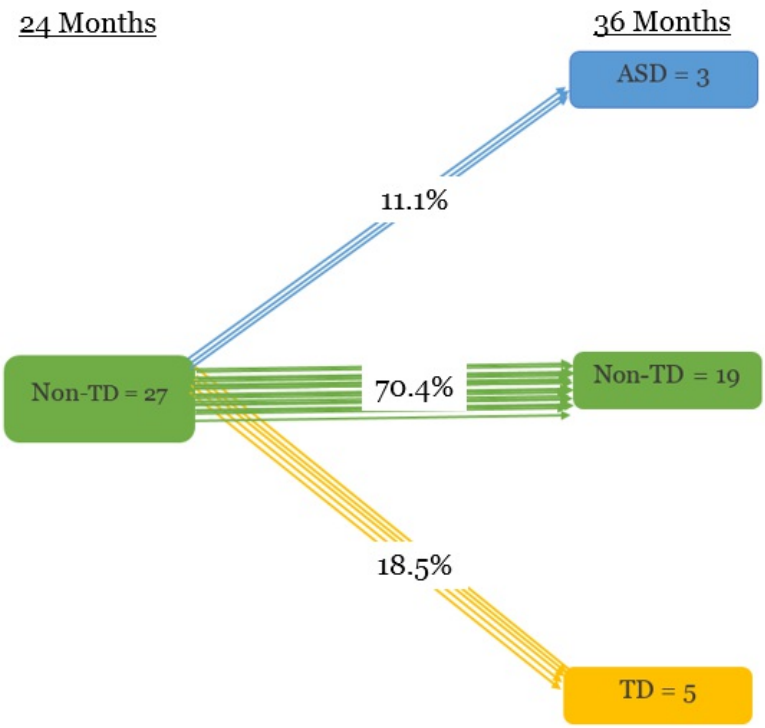
Background: Autism Spectrum Disorder (ASD) is the term used to describe a cluster of neuro-developmental conditions comprising social and communication impairments and the presence of restricted patterns of behaviours and interests. Co-morbid Internalising and Externalising symptoms are prevalent and often have greater negative impact on functioning than do the core ASD symptoms themselves. Significant heterogeneity is apparent across every facet of ASD, both in terms of core and co-morbid symptoms. However, factors that may account for such heterogeneity remain poorly understood. Given the substantial body of research showing both the positive and negative impacts of temperament on social, emotional, and behavioural outcomes outside the context of ASD, it seems clear that research on temperament in the context of ASD may hold significant potential for informing our understanding of the variability inherent in individuals' developmental trajectories and outcomes.
Objectives:
To explore the extent to which Internalising and Externalising symptoms may vary as a function of temperamental differences among young children between 2- and 3-years of age (when ASD is often diagnosed), and in conjunction with the Broader Autism Phenotype (BAP) and specific ASD symptom presentation.
Methods:
Mothers of 60 toddlers completed the Short Temperament Scale for Toddlers and the Behavior Assessment System for Children when toddlers were aged between 2 and 3 years. Thirty children had an older sibling diagnosed with ASD (BAP) and around half of them met criteria for an ASD diagnosis (BAP-ASD) by 3 years of age. The older sibling of 30 children did not have ASD. All children were assessed for cognitive level using the Mullen Scales of Early Learning and children in the BAP group were assessed for ASD symptoms using the Autism Diagnostic Observation Schedule (ADOS).
Results:
Toddlers in the BAP group had more Externalising, t(45)=2.98, p=.005 (*Cohen's d*=.89) and Internalising Problems, t(45)=2.54, p=.015, d=.76, than those without a sibling with ASD. There was also the suggestion of more Externalising Problems among the BAP-ASD compared to the BAP-non ASD subgroup, t(21)=1.32, p=.203, d=.58, but there was no evidence of subgroup differences on Internalising Problems, t(21)=.51, p=.619, d=22. While no differences on global Easy/Difficult Temperament were detected between the BAP and control group, t(35.8)=.12, p=.908, d=.04, there was a suggestion of more difficult temperament among the BAP-ASD subgroup, t(21)=1.67, p=.109, d=73. For the whole sample, however, more difficult temperament was significantly associated with both externalising (r=.41, p<.01) and internalising symptoms (r=.58, p<.01) and the associations remained significant after controlling for the effect of BAP and cognitive level.
Conclusions:
This study replicated previous findings suggesting higher rates of Internalising and Externalising symptoms in individuals with the BAP, extending to demonstrate that this is already the case by toddlerhood. Furthermore, our findings suggest that temperament predicted both internalising and externalising traits over and above the influence of cognitive level, BAP status and ASD traits. Further longitudinal research is necessary in order to explore the directionality of the effect and to capitalise on the possibilities afforded through study of the construct of temperament in infants and children with ASD.

113 **180.113** The Stability of Atypical Developmental Outcomes in Young Children at Risk for Developing ASD

K. K. Powell[1]*, S. Macari*[1]*, E. Hilton*[1]*, S. F. Fontenelle*[1]*, J. Koller*[2] *and K. Chawarska*[1]*, (1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)School of Education, Hebrew University of Jerusalem, Jerusalem, Israel*

Background: Prospective studies of infants at risk for developing Autism Spectrum Disorder (HR-sibs) estimate that 18.7% of siblings develop ASD themselves (Ozonoff et al., 2011). Another approximately 19- 28% of siblings evidence other developmental atypicalities (Georgiades et al., 2013; Ozonoff et al., 2014). While the diagnosis of ASD made prior to age 3 is relatively stable in HR-sib cohorts (Ozonoff et al., 2015), the diagnostic stability and clinical presentation of the "atypical" group is less clear.
Objectives: To examine the stability of atypical developmental outcomes between 24 and 36 months in a high-risk sample.
Methods: Seventy-nine HR-sibs (68.5% males) were comprehensively assessed at the ages of 24 and 36 months utilizing the Mullen Scales of Early Learning, Vineland Adaptive Behavior Scales, and Autism Diagnostic Observation Schedule. For the Mullen and Vineland higher standard score indicates higher functioning, while a higher score on the ADOS indicates poorer functioning. Each participant was assigned a Clinician Best Estimate (CBE) diagnosis at each time point. The following CBEs were utilized: ASD (*Autistic Disorder* or *PDD-NOS*), non-TD (*Broader Autism Phenotype (BAP):* sub-threshold ASD-related symptoms that supersede other developmental delays, and *Developmental Delays*: language, cognitive, and/or behavioral problems), and TD (*no clinical diagnosis* or *mild symptom* presentation that did not warrant a diagnosis). Stability of diagnostic presentation and clinical features were subsequently evaluated in the non-TD group. Pearson correlations were conducted to examine the relationship between developmental skills, adaptive communication and socialization, and autism severity between 24 and 36 months.
Results: Of the 79 HR-sibs, 27 (34%) were identified as having BAP or other developmental issues (non-TD) at 24 months. At the age of 36 months, 19 (70.4%) maintained a non-TD classification, 5 (18.5%) were considered TD, and 3 (11.1%) met criteria for ASD. Verbal DQ (r(23)=.643, p<.01), Vineland Communication (r(22)=.757, p<.001), and Vineland Socialization (r(22)=.504, p<.05) were significantly correlated between 24 and 36 months, while Nonverbal DQ and ADOS severity were not (ps>.1).
Conclusions: Out of the 34% of HR-sibs identified as non-TD at 24 months, the majority (70.4%) continues to demonstrate difficulties consistent with non-TD presentations at 36 months. Approximately 20% of them appear to catch up to their TD peers, but in approximately 10%, symptoms worsen and are consistent with ASD. While verbal abilities and adaptive communication and socialization were significantly correlated across time points for the non-TD group, nonverbal abilities and autism symptom severity were not. Diagnostic stability and clinical presentation can be variable for many HR-sibs, particularly those demonstrating atypical developmental patterns early in life. The results of this study highlight the need for continued monitoring and later follow-up of HR-sibs to confirm later (and potentially more stable) diagnostic outcomes.

Figure 1. Diagnostic Stability of non-TD CBEs



114 **180.114** Using Child Behavior Checklist for Assessing and Detecting Peschool Children with Autism Spectrum Disorders

Y. T. Chiu, *W. H. Yu and C. C. Wu, Department of Psychology, Kaohsiung Medical University, Kaohsiung City, Taiwan*

Background: **C**hildren with autism spectrum disorders (ASDs) usually accompanied emotional and behavioral problems. Children with emotional and behavioral problems could resulte in more impartments on their social and communication distress, thus make stress on their caregiver.
Objectives: Child Behavior Check List 1.5-5 (CBCL/1.5-5) is a tool for evaluating emotional and behavioral problems of preschool children. Precious researches used CBCL/1.5-5 to screen ASDs children. However, there is no research in Taiwan. In this study, the CBCL/1.5-5 was used to assess and detect peschool children with ASDs.
Methods: 249 children aged less than 48 months old, including 99 children with ASDs, 114 children with developed delay (DD), and 36 children with typical development. The CBCL/1.5-5 was completed by the caregivers for measuring emotional and behavioral problems of all children.
Results: These three groups showed significantly different on the internalizing problems, total problems, withdrawn, attention problems, and pervasive developmental problems subscales. All of withdrawn, pervasive developmental problem and internalizing problems are better index for distihduishing children with ASDs from children with DD. Using signal detection procedure, T-score of 66 on the withdrawn subscale as the cut-off to distinguish children with ASDs from those with DD, the sensitivity and specificity were 72% and 70%, respectively; the pervasive developmental problems subscale use T-score of 70 as the cut-off to distinguish children with ASDs from those with DD, the sensitivity and specificity were 71% and 63%, respectively; the Internalizing problems scale use T-score of 63 as the cut-off to distinguish children with ASDs from those with DD, the sensitivity and specificity were 71% and 63%, respectively. The results revealed that using the withdrawn and pervasive developmental problems subscale as a screening index for fdeteding children with ASDs, it showed accepted validity.
Conclusions: Used the CBCL/1.5-5 as a screening tool for children with ASDs, the withdrawn and pervasive developmental problem subscale have moderate validity, suggest the two subscales can be screening tool in the clinical setting.

115 **180.115** Video-Referenced Ratings Assessing Social Behavior in Hispanic Toddlers

B. Benedict[1], *B. Harris-Olenak*[2], *T. Jacob*[2] *and J. N. Constantino*[3], *(1)VA Palo Alto Health Care System, Menlo Park, CA, (2)Family Research Center, VA Palo Alto Health Care System, Menlo Park, CA, (3)Washington University School of Medicine, Saint Louis, MO*

Background:
Childhood development involves a complex interplay of cognitive, communicative, and social skills; deficits in any of these areas comprise key characteristics of Autism Spectrum Disorders (ASD). Most important to this study is early detection of impairments in reciprocal social behavior (RSB) (i.e., the drive to engage others and ability to interpret and respond to interpersonal cues). Although psychometrically-sound diagnostic tools measuring RSB exist, instruments for assessing RSB in toddlers under age 2, a critical and rapid developmental period, have been only minimally validated (Marrus et al., 2015) and only within a Caucasian sample.
Objectives:
This study aimed to replicate previous findings by Marrus and colleagues (2015) in order to test the utility and external validity of the Video-referenced RSB (vrRSB) measure. Due to the largely biological, developmental nature of RSB, we predicted that results would replicate across samples.
Methods:
Hispanic families with twins were recruited from California birth records (large majority were bilingual). Of the 2874 families targeted for the CA-ERSB study, 335 families responded to the recruitment mailing, 41 families opted out, 143 families were ineligible, and 151 families enrolled in the study. As a part of a larger battery, enrolled families were administered vrRSB across two waves of data collection and the Modified Checklist for Autism in Toddlers (M-CHAT) and the MacArthur-Bates Communitive Disorders Inventory (CDI) across one wave of data collection. Descriptive statistics were conducted to examine vrRSB score distributions and sample characteristics. Chronbach's alpha and intraclass correlations examined test-retest reliability, Pearson correlations and independent samples t-test examined concurrent validity, and a repeated measures t-test examined developmental progression of RSB over a 6 month period.
Results:
Analyses indicted that scores on the vrRSB were continuously distributed. Six-month reliability (a = 0.814; ICC=0.687, p=0.000) and validity were established. Video-referenced RSB total scores were inversely correlated with receptive (r=-0.235, p=0.000) and expressive (r=-0.373, p=0.000) language scores on CDI and vrRSB total score means were significantly different for those who failed (n=46; m=34.09, SD=11.68) versus passed (n=254; m=20.84, SD=7.59) the M-CHAT (t=-7.42, df=52, p=0.000)]. In order to examine developmental progression of RSB, mean changes in vrRSB scores across wave 1 (m=22.83, SD=9.59) and wave 2 (m=20.07, SD=10.22) were examined. Results indicated improved social competency over time; change scores were in the expected direction and were significantly different across two time points (t=6.114, df=301, p=0.000).
Conclusions:
Results from Marrus et al. (2015) were replicated providing support for the external validity of the vrRSB across ethnicities and geographic regions. Like autistic trait ratings in school-aged children, toddlers' scores on the vrRSB demonstrated high inter-individual stability, moderate concurrent validity, and significant developmental progression over a six month. These findings supported "downward extension" of early detection of ASD and provided evidence for the vrRSB's ability to monitor changes over time. Thus, the vrRSB is a promising assessment option for early identification and intervention of ASD in diverse populations.

116 **180.116** Visual Search Cancellation at 36 Months in Autism: Search Strategies and Infant Predictors

ABSTRACT WITHDRAWN

Background: Enhanced visual search is one of the most replicated findings in the autism spectrum disorders (ASD) literature and has been documented as young as in infancy and toddlerhood. Visual search in this context often refers to locating one target amongst distracters—less research has investigated search strategies when there are multiple targets amongst distracters, and no studies to our knowledge have manipulated targets and distracters to investigate varying search strategies based on task requirements. It is possible that in ASD performance will be poorer in a multiple target cancellation task, in particular when targets represent a conceptual category as opposed to an exemplar and thus require conceptual knowledge. In contrast, it is possible that performance will be enhanced when exemplar targets are perceptually similar to distracters, thus requiring perceptual abilities known to be enhanced in ASD.
Objectives: This study sought to investigate cancellation performance in 36-month-olds at high and low risk for autism. Additionally, visual search performance for single targets earlier in childhood were used to predict cancellation performance at 36 months to determine if the abilities underlying single target visual search relate to cancellation performance.
Methods: Sixty-two 36-month-olds at high and low risk for ASD participated in the visual search cancellation task on a touchscreen monitor as a part of a battery of cognitive tasks. In this task, children were asked to search for and touch a) cats among inanimate objects (baseline, “exemplar search”), b) animals amongst inanimate objects (to test categorization, such that higher autistic symptoms were hypothesized to relate to worse performance, “conceptual search”), and c) dogs amongst furniture (to test for the ability to discriminate between perceptually similar objects, such that higher autistic symptoms were hypothesized to relate to better performance, “perceptual search”). The Autism Diagnostic Observation Scale (ADOS) was used to assess severity of autism symptoms.
Results: While controlling for motor and language abilities, ADOS social affect (SA) scores related to the difference between exemplar and conceptual search conditions in a combined measure of speed and accuracy, with poorer search related to high SA scores. To understand the origins of poor performance, we analyzed search strategies. Interestingly, ADOS repetitive and restrictive behavior (RRB) scores related to spatial search efficiency specifically in conceptual search, with more efficient search related to higher RRB scores. This may be due to children with low autistic symptoms using a conceptual strategy (all the camels are touched then all the bears, etc.), which is still strategic but not spatially efficient. There is some evidence for this hypothesis, with a negative relationship between measures of conceptual strategy and spatial strategy. Finally, there is a marginal negative relationship between single target visual search at 24 months and spatial search efficiency in conceptual search.
Conclusions: High autistic symptoms show counterintuitive continuous relationships with both poorer speed/accuracy as well as better spatial search efficiency. These relationships may be explained by poor conceptual knowledge resulting in less conceptually driven search.

117 **180.117** When Do the Developmental Trajectories of Siblings with ASD and BAP Diverge from Typically Developing Siblings?

E. Hilton, *K. K. Powell, S. Macari, A. Milgramm, P. Heymann, L. DiNicola, S. F. Fontenelle and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Younger siblings of children with ASD are at increased risk for developing ASD and Broader Autism Phenotype (BAP) (Ozonoff et al., 2011). BAP features include a wide range of subthreshold deficits and atypical behaviors in domains often affected in ASD. Extant evidence suggest that high-risk (HR) siblings with BAP already show developmental vulnerabilities and decreased social engagement by 12 months compared to typically developing (TD) infants without familial history of ASD (Ozonoff et al., 2014). More clinically informative would be to determine when the developmental trajectories of HR infants with typical and atypical development diverge.
Objectives: To examine when HR-sibs begin to diverge in regard to social and communication adaptive functioning and severity of autism symptoms.
Methods: All infants (n= 63, 66.7% males) underwent comprehensive evaluations at 12, 18, 24, and 36 months. Classification of ASD (n=15), BAP (n=15) and HR-TD (n=33) was based on a comprehensive assessment at 36 months. In order to examine divergence, the Vineland Adaptive Behavior Scales Communication and Socialization domains and the Autism Diagnostic Observation Schedule- Toddler (ADOS-T) were administered. A higher standard score on the Vineland Communication and Socialization domains indicates higher functioning, while on the ADOS-T a lower calibrated severity score indicates higher functioning.
Results: A repeated-measures age (3) x group (3) ANOVA indicated a significant main effect of group [$F(2, 62) = 10.49$, $p < .01$], a significant main effect of age [$F(2, 62) = 19.581$, $p < .01$], and a significant interaction of age by group [$F(2,62) = 1.99$, $p < .025$]. At 12 months, ASD displayed higher symptom severity on the ADOS than HR-TD ($p < .01$). At 18 and 24 months, ASD had higher ADOS-T severity ($ps<.01$) and lower Vineland Communication ($ps < .01$) and Socialization ($ps < .01$) scores. No significant group differences were found between BAP and HR-TD at 12 months ($ps > .1$). At 18 and 24 months, BAP demonstrated higher symptom severity on the ADOS ($p < .01$) and lower Vineland Communication scores ($p < .05$) than HR-TD. ASD had lower Vineland Socialization scores than BAP at 18 months ($p < .01$); all other comparisons between the two groups were non-significant.
Conclusions: Already at 12 months infants who later develop ASD show more severe autism symptoms than TD siblings. At 18 months, those with ASD continued to show higher ADOS scores and also demonstrated lower abilities on adaptive communication and socialization domains, with group differences remaining stable at 24 months. BAP and HR-TD were differentiated less often: only at 18 and 24 months on Vineland Communication and ADOS. Finally, BAP and ASD only differed at 18 months on adaptive socialization. By and large, BAP presented as intermediate to ASD and HR-TD, but more closely aligned with those with ASD. The distinctive findings on the adaptive socialization scale highlight the potential contribution of “social ability” in differentiating BAP from ASD. Future studies should further examine the role of social ability in the various atypical developmental trajectories of children at risk for developing ASD.

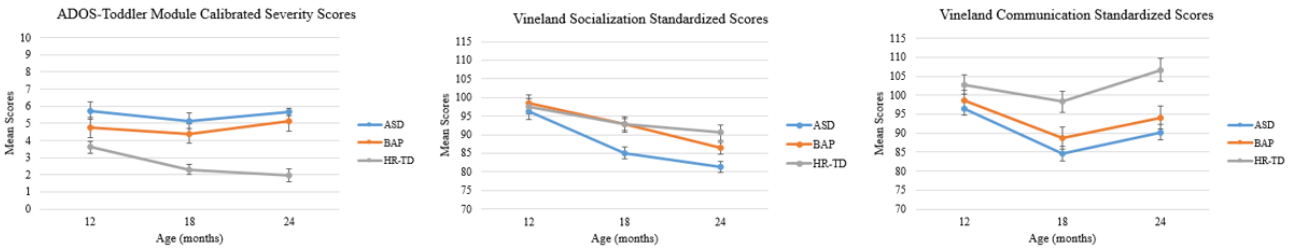


Figure 1. Mean scores of ASD, BAP, and HR-TD participants on the ADOS – Toddler, Vineland Socialization, and Communication domains at 18, 24, and 36 months.

118 **180.118** “Did Somebody Call My Name?” Neural Responses to Hearing Their Own Name in Infants at Low and High Risk for Autism Spectrum Disorder at 14 Months of Age

M. Arslan, *N. L. Dewaele, E. Demurie, P. Warreyn and H. Roeyers, Ghent University, Ghent, Belgium*

Background:
People attend to their own name even in noisy environments and use this as a signal to follow social conversations. Typically developing infants start to orient towards the sound of their own name already at 4-5 months of age, which was also observed by altered neural responses via event-related potentials (ERP). A reduced attention to this ostensive cue was however detected in infants who are at high risk for autism spectrum disorder (ASD) and it is considered to be an early sign of ASD.
Because enhanced attention to the own name may be important for language acquisition by functioning as a tool for speech segmentation, a reduction in this attention may result in weakened early social information processing, interfering with the development of social skills. Therefore, the own name as social cue may play a particularly significant role in the beginning of the second year of life, since at that age language acquisition progresses very fast.
Objectives:
The aim of this study was to investigate whether 14-month-old infants at high-risk for ASD show a different ERP pattern compared to infants at low-risk for ASD, in the way they process personal names and more specifically their own name. It was hypothesized that the infants at high-risk for ASD would show extenuated ERP responses to their own name compared to an unfamiliar name.
Methods:
Initially, data from 46 14-months-old infants at low-risk and high-risk for ASD were collected. After excluding data from 20 infants due to excessive movement and artifacts, data from 16 low-risk and 10 high-risk group infants were included in the analyses. ERPs were measured during an own name/unfamiliar name task with both balanced auditory and visual stimuli (Parise et al, 2010). The Mullen Scales of Early Learning (Mullen, 1995) were administered to assess cognitive abilities of the infants.
Results:
The stronger N200-600 component on the right parietal electrodes and significantly stronger positivity on the right frontal electrodes evidenced that the low-risk infants discriminated and paid more attention to their own name compared to the unfamiliar name. No such differences were detected within the high-risk group. Significant group differences were found during the own name presentations (right frontal ROI $p = .047$), yet both groups showed similar ERP patterns during the stranger’s name presentations. Despite the small initial subject size, differences were clear and in the expected direction.
Conclusions:

This study is the first study showing the different neural responses in 14-month-old infants that are at high-risk for ASD, to the unique and very important social cue which introduces periods of communication: “the own name”. The preliminary results of 26 subjects suggest that infants at risk for ASD have specifically diminished attention for their own name, rather than a general diminished attention for speech. The results of an extended sample will be presented at the conference.

119 **181.119** "You Never Stop Holding Your Breath": Narratives of Simplex and Multiplex Mothers with an Infant

C. Ponting[1], *E. Baker*[2], *S. S. Jeste*[1], *M. Dapretto*[3] *and T. Hutman*[4], *(1)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)University of California Los Angeles, Los Angeles, CA*

Background:
Understanding the holistic experience of parenting children with Autism Spectrum Disorder (ASD) is critical to support the family unit effectively. Many studies report an elevated caregiving burden among mothers of a child with ASD (e.g., Nealy et al., 2012). There is a need to better characterize the experience of mothers who have a younger child in addition to a child with ASD, as cognitions about parenting related to ASD likely affect other children in the household (Meirsschaut, Roeyers & Warreyn, 2010). Qualitative approaches have been recommended in the analysis of maternal caregiving experiences and coping with chronic stressors (Brannen & Petite, 2008; Folkman & Molzkowitz, 2004); yet narrative approaches are lacking in the study of simplex and multiplex families.
Objectives:
We used a qualitative approach to identify common themes among mothers parenting children with ASD and an infant. The objectives of the study were to understand meaningful experiences—both positive and challenging—related to caring for a child with ASD and an infant, and to compare these experiences between simplex and multiplex mothers.
Methods:
We conducted in-depth, semi-structured interviews with 20 mothers of a child with ASD and an infant enrolled in UCLA’s Infant Sibling Study (prior to conclusive diagnosis). At the time of the interview, infant siblings (IS) ranged in age from 9-35 months and affected siblings ranged from 3-10 years. In a quarter of the sample, the infant had at least two older siblings with ASD (multiplex). Interview questions addressed mothers’ perceptions of the relationship between the proband(s) and the IS, familial impacts of receiving the proband’s diagnosis, and formative experiences related to raising children with ASD while also raising an infant. Interviews (lasting 27-83 min) were transcribed and double coded for accuracy, and a codebook was established and validated using five pilot interviews, consistent with a thematic analysis approach (Braun & Clark, 2006).
Results:
We identified salient themes among mothers in three domains: 1) Benefits of parenting a child with ASD, 2) Challenges of parenting a child with ASD, and 3) Misconceptions about their child’s diagnosis. Preliminary sub-codes with the highest frequency in each domain, respectively, are: a) Increased Empathy b) Difficulty balancing time between siblings, and c) Heterogeneity in ASD presentation. We will report two additional sub-codes that reached saturation in each domain, and representative quotes have been selected for each. Forthcoming analyses compare the responses of simplex and multiplex mothers to pinpoint the unique challenges associated with caring for multiple affected children with varying, yet chronic needs.
Conclusions:
Utilizing a narrative approach provided access to a nuanced account of mothers’ experiences raising a child with ASD and a new baby—data that are inaccessible through the use of standardized measures. These findings are relevant for clinicians seeking to understand challenges faced by parents; affected children, who encounter a new sibling and a necessary reduction in the time devoted exclusively to their needs; and infants, who enter into an environment of elevated familial stress—which is implicated in suboptimal cognitive and language development in infancy (Keim et al., 2011).

120 **181.120** A Family Centered Perspective on Addressing Feeding Concerns of Parents of Children with ASD

A. Bonsall[1], *M. Thullen*[2] *and K. Sohl*[3], *(1)Occupational Therapy, University of Missuori, Columbia, MO, (2)Health Sciences, University of Missouri, Columbia, MO, (3)University of Missouri - Thompson Center, Columbia, MO*

Background:
Family-centered care for children with autism spectrum disorder (ASD) includes working in partnership with parents and providing supports and services that are responsive to parents’ needs. Children with ASD often display restrictive or rigid behavioral patterns related to eating such as only eating specific foods, only eating under specific circumstances, and general problem behaviors around mealtimes. Because behaviors related to feeding influence families, addressing parenting feeding concerns can be considered not only a child need, but also an aspect of family-centered care.
Objectives:

1. Identify the concerns of parents around feeding behaviors of their children with ASD.
2. Identify of the frequency that parents describe their children having received therapy in relation to parent feeding concerns.

Methods:
This paper draws from questions from an online survey sent to parents that had an ADOS on file at a local autism network treatment center. Respondents include 113 parents (90% female) of children with ASD (ages 5-13). Parents filled out surveys as well as open and close ended questions regarding feeding concerns. This paper focuses on three questions: 1) Has a therapist worked with your child on eating issues/behaviors? 2) Do you currently have or have you in the past had concerns about your child's eating behaviors? 3) Please describe the concerns you have or you had related to your child's eating behaviors? The results of the third question were coded thematically by researchers familiar with feeding issues. If a parent’s answer fit into more than one theme it was coded multiple times.
Results:
The results indicate that 41% of parents currently have or in the past have had feeding concerns but have not had a therapist work on feeding behaviors (see table 1). Table 2 lists the frequencies and percentage of parents that had each type of concern and if their child had worked with a therapist. Limited food variety was the most common concern (50 respondents) but was still infrequently addressed by a professional (34%). While there is a general lack of treatment for feeding concerns, the lack of treatment for overeating as a concern particularly stands out.
Conclusions:
This study found a gap between the feeding concerns of parents of children with ASD and professional services provided to treat those concerns. Although the causes for this gap were not clearly identified as part of this study, it is important for professionals and systems working with families of children with ASD to recognize that this is a gap. Minimizing that gap is an important aspect of providing family-centered care that addresses parents’ concerns.

Table 1

		Has a therapist worked with your child on eating issues/behaviors? Yes	No	
Do you currently have or have you in the past had concerns about your child's eating behaviors?	Yes	31 (27.4%)	46 (40.7%)	77 (68.1%)
	No	2 (1.8%)	34 (30.1%)	36 (31.9%)
		33 (29.2%)	80 (70.8%)	

Table 2

Parent mealtime concern	Examples	Frequency	% of parents that have had concerns addressed
Limited variety of food	"rarely tries new foods" "only eats same things"	50	34%
Poor nutrition/undereating	"concerned about nutrition" "not eating enough"	14	42%
Overeating	"obsessed with eating" "constantly hungry"	11	27%
Mealtime behaviors	"doesn't eat meals with us" "does not finish meals"	11	36%
Texture issues	"problems with textures" "only eats crunchy food"	11	45%
Mechanics of feeding	"pocketing food" "cramming" "not chewing food"	8	50%

121 **181.121** A Preliminary Investigation of the Perspectives of Young Men with ASD and/ or ADHD and Their Caregivers about Conscript Military Service (CMS)/ National Service (NS)

*P. Y. Chay[1], C. Cheok[2] and **I. Magiati**[1], (1)Department of Psychology, National University of Singapore, Singapore, Singapore, (2)Department of Addiction Medicine, Institute of Mental Health, Singapore, Singapore*

Background: Transition to adulthood can be challenging for many individuals with ASD and/or ADHD. In a number of countries, including Singapore, Conscript Military Service (CMS) or National Service (NS; hereafter referred to as NS) is compulsory for young adult men. For many men with or without ASD/ADHD, NS can be a rewarding, yet challenging experience. With approximately 1% of the population having ASD and more males than females being diagnosed, an increasing number of males with ASD and/or ADHD are likely to serve, but very little is known about their and their caregivers' perspectives.
Objectives: (i) to explore the men's and their caregivers' perceived opportunities and challenges in being enlisted for NS; (ii) to examine factors that may affect perceived NS-related distress in men with ASD/ADHD; and (iii) to explore perceived support needed from family, school, and Ministry of Defence (MINDEF) before NS in order to better support them in the transition to and during NS.
Methods: Participants included 42 caregivers and 17 15- to 19-year-old men with ASD/ADHD who were eligible for NS enlistment in Singapore. They were surveyed on their attitudes towards NS, perceived readiness, and perceived support needed for transition to NS. Measures of ASD and ADHD symptoms, emotional and behavioural issues, and perceived NS-related distress were administered in pen-and-paper or online format. Responses to open-ended questions were analysed thematically. Responses to close-ended questions and checklists were analysed quantitatively. Correlation and regression analyses examined factors that might explain reported NS-related distress.
Results: Most caregivers appreciated the benefits of serving NS, but did not wish their sons to face the potential challenges without the necessary support. 83% of the caregivers would want their sons to complete NS if their skills and strengths, as well as their needs, were carefully considered during placement– this figure was 53% when the young men themselves were asked.
A number of common themes relating to perceived opportunities and challenges were identified. NS was thought to potentially increase opportunities for social integration and to possibly enhance functional outcomes. However, there were many concerns about how others' limited understanding and unhelpful reactions towards their sons with ASD/ADHD might exacerbate the challenges. Common themes related to concerns centred on lack of appropriate support or management and limited awareness of ASD or ADHD in the community.
Men with ASD/ADHD who reported more emotional and behavioural issues were more concerned about NS, felt less prepared for it and reported more pre-enlistment distress than men with fewer emotional and behavioural difficulties. Participants perceived preparing men with ASD/ADHD for NS as an important collaborative effort and placed similar emphasis on the role that each of the stakeholders (family, school, MINDEF) could play.
Conclusions: Caregivers and men with ASD/ ADHD articulate their need for more information about the support currently available for young men with ASD/ ADHD before and during NS, and strongly advocate a more coordinated collaboration amongst families, schools and NS-related organizations to facilitate transition to NS for men with ASD/ADHD *before* actual enlistment takes place.

122 **181.122** A White Lie? Subjective Experience of Deception in Adults with ASD

*A. Duquette[1], M. Devaine[2], É. Petit[3], J. Daunizeau[4] and **B. Forgeot d'Arc**[5], (1)Psychology, Université de Montréal, Montréal, QC, Canada, (2)Brain and Spine Institute, Paris, France, (3)Hôpital Rivière-des-Prairies, Montréal, AK, Canada, (4)Brain and Spine Institute, INSERM, Paris, France, (5)Psychiatry, Université de Montréal, Montreal, QC, Canada*

Background: Masking or distorting information, like specific goals of an experiment or conditions, is common in psychology. Individuals in the autism spectrum are believed to particularly value truth and might therefore be negatively affected by deception. Because of the vulnerability of many participants, maintaining confidence in the hospital institution is essential. Besides, raising awareness on the subjective experience of participants in research using deception is a component of research/users partnership. Therefore, the ethical issue of using deception in individuals with ASD is major and conciliating scientific objectives with respect of integrity and rights of participants can be a challenge. However, the existing scientific literature shows little consideration for this issue and provides no consensual practice parameters.
Objectives: The goal of this study was to evaluate the impact of deception in individuals with ASD, under careful preparation and monitoring.
Methods: collaboration between researchers and local ethical board led to the development of a procedure for standardized debriefing and subjective experience assessment. First, an initial (deceived) belief assessment measures the efficiency of the deceptive manipulation. Then, the nature of the deception is disclosed to the participants, and a final belief assessment measures whether they understand that they had been previously deceived. Lastly, a Subjective Experience Self-Questionnaire, based on Lickert scales and free comments assesses satisfaction (specifically whether participants had fun, felt useful, welcome, well informed, respected and well paid) and

intention to participate in future studies. Adults with ASD and controls without ASD matched for age, IQ and gender took part to the study (n=48). Participants in the ASD group had been assessed with ADOS-G and met DSM-IV criteria for an ASD. All participants had FSIQ>85. Participants with self-reported depression (Beck depression Inventory score>20) were excluded. Following an experiment using active deception, initial and final belief assessment as well as subjective experience questionnaires were administrated to participants. Testing was monitored by the ethics board, using individual reports. Initial belief (affected by deception), final belief (corrected by debriefing) and subjective experience were compared between ASD and control groups.
Results: Initial belief attested that a large majority of participants of both groups were similarly deceived by the protocol, as intended. Final belief attested that all participants understood that they had been deceived. Global satisfaction was high in both groups but lower in ASD individuals (80% vs 89%, $F(1,46)=5.68$,$p<.05$). In both groups, fun was lower than satisfaction regarding reception, information, respect and pay. Intention to participate in the future was high (95% and 91%, *p*:ns). Participants less likely to participate again mentioned boredom and low pay.
Conclusions: Under careful preparation and monitoring, the use of deception in our experimental protocol did not reveal greater impact of deception in adults with ASD. Limits of the study include satisfaction data collection by the experimenter herself and lack of follow-up. Altogether, although risk-benefit balance and appropriate action should be individually considered for each study, the present work provides materials and guidelines for future experiments using deception in participants with ASD.

123 **181.123** ABA Parent Training in Spanish for Children with ASD

***E. Rotheram-Fuller**, K. S. Turner, H. Park, T. Pinon, L. Parra and P. Miller, Arizona State University, Tempe, AZ*

Background: Training in Applied Behavior Analysis for parents of children with ASD can be a critical support for both parents and their children (Bearss, Johnson, Smith, Lecavalier, & Swiezy, 2015). Parent trainings have been shown to be effective in helping improve problem behavior (Bearss et al., 2015), reducing feeding issues and parental stress (Sharp, Burrell, & Jaquess, 2014), and increasing children's skill generalization across settings (Ingersoll & Dvortcsak, 2006). Unfortunately, however, these trainings have not been extensively studied with non-English speaking populations.
Objectives: The current study seeks to examine the feasibility and impact of a 10 week parent training intervention program conducted in Spanish, for Spanish-speaking parents of school-aged children with ASD.
Methods: This study was conducted at a clinical site where 75% of families were exclusively Spanish-speaking. Families were recruited who had at least one child with ASD, aged 6-8 years old. Nine families participated in the training program (n = 11 parents overall, with two spouses attending), which consisted of 6 group sessions, followed by 4 individual sessions. Sessions focused on teaching ABA terms, strategies, and application for issues with their own children. Families completed both parent and child measures before the training began (Vineland-II, Aberrant Behavior Checklist, Parent Stress Inventory, Home-Situations Questionnaire, etc.), including a diagnostic evaluation (ADOS-2 and KBIT-2) with their child. Throughout the intervention, ABC data and parent implementation efforts were recorded, and parents repeated the self-report surveys at the end of the training.
Results: Parent trainings are currently in session 5 of the 10 session sequence. Preliminary results suggest that the trainings have been appropriately adapted for the Spanish-speaking parents attending; the majority of parents have consistently attended sessions and report changes in their use of strategies as a result of participation. Participating children have a variety of behavioral challenges, and each family has successfully collected information on their child's behavior. Longer-term effects on parent and child behavior, and social validity of trainings will be collected at completion.
Conclusions: It is important to consider adaptations needed for non-English speaking families with children with ASD. In this particular population, there was a wide variety of parent knowledge and advocacy, which is increasingly difficult with the language barrier. Additional resources are needed to better support non-English speaking families in ways that allow them access and information vital to their child's success.

124 **181.124** ASD Community Interest in an Online National Autism Cohort, Incentives for Participation, Engagement Resources, and Research Topics of Interest

***J. Manoharan**[1], V. J. Myers[2], A. M. Daniels[2], L. Green Snyder[2], P. Feliciano[2] and W. K. Chung[2], (1)Simons Foundation, New York, NY, (2)SFARI, Simons Foundation, New York, NY*

Background:
To further understand the genetic and environmental factors that increase autism risk and to advance the field toward improved treatments, research studies involving thousands of individuals with autism spectrum disorder (ASD) are needed. While a number of large autism cohorts exist, no single nationwide cohort that combines online accessibility, ability to recontact, and the collection of genomic, environmental, and longitudinal behavioral and medical information on all participants is available to the scientific research community. SFARI is launching SPARK to recruit, engage and retain 50,000 individuals with ASD and their family members.
Objectives:
The aims of the current study are to gauge the ASD community's interest in participating in SPARK, to evaluate enablers to participation and engagement, including the extent to which families would be interested in receiving individual genetic results specific to autism from the study, and research topics of interest.
Methods:
An anonymous online survey was distributed to a total of 16,031 research participants of the Interactive Autism Network (IAN) over 5 weeks. Respondents were asked if they were interested in participating in a national autism cohort and in what ways. They were also asked to identify incentives for participation, resources that would enhance participation, and about their interest in receiving personal genetic information about genetic causes of autism in their family.
Results:
A total of 943 parents/legal guardians and 98 adults with ASD completed the survey. 79% of parents/guardians and 80% of adults with ASD reported that they would be interested in participating in a national autism cohort. While 71% of respondents reported that they would be willing to participate online, 28% also reported a willingness to participate in person. When asked to select features that would increase interest in participating, both parents/guardians (69%) and individuals with autism (60%) indicated that they were interested in return of individual genetic results about the cause of their ASD. The most frequently requested resources were access to autism-specific educational apps and websites (57%) and access to articles about ASD research (51%), for parents/guardians and adults, respectively. Both groups indicated interest in participating in a genetic research study that would determine if their child/they had a known genetic cause of autism (71%, 73%, respectively). Overall, topics of greatest interest were related to community services and programs for individuals with ASD (77%) for parents/legal guardians and how autism impacts the brain (81%) for adults.
Conclusions:
Findings from this study indicate that among survey participants there is significant interest in participating in an online national autism cohort. There was strong interest in return of individual genetic results. Respondents reported a high level of interest in participating in research. SPARK aims to fill this knowledge gap and stimulate more robust engagement and participation from a broad and diverse sample of the autism community in clinical research.

125 **181.125** Adaptive Social Communication in Children with ASD As a Predictor of Parent Stress

***S. W. Nowell**[1], J. Amsbary[1], J. Page[2] and G. T. Baranek[1], (1)UNC Chapel Hill, Chapel Hill, NC, (2)Education and Psychology, UNC Chapel Hill, Chapel Hill, NC*

Background: Research examining stress in parents of children with autism spectrum disorder (ASD) indicates that these parents report higher levels of stress in comparison to parents of typically developing children (Dawson et al., 2004) and children with other developmental disabilities (Estes, Munson et al. 2009). Deficits in adaptive behaviors may place increased burden on parents because their child requires more assistance to perform everyday activities. Although there is a body of research examining the correlation of maladaptive behaviors with parent stress (e.g. Hall & Graff, 2011), there is a paucity of research examining the linkages between deficits in adaptive behavior within specific skill domains and parent stress. Identifying the key variables contributing to parent stress is critical to develop targeted interventions that support the whole family (Hayes & Watson, 2013).
Objectives: The purpose of the present study was to explore the specific nature of adaptive social communication skills on parent stress. We were interested in examining if adaptive social communication skills explain a unique amount of variance in parent stress after controlling for age and IQ. We hypothesized that some of the variance in reported parent stress on the *Parenting Stress Index-Short Form*(Abidin, 1990) would be explained by adaptive social communication skills. Further, we hypothesized that adaptive social and communication abilities would account for the most variance in the Parent-Child Dysfunctional Interaction subscale of the PSI because this subscale seemed most likely to be impacted by a child's deficits in social- communication abilities.
Methods: Data for 667 children with ASD between 3 and 14 years were drawn cross-sectionally from an extant longitudinal survey conducted with a national sample. Parent stress was measured using the *Parenting Stress Index-Short Form* (PSI). Measures of adaptive social communication skills included: the Communication Domain Standard Score and the Socialization Domain Standard Score from the *Vineland Adaptive Behavior Scales-Second Edition*(VABS-2; Sparrow et al., 2005) and a parent report of their child's verbal expressive language level. The child's IQ as reported by parents, and the child's chronological age in months were control variables in the model. A multiple regression analysis was conducted to predict PSI Total Score from VABS Socialization Standard Score, VABS Communication Standard Score, and Parent Expressive Language Estimate after controlling for age and IQ.
Results: After controlling for the variance accounted for by chronological age and IQ (1.584%), the adaptive social and communication variables accounted for 7.76% of the variance in parent stress on the PSI Total Score ($p<.001$). Linear regression models were run for each PSI subscale, which confirmed our hypothesis that deficits in social and communication abilities accounted for more variance in the Parent-Child Dysfunction ($R^2 = .070$) subscale than the Difficult Child Subscale ($R^2 = .054$) or the Parent Distress Subscale ($R^2 = .036$) after controlling for age and IQ.
Conclusions: Our findings indicate that adaptive social communication skills in children with ASD are contributing to parent stress. Clinical implications of these findings include further consideration of the needs of the entire family when developing treatment goals for children with ASD.

126 **181.126** Assessing Parents' Perspectives on Autism Biomarker Discovery

A. Yusuf[1] *and M. Elsabbagh*[2]*, (1)McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, PQ, Canada*

Background: Research on understanding biomarkers for autism spectrum disorders (ASD) provides the potential to identify and monitor children at risk for ASD earlier than currently possible, thus facilitating access to personalized care. However, the complexity of the role of biomarkers in ASD coupled with the heterogeneity of ASD warrants a cautious translation of research findings in this field.
Based on previous models of community engagement in autism research (Walsh et al., 2011; Elsabbagh et al., 2014), systematically understanding the priorities and needs of the intended beneficiaries of research would inform this area of research. Our previous scoping review revealed limited examples of an empirical assessment of priorities and needs of beneficiaries (Yusuf and Elsabbagh, under review): thus far, few studies have examined parents' attitudes towards autism research in general and biomarker discovery in particular. Some current knowledge gaps include 1) the extent to which priorities of research on ASD biomarkers are valued by beneficiaries; 2) the potential utility of biomarkers to inform care; and 3) the perceived balance of risk and benefits from putative biomarkers for ASD.
Objectives: Despite emerging findings (Narcisa et al., 2012; Trottier et al., 2013; Wydeven et al., 2012) we could not identify validated tools to assess parent perspectives on biomarker discovery. Therefore, the goal of the study is to develop a questionnaire for use with parents of children with ASD on their needs and priorities for biomarker discovery.
Methods: Questionnaire items were adopted from results of a scoping review, focusing on three constructs: 1) general priorities for research on ASD biomarkers; 2) current and potential utility of biomarkers to inform care; and 3) perceived social impact of biomarker discovery.
The items were reviewed by a parent of a child with autism and by experts in the field of autism biomarkers. The updated version was then *pre-tested* through a series of cognitive interviews of parents of a child with ASD (n=8) to ensure that the items could be understood, in the same way across participants, and as intended (Collins, 2004). The on-line questionnaire was pilot tested among parents of children with ASD (n=10). All participants have a male child with ASD with an average age of 15 years old (SD=3.5).
Results: Pilot data suggest that parents consider the following priorities for biomarker discovery as *very important*: understanding how the brain develops in ASD and the developmental pathways in ASD. Potential uses of biomarkers rated as *very important* include using biomarkers to help develop behavioural interventions and to treat ASD-related medical issues. Half of the participants considered using biomarkers to identify ASD during pregnancy as of little importance. All participants agreed that further understanding of biomarkers for ASD would help others perceive their child more positively, but half did not think that it would change their experience as a parent.
Conclusions: Preliminary results suggest that it is feasible to empirically assess parents' perspectives on autism biomarker discovery. Future administration of the questionnaire in the target population would inform the translation of biomarker discovery to address families' needs.

127 **181.127** Assessment and Intervention for Anxiety and Problem Behavior in Children with Autism Spectrum Disorder and Intellectual Disability

ABSTRACT WITHDRAWN

Background: Despite the increased risk for anxiety disorders in youth with autism spectrum disorders (ASD), there is a lack of research on the functional assessment and treatment of anxiety and related problem behavior in children with ASD, particularly for those with an intellectual disability (ID).
Objectives: (1) To evaluate a multimethod strategy for the assessment of anxiety and problem behavior in children with ASD and ID; (2) To examine a multicomponent intervention plan to treat anxiety and related problem behavior in children with ASD and ID.
Methods: In Study 1 (the Assessment study), for three children with ASD and ID, anxiety was operationally defined using: (1) behavioral data from anxious behaviors, (2) affective/contextual data from parent-report and blind observer ratings of appearance of anxiety, and (3) physiological data (heart rate and respiratory sinus arrhythmia). A functional assessment of problem behavior during High- and Low-Anxiety conditions was conducted. In Study 2, we then developed treatments for the anxiety and associated problem behavior in these same three children. A multiple baseline design was used to evaluate the effectiveness of a multicomponent intervention package, incorporating individualized strategies from Applied Behavior Analysis (ABA), Positive Behavior Support (PBS), and Cognitive Behavioral Therapy (CBT).
Results: In Study 1, higher levels of problem behavior and heart rate, and lower levels of respiratory sinus arrhythmia, were found in the High-Anxiety than Low-Anxiety conditions (Moskowitz, Mulder, Walsh, McLaughlin, Zarcone, Proudfit, & Carr, 2013). In Study 2, following intervention, all three participants showed substantial decreases in anxiety and associated problem behavior in the situations that had previously been identified as anxiety-provoking (Moskowitz, Walsh, Mulder, Zarcone, McLaughlin, Proudfit, & Carr, in preparation). Additionally, the children showed changes in physiological arousal during intervention, suggesting parallel processes of improved coping and habituation (Moskowitz, Walsh, et al., in preparation).
Conclusions: Implications for the assessment and treatment of anxiety in this population using a multimethod approach are discussed.

128 **181.128** Associations Between Co-Parenting Quality and Challenging Child Eating Behaviors in Families of Children with ASD

M. Thullen[1]*, A. Bonsall*[2]*, K. Sohl*[3] *and T. N. Takahashi*[4]*, (1)Health Sciences, University of Missouri, Columbia, MO, (2)Occupational Therapy, University of Missuori, Columbia, MO, (3)University of Missouri - Thompson Center, Columbia, MO, (4)University of Missouri Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background:
While studies have examined stress among parents of a child with Autism Spectrum Disorder (ASD), little research addresses how parents work together in caring for a child with ASD. Different aspects of parental relationships such as support for spouse can promote well-being for parents facing elevated stress related to having a child with ASD

(Brobst et al., 2009). The concept of co-parenting addresses how parents relate to one another specifically in their roles as parents. A common stressor for parents is aversive and restrictive eating-related behaviors among children with ASD (Davis & Carter, 2008; Phetrasuwan & Shandor Miles, 2009)
Objectives:
This paper examines how co-parenting among parents of children with ASD is associated with their assessment of challenging eating behaviors and parenting stress.
Methods:
112 primary caregivers of a child (aged 5-13) with an ASD diagnosis responded to an emailed online survey about their experiences parenting. The mean age of respondents was 39.9 years (*SD* = 6.8), 90% were the child's mother figure (biological, step-, grand-, or adoptive), and 86% were co-residing and married to the co-parent. The mean age of the child was 9.5 years (*SD* = 2.5) and 81% were male.
Co-parenting quality was assessed using The Coparenting Relationship Scale (CRS; Feinberg, Brown, & Kan, 2012), a 35-item questionnaire assessing the degree of agreement on parenting issues, received support, satisfaction with balance of parenting-related labor, and child exposure to conflict.
Perceptions of child eating challenges were assessed using the Brief Autism Mealtime Behavioral Inventory (BAMBI; Lukens & Linscheid, 2008), an 18-item questionnaire that includes frequency of challenging eating behaviors as well as ratings of behaviors as problematic. Four subscales have been demonstrated within this measure (DeMand, Johnson, & Foldes, 2015): food selectivity, disruptive mealtime behaviors, food refusal, and mealtime rigidity.
Parenting stress was measured using the Parenting Stress Inventory Fourth Edition Short Form (PSI-4-SF; Abidin, 1990), a 36-item instrument summed to yield a total parenting stress score.
Results:
Bivariate correlations revealed expected and novel findings (Table 1). As expected, challenging eating behaviors were associated with greater parenting stress and better quality co-parenting was associated with less parenting stress. Co-parenting quality was associated with one particular aspect of eating challenges. When parents reported greater frequency of child disruptive behaviors at mealtimes they also reported exposing their child to more conflict ($r = .24$, $p < .05$). When parents reported a greater number of child disruptive behaviors at mealtimes as problematic they reported exposing their child to more conflict ($r = .20$, $p < .05$), feeling less supported by their co-parent ($r = -.22$, $p < .05$), and less satisfaction with the balance of labor ($r = -.24$, $p < .05$).
Conclusions:
The unique challenge to co-parenting presented by disruptive mealtime behavior is more evident based on parents' assessment of the impact of the behavior compared to their assessment of the frequency. Helping parents to be coordinated in their management of disruptive mealtime behaviors may help reduce the behaviors and support their co-parenting efforts more broadly.

129 **181.129** Autism Community Interest in and Use of Mobile Applications and Web-Based Tools for Tracking ASD-Related Information

V. J. Myers, *J. Manoharan, A. M. Daniels, L. Green Snyder, P. Feliciano and W. K. Chung, SFARI, Simons Foundation, New York, NY*

Background: The accessibility of mobile applications/web-based tools for tracking health information has increased in recent years, allowing for many new technologies to be developed for tracking autism spectrum disorder (ASD)-related behaviors and information. At the *International Meeting for Autism Research*(IMFAR), technology presentations have increased from eight in 2004 to 36 in 2008 [1]. While there are many education, communication, recreation and tracking technologies available for ASD, few people use them. One study found that only 25% of participants reported using technologies on a range of devices for people with ASD [2]. While many mobile applications/web-based tools are available for tracking ASD-related behaviors and information, more research is needed to ensure that these products align with users' needs and goals.
Objectives: The aim of this study was to survey interest in and use of mobile applications/web-based tools to track ASD-related information within an online community of parents/guardians of children with ASD.
Methods: An anonymous online survey was distributed to 16,031 participants of the Interactive Autism Network (IAN) over five weeks. The survey's primary aims were to assess the autism community's interest in participating in SPARK, a SFARI-supported web-based autism research study, as well as use of/interest in mobile applications/web-based tools to track ASD behaviors and related information. For the latter aims, respondents were asked to report on their past and present use of mobile applications/web-based tools in the areas of recreation, social/communication skills, education, and organizing and tracking, as well as interest in using applications for tracking ASD-related behaviors of their children. Data were abstracted from SurveyMonkey and analyzed using Stata, version 12.0.
Results: A total of 943 parents/guardians of children with ASD completed the survey. Eighteen percent of parents/guardians reported they had used a mobile application/web-based tool to track ASD-related information about their child/dependent. Among all parents/guardians, the most important features in an ASD-related mobile application/web-based tool were ease of use (75%), low cost (63%), ability to use on multiple devices (36%), and multiple features (36%). Among all respondents, parents/guardians were primarily interested in tracking daily behaviors (63%), specific events (51%; e.g. tantrums) and connections between two things (49%; e.g. behavior

and diet). Seventy-four percent of parents/guardians agree that they would be willing to spend several minutes a day (>5 minutes) entering data into a mobile application/web-based tool if they could see those changes in their child's/dependent's behavior visualized over time.
Conclusions: Findings from this study demonstrate that, despite participating in online research, few parents/guardians in IAN use mobile applications/web-based tools to track ASD-related information about their children/dependents. However, many parents/guardians said that they would spend several minutes a day entering data into a mobile application/web-based tool if they could visualize changes in their child's/dependent's behavior over time. Needs and desires of parents/guardians who currently use mobile applications/web-based tools closely matched those that had not previously used these tools. When developing such resources for SPARK, further user-testing is crucial to ensure that technologies are easy to use, engaging and collect/track information that is useful to families affected by ASD.

130 **181.130** Benefits of Physical Play for Fathers of Children with Autism

*J. L. Bloom[1], **M. N. Gragg**[1] and S. Horton[2], (1)Psychology, University of Windsor, Windsor, ON, Canada, (2)University of Windsor, Windsor, ON, Canada*

Background: Research suggests that fathers have become more involved with their children with Autism Spectrum Disorders (ASD) than in previous years, including engaging in play interactions with their children. For fathers of typically developing children, engaging in physical play has been associated with various benefits including greater happiness, a higher sense of self-worth, better communication, and lower stress. The benefits of engaging in physical play for fathers of children with ASD have not been directly studied. Potential benefits for fathers included improvements in parenting stress, which is a challenge that fathers of children with ASD typically experience. Physical play could also work to develop the father-child relationship.
Objectives: The present study investigated fathers' physical play with their children with ASD, and whether this was related to benefits for fathers. The present study also investigated whether physical play was related to fathers' satisfaction with play and relationship quality with their children with ASD. Other exploratory questions were investigated, including fathers' advice about play to other fathers; any similarities/differences in their play with their typically developing children; strategies for facilitating play; future aspirations for play; and how play affects the father-son relationship.
Methods: Fathers (i.e., biological, step-, adoptive-, foster-) of sons with ASD aged 4-11 ($N = 60$) completed an online survey that included ASD screening, questions on the frequency of fathers' physical play and fathers' well-being, and several short-answer questions. Fathers ($M_{age} = 39.9$) were primarily Caucasian, married, from Canada, biological fathers, and lived in the same home as their children with ASD ($M_{age} = 6.9$). A sub-sample of these fathers ($N = 20$) also completed a phone interview during which they answered more exploratory questions.
Results: Multiple regression analyses revealed that more frequent physical play (i.e., tickling, piggyback riding) reported by fathers significantly predicted lower parenting stress scores. More frequent physical play was also significantly related to higher satisfaction with play and higher relationship-quality for fathers with their children with ASD. Themes of *Physical Play, Relationship Building, Child Limitations for Play, Father's Role,* and *Toys and Games*were identified in the interview and short-answer responses.
Conclusions: Results suggested that fathers' benefits of more frequent physical play with their children with ASD included lower stress and greater relationship quality. This finding is consistent with the literature on fathers of typically developing children. Fathers' qualitative responses supported this finding. As one father stated, "to be able to play with him and have that interaction is very good for my emotional kind of state of mind". Implications for conceptualizing father-child play and for fathers' involvement in, and benefits of, intervention programs will be discussed. Fathers also shared a list of the toys and games that they used to facilitate play with their children with ASD, to disseminate to fathers and ASD organizations.

131 **181.131** Bilingualism and Autism: Exploring Parents' Attitudes and Experiences

***S. Hampton**, H. Rabagliati, A. Sorace and S. Fletcher-Watson, University of Edinburgh, Edinburgh, United Kingdom*

Background: Autism is associated with language and communication difficulties including delay in language onset in early childhood. Bilingualism likewise is associated with delayed onset of language in typical children. However, bilingualism may also confer advantages in cognitive domains (e.g. theory of mind) as well as facilitating community integration, family coherence and well-being. Thus parents of children with autism are presented with a dilemma when deciding whether to raise their children bilingually, and require an evidence base to inform their decisions. Research into the implications of bilingualism for those with autism, however, is scarce, meaning families and practitioners have little information to assist them in their decision-making.
Objectives: This study aimed to explore how bilingual parents in the UK decide on what language practices to adopt for their child with autism, in order to identify community priorities and define specific variables for investigation in future research.
Methods: Semi-structured interviews concerning the experience of raising a child in a bilingual household were conducted with bilingual parents with a child with autism (n=17), and a matched group of bilingual parents with a typically developing child (n=18).
Results: Thematic analysis revealed large areas of overlap between parents of children with and without autism in regard to their decision-making about raising their children bilingually. Factors included child characteristics, family dynamics, and preserving heritage. However there were also topics raised by parents of children with autism which were specific to this group. First, parents with a child with autism felt that a bilingual environment would hinder their child's linguistic development, causing confusion and exacerbating existing language delays – and this concern was related to the language level of the child in complex ways. Second, parents identified a number of ways in which they felt bilingualism could provide social and cognitive benefits, particularly in flexible thinking and communication skills. Third, parents reported a negative influence from professionals who sometimes advised against bilingualism, and referenced the lack of availability of resources for early years support in multiple languages. Finally, the findings also indicated an unanticipated role for bilingualism in providing high quality linguistic and social input for children with autism: parents felt less linguistically restricted when interacting with their child using their native language and further felt that this language facilitated a strong emotional bond with their child.
Conclusions: It is essential to build an evidence base to enhance family decision-making in this area. Some influences on the decision-making of parents with a child with autism were shared with parents of typical children but unique concerns were also raised. Our findings point to the importance of considering not just linguistic and cognitive consequences of bilingualism, but also factors such as family coherence and community integration, in future research in this field.

132 **181.132** Building Sibling Relationships: The Effects of Sibling Support on Siblings and Children with Autism

***E. A. Jones**[1], D. M. Fienup[1], N. Neil[2], T. Fiani[1], S. McHugh[3] and S. Izquierdo[1], (1)Department of Psychology, Queens College and The Graduate Center, CUNY, Queens, NY, (2)Michigan State University and the DOCTRID International Research Institute, east lansing, MI, (3)Department of Psychology, Queens College, CUNY, Queens, NY*

Background: Autism spectrum disorder (ASD) affects the entire family system and, in turn, the family affects outcomes for individuals with ASD. Family members, including siblings, may be affected by the presence of a family member with ASD. Siblings may show adjustment and skill needs; the sibling relationship may be strained. Improving sibling adjustment and the sibling relationship may be valuable for lifelong outcomes for individuals with ASD as siblings play a critical support role throughout the life of an individual with ASD. Support groups are one way to address the needs of siblings and improve sibling relationships. Only a few studies (Smith & Perry, 2005) suggested the effectiveness of support groups specifically for siblings of children with ASD. In an initial study, we found improvements in sibling adjustment and relationship following participation in a support group. After this pre-post comparison we are following up with a randomized control trial, comparing a support group to an attention only control condition.
Objectives: The purpose of this investigation was to evaluate the effects of a support group targeting siblings of children with ASD on sibling's knowledge about ASD, coping skills, peer network and, adjustment as well as the sibling relationship using self and parent-reports and observational measures in a randomized-control trial.
Methods: To date, 28 siblings of children with ASD aged between 3 and 16 years have completed participation with their 24 siblings with ASD aged between 3 and 18. An additional 11 siblings and 4 children with ASD will complete participation this fall. We randomly assigned siblings to a 1-hour group social group (control group) or support group, for 10 weeks. The support group lessons and activities focused on issues related to having a sibling with ASD for a period of 10 weeks. The social group involved similar activities with a focus on general social interaction and friendship. Pre- and post-measures evaluated sibling's knowledge and adjustment, family functioning, and sibling relationship measured through sibling and parent report as well as direct observation of sibling interactions.
Results: Initial analyses indicate that children who participated in the support group showed greater improvement on three of the four coping domains from pre to post. We are continuing to analyze other scales and data collection continues with new sibling dyads.
Conclusions: Support groups show promise in addressing the individual needs of siblings of children with ASD as well as fostering the sibling relationship. Findings of the current RCT indicate improvements in coping skills for siblings who attended the support group compared to those who attended the social control group. This builds on our preliminary studies which indicated improvements in depression and anxiety as well as sibling interactions. Continued data collection and analyses will allow us to examine additional measures of sibling adjustment, family functioning, and the sibling relationship.

133 **181.133** Caregiver's Experience of Universal ASD Screening – Would They Do It Again?

***M. E. Villalobos**[1], T. P. Gabrielsen[2], J. Miller[3], N. Buerger[4] and J. Viskochil[5], (1)Psychiatry, TEACCH Autism Program University of North Carolina Chapel Hill, NC, Asheville, NC, (2)Brigham Young University, Provo, UT, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)University of Utah, Salt Lake City, UT, (5)Utah Autism Research Program, Salt Lake City, UT*

Background: Universal ASD screening raises a unique set of challenges for families, who likely come from a wider range of ethnic, racial, and socioeconomic backgrounds, and who may not have even considered that their child may have some developmental concerns before they are notified that their child screened positive. A better understanding of caregiver's experiences is needed in order to support early identification efforts.
Objectives: The purpose of the study was to obtain the perspectives of caregiver's experiences as part of a community-based universal screening study as a way to better

identify challenges and supports to early ASD identification.
Methods: Twenty-four caregivers who participated in a universal community-based screening study (The EACH Child Study; Miller et al 2011) participated. Eleven families had a child with language delays and 13 were classified as ASD. Caregivers were interviewed at follow-up (mean age = 43months) and were asked to complete the Parenting Stress Index (PSI), the Reaction to Diagnosis Interview, and a survey about the experience of the screening and diagnostic evaluation, and what they did for follow-up.
Results: Caregivers rated the process of completing the screening measures in the pediatric setting as "easy to complete" and "not bothersome as part of their visit." Overall, caregivers reported positive phone-follow-up and in person screening experiences; however, caregivers of children in the ASD reported the initial diagnostic feedback to be challenging. Reaction to diagnosis results indicated caregivers of children with ASD experienced uncertainty and/or denial initially. Further, ASD caregivers reported cumbersome experiences navigating the EI service system, lack of resources, language barriers, social support, familial support and spousal communication as challenges following initial feedback. Approximately 6/24 caregivers did not report developmental concerns prior to screening; 3 had no previous understanding of ASD; 14 reported minimal understanding and 9 reported "moderate" understanding (e.g. knew someone with ASD). Results of the PSI indicated similarly elevated levels of parental stress in both the ASD and language delay groups (M = 78.15 SD =23.13). Components of the process that helped caregivers navigate the process included positive experiences with providers, family support and entry into early intervention. Despite reporting challenges, all caregivers stated that they would participate in the screening study again for a younger child. Lastly, approximately 16 of the families followed through with treatment recommendations and 8 did not (6/8 were in the language delay group).
Conclusions: While much evidence exists to demonstrate the effectiveness of EI for ASD, we are only beginning to understand the impact of screening in "real world" settings. The caregiver perspectives from this community-based universal screening sample highlight the challenges and supports faced by families following a positive screen for ASD. Caregivers reported high levels of stress-particularly around initial diagnosis and challenges navigating the EI system. Lack of knowledge of ASD and limited social supports/spousal supports significantly impacted access to EI. More research into the experience of families in real world settings is needed in order to ensure the promise of early screening and identification is realized.

134 **181.134** Caregiver's Perspectives on the Sensory Environment and Participation in Daily Activities for Children with Autism Spectrum Disorders

***B. A. Pfeiffer**, Rehabilitation Sciences, Temple University, Philadelphia, PA*

Background: Participation in daily activities is the context in which children acquire valued life skills and competencies (Dunst, 2002; Law, 2002), and as such is an important factor in development, health, and quality of life (WHO, 2009). Caregivers support a child's participation in order to facilitate growth and skill development, ultimately leading to their independence in daily activities. Although participation in these everyday activities is considered routine for most young children and their families, it is often more challenging for children with Autism Spectrum Disorders (ASD). Children with ASD and their caregivers face barriers within the environment due to unique characteristics of ASD that reduce the number and diversity of activities in which they participate (Bedell et al., 2012; Law et al., 2013). For example, it is estimated that up to 95% of individuals with ASD have unusual reactions, such as hyper- and hypo-reactivity to sensory stimuli in the environment (Ben-Sasson et al., 2009). Research identifies differences in sensory processing as a risk factor for limitations in participation (Bar-Shalita, Jean-Jacques & Shula, 2008). This reduced engagement may negatively impact the development and quality of life of the child with ASD.
Objectives: The objective of this study was to explore participation in daily activity among families of children with ASD and the perceived influence of sensory environments. Specifically, the study explored the sensory environmental factors that enhance or limit participation, as well as the methods parents or caregivers use to support participation for their child.
Methods: A phenomenological design was used to guide data collection and analysis of recorded interviews from 34 caregivers of children with ASD ages 3 to 7. Data collected for the study included semi-structured interviews, member checks, and demographic information. Interviews were transcribed and crosschecked. Two or more researchers analyzed the data to ensure the reliability of the analysis. Descriptive statistics were used to analyze demographic information.
Results: Qualitative analysis identified reoccurring themes that describe the impact of the sensory environment on participation in the young child with ASD, as well as a parental decisional-making process and strategies to support participation. Participants reported that environmental match was important in enabling their children's participation. Caregivers described a participation decision-making process in which they distinguished between essential and non-essential activities. Additionally, the amount of effort required by the parents to enable their child's participation was a key factor in deciding what activities parents would prioritize for their children. There were 6 common strategies implemented by caregivers to improve person and environment fit necessary to enable participation. Strategies either directly related to the sensory factors of the environment, or focused on reducing behavioral responses associated with sensory factors.
Conclusions: This study identifies important considerations to enhance participation in the home and community environments for the child with ASD including the decision making process of the family and strategies integrated into daily routines to improve environmental fit.

135 **181.135** Caregivers' Perspectives on Facilitators and Barriers to Early Identification of Children with ASD

***E. Crais**[1], C. S. McComish[2], E. F. Kertcher[3], S. R. Hooper[4], R. Edmondson Pretzel[5], S. Mergner[5] and M. E. Villalobos[6], (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Division of Speech & Hearing Sciences, University of North Carolina, Chapel Hill, NC, (3)Division of Occupational Science/Occupational Therapy, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Psychiatry TEACCH, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Finding effective solutions to the gap between research and practice presents a major challenge for the autism community. Over the past several decades, there has been an evolving recognition that the traditional intervention research model in which the flow of information is from research to practice is outmoded and ineffective (Wallerstein & Duran, 2010). As noted by Stahmer and colleagues (2011), one means to bridge the gap is through understanding the perspectives of community stakeholders regarding the benefits and barriers of specific practices and early intervention services.
Objectives: The current study was designed to gain the perspectives of North Carolina caregivers of children with ASD regarding the facilitators and barriers to early identification, evaluation, and entry into early intervention services.
Methods: Eight focus groups (4 English speaking, 2 Spanish speaking, 2 American Indian) with 55 caregivers of young children diagnosed with ASD were conducted in six regions of North Carolina. Caregivers were asked to describe the facilitators and barriers within three time periods: between first concerns and consulting with a professional, up through the diagnosis, and through entry into early intervention. Caregivers were also asked to discuss how these processes could be improved.
Results:
Across the three time periods, caregivers highlighted many similar barriers in the early identification and intervention process, including: not knowing who/where to go, getting conflicting advice, disagreements within and outside the family, their own uncertainty or "denial" (as described by caregivers), moving through multiple providers to get answers, limited resources, professional and parental lack of knowledge, and family and cultural beliefs. They also had particularly negative experiences during their first conversations with professionals and within the process of getting a diagnosis. In contrast, caregivers reported few facilitators; however a small minority of families noted professionals (physician, early care provider) or a family member first raised concerns and then linked them with professional services. There were some differences highlighted between cultural groups especially related to language and cultural barriers and lack of resources in rural and American Indian communities. Caregivers provided many suggestions about how early identification, evaluation and diagnosis, and intervention entry could be facilitated. Suggestions included having navigators to guide them through the processes, clear guidelines/roadmaps of printed materials for decision making, better connections with local resources, enhanced education for professionals (physicians, teachers), and more parent-to-parent opportunities.
Conclusions:
The parent perspectives shared during the focus groups contain a rich source of information for professionals interested in improving the early identification, evaluation and diagnosis, and entry into intervention services for children with ASD and their families. In addition, the personal experiences shared by the participants could be influential in affecting policy at local, state, and national levels, as well as informing research agendas in the coming years.

136 **181.136** Caring for Adults with Autism: Impact on Families

***R. K. Sandercock**[1], M. R. Klinger[1], E. M. Lamarche[2] and L. G. Klinger[3], (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC*

Background: While an emerging body of literature addresses the financial and mental health impact of raising a child with Autism Spectrum Disorder (ASD) on the family (e.g., Karst & Van Hecke, 2012), very little is known about the impact of caring for *adults* with ASD on families.
Objectives: Caregiver survey data were used to examine the family impact of caring for an adult with ASD across multiple domains, including: (1) utilization of caregiver support services, (2) time spent providing care, and (3) financial burden.
Methods: A survey was completed by 189 parents or guardians of adults with ASD in middle adulthood (21-64 years of age, *M* = 35.5 years). Adults were diagnosed during childhood between 1970-1999 at the UNC TEACCH Autism Program. The survey included 17 questions regarding various aspects of family impact.
Results: Caregivers were asked about their use of personal mental health services related to caring for an adult with ASD. Overall, 51% of caregivers reported using counseling services since their adult with ASD left high school. However, only 24% reported seeking counseling in the past two years. Similarly, 48% of caregivers reported ever participating in support groups but only 14% reported using a support group in the past two years.
Overall, 47% of adults with ASD were living at home with family members. Families who continued to care for adults with ASD at home reported greater difficulties than families whose adult with ASD was living outside of the home. Specifically, families whose adult with ASD lived with them reported that they spent significantly more time in

caregiving activities (73% reported spending time in caregiving; 34% providing 24 hour per day supervision). In comparison, 31% of caregivers of adults living outside the home reported involvement in caregiving activities with 3% providing 24 hour supervision.
Families reported being involved in a variety of decision making activities for their adult with ASD including healthcare, finances, living situation, legal, treatment, work/day planning, and recreation decisions. 55% of caregivers with adults residing at home reported that they were involved in decision making in all 7 areas compared to 36% of caregivers with adults living outside the home.
Surprisingly, only 14% of caregivers reported increased financial burden since their adult child left high school.
Conclusions: Caregivers of adults with ASD reported significant involvement in decision making across all areas of adult life for their son or daughter. Caregivers of adults who live with family spend an especially large proportion of their time supervising and making decisions for the adult with ASD. Although many caregivers have, at some point, sought out services to support themselves in handling these challenges, there appears to be a decline in professional caregiver support as the adult with ASD ages. Caregivers report a high level of personal burden in supporting their adult children with little professional support. While this pattern may minimize financial costs associated with caring for an adult with autism, long term personal costs both for the caregiver and the adult with ASD need to be examined.

137 **181.137** Characterizing the Relationship Between Autism Severity and Aberrant Behavior on Caregiver Strain and Family Empowerment in a Minority Population

P. Trelles[1], *P. M. Siper*[2], *J. M. Jamison*[3], *E. Fourie*[4], *D. Halpern*[1], *A. T. Wang*[5], *J. Krata*[6], *E. Holl*[6], *J. Shaoul*[6], *B. Hernandez*[6], *L. Mitchell*[6], *J. D. Buxbaum*[5] *and A. Kolevzon*[3], *(1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center, New York, NY, (3)Psychiatry, Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, New York, NY, (4)Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, New York, NY, (5)Psychiatry, Seaver Autism Center at Mount Sinai, New York, NY, (6)YAI, New York, NY*

Background: Caregiver strain, a measure of burden on emotional and physical health, is significantly higher among parents of children with autism spectrum disorder (ASD) than other developmental disabilities. High levels of parental strain are associated with poor family functioning, inadequate child utilization of mental health services and lower quality of life reported by the parent. Importantly, ethnic disparities in the utilization of mental health services are also well documented and while parent-centered approaches have been shown to be efficacious in Hispanic samples, they are often underutilized. It is therefore necessary to better understand factors, such as parental stress, that may affect service utilization in order to improve long term outcomes for minority families affected by ASD.
Objectives: To characterize caregiver strain, sense of family empowerment and the relationship with symptom severity and cognitive ability in a minority sample of children with ASD.
Methods: Forty-one Black and Hispanic children between the ages of 5 and 12 participated in this study. All children met DSM-5 criteria for ASD based on a consensus diagnosis, which included a psychiatric evaluation, the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) and the Autism Diagnostic Interview-Revised (ADI-R). Standardized measures of cognitive functioning were also obtained. Caregivers completed the Caregiver Strain Questionnaire (CSQ), the Family Empowerment Scale (FES), and the Aberrant Behavior Checklist (ABC). The CSQ measures negative occurrences associated with caring for a child with emotional disturbances (i.e., missed days at work), as well as parental externalizing (i.e., anger) and internalizing (i.e., sadness and guilt) feelings relating to their child. The FES measures attitudes, behaviors, and knowledge of family empowerment. The ABC measures behaviors observed in individuals with developmental disabilities across five subscales: Irritability, Lethargy, Stereotypy, Hyperactivity, and Inappropriate Speech.
Results: The relationship between variables was examined using Pearson correlations. CSQ total scores were significantly correlated with ABC total scores (r=.588, p<.001). The CSQ Internalizing subscale was significantly correlated with several ABC subscales, including Irritability (r=.529, p<.001), Lethargy (r=.62, p<.001), Stereotypy (r=.382, p=.014), and Hyperactivity (r=.571, p<.001). The CSQ Externalizing subscale was significantly correlated with ABC Irritability (r=.426, p=.005) and Hyperactivity (r=.550, p<.001). CSQ total score was negatively correlated with the Attitude (r=-.439, p=.004) and Behaviors (r=-.318, p=.043) subscales of the FES. The FES Knowledge subscale was not correlated with the CSQ. There was no correlation between ADOS-2 total raw scores, ADOS-2 severity scores, or IQ on caregiver strain or sense of family empowerment. Caregiver report did not differ significantly between ethnic groups.
Conclusions: Results indicate that there is a strong relationship between caregiver strain and aberrant behavior in minority families affected by ASD. Children's externalizing behaviors were strongly associated with internalizing symptoms in caregivers. Less strain in caregivers was also correlated with empowering attitudes and behaviors, although greater knowledge was not associated with lower levels of strain. Importantly, ASD symptom severity and cognitive ability

138 **181.138** Communication about Sexuality Between Young Adults with Autism Spectrum Disorder (ASD) and Their Parents

K. Hartmann[1], *M. Urbano*[2], *T. V. Williams*[3], *A. L. Peterkin*[4] *and T. Kozikowski*[2], *(1)P.O. Box 1980, Eastern Virginia Medical School, Norfolk, VA, (2)Eastern Virginia Medical School, Norfolk, VA, (3)Virginia Consortium Program in Clinical Psychology, Norfolk, VA, (4)Psychology, Old Dominion University, Norfolk, VA*

Background: Sexuality is a difficult topic for most people to discuss given social rules, whether they are neurotypical or have any additional challenges such as ASD. Many families opt out of these conversations until a difficulty arises. For neurotypical children, sex education is part of their everyday peer interactions. Children with ASD, by their nature, shy away from peer interaction due to the many environmental and social factors that overwhelm their preference for information and emotion processing. By the time a child with ASD reaches puberty, they have already missed out on valuable peer interactions and learning about sexuality in interpersonal relationships. Exploring intimacies requires social interaction sophistication, self-knowledge, and communication with the other, all difficult for individuals with ASD.
Objectives: The present study intends to add to the current literature by exploring the sexual knowledge and practices of young adults with ASD and their communication with their parents/caregivers. Additionally, it aims to explore the comfort caregivers of young adults with ASD feel when discussing sexually related topics with their child. The level of support caregivers would like in addressing sexual topics with their young adult with ASD will be explored.
Methods:
This study aims to collect responses in an online survey from 200 young adults with ASD and their parents. Participants were asked to complete a series of questionnaires: a demographic questionnaire, a measure to confirm the presence of ASD symptomatology (ASQ-10), several measures related to sexual knowledge, experiences, and orientation (General Sexual Knowledge Questionnaire, Sexual Behavior Scale, Sexual Experiences Survey, Online Sexual Risk Behaviors, Klein Sexual Orientation Scale), and family communication (Family Sex Communication Quotient).
Results: Data analyses will compare descriptive statistics and frequency data to national statistics for sexual behaviors in neurotypical young adult populations. This study aims to investigate reliance on the internet for sexual information and activities, desire for privacy when engaging in sexual behaviors, overall desire for and engagement in sexual behaviors, instances of unwanted sexual advances, asexuality and same sex attraction, caregiver communication about sex, and caregiver concerns about their child's sexual development. Caregiver beliefs about their child's exposure to sex education will be compared to young adult reports of their exposure to sexual education.
Conclusions: This study is currently online but results not yet available. We hypothesize the following: Young adults with ASD will know more about sexuality than their parents anticipate, endorse reliance on the internet for information about sexuality, seek less privacy when engaging in sexual behaviors, express desires for intimate relationships on par with others in their peer group, be subjected to more instances of unwanted sexual interactions, and report higher rates of asexuality and same-sex relationships. Caregivers of individuals with ASD will report communicating with their child about sexual information and express worries about the sexual development of their child. Young adults with ASD engage in frequent family communication about sexual activities and will have accurate sexual knowledge.

139 **181.139** Comparison of Reported Social Support in Single and Two Caregiver Families with a Child with an Autism Spectrum Disorder

E. G. Schreiber, *Center for Autism Spectrum Disorders, Nationwide Children's Hospital, Westerville, OH*

Background: Raising a child with an Autism Spectrum Disorder (ASD) has been linked to significant stress as reported by the caregiver (Bluth et al., 2013; Hill- Chapman et al., 2013; Kissel & Nelson, 2014). Despite the challenges they face, caregivers of children with an ASD have been shown to be resilient. One area of adjustment and adaptation for these caregivers is social support (Bayat, 2007; Greeff & van der Walt, 2010). Parents raising a child with an ASD report higher levels of "actively seeking and accepting help" (Luther et al., 2005), however, they perceive less available social support in their environment as compared to parents raising a child without a disability (Obeid & Daou, 2015). Additionally, single caregivers of a child with an ASD report lower levels of social support than mothers living with a partner (Bromley et al., 2004).
Objectives: The current study aimed to better understand the differences between single caregivers versus two-caregiver families of a child with an ASD with regard to the social support they receive and perceive in their environment.
Methods: Female caregivers of a child (2-18 years) with an ASD were recruited through local autism schools, organizations, and social media to complete the study. Participants in the study were of single-caregiver families (n = 65) and those residing with another adult, regardless of relationship status (n = 188). The caregivers completed a demographic survey, the Family Support Scale, and open-ended questions regarding the support they were receiving and wanted to receive.
Results: The majority of the sample was Caucasian, had completed college coursework or a college degree, and reported to be Christian/ Protestant or of no religious affiliation. The mean age of the caregivers was 38.26 years. Additionally, there was a significant difference in reported household income (single-caregiver Md = under $30,000; two-caregiver Md= $30,000-$59,999).
After adjusting for household income, there was a significant difference in Total Family Support (F[1,250] = 8.87, p= .003) between single-caregiver and two-caregiver families. For single-caregiver families, kinship support and professional support were noted to be significantly more "helpful" than the other sources of support. For two-caregiver families, spouse/ partner support and professional support were noted to be significantly more "helpful" than the other sources of support. Additionally, both samples reported they were not receiving, but desired, both therapeutic resources for their child as well as financial resources.
Conclusions: As social support is associated with a reduction in parental stress, it is important for clinicians to provide support to caregivers directly and to provide information and aid to overcome obstacles in accessing desired social support. Additionally, as single-caregivers report less perceived social support in their environment, it

is essential for clinicians, social workers, case managers, or other individuals working with these families to assess areas of social support need and provide resources to increase the support they receive in order to decrease the discrepancy between types of caregivers.

140 **181.140** Compassion Meditation for Parents: Effects on Stress and Perceived ASD Severity

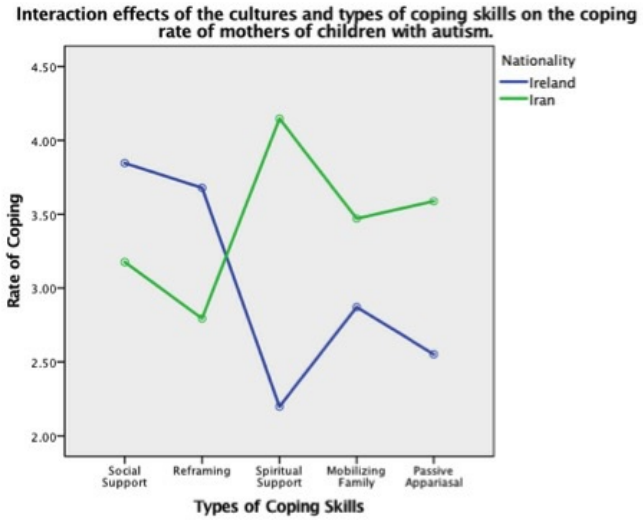
J. Mendelson[1], *S. Fernandez-Carriba*[1], *C. A. Saulnier*[1], *S. E. Gillespie*[2] *and A. Klin*[3], *(1)Department of Pediatrics, Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (3)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background:
Parents of children with Autism Spectrum Disorder (ASD), who are often required to be fully involved in their children's intervention, have higher incidence of depressive symptoms and stress than parents of typically developing children (Jeans et al., 2013). Whereas the practice of mindfulness and compassion meditation is reportedly associated with stress reduction in several populations (Cosley et al, 2010), there are very few studies describing mindfulness based interventions for caregivers of individuals with ASD (Bazzano et al., 2013, Dickens et al., 2014) and none to our knowledge using compassion meditation.
Objectives:
The goal of this research is to pilot-test Cognitively Based Compassion Training (CBCT), a mindfulness and compassion meditation protocol developed at Emory University and empirically validated in other populations, with parents of children with ASD in order to reduce stress in these parents and, in turn, impact the children's outcomes.
Methods:
Participants included 9 caregivers of children with ASD (age in years M±SD = 43.8 ±5.5; 8 females) recruited at the Marcus Autism Center in Atlanta, GA. Participants received CBCT over the course of 8-10 weeks and completed several measures before and after the training, with a follow-up at 2 months: perceived severity of the child's symptoms (Aberrant Behavior Checklist or ABC-Irritability Scale), stress and acceptance (Parenting Stress Index or PSI/SF, Perceived Stress Scale or PSS, and Acceptance and Action Questionnaire or AAQ), empathy and compassion (Interpersonal Reactivity Index or IRI), behavioral flexibility (Mindful Attention Awareness Scale or MAAS, and Behavior Rating Inventory of Executive Function or BRIEF-A), and parent-child relationship (Parenting Sense of Competence Scale or PSS).
Results:
Paired t-tests were utilized to evaluate pre-post changes in scores at the 0.05 significance level. Findings included a significant decrease in perceived severity of the child's symptoms as measured by the ABC-I (Time 1 M±SD = 11.7±8.06; Time 2 M±SD = 7.7±8.2) and a significant decrease in parent stress according to the total stress PSI scale (Time 1 M±SD = 94±28.35; Time 2 M±SD = 76.2±29.6) and the PSS scale (Time 1 M±SD = 21.7±3.09; Time 2 M±SD = 13.1±4.39). There was a significant increase in behavior flexibility according to the Behavior Regulation Index of the BRIEF-A, Inhibit scale (Time 1 M±SD = 11.4±1.26; Time 2 M±SD = 9±1.62) and Shift scale (Time 1 M±SD = 10±0.86; Time 2 M±SD = 7±1.29). Marginally significant differences were found in the direction expected in the Parenting Sense of Competence Scale (Time 1 M±SD = 70.1±9.46; Time 2 M±SD = 82.4±11.65; p=.05) and no significant differences in the three measures related to acceptance (AAQ), empathy (IRI) and mindfulness (MAAS) (n.s.). A second set of analyses including repeated measures analysis of variance for the only four participants that completed follow-up measures suggest that gains were maintained in the PSI, PSS and BRIEF scales.
Conclusions:
Taken together these promising results suggest that CBCT is a feasible training for parents of children with ASD, with potential benefits on their stress and their perceived children's severity. A randomized controlled trial should test its efficacy under controlled conditions.

141 **181.141** Coping Skills Among Mothers of Children with Autism in Ireland and Iran: The Effect of Culture

S. Torabian[1] *and S. A. Samadi*[2], *(1)San Jose State University, Los Altos Hills, CA, (2)University of Ulster, Karaj, Iran (Islamic Republic of)*

Background: Few disorders in children pose a greater threat to the psychosocial well-being of parents than autism. Several studies have demonstrated that many parents of children with autism experience depression or dysphoria. There is much evidence to suggest that the parenting burden falls more heavily on mothers therefore mothers might suffer more emotional consequences of that burden than fathers. The stress and coping processes associated with parenting a child with autism have been the subject of much research, yet the vast majority of this research has been majorly done in the United States and other advanced nations. This is the first study that compared the coping skills of mothers of children with autism between an Eastern Culture of Iran with a Western Culture.
Objectives: The research study was a descriptive survey design based on a convenience sample. Participants completed a 15-question demographic questionnaire and the 30-question Family Crisis Oriented Personal Evaluation Scales (F-COPESs).
Methods: Each respondent completed the Likert-type scale questionnaire ranging from 1 (strongly agree) to 5 (strongly disagree). The coping scale is a reliable and valid tool that measures coping strategies and level of adaptation. F-COPES has a Cronbach's alpha reliability of 0.86 and a test–retest reliability of 0.81. The F-COPES divides coping strategies into five subscales: (a) acquiring social support, (b) reframing, (c) seeking spiritual support, (d) mobilizing family to acquire and accept help, and (e) passive appraisal. For the Ireland population, 30 mothers were recruited from a nonprofit parental support group and various speech-language, occupational, and behavioral treatment centers in London area. For the Iranian population, 30 mothers were recruited from the Iranian Department of Special Education.
Results: A preliminary analyses revealed a significant effect of culture on coping skills of participants, $F(1, 66) = 12.06$, $p < .01$, $eta^2 = .15$. MANOVA further revealed a significant interaction effect between culture and the five subscales of the coping skills, $F(1,68) = 37.22$ $p < .001$, $eta^2 = .35$. Across the two cultures of the Ireland and Iran, mothers in the Ireland significantly displayed the two coping skills of "acquiring social support" and "reframing" more than the other three coping skills whereas mothers in Iran significantly displayed the three other types of coping skills of "seeking spiritual support", "mobilizing family to acquire and accept help, and "passive appraisal" (See Fig. 1).
Conclusions: The results indicate that culture might play a significant role on the coping skills of mothers of children with autism. While mothers in the Western Culture of Ireland might more actively acquired support from relatives, friends, neighbors, and extended family as well having the ability to redefine stressful events in order to make them more manageable (reframing), mothers in Eastern Culture of Iran coped with having a child with autism in a more spiritual way such as believing that it was God's faith, they seeked out more community resources and accepted help from others (mobilizing), and they appraised autism in ways of passive or inactive behaviors such as avoidance.



142 **181.142** Day-to-Day Technology Use and Training Needs of Teens with ASD and Typically-Developing Peers

C. A. Cohen[1,2] *and A. R. Marvin*[3], *(1)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD, (2)University of Baltimore, Baltimore, MD, (3)Painter Bldg 1st Fl, Kennedy Krieger Institute, Baltimore, MD*

Background:

The use of technology is ubiquitous in teens with autism spectrum disorder (ASD) and their typically-developing (TD) peers. Computer competency is needed for many careers. Research has not focused on the how people with ASD use technology in their day-to-day lives and whether that technology is accessible to them to meet their occupational, economic, entertainment, and information needs as they transition into adulthood, independent living, and the world of work.

Objectives:

To understand which technologies are used by teens with ASD and TD peers and parent-perceived needs for technology training.

Methods:

An anonymous 80-question survey developed in SurveyMonkey was administered to parents/ guardians of children ages 13-17 living in the US with and without ASD. Participants were recruited using the Interactive Autism Network (IAN) subject recruitment service and social media. The survey ran 09/09/2015-10/24/2015.

Results:

348 survey instances were completed: ASD= 264 (76%); TD=84(24%). Male-to-female gender ratios for TD (1:1) and ASD (5.87:1) were in the expected range.

Three groups were used for analysis: ASD with normal-or-above intellectual ability (ASD-Normal); ASD with lower-than-normal intellectual ability (ASD-Low); and TD. No TD teens were attributed with lower-than-normal intellectual ability.

Logistic regression was used to compare use of ASD-related apps and dedicated assistive devices (ASD groups only) and general use of devices across groups, controlling for the child's age, gender, race (white/non-white), and ethnicity (Hispanic/Non-Hispanic).

Use of ASD-related apps and dedicated assistive devices – ASD-only: intellectual ability was the only factor that differentiated groups, with use among ASD-Low>ASD-Normal (Apps: χ^2 =28.14; p<.001; d.f.=5. Dedicated Devices: χ^2=13.03;p=.023;d.f.=5).

Use of laptops, desktops, and notebook computers: intellectual ability was the only factor that differentiated groups, with ASD-Low using them less than the other groups (χ^2=22.52;p=.001;d.f.=6).

Use of tablets: Hispanic/Latino teens used tablets more than Not-Hispanic/Non-Latino teens (χ^2=15.61;p=.016;d.f.=6).

Gaming devices: Overall, ASD-Normal were using gaming devices more than other groups (χ^2=37.11;p<.001;d.f.=6). ASD girls (50.0%) were more likely to use gaming devices than non-ASD girls (23.8%) (p=.02 FET) and TD boys (85.7%) were more likely to use gaming devices than ASD boys (65.2%) (p=.01; FET).

Smartphones: 58.0% of ASD-Low, 75.8% of ASD-Normal, and 86.9% of TD teens were using Smartphones (χ^2=30.37;p<.001;d.f.=6).

Technology careers and training: ASD-Normal teens were more likely to be considering a career that highly-involved computers (53.9%) than TD (20.2%) or ASD-Low (23.3%) teens (χ^2=41.02;p<.001;d.f.=6). ASD-Normal teens also more likely to be learning computer repair (17.1%) than TD (7.1%) or ASD-Low (5.2%) teens; however, only boys were doing so (χ^2=19.31;p=.004;d.f.=6). ASD-Normal teens also more likely to be learning computer programming (38.0%) than TD (16.7%) or ASD-Low (12.7%) teens; however, more ASD-Normal boys (40.0%) were doing so than girls (22.2%) (χ^2=34.16;p<.001;d.f.=6). 86.5% of parents of ASD-Low, 68.8% of parents of ASD-Normal, and 41.7% of parents of TD teens wanted more computer training for their child (χ^2=48.02;p<.001;d.f.=6).

Conclusions:

Teens with autism are active technology users and many are considering careers in technology; however, technology training is falling short.

143 **181.143** Defining Parenting and the Role That It Plays in the Relationship Between Complexity of the Child's Neurodevelopmental Disorder and Family Impact

ABSTRACT WITHDRAWN

Background:

Parenting, a complex concept, with numerous definitions, has been defined as the attributions parents make regarding a child's behavior. Similarly, another definition centers around parents' use of certain types of behaviors, such as hostility. Parenting, as defined by both attributions and behaviors, is hypothesized as one factor that leads families to report a positive impact or negative impact in raising their child. For example, the parenting behavior of providing emotional support has consistently been associated with positive developmental outcomes in neurotypical children (Gray & Steinberg, 1999). Mothers of children with disabilities who make higher proportions of positive appraisals throughout their day, have families with higher levels of healthy adjustment (Trute et al., 2010). Whether parenting plays a similar role in families with a child with a neurodevelopmental disability (NDD) was investigated.

Objectives: To investigate whether parenting could be defined as a concept using a latent variable consisting of both attributions and behaviors; and, to verify whether it partially mediates the relationship between complexity of a child's neurodevelopment impairment and the family impact of raising a child with a NDD.

Methods: This study was part of the Parenting Matters! study (PI: Lucy Lach, Ph.D., Dafna Kohen, Ph.D., & Peter Rosenbaum, M.D.). A convenience sample was collected in major health centers servicing families with a child with a neurodevelopmental disorder across Canada. Mothers of 190 children age 4 to 13 years old (M = 8.11 years, SD = 2.41 years), and primarily male participated (62.1%). Children had diagnoses of either cerebral palsy (36.8%), ASD (27.9%), global developmental delay (19.5%), epilepsy (8.9%) or multiple impairment (6.8%). Measures used to collect data, included About My Child – 26 (AMC; Rosenbaum et al., 2008), Parenting Attribution Test (Bugental, 2004), National Longitudinal Study of Children and Youth Parenting Scales - Consistency, Positive Interaction, and Hostile/Ineffective (Strayhorn & Weidman, 1988), and the Family Impact of Child Disability Scale (Trute et al., 2009).

Results:

A model in which a latent variable for parenting was created from parenting attributions and parenting behaviors was tested with exploratory factor analysis. The goodness of fit indices were poor (e.g., CFI = 0, $RMSEA$ = .38, $SRMR$ = .27). Subsequently, individual parenting variables were entered as mediators between AMC complexity score and both positive and negative family impact but revealed no significance. The direct effect of AMC complexity score was significant and explained 44.7% of the variance in negative family impact of disability (R^2 = .195, F(1, 183) = 45.65, p < .001).

Conclusions: The latent variable of parenting was not established as consisting of both parenting attributions and behaviors. This affirms that defining parenting is complex, and may differ for children with a NDD. The results suggest that measures targeted specifically for the unique situation of parenting a child with a NDD are needed. The relationship between sources of stress such as complexity of the child's neurodevelopmental impairment and negative family impact suggests the need to address concerns about function in order to improve parents' appraisal of negative family impact.

144 **181.144** Defining the Characteristics and Needs of Females with ASD: An Inductive Approach

*S. N. Bargiela[1], R. L. Steward[2] and **W. Mandy**[3], (1)UCL, London, United Kingdom, (2)Robyn Steward, Suffolk, England, United Kingdom of Great Britain and Northern Ireland, (3)University College London, London, United Kingdom*

Background: Females are at substantially elevated risk of their autistic symptoms being unrecognised: their difficulties are commonly mislabelled, or missed entirely. In non-referred samples there are approximately two or three males for each female with autism spectrum disorder (ASD); whereas in clinically-ascertained samples the male-to-female ratio is at least four-to-one. This shows that many females with ASD never receive a clinical diagnosis, and the help that comes with it. Even when females with ASD are identified, they receive their diagnosis (and associated support) later than equivalent males. Females require more severe autistic traits compared to males to come to clinical attention, and teachers underreport autistic traits in their female pupils. This gender bias has serious consequences for the health and well-being of girls and women with ASD, and has been identified by the autism community as a key problem to be addressed by research.

Females with autistic difficulties are at high risk of going unnoticed and unhelped because there is a female autistic phenotype - a female-specific manifestation of autistic strengths and difficulties that does not fit the current, male-based consensus. To overturn current discrimination against girls and women with autistic difficulties, clinical scientists must provide a valid, empirically-based description of the female autistic phenotype; and the ways it impacts on likelihood of receiving a diagnosis.

Objectives: To study, in depth, the experiences and characteristics of females with ASD who had not received their diagnosis in childhood, in order to: (1) generate hypotheses about the female ASD phenotype and (2) to understand how the female phenotype impacts upon under-diagnosis of females' ASD.

Methods: Fourteen women aged between 18 and 30, with a clinical diagnosis of ASD in received in adolescence or adulthood, were recruited via snowball sampling and participated in a semi-structured interview. The data were subjected to intensive framework analysis.

Results: Framework analysis of the data yielded the following four themes specific to being a woman with ASD: (1) 'You're not autistic', which centred on experiences of having autistic difficulties missed by professionals who considered ASD to be a male condition, and included consideration of the costs of a late diagnosis; (2) 'Pretending to be normal' focusing on efforts made by females to camouflage their autistic characteristics; (3) 'Forging an identity as a woman', which concerned perceived conflicts between having an autistic and a feminine identity, and how this was resolved; (4) Passive to assertive described experiences women had of being victimised, and how some had grown more confident and less vulnerable as they embraced the positive aspects of their ASD.

Conclusions: The research highlights camouflaging of autistic characteristics as a key process for women with ASD, suggesting that it brings both advantages (e.g. better social function, higher employability) and disadvantages (e.g. missed diagnosis, pretending to be someone else). Also, further attention should be paid to the vulnerability to exploitation, including sexual abuse, reported by a substantial proportion of the sample; and to improving the knowledge of healthcare professionals about ASD in girls and women.

145 **181.145** Development and Validation of a Survey of Knowledge of Autism Spectrum Disorder

***L. K. Hansen**[1] and T. D. Barry[2], (1)University of Southern Mississippi, Hattiesburg, MS, (2)Psychology, Washington State University, Pullman, WA*

Background:

As autism spectrum disorder (ASD) is more commonly diagnosed, having knowledge of the disorder becomes increasingly important for educators, parents, and the general public. Previous research regarding knowledge of ASD has found that teachers may perceive themselves as possessing average knowledge regarding ASD but have low actual knowledge regarding specific aspects of the disorder (Williams et al., 2011). However, there has been little research regarding the level of awareness concerning ASD possessed by individuals outside of the educational sphere.
Objectives:
The primary goal of this study was to create a reliabile, valid measure to evaluate perceived versus actual knowledge of ASD. Furthermore, the current study also investigated factors related to ASD knowledge, including having a personal relationship with an individual with ASD, participating in ASD training, and source of ASD knowledge.
Methods:
A sample of 487 undergraduate students (86% female; 60% White, 35% Black, 5% Other race) was administered A Survey of Knowledge of Autism Spectrum Disorder (ASK-ASD). The ASK-ASD original item pool was comprised of 51 items, all of which were reviewed by experts with advanced degrees from a variety of disciplines (i.e., clinical child psychology, school psychology, occupational therapy, and physical therapy). Additionally, participants were administered a demographic form, a measure of knowledge of ADHD, and a measure of knowledge of HIV/AIDS.
Results:
Participants were moderately knowledge (65%) regarding ASD and perceived themselves to be moderately knowledgeable (M = 1.8, SD = .41). The correlation between perceived and actual knowledge was significant, r = .25, indicating a tendency for participants to accurately evaluate their own knowledge levels. An exploratory factor analysis (EFA) of the ASK-ASD revealed a two-factor structure of knowledge of ASD: Prognosis/Risk Factors Subscale (PRFS) and General Features Subscale (GFS). Twenty-eight items were deleted to facilitate the EFA and achieve simple structure. The ASK-ASD demonstrated test-retest reliability, with bivariate correlations between the first and second administrations ranging from .48 to .72. Internal consistency was adequate, with alpha values ranging from .57 to .61 for the total scale and subscales. The ASK-ASD also showed construct validity through bivariate correlations of both perceived and actual knowledge with ASD training and relationship with an individual with ASD. Furthermore, convergent validity was demonstrated through correlations between the ASK-ASD and a measure of ADHD knowledge, as well as a measure of HIV/AIDS knowledge. Moreover, significant correlations were found between gender and ethnicity with actual knowledge, r = .15 and r = -.20, respectively.
Conclusions:
The ASK-ASD was supported as a valid, reliable method to evaluate perceived and actual knowledge of ASD. In general, participants were moderately knowledgeable regarding ASD and could accurately perceive their own knowledge. Additionally, exploratory analyses revealed several interesting correlations between ASD knowledge, demographic characteristics, and source of ASD knowledge. Relations between gender, ethnicity, and actual knowledge indicated that female participants had higher knowledge compared to male participants and Non-White participants had lower levels of knowledge than White participants. Limitations of the study included the sample being limited to undergraduate students and the online survey format.

146 **181.146** Discrepancy in Social Support Perceptions As a Risk Factor for Siblings of Individuals with ASD

***J. A. Rankin**, T. S. Tomeny, L. K. Baker and S. W. Eldred, Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Typically-developing (TD) siblings of individuals with ASD are at risk for negative outcomes due to a variety of factors. One such factor is the severity of their sibling's ASD deficits (Meyer et al., 2011). Social support has been identified as a protective factor against these deficits on sibling adjustment (Hastings, 2003). However, the availability of support may not be as meaningful as the discrepancy between one's perceived importance of support and the amount of support available (Newcomb, 1990). Further, social support encompasses many distinct domains of support. Research in other populations illustrates that different forms of support may have differential effects on physical and mental health (Wong et al., 2014). However, social support discrepancy has not been examined in the adjustment of TD siblings of children with ASD.
Objectives: This study explored: 1) If social support discrepancy moderates the relation between ASD symptom severity in siblings with ASD and TD sibling adjustment problems, overall, and in terms of emotional and externalizing problems. 2) Which domain(s) of support discrepancy uniquely predict(s) TD sibling adjustment, while controlling for ASD symptom severity in siblings with ASD. 3) If the relation between ASD symptom severity in siblings with ASD and TD sibling adjustment is moderated by the unique domain(s) of support.
Methods: 113 Families completed study measures. Parents completed the Children's Social Behavior Questionnaire (CSBQ) about the child with ASD, assessing ASD symptom severity. TD siblings (Mage = 13.33, 50% male) self-reported emotional and behavioral functioning via the Strengths and Difficulties Questionnaire (SDQ), and social support availability and importance via the Child and Adolescent Social Support Scale (CASSS).
Results: Moderated multiple regression analyses were conducted to examine interactions via the computational tool, PROCESS (Hayes, 2013). Significant interactions emerged between ASD symptom severity and greater social support discrepancy (coded: importance minus availability) when predicting overall sibling maladjustment, B = .09, SE = .04 p = .03, and emotional problems, B = .04, SE = .02 p = .01. Separate regression analyses (Table 1) revealed that emotional support discrepancy was the only unique predictor of overall sibling adjustment,$\boldsymbol{\beta}$ = .51, p = .001, and externalizing and emotional problems (both $\boldsymbol{\beta}$ > .37, both p < .02). Finally, significant interactions between ASD symptom severity and emotional support discrepancy emerged predicting overall sibling maladjustment, B = .10, SE = .04, p = .01 (Figure 1), and both emotional, B = .04, SE = .02, p = .02, and externalizing problems, B = .03, SE = .01, p= .03.
Conclusions: Social support discrepancy moderates the relations between ASD symptom severity and overall and emotional adjustment problems in TD siblings. This was driven by emotional support discrepancy, which also moderated the relation between ASD symptom severity and externalizing problems. Findings highlight that support discrepancy may be more predictive of sibling adjustment than actual perceived support. Further, emotional support may be a particularly useful area to target for siblings and has unique predictive value over and above total and other domains of support discrepancy.

Table 1

Results of Multiple Regression Analyses of Support Discrepancy Types Predicting TD Sibling Overall Adjustment, Emotional Problems, and Externalizing Problems

	Criterion Variables		
Predictor Variables	Overall Problems	Emotional Problems	Externalizing Problems
Model 1			
ASD Symptom Severity	.25**	.09	.23*
R^2 (df)	.06** (1, 110)	.01 (1,110)	.05* (1,110)
Model 2			
ASD Symptom Severity	.24**	.08	.23*
Emotional Support Discrepancy	.51***	.37*	.53***
Appraisal Support Discrepancy	-.01	-.07	.004
Informational Support Discrepancy	-.18	-.03	-.23
Instrumental Support Discrepancy	.04	.20	-.11
ΔR^2 (df)	.17*** (4,106)	.22*** (4,106)	.12** (4,106)

Note. Standardized beta-weights reported for each predictor. Degrees of freedom reported in parentheses following each R^2 value.
*** $p < .001$. ** $p < .01$. * $p < .05$.

147 **181.147** Effectiveness of a Family Psychoeducation Program for Parents of Young Children with ASD

T. Takezawa[1], *T. Yoshikawa*[2] *and M. Inoue*[3], *(1)Education and Social Service, Institute for Developmental Research, Aichi Human Service Center, Kasugai, Aichi, Japan, (2)Child and Adolescent Psychiatry, Central Hospital,Aichi Human Service Center, Kasugai, Aichi, Japan, (3)Tottori University, Yonago, Tottori, Japan*

Background: Many parents of children with Autism Spectrum Disorders (ASD) are more likely to experience depression and stress than those of children with/without other types of disabilities. It could become much more pronounced when their children are diagnosed. Therefore, an appropriate program should be provided to reduce the parent's anxiety and parenting stress at a crucial time.
Objectives: The purpose of this study was to examine the effectiveness of a family psychoedeucation program for parents of young children with ASD.
Methods: Thirty-one parents participated in the program, and received a series of lectures on ASD and other related topics for 3 months. Beck Depression Inventory-Second Edition (BDI-II) and Parenting Stress Index Short Form (PS-SF) were used to measure the parent's anxiety and parenting stress. The participants also answered a questionnaire on degree of understanding and satisfaction with the program.
Results: BDI-II scores of the participants significantly decreased at the end of the program. Similarly, PS-SF scores also tended to decline although it was not a statistically significant change. Most participants developed a better understanding of ASD and had a high level of satisfaction with the program.
Conclusions: The results revealed that the program could be effective for reducing the depression of parents of young children with ASD. However, the program was not

effective enough to reduce parenting stress. A likely explanation is that the participants reacknowledged the problems and their responsibility as parents through the program. The program needs to be revised, focusing on reducing parenting stress more effectively. Starting at an early stage of awareness and diagnosis, family psychoeducation program could play an important role as one of the early family intervention programs for ASD.

148 **181.148** Emotional Difficulties in Parents of Children with Autism Spectrum Disorder

***A. P. Costa**, G. Steffgen and D. Ferring, University of Luxembourg, Esch sur Alzette, Luxembourg*

Background: Previous studies have demonstrated that parents of children with ASD are at a greater risk of increased stress and mental health problems (e.g., Totsika et al., 2011). Children with ASD have several emotional difficulties such as increased reactivity, difficulties with emotion regulation, and higher levels of alexithymia, which have been reported to be more important in the explanation of parents' difficulties than child's diagnosis (ASD/non-ASD; Herring et al., 2006). Family is the primary context where children learn emotional display and regulation rules and often parents and children share similar emotional styles. Therefore, it is possible that parents of children with ASD also present more emotional difficulties than parents of typically developing (TD) children.
Objectives: The aim of the present study was to analyze if parents of children with ASD present more emotional difficulties than parents of TD children and whether emotional difficulties in parents are related to their children's difficulties.
Methods: Seventy-eight dyads of parents-children participated in the study. Thirty-seven children were diagnosed with ASD and forty-one were TD children. Parent self-report, parent-informant report, and physiological measures were used as indicators of emotional difficulties in parents and children.
Results: *t*-tests revealed that parents of children with ASD reported significantly more difficulties with emotion regulation [$t(64) = -2.36$, $p < .05$], reported using less reappraisal [$t(76) = 2.13$, $p < .05$], and had lower respiratory sinus arrhythmia (RSA) at rest [$t(45) = 2.55$, $p < .05$] than parents of TD children. Parent-reported emotional reactivity in children was related to parents' self-reports of difficulties with emotion regulation [$r = .37$, $p < .01$], to self-report use of less reappraisal [$r = -.35$, $p < .01$], and to lower RSA [$r = -.30$, $p < .05$]. Additionally, lower RSA in children was related to parents' self-reported difficulties with emotion regulation [$r = -.26$, $p < .05$]. Two-path mediations revealed an indirect effect of children's parent-reported emotional reactivity in the relation between child's diagnostic and parents' self-reported difficulties with emotion regulation [$b = 6.67$, $\kappa^2 = .15$; $b = 2.27$, $\kappa^2 = .06$] and an indirect effect of children's RSA in the relation between child's diagnostic and parents' self-reported use of less reappraisal [$b = -0.44$, $\kappa^2 = .15$].
Conclusions: Although causality between emotional difficulties in parents and children with ASD could not be determined, the present study offers strong evidence for the presence of emotional difficulties in parents of children with ASD. Furthermore, it is suggested that emotional difficulties in children might play a determinant role in the understanding of emotional difficulties of parents that goes beyond their child's diagnostic (ASD/non-ASD).

149 **181.149** Emotional and Physiological Responses to Infant Crying in Parents of Children with ASD

***Y. Ozturk**[1], A. Bizzego[2,3,4], N. Mazzoni[5], T. Del Bianco[5], C. Furlanello[3] and P. Venuti[5], (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)Department of Information Engineering and Computer Science, University of Trento, Trento, Italy, (3)FBK - Fondazione Bruno Kessler, Trento, Italy, (4)SKIL Lab, Telecom Italia, Trento, Italy, (5)Department of Psychology and Cognitive Science, University of Trento, Rovereto, TN, Italy*

Background: Cry is a communication way children use to express their needs or wants. Numerous studies have indicated that adults perceive cry of infants with atypical development (in our case ASD) differently compare to cry of typically developing (TD) infants, such as unexpected and more negative.
Objectives: Our aim was to evaluate the emotional and physiological responses of parents of children with ASD and compare with parents of typically developing children during the listening of crying of children with two different developmental conditions: autism and typical development.
Methods: The participants comprised 30 parents (15 mothers: M age = 33.9 years, SD = 6.02; 15 fathers: M age = 38.1 years, SD = 7.15) of typically developing children (M age = 3.0 years; SD = 1.70) and 19 parents (11 mothers: M age = 40.5 years, SD = 3.78; 8 fathers: M age = 40.8 years, SD = 3.15) of children diagnosed with ASD (M age = 5.7 years; SD = 1.82). The experiment was structured into two parts; the first part stands for the physiological data acquisition (heart rate), whereas the second one stands for the behavioral data acquisition (stress, arousal and valence) during the listening of crying of children with ASD and TD.
Results: Parents of children with ASD and parents of TD children are not differentiated in terms of how they reported TD cry and ASD cry. Interestingly, physiological results showed that parents of children with ASD have higher heart rate than parents of TD children during both ASD cry and TD cry.
Conclusions: These findings highlight how parents of children with ASD perceive a signal from a child with ASD. Regarding to the clinical implications, an intervention program for parents of children with ASD might be helpful to attend atypical crying episodes so parents can correctly interpret the signal from their children.

150 **181.150** Engaging Underserved Communities in Identifying Barriers to Early ASD Diagnosis and Treatment

***J. Elder**[1] and S. N. Brasher[2], (1)College of Nursing University of Florida, Gainesville, FL, (2)Nursing, University of Florida, Gainesville, FL*

Background:
Clinical accounts indicate that disparities exist among families of children with Autism Spectrum Disorders (ASD), and that these disparities impede timely diagnosis and intervention. Further, families living in rural areas are more likely to have reduced access to proper care and use alternative, unproven, and potentially harmful treatments. Thus it is imperative to identify disparities among families of children with ASD, particularly those living in rural underserved communities, in order to minimize such disparities and improve diagnosis and intervention in children with ASD.
Objectives: To begin addressing disparities among families of children with ASD living in rural and typically underserved areas by engaging providers and families of children with ASD.
Methods: The investigators established a Community Advisory Board (CAB) of major stakeholders (e.g., parents of individuals with ASD, community-based healthcare service providers, school teachers). Next, they conducted four focus groups comprised of a total of 45 participants to determine barriers to early diagnosis/treatment, potential resources, and alternative treatment use. Sessions were audio-recorded, transcribed, and analyzed by three trained independent coders.
Results: Focus group participants reported several barriers to early diagnosis that included pediatricians' lack of knowledge related to ASD, parents' not recognizing signs and symptoms of ASD, inadequate screening tools, parental denial, prolonged wait time to see a developmental pediatrician, insufficient time spent with pediatricians during scheduled visits, and parental fear of social stigma associated with an ASD diagnosis. Barriers to early treatment were identified as cost of treatments, delayed diagnosis, lack of local providers, complicated referral process for treatments, limited transportation, parental denial, and lack of pediatricians' knowledge of available treatments and how to obtain those treatments. Participants also identified several alternative treatments commonly used in children with ASD, such as the gluten-free and casein-free (GFCF) diet, sensory integration therapy, B12 vitamins and other added vitamins, aromatherapy, chelation therapy, hyperbaric oxygen therapy, fish oils/omega-3 supplements, melatonin, music therapy, and forced eye contact.
Conclusions: As noted, participants reported barriers to early diagnosis and treatment as well as frequently used alternative treatments. There were also unique cultural issues in these remote communities that were identified as worthy of consideration in clinical practice and future research. To our knowledge, this project was the first to bring together both lay and professional stakeholders to identify the needs of underserved families of children with ASD living in these rural areas. Academic collaboration with stakeholders and community members who provide care to children with ASD is a critical step in addressing what is most important to these typically underserved individuals and their families and is a promising way to inform clinical practice and future research. Results from this initial work set the stage for an ongoing PCORI-funded Tier 1 project that is currently underway and aimed at improving the overall quality of life for all individuals with ASD and their families.

151 **181.151** Engaging the Next Generation in ASD Research – Experiences of the Ssc@IAN Family Registry

***J. S. Toroney**[1], J. K. Law[2], A. R. Marvin[3], C. White[4], E. Brooks[4], E. M. Arthur[5], W. K. Chung[6] and P. H. Lipkin[5], (1)Medical Informatics, Interactive Autism Network, Baltimore, MD, (2)Interactive Autism Network, Baltimore, MD, (3)Department of Medical Informatics, Kennedy Krieger Institute, Baltimore, MD, (4)Simons Foundation, New York, NY, (5)Kennedy Krieger Institute, Baltimore, MD, (6)SFARI, Simons Foundation, New York, NY*

Background:
ASD patient registries engage families in new research initiatives and facilitate longitudinal data collection. Child registrants who transition into adulthood provide a unique opportunity to enroll the next generation in ASD research. Established in 2011, the SSC@IAN represents over 1400 families who participated in the original Simons Simplex Collection study. In 2015, efforts were undertaken to engage and consent nearly 600 childhood participants from this cohort who had reached 18 years.
Objectives:
To determine the ability to engage and consent young adults, with and without ASD, who have been previously enrolled for research as children and require re-consent upon reaching 18 years.
Methods:
Parents of over-age-18 children were invited to complete an online form designating their child's appropriate legal status – legally independent vs. dependent. If independent, parents were given the option to invite the over-18 child to continue his/her participation in the registry. Over-age-18 participants, with and without ASD, were notified by email about the SSC@IAN and given the option to participate. Electronic consent was obtained. New participants were asked to provide current sociodemographic and medical information.
Results:
Invitations were sent to parents of 567 children who had reached 18 years: 304 probands with ASD (53.6%) and 263 unaffected siblings (46.4%). Parents were more likely to

respond for their children with ASD than their unaffected children [Proband: n=92 (30.3%); Sibling: n=47 (17.9%); $p<.001$; Fischer Exact Test (FET)]. Of the 92 probands, 43 (46.7%) were reported to be independent adults, 47 (51.2%) were dependent adults and 2 (2.2%) were reported as "other." One unaffected sibling was reported as "other" and the remaining 46 (97.9%) were reported as independent adults. There was no significant difference between the percentage of independent probands (n=37; 86.0%) and unaffected siblings (n=39; 84.8%) that parents invited to join the study as consented adults, and no significant difference between the percentage of independent probands (n=17; 45.9%) and unaffected siblings (n=23; 59.0%) who agreed to join the study as a consented adult (Figure 1).
Efforts to recruit adult probands took place with the re-engaging all registry participants. Overall, parents were less likely to engage if the proband was over age 18: 92 of 304 (30.3%) families of adult probands responded compared to 493 of 1082 (45.6%) families of child probands, $\chi^2(1, N=1386) = 9.49$; p=.002 (Yates correction).
Conclusions:
Established ASD patient registries provide a unique opportunity to engage multi-generational cohorts in research. Enrolled parents are able to be engaged to facilitate continued participation of their young adult children – an often difficult population to recruit. Parents were more likely to provide information about their adult son/daughter with ASD compared to his/her adult sibling; however there were no significant differences in obtaining consent from independent young adults with and without ASD. Overall, families with adult children were less likely to respond than families with children under 18. Specific challenges include re-engaging parents of over-age-18 participants, identifying appropriate legal status for adults with ASD, and communicating the potential role of unaffected adult siblings in future ASD research.

Parr*[9], *(1)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, Northern Ireland, United Kingdom of Great Britain and Northern Ireland, (3)Northumberland, Tyne & Wear NHS Foundation Trust, Newcastle upon Tyne, England, United Kingdom of Great Britain and Northern Ireland, (4)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (5)Newcastle University, IHS, Newcastle Upon Tyne, England, United Kingdom of Great Britain and Northern Ireland, (6)c/o Institute of Neuroscience, Autism Age, Newcastle upon Tyne, United Kingdom, (7)c/o Institute of Neuroscience, National Autistic Society, UK, Newcastle upon Tyne, United Kingdom, (8)c/o Institute of Neuroscience, Autismworks, Newcastle upon Tyne, United Kingdom, (9)Institute of Health and Society, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background:
We know very little about how autism is experienced in adulthood or its impact on the lives of individuals across the lifecourse. Although it has long been acknowledged that research with specific communities is important (Dickson-Swift, et al. 2008) there has been little guidance available on how best to undertake research with autistic adults and their relatives.
Objectives:
To develop a stakeholder-informed research approach for the meaningful engagement of adults on the autistic spectrum, and relatives, in a cohort study.
Methods:
A series of consultation meetings including autistic adults and family members was held over a 2 year period, prior to and during the initial stages of setting up a longitudinal cohort study (http://research.ncl.ac.uk/adultautismspectrum/). Around 50 individuals from the autism community contributed. Detailed notes were made at each of eight meetings that lasted between 2 hours and 1 day. All 'learning points' were extracted from multiple sets of notes by an experienced qualitative researcher, and mapped across four general themes.
Results:
Engaging adults with autism in cohort research
Recommendations included having autistic adults as paid researchers/advisors within the team, and identifying some of the range of challenges and needs of individuals so as to develop 'user-friendly' research processes. The need to gather information from a range of individuals, e.g. adults who are, and are not in contact with services; parents, siblings, partners, carers and others was identified. Ways of including individuals with intellectual impairment were suggested.
Quantitative research methods and materials
A range of ways to invite people to engage with a cohort study were discussed, e.g. mailshots, email, flyers, posters, online forums. Cohort questionnaire development focused on font size, spacing, and using plain text in materials, in addition to specific research question wording. The importance of individual variation in the time taken to complete questionnaires was identified. A key point was making the utility of the research for adults clear, and sending regular updates with snapshots of findings.
Qualitative research
Recommendations focussed on flexibility and respect as the key factors in approaching people and asking questions. Some key areas were: allowing different ways to

exchange information (for example text messages, emails or face to face discussions); setting aside extra time in discussions and interviews for information processing; exploring the use of visual materials for questions and responses; and not making assumptions that adults cannot do things but instead finding ways to support them in overcoming challenges.

Getting the environment right

The size and sensory impact of any meeting venue should be considered, to reduce overload from environmental stimuli. Interviews should be conducted where people are most comfortable. Payment for participation in interviews, in addition to reimbursement of travel costs, is appropriate.

Conclusions:

Our findings emphasise the need to utilise the skills and expertise of autistic adults and family members as part of the research team. We consider this has led to our research being more effective in involving, recruiting, engaging and encouraging adults on the autistic spectrum and their relatives to participate in the cohort study.

153 **181.153** Evaluating Patterns of Service Access and Interest in Families of Individuals with ASD

L. A. Pepa[1] *and S. L. Harris*[2]*, (1)Rutgers University, Douglass Developmental Disabilities Center, New Brunswick, NJ, (2)Rutgers University, Douglass Developmental Disabilities Center, Piscataway, NJ*

Background: The literature on family psychosocial outcome suggests that parents of individuals with ASD are at an increased risk of developing negative health outcomes, including anxiety and depression (Dunn et al., 2001). While the sibling outcome literature is more mixed, typically developing (TD) siblings may also be at an increased risk for psychosocial difficulties (Verte et al., 2003), with parent stress acting as a mediating factor (Meyer et al., 2011). Services for families are important to ensure their health and wellbeing, as well as their ability to be effective caretakers for individuals with ASD. Research on family support has several limitations, including fundamental difficulties with recruitment and retention of parents and siblings in projects aimed at family support (Ferraioli & Harris, 2013). Understanding the service interests of families, as well as factors predicting treatment access, is crucial in order to better serve families in the future.

Objectives: This study aims to identify 1) what support/services families are interested in, 2) what factors limit service access, and 3) what factors facilitate service access for this population.

Methods: An online survey was distributed to 158 families of individuals with ASD across the U.S. Families were recruited through a university-based program for individuals with ASD as well as ASD service and support networks. Respondents to the survey were parents who had one child with ASD and at least one TD child, per parent report. Parents filled out a series of questionnaires to measure ASD symptom severity (GARS-3; Gilliam, 1995), parent psychosocial health (GHQ-28; Goldberg, 1978), parent stress (PSI-4-SF; Abidin, 1995), and perceived social support (ISSB; Barrera et al., 1981). Participants were also given a family support questionnaire, inquiring about parent and sibling access to a set of 13 support services.

Results: Participants in the sample were largely women (59.5%), married (94.9%), White (85.4%), Non-Hispanic (85.4%), and had a Bachelor's level education (62.7%). Results suggest that parents have accessed support services for themselves (*M=8.23)* and for their TD child (*M=7.38)* in the past, and endorse a positive view of these services. A greater number of past services accessed was associated with the absence of a diagnosed psychiatric condition in the parent or sibling, higher severity scores on the GARS-3, lower scores of anxiety on the GHQ-28, increased social support on the ISSB, and increased parent stress as measured by the PSI. Family demographic variables (e.g., parent and child gender, child age, etc.) were also found to be related to service access. Descriptive information regarding interest in individual service type will be discussed, as well as models of service prediction.

Conclusions: Parents endorsed having accessed a range of services for themselves and their TD child. Certain individual and family-level variables were found to be significantly related to treatment access. Understanding factors that limit and facilitate treatment access can help guide clinical and research approach to family support. Future directions include replicating results in a more diverse sample, and investigating strategies for making services more accessible to families (e.g., integrating family support into ASD services).

Table 1

Means and Standard Deviations of Service Access/Interest for Parents and Siblings

	Whole Sample	Screen Pass	Screen Fail
Past Service Access			
Parents	8.23 (2.95)	8.59 (2.98)	6.77 (2.38)**
Siblings	7.38 (3.54)	7.71 (3.66)	6.09 (2.68)*

*$p<0.05$, **$p<.01$

Note. Parents reported accessing less services for their typically developing children, than for themselves, in the past ($M=7.38$) $t(156)=4.777$, $p<.01$. The Screen Fail sample (e.g., those families with a diagnosed psychiatric condition in a parent or TD sibling) was found to have accessed significantly less services than the Screen Pass sample across both parent $F(1,155)=81.79$, $p<.01$ and sibling areas $F(1,156)=66.36$, $p<.05$.

181.154 Examining the Impact of Medication Side Effects on Problem Behavior Displayed By Children with Autism Spectrum Disorder (ASD)

J. D. Bleiweiss, *Special Education, Hunter College, New York, NY*

Background: Problem behavior significantly impedes multiple aspects of quality of life for individuals with autism spectrum disorder (ASD), and thus represents a major priority for intervention. Psychotropic medications are commonly administered to treat such behavior; however, these agents are often associated with adverse side effects that may have a negative impact on daily activities. Many of the same symptoms such as fatigue, increased anxiety, and gastrointestinal discomfort have been identified in the behavioral literature, where they are referred to as "setting events," and are often associated with elevated levels of problem behavior. Thus, it is plausible that medication side effects may function as biological setting events, paradoxically exacerbating the very behavior the medication aims to treat.

Objectives: (1) To develop a comprehensive, contextualized assessment measure that assessed commonly occurring medication side effects to determine whether there is an association between the presence of these symptoms in specific home and community activities and a subsequent increase in problem behavior displayed in those same routines; (2) To demonstrate the effectiveness of using a multicomponent intervention plan to mitigate problematic routines during which side effects are present, resulting in a reduction in problem behavior displayed by individuals with ASD, as well as an overall improvement in family quality of life.

Methods: A series of studies were conducted, exploring the possibility that commonly occurring medication side effects may function as setting events, a class of contextual variables that alter ongoing stimulus-response relationships (Kantor, 1959). That is, the presence of side effects purportedly made certain home and community routines

more difficult for individuals, and this, in turn, produced greater levels of problem behavior. Nine children with autism spectrum disorder who were prescribed psychotropic medication to treat severe problem behavior participated. A comprehensive assessment was conducted to identify problematic contexts in which side effects were present, and multicomponent intervention packages were developed and implemented collaboratively with each family. A multiple baseline experimental design was used to demonstrate intervention effects for these high priority contexts.
Results: We demonstrated, experimentally, that the presence of medication side effects (such as fatigue, increased hunger, gastrointestinal discomfort, etc.) did negatively impact particular family-based activities, resulting in an exacerbation of problem behavior (see Figure 1 for results of Study 1 which examined problematic home-based routines). Additionally, significant improvements were noted in problem behavior, activity completion, and overall family quality of life following the implementation of the multicomponent interventions.
Conclusions: The value of conceptualizing medication side effects as biological setting events and the direct intervention implications arising from such a conceptualization are discussed.

Figure 1. Ratings of the level of intensity of medication side effects present in the experimental context, the level of difficulty of the routine, and the level of severity of problem behavior displayed in experimental context, as rated on 5-point Likert scales ranging from 1 "mild" to 5 "severe," for three participants in the baseline and intervention phases of Study 1 (Context: Home-based Routines).

 181.155 Examining the Relationship Between Gender, Age, Anxiety and Aggression in Children with ASD Using the Child Behavior Checklist
***A. K. Walsh**, K. Derochea, D. Peterson and E. Hanson, Developmental Medicine Center, Boston Children's Hospital, Boston, MA*

Background: Because it is frequently noted that aggressive behavior and anxiety problems are often seen in children with Autism Spectrum Disorders (ASD) and that these problems can have extremely negative consequences (Farmer, 2011; Kerns 2012), further examination is needed to fully understand the prevalence of anxiety and aggression in ASD at different ages and between genders. The Child Behavior Checklist (CBCL) is a widely used quantitative assessment that measures a child's mental health that includes levels of anxiety problems and aggressive behavior. This present study examines the relationship between age, aggression and anxiety; gender, aggression and anxiety as well as the correlation between aggression and anxiety in children with ASD.
Objectives: N/A
Methods: A sample of 843 children (69.5% male) with an ASD diagnosis who also met research criteria for ASD were examined. Participants' ages ranged from 22 months to 226 months (Mean= 102.5, SD= 43.8). CBCLs were examined with focus on Aggressive Behavior totals and Anxious/Depressed totals. Correlations between age and anxiety, age and aggression, gender and anxiety, gender and aggression, and aggression and anxiety were examined using Pearson Correlation in SPSS.
Results: Pearson Correlations were run using SPSS and measured relationships between age and anxiety, age and aggression, gender and anxiety, gender and aggression, and aggression and anxiety. Preliminary analyses indicated that there was no significant relationship between gender and anxiety (r=-.025, p-value=.474) or gender and aggression (r=-.067, p-value=.053). However, there was a positive, significant correlation between anxiety and age (r=.230, p-value≤.000) and between anxiety and aggression (r=.365, p-value≤.000). Analyses also suggested a significant negative correlation between age and aggression (r=-.318, p-value≤.000).
Conclusions: Results suggest that a strong, positive relationship between anxiety and age as well as between anxiety and aggression exists, while a strong negative relationship exists between age and aggression. Future research is needed to explore and further confirm these findings. Longitudinal data should also be examined to explore correlations within an individual's lifespan. Further research could also examine the relationship between rates of aggression and anxiety in children receiving appropriate therapies.

156 **181.156** Experiences Related to Deployment for Military Families with Children with ASD

J. Davis[1] *and E. H. Finke*[2]*, (1)Pennsylvania State University, State College, PA, (2)Pennsylvania State University, University Park, PA*

Background:
Military families are an underrepresented group in the ASD literature, despite the number of military dependents with a diagnosis of ASD reaching approximately 23,500 (Tricare, 2011). There has been little peer-reviewed research to date on military families with children with special needs or children with ASD; however, previous research has indicated the presence of need within this population. A survey by Ferrell and colleagues (2014) found that military spouses with a child with special needs perceived less informal and formal support than other military spouses. Davis and Finke (2015) interviewed 15 military spouses with children with ASD about their therapeutic experiences. Military spouses from this investigation reported challenges with relocation, deployment, Tricare, and military programs that resulted in negative impacts on their child's autism related services. Although Davis and Finke (2015) was a first step toward understanding this population, the experiences and needs of a larger sample of military families with children with ASD should be examined. Due to specific characteristics of military families, military families who have children with ASD may have unique service needs. The purpose of the current study was to describe the experiences of a larger sample of military families with a child with ASD during military deployments and separations to determine possible supports and factors related to their experiences.
Objectives:
The main objectives of this investigation were to describe the experiences of military families with a child with ASD during military deployments and separations, determine possible supports for these families, and investigate factors that may influence their experience (e.g., is the number of deployments related to the military spouse's rating of deployment satisfaction?).
Methods:
In order to determine the deployment experiences of a larger sample of military families with children with ASD, a self-administered online survey design was chosen. Surveys are a time and cost efficient design allowing researchers to collect self-reported data on personal experiences and generalize findings to a larger population (Rea & Parker, 2005). The survey was administered online mode to extend the "reach" of respondents who may live in a number of geographic regions (van Selm & Jankowski, 2006). Further, online surveys are cost effective, contain no interviewer bias or data entry error, and allow for easy follow-up and quick data collection (Rea & Parker, 2005; van Selm & Jankowski, 2006). A review of the literature on families of children with ASD and/or other disabilities (e.g., Renty & Roeyers, 2006; Dunst, Jenkins, & Trivette, 1984) and military families (e.g., Huebner et al., 2010; Blue Star Families, 2013) was used to generate the questions and responses for the survey.
Results:
Approximately 175 military spouses with children with ASD completed the deployment section of the online survey. Data analysis is currently on-going, but preliminary results suggest military families with a child with ASD experience challenges related to deployments and separations of their military member.
Conclusions:
Data analysis is currently on-going, but conclusions may impact clinical service providers, military programming and providers, and laws and policies.

157 **181.157** Factors Associated with Parent Satisfaction with Emergency Department Visits When the Patient Has Autism

S. Kirsch[1]*, J. Weaver*[2] *and D. Meryash*[3]*, (1)Pediatrics, Cohen Children's Medical Center, Lake Success, NY, (2)University of Toronto, Toronto, ON, Canada, (3)Pediatrics, Cohen Children's Medical Center / Hofstra NS-LIJ School of Medicine, Lake Success, NY*

Background: Providing optimum care in an emergency department or urgent care center (ED) to autistic (ASD) patients, who often have limited communication, hypersensitivity, ritualistic behavior, and need for routine, can be challenging for both families and ED staff. Published and anecdotal reports reveal that parents of autistic children are often frustrated with ED care, but associated or potentially causative factors have not been systematically studied. By tapping the unique perspective and insight of parents of children with ASD, effective opportunities for improvement can be identified.
Objectives: To identify factors influencing parent satisfaction with ED visits in order to inform both parents and ED staff on how better to prepare for effective care of their ASD children.
Methods: With the assistance of the Interactive Autism Network (IAN) Research Database at Kennedy Krieger Institute, Baltimore, an invitation was sent to 10,000 parents of ASD children to complete an anonymous internet survey if their child received care at an ED in the U.S. within the last 3 years and was 3-21 years old at the time. Using a 5-level Likert scale the respondents were asked whether they were "satisfied with the experience and the care provided." The survey also included questions about parent education and occupation, patient characteristics, parent expectations and preparation for the visit, and the ED experience itself, including ED staff characteristics and behaviors.
Results: Of 404 completed surveys, 379 (93.8%) were analyzed (excluding 25 reported patients without ASD). Of these, 223 (58.8%) respondents expressed satisfaction and 156 (41.2 %) dissatisfaction or neutrality with their ED experience. In bivariate analyses satisfaction was considerably less common when the patient was disruptive (50.7%) versus not disruptive (82.5%) during the visit (X^2=30.1; df=1; p<0.001). Satisfaction with the visit was also associated with waiting and treatment room wait times (both p<0.001) *that were shorter than expected* but *not* with *actual* waiting room time. Parent positive assessments of the ED staff on a variety of communication and professionalism skills parameters (e.g. talked with patient at appropriate developmental level) were also associated with satisfaction (all p<0.001). There was a trend toward satisfaction if the parent notified the staff at arrival of their child's disability (p=.072). Satisfaction was *not* associated with either of two proxies of severity of the patient's disability (restrictiveness of educational environment; communication competence), whether the patient has increased sensitivity to sensory stimuli, or parent education. Interestingly satisfaction was not more likely if the parent brought the patient's medical records to the visit. Further analysis using multiple logistic regression will assess the independent effects of these correlates on ED experience satisfaction. In addition the factors that correlate with disruptive behavior during an ED visit will be separately analyzed.
Conclusions: The patient's manifestation of disruptive behavior is a potent predictor of whether an ED visit is perceived by the parent as a positive experience or not. Otherwise, it appears that perception of a positive ED experience depends more on ED preparedness and staff training than on patient characteristics, including extent of disability.

158 **181.158** Families of Youth with ASD and Other Developmental Disabilities: A Theory-Based Intervention

J. J. Diehl[1,2]*, K. N. Bergman*[2]*, J. Kaboski*[2]*, C. Lee*[2]*, J. Likens*[1]*, H. Miller*[2] *and E. M. Cummings*[2]*, (1)LOGAN Community Resources, Inc., South Bend, IN, (2)University of Notre Dame, Notre Dame, IN*

Background: Few evidence-based programs exist to support families that include a child with Autism Spectrum Disorder (ASD) or other intellectual or developmental disability (IDD), despite documented evidence of their risk for heightened stress and conflict. Parents in these families are at heightened risk for increased stress, marital conflict, and parenting difficulties, particularly with the typically developing (TD) siblings. TD siblings are at risk for maladjustment and relationship problems. A critical need exists for an evidence-based program to ameliorate the impact of family stress and conflict on the overall well-being of parents and TD siblings.
Objectives: Our objective is to test the efficacy for parents, TD siblings, and children with ASD or other IDDs of the adaptation of a psycho-educational and communication training approach (Cumming & Schatz, 2012) and to examine the mechanisms associated with change processes that occur as a result of the program.
Methods: Participants were 30 families with a child with IDD and a TD sibling (11-17 years old) in a pilot intervention program designed to improve family communication. The majority of participants (N=20) were diagnosed with ASD (confirmed with the ADOS-2, Social Communication Questionnaire, and clinical judgment). Families were randomly assigned to either: 1) a parent-sibling (PS) treatment condition, or 2) a self-study (SS) control condition. Families completed prescreen, baseline, and posttest assessments of marital quality/satisfaction, parent-child communication and attachment, emotional security and adjustment, and dyadic (marital) and quadratic (i.e. parents,

TD sibling and child with IDD) problem-solving tasks that were coded for constructive and destructive conflict tactics and resolution. Families in the PS condition made four visits to the laboratory, during which parents and TD siblings received psychoeducational training and practiced a communication technique with a trained coach. Individuals with IDD in the PS condition participated in a structured activity during the first three weeks, which was incorporated into a family-wide psychoeducational session at week 4. Parents in the SS condition were given a syllabus and research-based materials to review over three weeks.
Results: Mixed ANOVAs revealed differences in the quality of dyadic and quadratic interactions from the pretest to posttest. Consistent with expectations, a statistically significant interaction was found between condition and time on observed constructiveness in family-wide interactions including the parents, TD sibling, and child with IDD, $F(1,11) = 5.16$, $p = .04$, with treatment families using more constructive strategies than control families at the posttest. In dyadic interactions, the degree of resolution for fathers, $F(1, 37) = 12.27$, $p = .001$, and mothers, $F(1,37) = 14.84$, $p < .001$, and constructiveness for mothers, $F(1,37) = 5.03$, $p = .03$, improved over time. Improvement in constructiveness of marital conflict was associated with increases in adolescents' emotional security at the posttest, $F(1,15) = 14.40$, $p < .001$.
Conclusions: Preliminary data showed promising benefits for both parents and TD siblings of individuals with ASD and other IDDs. The expected outcome of this study is an evidence-based, cost-effective intervention that is readily transferable to community-based centers, but additional research is needed with a larger sample size.

159 **181.159** Family Empowerment Among Parents of Children Newly Diagnosed with ASD

L. Corona[1], *S. A. Fox*[1], *M. L. Rinaldi*[1] *and K. V. Christodulu*[2], *(1)Center for Autism and Related Disabilities, Albany, NY, (2)Center for Autsim and Related Disabilities, Albany, NY*

Background: Parents of children diagnosed with autism spectrum disorder (ASD) often report high levels of parenting stress and low levels of parenting self-efficacy and overall well-being (Karst & Van Hecke, 2013). Parent empowerment has been implicated as a potential factor influencing parent responses to challenges associated with parenting a child with ASD (Weiss, MacMullin, & Lunsky, 2015). This suggests the value of targeting interventions to increase parent empowerment. Prior research has reported gains in family empowerment following participation in a parent support group (Banach et al., 2010). The present study sought to investigate changes in family empowerment following participation in an education-focused parent group for children newly diagnosed with ASD.
Objectives: The first objective of the present study was to examine relations among family empowerment, parent stress, and family quality of life in a sample of parents of children newly diagnosed with ASD. The second objective was to assess change in family empowerment following participation in a parent education program.
Methods: Participants in the present study were parents participating in a five-session parent education program designed to provide information and resources to families. Criteria for participation included having a child between the ages of twelve months and five years, six months who had been diagnosed with ASD within the past year. Prior to and following program participation, participants completed the Family Quality of Life Scale (FQOL; Summers et al., 2005), the *Parenting Stress Index – Short Form* (PSI-SF, 4th ed., Abidin, 2012), and the Family Empowerment Scale (FES; Koren, DeChillo, & Friesen, 1992). The FES has been used extensively with parents of children with disabilities and has three subscales targeting different aspects of parent empowerment (Family, Child Services, and Community Advocacy). Current results are based on data from 27 mothers and 19 fathers who attended the education program between July 2014 and October 2015. Data collection is ongoing.
Results: Bivariate correlations were used to investigate relations among family quality of life, parenting stress, and family empowerment (see Table 1). All FES subscales were positively correlated with family quality of life. However, only the Family subscale was significantly correlated with parenting stress ($r = -.56$, $p < .01$). Paired-sample *t*-tests were used to assess differences in family empowerment prior to and following the program. Caregivers reported higher family empowerment on all three subscales following program participation (Family, $t = 3.10$, $p < .01$; Child Services, $t = 3.04$, $p < .01$; Community Advocacy, $t = 2.51$, $p < .05$).
Conclusions: The results of the present study suggest that among parents of children newly diagnosed with ASD, family empowerment is positively associated with family quality of life. However, only empowerment specific to family interactions is associated with parenting stress. This finding indicates that empowerment related to community participation and service access may be less impactful for parenting stress. Finally, the present study provides initial support for the hypothesis that providing education to parents of children newly diagnosed with ASD may increase parent empowerment.

Table 1.

	Family Quality of Life	Parenting Stress	Parent Empowerment: Family	Parent Empowerment: Child Services	Parent Empowerment: Community Advocacy
Family Quality of Life	1.00				
Parenting Stress	-.536**	1.00			
Parent Empowerment: Family	.770**	-.556**	1.00		
Parent Empowerment: Child Services	.492**	-.138	.609**	1.00	
Parent Empowerment: Community Advocacy	.435**	-.183	.414**	.744**	1.00

**Correlation is significant at the 0.01 level (two-tailed).

160 **181.160** Feasibility and Initial Efficacy of Primary Care Stepping Stones Positive Parenting Program (Triple P) on Reducing Maladaptive Behaviors in Children Newly Diagnosed with Autism Spectrum Disorder

D. Zand[1], *M. W. Bultas*[2], *S. E. McMillin*[3], *K. Pierce*[4] *and D. McNamara*[4], *(1)General Academic Pediatrics, Saint Louis University, St Louis, MO, (2)School of Nursing, Saint Louis University, Saint Louis, MO, (3)Social Work, Saint Louis University, Saint Louis, MO, (4)General Academic Pediatrics, Saint Louis University, Saint Louis, MO*

Background: Concomitant behavioral problems, including tantrums, noncompliance, aggression and self-injury[1,2]are common among children with Autism Spectrum Disorder (ASD). These behaviors can be of comparable or greater concern to parents than the core symptoms of ASD and often are chief motivating factors for seeking diagnosis and treatment. While emerging parent mediated interventions (PMI) exist to address maladaptive behaviors among children with ASD, no evidence based practices exist for intervening with parents at the time of initial ASD diagnosis in a systematic, strength based, parent driven, and practitioner guided manner.
Objectives: To determine the feasibility and preliminary efficacy of a manualized, one-on-one, 4 session PMI (Triple P) with parents of children (ages 2 to 12 years) newly diagnosed with ASD.
Methods: A two-group, pre- post-test, open trial design with random assignment to intervention (N= 9) versus treatment as usual control (TAU; N=6) was employed. Eligible parents were recruited from an urban Autism Speaks-Autism Treatment Network diagnostic clinic, as well as from the surrounding community. Parent inclusion criteria consisted of being at least 18 years of age, being the child's legal guardian, having primary responsibility for raising the child, and having a specific behavioral concern about their child. Child inclusion criteria consisted of receiving a DSM 5 ASD diagnosis within the past year from either a psychologist or physician, being > 2 years and < 12 years old, and displaying moderate to severe behavior problems (Eyberg Intensity T-Score > 60).
Results: Compared to TAU, parents who received the intervention, reported statistically and clinically significant changes 4 weeks post-baseline in: child externalizing behaviors, ECBI Intensity $F(1,13) = 5.16$, $p < .05$, partial $\eta^2 = .31$; parenting competence $F(1,13) = 6.64$, $p < .05$, partial $\eta^2 = .36$; parenting resilience $F(1,13) = 6.52$, $p < .05$, partial $\eta^2 = .35$; family functioning $F(1,13) = 6.03$, $p < .05$, partial $\eta^2 = .35$; overall parenting stress $F(1,13) = 19.38$, $p < .001$, partial $\eta^2 = .66$; and parent-child interaction stress $F(1,13) = 6.66$, $p < .05$, partial $\eta^2 = .40$. Analyses indicated a 93% level of fidelity to the intervention, and high participant satisfaction with services ($M = 6.6$, $SD = .41$).
Conclusions: For children newly diagnosed with ASD, a 4 session PMI was superior to TAU in improving child behaviors, fostering parenting competence, reducing parenting stress, and improving family functioning. The intervention's focus on empowering parents is an innovative approach to current service delivery models, and holds the potential for assisting in the development and use of more family friendly, strength-based, patient-centered practices for working with parents of children newly diagnosed with ASD to diminish problematic child behavior.

161 **181.161** Five Factor Structure of Parenting Stress Index – Short Form in Evaluating Stress in Parents of Children with ASD

R. Mahajan[1], *V. Singh*[2], *A. Schrembs*[1], *J. Neely*[1], *M. Pinkett-Davis*[1] *and R. Landa*[1], *(1)The Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD*

Background:
Parents of children with autism spectrum disorder (ASD) experience high levels of stress compared to parents with children without ASD (Baker-Ericzn, Brookman-Frazee, & Stahmer, 2005). This has been attributed to child factors, parent factors, as well as dysfunctional parent-child interactions (Rivard, Terroux, Parent-Boursier, & Mercier, 2014). Parenting Stress Index-Short Form (PSI-SF; Abidin, 1990) is a quick screen for all 3 domains of parenting stress in a clinical setting (Parental Distress, PD, Difficult Child, DC and Parent Child Dysfunctional Interactions, P-CDI). It has been used to provide parent focused interventions to improve child outcomes in primarily non-ASD familes, but may also be of utility in assessing parenting stress in families with ASD children (Rao & Beidel, 2009). Given the unique multidimensional parenting challenges of ASD families, it is not known if the 3 factor structure of PSI-SF is valid for them and if the individual line items congregate within the same domains in ASD families as in families with non-ASD children (Zaidman-Zait et al., 2011).
Objectives:
To assess the validity of the three factor structure and individual line items of the Parenting Stress Index-Short Form (PSI-SF) in a large clinical sample of parents of children with ASD.

Methods:
The participants included 685 parents (90.51% mothers) of children evaluated at Kennedy Krieger Institute's Center for Autism and Related Disorders in an ongoing clinical research registry between June 2014 and June 2015. Mean child age was 6.02 years (range =1.42-11.95; 17.7% female). The parent completed PSI- SF prior to the child's evaluation. The 685 children were then evaluated by a multidisciplinary team to determine the presence or absence of ASD diagnosis using DSM – IV criteria. Of these, 410 were also administered ADOS-2. ASD diagnosis status was determined either from the child's medical record or from adapted Ohio Autism Clinical Impressions Scale (OSU Research Unit on Pediatric Psychopharmacology, 2005) filled by the evaluating clinicians. 458 children (66.86%) had a confirmed ASD diagnosis; in 177 children (25.84%) ASD was ruled out; for 50 children (7.30%), data were not available.
Results:
Unlike the 3 factor domains previously described in PSI-SF, exploratory factor analysis revealed the presence of a 5 factor structure for parents of children with ASD. The first domain was similar to the original PD domain in the PSI-SF. Differences were noted in DC domain and the P-CDI domains from the original with some items crossing over across the domains. We identified a 4thand a 5th domain specifically pertaining to "socio-emotional expectations" and "learning expectations" respectively. 3 items were found to be unique and did not correlate well with any of the domains.
Conclusions:
The three factor structure in the original PSI-F may be more valid for the normative sample of the population. For ASD families, the five factor structure identified in this sample may help identify the focus of parenting needs including parental socio-emotional and learning expectations so as to provide interventions that may positively influence child outcomes.

163 **181.163** How Do Parents Conceptualize Their Children's Autism Spectrum Disorder? Validating a Measure of Caregiver Perceptions

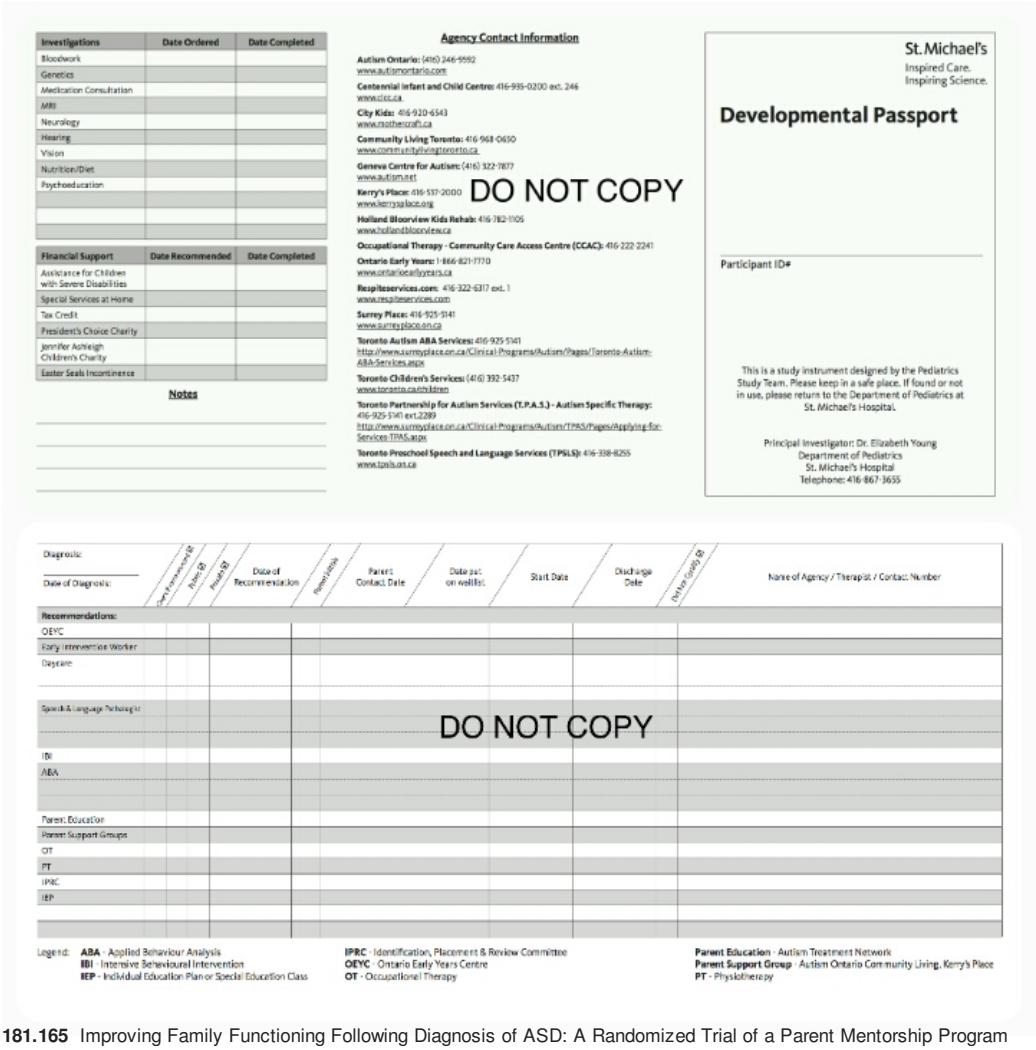
***S. S. Mire**, T. Tolar, J. R. Anderson, N. S. Raff and C. M. Brewton, Psychological, Health, & Learning Sciences, University of Houston, Houston, TX*

Background: Understanding how parents conceptualize their child's ASD diagnosis (i.e., understanding it, beliefs about course, perceptions of control over course and/or treatment) may help researchers and practitioners better support families. The Illness Perception Questionnaire-Revised (*IPQ-R*; Moss-Morris et al., 2002) is widely-used in studying chronic illness and is based on Leventhal et al.'s (1984) illness representation model. Though not an "illness", ASD is a chronic condition, requiring various treatment approaches across the lifespan (Aman, 2005; Shea & Mesibov, 2009). The *IPQ-R* was modified for use with ASD (Al Anbar et al., 2010); parent scores on this measure may predict ASD treatment selection (Dardennes et al., 2011; Mire et al., 2015). Perhaps parent perceptions as measured by the *IPQ-R* also represent cognitions that impact families of children with ASD in other important ways (i.e., parent and/or family stress, coping). However, to date the only investigation into the psychometric properties and use of the *IPQ-R* in ASD is limited to a small sample of French families (n=89) with parent-reported ASD diagnoses.
Objectives: Examine construct validity of the *IPQ-R* for families of children with confirmed ASD diagnoses, which allows investigating function of *IPQ-R* ordered categorical response items for assessing parental perceptions, and to verify the factor structure of *IPQ-R*as it relates to the constructs central to chronic health condition conceptualizations.
Methods: Parents of children and adolescents (n=362; child age M=13.44, SD=3.43) with confirmed ASD diagnoses from across North America were asked to complete the *IPQ-R*; data collection is complete. We are in process of evaluating different polytomous IRT-CFA models (e.g., direct and indirect IRT model) to analyze the ordinal (i.e., Likert scale) item-level data yielded from the collected *IPQ-R* to determine the number and nature of dimensions (i.e., factors) measured when used with families affected by ASD.
Results: Parents in this study (age *M*=46.10, *SD*=5.93) were likely to have a bachelor's degree or higher (73.5%) and higher-than-average family income (median: $100,000). In this sample, 72.6% of parents reported that their child's overall ASD severity was "moderate". Using the scoring criteria based on the original *IPQ-R* model (i.e., not with families of ASD), initial correlation analyses indicated the relationships of the items and subscales ranged from .12 to .80. An exploratory factor analysis indicated two additional factors when comparing with the original measure structure. Confirmatory factor analysis of the original *IPQ-R* factor structure indicated differences in the structure of three subscales when the measure is used with ASD. Forthcoming analyses will further examine construct validity of the *IPQ-R*for families of children with ASD using polytomous item response theory (IRT) models embedded in a confirmatory factor analytic (CFA) model.
Conclusions: Parents' cognitions may be critical mediators between family functioning and child outcomes among children with ASD. However, measurement of such parent perceptions and attributions is lacking. The *IPQ-R* has been widely used to study many chronic health-related conditions and may be a viable measure for better understanding parents' conceptualizations and ultimately treatment-seeking and coping behaviors among families of children with ASD.

164 **181.164** Improving Access to Care in Families of Children with Autism Spectrum Disorder: A Mixed Methods Study to Establish the Pediatric Developmental Passport As a Resource Tool for Parents

***E. Young**[1,2], C. R. Brown[1,3], M. C. Tassone[1,4,5], E. Lung[1], N. Bechard[1,3], J. Huber[1,6,7,8] and T. Jegathesan[1], (1)Pediatrics, Saint Michael's Hospital, Toronto, ON, Canada, (2)Department of Pediatrics, Division of Developemental Pediatrics, University of Toronto, Toronto, ON, Canada, (3)Faculty of Medicine, University of Toronto, Toronto, ON, Canada, (4)Department of Pediatrics, Faculty of Medicine,, University of Toronto, Toronto, ON, Canada, (5)Michael G. DeGroote School of Medicine,, McMaster University, Hamilton, ON, Canada, (6)Department of Pediatrics, Division of Pediatrics, University of Toronto, Toronto, ON, Canada, (7)School of Graduate Studies, Department of Rehabilitative Sciences (Department of Speech-Language Pathology), University of Toronto, Toronto, ON, Canada, (8)Division of Neurology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Receiving a new developmental diagnosis is challenging for families. Following a diagnosis of ASD, developmental pediatricians typically make recommendations for caregivers to access developmental services within their community. This self-referral process poses problems for families' access and navigation of developmental services. At St.Michael's Hospital, a large urban hospital focused on inner city health, pediatricians recognized many families were not accessing developmental services in a timely manner. Given the evidence for early intervention in children, there was enormous public pressure to reduce barriers for families' access to developmental services for their children.
Objectives: To address families' barriers to accessing and navigating developmental services, the aim of this study was to determine the utility and design of the Pediatric Developmental Passport (Passport) for physicians and families in our community using the Knowledge to Action Framework (KTA). We sought 1) to establish the current practice of recommending developmental services by physicians, 2) to identify gaps in practice and 3) to design a tool embedded within physician and caregiver needs.
Methods: A sequential exploratory mixed method study design within a KTA framework was used to study the creation and utility of the passport. The quantitative component of the study included a cross-sectional survey with developmental pediatricians and the qualitative component of the study included focus groups with developmental pediatricians and semi-structured interviews with caregivers. Descriptive statistical analysis and comparative thematic analysis was used.
Results: ***Quantitative: Needs Assessment.*** Eighty-eight percent of physicians reported to follow-up on their recommendations to families and most physicians (75%) felt their current approach could be improved**.** ***Qualitative Component*****: *Need for Tool.*** Physicians noted a need for a novel tool to communicate developmental recommendations as a result of their perception of families' poor compliance to developmental recommendations. As such physicians approved the initial design of the passport with recommendations. They suggested the utility of the passport needed to be verified among families, as they would be the primary users of the tool. ***Supports, Opinions and Reflections of the Passport.*** Caregivers reported the passport to identify clear goals for child's care and served as a quick summary of services in one document, highlighting the utility of knowing at a glance their progress in accessing developmental agencies. Caregivers also noted the potential impact of the passport in reducing caregiver stress. One parent said "*It would be really helpful when you go to the family doctor, or any other healthcare person, to catch them up on what's being done without having to explain it all.*" – *Caregiver 10*
Conclusions: Using a mixed method design with a KTA framework a novel tool called the Pediatric Developmental Passport was developed to be used as a communication tool for physicians and families to communicate recommendations for services and to track access at follow-up visits. The Passport will be an effective tool for physicians to communicate recommendations to families, reduce caregiver stress and increase physicians' ability to support and advocate for families. Further studies are being conducted to demonstrate successful implementation within a clinical setting.



165 **181.165** Improving Family Functioning Following Diagnosis of ASD: A Randomized Trial of a Parent Mentorship Program

E. Moody[1], *K. E. Kaiser*[2], *L. Kubicek*[3], *D. L. Sharp*[3] *and C. Robinson*[4], *(1)13121 E 17th Avenue, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)JFK Partners University of Colorado, Aurora, CO, (3)University of Colorado School of Medicine, Aurora, CO, (4)University of Colorado, Aurora, CO*

Background: Despite the growing prevalence of autism, there is a confusing array of treatment options available and little clinician support to families in acting on the treatment recommendations. Therefore families must often coordinate their own services. As a result, there is tremendous need for interventions that will help families understand and access the existing systems of care. Parent-to-Parent (P2P) mentoring programs are one strategy do this; however, there are few empirically validated P2P programs.

The ***Colorado Parent Mentoring Program*** (CPM) is a comprehensive support program that provides two sources of support: 1) parent training and education, and 2) P2P mentoring. Parent mentors were trained in a two-day program and paired with mentees. For mentees, study staff provided individualized education through individualized Action Plans. This is a family-centered process for determining treatment priorities, accessing resources, strategies for school collaboration and family care. They then received in -depth training regarding navigating systems of care in Colorado. Following these meetings, Mentors continued to support the family for 6 months.

Objectives: Develop and test a systematic P2P and parent education model.

Methods: CPM evaluated with a randomized controlled trial (RCT) with participants randomly assigned to either active participation (n=29) or a waitlist control group (n=32). Families were recruited following diagnosis from partner clinics and complete assessments prior to participation. Families in the active group are paired with a trained mentor and receive Action planning/Navigation meetings within 3 months of diagnosis. They then interacted with mentors at least monthly for 6 months. Waitlist control families received only care through usual sources. Post measures are collected after 6 months for all participants. Measures include satisfaction with program, Family Quality of Life Scale, Parenting Stress Index, Parenting Sense of Competence Scale, Monthly service utilization and qualitative interviewing.

Results:

Quantitative—Linear mixed models were used to assess the program's impact between the two groups over time. Significant improvement in Satisfaction with Disability Related Services was found in the active group. The waitlist group showed increased Rigidity in family functioning.

Qualitative—Thematic analysis of exit-interviews by two separate reviewers uncovered 6 major themes: 1) the program is highly acceptable and satisfying, 2) action planning is highly valuable in prioritizing services and locating access points, 3) families appreciate having actionable items to address their child's and family's needs, 4) families feel more empowered, less isolated and have a greater sense of community, 5) families often make a wide variety of intervention choices regardless of education, and 6) families appreciate having mentor for ongoing support.

Conclusions: The CPM program is a promising family support program with preliminary efficacy for improving satisfaction with care and preventing rigidity in the family dynamic. Parent mentors can be effectively trained to provide emotional support to other parents of children with ASD. Newly diagnosed families appear to have improved functioning as a result of this intervention; although, more research is needed on how best to support families.

166 **181.166** Informant Discrepancies in Parent and Sibling Self-Reported Emotional and Behavioral Adjustment Problems in Siblings of Individuals with ASD

J. A. Rankin*, L. K. Baker, S. W. Eldred and T. S. Tomeny, Psychology, The University of Alabama, Tuscaloosa, AL*

Background: The adjustment of typically-developing (TD) siblings of individuals with ASD is often of interest to researchers and clinicians (e.g., Hesse et al., 2013). Parents and siblings of individuals with developmental disabilities often differ in their reports of sibling adjustment, with parents tending to report more sibling adjustment problems (Guite et al., 2004). Little work considers whether these discrepancies exist specifically in ASD. ASD symptom severity, broader autism phenotype (B.A.P.) symptomatology, social support, and parenting stress have previously been evinced as predictors of sibling adjustment (Hesse et al., 2013; Meyer et al., 2011), but have not been explored in terms of the discrepancy between parent and sibling self-report. Further, consideration is lacking in how these discrepancies might affect parental functioning, although they may be related (Guite et al., 2004).

Objectives: This study explored if discrepancies between parent and self-reported sibling adjustment problems existed, and if so, which factors predict these discrepancies. Finally, the relationship between discrepancy and parent psychopathology was examined.

Methods: 113 parents completed the Strengths and Difficulties Questionnaire (SDQ) and Children's Social Behavior Questionnaire (CSBQ) about the TD sibling (*M*age = 13.33, 50% male), assessing emotional and behavioral functioning and B.A.P. symptoms, respectively; the CSBQ about the child with ASD, assessing ASD symptom severity; and the Symptom Checklist Revised - 10 (SCL-R 10) and Questionnaire on Resources and Stress (QRS-F) about themselves, measuring broad psychopathology and parenting stress, respectively. 113 TD siblings self-reported on the SDQ and the Child and Adolescent Social Support Scale (CASSS), measuring perceived social support.

Results: Paired sample t-tests revealed that siblings self-reported significantly more overall and externalizing adjustment problems compared to parent-report, (no significant differences in internalizing problems; see Table 1). Social support from parents, B.A.P. symptoms, and ASD symptoms and externalizing problems in the child with ASD

negatively correlated with sibling-parent SDQ discrepancy (Table 2). Regression analysis revealed that social support from parents, β = -.36, p < .001, and B.A.P. severity, β = -.50, p < .001, were unique predictors of SDQ discrepancy. Additionally, in parents who report more sibling maladjustment than their child, greater discrepancy predicted broad parent psychopathology over and above ASD and externalizing symptoms in the child with ASD and parental stress $\Delta F(1, 56) = 12.48$, p = .001, ΔR^2 = .16. This effect was not significant in overall discrepancy (p = .17).

Conclusions: On average, siblings self-reported more adjustment problems compared to parent-report, particularly in externalizing behaviors. This is surprising considering parents are thought to be better at rating externalizing behaviors than children, and alarming, as this scenario is often related to serious adjustment problems (Bein et al., 2015). Greater B.A.P symptomatology and support from parents predicted less discrepancy. Siblings who have higher B.A.P. symptomatology may report fewer adjustment issues, which closely resembles parent reports. Greater support from parents may result in a closer relationship where parents can better observe adjustment. Finally, parents who report more adjustment problems than their TD child's self-report may have more psychological adjustment problems themselves.

Table 1

Comparison of Mean Parent- and Self-Reported SDQ Overall and Sub-Scale Scores

SDQ (Sub)Scales	Parent-Report *M* (*SD*)	Self-Report *M* (*SD*)	Mean difference	Significance of difference (*p*-value) [1]
Total	7.56 (6.21)	10.13 (5.80)	-2.57	< .001
Externalizing Composite	1.76 (1.64)	2.61 (1.84)	-0.85	< .001
Emotional	2.64 (2.62)	3.11 (2.29)	-0.47	.061
Conduct Problems	1.01 (1.54)	1.83 (1.73)	-0.82	< .001
Hyperactivity	2.52 (2.32)	3.42 (2.47)	-0.90	< .001
Peer Problems	1.38 (1.80)	1.77 (1.60)	-0.39	.012
Prosocial Behavior	8.80 (1.72)	8.48 (1.60)	0.32	.052

Note. [1] Significance of difference calculated via two-tailed paired sample *t*-tests. SDQ = Strength and Difficulties Questionnaire. The externalizing composite was created by averaging the Conduct Problems and Hyperactivity Subscales.

Table 2

Correlations Among Variables of Interest

	1	2	3	4	5	6	7
1. SDQ Discrepancy	—	-.19*	-.43***	-.20*	-.13	-.22*	-.11
2. SDQ Externalizing – Child w/ ASD		—	.25**	.65***	-.10	-.115	.49***
3. CSBQ – TD Sibling			—	.36***	-.35***	-.25**	.20*
4. CSBQ – Child w/ ASD				—	-.09	-.11	.57***
5. CASSS Total					—	.74***	-.20*
6. CASSS from Parents						—	-.10
7. QRS-F Total							—

Note. SDQ = Strength and Difficulties Questionnaire. CSBQ = Children's Social Behavior Questionnaire SCL-R 10 = Symptom Checklist Revised – 10. QRS-F = Questionnaire on Resources and Stress (QRS-F). CASSS = Child and Adolescent Social Support Scale. SDQ Discrepancy = standardized difference score between sibling and parent report; positive scores indicate higher sibling reported adjustment problems compared to parent report.

167 **181.167** Investigating Relationships Among Parental Cognitions and Emotions, Child Characteristics, and Family Demographics Among Parents of Children with Autism Spectrum Disorder

ABSTRACT WITHDRAWN

Background: In recent years, research has demonstrated that parental cognitions and emotions predict family engagement in intervention programs developed for children with Autism Spectrum Disorder (ASD). For example, our previous research found that baseline measures of parental insightfulness moderated treatment effects among mothers of children with ASD participating in a randomized controlled trial of a responsiveness-based parent-mediated intervention (Focused Playtime Intervention [FPI]; Siller, Hutman, & Sigman, 2013). Therefore, there is a necessity to better understand parental cognitions and emotions among families of children with ASD.
Objectives: The current study aimed to investigate baseline relationships among the Insightfulness Assessment (Oppenheim & Koren-Karie, 2002) and the Reaction to Diagnosis Interview (Pianta & Marvin, 1993) in relation to a range of other parental cognitions and emotions (i.e., stress, understanding of child development, self-efficacy, perception of child attachment, and social support); child characteristics (i.e., nonverbal and language abilities and ASD symptoms); and family demographics among 70 mothers of children with ASD (chronological age: $M = 57.13$ months; $SD = 12.30$; male: $n = 64$) who participated in FPI.
Methods: At baseline, parents were asked to participate in two semi-structured interview measures: (1) the Insightfulness Assessment (IA) and (2) the Reaction to Diagnosis Interview (RDI). Parents were also asked to complete five questionnaires: (1) the Questionnaire of Resources & Stress (Konstantareas, Homatidis, & Plowright, 1992); (2) the Concepts of Development Questionnaire (Sameroff & Feil, 1985); (3) the Parenting Sense of Competence Scale (Johnston and Mash, 1989); (4) the Maternal Perception of Child Attachment (Hoppes & Harris, 1990); and (5) the Perceived Social Support Scale (Procidano & Heller, 1983). Children were administered the Mullen Scales of Early Learning (Mullen, 1995) and the Autism Diagnostic Observation Schedule (Lord et al., 2000). Parents were asked to complete a demographic questionnaire that included questions about the child's ethnicity/race, family constellation, and various indicators of family socioeconomic status.
Results: Analyses included a series of multiple regression models using SAS PROC REG. Findings revealed that mothers who demonstrated higher levels of insightfulness on narratives elicited by the IA demonstrated lower levels of stress, $t(62) = -2.24$, $p < .05$ and higher levels of self-efficacy, $t(62) = 2.19$, $p < .05$ and understanding of child development, $t(63) = 3.23$, $p < .01$. In addition, mothers who demonstrated higher levels of resolution in regards to their child's diagnosis on narratives elicited by the RDI demonstrated lower levels of stress, $t(62) = -2.84$, $p < .01$ and higher levels of self-efficacy, $t(62) = 2.67$, $p < .01$ and perceived social support, $t(64) = 2.98$, $p < .01$. None of the interaction terms were significant. Child characteristics and family demographics were unrelated to parental narratives on the IA and RDI.
Conclusions: The current study allows researchers to better understand relationships among parental cognitions and emotions, child characteristics, and family demographics among families of children with ASD. Findings contribute to research that aims to inform the efficacy of intervention programs.

168 **181.168** Links Between Autism Spectrum Disorder Diagnostic Status and Family Quality of Life

*A. G. McKechanie[1,2], **S. Fletcher-Watson**[3], V. Moffat[4] and E. C. Johnstone[5], (1)The Salvesen Mindroom Centre, The University of Edinburgh, Edinburgh, United Kingdom, (2)The Patrick Wild Centre, The University of Edinburgh, Edinburgh, United Kingdom, (3)University of Edinburgh, Edinburgh, Scotland, United Kingdom, (4)University of Edinburgh, Edinburgh, United Kingdom, (5)University of Edinburgh, Edinburgh, United Kingdom of Great Britain and Northern Ireland*

Background: Quality of life is often lowered, relative to the norm, in families with children with additional needs. This may be particularly the case where additional needs are accompanied by an autism spectrum disorder (ASD). Rates of diagnosis in Scotland (where this study took place) are low relative to the UK average, and global prevalence estimates. Therefore it is likely that some cases of ASD remain undiagnosed in Scotland. It is unclear what the consequences of this may be.
Objectives: We explore the effects of autism diagnostic status, investigating impact on family well-being of: i) diagnostic status; ii) access to services; iii) ASD symptom intensity; iv) presence of challenging behaviours and v) IQ.
Methods: Mothers (n=76) of young people (aged 13-22 years) with educationally-defined additional needs completed standardised questionnaires about quality of life, stress, service provision, challenging behaviour (Child Behaviour Checklist, CBCL) and presence and severity of ASD traits (Social Communication Questionnaire, SCQ). Participants were a sub-group selected from a large national teacher-referral study (n=465). The sample was divided, based on case history and SCQ scores into three groups: a) additional needs, SCQ score below threshold; b) additional needs, SCQ score above threshold and ASD diagnosis; c) additional needs, SCQ score above threshold, no diagnosis. In addition, a group of mothers of typically developing young people (n=17) completed standardised questionnaires on quality of life and on the behaviour of their son or daughter.
Results: Quality of life was highest, and stress lowest, in mothers of TD young people. Among the three groups with additional needs, higher SCQ scores were related to poorer quality of life and higher stress. This relationship was not explained by levels of challenging behaviour or IQ and was apparent across groups with and without a pre-existing ASD diagnosis.
The lowest quality of life and highest stress scores were evident in the group of mothers of young people who did not have a diagnosis of ASD but did exceed threshold on the SCQ. The two high-SCQ groups (with and without ASD diagnosis) did not differ on access to service provision, mean SCQ score or mean CBCL score. However mothers of young people with high SCQ scores but without ASD diagnosis did rate services as less useful than other groups.
Conclusions: Mothers of young people with additional needs experience lower quality of life and higher stress than mothers of typically developing young people. These adverse effects are stronger in the presence of ASD diagnosis, and strongest when there are signs of ASD but no diagnosis. This pattern is not explained by young people without ASD diagnosis having: higher levels of challenging behaviour; less access to services; low IQ. The study demonstrates that presence of ASD-like symptoms in the absence of diagnosis may be a particular cause of stress and poor quality of life for families.

169 **181.169** Living with Autism without Knowing: Receiving a Diagnosis after 50

***S. D. Stagg** and H. L. Belcher, Anglia Ruskin University, Cambridge, United Kingdom*

Background:
Autism was first included in the DSM in 1980, and classifications and behavioural symptoms have been refined in subsequent editions. Since its inclusion in DSM, the number of cases of diagnosed autism has been increasing, and prevalence rates are continually revised upwards. Individuals with autism born before 1980 are less likely to have received a diagnosis of autism, especially if they are relatively high-functioning. Our study investigated the experiences of individuals receiving a diagnosis of autism in their 50s.
Objectives:
Our aim was to recount the experiences of receiving a diagnosis of autism later on in life and to uncover commonalities within this experience.
Methods:
A free association narrative interview was conducted with nine individuals all of whom had received a diagnosis of autism within the past two years. Key questions were asked, but the individuals where able to take the interview in any direction they wished. A thematic analysis was performed on the data using an interpretive phenomenological perspective.
Results:
Participants recounted feeling different from others from an early age. All of the individuals had come to identify themselves as bad, evil or alien. Diagnosis, even in later life, was seen as a relief and a revelation, which enabled participants to re-evaluate their pasts and begin to explore their new identites. Many of the participants had sought a diagnosis after one of their children received a diagnosis of autism.
Conclusions:
Research into older adults with autism is an underdeveloped field. Researchers first need to explore the experiences of older adults with autism, in order to produce useful stakeholder centred research. The experience of receiving a diagnosis later on in life is largely positive and liberating. More research needs to find ways of identifying autism in individuals who may have jobs and families and do not consider themselves to fall within the traditional stereotyped image of autism.

170 **181.170** Making Your Own Way: A Qualitative Study of How Ontario Parents of Children with Autism Navigate Intervention

***S. J. Gentles**[1], D. B. Nicholas[2], K. A. McKibbon[3], S. M. Jack[4] and P. Szatmari[5], (1)CanChild Centre for Childhood Disability Research, McMaster University, Hamilton, ON, Canada, (2)University of Calgary, Edmonton, AB, Canada, (3)Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada, (4)School of Nursing, McMaster University, Hamilton, ON, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, Canada*

Background: Parents face substantial uncertainty and stress as they assume an unusually high proportion of the responsibility for navigating intervention to address autism-related concerns. There is a lack of holistic research explaining how parents cope and respond to the complexity and obstacles that characterize their situation as they navigate multiple forms of intervention across multiple systems of care, whether publicly-funded or private.
Objectives: The purpose of this qualitative study was to develop a social psychological explanation in the form of a substantive theory of how Ontario parents of children with autism navigate intervention under the complex informational conditions that characterize parents' shared situation.
Methods: Grounded theory methods, a constructivist approach, and symbolic interactionist analytic framework were chosen as appropriate means to guide research and achieve the study objectives. The findings are primarily based on 45 in-depth (90-minute) interviews with 32 mothers from different urban and rural Ontario regions (fathers participating in 3 cases), and 9 professionals with extensive expertise supporting parents. Documents were also analyzed.
Results: The central process of navigating intervention, labeled *making your own way*, consists of *adjusting to the need to navigate intervention*, in which parents construct the meanings that prepare and motivate them for responding to their contextual situation by *taking action to navigate intervention. Adjusting* consists of 4 interdependent sub-processes that together explain parents' action: *defining concerns*, *informing the self*, *seeing what is involved*, and *emotionally adapting* to problematic aspects of parents' situation. Emotionally adapting for new parents commonly involves accepting the possibility of autism, releasing culturally-based hopes and expectations for the child's future, accepting an uncertain and fearful future for the child, enduring the strains, and redefining one's roles and self according to new occupational requirements—all important and necessary means by which parents become prepared and motivated for *taking action*. The central process of *making your own way* can be further understood

according to three overlapping heuristic stages: *beginning the autism journey*, *handling transitions*, and *easing off*. Many parents develop a strong sense of urgency at one or more key points in their journey to which they commonly respond by *going into high gear*, expending substantial personal resources sometimes at unsustainable rates in the pursuit of intervention. Consequences of *going into high gear* and other aspects of *making your own way* will be discussed.
Conclusions: This research outlines a process in which parents' social psychological understandings provide an explanation for their actions as they navigate intervention, including an outline of the mechanisms by which both harms and benefits (affecting the child, parent, or family) can occur as a specific consequence of parents' process of *making their own way*. The findings will be informative to people from any jurisdiction concerned with modifying individual professional practice or broader care systems to optimize support for parents at various stages of their process, or journey; additionally, they suggest ways to harness parents' exceptional expertise, motivation, and energy to achieve better outcomes for the autism unit within a cooperative family-centered approach to intervention.

171 **181.171** Maternal Health of Transition Age Individuals with ASD

J. K. Law[1], *A. R. Marvin*[2], *J. S. Toroney*[3], *E. M. Arthur*[4] *and P. H. Lipkin*[4], *(1)Interactive Autism Network, Baltimore, MD, (2)Painter Bldg 1st Fl, Kennedy Krieger Institute, Baltimore, MD, (3)Medical Informatics, Interactive Autism Network, Baltimore, MD, (4)Kennedy Krieger Institute, Baltimore, MD*

Background:
Previous studies have focused primarily on the well-being of mothers of young, school-aged children; however, little is known about the well-being of mothers of teens/young adults with ASD, despite the recognized challenges of the transitional period.
Objectives:
To determine health outcomes, including contributing factors, in mothers of teens/young adults with ASD
Methods:
Maternal participants in the Interactive Autism Network (IAN) with at least one teen/young adult aged 15-29 were recruited to complete a questionnaire that incorporated the PROMIS Global Short Form, the Perceived Stress Scale (PSS), and the Waisman Activities of Daily Living Scale (W-ADL). Additional demographic questions were asked of the mother and general health-related questions for the child.
Results:
488 mothers completed responses for the PROMIS Global Short Form and the Perceived Stress Scale for themselves, and the W-ADL for their teen/young adult.
Primary factors associated with decreased health for mothers of teens/young adults with ASD are increased stress (strongly influenced by household income and the teen/young adult's general health), the presence of another child/young adult with ASD/other disability in the home, and the male gender of the affected child with ASD. See Path Analysis below ($\chi^2(54) = 173.13$; p<.001) and Figure 1.
Comparison to norms:
* Z-test for means compared mothers' mean score (*M*=48.51, *SD*=8.16) to the normed mean value of the **Global Physical Health** (PROMIS) Score (μ=50; σ=10); the result was statistically significant (*z*=-3.29, *p*<.001, two-tailed).
* Z-test for means compared mothers' mean score (*M*=45.88, *SD*=9.50) to the normed mean value of the **Global Mental Health** (PROMIS) Score (μ=50; σ=10); the result was statistically significant (*z*=-9.10, *p*<.001, two-tailed).
* Z-test for means comparing the mothers' mean score (*M*=17.34, *SD*=7.28) to the normed mean value of the **PSS** for females (μ=13.7; σ=6.6); the result was statistically significant (*z*=12.18, *p*<.001, two-tailed).
Path Analysis:
* Greater maternal perceived stress (PSS) + presence of another teen/young adult (15-29 years) in the home with ASD/disability were associated with lower **Global Physical Heath** (T Score), R^2 =.33, *F*(2,482)=116.51, *p*<.001.
* Greater maternal perceived stress + presence of another teen/young adult (15-29 years) in the home with ASD/disability + male gender of the ASD teen/young adult were associated with lower **Global Mental Health** (T Score), R^2=.56, *F*(3,479)=199.47, *p*<.001.
* Lower Household Income + poorer General Health of the teen/young adult were associated with increased p**erceived stress ,** R^2=.11, *F*(2,477)=28.99, *p*<.001.
* Mother being part of a couple (married/unmarried), white, having at least a two-year college degree, and being employed were all associated with higher **Household Income**, R^2=.37, *F*(4,466)=69.26, *p*<.001.
* Greater independence on the W-ADL is associated with better **General Health** in the teen/young adult, R^2=.11, *F*(1,486)=57.07, *p*<.001.
* Greater severity of ASD in the teen/young adult, the presence of intellectual disability, and poorer verbal skills were all negatively associated with independence as measured by the **W-ADL**, R^2=.50, *F*(3,465)=153.53, *p*<.001.
Conclusions:
This combination of child, maternal and social factors is similar to that reported for mothers of younger children with ASD. Family-centered ASD programs are needed to effectively address this complex set of issues.

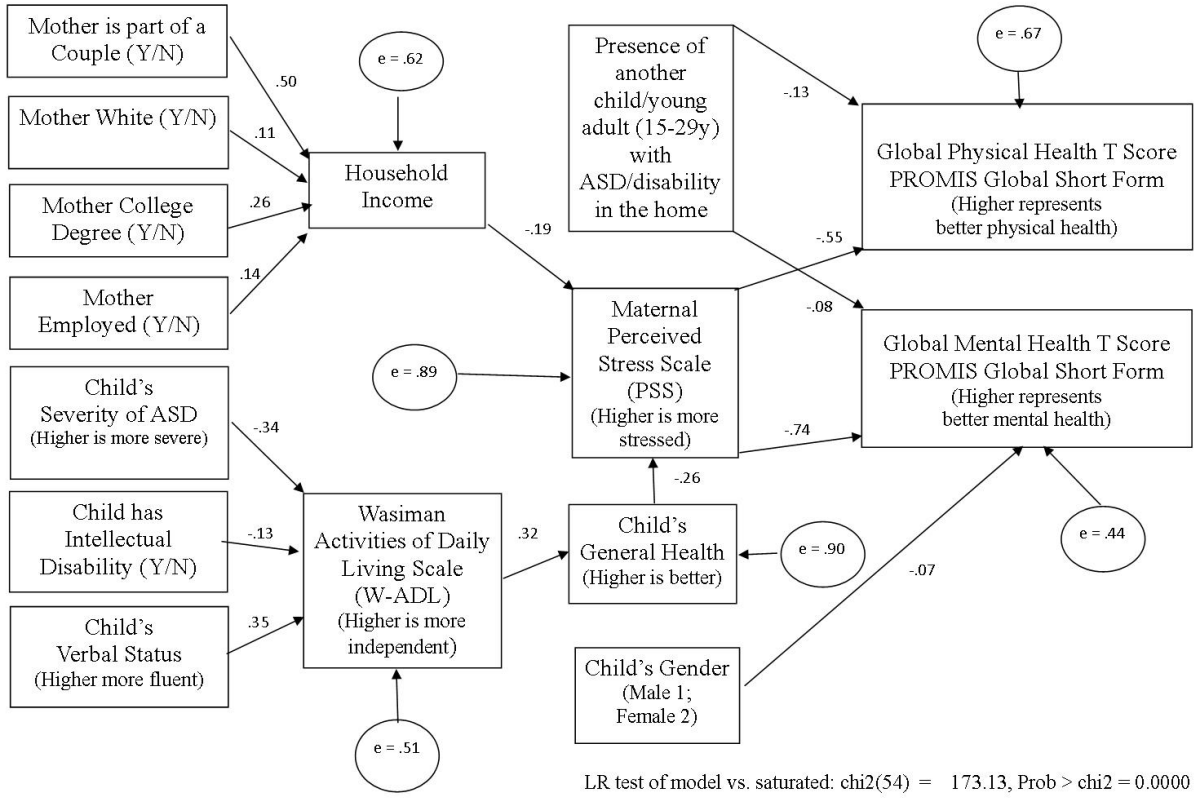

Figure 1 Path Analysis/Structured Equation Modeling

172 **181.172** Mindful Parenting: A New Approach to Supporting Parents of Children with Autism Spectrum Disorder

A. C. Voos[1], *T. Vernon*[1], *A. Navab*[2] *and E. McGarry*[3], *(1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Los Angeles, CA, (3)Koegel Autism Center, University of California Santa Barbara, Santa Barbara, CA*

Background: Research has consistently demonstrated that parents of children with Autism Spectrum Disorder (ASD) experience elevated levels of stress when compared to parents of typically developing and developmentally disabled children (e.g. Hayes & Watson, 2013). High levels of stress have been associated with more negative parenting practices (Baydar et al., 2003), and eliminate the positive effects of intervention for young children with autism (Osborne et al., 2008). Historically, parent stress has been targeted through skills based parent training programs. While parent training can help support parents around the time of initial diagnosis (Keen et al., 2010), reports of elevated levels of stress persist in those who have received extensive parent training (e.g. Singh et al., 2006; 2014). Research also suggests that parent training may be less effective for parents experiencing high level of stress (Robbins, Dunlap & Pleinis, 1992). This combined with research demonstrating that stress related to having a child with autism tends to be chronic and persistent over time (Dyson, 1993) calls for additional support for these parents.
Mindfulness, or awareness that emerges through nonjudgmentally paying attention, on purpose, to the unfolding of experience in the present moment (Kabat-Zinn 2003), is associated with increased life satisfaction, decreased depression and anxiety, improved emotion regulation, and decreased experiential avoidance (Keng, Smoski & Robins, 2011). Due to the normative level of stress that comes with parenting in general, researchers have introduced mindfulness to parents. Mindful parenting has been utilized with parents of children with disruptive and externalizing behaviors, and developmental disabilities (e.g. Bogels et al., 2008). Results indicate that mindfulness training increased happiness for the individual with the disability (Singh et al., 2004), decreased child behavior problems (Singh et al., 2006; 2007), and decreased parental stress (e.g. Ferraioli & Harris, 2013). Importantly, research also demonstrates that for parents of children with autism specifically, higher levels of mindful parenting are associated with lower levels of parental distress (Beer et al., 2013) and improvements in parent-child interactions (Coatsworth et al., 2010).
Objectives: The current study aims to investigate whether an 8 week mindful parenting group for parents of children with ASD (based on the curriculum by Bogels & Restifo, 2014) will increase parents' mindfulness, as measured by the Five Facet Mindfulness Questionnaire (Baer et al., 2006: FFMQ), and decrease parenting stress, as measured by the Parent Stress Index (Abdin, 1990; PSI)
Methods: Two groups (n=14) met weekly for 90 minutes, during which time parents were introduced to a meditation and mindful parenting exercise, and discussed their patterns and experience of parenting stress. Preliminary pre-post data will be assessed using dependent measures t-test.
Results: After participation, parents demonstrated decreased total stress $t(13) = -2.29$, $p = .020$ and child related stress, $t(13) = -2.10$, $p = .028$. Parents did not demonstrate significant increases in overall mindfulness, but importantly, demonstrated an increase in nonjudgmental attitude towards themselves $t(13) = 2.69$, $p = .009$.
Conclusions: This preliminary data suggests that group mindfulness training may help to support parents of children with ASD by reducing overall stress and self-judgment about their own experiences.

173 **181.173** Minimal Risk of Internalizing Problems in Typically-Developing Siblings of Children with HFASD

J. D. Rodgers[1], *A. Warhol*[1], *J. D. Fox*[2], *C. A. McDonald*[1], *M. L. Thomeer*[1], *C. Lopata*[1], *A. M. Darrow*[1], *A. L. Szyszkowski*[1], *A. A. Biscotto*[1] *and T. Sheffield*[1], *(1)Institute for Autism Research, Canisius College, Buffalo, NY, (2)Abilities First, Poughkeepsie, NY*

Background: There is a paucity of research on internalizing difficulties of siblings of children with high-functioning autism spectrum disorder (HFASD). Reviews describe a limited and conflicted field of findings (Meaden et al., 2010; Orsmond & Setzer, 2007) for research on siblings of children on the autism spectrum across the range of functional levels. Only three studies of internalizing problems in TD siblings of children with HFASD are available and these are limited in quality. Specifically, all three available studies (Verté, Roeyers, & Buysse, 2003; Ross & Cuskelly, 2006; Rao & Beidel, 2009) used only parent report information from the CBCL. If sibling depression and anxiety are clinically elevated, developing interventions and increasing focus on these children would become a priority for community and school-based mental health providers.
Objectives: This group comparison study examined (1) symptom level differences in anxiety and depression between TD siblings of children with HFASD and TD siblings of children with TD siblings and (2) source differences between parent-rated and child self-reported anxiety and depression across these groups.
Methods: Eighty-four children, ages 6-16 were participants in the study. Within the total sample were two groups: 42 TD siblings of children with HFASD and 42 TD siblings of TD children. Participating TD siblings were matched on age, gender, and ethnicity. Groups were equivalent on parent education. The TD siblings from both groups had no identified developmental, psychiatric, or educational conditions other than anxiety or depression. The HFASD reference siblings had to have a WISC-IV short-form IQ > 70, VCI or PRI factor score > 80 and an independent diagnosis of ASD from a licensed physician or psychologist. A majority of reference siblings (33, 78.6%) also had ADI-R confirmation of the diagnosis. The *Behavior Assessment System for Children-2* (BASC-2; Anxiety and Depression clinical scales), parent (PRS) and child report (SRP) were

collected. Siblings of reference children with HFASD were recruited from a pool of families participating in psychosocial interventions for their sibling with HFASD. TD siblings of TD children were recruited through public advertisement.
Results: Comparison of TD siblings of children with HFASD to TD siblings of TD children indicated no significant multivariate effect between groups for parent-reported internalizing problems (Wilk's $\lambda = 0.997$, $F[1,82] = 0.119$, $p = 0.888$) or self-reported internalizing problems (Wilk's $\lambda = 0.982$, $F[1,82] = 0.724$, $p = 0.488$). Source differences indicated no within-group (parent vs. self) multivariate effect for siblings of HFASD children (Wilk's $\lambda = 0.980$, $F[1,82] = 0.829$, $p = 0.440$) or siblings of TD children (Wilk's $\lambda = 0.992$, $F[1,82] = 0.336$, $p = 0.715$).
Conclusions: The current study did not support an increased risk of internalizing problems (anxiety and depression) in the TD siblings of children with HFASD. This is strengthened by consistent levels of internalizing problems by source. The current result does not support a higher risk of internalizing symptoms for siblings of children with HFASD, though clinicians should maintain awareness of these children and attend to clinical warning signs if presented.

174 **181.174** Parent Expectancies: A Self-Fulfilling Prophecy?

C. Kang[1], *A. C. Holbrook*[1], *S. Y. Shire*[1], *T. Smith*[2], *R. Landa*[3], *A. Kaiser*[4], *A. Gulsrud*[5] *and C. Kasari*[1], *(1)University of California Los Angeles, Los Angeles, CA, (2)Division of Neurodevelopmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (3)The Kennedy Krieger Institute, Baltimore, MD, (4)Vanderbilt University, Nashville, TN, (5)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background:
Parental beliefs and expectancies about their children's treatment may influence the overall outcome of treatment. This is because it is generally parents who provide consent for their children, determine their treatment participation, and manage attendance.
The Parent Expectancies for Therapy Scale (*PETS*, Kazdin & Holland, 1991) is a measure for assessing expectancies in parents of children treated for conduct disorder. Adapted versions of the *PETS* have been administered in several treatment studies for children with autism spectrum disorder (ASD). However, to our knowledge, analyses of the *PETS* and its correlates have not been conducted or validated with a sample of parents of children with ASD.
Objectives:
The current study determined the underlying factor structure of parent expectancies for parents of children with ASD using the *PETS*. Additionally, we examined the relationship between parent expectancies and parent participation in treatment.
Methods:
Participants:
The study is a secondary data analysis of three social communication intervention studies. Participants included 294 parents of preschoolers and toddlers with ASD.
Measures:
The *PETS* is a parent questionnaire that assesses the broad range of pre-treatment expectancies on a 5-point scale. The current study examined adapted versions of the *PETS* used across studies. The dataset only included questions that all three adapted scales had in common, leaving a total of 16 questions.
The Caregiver Quality of Involvement Scale (*CQIS*) is a therapist-rated, 4-item scale used to evaluate caregivers' levels of comfort, confidence, enthusiasm, and accuracy in implementing intervention strategies learned during parent training sessions. The *CQIS* was completed at the end of each parent training intervention session by the therapist.
Procedure:
An exploratory factor analysis (EFA) was conducted to determine the structure and relationships between variables of parent expectancies in the *PETS*. Data were analyzed using maximum likelihood with Comprehensive Exploratory Factor Analysis software. Composites of parent expectancies factors were then analyzed through correlations and linear regression with each of the parent involvement subscale scores.
Results:
The EFA revealed a four-factor structure, with latent factors related to credibility of treatment, belief in child improvement, parent involvement in treatment, and comparability to other treatments. Expectancies of treatment credibility were significantly correlated with all four components of parent involvement. Expectancies for child improvement were significantly correlated with three parent involvement subscales (comfort, confidence, accuracy). Regression analyses indicated that only expectation of child improvement significantly predicted level of parent comfort in implementing intervention during parent training ($F(1,180)=8.067$, $p=0.005$); all other regression analyses were nonsignificant.
Conclusions:
Parent pre-treatment expectancies pertaining to treatment credibility and child improvement were related to parents' involvement as rated by therapists. These findings indicate that credibility of treatment and belief in child improvement may be especially salient and motivating to parents of children with ASD. However, parent expectancies regarding their own involvement in treatment were not reflected in their involvement scores, highlighting that there may be additional factors influencing the predictive relationship between expectancies and involvement. As parent training in ASD intervention is a growing field, there is a need to better understand parent perspectives and experiences.

Table 1. Factor structure of the PETS

Item	Description	Factor 1 Credibility	Factor 2 Child Improvement	Factor 3 Parent Involvement	Factor 4 Comparison to Other Treatments
11	I believe this treatment will be valuable in treating areas of concern that I have for my child.	.71			
9	I believe that this treatment sounds reasonable for the difficulties that I have been experiencing with my child.	.68			
12	I believe this treatment will improve my child's adjustment at home or at school.	.59			
15	I believe the therapy described will be worthwhile.	.50			
6	I believe that all the information that I give out will be confidential.	.44			
*13	I believe this treatment will make my child worse.	.41			
1	How much do you believe the treatment will help you in being a parent?	.36			
7	Once therapy begins, I believe that my child will improve.	.35	.49		
4	I believe that my child will improve quickly.		.83		
*5	I believe that it will take a long time for my child to improve.		.58		
2	How much time do you think you will have to spent outside of sessions on task or activities related to treatment?			.76	
16	I believe I will have to do a lot of work outside of the sessions in order for my child to improve.			.52	
3	How much of a role do you believe that you will have in your child's treatment?			.35	
17	How will this treatment compare in effectiveness with medical treatment (e.g., medication) for your child?				1.00
18	How will this treatment compare in effectiveness with your own attempts at dealing with areas of concern you have for your child?				.38
**10	I believe that I will be motivated to work in this type of treatment with a therapist.

175 **181.175** Parent Perceptions of an Adapted Evidence Based Practice for Toddlers with Autism in a Community Setting

S. R. Rieth[1], *A. C. Stahmer*[2], *L. Brookman-Frazee*[3] *and T. Wang*[4], *(1)San Diego State University, San Diego, CA, (2)University of California at Davis MIND Institute, Sacramento, CA, (3)Autism Discovery Institute at Rady Children's Hospital – San Diego, San Diego, CA, (4)University of California, San Diego, La Jolla, CA*

Background:
Although data from parent-implemented Natural Developmental Behavioral Interventions (NDBIs) have shown positive effects on decreasing core symptoms of autism, there has been limited examination of the effectiveness of NDBIs in community settings. Additionally, parent perspectives of their involvement in parent-implemented early intervention have not been well studied. Project ImPACT is an NDBI that teaches families techniques to improve child social engagement, language abilities, imitation skills, and play (Ingersoll & Dvortscak, 2010). Rigorous single-subject methodology demonstrates children receiving Project ImPACT demonstrate gains in targeted skills, and parents use the intervention with fidelity in research settings.
Objectives:
The purpose of the current study is to examine parent perspectives and the initial impact on parent behaviors of Project ImPACT for toddlers at-risk for ASD when delivered by community providers. Specifically, mixed quantitative and qualitative methods were used to assess (1) observed changes in parent use of strategies to facilitate their child's social communication skills following community-implemented Project ImPACT; and (2) parent perceptions of effectiveness and feasibility of Project ImPACT.
Methods:
Participants included thirteen parents and their children with risk for ASD, recruited from four community-programs. Primary eligibility criteria included referral to a community provider trained in Project ImPACT and a child with a diagnosis of ASD or risk for ASD who was under 24 months of age at intake. Mean child age at intake was 15 months (*SD*= 3.01; range = 8-21 months) and a majority (76%) of families self-identified as Caucasian.
All families received a 12-week Project ImPACT curriculum to support their use of strategies to facilitate interaction and skill building in their children during daily routines and activities. Measures utilized for the current study included parent fidelity of implementation as rated by the research team, a satisfaction survey completed by the parents at the end of intervention, and qualitative, semi-structured exist interview completed with the parents by a member of the research team.
Results:
Significant improvements in parents' overall fidelity were observed from baseline (*M*=3.13) to 12 weeks (*M*=3.77; p< .01). Twenty percent of parents were considered to have met overall fidelity at baseline compared to 90% of parents at 12 weeks. Parent improvement on individual strategies will be examined and discussed.
Parents reported overall high satisfaction with the intervention (*M*=6.46; *SD*= .41; range = 5.7-7, out of 7 possible). Parent responses in the interviews also supported that general satisfaction was very high; all parents indicated they "believed" in the approach. Results will be described based on the emergent interview themes related to the parent coaching process, impressions of the intervention, and impact of the intervention on their own and their child's behavior.
Conclusions:
Findings from both qualitative and quantitative data indicate that parents had very positive perceptions of the feasibility, utility, and effectiveness of Project ImPACT when implemented by community early intervention providers. Further, observational data indicate that parents were able to learn and implement the Project ImPACT strategies in the relatively brief 12-session intervention period. Implications for the feasibility of adopting a parent-implemented treatment program will be discussed.

176 **181.176** Parent and Teacher Reported Child Characteristics Related to Parenting Stress in ASD

T. Ward[1], *T. Estrada*[1], *E. A. Lovell*[1], *R. Kramer*[1] *and B. Wilson*[2], *(1)Seattle Pacific University, Seattle, WA, (2)Clinical Psychology, Seattle Pacific University, Seattle, WA*

Background:
Parents of children with autism spectrum disorder (ASD) report higher parenting stress than parents of typically developing (TD) children (McStay et al., 2014). Research suggests children with ASD have more externalizing behaviors and lower adaptive functioning than TD peers (Towle et al. 2014), both of which predict higher parenting stress in this population (Hall, 2011; McStay et al., 2014). Further, agreement between parent-teacher ratings of behavioral and adaptive skills vary (Lane, Paynter, & Sharman 2013) and not entirely attributable to differential sample environments (Reed & Osborne 2013). This study helps elucidate the child characteristics related to parenting stress.
Objectives:
The purpose of this study was to examine how child behaviors influence stress in parents of children with ASD and to determine if there are differences among parent and teacher reports.
Methods:

Our sample included 138 children (ages 3:1 to 6:11), their parents, and their teachers. Eighty-one TD children (45% female) and 57 children with ASD (23% female) were examined. Intensity and frequency of parenting stress was measured using the parent-reported Parenting Events Questionnaire (Crnic & Greenberg, 1990). Externalizing behaviors and adaptive functioning was measured using parent- and teacher-reported Behavior Assessment System for Children (*BASC-2*; Reynolds, & Kamphaus, 2004).
Results:
Two separate serial mediation models were conducted using the SPSS macro PROCESS (Hayes, 2008), which provided bootstrapped estimates of the indirect effects based on 5000 resamples. In the parent report mediation model, results indicated status was positively associated with parent-reported externalizing behaviors (B = 8.03, $p < .001$) and negatively associated with parent-reported adaptive skills (B = -9.94, $p < .001$). The direct effect of status on parenting stress was not significant (B = -3.45, $p = .42$). Results supported the mediating role of the child's externalizing problems ($B = 6.28$, CI_{95} = 2.52 to 12.85) and the mediating role of the child's adaptive skills (B = 4.29, CI_{95} = .75 to 8.84) in the association between status and parental stress. Additionally, the results indicated that, compared to TD children, children with ASD had greater externalizing problems, which predicted lower adaptive skills and associated with higher parental stress (B = 1.62, CI_{95} = .39 to 3.80). An identical teacher report mediation model revealed a nonsignificant indirect effect of externalizing problems (B = 3.81, CI_{95} = -1.028 to 8.36) and the mediating role of the child's adaptive skills (B = 2.40, CI_{95} = -.16 to 6.42). Figures 1 and 2 display these results.
Conclusions:
Our results suggest greater parenting stress in parents of children with ASD occurs through a serial mediated pathway such that higher parent-reported externalizing behaviors predicted lower parent-reported adaptive functioning which predicted increased parental stress. However, when using teacher-reported externalizing behaviors and adaptive functioning, this association was no longer significant. Future research should explore if the differences in parent and teacher report of child behaviors indicate a true difference between parental and teacher perceptions of behaviors and how these perceptions may perpetuate or alleviate parent stress.

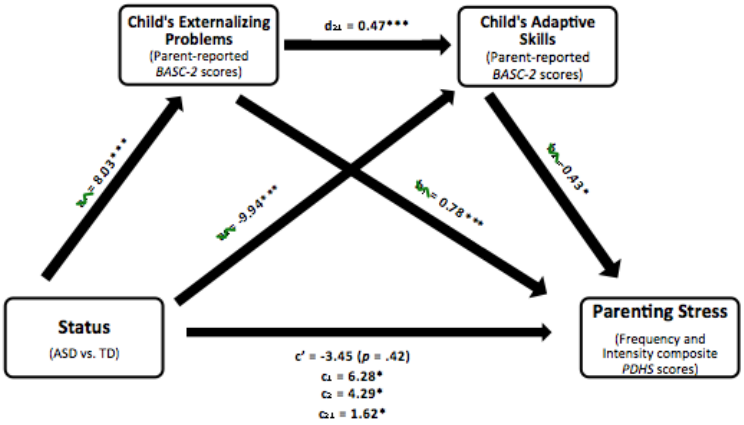

Figure 2. Parenting stress on teacher reported child externalizing problems and adaptive skills

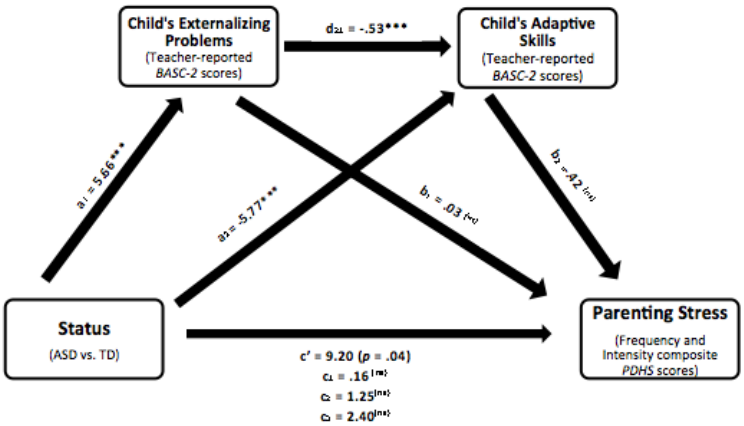
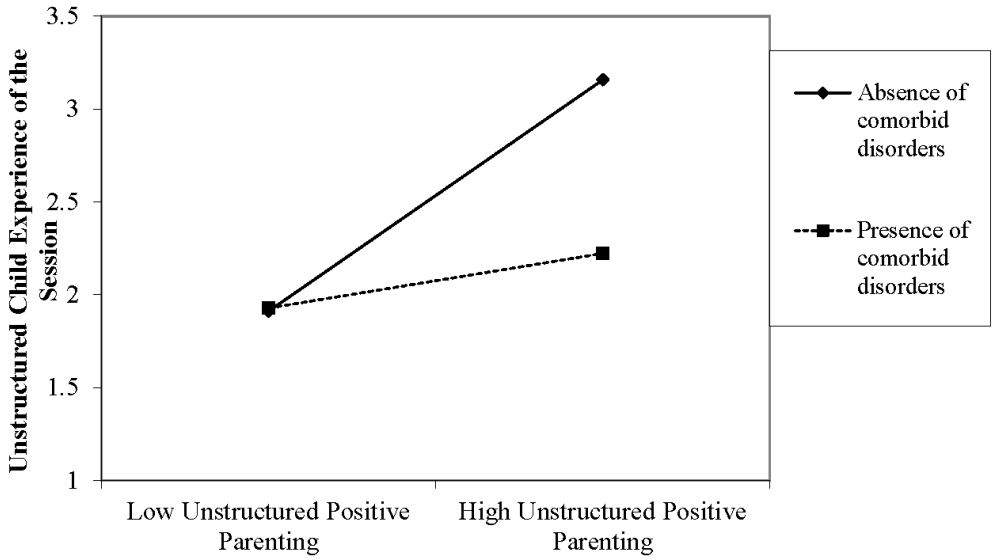


177 **181.177** Parent-Child Interaction in Children with Autism Spectrum Disorder Who Vary in Symptom Severity and Level of Functioning

L. J. Donnelly[1], *M. R. Brassard*[2], *A. Kolevzon*[1], *J. M. Jamison*[1] *and E. Fourie*[1], *(1)Psychiatry, Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, New York, NY, (2)School Psychology, Health and Behavior Studies, Teachers College, Columbia University, New York, NY*

Background: Parenting children with autism spectrum disorder (ASD) is understood to be extremely stressful and presents unique challenges. Research with typically developing (TD) children suggests that parent-child relationship difficulties and ineffectual/negative parenting practices are likely to exist in the context of high parental stress and child behavior problems. However, few studies have examined the full continuum of parenting behaviors in families of children with ASD.
Objectives: To examine three well-established components of parenting (emotional support, instruction/patience, and negative parenting) using a parent-child interaction task in a sample of children with ASD and a parent or caregiver.
Methods: Thirty children with ASD were included in this study (ages 5-12; racially and ethnically diverse sample). Diagnostic symptoms were assessed using the Autism Diagnostic Interview – Revised and the Autism Diagnostic Observation Schedule, Second Edition. The parent-child interaction was assessed using the Psychological Multifactor Care Scale – ASD Adapted Version (PMCS-ASD; Donnelly, Brassard, & Hart, 2014; Brassard, Hart, & Hardy, 1993); making this study the first time the PMCS-ASD was adapted for use in this population. Sessions were coded by independent raters for both child and parent behaviors. Through observations, two positive parenting factors were assessed: emotional support (e.g., displaying a supportive presence, praising, encouraging, calming, and warmth) and patience (e.g., scaffolding, guidance, limit setting, and positive affect). One negative parenting factor was also assessed (e.g., negative talk, interfering with materials or learning, lack of instruction, & absence of emotional support). Additionally, coders rated the child's experience of the session (e.g., observed success and competence, positivity of interactions) and child negativity towards the caregiver during the parent-child interaction. Correlational and regression analyses were conducted.
Results: Parents and caregivers of children with ASD demonstrated high rates of positive parenting and low rates of negative parenting. Similar to what has been reported in TD children (e.g., Brassard et al., 1993; Patterson et al., 1990; Webster-Stratton & Eyberg, 1982), children with ASD acted more negatively towards their parents when negative parenting was exhibited in the structured task (r_S=.433, p<.05). Positive parenting was positively correlated with the degree to which children were observed to have a good experience of the session (b=.671, p<.001), and this relationship was moderated by comorbidity of other disorders (mostly ADHD) in the unstructured session (b=-.513, p<.05), such that children without comorbid disorders were observed to have better experiences in the session when their parents exhibited greater amounts of positive parenting. The presence of comorbidity was also associated with the degree to which parents exhibited patience during the structured task (b^*=-.469, p<.01). Parents of children without comorbid diagnoses displayed higher levels of patience (r=-.538, p<.01) and less negative parenting (r=.471, p<.01).
Conclusions: Findings of high levels of positive parenting and low levels of negative parenting suggest that, despite challenging behaviors associated with ASD, parents of children with ASD generally display supportive and flexible parenting. However, the presence of comorbid diagnoses can negatively impact the parent-child relationship. Future directions include clarifying moderators of the parent-child relationship and developing tools to better support parents.

Figure 1. *Graph of the interaction between Unstructured Positive Parenting and Comorbid Disorders on Unstructured Child Experience of the Session*



Note. N=29; Absence of comorbid disorder n = 20 (this represents children only diagnosed with ASD or diagnosed with ASD and Intellectual Disability (ID)), Presence of comorbid disorder n = 9 (this represents children diagnosed with ASD and other comorbid disorders, including children diagnosed with ID if they were also diagnosed with other comorbid disorders).

178 **181.178** Parent-Teacher Communication about Children with Autism Spectrum Disorder: An Examination of Collaborative Problem-Solving

G. Azad[1], *M. Kim*[1], *D. S. Mandell*[1] *and S. Sheridan*[2], *(1)University of Pennsylvania School of Medicine, Philadelphia, PA, (2)University of Nebraska-Lincoln, Lincoln, NE*

Background: Parent-teacher communication is an essential component to establishing and sustaining successful family-school partnerships (Cheatham & Ostrosky, 2011; Dunst, 2002). One aspect of effective communication is the ability to problem-solve when presented with a student concern (Allen & Blackston, 2003). The extent to which parents and teachers problem-solve may be as important as any direct intervention for children with Autism Spectrum Disorder (ASD). There are numerous opportunities for parents and teachers of children with ASD to problem-solve, such as parent-teacher conferences and Individualized Education Program (IEP) meetings. However, a large percentage of families reported feeling dissatisfied during these interactions with school staff (Lake & Billingsley, 2000). Schools continue to struggle in creating consistent, reliable, two-way communication systems, particularly with low-income, minority families (Lo, 2008; Tucker & Schwartz, 2013). However, limited studies have examined the interactions between parents and teachers of children with ASD. There is a pressing need to investigate parent-teacher communication, particularly with regard to problem-solving behaviors.

Objectives: The purpose of this study was to examine the problem-solving behaviors of parents and teachers of children with ASD. Our aims were: 1) To examine the extent to which parents and teachers engaged in problem-solving behaviors when discussing students' concerns; 2) To examine differences between parents' and teachers' problem-

solving behaviors; and 3) To examine whether reported problem-solving behaviors differed from observed problem-solving behaviors.
Methods: Participants included 18 kindergarten-through-fifth grade autism support teachers and 39 parents of children with ASD. A majority of the teachers were female (89%) with an average age of 36 years (SD = 11.3); 83.3% identified as White. Parents were primarily mothers (95%) who averaged 34.9 years of age (SD = 6.2); 56.4% identified as African American/Black. Parent-teacher dyads were prompted to discuss and provide a solution for a problem that a student experienced at home and at school. Parents' and teachers' problem-solving behaviors were coded using the Engagement in Consultation Scale – Observer Form Revised (Sheridan et al., 2005). Parents and teachers self-reported on their problem-solving behaviors using the Parent/Teacher Participation in Problem-Solving Scales, respectively.
Results: Analyses included paired sample t-tests and McNemar's tests. Results showed that parents and teachers displayed low levels of the core elements of problem-solving. However, teachers were observed to display more problem-solving behaviors compared to parents. Generally, both groups reported engaging in more problem-solving behaviors than they were observed to display during the dyad observation.
Conclusions: The results from the present study were consistent with prior investigations examining communication between parents and teachers. Our findings suggest that teacher and parent training programs should include collaboration and positive approaches to problem-solving. A better understanding of how to support parent-teacher communication may empower family-school partnerships, and ultimately, outcomes for children with ASD.

179 **181.179** Parental Stress in Families with 16p11.2 Duplications and Deletions with and without ASD

T. Ward[1], *M. Frye*[2], *C. M. Hudac*[3], *J. Gerdts*[3], *F. K. Miller*[4], *R. Kincade*[5], *R. Bernier*[3], *E. Hanson*[6], *R. P. Goin-Kochel*[7], *J. E. Spiro*[8] *and W. K. Chung*[9], *(1)University of Washington Autism Center, Seattle, WA, (2)University of Washington, Psychiatry and Behavioral Sciences, Seattle, WA, (3)University of Washington, Seattle, WA, (4)Mary A. Rackham Institute (MARI), University of Michigan, Ann Arbor, MI, (5)University of Washington Psychiatry and Behavioral Sciences, Seattle, WA, (6)Children's Hospital Boston, Boston, MA, (7)Baylor College of Medicine, Houston, TX, (8)Simons Foundation, New York, NY, (9)SFARI, Simons Foundation, New York, NY*

Background:
Extant literature indicates parents of children with autism spectrum disorders (ASD) experience higher levels of parenting stress than parents of children with other disabilities and typically developing children (Dumas, et al., 1991). ASD related deficits in social and behavioral functioning are the factors associated with overall parenting stress (Davis & Carter, 2008). Given the incidence of 16p11.2 duplications and deletions implicated in ASD (Sanders et al., 2011), knowledge related to parental stress in families in this population with copy-number variations (CNVs) and ASD is needed.
Objectives:
The current study aimed to examine parental stress for parents of children 16p11.2 duplications and deletions with and without ASD from the well characterized Simons VIP sample (Simons VIP Consortium, 2012). Additional child phenotypic variables were examined in this population.
Methods:
Our analysis included parent and child data from probands with 16p11.2 duplications (n = 107) and deletions (n = 113), ages 10 months to 23 years 5 months and their parents. Of the probands examined, 36 had a diagnosis of ASD (assessment using ADOS-2, ADI and DSM-IV criteria). Parental stress was measured by the Parenting Stress Index (PSI; Abidin, 1990) total score. Child factors, including internalizing and externalizing t-scores from the Child Behavior Checklist (CBCL; Achenbach, 1991) and Full Scale IQ Standard Score from the Differential Ability Scale for Children (DAS; Elliot, 1990) were examined.
Results:
A 2 (ASD diagnosis, fixed, between groups) x 2 (CNV status, fixed, between groups) factorial ANOVA on parental stress showed a significant effect of ASD on parental stress, $F(1,213) = 7.416$, $p = .007$, $\eta^2 = .033$. There was no main effect of CNV status and no significant interaction between CNV status and ASD, indicating significantly higher levels of stress in parents with children diagnosed with ASD regardless of CNV type (see Figure 1). In children with ASD and 16p11.2 deletions there was strong positive correlations between externalizing behaviors and parental stress, $r = .61$, n = 23, p = .003; internalizing behaviors and parental stress $r = .49$, n = 23, p = .018; and no correlation between IQ and parental stress. No significant correlations were found in children with ASD-16p11.2 duplications. See Table 1 for correlations.
Conclusions:
Results indicate significantly elevated stress in parents with children ASD regardless of 16p11.2 duplication/deletion status. This suggests, that even when strongly controlling for etiological factors within a biologically defined group, it is ASD-associated behaviors and symptoms that are playing a strong role in parental stress. We further examined variables that have been previously associated with parental stress in the ASD population. These correlations revealed significant associations of parental stress in the ASD-deletion group and non-ASD-deletion/duplication groups with externalizing and internalizing behavior. Small sample size is likely driving the nonsignificant correlations of the ASD-duplication group (n=12), as it appears that many factors contribute to the complexity of parental stress in this population. Future research should examine parent-child traits that serve to precipitate, perpetuate and protect parental stress in this unique population affected by 16p11.2 CNVs.

180 **181.180** Parenting Children with ASD and Children with Anxiety Disorders: The Relationship Between Parental Stress, Anxiety, and Parenting Style and Child Symptom Presentation

C. A. Paisley, *S. M. Abdullahi, M. L. Braconnier, W. Silverman and P. E. Ventola, Yale Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Extant literature illustrates higher stress in parents of children with autism spectrum disorder (ASD) than those with other developmental disabilities and those with typically developing (TD) children. Child symptom severity, externalizing symptoms, parent-child relationships, and parent support have been shown to contribute to this increased stress, although results vary.

Objectives: We examined differences in parental stress and symptoms of psychopathology between three groups: parents of TD children, parents of children with anxiety disorders, and parents of children with ASD. This is the first study to examine differences between parents with children with ASD and parents of children with anxiety disorders and how child variables may differentially influence parenting stress and psychological functioning.

Methods: Participants included mothers or fathers of 47 children with ASD, 23 parents of TD children, and mothers of 101 children with anxiety disorders (e.g. generalized anxiety disorder, specific phobia, and selective mutism). Children were between 4 and 16 years of age. Parenting stress was assessed was using the Parental Stress Index-4th Edition (PSI-4), and symptoms of anxiety and depression were examined using the Beck Anxiety Inventory (BAI) and Beck Depression Inventory- Second Edition (BDI-II) respectively. To address parenting behaviors, parents completed the Parent's Report of Parental Behavior Inventory (PRPBI). Childhood anxiety and autism symptom severity were evaluated with the SCARED, CASI, and SRS, respectively.

Results: Parents of typically developing children and parents of children with ASD and anxiety disorders reported similar levels of anxiety and depressive symptoms, as assessed using the BAI and BDI-III. However, parents of children with ASD reported significantly higher levels of parenting stress than parents of typically developing children ($p < 0.05$). In both clinical groups, child anxiety symptom severity correlated significantly with parent anxiety symptom severity ($r=0.460$, $p < 0.01$ for ASD group; $r=0.219$, $p< 0.03$ for anxiety group).

In terms of parenting behaviors, as assessed using the PRPBI, parents of children with anxiety disorders reported higher levels of acceptance and firm control (the degree to which parents use strict discipline to control their child's behavior), as compared to parents of TD children or children with ASD ($p < 0.01$). In the children with anxiety disorders, child anxiety symptoms were positively correlated with parent acceptance, firm control, and psychological control (e.g. guilt or intrusiveness). In the children with ASD, social communication symptom severity, as assessed by the SRS, was negatively correlated with parent acceptance and psychological control.

Conclusions: Parents of children with ASD experience a high level of parenting stress; however symptoms of anxiety and depression are comparable to parents of TD children and parents of children with anxiety disorders. Child symptom presentation, though, is correlated with parent anxiety symptoms as well as parenting behaviors in both clinical groups.

The challenge of parenting a child with a developmental disability or psychiatric disorder cannot be understated, and it may lead to distinct parenting styles, views, and approaches. Continued work will further elucidate this relationship with the overall goal of developing more effective strategies for parents of children with disabilities,

particularly ASD.

181 **181.181** Parenting Work and Trajectories of Care – How Parents Develop a Sense of Personhood and Future Possibilities for Children with Autism

***J. S. Singh**, School of History and Sociology, Georgia Institute of Technology, Atlanta, GA*

Background:
Caring for and loving a child with autism can be an emotional journey for parents due to the many ambiguities and uncertainties tied to the diagnosis and potential for long-term care. There is also a limited understanding of the causes and no clear consensus on the most effective treatments and developmental outcomes. In the face of these many unknowns, parents must proactively adjust to an alternative destination, lead by love and determination, as well as hope for themselves, their family, and their child's future.
Objectives:
The purpose of this study is to investigate the ways in which parents rearticulate the meaning of autism to establish a sense of personhood for their child and possibilities for their future.
Methods:
This study is based on in-depth interviews with parents who have a child diagnosed with autism in the U.S. Twenty-three families were interviewed from May 2009 – October 2012. Nineteen family interviews consisted of the mother only and four family interviews consisted of both the father and mother. The data was analyzed using grounded theory methods in order to develop and refine ideas based on responses to questions that addressed parents' experiences of raising a child with autism and how they adjusted to limits place on their child and the uncertainties of the future.
Results:
Parents conducted a range of biographical work in order to maintain a positive identity of their child who does not fit the normative expectations of our society. At the diagnostic phase, parents had to first resist the narrow boundaries of what to expect in a child with autism. They did this by creating a range of positive expectations and opportunities for their children to grow mentally and emotionally. Second, these parents challenged and shaped their child's sense of personhood beyond the clinical diagnostic boundaries of autism by emphasizing various qualities and skills embodied by their child. As their children grew older, parents also described how they had to readjust their own expectations by focusing on ways to help their children be happy and able to care for themselves in the future.
Conclusions:
The experiences of how parents manage the daily and life long expectations of their child with autism are important perspectives, especially as the number of children diagnosed with ASD continues to increase. In the U.S., there are limited services once children with autism reach adulthood, making the impact on parents and caregivers of people with autism an important health policy issue. The data presented in this study offers a glimpse of the invisible work conducted by parents who challenge and negotiate the limits placed on their child and the types of work they conduct to create futures that only they can imagine. Parents are integral to the daily life and futures of children with autism and this study begins to acknowledge how specialized and important this type of work is toward shaping autism trajectories.

182 **181.182** Past, Present, and Future Self-Concepts in Undergraduates with ASD and Other Disabilities in Relation to Chronic Bullying and Use of Labels in Disclosure

***D. DeNigris**[1], P. J. Brooks[2], R. Obeid[3], C. Shane-Simpson[4], S. Shnaidman[5], E. Wawrzonek[6], W. Long[6], B. Cheriyan[6], J. D'Onofrio[7] and K. Gillespie-Lynch[8], (1)The Graduate Center & College of Staten Island, CUNY, New York, NY, (2)College of Staten Island, Staten Island, NY, (3)CUNY Graduate Center, New York, NY, (4)The Graduate Center & College of Staten Island, New York, NY, (5)Staten Island Technical High School, Staten Island, NY, (6)The College of Staten Island, CUNY, Staten Island, NY, (7)Center for Student Accessibility, City University of New York, College of Staten Island, Staten Island, NY, (8)CUNY Graduate Center, Brooklyn, NY*

Background: Although more students with ASD are entering college (Van Bergeijk et al., 2008), they have lower graduation rates than students with other disabilities (Newman et al., 2011). Despite challenges (Van Hees et al., 2014), many undergraduates with ASD do not disclose their disability to obtain accommodations (Newman et al., 2011). A history of bullying may contribute to disclosure decisions. Youth with ASD often experience bullying (Schroeder et al., 2011) and those who are bullied have difficulties trusting others (Humphrey & Symes, 2010). Adolescents with ASD who negatively define themselves and their disabilities may do so due to negative feedback from others (Humphrey & Lewis, 2011). Although emerging evidence suggests that bullying may continue into college (Gelbar et al., 2014), little is known about the degree to which bullying affects undergraduates with ASD in particular.
Objectives: We examined identity formation in undergraduates with ASD and other disabilities by relating a novel measure of identity (6-word autobiographies) to past and current bullying experiences and disability disclosure. We explored how the valence of 6-word self-descriptions changed over time (past: 5 years before college, present, future: 5 years after college) in relation to bullying and disability.
Methods: Undergraduates with ASD (n=12) or other disabilities (OD; n=6) were asked to provide six terms describing their past, present, and future selves, and to answer questions about bullying, disclosure, and college-related challenges. Students completed the SRS-2 (Constantino & Gruber, 2012), Spielberger (1983) STAI, and Rosenberg (1965) Self-Esteem Scale. Interviews were coded for valence of self-descriptions, presence and type of bullying, disclosure decisions, and challenges.
Results: No differences in responses based on disability status (ASD vs. OD) were observed. Most students reported having been bullied (75% ASD; 100% OD), with chronic, repeated bullying common (50% ASD; 83% OD). Bullying at college was reported by 57% of students with ASD and 60% with OD. Most students voluntarily disclosed diagnoses during the interview (58% ASD; 83% OD). Most reported academic (92% ASD; 67% OD) and non-academic (67% ASD; 67% OD) challenges. Students self-descriptions shifted from more negative to more positive from past to present to future, $F(2,34)=27.307$, $p<.001$. The magnitude of this shift was greater among chronically bullied students, $F(2,32)=6.164$, $p=.005$, who described their past-selves more negatively ($p=.013$) and present-selves more positively ($p=.040$) than their peers. Students who were chronically bullied were more likely to label their disability ($p=.013$). Bullying was not associated with self-reported symptoms, anxiety or self-esteem.
Conclusions: Students' experiences of chronic bullying impacted their perceptions of past and current selves. Findings suggest that negative perceptions of past selves who were chronically bullied give way to more positive self-perceptions when bullying becomes reduced in college. Students who were chronically bullied may label their disability to increase others' understanding. Bullying and other challenges were similar across college students with ASD and students with others disabilities, suggesting that a universal-design approach might benefit students with ASD and other disabilities.

183 **181.183** Positive and Negative Experiences of Mothers with Autism

***A. L. Pohl**, S. K. Crockford, C. Allison and S. Baron-Cohen, Autism Research Centre, University of Cambridge, Cambridge, United Kingdom*

Background: There is little awareness of parenthood as an identity and social role for adults with autism. The sensory, cognitive, and social aspects of autism impact individuals throughout the lifespan, but the experience of parenting in mothers with autism has not been addressed. We therefore sought to explore this, both to highlight areas of strength and to uncover areas of vulnerability.

Objectives: To explore the experiences of mothers with autism in the following areas: (1) pregnancy, childbirth and the postpartum period, (2) self-perception of parenting strengths and weaknesses, (3) communication with professionals in relation to one's child, (4) social experience of motherhood, including disclosing one's diagnosis of autism in a parenting context, and (5) interactions with social services and the family courts in the UK.

Methods: We used a community-based participatory research model, and recruited an advisory panel of mothers with autism. We co-developed and disseminated an anonymous, online survey for mothers with autism. We recruited 325 mothers with autism, and, for comparison, 91 mothers who did not have autism, but had a child with autism.

Results: Mothers with autism and comparison mothers were similar in age and marital status. There were differences in education (X^2=15.301, p<0.01), gender identity (X^2=9.354, p<0.01), and age at first birth (t=2.3482, p=0.02) between the groups. Mothers with autism were more likely to have experienced pre- (X^2=13.772, p<0.01) or postnatal (X^2=7.4339, p=0.02) depression. Mothers with autism reported greater difficulties in areas of parenting such as multitasking (X^2=43.417, p<0.001), coping with domestic responsibilities (X^2=30.355, p<0.001), and creating social opportunities for their child (X^2=7.8881, p<0.01). Communicating with professionals about their child was stressful for mothers with autism. Mothers with autism were more likely to report feeling misunderstood by professionals (X^2=18.356, p<0.001), greater anxiety (X^2=32.751, p<0.001) and selective mutism (X^2=39.679, p<0.001), and not knowing which details were appropriate to share with professionals (X^2=36.752, p<0.001). Mothers with autism were more likely to find motherhood an isolating experience (X^2=4.8558, p=0.03), worry about others judging their parenting (X^2=12.001, p<0.001), and feel unable to turn to others for support in parenting (X^2=14.717,p<0.001). Mothers with autism and mothers of children with autism were equally likely to have had contact with social services in the UK, with similar outcomes. Disturbingly, approximately 1 in 5 mothers of a child with autism, regardless of maternal diagnosis, were assessed by social services; of those, 1 in 6 had their child compulsorily placed for adoption. Finally, rates of allegations and investigations of suspected fabricated illness amongst children with autism and their siblings were two orders of magnitude higher than the known incidence the UK.

Conclusions: Mothers with autism would benefit from far more and better tailored support. Allegations of fabricated illness, and high rates of surveillance by social services suggest there may be discrimination towards mothers with autism. The stigma associated with autism may be a barrier to accessing services. Further research should

consider the mental health implications of being a mother with autism. There is a clear need for more and better autism awareness within the UK.

184 **181.184** Post-Diagnosis Family Experiences in a Pre-Elementary Age Population

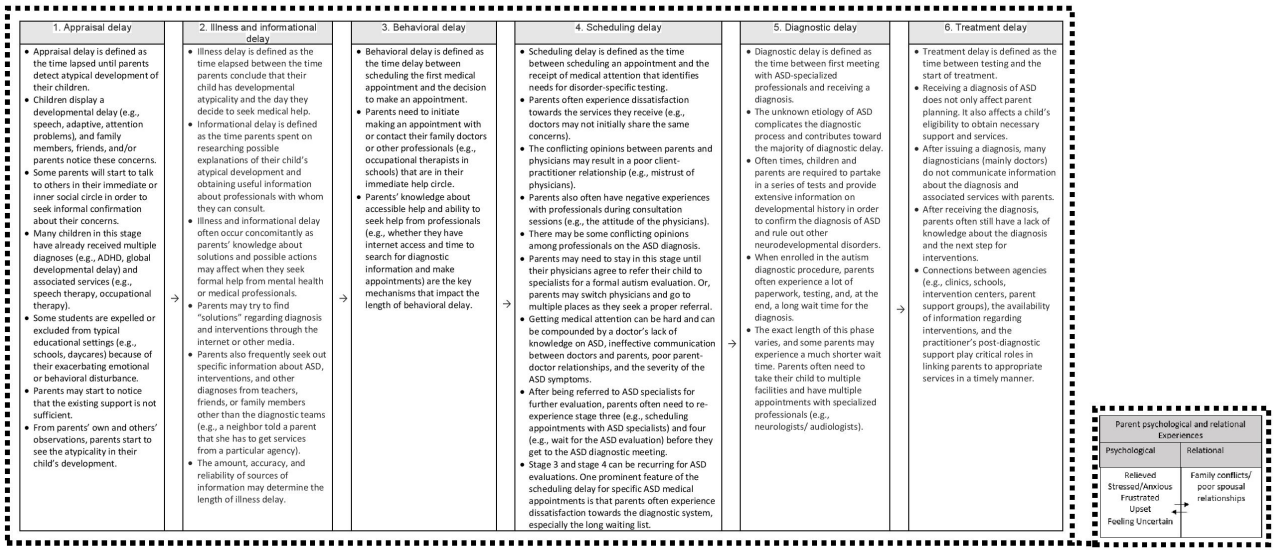
P. F. Turcotte[1], *L. J. Shea*[2], *G. Vivanti*[3] *and D. L. Robins*[4], *(1)A.J. Drexel Autism Institute, Cherry Hill, NJ, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)Olga Tennison Autism Research Centre, Melbourne, Australia, (4)Drexel University, Philadelphia, PA*

Background: Recognizing autism spectrum disorder (ASD) in children as early as possible is critical to putting in place proper supports and referral services. After a diagnosis, coordinating those services and navigating complex service systems has been shown to impact child development as well as family life.
Objectives: The objectives of this study are twofold: 1) Examine associations among socio-economic variables, and post-ASD diagnosis access to services, and 2) Determine how families' workforce participation is impacted following an ASD diagnosis.
Methods: Survey data from a statewide ASD-specific needs assessment was used for this study. Respondents included 279 parent/caregivers with a child with ASD who was pre-elementary school age. The survey included detailed questions on family experience before, during and after an ASD diagnosis. Chi-square tests of significance were conducted to determine differing distributions among variables of interest.
Results: Most (82.7%) respondents were White/Caucasian. Average age of the child was 4.5 years old and 80.3% were male. Over half (60.1%) of parents were college educated with a diverse range of household incomes in the sample; 31.4% earned less than $40 thousand, 32.6% earned $40-$79 thousand, and 36% earned $80 thousand or more. Most (72%) children were referred to Early Intervention services after receiving a diagnosis of ASD. Minority children were referred to Early Intervention at a significantly higher proportion (87.5% compared to 68.7% of White/Caucasian children, p = .008). Less than half (48%) of children who received an ASD diagnosis had a referral for a follow up appointment with their physician. There were no significant differences across major demographic variables (including race/ethnicity, parental education, and family income) in terms of referral to follow up appointments. After the ASD diagnosis, most families (82.1%) decreased work hours or stopped working outside the home. Preliminary analysis shows no significant difference in workforce participation after an ASD diagnosis among demographic variables.
Conclusions: The period of time following an ASD diagnosis is critical and has ramifications for long-term outcomes in children. Often, the ASD service system is complex and difficult to navigate for parents with newly diagnosed children. Our sample shows interesting distributions of post-diagnosis experience across demographic characteristics. Of note, children from minority populations were referred to Early Intervention (either private or state-funded) at a higher rate than Caucasian children. More examination is needed to investigate why individuals from minority backgrounds are using Early Intervention at a higher rate, and if non-minority populations are seeking other avenues of support. Further examination is also needed to determine the full effect of an ASD diagnosis on workforce participation, as the majority of our study sample had their workforce participation reduced for the respondent or their partner, which may impact quality of life for the family.

185 **181.185** Prediagnostic and Diagnostic Stages of Autism Spectrum Disorders: A Parent Perspective

W. H. Wong[1], *Y. Yu*[2], *J. H. McGrew*[2] *and L. A. Ruble*[1], *(1)University of Kentucky, Lexington, KY, (2)Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background:
Caring for a child with autism spectrum disorder (ASD) is stressful and tends to be particularly high during transition points, such as receiving the initial ASD diagnosis (Evan, 2010). However, there is little research examining the diagnostic process comprehensively (Braiden et al., 2010). Additionally, the existing literature about the diagnostic process suffers from four main problems; most studies (1) were small in scale, (2) were conducted in countries other than the United States (e.g., Abbott, Bernard, & Forge, 2012), (3) were retrospective (see Brogan & Knussen ,2003), often occurring years after the initial diagnosis; therefore, introducing potential biases in recall, and (4) used either exclusively qualitative or quantitative methods, which poses limitations on the depth and breadth of understanding the diagnostic stages when compared to mixed method designs (see Abbott et al., 2013).
Objectives:
To develop a model that attempts to give a detailed account of the sequence of events, experiences, and actions associated with the ASD diagnosis. It is hoped that this model will provide additional guidance to offer timely support to parents and improve the diagnostic experience for families of children with ASD.
Methods:
A mixed methods cross sectional design was used. Eighty caregivers of children with ASD who received an initial diagnosis within the past six months completed a set of measures regarding their diagnostic experiences.
Results:
Main Quantitative Results
The caregiver was most frequently reported to be the first person to suspect a problem with their child (69.2 %). In most cases (87.2%), language delay was the initial cause for parents' concerns. The mean time between first concern and diagnosis was 28.72 months (SD=27.12), however, more than 10% of parents experienced a lapse longer than 4 years. Length of diagnostic lag was unrelated to ASD severity (r = -.06, p >.05). On average, parents reported consulting with 3.33 (SD=1.26) professionals before receiving an ASD diagnosis. Pediatricians (55.13%) and psychologists (41.02%) were most frequently consulted. However, across professionals, pediatricians and general physicians were reported to be most likely to neglect early ASD symptoms and least likely to refer parents to appropriate professionals.
Main Qualitative Results
Grounded theory was used to analyze the qualitative responses with regard to parents' experience during the prediagnostic and diagnostic process. Six core themes were identified: "heightened awareness," "initial search," "dissatisfaction with medical or associated processionals," "long process/delay," "feeling uninformed," "parent psychological and relational experiences," and "diagnosis goals." When participant responses were viewed as a whole, a set of commonly experienced steps or stages emerged that seemed to characterize the process of obtaining a diagnosis.
Conclusions:
The authors adapted the patients' health seeking model by Andersen and Cacioppo (1995) to understand the present data. A six-stage model (i.e., appraisal delay, illness and information delay, behavioral delay, scheduling delay, diagnostic delay, and treatment delay) was developed to capture and understand the prediagnostic and diagnostic experiences of children with ASD and their parents. See Graph 1 for the model. Implications and potential interventions based on the six-stage model will be discussed in the presentation.



186 **181.186** Predictors of Somatic Problems in Parents of Adolescents and Young Adults with Autism

M. Uljarevic[1]*, R. Y. Cai*[2] *and A. L. Richdale*[2]*, (1)Bundora Campus, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, Melbourne, Australia*

Background:
Parenting a child with autism is a situation of chronic stress for some parents. The negative effects of chronic stress on mental health of this group of parents is well established, however, little is known how chronic stress affects the somatic health in parents. The few studies that have looked at this issue have reported that parents experience high levels of health problems.
Studies have begun to identify pattern of individual and environmental differences that might make parents more susceptible to the negative psychological effects of chronic stress. However, factors that might put parents at increased risk for developing somatic problems are currently unknown.
It has been suggested that factors of intolerance of uncertainty, avoidant emotion regulation styles, lower mindfulness and social support increase the risk for both the mental and somatic health consequences of stressors because they can prolong stress-related affective and physiological activation, both in advance and following stressors. An additional factor that might be associated with somatic health problems in parents of children with autism is the presence of broader autism phenotype traits.
Objectives:
To identify factors associated with somatic problems in parents of individuals with autism.
Methods:
Fifty one parents of adolescents and young adults with autism (M_{age}= 50.19 years, SD_{age}= 5.78; 47 females) completed questionnaires assessing somatic health (COMPASS-31), anxiety (Cross-D), depression (PHQ-9), autistic traits (AQ), emotion regulation (ERQ), mindfulness (MAAS), social support (SSQ-6), and intolerance of uncertainty (IOU-12). This study forms part of the Australian Autism CRC longitudinal study of school leavers; recruitment is ongoing.
Results:
Variables significantly associated with the CASS-31 total score were entered into the hierarchical regression model (CROSS-D, r= .46, p= .001; PHQ-9, r= .47, p=.001; MAAS, r= -.54, p<.001; SSQ-6, r= -.55, p<.001; AQ, r= .28, p= .048; IOU-12, r= .33, p= .019). Parental traits were entered in the first step, with MAAS being independent significant predictor (t = 3.46, p = .001, β = .463) but AQ (t= .994, p = .326, β = .146) and IOU-12 (t= .423, p = .674, β = .065) not. MAAS stayed as an independent significant predictor (t= 2.92, p = .005, β = .369) after the SSQ-6 Satisfaction score was entered in the next step with SSQ also being unique predictor (t= 3.14, p = .003, β = .382). Finally, DSM-5 DAS and PHQ-9 were entered in the final step in order to control for the effects of anxiety and depression. The final model accounted for 35.5% of variance, with MAAS and SSQ-6 Satisfaction as unique predictors (t = 2.506, p = .016, β = .360 and t = 2.86, p = .007, β = .377 respectively) of CASS-31 total scores.
Conclusions:
Our study identified lower mindfulness and lower levels of social support as potential contributing factors to poor somatic health in parents of individuals with autism. Identifying such factors is a crucial first step in developing intervention programmes to provide support for parents.

187 **181.187** Problematic Mealtime Behaviors Identified in Chinese American Children with ASD

H. L. Gray *and H. M. Chiang, Teachers College Columbia University, New York, NY*

Background: Up to 89% of children with ASD have been reported to have some type of eating problems which can include limited food variety, food neophobia, rigid routines around mealtimes in the form of using the same utensils or dishes, food refusal, and difficulties with texture. Research is needed to better understand feeding difficulties in diverse population to improve intervention strategies and parent education programs tailored to particular culture and context.
Objectives: To assess parents' perceived mealtime behaviors of their children with ASD, particularly in Chinese American population resided in New York City.
Methods: Thirty one Chinese American parents who enrolled in a parent education program participated in the Brief Autism Mealtime Behavior Inventory (BAMBI) questionnaire. The BAMBI is a validated assessment tool with 18 items asking mealtime behaviors typically displayed in children with ASD. The questionnaire was provided both in English and Chinese languages to accommodate participants' needs. Response options were 5-point Likert-type answers (Never to almost every meal). In addition, parents were asked to identify whether or not each item was a problem for their family. Descriptive statistics and correlation coefficients were calculated, using SPSS statistical software. Higher scores represent more problematic mealtime behaviors.
Results: The following describes mean score for each mealtime behavior category: "prefers crunchy foods"=3.8 (SD 1.1), "unable to remain seated"=3.3 (SD 1.4), "eating only soft foods"=2.8 (SD 1.3), "limited variety"=2.8 (SD 1.3), "selective eating"=2.8 (SD 1.1), "inflexible mealtime"=2.6 (SD 1.4), "prepared in a particular way"=2.3 (SD1.2), "food refusal"=1.9 (SD 0.8), "aggressive behaviors"=1.3 (SD 0.5) on a 5-point scale. Top 5 behaviors identified as a problem by Chinese American parents were: (1) 54%, only prefers "crunchy" foods (e.g. snacks, crackers); (2) 48%, not willing to try new foods; (3) 46%, does not remain seated at the table until the meal is finished, (4) 44%, dislikes certain foods and won't eat them, and (5) 39%, does not accept or prefer a variety of foods. There was a significant association between food refusal and aggressive behaviors at mealtime (r=0.7; p<0.01).
Conclusions: To our knowledge, this is the first study examining Chinese American parents' perceived mealtime behaviors of their children with autism. Chinese Americans often eat differently than typical Americans do. Our findings may aid in developing appropriate intervention strategies and educational resources tailored to Chinese American population and have implications for other ethnic groups.

188 **181.188** Quality of Life in Families with a Transition Aged Young Adult on the Autism Spectrum from the Perspective of Adult Sisters

L. A. Crabtree[1] *and* ***B. B. Demchick***[2]*, (1)Towson University, Lutherville, MD, (2)Towson University, Towson, MD*

Background: Characteristics of Autism Spectrum Disorder (ASD) present unique challenges to families. Raising children with ASD is energy intensive and may necessitate a revision of familial roles and productivity. Transitioning to adulthood is particularly challenging for those with ASD and their families, as family members are often faced with increased caretaking demands (Graetz, 2010). This impacts family quality of life (FQOL), or the dynamic sense of well- being of the family. Research suggests that quality of life (QOL) of siblings is affected by a brother or sister with ASD, yet findings are inconsistent. Some studies suggest that typical siblings have restricted family interactions and reduced support; others find a high level of resilience. Discrepancies may be attributed to factors of severity of ASD, gender of the typical sibling, and age or number of siblings (Howlin et al., 2014).
Objectives: The purpose of this qualitative phenomenological study was to explore FQOL in families with a young adult severely impacted by autism from the perspective of adult sisters. Researchers planned to examine all siblings, however only sisters responded to requests for interviews, which may point to differences between brothers and sisters. Research questions were:
How do sisters describe their quality of life (past, present, and future)?
How do sisters describe experiences growing up?
How have services and supports for a sibling with ASD affected their family quality of life?
How have sisters' roles and occupations been impacted by a sibling with autism?
Methods: Participants were eleven sisters of young adults with ASD, recruited from families who had participated in previous phases of research on FQOL (Demchick, Eskow, & Crabtree, 2014). Sisters aged 18 -30, participated in a 1-2 hour semi-structured interview which was recorded and transcribed with permission and a second phone interview to confirm findings. Transcripts were coded by two investigators to ensure trustworthiness. Atlas.ti, was used to manage data. Important statements that provided an understanding of how the participants experienced the phenomenon were extracted from transcripts. Data were organized into meaningful clusters, and initial codes were formed. Researchers approached the data with an open attitude to allow meanings to emerge. Clusters of meaning were tied together into themes.
Results: Four themes were identified. 1) Characteristics of autism impact sisters' experiences and quality of life. 2) Limited supports restrict participation of those with ASD as well as that of the sisters. 3) A sibling with autism positively affects the sisters' personal attributes and occupations. 4) As parents age, all sisters plan to assume some caregiving responsibility for their sibling with ASD. Additionally, the sisters from families of more than two children reported that sisters assume far more responsibility for the sibling with ASD than brothers did.
Conclusions: Most sisters of individuals with ASD perceive their FQOL as positive, but suggested that more supports and services for themselves and their siblings with ASD, especially during puberty and the transition process, would benefit their overall participation and QOL. Results emphasize the importance of supports and services in meeting family needs.

189 **181.189** Reliability of Parent and Teacher Perspectives on Child Functioning in a Large Urban Sample of Children with ASD

K. S. Dickson[1], *A. C. Stahmer*[2], *S. R. Rieth*[3] *and J. Suhrheinrich*[4], *(1)Psychiatry, UCSD, San Diego, CA, (2)University of California at Davis MIND Institute, Sacramento, CA, (3)San Diego State University, San Diego, CA, (4)University of California San Diego, La Jolla, CA*

Background:
Cross-informant ratings are considered best clinical practice when assessing child functioning. However, data overwhelmingly support significant variability in ratings across informants. While the majority of this research has focused on typically developing children, recent work examining cross-rater agreement in ratings for children with ASD has found similar variability in ratings of functioning (Stratis & Lecavalier, 2014). The majority of this work has focused on emotional and behavioral problems; little work to date has examined parent/teacher ratings of children's functioning more broadly, especially within a large-scale, diverse sample.
Objectives:
The purpose of this study is to systematically evaluate agreement between parent and teacher ratings of child functioning using standardized rating scale assessments.
Methods:
Participants in the current sample were part of a large study examining the effectiveness of a naturalistic behavioral intervention in school settings. Participants included 289 children, 3-11yrs old (M = 4.08, SD =3.21) who were served for ASD in public school programs. Participant measures were collected in the beginning and end of the school year. Parents and teachers of participating children completed the Vineland Adaptive Behavior Scales- II (VABS) and Pervasive Developmental Disorder Behavioral Inventory (PDDBI) at each time point.
Results:
Cohen's kappa was used as a measurement of agreement between teachers and parents. Overall, data indicate only slight agreement between teacher and parent ratings across domains of each assessment, with Kappa's ranging from .03 to .10. On the PDDBI, there was agreement on 33.3% of domains at both the beginning and end of the school year. On the VABS, agreement was higher at the beginning (43.7%) compared to the end (37.5%) of the school year. Parent and teacher ratings were significantly reliable ($p < .04$) on 18.8% of VABS domains and 20% of PDDBI domains at both time points. When specifically considering these domains, three domains (PDDBI Expressive Language and Expressive Social Communication Abilities Composite and VABS Written) showed improved parent/teacher agreement from Fall to Spring. In contrast, three domains (PDDBI Semantic/Pragmatic Problems and VABS Play and Leisure skills and Fine Motor skills) showed declines in agreement from Fall to Spring. Potential moderating variables will be discussed.
Conclusions:
The reliability in parent and teacher ratings of various domains of children's functioning is highly variable. Data suggest only slight agreement between raters as well as an inconsistent pattern of change in agreement over time. Overall, these results support the larger literature demonstrating variability in cross-informant ratings of children's behavior. The significant variability in teacher and parents' ratings of functioning for children with ASD seen here warrants further exploration.

190 **181.190** Technology Use By Adolescents with Autism: It's Not Just for Playing Video Games and Watching Animated Movies

S. Hedges, *UNC Chapel Hill, Chapel Hill, NC*

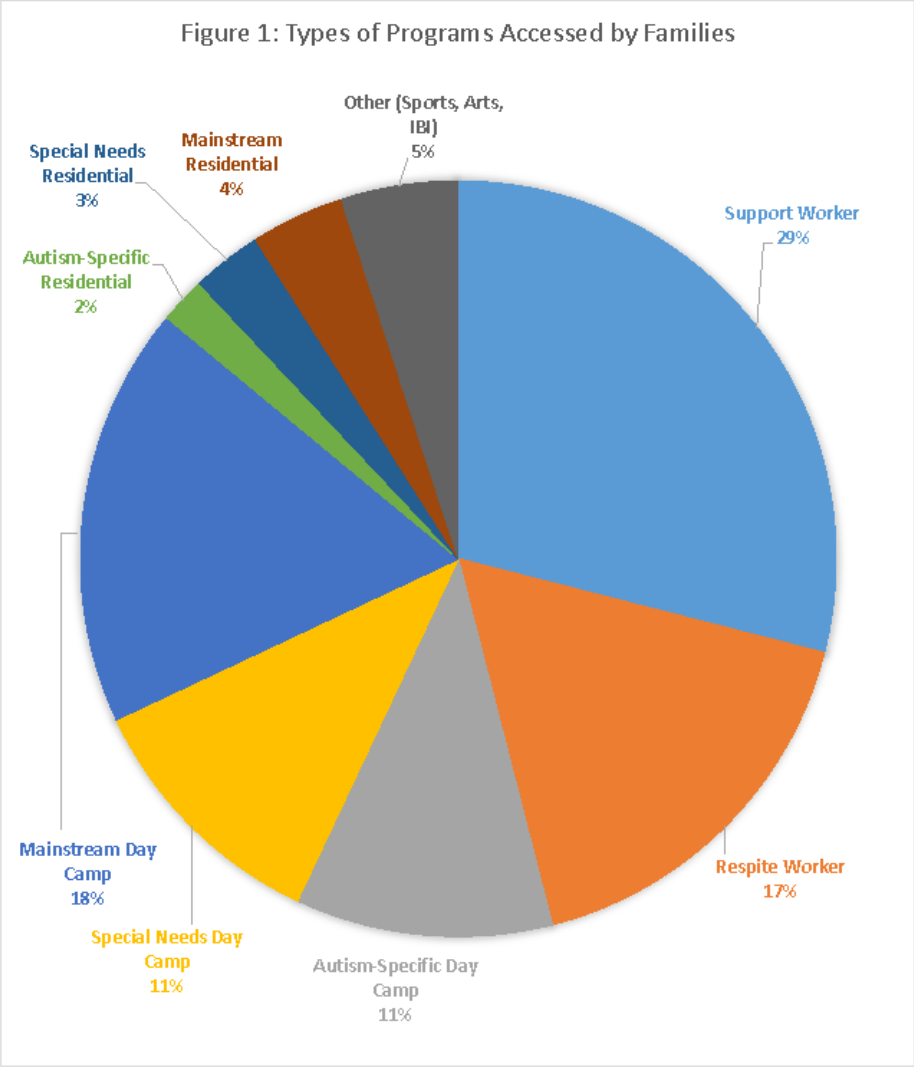
Background: New technologies have the potential to lead to novel, more efficient, and cost effective supports that may enhance quality of life for individuals with autism and their families. Research has shown that many individuals with autism have an affinity to screen-based technology and use it widely for recreation (e.g. to watch videos and play video games). However, the use of technology as a support by students with autism remains largely unexplored.
Objectives: To describe the forms of technology used by high school students with autism and for what purpose. To gain insights into student perceptions of the benefits of technology use as well as possible barriers to use in the school context.
Methods: Paper surveys were given to 174 high school students with autism across three states in the U.S. (North Carolina, Wisconsin, California). Follow-up qualitative interviews were conducted by email with 15 survey respondents to gain deeper insights into their perspectives.
Results: The majority of respondents (84%) bring internet capable technology with them to school each day and actively use technology to learn, stay organized, and to enhance their communication and social interactions. For example, they use technology to look things up on the internet (98%), to make presentations (88%), and to collaborate with other students on assignments (64%). But more than half indicated they are not permitted to use technology in all classes and 57% said that technology can be a distraction. Some students shared their strategies to reduce the distraction factor. The majority (82%) use technology to communicate with friends and roughly half indicated they use technology to socialize because it makes it easier to locate people with similar interests. Surprisingly, respondents prefered texting (69%) to email (64%) and the majority are active on a variety of social media websites. Not surprising, the majority (97%) believe they are good at using technology and 68% want to study a technology related subject in college. While only 30% had taken an online course, 55% of respondents said they would like to take one in the future. 78 participants wrote in specific apps and technology tools they use for support throughout the day including apps to help them handle stress and to sleep.
Conclusions: Many teens with autism are carrying powerful technology tools with them to school each day with the potential to ameliorate or bypass many of the deficits associated with autism. These tools are helping some of them to learn, stay organized, to communicate, and to find friends. Opportunities exist for researchers, practitioners and families to encourage and enhance technology use as a support tool.

191 **181.191** The Impact of March Break and Summer Program Funding on the Stress of Caregivers of Children with Autism

J. M. Bebko[1], *C. A. McMorris*[1], *B. L. Ncube*[1], *O. M. Jon*[2], *J. H. Schroeder*[1], *G. Kontosic*[3], *L. Verbeek*[3] *and M. Spoelstra*[3], *(1)York University, Toronto, ON, Canada, (2)McMaster University, Hamilton, ON, Canada, (3)Autism Ontario, Toronto, ON, Canada*

Background: Those raising children with Autism Spectrum Disorders (ASDs) face unique challenges, with the severity of symptomatology varying within a wide range of behavioral, communication and social skill levels. Consequently, research indicates that parents of children with ASDs report higher levels of stress than parents of those with other developmental disabilities or parents of typically developing children (Estes et al., 2009; Weiss et al., 2012). Support programming such as respite service are often cited as major factors that aid to reduce parental stress (Cowen, & Reed, 2002); however, the financial burdens placed on families seeking such services can be overwhelming. Autism Ontario is a service provider and family advocacy centre for individuals and families affected by ASD in Ontario, Canada. In addition to other services, Autism Ontario offers families the opportunity to apply for funding that can subsidize children to attend external programs during March and summer breaks.
Objectives: The goal of the present study was to examine the impact of funding for ASD support programming and its perceived effect on parental stress levels. Additionally, this study will explore how funding was utilized by families, what programs children participated in, what skills were obtained by children with ASD, and most importantly, how these factors relate to parent's levels of stress.
Methods: An online survey was circulated to parents who had applied for March or Summer Break program funding from 2007-2011. A total of 695 caregivers of children with

ASD completed the survey, 477 of whom indicated they had received either March or Summer break funding at least once during the 2007-2011 period. The survey obtained feedback related to basic demographic information, languages spoken by the families, years of Canadian residence, whether parents felt a reduction in stress, and how funding impacted their decision to enroll children in camps or seek respite help. Parents were also asked to describe the type of program in which their child participated (e.g., mainstream day or residential camps, autism-specific camps) as well as the length of time spent in each program. Respondents were asked if their child had made observable improvements in areas such as self-regulation, aggression, stereotypical behavior, improved communication, and social interaction.
Results: Support workers accounted for over 25% of funding expenditure with 50% of families placing their child in programs lasting 5-7days. Importantly, 31% of respondents stated they would not have been able to take advantage of support programs without subsidization. Approximately 78% of caregivers reported a significant decline in stress from their child's program participation. Finally, results revealed a wide-spread improvement for ASD children in social skills and increased interaction with others.
Conclusions: The current findings highlight that the funding provided by agencies, such as Autism Ontario, offer a critical financial opportunity to those families who would not otherwise be able to afford these support services. Access to supplemental programming, such as residential and day camps, is reported to have significantly benefitted families and their children with ASD, shown by an improvement in skills and significant reduction in parent's stress.



192 **181.192** The Influence of Ethnic Culture on Profiles of Stress and Coping in Caregivers of Children with Autism Spectrum Disorder

T. V. Williams[1], *K. Hartmann*[2] *and M. Urbano*[2], *(1)Virginia Consortium Program in Clinical Psychology, Norfolk, VA, (2)Eastern Virginia Medical School, Norfolk, VA*

Background: High parental stress is associated with parental depression, anxiety, and use of harsh parenting techniques. The impact of parental stress is magnified for a child with a diagnosis of ASD. African American families traditionally face additional stressors including structural racism, discrimination, fewer financial resources, and single parent homes. The literature suggests that African American families rely on more varied coping styles to manage the burden of additional stressors. Coping styles are likely influenced by individual acculturation to native culture versus the Euro-American majority culture in the United States.
Objectives: The present study intends to add to the literature by exploring African American caregivers' experiences when caring for a child with ASD in comparison to their

ethnic majority counterparts. This research compares the stress and coping profiles of three cultural groups: Caucasian caregivers, African American caregivers that are more acculturated with the majority culture, and African American caregivers that ascribe to more traditional African American cultural beliefs.
Methods: We are aiming to collect responses from a minimum of 100 caregivers of children with ASD. Data collection is ongoing with 41 completed participants at the time of abstract submission. Caregivers were asked to complete a series of questionnaires in an online survey. The measures include: a demographic questionnaire, a measure to confirm the presence of ASD symptomology (Autism Spectrum Rating Scale), five measures related to parental stress and coping (Parenting Stress Index, Autism Parenting Stress Index, The Proactive Coping Inventory, Coping Strategies Inventory, Brief RCOPE), and a measure of acculturation to African American culture (The African American Acculturation Scale- Revised). Participants completed the survey online and were provided with an electronic gift card for participation.
Results: Hierarchical Discriminant Function Analysis (DFA) will be used to predict group membership using variables of interest from the coping and stress measures. Demographic information will allow us to control for differences due to socioeconomic status. The initial DFA will determine if there are significant differences between the three racial groups on stress and coping variables. The DFA will also determine if the model reliably predicts membership to a given racial group based off of the predictor variables. The DFA will be followed up with canonical functions to determine which variables account for the biggest differences among the three groups.
Conclusions: We anticipate that of the three groups, Caucasian families will report experiencing the most stress, followed by highly acculturated African American families. In line with the literature suggesting that traditional African American families learn more coping styles because of additional exposure to stress, it is anticipated that less acculturated African American caregivers will report the most frequent use of a variety of coping behaviors. This study will supply mental health providers with a window into understanding how racial minority caregivers' perceptions and needs differ from that of racial majority populations, and how services may be best tailored to work within a caregivers' cultural framework.

193 **181.193** The Longitudinal Impact of Marital Adjustment and Social Support on Stress in Primary Caregivers of Children with ASD

Y. Yu *and J. H. McGrew, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background: Caregivers of children with ASD report higher levels of stress and lower levels of marital adjustment (e.g., Benson & Kersh, 2011; Freeman et al., 2011; Risdal & Singer, 2004). Increased social support, a stress buffer, may moderate these impacts and has been consistently related to decreased negative outcomes for caregivers of children with ASD and their families (e.g., Stuart & McGrew, 2009). Social support can be both general and specific to the stressor. For example, received support from ASD providers and the ASD community has been associated with decreased stress in parents of children with ASD following diagnosis (Stuart & McGrew, 2009). Another critical social resource is the relationship with one's spouse or significant other. Both cross-sectional and longitudinal analyses have shown that marital adjustment can buffer stress of having a child with ASD (e.g., Kersh et al., 2006). Moreover, social support accumulates, that is, caregivers receive support from various resources (e.g., general social support from families and friends, contextual social support from the ASD providers and community, marital support), and these resources may compensate for each other or interact in their impact on caregiver outcomes.
Objectives: The current study examined the cross-sectional and longitudinal relationships among general and contextual social support, marital adjustment, and outcomes in primary caregivers of children with ASD shortly after receiving the diagnosis. Specifically, we examined whether there is a compensatory or additive mechanism among sources of social support in their impact on caregiver outcomes.
Methods: Primary caregivers of children diagnosed with ASD within the past six months (N = 79) were first recruited at baseline and again 12 months later (N = 65). Participants were assessed on caregiver outcomes using predictors within the double ABCX model (McCubbin & Patterson, 1983), e.g., life demands, social support, marital adjustment.
Results: At baseline, marital adjustment correlated with caregiver burden (r =-.56, p<.001), family burden (r =-.48, p<.001), and mental health-related quality of life (r = .25, p =.04). Multivariately, marital adjustment (*Beta* = -.26, p = .02) and general social support (*Beta* = -.46, p<.001) predicted baseline caregiver stress, R^2 = .59, F (6, 58) = 13.69, p<.001; life demands (*Beta* = .33, p = .005) and general social support (*Beta* = -.33, p = .012) predicted family burden, R^2 = .51, F (6, 58) = 10.19, p< .001. Longitudinally, controlling for baseline caregiver outcomes, as well as parent, family, and child factors at baseline and changes in those variables, the results showed that interactions between contextual social support from the ASD community and providers and marital adjustment (*Beta* =-.32, p = .024) predicted caregiver stress at follow-up, R^2 =.74, F (20, 58)= 8.38, p< .001.
Conclusions: An additive model was supported. When caregivers perceive low contextual social supports from the ASD community and ASD providers, the level of their marital adjustment does not impact their long term caregiver stress level; however, when they perceive high levels of contextual social support, better marital adjustment predicted decreased stress long term.

194 **181.194** The Relationship Between Pain and Problem Behavior in Predicting Parent Stress in Families of Children with Autism

C. E. Walsh[1] *and M. Tudor*[2]*, (1)University of Colorado Denver, Denver, CO, (2)Stony Brook University, East Setauket, NY*

Background: Studies have shown that children with ASD have increased severity and incidence of pain symptoms compared to typically developing children and children with other disorders (Herbert, 2005). Pain has also been shown to act as a setting event for problem behavior in children with autism spectrum disorder (ASD) and is one of the strongest predictors of parent stress. Parents of children with ASD who also experience physical illness tend to be more intensely involved in their caregiver role and are also more likely to experience stress (Krulik et al., 1999). Further, children with ASD may have difficulty communicating pain symptoms and are more likely to exhibit challenging behavior when sick (Carr & Blakeley-Smith, 2006). Currently, the relationship between child pain symptoms, problem behavior, and parent stress is unknown in parents of children with ASD; however, it is important to better understand this relationship in order to further address these issues in treatments for challenging behavior. **Objectives:** (1) To examine the relationship between pain symptoms, parent stress, and problem behavior; and (2) To determine the role of parenting style in the relationship between pain symptoms, problem behavior, and parent stress. **Methods:** Participants included 148 parents of children with ASD who were recruited from a Northeast local chapter of the Autism Society of America. Parents completed standardized self-report measures of pain symptoms, problem behavior, parent stress, and parent coping style They were compensated with a $20 Amazon.com gift card. **Results**: Multiple regression analyses indicated that child pain was significantly positively related to parent stress for those children with high problem behavior, r(99) = .403, p < .001, whereas it was not significantly related to parent stress for children with low problem behavior, r(33) = .04, p = .53. There was a significant interaction between pain symptoms and parent protectiveness to predict parent stress, t(128) = 2.62, p = .01 (β = .23). There was a significant, negative correlation between parent protectiveness and parent stress when child pain was low, r(99) = -.25, p = .05, and a significant, positive correlation when child pain was high, r(33) = .29, p = .02. **Conclusions:** Results showed that problem behavior was a moderating factor between pain and parent stress and there was a significant interaction between pain and problem behavior predicting stress. Pain could be functioning as a setting event such that when pain is present it might increase the likelihood that problem behavior will occur. An overprotective parenting style also moderated the relationship between pain and parent stress. This suggests that parents who respond to their child's pain by reducing demands or by increasing attention to the child's pain might be exacerbating the behavior problems and thus increasing parent stress. From a systems perspective it is important to acknowledge various factors that maintain a child's behavior and also produce parent stress. The novel model presented here indicates the importance of providing interventions that involve families with a main goal of increasing quality of life for the family.

195 **181.195** The Relationship Between the Behavioral Symptomology of Children with Autism Spectrum Disorder and Their Siblings' Psychological Functioning

E. A. Roth[1]*, G. M. Kuravackel*[2] *and D. Wohlfarth*[1]*, (1)School of Professional Psychology, Spalding University, Louisville, KY, (2)Pediatrics, University of Louisville School of Medicine, Louisville, KY*

Background: Some research has demonstrated that siblings of children with ASD are not at an increased risk of developing internalizing and externalizing behaviors (Dempsey et al., 2012; Macks & Reeve, 2007). Other research has shown detrimental effects on this population's behavior, psychological functioning, and quality of life (QOL) (Hastings, 2003; Ross & Cuskelly, 2006; Verte et al, 2003). Some researchers have found an increase in anxiety rates among this population (Orsmond & Seltzer, 2009; Pollard et al., 2013), while other researchers have not found similar results (Shivers et al., 2013). Previous research has assessed the relationship between the diagnosed child's behavioral symptomology and the participating family and sibling's psychological well-being (Hartley et al., 2012; Hastings, 2007; McStay et al., 2014; Freedman et al., 2012, Seltzer et al., 2009).
Objectives: The purpose of this study is to further investigate the psychological development of siblings of children with ASD. Little research has been conducted on siblings of children with ASD, and of the research that exists, conflicting evidence is present as to the psychological well-being of siblings of children with ASD. Of specific interest in this study will be the presence of anxiety symptoms and QOL. The relationship among the diagnosed child's behavioral symptomology and the participant's anxiety level, QOL, and psychological functioning will be the primary focus of this study. Additionally, this study will look at the relationship between multiple demographic characteristics in comparison to the presence of anxiety symptoms, QOL and psychological functioning. It is important to understand the significant relationship between any demographical variables and the presence of anxiety, psychological health, and QOL.
Methods: This specific poster presentation will look at the relationship between the child with ASD's behavioral symptomology (as measured by the Aberrant Behavior Checklist [ABC]) and the participant's psychological functioning (as measured by the Achenbach Child Behavior Checklist [CBCL]), anxiety (as measured by the Screen for Childhood Anxiety Related Emotional Disorders [SCARED]), and quality of life (as measured by the KINDL). Initial data collection has begun at a local Autism Center and will be completed, along with comprehensive analyses, prior to the IMFAR International Meeting.
Results: Multiple chi-square analyses will demonstrate relationships between the diagnosed child's behavioral symptomology and the participant's psychological functioning, specifically, anxiety and quality of life. Results are expected to continue to exhibit that the more serious a siblings' behavioral symptoms are, the more likely the participant will have increased anxiety and lower psychological functioning and quality of life.

Conclusions: The effects of a diagnosed child's behavioral symptomology is expected to have a detrimental effect on the participating sibling's psychological functioning, anxiety, and quality of life.

196 **181.196** The Role of Grandparents in the Identification of a Grandchild's Autism Spectrum Disorder and the Information Sources They Utilize

J. Hillman[1], *A. R. Marvin*[2], *J. K. Law*[3] *and C. Anderson*[4], *(1)Applied Psychology, Penn State Berks College, Reading, PA, (2)Kennedy Krieger Institute, Baltimore, MD, (3)Interactive Autism Network, Baltimore, MD, (4)Department of Interprofessional Health Studies, Towson University, Towson, MD*

Background: Early diagnosis and intervention is essential for children with Autism Spectrum Disorder (ASD). Although previous research suggests that grandparents often play a role in helping families cope with having a child with ASD, little is known about the role that grandparents may play in recognizing the condition itself. It also remains unclear what informational resources grandparents use to learn about ASD.
Objectives: The goal of the study was to examine the extent to which grandparents played a role in the recognition of a grandchild's ASD, and to ascertain factors associated with such recognition. A secondary goal was to identify what resources grandparents turned to for ASD information. Such knowledge may help foster early diagnosis and guide professionals in the development of educational materials.
Methods: Grandparents were recruited through web or email-based announcements from the Kennedy Krieger Institute's Interactive Autism Network (IAN) Research project, the Autism Speaks Foundation, the Grandparent Autism Network, and the American Association of Retired People (AARP). Participants participated anonymously in an online survey designed to be completed in approximately 30 minutes. Participants were required to live in the U.S. or its territories, and to have at least one grandchild with an ASD. The grandchild had to be the biological, adoptive, or stepchild of the respondent's biological or adopted son, stepson, daughter, or stepdaughter.
Results: A total of 1881 participants completed the online survey, including 1534 grandmothers (81.6%) and 347 grandfathers (18.4%), who also identified as maternal (63.4%) or paternal (35.6%) grandparents.
More than 75% of grandparents indicated that they had played a role in identifying their grandchild's ASD, with 27.5% "independently raised concerns about [their grandchild's] development" and 48.2% "supporting others who raised concerns." A binomial regression analysis (X^2=207.76, p<.001, Nagelkerke R^2=.18) revealed that middle-aged, working grandmothers who lived within 25 miles of their grandchild were significantly more likely to play a role in ASD identification; grandparental lineage (maternal vs. paternal), education level, and urbanicity were unrelated. The younger the age that grandparents reported that they first worried about their grandchild's development (x=2.08 years, sd=1.95), the younger the age that their grandchild first received an ASD diagnosis, (x=3.10 years, sd=2.12), r=.43, p<.001.
Grandparents turned to their son or daughter (80.7%), their son- or daughter-in-law (30.9%), autism therapy providers (e.g., speech, OT, ABA; 35.3%), school personnel (28.5%), medical professionals (20.7%), mental health providers (e.g., psychologists; 12.2%), and advocacy or government organizations such as Autism Speaks (72.5%), the Autism Society of America (24.2%), the Centers for Disease Control or National Institutes of Health (8.9%) for ASD information.
Conclusions: The majority of grandparents played a role in identifying their grandchild's ASD. More than one quarter were the first to raise concerns about a grandchild's development. Encouraging professionals to include grandparents in the diagnostic process, particularly middle-aged grandmothers who live within 25 miles of their grandchild, may offer benefits for the early detection of ASD. Professionals and organizations can also be encouraged to target materials specifically for grandparents.

197 **181.197** Understanding Health Care Disparities Among Families of Children with ASD: The Role of Advocacy, Empowerment, and Parent-Professional Relationships

K. A. Casagrande *and B. Ingersoll, Michigan State University, East Lansing, MI*

Background: Children with ASD have complex service needs due to a unique combination of core symptoms and comorbid conditions that affect child and family functioning. Consequently, these families utilize a greater number of services than families of children with other special healthcare needs. However, they also report more unmet service needs and less satisfaction with the services they receive. These disparities are even more pronounced in low-SES families. This may be due in part to the factors that support access to services, such as parental advocacy, parent empowerment, and parent-professional partnerships, which may differ across high and low SES families.
Objectives: This analysis will address two questions: 1) what might explain differences in service adequacy based on family SES; and 2) who is likely to advocate for services if their needs are not met.
Methods: Parents of children with ASD (n=248; M=9.9 years old) completed a 30-minute anonymous survey. The survey included a demographics questionnaire, services inventory, Autism Behavior Checklist, Family Empowerment Scale, Family-Professional Partnership Scale, and an advocacy questionnaire designed for this study. Recruitment utilized both online and in-person data collection strategies in an effort to maximize the diversity of the sample. Parent education (college degree vs. no college degree) was used as a proxy for SES.
Results: An independent samples t-test demonstrated that higher SES families (M=.48, SD=.29) were more likely to perceive their services as adequate than lower SES families (M=.35, SD=.22), t(246)=-3.70, p<.001. Parent empowerment, parent-professional partnerships, and parent advocacy were examined as potential mediators of this relationship. Controlling for child's age and level of severity, parent-professional partnership was a significant mediator of the effect between SES and service adequacy (Sobel test: z=2.81, se=.017, p<.005).
To examine potential predictors of parent advocacy, multiple regression was used. Child severity (β=-.157; p=.018), service adequacy (β=-.170; p=.017), and parent empowerment (β=.229; p=.001) were each independent predictors of parent advocacy. Controlling for child severity, a moderated regression found that service adequacy and parent empowerment interacted to predict parent advocacy, (ΔR^2=.013, $F\Delta$(1,243)=3.706, p=.055), such that parents who experienced a low level of service adequacy and high level of parent empowerment were most likely to advocate for their child.
Conclusions: As families have a finite amount of time, energy, and resources, it is important to understand how they can most effectively navigate the service system. Results suggest that parent-professional partnerships may be an important factor that explains some of the disparities in service adequacy for lower-SES families. Additionally, for those families who do not receive adequate services, empowerment may be an important component in making the decision to advocate. Strategies aimed at reducing disparities in service adequacy for lower-SES families of children with ASD should consider methods for improving parent-professional partnerships and increasing parent empowerment. It will be important to expand the study in order to determine if the trending results reach significance in a more diverse sample.

198 **181.198** Understanding Oral Care Challenges in Children with Autism Spectrum Disorder: A Mixed Methods Study

L. I. Stein[1], *B. F. Henwood*[2], *R. N. Bluthenthal*[3], *J. C. Polido*[4] *and S. A. Cermak*[1], *(1)Occupational Science & Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Social Work, University of Southern California, Los Angeles, CA, (3)Preventive Medicine, University of Southern California, Los Angeles, CA, (4)Dentistry, Children's Hospital Los Angeles, Los Angeles, CA*

Background: It is well established that oral care is an important component of pediatric healthcare. However, children with autism spectrum disorder (ASD) and other developmental disabilities are at risk for poorer oral health and quality care.
Objectives: It is essential to identify and understand the barriers to quality oral care experienced by children with ASD and their caregivers. This mixed methods sequential explanatory study, the first on this topic to incorporate qualitative methods, will enable us to better understand how families of children with ASD experience oral care in the dental office.
Methods: Focusing on caregivers of children 5-10 years with ASD (n=106), quantitative methods using a 37-item survey were used to identify the types and degree of oral care challenges that affect children with ASD. Survey data were analyzed descriptively. Surveys were followed by qualitative methods to provide a more in-depth understanding of challenges. Two focus groups of parents of children with ASD 5-10 years lasting 2.5-3 hrs in duration each were conducted (n=9 participants total). Qualitative data were analyzed using a template coding approach based on the three domains of office-based oral care challenges covered in the survey.
Results: In the quantitative phase, parent respondents reported difficulties with access to care (37%) and that dentists had inadequate training to work with children with special healthcare needs (58%). Over 50% of parents reported that sensory sensitivities increased in the dental environment and made dental appointments challenging. They also reported that their child's uncooperative behaviors increased at the dental office (53%) and made it difficult for dentists to clean their child's teeth (64%) and that these behaviors led to the use of pharmacological methods (e.g., general anesthesia) to perform routine dental care (77% of those whose children had required drug interventions to perform routine care).
In the qualitative follow-up several related themes emerged. The first theme, *Difficult to Find the Right Dentist*, emphasized access challenges and included subthemes regarding dentist's refusals to treat their child, dentist misrepresentation to caregivers (e.g., dentist stating that they have experience/are comfortable working with children with ASD), difficulties with obtaining referrals to find an appropriate dentist, and the excessive cost of treatment. The second theme, *All the Sensory Devices Just Make Him So Uncomfortable,* focused on difficulties related to sensory sensitivities from stimuli of all modalities encountered during care. The third theme, *It Looked Like They Were Torturing Him,* delved into the use of restraint by a parent and/or dental professional during routine oral care and the complex perceptions of this practice. The last theme was *Drugs: A Mixed Bag*, which explored differing perspectives on the use of pharmacological methods such as nitrous oxide and general anesthesia to enable routine oral care.
Conclusions: These findings provide greater insight into the challenges experienced by children with ASD and their parents. This information has the potential to improve patient-centered care for this population by helping professionals identify priorities for efforts to address the oral health-related needs of this population.

Poster Session
182 - International and Cross-Cultural Perspectives

199 **182.199** Feeding Problems in Children with Autism Spectrum Disorders: Evidence from a Developing Country

P. Malhi[1], *L. Venkatesh*[2], *B. Bharti*[2] *and P. Singhi*[2], *(1)Post Graduate Institute of Medical Education and Research, Chandigarth, UT, India, (2)Pediatrics, Post Graduate of Institute of Medical Education and Research, Chandigarh, India*

Background:
Studies have documented that children with Autism Spectrum Disorders (ASDs) experience a range of eating and feeding difficulties including food selectivity and food refusal and these problems can lead to inadequate nutrition over time. Despite evidence to support feeding problems in children with ASDs, no study has examined eating behaviors of children with ASDs from India.
Objectives:
To examine the eating behaviors of children with ASDs and to compare it with an age and socio-economic matched group of typically developing children.
Methods:
Children with a diagnosis of Autistic Disorder (AD) and Pervasive Developmental Disorder Not Otherwise Specified (PDDNOS) aged 4 to 10 years were eligible for the study. The exclusion criteria included any neurological or systemic illness or current use of any drugs known to alter eating behaviors. A total of 63 ASD children (Mean= 6.1 years, SD=1.9) meeting criteria were recruited from the Department of Pediatrics of a tertiary care hospital in North India. The ASD sample included: Boys=90.4%, AD = 86%. An age and socio-economic status matched control group of typically developing children (N=50) was also recruited. Eating behaviors were evaluated using the Children's Eating Behavior Inventory (CEBI, Archer, Rosenbaum, & Streiner, 1991). It comprises of 40 items and assesses eating problems and mealtime behaviors. Responses are scored on a five point rating scale (ranging from never to always) to measure the frequency of eating behaviors and whether each behavior presents a problem. A list of common foods, specific to the Indian diet, including proteins, starches, dairy, fruits, and vegetables was prepared to measure food selectivity. In addition, height and weight was measured and Body Mass Index (BMI) computed. The study was approved by the ethics committee of the Institute.
Results:
The ASD group had significantly higher total scores on the CESI (t= 3.2, P=.002) and more feeding problems (t =3.7, P=.001) as compared to the control group. Eating problems of the ASD children included not chewing food or feeding self as expected for age, not enjoying eating, taking a long time to eat, eating inadequate amounts of food, and meal times being prolonged and stressful for the family. The height, weight, and the BMI, however, did not differ for the two groups of children. As compared to typical controls, children with ASD ate fewer foods (57.8 vs. 51.0, P=.001), particularly fruits, vegetables, and meat products. Feeding difficulties of the ASD children did not differ by socio-economic status or education of the mother. However, severity of ASD was related to eating problems and children with severe autism, as measured by the Childhood Autism Rating Scale (CARS) had significantly higher total CESI scores (t= 2.2, P=.030).
Conclusions:
Children with ASD are at a high risk for eating problems and this may be associated with long term nutrient inadequacies. Clinicians should routinely screen ASD children for eating difficulties and initiate appropriate interventions.

200 **182.200** Implementation of the Latin American Autism Spectrum Network Caregiver Needs Survey

A. Rattazzi[1], *C. S. Paula*[2,3], *R. A. Garcia*[4], *G. Garrido*[5], *C. Montiel-Nava*[6], *D. Valdez*[7,8], *A. Rosoli*[9], *S. H. Cukier*[1], *G. Rodrigues da Cunha*[3,10], *M. Irarrazaval*[4,11], *M. Rodriguez*[12] *and V. Besio*[13], *(1)PANAACEA, Buenos Aires, Argentina, (2)Department of Psychiatry, Federal University of Sao Paulo, Sao Paulo, Brazil, (3)Mackenzie Presbyterian University, Sao Paulo, Brazil, (4)Universidad de Chile, Santiago, Chile, (5)School of Medicine- Child Psychiatry Clinic, Universidad de la República, Montevideo, Uruguay, (6)La Universidad del Zulia, Maracaibo, Venezuela, (7)FLACSO, Buenos Aires, Argentina, (8)UBA, Buenos Aires, Argentina, (9)OEI, Santo Domingo, Dominican Republic, (10)Federal University of Sao Paulo, Sao Paulo, Brazil, (11)Millennium Institute for Research in Depression and Personality, Santiago, Chile, (12)Hospital Británico, Montevideo, Uruguay, (13)Universidad de la República, Montevideo, Uruguay*

Background: ASD knowledge, services and research infrastructure in Latin America are limited and unevenly distributed. In 2015, researchers from Argentina, Brazil, Chile, Uruguay, Venezuela and Dominican Republic constituted the Latin American Autism Spectrum Network (Red Espectro Autista Latinoamerica – REAL) in order to conduct international research collaborations related to ASD. The first project undertaken by REAL was the translation, adaptation and implementation of the AS Caregiver Needs Survey. The AS Caregiver Needs Survey was developed by Autism Speaks to assess the needs of families affected by autism in partner countries of its Global Autism Public Health Initiative. It is intended for parents or primary caregivers of individuals with a professional diagnosis of autism spectrum disorder. After translation, adaptation, back translation and pilot testing of the survey, REAL researchers reached a final version by consensus, taking into account caregiver suggestions collected during the pilot phase.
Objectives: To provide a comprehensive picture of the major needs and challenges faced by families affected by ASD in REAL countries with the purpose of successfully enhancing awareness, improving services, and developing long-term policy solutions related to ASD.
Methods: The Caregiver Needs Survey will be broadly disseminated via social networks in REAL countries during a period of 4 months (November 2015-February 2016) so that caregivers can complete it online, either assisted by a clinician or not. The survey solicits information about family demographics, affected individual characteristics, service encounters and parent/caregiver perceptions, including stigma. It is estimated that more than 3000 surveys will be completed in total. After the collection of completed surveys, REAL researchers will proceed to data cleaning and data analysis, and will draft a country and regional report.
Results: A summary of the results from the Caregiver Needs Survey in each REAL country will be presented, and regional similarities and differences will be analyzed.
Conclusions: The assessment of needs and challenges faced by families affected by ASD in different Latin American countries is essential for the identification of knowledge gaps, service needs, and stigma. It is also important in the development of culturally relevant strategies for raising autism awareness, guiding the implementation of successful and improved ASD clinical and educational services at the national and regional levels and setting priorities for future national and regional research collaborative efforts. In this era of globalization, REAL is an attempt to generate a collaborative workforce in order to readily identify the best ways to approach issues related to ASD in Latin America.

201 **182.201** Validation of the Arabic Version of the Social Communication Questionnaire (SCQ)

M. Aldosari[1], *F. Alshaban*[2], *M. Ouda*[3], *S. F. Elhag*[2], *H. F. Alshammari*[2], *A. Alsaleh*[4] *and E. Fombonne*[5], *(1)Center for Pediatric Neurology, Cleveland Clinic Foundation, Cleveland, OH, (2)Neurological Disorders Research Center, Qatar Biomedical Research Institute, Doha, Qatar, (3)National Guard Health Affairs, Riyadh, Saudi Arabia, (4)King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, (5)Oregon Health & Science University, Portland, OR*

Background:
There is a scarcity of validated autism screening and diagnostic tools for Arabic-speaking individuals which presents a major challenge to clinicians as well as researchers in many countries around the world.
Objectives:
The objective of the study is to evaluate the sensitivity and specificity of the Arabic Version of SCQ.
Methods:
As part of the first country-wide Autism Prevalence Study that is ongoing in Qatar, we translated the Social Communication Questionnaire (SCQ) to Arabic and worked with Western Psychological Services (WPS) to have the back-translation reviewed by author-assigned reviewer. Multiple review cycles were needed prior to agreeing on the final version. The ASD sample was recruited from the Shafalah Autism Center in Qatar (N=35) and form 10 Autism Centers and classes in Saudi Arabia (N=97). The control sample were recruited from 8 schools in Qatar (N=778 recruited by mailing SCQ forms to the families) and 10 schools in Saudi Arabia (N=247 recruited by distributing forms to schools by two of the authors). The study was carried between February and September 2015. We evaluated the sensitivity and specificity of the Arabic SCQ using the published cut-off value of 15.
Results:
The pilot sample included 1060 (132 ASD and 928 Control). We are continuing to recruit more children. The boy to girl ratio was 2.14:1 (92/42; 68.2% male) in the ASD group. In the control group, the corresponding values were 0.60:1 (346/579; 37.3% male). The mean SCQ total score was significantly higher in cases as compared to controls (20.79 (SD=6.4) vs 7.26 (SD=5.0); p<.0001). As expected, the variability was larger in cases than in controls as illustrated by the standard deviations. A total of 184 children (109 cases, 75 controls) had scores equal or above the cut-off of 15; the remaining 23 cases (17.4% of the cases) had scores below the cut-off. An ROC analysis was performed to examine the overall performance of the SCQ. The area under the curve showed excellent discrimination between cases and controls (AUC=0.937; 95%CI: .915-.959). For the established cut-off of 15, sensitivity and specificity were of .826 and 0.919, respectively. Adjacent values for the cut-off were associated with slightly lower overall performance as defined by the sum of the sensitivity and 1-specificity (Yougen index).
Conclusions:
The findings from this study validates the use of the Arabic SCQ as screening instrument with the original published cut-off values.

202 **182.202** An International Review of Autism Knowledge Assessment Measures

A. J. Harrison[1], *M. M. Slane*[1], *L. Hoang*[2] *and J. M. Campbell*[3], *(1)University of Georgia, Athens, GA, (2)Skidmore College, Saratoga Springs, NY, (3)University of Kentucky, Lexington, KY*

Background:
Low-levels of knowledge about ASD symptoms, etiology and treatment can profoundly increase the amount of burden experienced by families with children diagnosed with ASD. Lower ASD knowledge often results in the proliferation of stigmas and misconceptions that disadvantage families impacted by ASD (Khan et al., 2012). ASD-specific knowledge deficits also play a key role in current disparities in the timing and quality of ASD services throughout the United States and globally, particularly in low- and middle-income countries.
Objectives: A primary goal of this review was to examine global use of ASD knowledge measures published in peer-reviewed journals and assess measure adherence to psychometric standards guidelines that define "well-established assessment" practices (Cohen et al., 2008).
Methods:
The present study conducted a systematic review of Western and International literature to examine quantitative measures used to specifically assess ASD knowledge published in. This review identified 39 unique ASD knowledge measures across 52 studies.
Results:
Peer-reviewed research reveals the construct of ASD knowledge has been examined in 18 different countries around the world, 50% (n = 26) were conducted in North America, 15% (n = 8) in the Eastern Mediterranean region, 13% (n = 7) in Europe, 10% (n = 5) in the Western Pacific region, 8% (n = 4) in Africa, and 4% (n = 2) in Southeast Asia. Measures used in each study were evaluated in terms of psychometric strength. Of the 52 studies reviewed, only 7.7% were rated as using a measure with strong psychometric support compared to 46.2% that were rated as using a measure with no reported psychometric support. Most measures examined did not meet the definition for a "well-established assessment" as most researchers developed independent surveys for their specific study. As evidence of this, among the 39 measures examining ASD knowledge, only four meet this best practice assessment standard (Stone, 1987; Bakare et al., 2008, Ross & Cuskelly, 2006; Segall, 2008). Additionally, we examined subdomains of ASD of knowledge assessed. Of 39 different measures, 46.2% (n = 18) examined specific subdomains of ASD knowledge through the use of subscales, such as diagnosis and symptoms, etiology, and treatment (e.g., Bakare et al., 2009; Furnham & Buck, 2003; Heidgerken et al., 2005; Koyama et al., 2009; Kuhn & Carter, 2006; Segall & Campbell, 2012; Shaukat et al., 2014).
Conclusions:
While demonstrating the international relevance of examining the construct of ASD knowledge, this review reveals important concerns about psychometric quality of ASD knowledge measures currently utilized and a lack of measurement consistency in the field. Without defensible utility, inferences made from existing ASD knowledge instruments may counterproductively misguide efforts to study ASD knowledge and related constructs. Based on these findings, we present recommendations for the development of a cross-culturally valid and psychometrically sound measure of ASD knowledge is discussed. Progress toward a more psychometrically sound measure of ASD knowledge is imperative if we are to accurately assess the nature and extent of knowledge disparities and develop successful methods for reducing the impact of low ASD literacy on families.

203 **182.203** Procedures and Compliance of a Video Modeling Intervention for Parents of Children with ASD

C. S. Paula[1,2], *J. J. Mari*[3], *D. Bordini*[4], *D. Brunoni*[5], *S. C. Caetano*[6], *H. Brentani*[7], *T. Ribeiro*[7], *M. C. C. Martone*[8], *G. Rodrigues da Cunha*[9] *and L. Bagaiolo*[6], *(1)Mackenzie Presbyterian University, Sao Paulo, Brazil, (2)Department of Psychiatry, Federal University of Sao Paulo, Sao Paulo, Brazil, (3)Psychiatry, Federal University of São Paulo, São Paulo, Brazil, (4)Departament of Psychiatry, Federal University of São Paulo (UNIFESP), Sao Paulo, Brazil, (5)Development Disorders Program, Mackenzie University, São Paulo, Brazil, (6)Department of Psychiatry, Federal University of São Paulo (UNIFESP), São Paulo, Brazil, (7)Department of Psychiatry, University of São Paulo (USP), São Paulo, Brazil, (8)Universidade Federal de Sao Carlos, São Carlos, Brazil, (9)Federal University of Sao Paulo, Sao Paulo, Brazil*

Background:
Video modeling using ABA techniques is one of the most promising procedures to improve social skills in the ASD population. This method requires less time for training/implementation than live modeling, which can enable its use on a large scale. These aspects are particularly relevant in low-middle-income countries like Brazil, where there is a lack of specialized, trained professionals. However, there are a few studies using video modeling specifically for ASD parental training and most of the clinical trials focus on high-functioning ASD.
Objectives:
(1) to describe a low-cost video modeling parental training intervention based on ABA to improve eye contact, joint attention and decrease disruptive behaviors among children with ASD and (2) to assess the compliance of these participants.
Methods:
Study Design: descriptive study of a clinical trial. **Site**: three specialized health units for children with ASD in São Paulo-Brazil. **Sample**: 66 parents of children with ASD aged 3-6 and with IQ lower than 70, randomized into two groups: 36 families as the intervention group and 36 families as the control group (receiving treatment as usual). *Inclusion criteria*: children having (1) an ASD diagnosis according to the Brazilian version of the ADI-R and a clinical evaluation based on DSM-V, and (2) IQ 50-70 assessed by the SON-R 2½-7, a non-verbal standardized instrument validated in Brazil. **Intervention Model:** the primary outcome of the intervention was to assess the impact of video modeling training on eye contact, joint attention, and disruptive behaviors. The intervention was carried out during 22 weekly sessions. **Assessments**: a package of standardized instruments to assess participants before and after the intervention. To evaluate children: ADI-R; SON-R 2½-7; Autism Behavior Checklist–ABC; Vineland Adaptive Behavior Scales; Eye-tracking tasks; Structured Observation for Autism Screening-OERA; Child Behavior Checklist-CBCL and SNAP-IV Rating Scale. To evaluate parents: Hamilton Depression Rating Scale, Zarit Burden Interview and Adult Self-Report Scale- ASRS-18.
Results:
One of the main results of the study was the development of 15 standardized videos, with varied themes for parents to use on a daily basis with their ASD children. The main themes were related to: (i) management of disruptive behaviors, (ii) prompting hierarchy, (iii) preference assessment, and (iv) acquisition/improvement of eye contact and joint attention.
Compliance with the full intervention program varied from good (75-100% frequency) to reasonable (50-74% frequency) in 70.6% of the participants from the intervention group, distributed as follows: good compliance 32.4% of the group (11 families) and reasonable compliance 38.2% of the group (13 families). 29.4% of the sample (10 families) did not achieve good/reasonable compliance, distributed as follows: 5.9% (2 families) low compliance (25-49% frequency), and 23.5% (8 families) no compliance (0-25%).
Conclusions:
The video modeling parental training model seems promising, feasible, and an inexpensive way to offer assistance to children with ASD and low IQ. After proving its efficacy, this model can be replicated in bigger samples and populations with a lack of access to treatment services, making a major impact on ASD treatment in Brazil and potentially in other Portuguese speaking countries.

204 **182.204** Behavioral Treatment and Educational Intervention Received By Children with Autism in Ethiopia

W. Zeleke *and M. Chitiyo, Duquesne University, Pittsburgh, PA*

Background: Autism is one of the childhood disorders that has received a lot of attention in most developed countries. There is a clear imbalance of knowledge about autism spectrum disorders and its intervention worldwide. Most of what we know about the epidemiology, diagnosis, and treatment of autism is based on research conducted in developed countries. A few studies conducted in various African countries report that the awareness of autism in Africa is beginning to improve and parents of children are striving to find service for their children with autism. That is certainly the case in Ethiopia too. However, our knowledge about the current practice on autism intervention and how children with ASD and their parents received service in Ethiopia is limited due to lack of scientific studies.
Objectives: The Autism treatment and service providers' confidence survey was developed mostly based on the work of Green etal (2006) to identify strategies used in behavioral treatment and education of children with ASD in Ethiopia and to measure the level of confidence that the service providers have in providing the service for children with ASD
Methods: Using convenience/ purposive sampling, 102 service providers (teachers, nurse, psychologist, social worker, special need educators and therapeutic care worker) completed the survey. Descriptive statistics and t-test used to analyze the results.
Results: Skill based intervention such as *self help skills, play, using rewards, art therapy, music, sand/clay therapy, and ABA* was the most frequently used intervention, followed by Interrelationship based (*modeling, direct instruction, social skills, social stories, experiential activity*) intervention and intervention focused on Language and Communication base treatment. Absence of pre-service and in-service training on autism found to be the common problem that the participants reported. Sixty five percent of the participants also rated their confidence on understanding and treating autism spectrum disorder low.
Conclusions: Result highlighted clear implication for pre-service and in-service training and the need for continued research to document the intervention strategies use in autism center in Ethiopia

205 **182.205** Ignoring the Odds: The RISE in Autistic Spectrum Disorder in Libyan Children and EARLY TV Viewing "Libyan Vision"

ABSTRACT WITHDRAWN

Background: There is a strong belief among most Libyan's newly married couples that early TV viewing can be responsible for Autism in children. Anecdotal and clinical reports indicate that early use of television can be a clinically significant problem to the extent that it may lead to impairment of communication and socialization. However, this phenomenon has not been examined thoroughly in Arabic population.

It's estimated that approximately 7 out of every 1000 Libyan children has an autism spectrum disorder, according to Zeglam and etal's study. Children with autism seem to be particularly drawn to certain channels and programs on satellite TV.
Objectives: to examine the prevalence of ADS in Tripoli, Libya and correlates of early TV viewing among a large nationally representative sample of children with ASD.
Methods:
This was a large hospital-based study. The study's two-stage sampling involved first studying the prevalence of ASD; and then All the families of children with ASD attended between Jan.2015 and Jun.2015 (267 children) weighted to be nationally representative of children with ASD were asked two specific questions related to TV watching. All children enrolled in this category did met full DSM-V criteria for an ASD. We compared these children with those who are normal and attends mainstream nurseries.
We examined two dependent measures of TV use. A measure of duration of exposure and a measure of age exposure. Children were identified as having an ASD through screening of all children referred to the Neurodevelopment Clinic of Al-Khadra Teaching Hospital (NDC-KH), Tripoli, Libya between June 2011 and June 2015 with the diagnosis of speech and language disorders or behavioral difficulties. Children were reviewed, scored and classified by a clinician (AZ) as having ASD if they displayed behavioral abnormalities consistent with DSM-IV & V for diagnosing ASD.
Results: Total number of children seen in all Pediatric clinics were 321251.Children diagnosed with ASD were 2170 which gives the prevalence of 7:1000.
Using Mann-Whitney test we found that 15% of infants and toddlers watched TV on an average of 2 - 4 hours a day while 46% watched TV for more than four hours (p-value < 0.001). 34% & 33% of infants and toddlers were put in front TV in the first six months and between six and 12 months of age respectively. Only 10% of children watched TV after first 12 months of age (p-value< 0.001).
Infants under age of 12 months watched an average of about 4 hours of TV a day.
Conclusions: Consistent with our expectations, we found a very high rate of use of TV among children with ASD. Our findings conclusively demonstrate that early exposure to TV can account for the rise in prevalence of ASD in Libya over the last five years. The current study is the first to examine the prevalence and correlates of TV use among a large nationally representative sample of children with ASD in Libya and probably in Africa. Our study has provided support that early TV viewing might be associated with autism.

206 **182.206** Pattern of Behavioural Deficits Among Nigerian Children with Autism

A. T. Olagunju[1], *Y. O. Oshodi*[2], *M. A. Oyelohunnu*[3], *E. A. Campbell*[3], *B. Fadipe*[3], *C. S. Umeh*[4], *O. F. Aina*[4], *W. A. Oyibo*[5], *A. E. Lamikanra*[6], *A. Lesi*[7] *and J. D. Adeyemi*[4], *(1)Department of Psychiatry, College of Medicine, University of Lagos, Lagos, Nigeria, (2)Department of psychiatry,, College of medicine, university of Lagos., Lagos, Nigeria, (3)Department of Psychiatry, Lagos University Teaching Hospital, Lagos, Nigeria, (4)Department of Psychiatry, College of Medicine, University of Lagos, Lagos, Nigeria, (5)Department of Medical Microbiology and Parasitology, College of Medicine, University of Lagos, Lagos, Nigeria, (6)Wuhan Polytechnic University, Frisco, TX, (7)Department of Pediatrics, College of Medicine, University of Lagos, Lagos, Nigeria*

Background: Beyond diagnosis of autism spectrum disorder (ASD), interventions are best if need-tailored and predicated on what is known about specific behavioural deficits.
Objectives: This study is set to profile behavioural and emotional problems among children with ASD in a resource restricted setting.
Methods: The study participants were made up of 100 children with ASD and their caregivers recruited during the annual autism project done in 2014 and 2015. This autism program is anchored through the collaborative partnership among College of Medicine, University of Lagos; Guaranty Trust Bank and Blazing Trail International, USA. A designed questionnaire was used to collect socio-demographic, clinical and psychosocial characteristics of the participants. Following screening with the Modified Checklist for Autism in Toddlers (M-CHAT) and Childhood Autism Spectrum Test (CAST), clinical diagnosis of ASD was done based on DSM-V criteria. Subsequently, the Strengths and Difficulties Questionnaire (SDQ) was used to profile behavioural and emotional problems across multiple dimensions among the participants.
Results: The mean ages of the children, their mothers and fathers were 7.7(±5.7), 38.9 (±6.7) and 43.7 (±7.2) years respectively. Majority of the children (74%) were males and more than four-fifths of their mothers (87%) and fathers (81%) had tertiary education. Close to two-thirds (63%) of the children with ASD reported various degrees of difficulties as shown by overall SDQ score that ranged from high (39%) to raised (24%) difficulties. The domain score on peer problems showed the worse level of deficits, with up to 80% reporting more than average difficulties, while 67%, 36% and 17% of participants reported considerable behavioural difficulties with respect to hyperactivity, prosocial and emotional issues respectively. All participants indicated this encounter to be their index evaluation despite 80.5% of them having had the behavioural problems for more than one year.
Conclusions:
Our study observed varying degrees of difficulties across the behavioural dimensions of SDQ among children with ASD, with worse deficits reported on domains capturing "externalized symptoms". Given the array of "unattended'' behavioural problems profiled among children with ASD, there is need for sustained resources including research, training and intervention to address these behavioural challenges.

207 **182.207** Translation and Cultural Appropriateness of the ADOS-2 in Afrikaans

ABSTRACT WITHDRAWN

Background: A key need in diagnostic practice for autism spectrum disorder (ASD) in South Africa is to generate acceptable and valid diagnostic tools in the official languages of the country. The Autism Diagnostic Observation Schedule-2 (ADOS-2) is one of the "gold standard" diagnostic aids for ASD and it is increasingly used in South Africa. However, its use is limited to English-speakers, as it has not been translated into any of South Africa's other 10 official languages. Moreover, the cultural appropriateness of this tool for the local cultures of South Africa, or the implications of low socio-economic status has not been explored.
Objectives: Given that approximately 50% of the population of the Western Cape province of South Africa speak Afrikaans as primary language, we wanted to focus on the Afrikaans ADOS-2. The primary objective was to determine the cultural appropriateness of the tool for Afrikaans-speakers in low to middle income communities. Three components associated with method bias were examined 1) the language used in the Afrikaans-translated ADOS-2, 2) the social interactions and activities in the ADOS-2, and 3) the ADOS-2 materials.
Methods: A mixed method and qualitative thematic approach was used to analyse the data collected through interviews and questionnaires. The ADOS-2 was translated into Afrikaans and we assessed its cultural appropriateness for the 'coloured' (mixed ancestry) population from low to middle socio-economic backgrounds residing in the Western Cape. An ethnographic investigation of play, social interaction, and social activities was conducted in a community sample (n = 40) and the Afrikaans ADOS-2 was pre-piloted in a clinical sample (n = 7). The ethnographic component was included given that there was no existing literature for this socio-cultural group. Community sample participants were interviewed and asked questions pertaining to what games their children played, what materials they played with, and whom they played with (on own, with peers, with adults). ADOS-2 materials were shown to community and clinical sample participants, who were asked to comment on their children's familiarity with the materials.
Results: The findings highlighted numerous unique aspects of the vernacular of Afrikaans spoken by this population ("Kaaps") including the dialect spoken and use of code-switching (rapid switching between Afrikaans and English). The ethnographic exploration of play (on own, with peers, with adults) indicated that the social interaction expectations in an ADOS-2 assessment between child participant and examiner and adults seemed culturally appropriate and that most of the ADOS-2 materials and activities were familiar and appropriate. The materials raising the most concern included the frog toy (fear-inducing) and the PinArt (unfamiliarity). Gender stereotypes associated with play materials were also noted frequently.
Conclusions: With appropriate cultural and clinical sensitivity during administration, we found the Afrikaans ADOS-2 to be useful and culturally appropriate for Afrikaans-speaking, coloured individuals from low socioeconomic backgrounds in the Western Cape. We recommend a similar parallel process when translating the ADOS-2 into other languages spoken in South Africa, as well as a similar ethnographic exploration in other communities where little is known about play, social interaction, and social activities.

208 **182.208** Prevalence and Capacity Building in Brazil

C. S. Paula[1], *D. Bordini*[2] *and R. Lowenthal*[3], *(1)Developmental Disorder Program, Mackenzie Presbyterian University, Sao Paulo, Brazil, (2)Departament of Psychiatry, Federal University of São Paulo (UNIFESP), Sao Paulo, Brazil, (3)Ambulatorio de Autismo Marcos T Mercadante, CAISM, Santa Casa de São Paulo, Sao Paulo, Brazil*

Background: In Brazil, a single study reporting ASD prevalence in the childhood has estimated a rate of 0.3%, which is probably an underestimate due to methodological limitations. This research also showed that most of the positive cases had no previous diagnosis of ASD, and it is known that early identification is one of the main predictors of functional outcome and social adaptation in patients with ASD.
Objectives: (1) to present results from a recent prevalence study conducted in four Brazilian regions; (2) to evaluate the impact of a pilot training program on ASD identification offered to professionals from the Public Health system.
Methods: Study 1 **-** *Design*: Multicenter cross-sectional-study. *Sample/Settings*: 1,715 students (aged 6-16) from 2nd-6th grade enrolled in elementary public school, from four towns from four out of five Brazilian regions, were randomly selected. *Instruments*: (i) screening ASD: subscale of the K-SADS-PL; (iii) Estimated IQ: two subtests (Vocabulary and Blocks) of the WISC-III; (iii) Service use: structured questionnaire developed by our research team.
Study 2 **–** *Participants/training program*: the training program offered to 20 primary care providers (most pediatricians) consisted of five three-hour weekly training sessions comprising two hours of lectures and one-hour case discussion. The main themes delivered by ASD experts were: epidemiology; ASD symptoms and early signs; and evidence-based treatments. The main objective of the training was to improve detection of suspected cases of ASD and to refer them to the single local specialized unit. *Assessments*: (1) to measure the knowledge acquisition, a structured questionnaire comprising of 13 multiple-choice questions and vignettes of clinical ASD cases was developed by our research team (applied before and immediately after the training). (2) to identify changes in the clinical practice, we compared data on the amount and

profile of suspected ASD cases referred for these professionals to the specialized unit, four months before and after the conclusion of the training.
Results: Study 1**:** the estimated prevalence rate was 1%. Among the positive cases, (a) 62.5 % were male; (b) 12% had average/normal IQ; and (c) only 56.3% had been seen by a health specialist (psychologist/neurologist/psychiatrist) in the previous year, and 37.5% had received specialized educational support in the same period.
Study 2: health providers significantly improved their ASD knowledge after training in comparison with pre-training [mean score 6.73 vs 9.18 ($p<0.01$)]. Clinical practice also changed: they had referred 6 times as many suspected cases of ASD to a specialized mental health service four months after the training program in comparison with the previous four months.
Conclusions: The prevalence of ASD identified in this study is in accordance with international rates. Only a small proportion of youth with ASD had been seen by a health/educational specialist in the previous year. The pilot training-model presented seems a promising, feasible and inexpensive way to improve early identification of ASD in the primary care system.

209 **182.209** Self-Descriptions By Individuals with Autism Spectrum Disorder in New Delhi and Los Angeles: The Power of Cultural Context

ABSTRACT WITHDRAWN

Background:
Most research on ASD to date has focused on the immediate social skills, rather than the broader cultural skills, of individuals with ASD. Cross-cultural research has shown that cognitive and emotional patterns may differ significantly across cultural contexts. For instance, decades of research have shown that individuals in Western cultures have overall more autonomous, and more abstract, self-concepts, compared with individuals in non-Western cultures, who have more social and specific self-concepts (Markus and Kitayama, 1991; Rhee et al. 1995). It is unclear whether individuals with ASD, who have impairments in self- and other-understanding, will acquire the relevant cultural patterns regarding self- and other-concepts; or whether their social impairments will extend to broader cultural impairments. Here we present the first test, to our knowledge, of self- and other-concepts in a cross-cultural sample of individuals with ASD in Los Angeles, USA, and New Delhi, India.
Objectives:
To determine whether self-descriptions by Americans with ASD are more autonomous and abstract, and less social and specific, than those of Indians with ASD, as would be predicted from their cultural context (Rhee et al., 1995).
Methods:
Thirty-two high-functioning youth with ASD (6 females; *M*=12.4), and 30 age-, gender- and IQ-matched typically developing (TD) controls were interviewed in Los Angeles. Twelve high-functioning adults with ASD (2 females; *M*=25.1) and 12 TD adults, matched for age, gender, language preference and income, were in interviewed in New Delhi. Participants were asked to describe themselves in as many ways possible, starting with "I am…". Transcripts were parsed into phrases and coded by 2 coders blind to location and diagnosis according to 28 sub-categories (e.g., traits, evaluations, emotional states), categorized as social/autonomous and abstract/specific based on Rhee et al. (1995).
Results:
Participants with ASD provided marginally fewer relevant responses, compared with TD participants, across both cultures ($F(1,94)=3.02$, $p=.086$). Individuals in Los Angeles were significantly more likely to self-describe in autonomous ($F(1,85)=9.33$, $p<.01$) and abstract ($F(1,85)=51.5$, $p<.001$) ways, compared with individuals in New Delhi. We found no significant effect of Group, nor interaction effect, for either axis of interest: social/autonomous and specific/abstract.
Conclusions:
Our findings demonstrate that, despite their difficulties with self- and social-understanding, individuals with ASD *are* sensitive to their cultural contexts. Indeed, group differences between TD and ASD individuals appeared insignificant compared with the significant cross-cultural differences in self-description between individuals in New Delhi and Los Angeles. Care was taken to match ASD and TD individuals in each culture on relevant characteristics; though our cross-cultural comparison is limited in that American participants were youth, and Indian participants were adults. Our findings have important social implications: demonstrating that (a) individuals with autism *can* acquire cultural schemas from their surroundings; and that (b) relatively speaking, ASD and TD individuals in each local culture share a much more similar self-concept than do individuals from different cultures.

210 **182.210** The Profile and IMPACT of ASD and Other Neurodevelopmental Disorders: Comparison and Predictors from India

***B. Koshy**, M. Manoharan, R. Roshan, L. Samuel and R. Beulah, Developmental Paediatrics, Christian Medical College, Vellore, Vellore, India*

Background:
Autism spectrum disorders (ASD) and other neurodevelopmental disorders (NDD) impact families adversely. Published studies state that families of children with ASD report a higher impact than those with other NDD. There is a paucity of data evaluating these concepts in the Low Middle Income Countries (LMIC).
Objectives:

1. To compare the profiles and impact on families of children with ASD and those with other NDD
2. To understand the predictors for the impact on families of children with either disorder

Methods:
All families who were welcomed to an inpatient residential facility attached to the Developmental Paediatrics Unit in a tertiary care centre in India for detailed assessment and interventions from January 2015 to September 2015 were included in the analysis. The child was diagnosed by a multidisciplinary team of paediatricians, psychologists and therapists. The ASD diagnosis was confirmed by DSM-V and Childhood Autism Rating Scale (CARS). The Revised Impact on Family questionnaire was administered to all families to assess the impact.
Results:
196 children, 114 NDD and 82 ASD were included in this study. The distribution of age and developmental delay were similar in both groups. The ASD group had significantly more proportion of males (p=.00). Mother's education was higher for the ASD group than the NDD group (p=.05); both groups significantly better than the national average (p=.00). Professional occupation for fathers was reported significantly higher for the ASD group than the NDD group (p=.01); both groups significantly better than the national average (p=.00).
Both families of children with ASD and other NDD reported high impact on the family. There was no significant difference between the reported impact of ASD and NDD (37 and 37.75 respectively; p=.99). None of the usual factors including age, gender, associated developmental delay, mother's education, father's occupation and associated sleep problems predicted the impact on family. The severity of autism also did not predict the impact model for families of children with ASD.
Conclusions:
Families who actively sought help for both ASD and NDD belonged to a better socio-economic class compared to the average Indian demographic profile. Both ASD and NDD have high impact on families. Further studies need to evaluate the care seeking pattern of families as well as alternate models for impact on family for developmental disorders including ASD in the Low and Middle Income countries.

211 **182.211** Communication and Interaction in Autism Research - Perspectives from Volunteers and Scientists

***J. J. Finnemann**[1,2] and K. Plaisted Grant[1], (1)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (2)Brain Mapping Unit, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:
Recent years have seen an increased awareness of the cultural and ethical challenges in autism research and the unease within the autism community with regard to the perceived attitudes of scientists conducting research into ASC (Pellicano & Stears, 2011). A large-scale study on the landscape of autism research pointed out that the autism community is not satisfied with the distribution of funding for different areas of research and furthermore that there is a discrepancy between researchers' perceived engagement with the autism community and the experience of autistic people themselves (Pellicano et al., 2014).
Objectives:
This study aims to achieve a better understanding of the dynamics that underlie the apparent 'rift' between autism researchers and individuals with ASC with a particular focus on the communication and interaction between researchers and study volunteers.
Methods:
Individuals with ASC and autism researchers were invited to fill in a mixed-methods survey covering the following topics: involvement in autism research, ethical concerns about autism research, relevance & impact of autism research, communication of research results, media representation of autism, misconceptions in autism research, community engagement in autism research and the idea of neurodiversity.
The questionnaire was piloted with a small sample of ASC participants (N=16) in 2011 and feedback about the issues covered and the format of the survey was obtained.
To date, 100 individuals with ASC and 65 autism researchers have completed the survey; data collection is on-going until mid-2016.
Quantitative data is analysed with the appropriate chi-square and regression analyses whilst a grounded theory approach is used to elaborate on data trends and code the answers to open-ended comments.
Results:

The level of concern about ethics in autism research was similar in both groups (χ^2=1.56, p=0.21), but the areas of concern differed between the groups with the exception of the search for a cure which was mentioned by both groups. In addition to these concerns, individuals with autism were on average less optimistic about the potential of research to improve the lives of people with autism (χ^2=12.20, p=0.0005) and the majority (58%) was not satisfied with the way research was communicated to them. However most respondents would still like to be more involved in research (84%). At the same time researchers stressed that they would like to see more translational goals in research and improved communication between participants and scientists, but notably significantly more ASD participants felt that there is a divide between the scientific and the autism community (χ^2=8.898, p=0.003).

Conclusions:

The survey illustrates that while researchers and individuals with autism agree about certain aspects concerning the quality, purpose and ethical challenges of research, there are also still areas of disconnect and dissatisfaction. While one has to recognise a certain diversity of opinion, the emerging themes of this survey suggest that culturally sensitive research approaches and meaningful community involvement could improve the relevance of the research that is conducted. It remains to be seen what format best supports a mutual transfer of expertise between researchers and research participants to address these disparities.

212 **182.212** Social Desirability, Collectivism/Individualism and Stigma Towards Individuals with Autism Spectrum Disorders (ASD) in Japanese and American College Students

F. Someki[1], *M. Torii*[2] *and K. Gillespie-Lynch*[3], *(1)College of Staten Island, Staten Island, NY, (2)Kobe University, Kobe, Japan, (3)City University of New York, College of Staten Island, Staten Island, NY*

Background:

Stigma associated with ASD is apparent around the world (e.g., Dachez et al., 2015; Jones & Harwood, 2009; Bie & Tang, 2015). Recent cross-cultural research revealed that stigma towards ASD is higher in Japan and Lebanon than it is in the U.S. (Obeid et al., 2015; Someki et al., 2015). In Lebanon, where autism services and research are scarce, higher stigma co-occurs with reduced knowledge relative to the U.S. (Obeid et al., 2015). However, stigma is also heightened in Japan, which has a relatively long history of autism research (Volkmar et al., 2007). Therefore, knowledge differences are unlikely to be the only factor underlying cross-cultural differences in stigma.

Both Lebanon and Japan are more collectivistic than the U.S. (Matsumoto et al., 2008). Collectivism is more common in relatively homogeneous cultures like Japan while individualism occurs more in heterogeneous cultures like the U.S. (Triandis, 1993; Hofstede, 1980). Individualistic societies may be more tolerant of differences (Triandis, 1993), which might lessen stigma towards ASD. Social desirability may also influence self-reports of stigma. Individuals who value social desirability are guided by the desire for social approval, which is more important in collectivistic societies. Being female and greater ASD knowledge were significantly associated with reduced stigma towards ASD in the U.S. but not Lebanon (Obeid et al., 2015). In the current study, we examine if ASD knowledge, individualism-collectivism, social desirability and gender underlie heightened stigma in Japan relative to the US.

Objectives:

1) Compare stigma associated with and knowledge about ASD among Japanese and American college students; and 2) Examine if gender, ASD knowledge, social desirability and collectivism-individualism underlie cross-cultural differences in stigma.

Methods:

A total of 391 American college students (234 women, 157 men) and 165 Japanese students (41 women, 124 men) completed an online survey consisting of a demographic questionnaire, Social Distance Scale (assessing stigma; Gillespie-Lynch et al., 2015), Adapted Autism Awareness Scale (assessing knowledge; Gillespie-Lynch et al., 2015), Social Desirability Scale (Reynolds, 1982) and Vertical-Horizontal Individualism-Collectivism scale (Triandis & Gelfand, 1998).

Results:

American students reported less stigma towards ASD, $F(1,549) = 104.43$, $p < .001$, than Japanese students. However, there was no difference across countries in overall ASD knowledge, $F(1,549) = .005$, $p = .94$.

A regression analysis revealed that being Japanese ($\beta = -.31$; $p<.001$), being male ($\beta = -.01$; $p=.045$), less ASD Knowledge ($\beta = -.33$; $p<.001$), less social desirability ($\beta = .10$; $p=.008$), and higher individualism relative to collectivism ($\beta = .15$; $p<.001$) were associated with greater stigma towards ASD.

Conclusions:

Despite comparable overall ASD knowledge, Japanese college students exhibited greater stigma towards ASD than American students. Cultural and individual factors contributed to stigma but did not account for cross-cultural differences in stigma. Therefore, cultural differences between Japan and the U.S. that were not assessed in the current study (such as possible effects of people with ASD on productivity) likely contribute to stigma towards ASD.

213 **182.213** Environmental Factors in Autism Spectrum Disorder: A Case Control Study from Tunisia

N. Gaddour, *T. Brahim, S. Missaoui, R. Ben Moussa and L. Gaha, University of Monastir, Monastir, Tunisia*

Background: Incidence of Autism Spectrum Disorder (ASD) is increasing dramatically. Although, ASD has a high genetic basis, the role of environmental factors is undeniable.

Objectives: to investigate environmental factors that may interfere with ASD physiopathology

Methods:

A case-control study was conducted from July 2014 to August 2015, at the Child and Adolescent Psychiatry Unit at the University Hospital of Monastir. We included all outpatients diagnosed with ASD seen during their routine follow-up. A control group was chosen randomly in 4 different kindergarten of the region of Monastir. Each group included 200 children, with a sex ratio M/F of 4.2 and a mean age of 3.3 years. ASD was diagnosed according to DSM-IV criteria (including autistic disorder, Asperger's disorder and PDD-NOS) by certified Child and Adolescent Psychiatrists and the Childhood Autism Rating Scale (CARS). We excluded children with neurological or genetic comorbidities. In the control group, we excluded children with abnormal m-CHAT or abnormal psycho-emotional development.

Environmental factors were assessed by a structured questionnaire eliciting obstetric, family and social factors. One-way ANOVA test was used for statistical analysis.

Results:

Statistically significant differences were found for the use of ovulation induction by the mother, and for the proportion of first borns, both factors being more prevalent in ASD group. Partner violence and use of physical punishment were also significantly more reported in ASD group.

No statistical difference was found for the following factors:

- Age of the mother or the father,
- In vitro fertilization and twin pregnancy,
- Mother depression during pregnancy and the use of antidepressant medication during pregnancy
- Work of the mother and duration of maternal leave
- Breastfeeding duration
- Presence of multiple attachment figures

Conclusions:

Some environmental factors may be associated with autism in a way that needs to be further assessed.

214 **182.214** Analysis of Support Devices for Inclusive Education of Students with ASD in the City of Buenos Aires, Argentina

D. Valdez[1,2] *and L. Sueiro*[1], *(1)FLACSO, Buenos Aires, Argentina, (2)UBA. Universidad de Buenos Aires., Buenos Aires, Argentina*

Background:

In Argentina the UN Convention on the Rights of Persons with Disabilities (CRPD) has constitutional status. In practice, this has meant a series of changes in public policies regarding educational inclusion of students with ASD. Historically the families of children with ASD, nucleated in different organizations, have raised claims against policies of exclusion and segregation, calling for support for inclusive education of their children.

Objectives:

The aim of our research is to investigate and analyze current support devices for inclusive education for students with ASD in the Educational System of the City of Buenos Aires offers, considering the public and private sectors in primary and secondary levels. What are its scope and limitations. What are the views of stakeholders protagonists of these formats in the local educational community, teachers and families. What human and material resources they are involved in these processes of inclusion. That is, what transformations and transitions are presented today from the proposals of support devices for learning in mainstream schools and special school. And finally, what future prospects can be drawn from in-depth analysis of the current situation.

Methods:

Participants: 177 students with ASD, through surveys completed by teachers and families.

We have developed two types of surveys: "S" ("School") and "F" ("Family"), which have been distributed in schools and among families.

"S" Survey consists of 30 questions and was given to different school actors (teachers, administrators, supervisors, support teachers) both in mainstream and special schools.

Survey "F" consists of 21 questions and was distributed among relatives of students with ASD of the City of Buenos Aires.

Both surveys share 14 questions, while the remaining questions are specific to each type of survey.

Surveys were self-administered by each participant and their distribution was done in two ways: virtual and in person, according to the possibilities of the participants. After the collection of completed surveys, will proceed to data cleaning and data analysis, considering the different variables and the interaction between these.
Results:
Among the barriers to educational inclusion respondents note the lack of inclusive education policies and projects; prejudice, fear or lack of inclusive values in the educational community and the lack of training of teachers.
The analysis and interpretation of further results is in progress and will be added later.
Conclusions:
Expected from a current state of the situation with regard to supporting devices for the inclusion in the educational system of the City of Buenos Aires, with voices of the actors, directors, teachers and families of students with ASD. In a second phase will be interviewed students with ASD.
This will help provide educational services and support devices increasingly tailored to the needs of people with ASD learning. We believe that our research, the first in the area covering entire education system of the City of Buenos Aires, may contribute to the design of inclusive public policies in education, in order to improve the quality of life and possibilities of autonomy and self-determination of people with ASD.

215 **182.215** The Education Program Changed Knowledge and Stigma Associated with Autism Spectrum Disorder in Japanese High School Students

M. Torii[1] *and F. Someki*[2]*, (1)Kobe University, Kobe, Japan, (2)College of Staten Island, Staten Island, NY*

Background: Autism spectrum disorders (ASD) is often misunderstood in Japan (Koyama et al., 2008), and stigma associated with ASD in Japanese college students was higher than their American counterparts (Someki et al., 2015). Furthermore, even though factors such as gender (i.e., females report less stigma than males) are known to affect stigma associated with ASD in the U.S. (e.g., Tipton & Blacher, 2013), the same tendency was not observed in Japan (e.g., Someki et al., 2015). In contrast, accurate knowledge about positive outcomes of people with ASD contributed to less social distance (i.e., less stigma) in Japanese high school students (Torii et al., 2015). These findings suggest that, in different cultures, different factors impact on stigma towards people with ASD.
Objectives: The purpose of this study was to 1) examine the effectiveness of the education program to increase knowledge and decrease stigma (i.e., less social distance) associated with ASD in Japanese high school students, and 2) examine the relations between stigma and knowledge about ASD, previous direct experiences with ASD, previous learning experiences about ASD, and previous exposure to ASD information in mass media.
Methods: A total of 1,111 high school students (453 males, 649 females) in an urban city in Japan participated in the study. Each participant filled out the pre- and post-test with 32 items: 3 demographic information items (e.g., age, gender), 6 items on previous direct experiences with people with ASD, 9 items on knowledge about ASD, 7 items on life style, and 7 items on social distance towards people with ASD (i.e., stigma measure: Bogardus, 1933). For the intervention, the first author, an expert in ASD, gave a lecture to the participants about these disabilities.
Results: The ASD knowledge mean scores significantly decreased (i.e., gain in ASD knowledge) from the pre-test (M= 2.55, SD= 0.55) to the post-test (M= 2.06, SD= 0.68), t (1,050) = 25.60, p< .01. Further, the social distance mean scores also decreased (i.e., less stigma) from the pre-test (M= 2.36, SD= 0.64) to the post-test (M= 2.12, SD= .64), t (1,076) = 16.35, p< .01. In terms of the relation between stigma and other factors, more accurate knowledge about ASD was strongly correlated with less social distance (i.e., less stigma: Z = .449, p< .01). Additionally, previous experiences interacting with students with ASD, Z =.109, p< .01, learning experiences about ASD in the classroom, Z = .101, p< .01, and previous exposure to ASD information through mass media, Z = .125, p< .01, were all positively related to lesser social distance (i.e., more experiences were related to less stigma).
Conclusions: The ASD education program was proven to be effective for increasing accurate knowledge on ASD as well as lowering stigma associated with ASD in Japanese high school students. Further, more accurate knowledge on ASD as well as previous direct interactions with students with ASD, opportunities to learn about these disabilities, and exposure to information about these disabilities were all correlated with lesser stigma associated with ASD.

216 **182.216** A Profile of Children with Autism in Ethiopia from the Perspective of Parents

W. Zeleke *and M. Chitiyo, Duquesne University, Pittsburgh, PA*

Background: One of the important aspects of autism that could be helpful to researchers in developing relevant interventions for children ASD in Africa is understanding the specific characteristics of ASD in the region. Unfortunately, there are still many unanswered questions on characteristics of ASD in Africa. For example, current research suggests that the stereotypic repetitive behaviors and activities characteristic of ASD are uncommon in Africa (Mankoski et al., 2006). But that research is not conclusive; it will be important to ascertain this difference in terms of specific behaviors. Also, even though Khan and Hombarume (1996) reported autistic typical behaviors among their sample of participants, the sample comprised of children with intellectual disabilities, which could confound the outcome. It is these lingering uncertainties that make the characterization of ASD in Africa unclear.
Objectives: This study aimed to investigate the characteristics of ASD in Ethiopia and to establish a profile of children with ASD in order to promote a better and clearer understanding of the disorder in Ethiopia. It is anticipated that such an effort could enhance better understanding of the disorder and promote better treatment outcomes among the African population
Methods: Survey questionnaires and Focus Group Discussion (FGD) were used to collect data from 85 parents of children with ASD. Descriptive and inferential statistics were run to analyze the data.
Results:
The majority of research participants (85%) reported that even though they noticed their child disability as early as two years old, the average age when their child see a professional for diagnosis was five years old. Parents' reason for seeking help from professional for their child with ASD found to be related to cultural, social, economic and educational factors. Diagnoses for the children was conducted by either a physician or pediatrician (n=55), either a psychologist or counsellor (n=18), or a psychiatrist (n=12). The symptoms leading to the diagnoses included behavioral (n=38), language/communication (n=26), social skills (n=2), or health (n=10). While most did not indicate the types of therapy that the children were receiving, a few indicated their children were receiving speech therapy (n=2) and behavioral therapy (n=21). Some of the children had been receiving therapy for as long as 12 years; 24 indicated that they had noticed change as a result of the therapy while 21 indicated not seeing any change; 20 did not respond.
Conclusions: Parents' awareness of autism is important for early dedication of ASD. It is also noted that cultural context may significance affect the age of identification of the symptoms, seeking intervention, and parents' understanding of the characteristics of autism.

217 **182.217** Age of First Diagnosis in Asian Children at a Regional Autism Clinic

M. Lambha[1]*, J. Mendelson*[2]*, J. Hamel*[3]*, N. Bhuiyan*[4]*, C. Hall*[4] *and D. R. Ussery*[5]*, (1)Marcus Autism Center/Children's Healthcare of Atlanta, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA and The University of North Carolina at Greensboro, Greensboro, NC, (3)Clinical Assessment and Diagnostics, Marcus Autism Center/Children's Healthcare of Atlanta, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (5)Marcus Autism Center, Atlanta, GA*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication, social interaction and restricted, repetitive patterns of behavior/interests (American Psychiatric Association, 2013). ASD diagnoses can be made as early as two years of age (Charman & Baird, 2002), allowing for earlier intervention, which leads to improved outcomes (Dawson, Rogers, & Munson, 2010; Eapen, Crncec, & Walkter, 2013; Reichow, 2012). While prevalence rates of autism has increased and the age of diagnosis has decreased among US children, ethnic differences exist in age of diagnosis (CDC, 2014). Studies have begun to investigate ethnic differences in age of first diagnosis, which has resulted in mixed findings for Asians. Specifically, some research has found that the age of first diagnosis is older in Asians as compared to other ethnicities in the US (Mandell, et al, 2009). In contrast, other research suggests that no significant difference exists between these groups (Windham, et al., 2011).
Objectives: This study examined the age of first diagnosis of Asian children at a regional autism clinic as compared to the ADDM Network's (CDC, 2014) national and state samples (comprised of Caucasian, Hispanic, Asian, and African American children). Further, a comparison was made between the Asian sample and the overall clinic sample. It was hypothesized that the age of first diagnosis for the Asian clinic sample would be significantly older as compared to the age of first diagnosis for the ADDM Network (nationally and regionally) and the overall clinic sample.
Methods: Data from the clinical sample of 59 Asian children (aged 23 to 128 months) who were diagnosed with ASD a regional autism clinic was used. Data from record review included information regarding age (M=55.85 months) and gender (male N = 49; female N = 10). Data from this sample were compared to the ADDM Network's reported national and state mean age of diagnosis using one-sample T-tests.
Results: This sample of Asian children (n=59) did not differ significantly from national norms (CDC, 2014) in terms of age of first diagnosis (53 months), nor did they differ significantly from the overall clinic sample (56 months). However, the age of diagnosis was significantly older than the average for their region as reported by the CDC (2014) (49 months; t=2.22; p<.05), mirroring results from previous work. Further analyses will be conducted to examine possible relations between IQ and region of origin, with age of diagnosis.
Conclusions: Asian children receive a first time ASD diagnosis at an older age within a regional autism clinic when compared to the overall state sample of children. Factors contributing to this may include cultural and/or family influences. This is concerning because important intervention services are implemented later in development and may have less optimal outcomes (Reichow, 2012). However, the findings are not consistent with the national sample and the regional autism clinic, where the age of diagnosis is similar for both samples. This finding shows that compared to the national sample, Asian children from the clinic are being diagnosed at a similar age.

218 **182.218** Barriers to Diagnosis and Treatment of Autism Spectrum Disorder in Latino and White Non-Latino Families

*K. Zuckerman[1], O. J. Lindly[2], N. M. Reyes[3], **A. E. Chavez**[1], K. Macias[4], A. Folan[3], K. Smith[5] and A. M. Reynolds[3], (1)Oregon Health & Science University, Portland, OR, (2)Oregon State University, Portland, OR, (3)University of Colorado - Denver, Aurora, CO, (4)UCEDD Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA, (5)Children's Hospital Los Angeles, Pasadena, CA*

Background: Latino children are diagnosed with autism spectrum disorder (ASD) less often and at older ages than white non-Latino children. Early ASD diagnosis is associated with improved child functioning and better family outcomes. Little is known about barriers families experience to ASD diagnosis, how these barriers differ according to ethnicity and family language, and whether diagnostic barriers relate to subsequent ASD treatment use.
Objectives: To compare barriers to ASD diagnosis and rates of ASD-related service use among Latino and white non-Latino families.
Methods: We surveyed a random sample of parents of Latino and white non-Latino children with ASD seen at academic autism specialty clinics in California, Colorado, and Oregon. Study population included families of children age 2-10 with ASD diagnosis verified by DSM-4-TR or DSM-5 criteria and administration of the Autism Diagnostic Observational Schedule (ADOS). Parents completed a mixed-mode survey in English or Spanish. Survey assessed experience of 15 possible barriers to ASD diagnosis as well as hours of current therapy use. Bivariate and multivariate analyses compared frequency of specific barriers to ASD diagnostic care, total number of barriers, and rates of therapy service use among Latino families with limited English proficiency [L-LEP], Latino families with English proficiency [L-EP], and white non-Latino [WNL] families. Race/ethnicity were per parent report. English proficiency was defined as parent report of speaking English less than “very well.”
Results: 357 families (L-LEP: n=94, L-EP: n=95, WNL: n=168) completed the survey. Families experienced a median of 8 barriers, with L-LEP families experiencing the most barriers (Adjusted Incidence Rate Ratio 1.15 [1.05-1.27] compared to WNL). The most frequent barriers experienced overall were "Diagnostic process stressful for family" (74.9% of families) and "Parent lacked knowledge about ASD" (71.4% of families). On multivariate analysis, the following barriers were more frequent among L-LEP families compared to WNL families: “Parent was afraid to ask for help due to legal problems (Adjusted Odds Ratio [AOR] 13.00, 95% Confidence Interval [5.18-32.62]), “Parent lacked knowledge about ASD” (AOR 3.12 [1.37-7.13]), “Diagnostic process stressful for family (AOR 2.90 [1.37-7.13]), and “Difficult to trust providers” (AOR 2.71 [1.55-4.76]). L-EP and WNL families reported similar barriers, except “Diagnostic process was stressful,” which was less frequent among L-EP compared to WNL (AOR 0.51 [0.29-0.90]). In analyses of service use, experiencing more barriers was significantly associated with currently using <1 hour per week of services per week (AOR 0.40 [0.29-0.54]). L-LEP families were likely than WNL families to receive <1 hour/week of therapy compared to children in WNL families (AOR 3.84 [1.57-9.40]). There were no differences in therapy hours between L-EP and WNL families.
Conclusions: English proficiency is an important marker of barriers to ASD diagnosis and treatment among Latinos with ASD. Children in L-LEP families experienced more frequent and different types of barriers to ASD diagnosis than children in L-EP and WNL families. Improving family knowledge about ASD and trust in providers and the health system may help L-LEP families access earlier diagnosis and treatment.

219 **182.219** Differences in Neuropsychological and Behavioral Profiles of White and Asian Children with Autism Spectrum Disorder (ASD)

***C. Luong-Tran**[1], L. Kenworthy[2], C. Rothwell[3,4], A. B. Ratto[5], L. Mohamed[6], R. E. Shafran[7] and L. G. Anthony[8], (1)Neuropsychology, Center for Autism Spectrum Disorders, Children's National, Rockville, MD, (2)Children's Research Institute, Children's National Medical Center, Rockville, MD, (3)Catholic University of America, Washington, DC, (4)Center for Autism Spectrum Disorders, Children's National Medical Center, Rockville, MD, (5)Children's National Medical Center, Silver Spring, MD, (6)Yale Child Study Center, New Haven, CT, (7)Department of Psychology, Columbia University, New York, NY, (8)Children's National Medical Center, Rockville, MD*

Background: Asian-American children are less likely to be identified with Autism Spectrum Disorder (ASD) relative to White children (CDC, 2014). Understanding the impact of cultural differences on symptom presentation, as well as symptom identification, is important for closing this gap and for guiding appropriate treatment planning. Although researchers have found that cultural factors can account for differences in the neuropsychological profiles of typically developing racial minorities relative to their White peers (e.g., Ardila, Rosselli, Matute & Guajardo, 2005; Kelkar, Hough & Fang, 2013; see also Ponton & Corona-LoMonaco, 2007), no known research studies have compared neuropsychological outcomes of Asian and White children with ASD.
Objectives: This study aims to address the gap in cross-cultural ASD research by comparing executive function (EF) and behavioral profiles of Asian-American and White-American children with ASD.
Methods: Data from participants evaluated at an outpatient neuropsychology clinic between 2014-2015 were drawn from an IRB-approved clinical database. 19 Asian and 19 Caucasian children with ASD were matched by age (*M*=7.97, *SD*=3.80), gender (89.5% male), and nonverbal IQ (*M*=101.53, *SD*=22.35). Parents and teachers completed the ADHD Rating Scale, Behavior Rating Inventory of Executive Function (BRIEF) and Child Behavior Checklist (CBCL). Performance tests included various Wechsler intelligence scales, the Differential Ability Scales, Second Edition (DAS-II), the Test of Everyday Attention for Children (TEA-Ch), and the Tower of London (TOL).
Results: Independent samples t-tests indicated that teachers of students with ASD reported more problems with inattention ($t(21)=-2.961$, $p<.01$) and hyperactivity ($t(21)=-2.729$, $p<.01$) in White children than in Asian children on the ADHD Rating Scale. Parents of Asian children endorsed fewer problems with inhibition, shifting, emotional control, and planning/organization on the BRIEF, while parents of White children rated them to have clinically significant deficits in the same areas. Similarly, teacher responses to the BRIEF identified fewer problems with planning/organization in Asian students. No differences were found on performance tests of EF. Teachers and parents reported greater concerns for aggression and externalizing behaviors in White children on behavioral checklists. Parents of Asian children additionally reported significantly less concerns for internalizing behaviors.
Conclusions: There are clear differences in parent/teacher reports of executive dysfunction and behavioral problems between Asian and White children, while performance test results are similar between groups. In general, White children are perceived to have more (and clinically significant) difficulties in behavior regulation relative to Asian children. This could be related to referral bias, differences in cultural perception/attribution of problems, or cultural differences in the manifestation of problems. This could also represent problems in the cultural sensitivity of parent/teacher report tools. Further research and analysis is needed to confirm these findings.

220 **182.220** Factors Underlying Cross-Cultural and Gender Differences in Stigma Towards ASD: Insights from an Online Training for College Students in Lebanon and the United States

***K. Gillespie-Lynch**[1], N. Najjar Daou[2], M. J. Sanchez Ruiz[3], R. Obeid[4], P. J. Brooks[5], S. K. Kapp[6], F. Someki[5], N. Silton[7] and R. A. Habib[3], (1)CUNY Graduate Center, Brooklyn, NY, (2)American University of Beirut, Beirut, Lebanon, (3)LAU, Beirut, Lebanon, (4)CUNY Graduate Center, New York, NY, (5)College of Staten Island, Staten Island, NY, (6)University of California, Los Angeles, Los Angeles, CA, (7)Marymount Manhattan College, Manhattan, NY*

Background:
In previous work, we documented that stigma towards ASD was heightened in more collectivistic countries (Lebanon and Japan) than in the US. Collectivism has been positively associated with mental health stigma in the UK (Papadopoulos et al., 2013). In our prior work, stigma was higher among males than females in the US; such gender differences were less apparent in Lebanon and Japan. This pattern may arise from individualism-collectivism as gender differences in personality are heightened in more individualistic countries (Costa et al., 2001). Higher quality contact with individuals with ASD is associated with increased acceptance (Gardiner & Iarocci, 2013). We hypothesized that individualism-collectivism, quality of contact, and personality differences might underlie cross-cultural and gender differences in stigma towards ASD.
Objectives:
Examine (1) factors contributing to differences in ASD stigma in Lebanon and the US, and (2) factors that contribute to reductions in stigma following training.
Methods:
College students in Lebanon (N=672) and the US (N=563) completed an online survey, which included pre-tests (assessing ASD knowledge and stigma), an ASD training, which included a manipulation of contact, post-tests, and assessments of individualism-collectivism, social desirability, openness to experience, trait emotional intelligence, autism symptoms, and quality of contact with individuals with ASD. Participants were randomly assigned to one of three “contact” conditions, varying the alleged creator of the training (an autism researcher or a nonverbal or verbal person with autism).
Results:
Due to large numbers of comparisons, $\alpha=.001$. An initial regression analysis with country and gender as predictors of baseline stigma replicated findings of higher stigma in Lebanon, and among men (ps<.001). When the following predictors were included, lower ASD knowledge, lower quality of contact, less openness, lower collectivism, and being male were associated with heightened stigma (ps <.001). Country (p=.009), individualism (p=.013) and social desirability (p=.022) were marginally associated with stigma. Emotional intelligence and symptoms were unrelated to stigma.
Following training, participants reported less stigma (p<.001), with the magnitude of the reduction positively associated with quality of contact (p<.001) and marginally associated with knowledge (p=.004), emotional intelligence (p=.013) and openness (p=.039). The manipulation of contact, social desirability, and symptoms were unrelated to stigma reductions.
Conclusions:
Counter to our hypothesis, greater collectivism was associated with less stigma. The measure of individualism-collectivism used has a vertical dimension (acceptance of inequality) and a horizontal dimension (viewing people as equal) that intersects with the dimension of individualism-collectivism. Greater acceptance of inequality was associated with higher stigma in the current sample. Greater quality of contact and ASD knowledge were associated with lower stigma; both were low in Lebanon where autism resources are scarce. Prior contact predicted the degree to which stigma was reduced with training, which suggests that interventions should include direct contact with people on the spectrum. Our manipulation of “contact” (via the alleged creator of training materials) lacked actual engagement and was ineffective. Findings suggest that equalizing experiences (such as contact) and personality characteristics that contribute to such experiences (such as openness) may reduce stigma towards ASD.

221 **182.221** Factors Effecting the Age at Diagnosis of Autism Spectrum Disorders in the Kingdom of Saudi Arabia

F. Alnemary[1], *F. Alnemary*[1], *H. M. Al Dhalaan*[2], *G. Simon-Cereijido*[3] *and A. Hernandez*[4], *(1)UCLA, Los Angeles, CA, (2)King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, (3)Communication Disorders, Cal State LA, Los Angeles, CA, (4)Applied & Advanced Studies in Education, California State University Los Angeles, Los Angeles, CA*

Background:
Providing the autism spectrum disorders (ASD) diagnosis early in childhood warrants access to early intervention programs, yet many children are not diagnosed until later in life. While extensive buddy of research is available about factors affecting the age at ASD diagnosis in the western countries, little attention has been directed toward this area of research in Middle Eastern countries.
Objectives:
This study attempted to bridge the gap by identifying these factors among children with ASD in the Kingdom of Saudi Arabia (KSA).
Methods:
Regarding access to and use of services, survey data were collected from 205 caregivers of children with ASD in the KSA or of Saudi citizenships in other counties and were younger than 21 years. Multivariate regression analysis was utilized to characterize the associations of clinical and demographics predictors with the age at diagnosis.
Results: The median age at diagnosis was 3.0 years and was strongly predicted by residing outside the KSA followed by the having no comorbidity, engaging in challenging behavior in first two years, not responding to name in the first two years, and the child age.
Conclusions:
Establishing public laws to ensure access to early developmental screening and comprehensive diagnostic evaluation along with utilizing video-conferencing to provide diagnostic services have the potential to ameliorate disparities in the age at diagnosis in the KSA.

222 **182.222** Study of Changes in Caregiving-Related Parental Stress after Parent Training in Evidence-Based Techniques

M. Diamond[1], *L. Keenan*[2] *and M. Habash*[3], *(1)A Global Voice for Autism, Minneapolis, MN, (2)A Global Voice for Autism, Abu Dhabi, United Arab Emirates, (3)A Global Voice for Autism, Ottawa, ON, Canada*

Background: Families affected by autism in the West Bank experience significant political, socioeconomic and cultural barriers when attempting to access evidence-based autism services. Studies have shown that mothers of children with autism in communities with access to resources experience stress similar to that of a combat soldier. For families who live in communities without resources, this stress is even greater. The lack of professionals qualified to diagnose autism and to provide intervention for children on the spectrum increases parental stress and leads families to feel isolated in raising their children with autism. This study measures changes in parental stress before and after teaching parents evidence-based techniques for supporting their children with autism at home and in the community.
Objectives: To assess changes in parental stress, as related to caregiving for a child with autism prior to and following training in evidence-based intervention techniques.
Methods: A total of twenty-four families (n=24) of children who have been diagnosed with autism spectrum disorders in Jenin and Ramallah Palestine participated in this study, with sixteen families from Jenin and eight families from Ramallah. Primary caregivers answered questions about their own stress and comfort managing their child's behaviors at home and in the community prior to and after taking part in a 12-week parent-training program. Quantitative and qualitative data were collected and analyzed.
Results: Results across the Jenin and Ramallah groups suggested that teaching parents how to utilize evidence-based practices to teach their children with autism new skills significantly decreases parental stress as related to caregiving for children with autism. Furthermore, we observed that teaching parents that they are not at fault for their child's autism is a significant factor in reducing parental stress.
Conclusions: Parent training can benefit parents in conflict-affected communities by teaching them strategies to support their children at home and in the community. Teaching parents that they are not the cause of their child's autism also decreases stress for these caregivers.

223 **182.223** Factor Structure and Psychometric Properties of an Arabic Version of the Autism Knowledge Questionnaire

F. Alnemary[1] *and A. Hernandez*[2], *(1)UCLA, Los Angeles, CA, (2)Applied & Advanced Studies in Education, California State University Los Angeles, Los Angeles, CA*

Background:
The Autism Knowledge Questionnaire (AKQ) was originally developed by Stone (1987) and then modified by Schwart and Drager (2008). The updated version included 20-items that aimed to assess professionals and parents knowledge about etiology, diagnosis, and specific features of autism spectrum disorder (ASD). A four point Likert-type scale (1- Strongly agree, 2- Agree, 3- Disagree, 4-Strongly disagree) is used to respond to the items. Previous research has demonstrated the reliability and validity of this measure in Western countries (e.g., United State; Heidgerken, Geffken, Modi & Frakey, 2005). Yet, no attempt has been made to validate this instrument in Arab world countries.
Objectives:
The purpose of this study was to adopt and examine the psychometric properties of the AKQ among parents of children with ASD in the Kingdom of Saudi Arabia (KSA).
Methods:
A total of 205 caregivers, mostly fathers (61%), of children with ASD and were younger than 21 (M = 8.0; 3.5 SD) years completed an online survey including the AKQ (*See table 1 for sample characteristics*). Exploratry factor anaylsis was used. The Principal Axis Factoring extraction method was selected due to the skewedness of data while Promax rotation method was used as factors were correlated (Costello & Osborne, 2005). The scree plot with the exclusion of the inflexion point's criterion was used to determine the number of factors (Field, 2013).
Results:
Of the 20 items, only 12 items underlie four factors. These factors included: Criteria Necessary To Be Diagnosed With Autism (CN), Descriptive Features (DF), Cognitive Features (CF), and Social Communication Features (SCF). Regarding reliability, Cronbach's alphas for the CN, DF, CF and SCF were 0.67, 0.48, 0.50, and 0.52, respectively. The Cronbach's alphas of these subscales were deemed sufficient, as the instrument is in an early stage of investigation (Field, 2013).
Conclusions:
The AKQ was adopted into Arabic and resulted in excluding some items. However, the modified questionnaire is more suitable to examine parents' knowledge of ASD in the Arab world.

224 **182.224** Study of Changes in Autism Sibling Behavior and Attitudes after Participation in Sibling Support

M. Diamond[1], *L. Keenan*[2] *and M. Habash*[3], *(1)A Global Voice for Autism, Minneapolis, MN, (2)A Global Voice for Autism, Abu Dhabi, United Arab Emirates, (3)A Global Voice for Autism, Ottawa, ON, Canada*

Background: Due to the autism stigma in the Middle East, many family members of children with autism do not talk about their family member's diagnosis outside of the home. Because of this, many siblings of children with autism have never shared their sibling's diagnosis with anyone else and have a limited understanding of autism and how to interact with their sibling. This study measures increases in sibling confidence, understanding of autism and desire to support siblings with autism after participation in a sibling support program.
Objectives: To assess changes in sibling confidence, understanding of autism and desire to support their siblings with autism before and after participating in a sibling support program.
Methods: A total of thirty-three siblings (n=33), between the ages of six and fourteen, of children who have been diagnosed with autism spectrum disorders from Jenin and Ramallah Palestine participated in this study, with 9 siblings from Ramallah and 24 siblings from Jenin. The siblings answered questions verbally at the beginning and end of sibling support sessions and their responses were recorded in writing. Quantitative and qualitative data were collected and analyzed.
Results: Results across the Jenin and Ramallah groups suggested that meeting other siblings of children with autism and learning about their siblings' diagnoses had a substantial impact on participating siblings' desire to support their siblings with autism. Discussions that occurred between siblings also suggest the value of siblings with autism developing relationships with other children with similar experiences. Autism stigma and a desire to hide the autism label from siblings were identified as primary factors preventing social interactions between siblings of children with autism.
Conclusions: Siblings can benefit from sibling support through the formation of friendships with other children with similar experiences, and through increased self-confidence in supporting their siblings with autism. Reducing autism stigma will increase social acceptability of talking about autism diagnoses in Palestine and will facilitate the formation of relationships between siblings of children with autism.

225 **182.225** Study of Effects of Parent Training on Parental Activation in Conflict-Affected Communities in Palestine

M. Diamond[1], *L. Keenan*[2] *and M. Habash*[3], *(1)A Global Voice for Autism, Minneapolis, MN, (2)A Global Voice for Autism, Abu Dhabi, United Arab Emirates, (3)A Global Voice for Autism, Ottawa, ON, Canada*

Background: In spite of frequent autism diagnoses, few services exist to support children with autism and their families in the West Bank, Palestine. Due to the lack of evidence-based programs to support children with autism, many families rely on professionals with little training that use methods with no evidence-based backing and see

few results. These parents develop feelings of hopelessness and believe that nothing will help their children with autism acquire skills. This study investigates the impact of parent training on parental activation in the support of their children with autism in Ramallah, Palestine.
Objectives: To assess changes in parental activation in Palestinian mothers after participation in a 12-week parent training program about evidence-based practices.
Methods: A total of eight families (n=8) of children who have been diagnoses with autism spectrum disorders in Ramallah, Palestine participated in this study. The primary caregiving parent completed Insignia Health's Patient Activation Measure as well as an assessment of parental confidence as related to their child's care in Arabic prior to participating in a 12-week parent-training program. Caregivers and their children with autism then participated in a 12-week parent-training program that included both didactic and theoretical training components. At the end of the program, primary caregivers completed the Patient Activation Measure and parental confidence measure again and changes in activation levels were calculated.
Results: Results suggested that parent training resulted in increased parental confidence in supporting their child's needs as well increased parental activation and ownership over the care of their child with autism. In the six months following the program, we found that parents with higher activation levels at the end of the program had a greater retention rate in the program's follow-up components while there was attrition from caregivers with lower activation scores.
Conclusions: Parent training can increase parental activation by showing parents in conflict-affected communities that they can take ownership of their child with autism's care. Furthermore, parents with higher activation levels are more likely to follow through with support programs for their children with autism and to prioritize their child's needs.

226 **182.226** Development and Adaptation of a Parent-Mediated Behavioral Intervention for Children with Autism Spectrum Disorder in Rural Bangladesh

J. M. Blake[1], *E. Rubenstein*[2], *P. C. Tsai*[3], *H. Rahman*[4], *S. R. Rieth*[5], *J. Chan*[6], *A. Hasmot*[4], *S. Mehra*[1], *A. A. M. Hanif*[4] *and L. C. Lee*[3], *(1)Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, University of North Carolina, Chapel Hill, NC, (3)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Johns Hopkins University Bangladesh, Gaibandha, Bangladesh, (5)San Diego State University, San Diego, CA, (6)University of California, San Diego, San Diego, CA*

Background: Timely access to behavioral intervention services has been shown to promote positive outcomes for children with Autism Spectrum Disorder (ASD). However, for many children living in low and middle income countries (LMICs), ASD services are rarely available or affordable. In rural northwestern Bangladesh, the lack of existing infrastructure is coupled with low literacy rates, extreme poverty, a dispersed population, limited resources, and inconsistent schooling for children. The combination of these factors makes it extremely difficult to establish clinic or school based ASD intervention programs. Little is known about adapting and implementing interventions and services in such rural communities, but in-home parent-mediated interventions are likely a feasible, low cost, and sustainable approach to address the needs of children with ASD in LMICs.
Objectives: We aim to describe the process of developing and adapting a sustainable parent-mediated ASD intervention for a community in rural Bangladesh and highlight the challenges and barriers to cultural adaptation and implementation.
Methods: In rural northwestern Bangladesh, researchers from the US and Bangladesh have been conducting research as part of a maternal and child health project called JiVitA aimed at improving pregnancy, birth, and child growth and development outcomes. Recently, a community based ASD study aimed to screen and test for ASD and examine risk factors in the study population. The current work builds on this recently completed study. The intervention was developed based on Pivotal Response Training (PRT) techniques and positive behavior support tools. Study investigators worked with US based PRT experts to familiarize themselves in these techniques and develop strategies and educational materials that could be used in a low resource and low literacy community. Study investigators then spent two months in the JiVitA study area to better understand the community's culture and needs. While there, investigators trained a JiVitA master's level child developmental psychologist in this intervention and used his expertise to further culturally adapt the materials. Field implementation is scheduled for winter 2015 and will include two half-day group sessions for parents followed by three individual in-home coaching sessions delivered by the project trained psychologist under the supervision of the study investigators.
Results: Through developing and adapting this intervention, we have gained insight into implementing ASD interventions in a rural Bangladeshi setting where community plays a key role in family dynamics with the broader community oftentimes acting as one family unit. Persons with disabilities (and their families) are often stigmatized within the community. Interventions need to be structured to avoid excess attention to the family or provide a lesser version of the intervention to the whole community. Furthermore, the relationship between parent and child is inconsistent across cultures. Any intervention needs to carefully consider the culturally appropriate role of the interventionist when supporting families of children with ASD.
Conclusions: Developing and adapting ASD behavioral interventions in a LMIC requires careful consideration of an area's knowledge about ASD, approach to parenting, acceptance of disability, cultural child behavior norms, and interaction between the family and community. Further results and findings will be discussed.

227 **182.227** Challenges to Autism Diagnosis and Service Delivery in the Gaza Strip

M. Habash[1] *and I. Habash*[2], *(1)A Global Voice for Autism, Ottawa, ON, Canada, (2)O.B.C, Ottawa, ON, Canada*

Background: The majority of the population in the Gaza Strip still live in refugee camps. The region has suffered major political and economic challenges for many year. Those facts have made the efforts to conduct autism prevalence studies in the Gaza Strip very challenging. Furthermore, organizations and institutions working in the autism domain have not been able to improve the diagnosis or the delivery of services to those who need such services. In particular, cultural and economic barriers have impacted the population of the refugee camps more that those who live in the cities, leading to less chances of children with autism being diagnosed or receiving any form of services.
Objectives: The purpose of this paper is to investigate the challenges facing families of children with autism dwelling the refugee camps in the Gaza Strip and to determine opportunities to provide better access to services for those families.
Methods: Quantitative and qualitative data is collected for this study through volunteer participants and institutions working in the region. A survey has been developed to be using during interviews with families of children suspected to have autism spectrum disorders as identified by public health workers or a professional. The study also utilizes autism prevalence data that was recently published.
Results: This is an ongoing study expected to complete in February 2016. Results will be available upon completion of the study.
Conclusions: The results from this study are expected to highlight the challenges and barriers to accessing services for diagnosis and interventions for families living in the refugee camps in the Gaza Strip, and compare those results to services received by people living outside the refugee camps.

228 **182.228** Engaging Low-Income Latino Families in a Community-Based Executive Function Intervention for Children with ASD or ADHD

J. Safer-Lichtenstein[1], *A. B. Ratto*[2], *M. Biel*[1], *L. Kenworthy*[3], *L. G. Anthony*[4] *and B. J. Anthony*[5], *(1)Georgetown University, Washington, DC, (2)Children's National Medical Center, Silver Spring, MD, (3)Children's Research Institute, Children's National Medical Center, Rockville, MD, (4)Children's National Medical Center, Rockville, MD, (5)Georgetown University, Catonsville, MD*

Background:
Low-income Latino families face critical disparities in access to and involvement in diagnostic and treatment services for autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD). The factors that contribute to this problem are both socioeconomic, including lack of financial resources to pay for services, and cultural, such as lack familiarity with research and medical systems. The handful of prior studies that have investigated the application of treatments for neurodevelopmental disorders with ethnic minority children have indicated that cultural adaptations are likely needed for the successful implemention, although the types of adaptations needed is unclear.
Objectives:
This study made use of Diffusion of Innovation (DOI) theory, which provides a framework for understanding how individuals and groups adopt new behaviors, in this case participation in treatment research, to identify the methodological considerations and adaptations made to research procedures in order to effectively recruit and engage low-income Latino families. Information was collected during the implementation of a PCORI-funded, comparative effectiveness study of two community-based executive function interventions for children with ADHD or ASD.
Methods:
Changes in procedures and measures were crafted based on initial consultation with stakeholders, as well as experiences during implementation of different components of the study: 1) initial contact with parents made by school personnel during the process of identifying potential participants in the study; 2) consultation with a stakeholder advisory board of community advocates, practitioners, and parents; 3) translation of materials and measures by multiple bilingual members of the research team; 4) parent trainings during which families received information on their child's intervention and support strategies to use at home; and 5) contact between parents and a Latina Family Navigator to offer support and answer questions about the program.
Results:
Methodological adaptations to the research protocol were made to more effectively engage Latino families, leading to important lessons regarding their involvement in research process and community based treatment. Within the DOI framework, these adaptations were related first to increasing *awareness* of the link between the intervention and family needs by providing information on the child's problems and how the intervention addresses them. Adaptations were also linked to three key characteristics of the interventions and research protocols that DOI research has identified as influential in determining adoption of innovations: (1) incorporating the role of family in influencing decisions related to engagement, including perceptions of diagnosis and treatment and forming relationships with trusted community members and organizations enhanced *compatibility* with the needs and existing values of families; (2) scheduling logistics, language and educational barriers, financial strain and time constraints were addressed to reduce the *complexity* or the level of difficulty of requirements and procedures; and (3) providing information to establish the *relative advantage* of the interventions over other options.

Conclusions:
The strategies utilized in this study and pragmatic adaptations made over the course of the trial highlight the need for a thoughtful and flexible approach to working with low-income, Latino families in community-based research.

229 **182.229** Autism on the Screen: Shaping Public Knowledge of Autism

A. Nordahl-Hansen[1], *M. Tøndevold*[2] *and S. Fletcher-Watson*[3], *(1)University of Oslo, Oslo, Oslo, Norway, (2)Institute of Special Need Education, faculty of Education, Oslo, Norway, (3)University of Edinburgh, Edinburgh, United Kingdom*

Background:
The film *Rainman* (1988) was a breakthrough in depicting characters with autism spectrum disorders (ASD). In representations since that time, the character's diagnosis may be clearly stated, as in *Rainman*, or diagnostic speculations may stem from the general public (as in the character of *Sheldon Cooper* in *Big Bang Theory*). Despite increases in estimated prevalence of ASD diagnosis globally, most people do not have substantial direct personal experience of the condition. Therefore, it is likely that depictions of characters with ASD on screen have substantial influence on public attitudes towards and knowledge of ASD.
Objectives:
To investigate how characters with ASD are portrayed on screen when assessed against diagnostic criteria. Sub-topics include: a) whether evidence suggests that those characters not explicitly labelled as having an ASD diagnosis would receive a diagnosis in real life; and b) whether specific characteristics associated with ASD (e.g. savant skills) are over-represented on screen.
Methods:
Clinical best estimate evaluations of n=10 characters from film and television were made using DSM-5 and ICD-10 diagnostic criteria. Two raters agreed an evaluation method in partnership drawing on evidence from two characters, and subsequent ratings were performed independently. Raters have at least 15 years' expertise working with autism including work in diagnostic services.
Results:
Characters demonstrated an almost perfect match to diagnostic criteria from both DSM-5 and ICD-10. Thus representations of ASD on screen are not misleading, but could be described as archetypal. The prevalence of savant-like skills is much higher than in the true population. Characters on screen who are not explicitly labelled with a diagnosis do display the full complement of traits employed in diagnosis, but not to an extent that these impact negatively on daily living, and thus real life diagnosis would not necessarily be sought or warranted in these cases.
Conclusions:
Representations of ASD on screen cannot be described as inaccurate, apart from an over-representation of savant skills. In contrast, on-screen characters with ASD present with every associated trait. Narrative imperatives may drive the over-representation of savant skills on screen. This may also explain why characters in long-standing TV series seem to be immune to many of the difficult consequences of autism.
Characters with ASD in television and film play a role in shaping knowledge and awareness of ASD in society. In an ideal world screen representations would not only be diagnostically accurate but also do justice to the obstacles faced by people on the spectrum, while illustrating how people with ASD can achieve great things in a supportive environment. There are examples of both of these representations in our sample, but it is impossible to represent in an individual character the heterogeneity of the autism spectrum. This may contribute to the frequent objections raised by the autism and Autistic communities to characters with ASD on screen. Therefore a goal for the community might be to encourage larger numbers of incidental characters with ASD on screen in order to present a more nuanced picture of the multiple facets of the condition.

183 - Interventions Pharmacologic
11:30 AM - 1:30 PM - Hall A

230 **183.230** Brief Outcomes in Autism Tool (BOAT): Use of a Novel Outcomes Tool to Improve Medication Management in Persons with Autism Spectrum Disorders

E. Pedapati[1], *R. Shaffer*[2], *E. Fox*[3], *L. K. Wink*[4], *R. Ittenbach*[5], *J. S. Anixt*[6], *M. Sorter*[3], *I. A. Badran*[7] *and C. Erickson*[8], *(1)INSAR Cincinnati Children's Hospital Medical Center, Anderson, OH, (2)Cincinnati Children's Hospital Medical Center, Harrison, OH, (3)Division of Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)Division of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (7)Cincinnati Children's Hospital Medical Center, Mariemont, OH, (8)Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Many persons with autism spectrum disorders (ASD) suffer from behavioral problems that lead caregivers to seek treatment. The use of medication as an intervention has been climbing rapidly, with recent estimates reporting that the majority of persons, including children, with ASD are treated with at least one psychotropic medication. There is a pressing need to have robust measures that assess not only the impact of medications on symptoms, but also concurrently measure key aspects of pharmacotherapy itself.
Objectives: We sought to develop an instrument to quantify behavioral changes and assess the quality of pharmacotherapy that could be easily and quickly be completed by caregivers in an outpatient setting, both at an initial encounter and for repeated measures. The goal of this scale is to provide valid and reliable caregiver reported measures to guide clinical decision making, especially of the use of pharmacotherapy in ASD.
Methods: We report on a novel ASD-specific 16-item care-giver assessed outcome measure, the Brief Outcomes in Autism Tool for Medications (BOAT-M) that measures clinically relevant dimensions related to pharmacotherapy in youth with ASD including acute symptom burden, overall caregiver perception of medication benefit, medication compliance, effect of medication changes, and non-specific and ASD-specific chronic symptom burden. We describe the design and creation of this measure, including the analysis of a preliminary data set to support the validity and responsiveness of the BOAT-M. The Clinical Global Severity (CGI-S) and Improvement (CGI-I) scale served as a standard to assess the clinical utility of the BOAT-M.
Results: A retrospective chart review of the BOAT form of 253 persons treated over a 3 month period at an outpatient academic child psychiatry practice specializing in developmental disabilities. Two-hundred and fifty three subjects were included in this analysis with basic demographic characteristics and chronic symptom burden presented in Table 1. The summation BOAT-M score (Figure 1) was significantly correlated with the CGI-S for all subjects ($n=233$; $r=0.403$; $p < 0.01$) and ASD subjects ($n=143$; $r=0.374$; $p<0.01$). Normality was confirmed with examination of a Q-Q plot. A higher chronic symptom severity subscale score (SS) was present between ASD and typically developing persons (TDC) ($t=3.5740$; $p < 0.001$). Subscales and clinical measures are reported in Table 2.
Conclusions: The BOAT-M is a 16 item, rapid, self-administered behavioral measure directed toward caregivers with children with developmental disabilities that is divided into 5 scored subscales and 1 summation score. The subscales are Behavioral Severity (BS), Mediation Compliance (CC), Medication Benefit (MB), Medication Change (MC), and Symptom Severity (SS). Initial psychometric properties indicate the summation score is highly correlated to a standardized clinical measure. In addition, chronic symptom burden can be delineated from acute behavioral symptoms. Future directions will investigate changes between multiple visits and sensitivity to treatment response.

231 **183.231** Improvement of Daily Living Skills in Adolescents and Adults with Fragile X Syndrome Following MDX (Metadoxine Extended Release) Administration

E. Berry-Kravis[1], *J. Rubin*[2], *E. Harary*[3] *and Y. Daniely*[3], *(1)Pediatrics; Biochemistry; Neurological Sciences, Rush University Medical Center, Chicago, IL, (2)Alcobra Pharma, Plymouth Meeting, PA, (3)Alcobra, Ltd, Tel Aviv, Israel*

Background: Fragile X Syndrome (FXS) is a rare genetic disorder characterized by Intellectual Disability and/or Learning Disability in association with a constellation of neuro-behavioral problems, including Autism Spectrum Disorder (ASD), Attention Deficit Hyperactivity Disorder (ADHD), anxiety, and repetitive behaviors. Metadoxine (pyridoxol L-2-pyrrolidone-5-carboxylate) is an ion-pair salt of pyridoxine (vitamin B6) and 2-pyrrolidone-5-carboxylate (PCA, also known as L-PGA) that has been used outside of the US in an immediate-release form for more than 30 years to treat acute alcohol intoxication, alcohol withdrawal syndrome, and chronic alcoholic liver disease. Metadoxine extended release (MDX) is a dual-release formulation of metadoxine, demonstrated to be a modulator of GABAergic transmission with a monoamine-independent mechanism of action, and which reverses phenotypes in the mouse model of FXS. In a phase 2, 6-week, randomized, multi-center, double-blind, parallel, flexed- and fixed-dose trial of MDX compared with placebo in adolescents and adults with FXS, the ADHD-RS IV, the primary outcome failed to show improvement, while the Vineland II Daily Living Scale (DLS), a secondary outcome, was significantly improved on MDX versus placebo.
Objectives: To fully characterize the effects of MDX on the Vineland-II DLS in FXS.
Methods: Subjects enrolled in the study were males and females with molecular diagnosis of FXS, (≥200 CGG repeats, in *FMR1*) 14 to 55 years, with a score ≥12 on the inattentive subscale of the ADHD RS-IV. Improvements in the group assigned to MDX, in comparison with the placebo group, with a secondary efficacy assessment, the Vineland Adaptive Behavior Scale, Expanded Interview Form, Second Edition (Vineland-II) DLS were characterized in detail by using item analysis and correlating results with other outcomes.

Results: 62 subjects were randomized (MDX 30; placebo 32). The primary analysis, the MMRM LS mean change from baseline to week6/early termination in the ITT population was significant on the DLS domain standard score (p=0.04) and the community subdomain v-scale score (p=0.004), and was not significant for the personal and domestic subdomain v-scale scores. These results were strengthened when the ITT population was limited in a post-hoc analysis to subjects with normalized IQ from 40-85 and ages 14-40.
Analysis of individual items in the DLS domain demonstrated significant effects ($p<0.05$) for several questions such as: seeks medical help in emergencies, plans and/or organized daily work, and carries out multi-step tasks. For most of these items, the MDX placebo difference in the mean change from baseline to week 6/ET was 0.5 to 1, demonstrating a categorical improvement. Items from objective secondary measures in the trial directly assessing the subject (KiTAP Distractibility and Go/No-Go computerized tests, and RBANS-List Learning), produced supportive correlations ($r>0.25$, $p<0.05$) with improvements on the DLS domain.
Conclusions: MDX demonstrated a statistically significant effect on the Vineland-II DLS domain in FXS. Item analyses suggested clinically meaningful changes in areas related to daily living skills, and correlations with other objective outcomes strengthened the effect.

232 **183.232** Medication Knowledge, Attitudes, and Readiness for Transition to Healthcare Self-Management in ASD

L. B. Silverman[1], *K. M. Brown*[2], *M. A. Steingraeber*[2], *J. Aldrich*[1], *T. Smith*[1], *D. Harris*[3] *and L. P. Shone*[3], *(1)Division of Neurodevelopmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (2)University of Rochester, Rochester, NY, (3)American Academy of Pediatrics, Elk Grove Village, IL*

Background: An estimated 30 to 60 percent of individuals with autism spectrum disorder (ASD) take at least one psychotropic medication. Despite widespread use, little is known about child and caregiver knowledge of medication regimens, attitudes towards taking medications, and perceived readiness for medication self-management. Addressing these questions has significant implications for adherence and treatment outcomes.
Objectives: To quantify medication knowledge, attitudes, and perceived readiness for transition to healthcare self-management in adolescents with ASD and their parents.
Methods: Participants were 22 high-functioning adolescents with ASD between 14 and 17, and 22 of their parents. Both groups completed an hour-long interview and electronic survey addressing these topics. Medication knowledge was quantified via survey questions asking for a list of current medications, and reasons for each medication. Medication attitudes were measured using a modified version of the South Hampton ADHD Medication Behaviour and Attitudes Scale (SAMBA; Harpur et al., 2008). Participants indicated the extent to which they agreed with statements about medication use, via a 32-item, 5-point Likert scale (1=strongly disagree, 5=strongly agree). Mean subscale scores were calculated, quantifying perceived costs and benefits of medication, patient stigma, and resistance to treatment. Readiness for healthcare self-management was measured via the Transition Readiness Assessment Questionnaire (TRAQ; Sawicki et al., 2011). Participants indicated their skill level related to healthcare self-management, via a 20-item, 5-point Likert scale (1=No-I don't know how, 5=Yes-I always do this when I need to). Mean subscale scores were calculated, quantifying ability to manage medications, keep appointments, track health issues, and talk with providers.
Results: The mean number of medications taken by adolescents was 2.68 ((1.94); per parent report) and 1.33 ((1.20) per child report). A reason for taking every medication was provided by 100% of parents, and only 65% of adolescents. Mean SAMBA scores in both groups indicated a perceived low to moderate cost of medication use (child: 1.94 (.69); parent: 1.40 (.50)), resistance to the medication regimen (child: 1.82 (.63); parent: 1.73 (.54)), and stigmatization (child: 1.89 (.83); parent: 1.51 (.66)), while the benefits of medication were rated as moderate to high (child: 3.79 (.71); parent: 3.93 (.82)). Mean TRAQ subscale scores indicated very limited readiness for healthcare self-management: medication self-management (child: 1.49 (.84); parent: 1.05 (.83)), appointment keeping (child: 0.69 (.80); parent: 0.18 (.29)), healthcare tracking (child: 1.01 (1.06); parent: 0.45 (.66)), and talking to providers (child: 2.25 (1.13); parent: 1.89 (.65)). Intraclass correlations demonstrated a significant positive relationship between child and parent scores on the SAMBA's medication benefits subscale ($r=.56$, $p=.04$) and the TRAQ's medication management subscale ($r=.72$, $p=.004$); all other correlations between child and parent scores were non-significant.
Conclusions: These findings suggest that individuals with ASD and their parents regard medication as beneficial, but parents and adolescents agree that adolescents have limited knowledge about their medications and feel unprepared to manage their own healthcare. These findings emphasize the need for enhanced education around healthcare self-management in transition planning for adolescents with ASD.

233 **183.233** Mental Comorbidities and Use of Psychotropic Medications in Patients with Autism Spectrum Disorder in the United States

R. C. Ong[1], ***R. Houghton***[1], *A. Surinach*[2] *and F. Bolognani*[1], *(1)F. Hoffmann-La Roche, Basel, Switzerland, (2)Genesis Research, Hoboken, NJ*

Background:
Patients with autism spectrum disorder (ASD) are known to have a range of social, communication, behavioral, sensory and motor difficulties. Other mental disorders are common among patients with ASD. Psychotropic medications may be used to treat these comorbidities.
Objectives:
The objectives of this study were to investigate among patients with ASD the frequencies of concurrent mental diagnoses and use of psychotropic medications, and to investigate factors associated with psychotropic medication use.
Methods:
This retrospective observational study utilized administrative claims data based on multiple commercial health plans in the United States (MarketScan® Commercial Database). ASD patients of all ages were identified by having at least two ASD diagnoses (ICD-9-CM code of 299.0x, 299.8x, or 299.9x) in the database between 2000 and 2013, and having at least one of the ASD diagnoses given during the year 2013, i.e. the year of interest for this analysis. A total of 38,071 ASD patients were identified. Mental disorders of interest included epilepsy, sleep disturbances, attention-deficit disorder (ADD), anxiety disorder, depression, bipolar disorder, schizophrenia, and conduct disorder. Any prescription filled for any psychotropic drug class was investigated, with classes of interest being antidepressants, stimulants, antipsychotics/tranquilizers, anticonvulsants, anxiolytics/sedatives/hypnotics, and hypotensive agents (limited to clonidine and guanfacine).
Results: The age in the cohort ranged from 3 to 65 years. Among the ASD patients identified, more than half (56%) had a claim for a concurrent mental disorder of interest, with ADD (33%), anxiety disorder (20%), and conduct disorder (11%) being the most common conditions. Most of the patients (63%) had a filled prescription for a psychotropic drug, with antidepressants (32%) being the most common drug class, followed by stimulants (29%) and antipsychotics/ tranquilizers (26%). Among all mental conditions investigated, patients with bipolar disorder in addition to their ASD diagnosis were most often given psychotropic medications (95%). The proportion of patients who received psychotropic medications increased with age. More than one-fifth (21%) of patients aged 2-4 were diagnosed with additional mental conditions, but only 12% of patients in this age group received psychotropic medications. Although psychotropic medication use was common in patients with comorbid mental conditions (83%), many patients (36%) without those conditions also received psychotropic medication. Results from adjusted multivariate logistic regression indicated that the likelihood of patients receiving psychotropic medication increased with patient age and the presence of any of the mental conditions of interest.
Limitations:
Diagnosis of ASD or any of the comorbidities of interest was based on claims data. Reasons for initiating treatment with psychotropic medications cannot be assessed.
Conclusions:
Mental comorbidities and psychotropic medication use were common in ASD patients in the United States. Interestingly, psychotropic medication was prescribed in patients without concurrent mental conditions, suggesting a broader use of this class of drugs. Finally, the use of psychotropic medication is less likely in childhood.

234 **183.234** Oxytocin-Based Pharmacotherapy for Autism Spectrum Disorders: Investigating the Immediate and Long-Term Effects from a Neural and Behavioral Perspective

S. Bernaerts[1], *J. Prinsen*[1], *C. Dillen*[2], *E. Berra*[1], *S. Brams*[1], *N. Wenderoth*[1,3] *and* ***K. Alaerts***[1], *(1)University of Leuven - KU Leuven, Leuven, Belgium, (2)Child and Adolescent Psychiatry, KU Leuven, Leuven, Belgium, (3)ETH Zurich, Zurich, Switzerland*

Background:
Autism spectrum disorders (ASD) are characterized by impairments in social communication and interaction. To date, no pharmacological treatments exists targeting the core symptoms of ASD. The past years, the pharmacological use of a neuropeptide, called oxytocin (OT), has gained increasing interest from the research community to explore its potential for elevating the core social deficits in ASD. In the brain, OT acts as a neurotransmitter where it is considered to form a mediator of prosocial behavior by increasing social salience, social motivation, and social awareness.
Objectives:
With this study, we aim to evaluate both immediate (single-dose) and long-term (multiple dose) effects of OT administration in adult male patients with ASD in a double-blind randomized placebo-controlled trial. Both neural and behavioral measures are assessed.
Methods:
A multi-modal neuroimaging approach is adopted to assess neural effects (i) at baseline; (ii) after a single-dose (24 IU) of nasal spray administration (OT or placebo); (iii) after 4 weeks of daily nasal spray administration; and (iv) one month post-trial to assess potential retention effects. Behavioral changes are assessed using emotion processing tasks and questionnaires assessing social responsiveness, attachment, mood state, and quality of life. Sixteen male patients with ASD (8 OT/ 8 placebo) are currently enrolled in the study and recruitment is still ongoing. All patients are characterized using IQ and ADOS-scales and thoroughly screened for adverse indications for participation in fMRI research.
Results:
To date, we only have preliminary data available assessing changes in functional connectivity based on resting-state fMRI scans. Resting-state fMRI is a technique for measuring spontaneous fluctuations in low-frequency brain activity while participants are at rest in the scanner (not performing an explicit task). An exploratory analysis was

conducted to assess changes in whole-brain functional connectivity after a single-dose (immediate effect) or after 4-weeks of daily nasal spray administration (long-term effect). Retention data (one month post-trial) are not yet available.
Changes in whole-brain network connectivity were identified for several regions of the social brain (e.g. fusiform gyrus, orbito-frontal cortex, frontal operculum, insula). Interestingly, changes in network connectivity of these regions were evident both immediately after a single dose of OT, as well as after 4-weeks of daily OT administration. After long-term OT administration (not after a single-dose) connectivity changes were additionally identified for the thalamus and middle/superior temporal gyri. These preliminary results are in agreement with results of a recent voxel-based meta-analysis of 11 task-based fMRI studies exploring single-dose effects of OT in neurotypical individuals (Wigton et al., 2015). This study similarly identified the insula, temporal lobes, thalamus and (pre/orbito) frontal cortex as the most implicated regions.
Conclusions:
Our highly preliminary results provide first indications that OT can induce changes in network connectivity of the social brain in patients with ASD. Further research is however necessary to explore whether these neural changes can be replicated in larger samples; whether and how they are paralleled by behavioral changes and whether the effects will outlast the time of intervention.

235 **183.235** Pattern of Use of Psychotropic Medication in Patients with Autism Spectrum Disorder in the United States

R. C. Ong[1], *R. Houghton*[1], *A. Surinach*[2] *and F. Bolognani*[1], *(1)F. Hoffmann-La Roche, Basel, Switzerland, (2)Genesis Research, Hoboken, NJ*

Background: Patients with autism spectrum disorder (ASD) have a range of social, communication, behavioral, sensory and motor difficulties, and, additionally, often have other mental conditions. The use of multiple psychotropic medications in ASD patients, singly or in combination, has been reported in previous studies.
Objectives: The objectives of this study were to investigate the pattern of use of psychotropic medications in terms of length of treatment (LOT) as well as factors associated with psychotropic medication polypharmacy among commercially insured patients with ASD in the United States.
Methods: This retrospective observational study utilized administrative claims data based on multiple commercial health plans in the United States (MarketScan® Commercial Database). ASD patients of all ages were identified by having at least two ASD diagnoses (ICD-9-CM code of 299.0x, 299.8x, or 299.9x) in the database between 2000 and 2013, and having at least one of the ASD diagnoses during the year of 2013, i.e. the year of the interest for this analysis. A total of 38,071 ASD patients were identified. Polypharmacy was defined as the concurrent use of two or more psychotropic medications in at least two drug classes for 30 consecutive days or longer. LOT was defined for each medication class as the sum of supply days for medications in the class; a day supplied with multiple drugs within the same class was counted as one day. Psychotropic drug classes of interest were antidepressants, stimulants, antipsychotics/tranquilizers, anticonvulsants, anxiolytics/sedatives/hypnotics, and hypotensive agents (limited to clonidine and guanfacine). Mental disorders of interest included epilepsy, sleep disturbances, attention-deficit disorder (ADD), anxiety disorder, depression, bipolar disorder, schizophrenia, and conduct disorder.
Results: The age in the cohort ranged from 3 to 65 years. For most of the drug classes investigated, patients were given medications for >200 days on average in 2013, regardless of the presence of concomitant mental conditions. However, for anxiolytics/sedatives/hypnotics, LOT was shorter (<100 days). Among patients who received psychotropic medications, mean and median LOT increased with age. Of all ASD patients, 35% had psychotropic polypharmacy. Polypharmacy was rare among patients <5 years of age (2%), but was 49% for patients aged 18 years and older. Although polypharmacy was common among patients with mental comorbidities (49%), many patients (17%) with none of the conditions of interest had polypharmacy. Polypharmacy was most commonly observed among patients with bipolar disorder (82%), followed by patients with schizophrenia (76%) and depression (62%). Adjusted multivariate logistic regression indicated that patients who were older, and those who had a claim for any of the mental conditions of interest, were more likely to have received psychotropic polypharmacy.
Limitations: Diagnosis of ASD or any of the comorbidities of interest was based on claims data. Reasons for initiating treatment with psychotropic medications cannot be assessed.
Conclusions: Our study showed that psychotropic polypharmacy was associated with older age and comorbid mental conditions. Almost a fifth of ASD patients without mental comorbidities received polypharmacy, despite limited evidence supporting the safety and effectiveness of these combinations.

236 **183.236** Predicting Response to Pregnenolone Treatment of Irritability in Autism Spectrum Disorder – Preliminary Neurosteroid Metabolomic Analysis

L. K. Fung*, W. Sun, R. A. Libove, S. Tanaka, J. M. Phillips, J. Rajadas and A. Y. Hardan, Stanford University, Stanford, CA*

Background: Pregnenolone (PREG) is the precursor of endogenous pharmacologically active neurosteroids. When orally administered in humans, PREG is converted to multiple metabolites, including allopregnanolone (a $GABA_A$ receptor agonist). We recently reported the results of an open-label trial of PREG in the treatment of adults with autism spectrum disorder (ASD). We found that PREG reduced the levels of irritability and associated aggressive behaviors as measured by the Aberrant Behavior Checklist – Irritability subscale (ABC-I). PREG was also found to be well-tolerated by the study participants.
Objectives: To explore the associations between response to PREG and plasma concentrations of metabolites of PREG before and after 12-week trial of oral PREG.
Methods: PREG was initiated at 50mg twice daily in weeks 1 and 2, then increased by 50mg twice daily every 2 weeks to a final dose of 250mg twice daily which was maintained from weeks 9 to 12. Primary outcome measure was the ABC-I. Response was defined as change of ABC-I of 7 or greater. Concentrations of PREG and its metabolites in plasma samples were quantified by liquid chromatography-mass spectrometry. Analytes measured include PREG, PREG sulfate, progesterone, allopregnanolone, dehydroepiandrosterone (DHEA), DHEA sulfate, testosterone, estradiol, and cortisol. Levels of sex hormone binding globulin (SHBG) in the plasma samples were determined by an enzyme-linked immunosorbent assay (ELISA). Free levels of testosterone were calculated from total testosterone concentration, SHBG concentration, and published values of albumin concentration and association constants of albumin and SHBG. Two-tailed student t-tests were performed to compare metabolite concentrations between responders and non-responders. Regression analyses were also performed to determine the strengths of correlations between the change in ABC-I and the levels of metabolites.
Results: Twelve individuals with ASD (mean age 22.5) participated in this open-label study. PREG yielded improvement in the primary measure, ABC-I [17.4±7.4 at baseline; 11.2±7.0 at 12 weeks (p=0.028)]. Six participants were found to be responders to PREG treatment, while the rest of the six participants did not reach the responder criteria. Mean baseline PREG plasma concentration in the responder group (1.5±0.4ng/mL) was found to be lower (p=0.039) than the non-responder group (2.2±0.7ng/mL). Furthermore, week 12 total testosterone plasma concentration in the responder group (1.8±1.3ng/mL) was found to be lower (p = 0.0097) than the non-responder group (3.8±0.7ng/mL); week 12 free testosterone plasma concentration in the responder group (6.4±4.8pg/mL) was found to be lower (p = 0.0054) than the non-responder group (14.4±2.7pg/mL). Finally, correlation analyses revealed a negative correlation between the reduction of ABC-I and week 12 total testosterone level (coefficient of determination $R^2 = 0.40$).
Conclusions: Preliminary analysis found that baseline PREG and 12-week testosterone (both free and total) levels were associated with reduction of ABC-I. These findings suggest that effectiveness of PREG might be related to testosterone blood levels and additional research is needed to replicate these findings in a controlled trial.

237 **183.237** Psychotropic Medication Trends Among Children and Youth Diagnosed with Autism Spectrum Disorder in a Specialized Paediatric Clinic

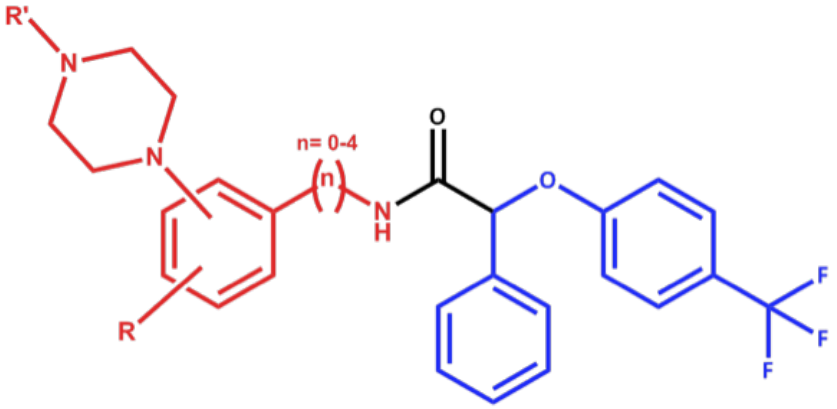
L. A. Siapno[1], *A. Dupuis*[2] *and S. Smile*[3], *(1)Developmental Paediatrics, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background:
Psychotropic medications are primarily directed towards treating comorbid symptoms, rather than core symptoms of autism spectrum disorder (ASD) in children. The rate of polypharmacy among children with ASD ranges from 10-20%. There is a paucity of studies examining psychotropic medication use over time among children with ASD.
Objectives:
This study examined if there is an effect of an ASD diagnosis on the number and change in the number of medication classes at two time points (year 1 and year 5) compared to baseline (time of initial consult).
Methods:
Medical records of children seen in a Psychopharmacology Clinic in a tertiary hospital setting in Toronto, Canada during 2006 and 2013 were reviewed. Cases were divided into two groups, namely i) ASD and ii) non-ASD. The variation on the number and types of psychotropic medication classes based on psychiatric, medical diagnosis and behavioural symptomatology was examined.
Results:
Three hundred and five medical records were included in the review. Eighty three percent (254/305) of cases had a diagnosis of ASD and 16.7% (51/305) non-ASD. The majority of cases (76%) were referred for irritability and aggression. A greater number of cases with ASD (45.2%) were on one psychotropic medication class and 23.6% were on two psychotropic medication classes at their initial consult. Antipsychotics were the most commonly prescribed medication class. Cases were more likely to be prescribed more psychotropic medications than taken off at the initial consult. The number of subjects who went on or off psychotropic medication was similar between groups with the ASD group slightly more likely to increase medications. An increased number of psychotropic medication classes were 2 to 3 three times more likely to occur than a decrease in the number of classes at the first year consult.
Conclusions:
Among children with ASD, prescribing trends remain relatively stable with one to two classes of psychotropic agents. There is no effect of an ASD diagnosis in the number and change pf medication classes over time.

238 **183.238** SAR of Phenoxyacetic Acid Analogs As Synergistic Dual Activity Serotonergic Ligands for Potential Use in ASD

L. Tran[1], *O. M. Ghoneim*[1] *and A. A. Khalil*[2], *(1)University of Saint Joseph School of Pharmacy, Hartford, CT, (2)Qatar University-College of Pharmacy, Doha, Qatar*

Background:
Repetitive/stereotypic behaviors are one of Autism Spectrum Disorder's (ASD) main domains and include persistent preoccupation with an object, phrase, or body movement that hampers educational or social interventions, and creates disturbance in the life of individuals and their caregivers. Currently, Selective Serotonin Reuptake Inhibitors (SSRIs) are used as first-line treatment for Obsessive-Compulsive Disorder and have been successfully used to treat repetitive behaviors in ASD individuals. SSRIs inhibit serotonin (5-HT) reuptake by blocking the serotonin transporter on the presynaptic neuron, as a way to increase synaptic serotonin. Another pathway to increase serotonin levels is to manipulate serotonin autoreceptors such as 5-HT_{1A}, 5-HT_{1B}, and 5-HT_{1D} receptors by regulating the synthesis of serotonin in the synapse based on demand. Accordingly, high 5-HT level in the synaptic cleft (enhanced by SSRIs) will stimulate the autoreceptors to decrease 5-HT synthesis and therefore counteract SSRIs. As a result, the 4-6 week delay in the therapeutic effect of SSRIs may be attributed to the time needed for the 5-HT autoreceptor to be desensitized. Co-administration of SSRIs with 5-HT autoreceptor antagonists is advantageous over SSRIs alone with respect to the magnitude of extracellular brain 5-HT levels produced. Encouraged by this fact, our laboratory has been investigating the combination of 5-HT uptake inhibition and autoreceptor antagonism in one molecule to act as synergistic dual-activity serotonergic ligand.
The design of the dual functional ligand comprises of structural features responsible for serotonin reuptake inhibition derived from fluoxetine (blue side; Figure 1) tethered to structural features responsible for autoreceptor inhibition from the non-selective autoreceptor antagonist GR-127935 (red side; Figure 1). Two compounds that provide proof of our pharmacologic concept include, OG-103 and JDO-106 as *in vitro* dual functional serotonergic ligands. Both compounds achieved 90-100% inhibition of 5-HT uptake when tested at 10 µM concentrations, which indicates activity from the blue side. However, their effect on 5-HT autoreceptor antagonism varied, indicating improvements can be made to the autoreceptor inhibition component.
Objectives:
Establish a structure activity relationship (SAR) of these fluoxetine-derived compounds called the LG-series, to achieve lead compound(s) that can effectively inhibit 5-HT uptake and antagonize 5-HT autoreceptors concomitantly.
Methods:
We used a four-step synthetic scheme. Briefly, a Williamson ether synthesis of trifluoromethylphenol and methyl-bromophenylacetate provided the ester core, followed by hydrolysis to yield the substituted phenoxyacetic acid. Coupling the acid with varying amines/anilines resulted in the wide varieties within the LG-series.
Results:
Eleven final compounds were synthesized in our laboratory from the LG-series encompassing amines/aniline of diverse steric and electronic characteristics. The biological screening of the LG-series was conducted at Eurofins/CEREP, Inc. The synthetic scheme, reaction conditions, and the effect of the various amines on the inhibition of the 5-HT uptake and serotonin autoreceptors will be presented.
Conclusions:
Our findings suggest that phenoxyacetic acid analogs can be used as a potential new class of agents with synergistic dual activity serotonergic ligands for repetitive behaviors modulation in ASD.



239 **183.239** The Influence of Sensory Integration on Behavior, Cognition and Mood in Autistic Children: A Pilot Study

C. Gouws*, Biokinetics and Sport Science, University of Zululand, Richardsbay, South Africa*

Background: The spectrum of treatment for autism is still poorly understood. Autism is typically characterized by developmental disruptions in social-emotional behaviour and communication. This condition/ disorder can be divided into three different types; depending on the severity of autism, of which each is treated differently. Sensory integration can be used to improve an autiistic child's problem areas, and is also applied to maintain the senses.
Objective: The importance of this pilot-study was to determine if a change in the behaviour, cognition and mood exists/occurs after undertaking/participating ina sensory integration intervention programme. Additionally, the study was designed to determine the time frame for the effects of a sensory integration intervention programme to be observed, as well as which test elicited the highest improvement in sensory integration in autistic children.
Method: Eleven males and one female of all ethnic groups, between the ages of 2 and 7 years, were initially recruited from special needs schools in the Richards Bay area of Northern KwaZulu-Natal, South Africa. Participants were tested using *the Sensory Processing Disorder Checklist* for the baseline measurments and the *Short Sensory Profile Checklist* was used for the pre/post-testing .
Results: A powerful, positive correlation was observed between pre-and post-testing for behavior, mood, cognition (r = .761). Paired t-tests demonstrated no significant changes in each class between baseline and post-test tactile sensitivity, taste/ smell sensitivity, underesponsive sensations, auditory filtering, low energy/ weak and visual/ auditory sensitivity. Movement sensitivity demonstrated a significant increase in the post-test ().
Conclusion: In conclusion, the effects of a sensory integration intervention programme positively influences an autistic child's movement sensitivity, which assists with mood control, cognition and overall behaviour.

Oral Session - 11A
185 - Genetic Mouse Models of Syndromal Autism Spectrum Disorder
1:45 PM - 2:35 PM - Hall B

1:45 **185.001** Initial Characterization of a New Loss-of-Function Mouse Model of the Autism Susceptibility Gene Chd8

J. L. Silverman[1], *M. C. Pride*[1], *I. Zdilar*[2], *A. L. Gompers*[2], *K. Zarbalis*[3], *J. N. Crawley*[1], *A. Visel*[4], *D. Dickel*[4], *L. A. Pennacchio*[4] *and A. S. Nord*[2], *(1)Psychiatry and Behavioral Sciences, MIND Institute, Sacramento, CA, (2)Center for Neuroscience, Davis, CA, (3)Department of Pathology and Laboratory Medicine, Shriners Hospitals for Children, Northern California, Sacramento, CA, (4)Lawrence Berkeley National Laboratory, Berkley, CA*

Background: Autism spectrum disorder (ASD) is a heterogeneous disease in which prominent efforts are being made to define subtypes with genetics and behavior. Recent successes using genetic based subtype identification have identified the chromodomain helicase DNA-binding protein 8 (*CHD8*) as a likely candidate for a specific subtype of ASD (Bernier et al., 2014, O'Roak et al., 2012, Talkowski et al., 2012 and Neale et al., 2012). *CHD8*, located on 14q11.2, binds to β-catenin and has major chromatin remodeling functions (Thompson et al., 2008). However, in vivo studies of the functional and phenotypic consequences of heterozygous mutation are lacking. To evaluate biological and behavioral consequences of *Chd8* mutations, we used targeted genomic engineering, to generate a mouse line harboring a loss-of-function mutation in *Chd8*.
Objectives: The present experiments in *Chd8* mice were designed to: 1) validate our genetic engineering of mice heterozygous for the *Chd8* mutation, 2) begin a behavioral characterization of phenotypes of high relevance to ASD, and 3) demonstrate the power of integrated genomic, neuroanatomical, and behavioral approaches towards revealing the effects of heterozygous *Chd8* mutation using a novel preclinical model of ASD.
Methods: Genetic engineering via the Cas9/CRISPR system was employed to generate one of the first *Chd8* mutant mouse lines. Briefly, synthetic guide RNA was injected along with Cas9 mRNA to mouse oocytes, and F0s carrying mutations were genotyped and bred to expand lines that harbored a mutation. We selected a line that harbors a

short deletion in the fifth exon of *Chd8* causing a frameshift resulting in a predicted loss-of-function allele. A battery of behavioral assays relevant to ASD, as well as numerous control assays to detect confounds in physical health or ability to evaluate complex behaviors were conducted as previously described (Crawley et al., 2007; Silverman et al., 2010, 2012). This inventory focused on domains that are affected in ASD, such as sociability, social communication, repetitive behavior, cognition, sensorimotor function and anxiety-like behaviors.
Results: Consistent with an earlier study, *Chd8* mutations are associated with early embryonic lethality in homozygous carriers, with no homozygous mice observed in the first five litters examined. In preliminary studies comparing mRNA generated via deep RNA sequencing performed on forebrains of heterozygous and wildtype littermates at different embryonic and postnatal ages, we have identified *Chd8* haploinsufficiency and associated changes of gene expression. Female mice with the *Chd8* haploinsufficient mutations exhibited motor deficits, anxiety-like behavior on the elevated plus-maze, and learning and memory deficits on both cued and contextual fear conditioning compared to wildtype control mice. Mutant males exhibited a trend toward anxiety-like behavior on another anxiety-related task, light↔dark transitions. Lower acoustic startle responses were also noted in the *Chd8* mutant males compared to wildtype littermate control mice.
Conclusions: We discovered important clinically relevant behavioral phenotypes in our novel *Chd8* mutant model of ASD. These preliminary studies also observed substantial sex differences in behavioral phenotypes, analogous to the clinic ASD literature. Our findings highlight the need to further examine this unique *Chd8* mouse model with extensive pathophysiology and behavioral phenotyping efforts.

1:57 **185.002** Total Brain Volume Increase and Selective White Matter Loss in the Hgsnat(-/-) and Sgsh (-/-) Mouse Models Related to Sanfillipo Syndrome

J. P. Lerch[1], *R. Yuen*[2], *A. Creighton*[3], *L. Spencer Noakes*[1], *B. J. Nieman*[1], *L. Nutter*[3], *S. W. Scherer*[2] *and J. Ellegood*[1], *(1)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (2)Centre for Applied Genomics (TCAG), Hospital for Sick Children, Toronto, ON, Canada, (3)Canadian Mouse Mutant Repository, Toronto Centre for Phenogenomics, Toronto, ON, Canada*

Background: Sanfillippo syndrome (SFS) is a rare autosomal recessive lysosomal storage disease, also known as mucopolysaccharidosis (MPS) III. There are four different types, A-D, all of which are indistinguishable in the clinic. *HGSNAT* (heparan-α-glucosaminide N-acetyltransferase) and its mutations are associated with SFS type C and the *SGSH*(N-sulfoglucosamine sulfohydrolase) and its mutations are associated with SFS type A. In a recent report (Rumsey et al. 2014) it was determined that 13 of 21 children diagnosed with SFS type A also met the criteria for autism diagnosis.
Objectives: To provide a first screen of two novel homozygote knockout mouse lines – C57BL/6N-*Hgsnat*^{em4Tcp} and C57BL/6N-*Sgsh*^{em3Tcp}.
Methods:
Mouse lines were generated using Cas9, to introduce frameshift indels in the coding regions of their respective genes. In total, 39 fixed mouse brains were examined. 16 of which were WT (C57BL6/N), 11 *Hgsnat*(-/-) mice, and 13 *Sgsh*(-/-) mice. The mice were P60 ± 2 days and equally distributed between both sexes. We used whole brain MRI to provide an indication if – and where – mutations in these genes affect the brain.
MRI Acquisition – A multi-channel 7.0 Tesla MRI scanner was used to acquire anatomical images of the brain. A T2-weighted, 3-D fast spin-echo sequence was used (restricting sampling to a circular region in the two phase encode dimensions). This sequence yielded an image with 40 µm isotropic voxels (3D pixel) in ~14 h.
Data Analysis – To visualize and compare any differences the images are registered together. The goal of the registration is to model how the deformation fields relate to genotype (Lerch et al., 2008). Volume differences are then calculated either in individual voxels or for 159 different segmented brain regions in each groups (Dorr et al. 2008, Ullmann et al. 2013, and Steadman et al. 2014). Multiple comparisons were controlled for using the False Discovery Rate (FDR) (Genovese et al., 2002).
Results:
For both the *Hgsnat*(-/-) and *Sgsh*(-/-) mice the total brain volumes were significantly larger than the WT mice (450 mm^3 ± 7 for *Hgsnat*, and 450 ± 11 for *Sgsh* versus 432 ± 14 for the WT, FDRs <1%); therefore, relative volumes were examined to account for these differences. 14 regions were found to be significantly different in the *Hgsnat*(-/-) brains, and 27 regions were found to be different in the *Sgsh*(-/-) brains. Since mutations in both genes are implicated in SFS, it is not surprising that the same 14 regions affected in *Hgsnat* null mice were also affected in *Sgsh* null mice albeit to a greater extent. Analysis of the images voxelwise shows a similar pattern of differences in both models, but with the Sgsh(-/-) mice showing a stronger phenotype (Figure 1). Interestingly, despite a total brain volume increase, the white matter is decreased in both models, with the anterior commissure, cingulum bundle, corpus callosum, internal capsule all found to be smaller.
Conclusions: These two SFS models show very similar characteristics with decreased volume in several white matter tracts despite an overall increase in total brain volume.

2:09 **185.003** Mechanisms Underlying Sensitive Periods for Treatment of Cerebellar Mediated Autistic Behavior

J. Ellegood[1], *Y. Chu*[2], *J. P. Lerch*[1], *W. Regehr*[3], *M. Sahin*[4] *and* ***P. Tsai***[5], *(1)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (2)Neurobiology, Harvard Medical School, Cambridge, MA, (3)Neuroscience, Harvard Medical School, Boston, MA, (4)Department of Neurology, Boston Children's Hospital, Boston, MA, (5)6000 Harry Hines Blvd, University of Texas Southwestern Medical Center, Dallas, TX*

Background:
Autism Spectrum Disorders (ASDs) are prevalent neurodevelopmental disorders marked by social impairments, repetitive behaviors, and cognitive inflexibility. Despite a prevalence exceeding 1%, underlying mechanisms are poorly understood while targeted therapies and their guiding parameters are needed. Recent evidence has implicated the cerebellum in ASD pathogenesis, and we have recently demonstrated that cerebellar dysfunction is sufficient to generate autistic-like behaviors in a mouse model of Tuberous Sclerosis Complex (TSC).
Objectives:
The developmental windows during which behavioral dysregulation emerges and the time windows of treatment efficacy for ASD and the underlying circuit and cellular mechanisms remain poorly understood. In this study, we sought to delineate these sensitive periods for treatment of ASD behaviors and to examine the underlying cellular, physiologic, and circuit based mechanisms.
Methods:
In this study, we utilize the mechanistic target of rapamycin (mTOR) specific inhibitor rapamycin in a cerebellar Tsc1 mouse model of monogenic ASD, performing behavioral analysis, electrophysiologic studies, anatomic characterization, and MRI based structural connectivity.
Results:
Using these methods, we define distinct treatment sensitive periods for autistic-like – motor, social, and repetitive/restricted – behaviors, periods that extend into adulthood for social and motor behaviors. Moreover, we identified anatomic, cellular, and electrophysiologic parameters that underlie behavioral rescue. Lastly, using volumetric MRI and structural covariance measures, we identified patterns of connectivity between cerebellar and cortical regions implicated in clinical ASD that are disrupted in mutant mice. We further demonstrate that alterations in clinically relevant connectivity respond to rapamycin therapy, consistent with demonstrated behavioral rescue.
Conclusions:
These findings, thus, not only define treatment parameters but also provide a mechanistic and structural basis for targeted, behavioral rescue in ASD.

2:21 **185.004** Social Encounters Reveal Brain Region-Specific Gene Expression Changes in Shank3 Null Mice

A. Anacker[1], *T. D. Rogers*[2] *and J. Veenstra-Vander Weele*[3], *(1)Columbia University, New York, NY, (2)Vanderbilt University Medical Center, Nashville, TN, (3)New York State Psychiatric Institute / Columbia University, New York, NY*

Background: Deletions or mutations in *SHANK3* lead to Phelan-McDermid syndrome (P-MS), one of the most common known genetic causes of autism spectrum disorder (ASD). Mice with disruptions in *Shank3* show deficits in social behavior and may provide a window into the networks and circuits underlying P-MS specifically and perhaps ASD more broadly.
Objectives: The goal of the present study was to examine the transcriptional response to a social stimulus in specific brain regions.
Methods: Adult male mice with a deletion in exons 13-16 of the *Shank3* gene, or their wildtype littermates, were exposed to a social or non-social stimulus for 30 minutes. Ten hours later, tissue was extracted from the prefrontal cortex, medial amygdala and lateral amygdala for RNA sequencing analysis (Illumina HiSeq 2000). Count-based differential expression analysis was performed (edgeR_3.4.2) for the following comparisons: 1) mutant vs wildtype in nonsocial condition, 2) mutant vs wildtype in social condition, 3) social vs nonsocial in wildtype, 4) social vs nonsocial in mutant, and 5) the interaction across genotypes and conditions. Analyses of the differentially expressed genes in each comparison ($p<0.05$) were performed using WebGestalt for Gene Ontology, KEGG, and Wikipathway analyses, and using Ingenuity Pathway Analysis for Canonical Pathway, Disease and Function, and Network analyses. Differentially expressed genes were also compared to genes implicated in ASD, as collected in the SFARI Genes database.
Results: Genes implicated in ASD were significantly enriched among differentially expressed genes in all brain regions, particularly in the mutant versus wildtype comparisons in the non-social condition ($p\leq0.0001$), as well as in the interaction analysis across genotypes and conditions ($p<0.03$). Pathway analyses revealed that genes involved in neuronal signaling and development were differentially expressed in nearly all comparisons, across all brain regions examined. Genes relevant for behavior, developmental and neurological disorders were also enriched. The axonal guidance signaling pathway was one of the most consistently significant canonical pathways identified as having enriched gene networks, particularly in mutant vs wildtype comparisons (p ranging from 0.00359 to <0.0001).
Conclusions: These findings indicate that the *Shank3* null mouse model has changes in gene expression relevant to ASD, indicated by the prevalence of autism-associated genes, as well as the consistent enrichment of pathways relevant for neuronal signaling and development. Future studies may elucidate the role of specific networks in the social deficits observed in *Shank3* null mice.

Oral Session - 11B

186 - Integrated Approaches and Insight from Related Disorders

2:40 PM - 3:30 PM - Hall B

2:40 **186.001** Genome Wide Association Studies of Empathizing and Systemizing

V. Warrier[1], *R. Toro*[2], *P. Smith*[3], *B. Chakrabarti*[4], *N. Litterman*[5], *T. Bourgeron*[6] *and S. Baron-Cohen*[3], *(1)University of Cambridge, Cambridge, England, United Kingdom, (2)Institut Pasteur, Paris, France, (3)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (4)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (5)23andMe, Mountain View, CA, (6)Institute Pasteur, Paris, France*

Background: Autism Spectrum Conditions (autism) are neurodevelopmental and are characterized by difficulties in social interaction and communication alongside unusually repetitive and stereotyped behaviours, unusually narrow interests, and resistance to unexpected change. Several lines of evidence suggest that, on average, individuals with autism have preserved systemizing abilities but are impaired in select domains of empathy. The genetic architecture of these traits have not been investigated. We investigated the heritability of these two traits and the genetic correlation between these traits and five psychiatric conditions, including autism.
Objectives: (1) To identify common genetic variants associated with self-report measures of empathing and systemizing; (2) To quantify additive heritabilities explained by the common variants and the differences in heritability of these traits in typical males and females; (3) To identify enrichment in biological pathways; (4) To calculate the genetic correlation between these traits and other psychiatric conditions, including autism.
Methods: We collaborated with 23andMe Inc., a personal genetics company, to perform a genome wide association study (GWAS) of empathy (measured using the Empathy Quotient (EQ), n = 46,861) and systemizing (measured using the Systemizing Quotient-Revised (SQ-R), n = 51,564). Sex specific analyses were performed to identify sex-specific architecture. Linkage disequalibrium (LD) score regression was used to calculate inflation in p-values due to unaccounted population stratification, heritability, and genetic correlation. We calculated genetic correlation between the psychological traits and five psychiatric conditions (autism, schizophrenia, anorexia nervosa, bipolar disorder, and major depressive disorder) using summary GWAS data from the Psychiatric Genomics Consortium. Pathway analysis was performed to identify enriched biological networks, gene sets, and tissue specific expression.
Results: We identified two significant loci associated with systemizing, and one with empathy. Additionally, we identified a locus that was significant in the males-only subset with systemizing. Approximately 11% of the variance for both the traits is explained by additive genetic effects of the SNPs examined. There was no statistical difference between male and female heritabilities. As expected, empathy had a negative genetic correlation (i.e SNPs contributed to higher autism risk but lower empathy) with autism, and systemizing had a positive genetic correlation with autism (i.e SNPs contributed to higher autism risk and higher systemizing). Unexpectedly, both systemizing and empathy were positively correlated with other psychiatric conditions, namely schizophrenia, major depressive disorder, anorexia nervosa, and bipolar disorder.
Conclusions: The study shows that empathy and systemizing are genetically correlated with several psychiatric conditions. Though males and females perform differently on the SQ-R and the EQ, their additive heritabilities are not statistically different.

2:52 **186.002** Homozygous Deletions of Non-Coding DNA Sequences in Autism Spectrum Disorder

K. Schmitz-Abe[1,2], *G. Sanchez-Schmitz*[1,2], *E. M. Morrow*[3], *M. Greenberg*[1,2], *T. W. Yu*[1], *C. A. Walsh*[1,2] *and K. Markianos*[1,2], *(1)Harvard Medical School, Boston, MA, (2)Children's Hospital Boston, Boston, MA, (3)Department of Molecular Biology, Cell Biology and Biochemistry and Institute for Brain Science, Brown University, Providence, RI*

Background:
Noncoding DNA comprises 99% of the genome but methods for identifying its contribution to disease have greatly lagged our understanding of protein-coding mutations. Autism Spectrum Disorder (ASD), associated with defects in social and/or cognitive function, has previously been linked to *de novo* Copy Number Variants (CNVs), *de novo* Single Nucleotide Variants (SNVs) or inherited recessive biallelic SNVs; however, most cases remain unexplained.
Objectives:
We analyzed CNVs and homozygosity in 187 families ascertained through the Homozygosity Mapping Collaborative for Autism (HMCA), an ASD cohort highly enriched for families that are consanguineous (792 individuals). We compared findings in our cohort to data from the Autism Genetic Resource Exchange cohort (AGRE, 740 families, 2985 individuals) and from the Simons Simplex Collection (SSC, 1,027 families, 3881 individuals).
Methods:
CNV detection, annotation, and analysis were done using a custom build, rule based “Variant Explorer” pipeline. It uses concordant calls between multiple algorithms to maximize specificity, and classified as common/rare based on overlap with 1,251 HapMap controls processed by the same pipeline.
Results:
In consanguineous families, children affected with ASD are significantly enriched for autosomal homozygous deletions compared to unaffected siblings (17% versus 4%, $p<0.001$). Most homozygous deletions were small (<50 kb) and only a few were predicted to result in protein inactivation through coding exon disruption. In contrast, affected children were significantly enriched for homozygous deletions in DNA regulatory regions, with regions disrupting ENCODE histone methylation peaks, a rate much higher than predicted by chance ($p<0.001$).
Conclusions:
While the importance of regulatory elements has been previously anticipated, such non-coding variants are not as readily identifiable as the disruption of coding sequence. High consanguinity allows us to study biallelic deletions and take advantage of the favorable signal to noise ratio provided by complete loss of coding or regulatory regions. The importance of biallelic deletions is supported by two lines of evidence: 1) a significantly higher rate of biallelic deletions in affected children relative to their unaffected siblings ($p<0.001$), and 2) a striking enrichment/depletion pattern of intersection between biallelic deletions and ENCODE control regions in affected/unaffected children ($p<0.001$). While (1) provides unambiguous evidence for the role of biallelic deletions in recessive ASD, the ENCODE analysis provides formal evidence for the mode of action of a significant subset of biallelic deletions.
The biallelic deletions regions identified here represent an important starting point to the understanding of the role of patterned gene activation/regulation in cognitive and social function. ASD in general appears to show an especially important role for gene dosage in causation, given the central importance of heterozygous CNV and SNV all of which affect gene dosage, and the importance of hypomorphic recessive mutation. Upon neuronal depolarization neurons are known to show rapid and reversible changes in the levels of expression of a large number of activity-regulated genes, and this temporally regulated transcriptional program is known to be essential for the functional changes that underlie memory formation and learning. Biallelic noncoding mutations, or heterozygous mutations affecting gene dosage, may well cause disease by disrupting such finely tuned transcriptional programs.

3:04 **186.003** Combining Autism and Intellectual Disability Exome Data Yields Insight into Both Disorders

J. D. Buxbaum[1], *A. E. Cicek*[2], *L. Klei*[3], *B. Devlin*[4] *and K. Roeder*[2], *(1)Mount Sinai School of Medicine, New York, NY, (2)Carnegie Mellon University, Pittsburgh, PA, (3)University of Pittsburgh Medical Center, Pittsburgh, PA, (4)University of Pittsburgh, Pittsburgh, PA*

Background: Autism spectrum disorder (ASD) is known to have a complex genetic architecture. Recently, exome sequencing studies have enjoyed great success using de novo single nucleotide variants (SNVs) and short indels to identify risk genes. However, calculations indicate that there are hundreds of additional genes that confer risk yet to be discovered.
Objectives: ASD and intellectual disability (ID) are known to co-occur and consequently their risk genes show considerable overlap. These findings motivate an analysis that contrasts and combines discoveries in ASD and ID.
Methods: The Autism Sequencing Consortium (ASC), in collaboration with the Deciphering Developmental Disabilities (DDD) consortium, assimilated published exome sequencing data from 6564 probands and controls. We used TADA (Transmission And De novo Association) to identify likely risk genes in both disorders individually and we combined the trios to find additional genes that affect risk for both disorders. We applied the algorithm DAWN (Detecting Association With Networks) to networks estimated from brain gene expression data to discover subnetworks of interacting risk genes. We then determined which gene networks communities showed enrichment of ASD and ID risk genes.
Results: Our results revealed 31 and 64 risk genes (FDR < .05) associated with risk for ASD and ID, respectively (with 12 genes identified in both), and 16 additional genes when combining the data. Based on the pattern of de novo loss-of-function (dnLoF) variants, we estimated that the total number of autosomal dominant genes in which a dnLoF imparts substantial risk for ASD and ID, respectively. We estimated a 95% confidence interval for ASD of 500-950 and for ID of 185-225. Relative to the mean NVIQ in the sample, a proband with LoF mutation in one of the genes with the strongest signal for both disorders (ASD.ID) had an average drop in NVIQ of 24 points and a LoF mutation in an ID-related gene produced a similar reduction in NVIQ in the ASD proband. A LoF mutation in an ASD-related gene, which was not also implicated in ID, was associated with a weaker effect on NVIQ, reducing it relative to the sample mean by almost 12 points. We identified two functional ASD clusters enriched for chromatin modification. We used those components to identify which targets are enriched for ID-related risk genes. Genes strongly affecting cognitive function were primarily represented in clusters involving chromatin modification, implicating gene regulation as a mechanism shared by ID and ASD. Moreover, the results highlight disruption of corticofugal projections neurons as a source of risk.
Conclusions: We estimated that there are significantly fewer ID-related genes and that a large fraction of the ID-related risk genes are also ASD-related. Genes found in ID

samples had a marked impact on IQ even in ASD, compared to genes identified only in ASD. Genes strongly affecting cognitive function mapped to ASD gene networks involving chromatin modification. The results implicate disruption of neocortical development as a mechanism shared by ID and ASD.

3:16 **186.004** Genes with Extremely High Penetrance for Autism Are Often Involved in Largescale DNA Remodeling

E. L. Casanova[1], *H. Chakraborty*[2], *N. S. Sumi*[3] *and M. F. Casanova*[4], *(1)Biomedical Sciences, University of South Carolina, Greenville, SC, (2)Biostatistics and Epidemiology, University of South Carolina, Columbia, SC, (3)Epidemiology and Biostatistics, University of South Carolina, Columbia, SC, (4)Pediatrics and Biomedical Sciences, University of South Carolina School of Medicine, Greenville, SC*

Background: Rates of autism comorbidity vary across genetic syndromes, though underlying causes have been poorly addressed. While there has been much interest surrounding neurite and synapse involvement in autism's etiology, studies suggest there may be earlier embryonic disturbances in genetic syndromes associated with autism that are a reflection of the associated gene dysfunction.
Objectives: To determine whether genetics underlying monogenic forms of intellectual disability (ID) that are highly-comorbid with autism vary in comparison to IDs with low-to-no rates of autism comorbidity and in what ways that occurs.
Methods: A group of 492 forms of ID were curated using the Online Mendelian Inheritance in Man (OMIM) database as well as the larger literature. ID's were grouped according to comorbidity with autism: ID only, ID with highly-comorbid autism (ID/HCA), and ID with variable autism (VarAut). Minimum comorbidity cut-off for inclusion within ID/HCA was 20% for autosomal conditions and 30% in males for X-linked. Gene functions were assessed using a combination of Gene Ontology (GO) and UniProt/Swiss-Prot databases. These databases and The Human Protein Atlas (HPA) were used for confirmation of GO's Cellular Component results. Analyses for GO, frequency of "regulatory" genes across groups and within ID/HCA subgroup, and frequency of transcription factors across the ID/HCA upper/lower comorbidity ranges were performed using proportions comparisons. Analyses concerning ID/HCA interaction with the core protein-protein interaction (PPI) network (Wnt, Shh, Ncor, SWI/SNF, Notch, Erk1/2, TGF-β/BMP) were analyzed using 2-tailed heteroscedastic T-tests with Bonferroni correction for multiple comparisons ($\alpha = 0.0167$).
Results: Compared to ID only and VarAut, ID/HCA genes exhibited an extreme enrichment in protein functions associated with epigenetic, post-transcriptional, and translational regulation (called "regulatory") ($p < 0.001$ across all comparisons). Genes from this group were highly enriched in the GO term, "regulation of gene expression (GO:0010468)". In agreement with this finding, when we looked at "regulatory" gene function, a subgroup that comprised approximately 2/3rd of ID/HCA, more than half of genes within the upper range of comorbidity (median = 62%) were largescale DNA remodelers (i.e., heterochromatin remodelers, ubiquitin ligases, and methylation regulators); meanwhile, more than 2/3rd of the lower range were transcription factors/repressors ($p = 0.0216$; 95% CI of difference of proportions: 0.0588, 0.7412). In addition, approximately 80% of the "regulatory" gene products were located primarily within the nucleus of the cell. Finally, in contrast to other forms of ID, gene products associated with ID/HCA centered around a core PPI network that is foundational to axial patterning of the CNS as well as later processes of neural maturation and plasticity ($p < 0.001$ across all comparisons). Of particular note to this project, genes associated with 19 of the ID/HCA conditions are not currently included within the SFARI Gene Database.
Conclusions: These results indicate that high mutation penetrance for the autism phenotype is afforded most strongly by epigenetic, post-transcriptional, and translational regulators. Largescale DNA remodelers predispose towards highest penetrance, followed by specific transcription factors/repressors. In addition, our curated list suggests that the SFARI Gene Database is missing an important subset of highly-penetrant risk genes.

Oral Session - 12A
187 - Natural Language Processing
1:45 PM - 2:35 PM - Room 307

1:45 **187.001** Developmental Deviance of Item-Level Responses on Standardized Language Measures Correlates with Autism Spectrum Disorder Diagnosis

A. E. Hare-Harris[1], *M. W. Mitchel*[1], *B. R. King*[2], *S. M. Myers*[1], *B. Greene*[3], *C. L. Martin*[1], *J. F. Flax*[3] *and L. M. Brzustowicz*[3], *(1)Autism & Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA, (2)Computer Science, Bucknell Univeristy, Lewisburg, PA, (3)Genetics, Rutgers University, Piscataway, NJ*

Background: Developmental deviance (DDEV) refers to the non-sequential attainment of milestones within a developmental domain. This observation is in contrast to developmental delay (DD), where milestones are reached in the typical sequence, but the timeline of attainments is delayed. There is evidence that DDEV is associated with certain neurobehavioral diagnoses, such as autism spectrum disorder (ASD). Clinically, the attainment of developmental milestones is assessed through standardized measures of developmental domains. Many psychometric tests are arranged hierarchically, and on the surface, two individuals with the same overall score on a clinical measure may appear to be impaired to a similar extent. However, at the itemized level, individuals with DDEV exhibit a more scattered pattern of incorrect answers. Differentiating between DDEV and DD may inform prognosis and predict long-term outcomes.
Objectives: We used a modified measure of scatter, called *inefficiency*, to differentiate between DD and DDEV using standardized measures of language ability. We tested the accuracy of inefficiency to predict ASD diagnosis, and by extension DDEV, among probands from the New Jersey Language and Autism Genetics Study (NJLAGS) cohort.
Methods: NJLAGS consists of 157 families (500 individuals) ascertained for at least one individual with ASD and another with language impairment (LI). All individuals were given the Clinical Evaluation of Language Functioning (CELF) and Comprehensive Assessment of Spoken Language (CASL). Four phenotypic groups were defined: unaffected, ASD, LI, and LI+ASD. A hierarchical clustering model was fitted to each subtest to investigate if clusters of item responses correlate with an individual's diagnosis (LI or LI+ASD) regardless of scatter and ceiling effects. Inefficiency was defined for each subtest as the product of the total number of subtest items and the sum of the weights (percentage of unaffected family members who correctly answered the item) of the items missed. Group differences in inefficiency across subtests were assessed using ANOVA. We fit a generalized linear model to determine diagnostic outcomes of inefficiency with IQ and age included as covariates.
Results: Hierarchical clustering analysis indicated that the LI and LI+ASD groups segregate according to their item responses for subtests of the CASL and CELF. Overall raw scores did not differ between the LI and LI+ASD groups; however, the LI+ASD group had consistently higher inefficiency scores than the LI group for all language measures. The following subtests reached significance ($p<0.001$): CASL Nonliteral Language (NL), Pragmatic Judgement (PJ), Meaning From Context (MFC), and CELF Recalling Sentences (RS), Word Definitions (WD), and Word Classes (WC) subtests. When controlling for age and IQ, inefficiency was able to accurately predict ASD diagnostic status among the LI and LI+ASD groups for the NL ($p=0.002$), PJ ($p=0.009$), MFC ($p=0.005$) and RS ($p=0.005$) subtests.
Conclusions: Individuals with LI+ASD exhibit more DDEV, as measured by inefficiency, across measures of expressive, pragmatic, and metalinguistic language compared to individuals with LI. By distinguishing between DDEV and DD, inefficiency was able to predict ASD diagnosis among LI/LI+ASD probands. Inefficiency can be applied to measures across multiple developmental domains in order to characterize developmental profiles of individuals with DDEV/DD.

1:57 **187.002** Using Social Communication Dynamics Measures for Diagnostic Purposes in Adolescents with Autism Spectrum Disorder

V. Romero[1], *P. Fitzpatrick*[2], *R. Schmidt*[3] *and M. Richardson*[1], *(1)University of Cincinnati, Cincinnati, OH, (2)Psychology Department, Assumption College, Worcester, MA, (3)College of the Holy Cross, Worcester, MA*

Background: Children with Autism Spectrum Disorder (ASD) exhibit impairments in social interactions and at the core of these impairments are social communication deficits. Recent advances in the quantitative and computational measurement of conversational content has resulted in a novel set of methods that might provide a more objective and reliable way of identifying the conversational biomarkers of ASD, as well as a better understanding of the time-evolving dynamics of social communication in these individuals.
Objectives: The current study has two objectives: (1) to validate the use of newly developed computational measures of conversational interaction for assessing deficits in social communication in adolescents with ASD; and (2) to further identify whether deficits in social communication are interrelated to deficits in the social motor coordination that supports effective social interaction.
Methods: Twenty-four children previously diagnosed with ASD completed the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) and a battery of social motor coordination tasks. The conversations that each participant had with the clinician during the ADOS-2 administration were evaluated using Discursis, a computational time-series method that analyzes the conceptual and semantic content of an exchange between two or more individuals. Various measures were extracted to quantify different aspects of the conversation (e.g. self-similarity, other-similarity). Additionally, a measure of the child's social motor coordination ability was obtained (e.g. coherence). Of particular interest is the relationship between ASD symptom severity and the dynamical measures of communication and social motor coordination and the degree to which some of these dynamical measures better predict ASD communication deficits.
Results: Some Discursis measures were correlated with some ADOS-2 sub-category scores (e.g. social affect), as well as the composite score obtained from the test. Stepwise regressions confirmed that Discursis measures can be used to predict composite scores and traditional multiple regression showed that by including a measure of social coordination we are able to account for more of the variability present in ADOS-2 composite scores as well as some sub-category scores.
Conclusions: This pilot data provides some mixed results, but indicates that Discursis could be a sensible and important addition to our diagnostic procedures that would help us better understand the communicational deficits exhibited by some children with ASD. Furthermore, it seems that the social motor coordination that takes place during conversations is interrelated to the verbal communication and necessary to quantify for further understanding of this deficit. Finally, the addition of these measures has the potential to improve our diagnostic tools, as well as help with planning what types of treatment will most benefit the specific child once diganosed.

2:09 **187.003** Linguistic Markers of Autism Spectrum Disorder: Classification Sensitivity and Specificity of Language Produced during Clinical Evaluations

J. Parish-Morris[1], *R. T. Schultz*[2], *M. Y. Liberman*[3] *and C. Cieri*[3], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Linguistic Data Consortium, University of Pennsylvania, Philadelphia, PA*

Background: Infants and toddlers later diagnosed with autism spectrum disorder (ASD) often experience significant language delays, and concern about language is one of the first reasons parents seek evaluation (Tager-Flusberg, Paul, & Lord, 2005). Gold-standard clinical evaluations of ASD include administration of the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2000), which is based on a series of 0-3 ratings that sometimes differ from clinician to clinician. Given the importance of early identification and intervention for maximizing positive outcomes, it is crucial to develop objective, quantitative measures that can aid in diagnosis, inform intervention decisions, and predict trajectory. Computational linguistics methods and machine learning offer novel ways to analyze highly granular language data, revealing variation that may be informative for accurate, objective diagnosis and phenotypic characterization. For example, markers such as reduced co-articulation may reflect the increased cognitive and behavioral "rigidity" that characterizes ASD. Inter-turn pause length, an aspect of prosody that quantifies the gap between speaker turns, may relate to perceptions of pragmatic comptence. When pauses are too short (interrupting or speaking over a conversational partner) or too long (awkward silences), smooth conversational interactions are disrupted. In this preliminary research, we explore four potential linguistic markers of ASD: word choice, speech rate, inter-turn pause length, and rates of conversational turn-taking.
Objectives: Using a machine-learning approach, determine whether features of natural language produced during the ADOS distinguish ASD from typically developing controls (TDC).
Methods: Thirty-two participants aged 6-14 years (18 ASD, 14 TDC), individually matched on sex ratio, age, and IQ) were administered the ADOS during a clinical evaluation. 20-minute segments were transcribed, and parent reports of social responsiveness were collected (SRS; Constantino et al., 2003).
Results: First, we applied naïve Bayes classification to word choice (words produced by children during the evaluation) to assess the sensitivity and specificity of diagnostic classification based on this variable. Weighted log-odds calculations with leave-one-out-cross-validation resulted in 14/18 children correctly classified as having ASD and 100% of TDC participants classified correctly. Receiver Operating Characteristic (ROC) analyses showed high sensitivity and specificity using this classification metric, with area under the curve=92%, CIs 82%-100%, $p<.001$ (Figure 1a). In addition, we observed that participants with ASD spoke significantly more slowly (reduced speaking rate is associated with less co-articulation; Figure 1b), used significantly fewer words per turn, and had significantly longer inter-turn gaps than TDC participants. To assess continuous relationships between linguistic variables and clinical phenotype, we conducted Pearson correlations: results revealed that speaking rate, rate of conversational turn-taking, and overall speaking time correlated with symptom severity as measured by the SRS (rs range from -.34 to -.44, all ps<.01) but not with IQ or age. These promising preliminary findings with a relatively small sample are consistent with the literature and highly suggestive of real effects.
Conclusions: Computational linguistics represents a promising new way to parse heterogeneity and aid in diagnostic classification of ASD. New data from more heterogeneous populations are currently being analyzed, with the goal of increasing sample size and classification power.

Figures 1a & 1b. 1a. ROC curve showing ability of a classifier to separate cases from controls, using specific words produced by participants during the ADOS. 1b. The ASD group demonstrated significantly slower speech rates than the TDC group, shown as a function of number of words.

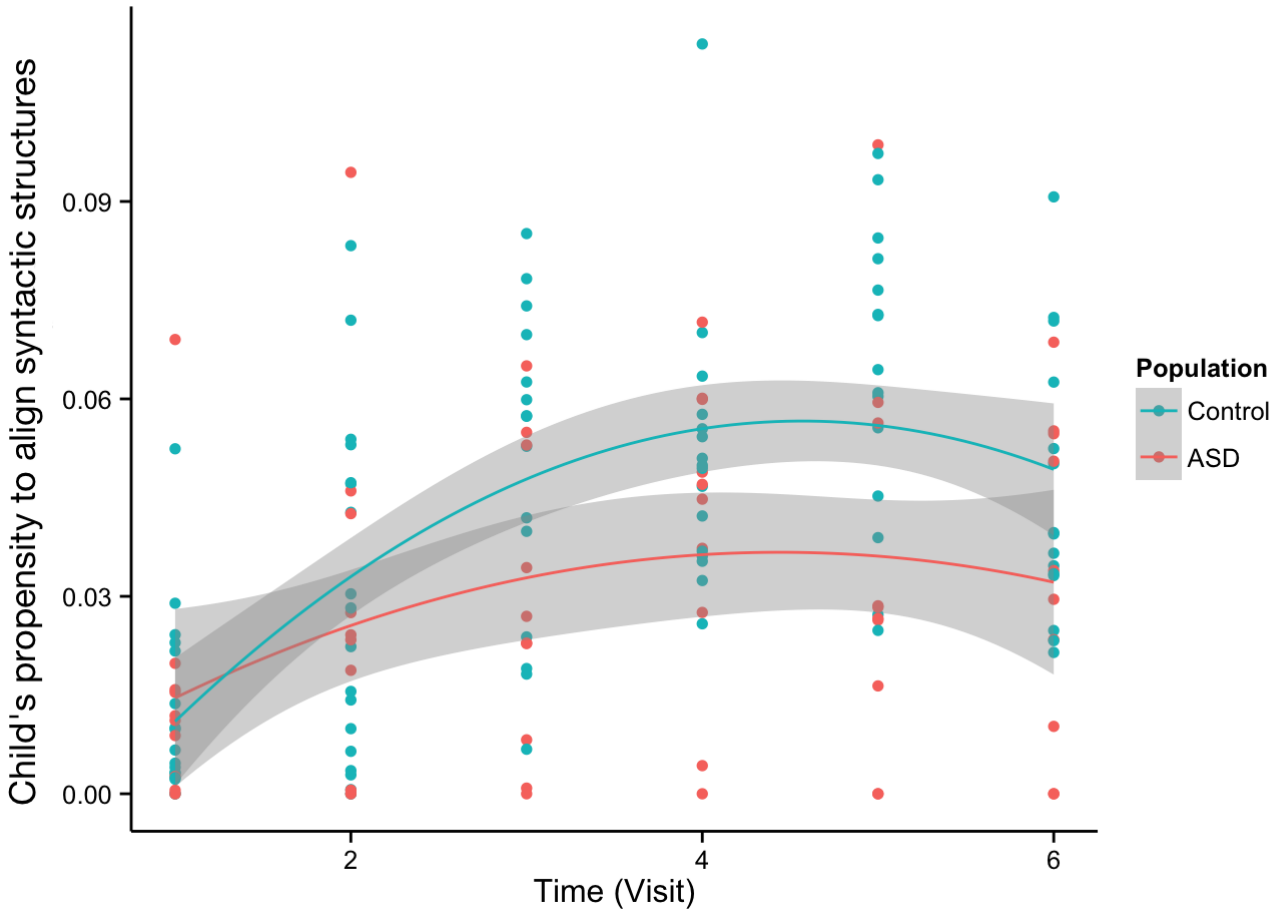
2:21 **187.004** Learning to Interact: Developmental Trajectories of Linguistic Alignment in ASD

R. Fusaroli[1,2], *E. Weed*[3] *and L. Naigles*[4], *(1)Center for Semiotics, Aarhus University, Aarhus, Denmark, (2)Interacting Minds, Aarhus University, Aarhus, Denmark, (3)Aarhus University, Tranbjerg J, Denmark, (4)University of Connecticut, Storrs, CT*

Background: Interactive alignment (IA) has been argued to underlie not only successful social interactions (Pickering & Garrod, 2004), but also language development. By re-using each other's words, the child and the caregiver engage each other, and the child acquires new linguistic items and receives feedback on their use (Nguyen & Delvaux, 2015; Messum & Howard 2015). IA has been shown to be unimpaired in high-functioning children and adults with ASD during highly structured task-oriented conversations (Hopkins et al, 2014; Slocombe et al 2014; Allen et al 2011). However, little is known about how the ability to align develops, and whether it is impaired in everyday unstructured interactions.
Objectives: We ask two questions: i) does IA evolve over time as children becomes a more competent speakers? and ii) is IA impaired in children with ASD?
Methods: We analyzed spontaneous speech in parent-child dyads from a longitudinal corpus (6 visits over 2 years), consisting of 30 minutes of controlled playful activities between parents and 66 children (33 ASD; MA = 33 months) and 33 initially-language-matched (Mullen EL, RL) typically developing (TD; MA = 20 months) (cf. Goodwin et al. 2012). Lexical and syntactic alignment was calculated between neighboring utterances as the probability of words (lexical) or parts of speech (syntactic) to be repeated, normalized by the length of the utterances involved. Syntactic alignment was calculated excluding repeated lexical items to maximally distinguish it from lexical alignment. To assess the development of alignment we used mixed-effects growth curve models. The models included gender, Mullen scores (Mullen 1995), and ADOS (Gotham 2009) scores as fixed factors.
Results: Across groups, we observed a general increase of alignment over time, with two primary effects: (1) *Development had significant linear and quadratic components* (lexical linear: β=0.76, SE=0.2, t-stat=3.88, p=0.0001; lexical quadratic: β=-0.56, SE=0.18, t-stat=-3.07, p=0.002; syntactic linear: β=1.12, SE=0.44, t-stat=2.53, p=0.011; syntactic quadratic: β=-0.95, SE= 0.45, t-stat=-2.12, p=0.034). (2) *Children with ASD displayed a lower degree of alignment*(lexical: β=-0.01, SE=0.01, t-stat=-1.96, p=0.05; syntactic: ASD: β=-0.07, SE=0.04, t-stat=-2, p=0.045). There were main effects of ADOS and Mullen scores: higher Mullen is related to higher lexical (β=0.01, SE=0.01, t-stat=1.94, p=0.05) and lower syntactic alignment (β=-1.16, SE=0.33, t-stat=-3.48, p<0.0001); higher ADOS is related to lower lexical (β=-0.13, SE=0.05, t-stat=-2.6, p= 0.01)

and syntactic alignment (β=-0.09, SE= 0.04, t-stat=-2.47 p=0.013). Gender had no impact. None of these factors interacted significantly with time.
Conclusions: Our data support the hypothesis that children's propensity to lexical and syntactic alignment develops over time. Contrary to previous findings on older populations, in our analysis of unstructured play between children and caregivers, we found that interactive alignment was impaired in the ASD group, as a function of symptom severity and intellectual functioning. This has important implications for understanding linguistic and social development in ASD. More work is needed to investigate how alignment develops at later ages, how alignment in unstructured contexts relates to alignment in structured task-oriented conversations, and what effect reduced alignment has on language development in ASD.



Oral Session - 12B
188 - Minimally Verbal Individuals with ASD
2:40 PM - 3:30 PM - Room 307

2:40 **188.001** Minimally Verbal Children with ASD and Cognitive Impairment: Do Definitions Matter?

V. Hus Bal[1,2], *T. Katz*[3,4], *S. L. Bishop*[1,2] *and K. Krasileva*[1], *(1)Department of Psychiatry, University of California San Francisco, San Francisco, CA, (2)STAR Center for ASD & NDDs, San Francisco, CA, (3)Autism and Developmental Disabilities Clinic, University of Colorado School of Medicine, Aurora, CO, (4)Children's Hospital Colorado and JFK Partners, Aurora, CO*

Background:
Guidelines for defining "minimally verbal" (MV) have been proposed (e.g., Kasari et al., 2013); however, to date, studies have used a variety of methods to classify samples. It is unknown how different parent-report or direct assessments used to classify MV samples compare. Some instruments may yield a very narrowly defined group of MV children, which may limit variability and make it difficult to identify dimensions that affect later language acquisition or other outcomes. This has implications for answering basic questions, such as the extent to which cognitive and language skills overlap in children with nonverbal cognitive impairment (i.e., NVIQ<70). A better understanding of methods used to define MV children is important to advancing understanding of this understudied group.
Objectives:
To examine how using different instruments to define MV cohorts affects sample characteristics (demographics; ASD symptom, cognitive and adaptive profiles) and the overlap between cognitive and verbal abilities in children with NVIQ<70.
Methods:
Children with ASD between 6 and 18 years old (N=2044) were drawn from the Simons Simplex Collection. All children had the ADI-R, Vineland, ADOS, cognitive assessment and parent questionnaires. Children were divided using the following MV definitions: ADOS Module 1 (No words/Some words), ADI-R language level (<5 words, 5+ words/no flexible phrases), Vineland Expressive age equivalent (<18 months), Social Communication Questionnaire (item 1 indicating no phrases) and parent estimate of vocabulary (none, 1-5, 5-25 words). Within children with NVIQ <70, MV children (ADOS Module 1, some words vs. no words) and verbal children (ADOS Module 2-4) were compared.
Results:
328 children (16% of the sample) were classified as MV. Of the 328, 24% were MV on two instruments and 38% on three or more. Most children (93%) were administered an ADOS Module 1 and 61% were reportedly not using daily, flexible phrases (ADI-R). Defining MV on the basis of the ADOS yielded the largest group with the most discrepancies across measures (e.g., 62% MV on ADI-R). Across MV definitions, 44-60% of children had VIQ<NVIQ profiles (i.e., VIQ 1+ SD below NVIQ), with as many as 15% of children with NVIQ>70.
Within the NVIQ<70 group (n=507), MV children were younger ($F(2,504)=12.63$, $p<.001$) and had lower VIQ ($F(2,504)=222.97$, $p<.001$) and NVIQ ($F(2,504)=122.95$, $p<.001$) than verbal children. A higher proportion of MV children (45%) had VIQ<NVIQ profiles than verbal children (20%; $X^2=78.82$, $p<.001$). MV children had less severe current social-communication impairments on the ADOS ($F(2,504)=24.38$, $p<.001$), but more past symptoms on the ADI-R ($F(2,504)=34.59$, $p<.001$).
Conclusions:
While no single approach is obviously "best," these results demonstrate how using different instruments to define MV samples affects sample composition. Results will inform comparisons across existing samples and design of studies ascertaining new samples of MV children. Within children with NVIQ<70, verbal and MV children differed on several characteristics. Nearly half of MV children exhibited VIQ<NVIQ profiles, suggesting a distinct subgroup of MV children whose language impairments are not attributable to general cognitive impairment. This highlights the need for future research to understand the unique strengths and challenges of MV children with ASD.

2:52 **188.002** What Predicts Speech Development in Young, Minimally Verbal Children with ASD?

P. Mirenda[1], *I. M. Smith*[2], *E. Duku*[3], *P. Szatmari*[4], *S. E. Bryson*[5], *E. Fombonne*[6], *T. Vaillancourt*[7], *J. Volden*[8], *L. Zwaigenbaum*[9], *S. Georgiades*[3], *T. Bennett*[3] *and M. Elsabbagh*[10], *(1)University of British Columbia, Vancouver, BC, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (3)McMaster University, Hamilton, ON, Canada, (4)Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)Dalhousie University, Halifax, NS, Canada, (6)Oregon Health & Science University, Portland, OR, (7)University of Ottawa, Ottawa, ON, Canada, (8)University of Alberta, University of Alberta, AB, Canada, (9)University of Alberta, Edmonton, AB, Canada, (10)McGill University, Montreal, PQ, Canada*

Background: Current estimates are that 10%-30% of children with autism are minimally verbal (MV); that is, they fail to acquire spoken language beyond a minimal level by the time they enter school, despite access to early intervention (Kasari, 2013). Past research suggests that nonverbal IQ (NVIQ), ASD severity, imitation skills, and/or joint attention skills at the time of diagnosis predict language outcomes in general (Ellis Weismer & Kover, 2015; Norrelgen et al., 2014; Thurm et al., 2014). However, no study to date has examined the extent to which changes in these variables are predictive of outcomes in children who are MV at the time of diagnosis.
Objectives: The purpose of this study was to examine the extent to which NVIQ, ASD severity, imitation and joint attention skills at diagnosis, and changes in imitation and joint attention over the first 6 months thereafter predict verbal status of children with ASD who were MV at diagnosis.
Methods: Data were drawn from the Canadian *Pathways in ASD* study and included only children who were MV at the time of diagnosis (T1) and for whom the data required to assess verbal status at age 6 were available. Participants were 91 children (89% males) from five Canadian provinces (mean age at T1 = 33.7 mo; range = 19-55 mo). MV

status at diagnosis was established by research-reliable assessors using two criteria: (a) code of 1 or 2 on question 30 (Q30) of the Autism Diagnostic Interview-Revised (ADI-R), and (b) code of 3 or 8 on Module 1 of the Autism Diagnostic Observation Schedule (ADOS). At T1, the Merrill-Palmer-Revised Scales of Development was used to measure NVIQ, and the Multidimensional Imitation Assessment (MIA) and Early Social Communication Scales (ESCS) were used to measure imitation and joint attention, respectively. In addition, 66 children completed the MIA and ESCS six months after T1 (T2), and all children were re-assessed with the ADI-R and ADOS at age 6 (T3). Verbal status at T3 was established based on ADI-R Q30 and the ADOS Module completed at that time. Correlation and multinomial regression analyses were conducted to examine the predictors of verbal status at T3.

Results: Of the total sample (N=91), 37.4% remained MV at age 6, 16.5% had words but not phrases, 27.5% had phrase speech, and 18.7% had fluent speech. Neither MIA or ESCS scores at T1 predicted verbal status at T3; the only significant predictor was T1 NVIQ. For the subsample (n=66), MIA Total change scores and ESCS Responding to Joint Attention change scores from T1-T2 were directly related to higher verbal status at T3.

Conclusions: NVIQ at the time of diagnosis and gains in imitation skills and responding to bids for joint attention during the first six months post-diagnosis (associated for many with the onset of early intervention) predicted verbal status at age 6. These results might be useful to guide decision-making related to the effectiveness of early interventions designed to support speech development in young children who are MV at diagnosis.

3:04 **188.003** Understanding the Changing Face of Autism: Determining Language Profiles of Children with ASD at Age Three Years

E. C. Bacon[1], *S. Osuna*[2], *C. Carter*[1], *D. Cha*[1], *S. Pence*[1], *E. Courchesne*[1] *and K. Pierce*[1], *(1)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA, (2)San Francisco Clinical Research Center, San Francisco, CA*

Background:
Estimates in the literature have long referenced that 20-50% of children are nonverbal (Eigsti, 2011; Lord et al., 2004; Tager-Flusberg et al., 2005). However, these estimates are likely inaccurate given earlier identification and treatment of ASD, and changes in diagnostic criteria. Consequently, fine analysis of natural language, beyond standardized scores, is needed to further understand the language profile of toddlers with ASD. Research in this area is emerging (Tek et al., 2013), but further research with large samples and comparisons to other delay groups is needed.
Objectives:
This study aimed to provide a detailed characterization of language abilities of children with ASD at age three, when most children receive a final diagnosis, and provide a more modern estimate regarding the percentage of ASD children with functional language.
Methods:
Participants were recruited from the general population largely via the 1-Year Well-Baby Check-Up Approach (Pierce et al., 2011) and included 109 with ASD, 60 typically developing (TD), and 42 with language delay (LD; note: 52% of the LD group had a transient diagnosis and did not show persistent delay). Data were analyzed from a ten-minute free-play interaction between the child and parent when children were between 30-42 months of age (M=34.95). Spoken language was assessed globally, and children with 15 words or fewer were categorized as minimally verbal (Paul et al., 2013; Tager-Flusberg, 2009). Partial-interval scoring was conducted to code features of the child's and parent's speech (see table 1). MANOVAs were conducted to compare differences between groups.
Results:
Thirty-four children with ASD used fewer than 15 words during the assessment, and four used no words. MANOVA analyses revealed significant effects between groups for many language features (see table 1). The largest effect sizes were seen for word approximations ($F=39.523$, $p < .000$, $\eta^2 = .275$), full words ($F=54.353$, $p < .000$, $\eta^2 = .343$), MLU ($F=40.126$, $p < .000$, $\eta^2 = .278$), child initiations ($F=43.591$, $p < .000$, $\eta^2 = .295$), child response ($F=19.441$, $p < .000$, $\eta^2 = .157$), and Wh- questions ($F=26.061$, $p < .000$, $\eta^2 = .200$). The aforementioned variables, also showed significant differences between ASD and TD children, as well as ASD and LD. See Figure 1 for a sample of language features across groups. Children with a persistent language delay versus a transient delay will be further analyzed in the future.
Conclusions:
Thirty-one percent of the children with ASD presented as minimally verbal, and only 3.7% used no words at all, suggesting that the idea that up to 50% of children with ASD are nonverbal is outdated. Children with ASD showed delays across variables and showed more impairment than LD and TD groups. Children with ASD and LD had similar usage of grammatical markings, although both were reduced compared to TD children. The social use of language was markedly different in children with ASD compared to LD and TD, as children with ASD also showed reduced initiations and responses to their parent, although their parents initiated to them just as frequently as other parents.

Table 1. Coding Examples and MANOVA Results.

Child Vocalization/Word Level Coding					
Code	**Function**	**Examples**	**F**	**Sig**	**Partial Eta Squared**
Unidentified Sounds	Non-word sounds/vocalizations	"Bah," "tuh"	3.995	.020	.37
Babbling	Sound reduplications	"bababa"	8.821	.000	.078
Sound Effects	Sounds used during play to accompany play scenarios	"Vroom" "Moo"	1.247	.290	.012
Word Approximation	An imperfect or unclear attempt at a word	"Ba" (ball)	39.523	.000	.275
Fully Articulated Word	Clearly articulated word	"Yes"	54.353	.000	.343
Self-Stimulatory Speech	Repetitive sounds composed of only vowel sounds	"Aa-ee aa-ee"	4.365	.014	.040
Child Phrase Level Coding					
Code	**Function**	**Examples**	**F**	**Sig**	**Partial Eta Squared**
Immediate Echolalia (Exact)	Repeating the exact word, phrase or part of phrase said immediately prior by the caregiver	Parent: Hello Thomas! Child: Hello Thomas!	.511	.601	.005
Immediate Echolalia (Partial)	Repeating part of the sounds, word, phrase or part of phrase said immediately prior by the caregiver. This must be altered in some way.	Parent: Get the car! Child: The car!	3.848	.023	.036
Delayed Echolalia	Repeating a sound, word, or phrase that has not recently been said by another person in the environment	Parent: Let's play with baby! Child: Elmo's world! Elmo's world!	.608	.546	.006

Initiation	Child makes statement or asks a question	Child: Let's play with baby!	43.591	.000	.295
Response	Child responds to statement or question asked by caregiver	Parent: "Do you want the ball?" Child: "No"	19.441	.000	.147
Mean Length of Utterance	Mean number of words in phrases spoken by child during assessment	Ex: 2.5	40.126	.000	.278
Parent Language Coding					
Code	**Function**	**Examples**	**F**	**Sig**	**Partial Eta Squared**
Initiation	Question, command, or attempt to capture child's attention	"Pass the doll," "What is that?"	1.344	.263	.013
Response	Repeating the child's words or answering a question	Child: "Can we play?" Parent: "Yes!"	16.903	.000	.140
Narration	Descriptions of the play environment or the use of non-directive speech such as sound effects or singing	"Baby is sleeping"	6.394	.002	.058
Discipline	Used to regulate a child's behavior	"No, don't throw that"	.632	.533	.006
Praise	Intended to encourage or praise the child	"Good job!"	3.249	.041	.030
Morpheme scoring (Brown, 1973)					
Order of Acquisition	**Morpheme**	**Example**	**F**	**Sig**	**Partial Eta Squared**
1	Present progressive - *ing* (no auxiliary verb)	Mommy driv*ing*.	8.516	.000	.076
2	*In*	Ball *in* cup.	15.993	.000	.133
3	*On*	Doggie *on* sofa.	13.536	.000	.115

3:16 **188.004** Exploring Visual Social Attention in Minimally Verbal Children and Adolescents with ASD

D. Plesa-Skwerer[1], *A. Chu*[2], *B. Brukilacchio*[3] *and H. Tager-Flusberg*[1], *(1)Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Harvard Graduate School of Education, Somerville, MA*

Background: Attending preferentially to social information in the environment is important in developing socio-communicative skills and language. Research using eye-tracking to explore how individuals with autism spectrum disorders (ASD) orient to and engage attention towards various stimuli surged in the last decade (Guillon et al., 2014). However, studies rarely included nonverbal/minimally verbal individuals (MV_ASD); investigating their spontaneous viewing patterns could provide insights into the possible connections between social attention deficits and failure to acquire spoken language.
Objectives: We used eye-tracking to examine whether distinctive patterns of attending to and processing social information differentiate minimally verbal from verbal individuals with ASD (V_ASD) when viewing naturalistic dynamic scenes.
Methods: Participants were 38 MV_ASD and 19 V_ASD children and adolescence between 5; 8 and 18 years, matched on age. The eye-tracking task (modeled after Chawarska et al., 2012) involved short video-clips showing an actor seated behind a table, making a snack or wrapping a book. Four interesting objects surrounded the actor. Areas of interest (AOIs) were defined around each object and the actor's face, eyes and hands. The videos were divided into 6 episodes based on the actor's behavior: most salient were 3 episodes, one showing the actor looking toward the camera addressing the viewer directly, another showing a toy-spider moving on the table and the actor's gaze following the spider's movement (expected gaze shift); the third showing the spider moving again, but the actor looked toward the unmoving object diagonally opposite from the toy-spider (unexpected gaze shift). The variables of interest were proportion of looking time in each AOI, by episode, relative to total time spent looking at the screen.
Results: Relative to total movie duration both V_ASD and MV-ASD participants spent proportionally more time looking at the actor compared to the objects (71.3% vs. 28.7% and 65% vs. 35%, respectively) and increased their attention toward the actor's face when she started talking. However, in the segments that entailed interpreting the actor's gaze shift toward and away from a surprising moving object, fewer MV_ASD participants showed fixations on the actor's face (26.3% in segment 3 and 39.5% in segment 5) compared to the V_ASD participants (61.5% and 67%, respectively). Only 15.8% of the MV_ASD group followed the actor's unexpected gaze shift, compared to 39% of the V-ASD participants who displayed a triadic pattern of visually scanning the scene, involving the toy-spider, the actor's face/line of regard and the object toward which the actor shifted gaze.
Conclusions: These findings underscore the need to qualify the widely-held assumption that individuals with ASD distribute attention between objects and persons in atypical ways, by examining the social-inferential challenges of the scenes viewed. The differences in visual scanning patterns found between MV_ASD and V_ASD participants reflect decreased attention to behaviors that entail inferring the underlying intentions of the actor. Consequently, minimally verbal children with ASD may be less able to learn from interactive opportunities involving joint attention, which may further impair their ability to detect and interpret social cues and affect their acquisition of language.

Oral Session - 13A
189 - Identifying Autism Pathogenesis using Human Induced Pluripotent Stem Cells (iPSCs)
1:45 PM - 2:35 PM - Room 308

1:45 **189.001** Using iPSCs to Model Angelman and Chromosome 15q11.2-q13 Duplication (Dup15q) Syndromes

S. Chamberlain[1], *N. Germain*[1], *J. S. Hsiao*[1] *and C. Sirois*[1,2], *(1)Genetics and Genome Sciences, University of Connecticut Health Center, Farmington, CT, (2)Neuroscience, University of Connecticut Health Center, Farmington, CT*

Background: Angelman syndrome (AS) is a neurodevelopmental disorder with profound impacts on cognitive function, speech/language, and seizure susceptibility that is most frequently caused by deletions of maternal chromosome 15q11.2-q13. Autism is frequently diagnosed in individuals with AS. Conversely, duplications of maternal chromosome 15q11.2-q13 are one of the most common cytogenetic anomalies associated with autism. Cognitive function, speech/language, and seizure susceptibility is also impacted in individuals with Dup15q syndrome. Disruption in the copy number of one gene, *UBE3A*, underlies both disorders.
Objectives: To develop human iPSC models of AS and Dup15q syndromes to 1.) understand the local gene regulation underlying these disorders, 2.) to identify cellular phenotypes associated with both disorders, and 3.) to test potential therapeutic approaches to restore normal 15q gene expression.
Methods: iPSCs from AS and Dup15q patients were generated from patient fibroblast, cord blood, or peripheral blood samples using retrovirus, lentivirus, episomal, and sendai virus reprogramming methods. Genome editing using CRISPR/CAS9 technology was used to modulate gene regulation. iPSCs were differentiated into forebrain cortical neurons using an embryoid body-based or monolayer protocol. RT-qPCR and RNA-Seq were used to quantify local and global gene expression. Microscopy and electrophysiology were used to investigate cellular phenotypes.
Results: We have generated iPSCs from several individuals with AS and Dup15q syndromes and have differentiated them into forebrain cortical neurons. We have genetically corrected AS iPSCs and have modulated expression of UBE3A in iPSCs and neurons using a variety of methods. We compared 15q gene expression between the different iPSC lines as well as from their neuronal derivatives. We found that gene expression closely followed copy number in iPSCs, but deviated somewhat from copy number in iPSC-derived neurons. Early electrophysiology experiments and examination of dendritic spine morphology corroborate a defect in neuronal development.
Conclusions: Human iPSCs derived from individuals with AS and Dup15q syndrome provide an attractive model to study gene expression and cellular phenotypes of neurodevelopmental disorders, including ASD. They can be used to gain important insight into the neuronal development deficits underlying these autism-related disorders, as well as to test potential therapeutic approaches.

1:57 **189.002** ASD Patient-Derived Neural Stem Cells Exhibit Defective Proliferation in Comparison to Sibling Control

M. Williams[1], *S. Prem*[2], *C. Pinto*[3], *X. Zhou*[4], *P. G. Matteson*[5], *P. Yeung*[6], *C. W. Lu*[6], *Z. Pang*[6], *J. H. Millonig*[4] *and E. DiCicco-Bloom*[7], *(1)3rd Floor, Rm 354, Graduate School of Biomedical Sciences, Piscataway, NJ, (2)Neuroscience, Graduate School of Biomedical Sciences, Piscataway, NJ, (3)Rutgers University, New Brunswick, NJ, (4)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (5)Rutgers University, Piscataway, NJ, (6)Child Health Institute of New Jersey, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (7)Rutgers University - Robert Wood Johnson Medical School, Piscataway, NJ*

Background:
Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by abnormalities in social interactions and stereotyped/restrictive behavior. The study of

ASD etiology has been hindered by disease heterogeneity and difficulties in creating representative mouse models. To examine neurobiological deficits in idiopathic autism, we (NJ Autism Center of Excellence; PI Millonig) generated iPSC lines from 8 severely affected males with ASD and their unaffected brothers (Sib) and derived neural stem cells (NSCs) to study fundamental developmental processes.
Objectives: Our goal is to uncover potential differences in proliferation in idiopathic autism patient-derived NSCs by using developmentally relevant exogenous factors (EFs). We have examined an array of EFs including FGF, pituitary adenylate cyclase-activating peptide, BDNF, NT3, 5-HT, H_2O_2 and MeHg.
Methods:
To define effects, cells were grown at high density (50K cells/cm^2) without and with EFs. At 48h cells were labeled with tritiated thymidine to assess DNA synthesis and EdU for S-phase entry. In parallel, single cell analyses were conducted by acutely dissociating high-density cultures, plating at low density (10K/cm^2) and fixing at 2h for immunostaining. Further, sister cultures were dissociated every 48h for 6 days to quantify live cell numbers via hemocytometer. To address possible variability, studies were performed blind, and all results have been replicated in multiple NSCs obtained from 2-3 independent iPSC lines for each subject.
Results:
As might be expected, FGF induced increases in DNA synthesis and S-phase entry by ~50% at 48h. These early increases predict 50% – 100% increases in cell numbers by 4 and 6 days. Though both ASD and sibling NSCs show a response to FGF stimulation, ASD NSCs from a single-family comparison exhibit a remarkable proliferation defect under baseline conditions. At 48 hours ASD NSCS display a 50% reduction in DNA synthesis. Additionally, ASD NSCs exhibit a 33% reduction in the proportion of cells entering S-Phase as well as a 75% reduction in cell numbers after 6 days in culture. Furthermore, preliminary results suggest ASD NSCs have differential proliferative responses to growth regulator, 5-HT, and greater sensitivity to environmental toxicant, MeHg, in comparison with sibling control.
Conclusions:
In aggregate, our results indicate that we are able to employ EFs to discover differences in ASD-implicated biological processes, namely proliferation. Ultimately, this methodology may lead to the development of personalized pharmacological treatment for ASD individuals. Future studies will examine underlying mechanisms by assessing NSC cell death, cell cycle machinery, mRNA transcriptome, and metabolomic profiles.

2:09 **189.003** Decreased Overall Network Activity in iPSC-Derived Cortical Neurons in Individuals with Idiopathic Autism

*E. Artimovich[1], A. W. Phillips[1], B. A. DeRosa[2], J. E. Nestor[1], M. L. Cuccaro[2], D. Dykxhoorn[2] and **M. W. Nestor**[1], (1)The Hussman Institute for Autism, Baltimore, MD, (2)The Hussman Institute for Human Genomics, Miami, FL*

Background:
The early establishment of functional cortical neural networks is an important step in overall brain development, and may be impaired in individuals with autism. Understanding the physiological characteristics of network-level activity and the effect that autism-related genes have on that activity is paramount to developing genotype-phenotype relationships at the cellular level in autism spectrum disorder (ASD).
Objectives:
To use cell based assays to interrogate network-level electrophysiological activity, calcium transients, and other aspects of synaptic function from induced pluripotent stem cell (iPSC)-derived cortical neurons in ASD individuals with putative risk contributing genetic variants (Cukier et al., 2014).
Methods:
iPSC lines were created from peripheral blood mononuclear cells (PBMCs) of individuals with autism (N=5) and unrelated, sex-matched controls (N=3 lines). iPSCs were derived into neurons with transcriptional lineages resembling cortical neurons (DeRosa et al., 2012). Neurons were plated and differentiated into mixed networks for 0, 14, 28, and 35 days. Developing networks were interrogated with multi-electrode array (MEA) recordings, measurements of calcium transients using Fluo-4, and fixed and stained for relevant morphological markers.
Results:
Lines from ASD individuals demonstrated significantly decreased network spiking activity from MEA recordings ($p < 0.001$, ANOVA) as well as decreased numbers of calcium transients ($p < 0.05$, t-test). Additionally, ASD lines showed significant differences in measures of neurite morphology ($p < 0.001$, ANOVA) at early neuronal differentiation times.
Conclusions:
The results of this study suggest that in iPSC-derived neurons derived from individuals with ASD, there may be early deficits in network activity and morphology based on a combination of cell based assays, including MEA, Fluo-4 measured calcium transients, and quantification of neurite outgrowth.

2:21 **189.004** Functional Effect of GRIN2B Alterations in Humans Neuro Progenitor Cells, a Model for Intellectual Disabilities

***G. Maussion**, Douglas Mental Health Institute, Montreal, QC, Canada*

Background:
Gene mutations and chromosomal rearrangements are found in a proportion of patients diagnosed with autism spectrum disorders (ASDs) or intellectual disabilities (IDs). Modifications at the DNA level are likely responsible for altering neurodevelopmental programs; however, the molecular mechanisms that links mutations with altered sub-cellular and cellular processes leading to neuronal dysfunctions are poorly understood. A new approach which may help to better understand such mechanisms involves using human neuroprogenitor cells (NPCs) derived from induced pluripotent stem cells (iPSC). In fact, proliferation and differentiation processes of such cells determined to become neurons, glia or oligodendrocytes can be easily observed in vitro, in physiological and pathological contexts.
Several studies have reported mutations, deletions, or disruptions of *GRIN2B* gene in cases diagnosed with ASDs or neurodevelopmental disorders. *GRIN2B*gene is located on chromosome 12p12. That gene codes for an NMDA receptor subunit which plays important roles at pre and post natal stages in synaptic development and glutamatergic neurotransmission.
Objectives:
The main objective of that study is to understand how alterations in GRIN2B gene may lead to an altered neurodevelopmental program using neural progenitor cell models. At a molecular level, we aim to identify the genes and gene networks that are deregulated in a model of GRIN2B silencing or in a NPC cell line from a patient with GRIN2B mutation.
We would determine if those changes at the DNA or at the RNA levels could affect cell morphology and electrophysiological properties.
Methods:
DNA from patients diagnosed with ASD or ID were analysed using deep sequencing. NPCs producing sh-RNA that targets *GRIN2B* gene or derived from patients with a *GRIN2B* mutation were expanded and differentiated for 30 days. Whole transcritptome profiling was performed on the *GRIN2B*silenced cell lines using RNA sequencing. Differentially expressed genes were validated by quantitative real-time PCR. 3D reconstructions and electrophysiological recordings were done to assess morphology and glutamate receptor function, respectively.
Results:
Gene expression analysis performed on the model of *GRIN2B*silencing shows that differentially expressed genes are related to synapse functioning and ion transport. We have validated the differential expression of many mRNA glutamatergic subunits such as GRIK1, GRIK2, GRIA1, GRIA2 and GRIA4. Preliminary data of 3D reconstruction suggest that GRIN2B silenced cells present dendritic abnormalities.
Conclusions:
These data suggest that reduced dosage of GRIN2B affects the expression of other mRNA coding glutamatergic subunits which potentially alter crosstalks between receptors and consequently dendritic spine development. These mechanisms may be crucial in the pathophysiology of ASDs and IDs.

Oral Session - 13B
190 - Pharmaceutical Interventions for ASD
2:40 PM - 3:30 PM - Room 308

2:40 **190.001** The Role of Precompetitive Consortia, Data Sharing and Regulatory Science in Catalyzing Innovation for Autism Spectrum Disorders

***D. T. Stephenson**[1], B. Abrahams[2], K. Romero[3], J. Larkindale[4], J. McPartland[5], L. Fitzgerald[6], H. Mayer[7], J. E. Spiro[8], M. T. Pletcher[9] and W. Spooren[10], (1)Critical Path Institute, Tucson, AZ, (2)Albert Einstein College of Medicine, Bronx, NY, (3)Critical Path Institute, tucson, AZ, (4)critical path institute, tucson, AZ, (5)Yale Child Study Center, New Haven, CT, (6)LW Fitzgerald Consulting, LLC, east lyme, CT, (7)Shire, Lexington, MA, (8)Simons Foundation, New York, NY, (9)Autism Speaks, Boston, MA, (10)Roche, Basel, Switzerland*

Background: The lack of success in development of effective therapies for Autism Spectrum Disorders (ASD) suggests that public private partnerships are catalysts to tackling the challenges and sharing costs and risks amongst diverse stakeholders. The Innovative Medicine's Initiative's European Autism Interventions - A Multicentre Study for Developing New Medications (EU-AIMS) and the nascent Autism Biomarkers Consortium for Clinical Trials (ABC-CT) initiatives serve as a striking examples of the positive impact that can be achieved in precompetitive alliances for ASD. Regulatory agencies in the U.S., Europe and Japan have identified drug development tool platforms

to accelerate drug development.
Objectives: This presentation aims to highlight existing initiatives in ASD and opportunities for future expansion and extension in the areas of regulatory science and innovation.
Methods:
Critical Path Institute is a nonprofit organization that is dedicated to accelerating drug development by delivering on the mission outlined by the U.S. Food and Drug Administration's (FDA's) critical path initiative. Fundamental to the mission of C-Path consortia is the sharing of patient level data from longitudinal natural history studies and legacy clinical trials, and transformation of those data into generalizable and applicable knowledge to advance therapies for specific diseases. C-Path consortia are comprised of industry members, regulatory agencies, academic experts, government agencies and patient advocacy organizations that collaborate to achieve regulatory milestones not achievable by any one organization. Data standardization, database development and integration are core to the success of all C-Path consortia.
Results:
Diseases to date that have achieved positive qualification opinions from both European Medicines Agency and FDA enabled by C-Path's consortia include Alzheimer's disease, Polycystic Kidney Disease and Tuberculosis. For example, an Alzheimer's disease (AD) clinical trial simulation tool has been made publically available and represents a milestone that serves to encourage the advancement of drug-disease-trial models and promises to increase the probability of success in future AD therapeutic trials. The applicability of a similar path for ASD holds tremendous promise. Recently launched C-Path consortia are focused on pediatric drug development including Duchenne Muscular Dystrophy (D-RSC), International Neonatal consortium (INC) and a pediatric clinical trial network (PTC) focused on trial recruitment. Success of C-Path consortia is enabled by collaborations with other global initiatives. The prospects for the future in integrative collaborations and global data sharing initiatives include alliances with fNIH biomarkers consortium, NIMH, IMI EU-AIMS, SFARI/Simons Foundation, academic institutions and investigators, industry sponsors, Autism Speaks and other patient-driven initiatives.
Conclusions: Regulatory science strategies enabled by active collaboration of diverse stakeholders promises to encourage and incentivize sponsors to discover and advance therapies for ASD.

2:52 **190.002** Gene Therapy in Fragile X Syndrome

***D. R. Hampson**, Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada*

Background: Fragile X Syndrome (FXS) is a genetic disorder causing cognitive impairment and is one of the leading known genetic causes of autism. The genetic aberration is caused by an expanded CGG repeat in the 5' untranslated region of the FMR1 gene on the X chromosome. The expanded CGG repeat causes an elimination or severe reduction in the level of Fragile X Mental Retardation Protein (FMRP), an mRNA binding protein that controls translation of its bound mRNA substrates.
Objectives: To determine if FMRP transgene expression in the CNS could reverse phenotypic deficits in the Fmr1 knockout mouse model of fragile X, we used a single-stranded adeno-associated viral (AAV) vector that contained a major isoform of FMRP.
Methods: The vector was delivered to the brain via a single bilateral intra-cerebroventricular injection into neonatal Fmr1 knockout mice.
Results: Treated Fmr1 KO mice displayed prominent FMRP transgene expression in most regions of the forebrain but little or no expression more caudal regions. Reduced levels of the synaptic protein PSD-95, and abnormal motor activity, anxiety, and acoustic startle responses observed in Fmr1 KO mice, were fully or partially rescued by treatment with AAV-FMRP. We also demonstrate that mRNA for MeCP2, an epigenetic modulator mutated in Rett Syndrome, is substrate for FMRP and that MeCP2 protein levels are elevated in the Fmr1 mouse brain. Further analysis revealed a correlation between motor activity and levels of MeCP2, suggesting that motor hyperactivity in fragile X could be linked to elevated brain MeCP2 expression.
Conclusions: Our results provide proof-of-principle that gene therapy using a viral vector can correct specific behavioral abnormalities in a mouse model of fragile X syndrome. The results indicate that early postnatal administration of AAV-FMRP facilitates vector diffusion and distribution within the CNS. Early postnatal treatment may promote normal neurogenesis and maturation of the brain and might have contributed to the behavioral rescue subsequently seen in adult mice. Finally, our findings also raise the intriguing possibility that MeCP2 over-expression could contribute to the fragile X phenotype.

3:04 **190.003** A Double-Blind, Placebo-Controlled Trial of Memantine Vs. Placebo in Children with Autism Targeting Neurocognitive Outcomes

***L. Soorya**[1], S. Youngkin[2], S. J. Lee[3], J. W. Lee[2], A. Mischel[2], D. Graber[2], D. Grodberg[4], H. T. Rieger[5], D. Zaghloul[6] and E. Anagnostou[7], (1)Suite 603, Rush University Medical Center, Chicago, IL, (2)Rush University Medical Center, Chicago, IL, (3)Rush University Medical Center, Hoffman Estates, IL, (4)Yale Child Study Center, New Haven, CT, (5)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (6)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (7)University of Toronto, Toronto, ON, Canada*

Background: Abnormalities in the modulation of the glutamate system and glutamatergic function have been reported in disorders affecting a variety of behavioral and neurological domains, such as cognitive flexibility, memory, and motor function. Impairments in memory and motor deficits in individuals with ASD are well documented. Whereas the neurobiology of such deficits is an area of active research, there is a paucity of intervention research for such deficits in autism. Memantine, an NMDA inhibitor, may provide improvements in memory and motor praxis/expressive language skills in children with autism.
Objectives: The study was initially designed as a large, multi-site, randomized trial to evaluate the tolerability of memantine and primary efficacy on memory and motor planning. Budgeting and recruitment changes resulted in narrowing the original trial objectives to a signal finding study at two sites. Treatment targets include apraxia, expressive communication, memory, motor skills, and adaptive skills in children with ASD in a double-blind, placebo-controlled parallel study.
Methods: Children with ASD and phrase speech were recruited. Participants (n=23), ages 6-12 (M=9.45, SD=2.03) were randomized at a 1:1 ratio to treatment with memantine or placebo for 24 weeks. Memantine and placebo were initiated at 3 mg and the dose was titrated up 3 mg a week for a maximum of dose of 12 mg depending on weight. Apriori defined outcomes included: apraxia and expressive language (primary); and memory and adaptive skills (secondary). Exploratory measures included additional neurocognitive tests of memory, fine & gross motor skills and apraxia; as well as functional outcomes measures (e.g. maladaptive behavior, social communication skills). All outcomes were collected at three time-points: baseline, Week 12, and Week 24. MANOVAs were conducted on change score composites for each primary outcome domain and individual subtests scores by domain (e.g. neurocognitive, functional skills, behavior).
Results: Memantine was well-tolerated with no significant adverse events reported during the trial. Initial analyses were guided by the analytic protocol for the original, large clinical trial. No significant effects were found on composite change scores on apraxia subtests of the NEPSY2 (e.g. oromotor sequences, manual motor sequences, imitating hand postures) or expressive language measures (e.g. EVT2 and NEPSY2 repetition of nonsense words). Exploratory analyses for the revised signal finding protocol included analyses of individual neurocognitive and functional outcome measures. Results suggest trends on measures of motor proficiency, apraxia, and expressive language. One representative test was selected for each domain and entered into a MANOVA: *motor proficiency, expressive language, verbal memory, and visual-spatial memory*. The MANOVA indicated an overall trend for facilitative effects of memantine on neurocognitive outcomes after 6 months of treatment (F=3.056, df=4, p=.050). Effect sizes were moderate to strong (partial eta squared = .449). Future analyses include evaluation of composite scores, responder analyses, and covariates of treatment response to support the development of larger, randomized controlled trials targeting neurocognitive outcomes.
Conclusions: This 24-week randomized placebo-controlled pilot study suggests that memantine may improve understudied neurocognitive domains including motor proficiency and expressive speech in school-aged children with ASD.

3:16 **190.004** The Effects of a Novel Vasopressin V1a Antagonist in Combination with Others' Gaze Behaviors on Attention to Others' Heads in Adults with ASD

***C. Foster**[1], M. del Valle Rubido[2], J. McCracken[3], E. Hollander[4], L. Scahill[5], L. Boak[6], O. Khwaja[2], F. Bolognani[7], P. Fontoura[8], D. Umbricht[2], S. S. Jeste[9], E. S. Kim[10], R. J. Jou[11], C. A. Wall[1] and F. Shic[1], (1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)F. Hoffmann - La Roche AG, Basel, Switzerland, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)Albert Einstein College of Medicine, Mamaroneck 10543, NY, (5)Pediatrics, Marcus Autism Center, Atlanta 30329, GA, (6)F. Hoffmann-La Roche AG, Basel, Switzerland, (7)F. Hoffmann-La Roche, Basel, Switzerland, (8)Roche Pharma Research and Exploratory Development, Basel, Switzerland, (9)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (10)The Children's Hospital of Philadelphia, Philadelphia, PA, (11)Yale Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Oxytocin and vasopressin appear to modulate neural circuitry and behavioral responses associated with social cognition (Zink et al., 2010; Heinrichs et al., 2008), providing a potential target for pharmacological intervention. Eye tracking has been used extensively in ASD research for examining social deficits (Boraston et al., 2007), and it has the potential to be developed as a robust and sensitive outcome measure for clinical trials.
Objectives: To explore the impact of a novel vasopressin receptor V1a antagonist, RG7713, vs. placebo on looking patterns influenced by the gaze behaviors of others in high-functioning adults with autism.
Methods: High-functioning adults (N=17; M_{age}=23.4 years, range=18 to 40 years) with autism participated in a multi-center randomized, double-blind, placebo-controlled, crossover study of the effects of RG7713. Participants completed two visits following identical procedures with the exception of a crossover for the compound administered (RG7713 vs. placebo). Participants in dosing Order 1 received RG7713 compound during their first visit (Day 1), while those in dosing Order 2 received RG7713 during their second (Day 2). Visits included: (1) pre-infusion assessments and eye-tracking battery, (2) a 2 hour IV infusion of RG7713 or placebo, (3) post-infusion assessments and eye tracking battery. The eye-tracking battery included an activity monitoring task, in which participants viewed 12 20s video clips of 2 actresses interacting and engaging in a shared activity. The task was parsed into two gaze conditions: (1) the actresses fixated on the shared play activity (activity gaze), (2) the actresses fixated on each other (mutual gaze). Analyses were conducted to examine the effects of RG7713 vs. placebo on the proportion of time spent attending to the actresses' heads (%Head).

Results: Linear mixed model analyses revealed a main effect of drug (p<.05, d=.29) and gaze condition (p<.01, d= 0.53) on %Head. Participants exhibited a larger %Head post-RG4914 vs. both pre-infusion (p <.05, d= 0.15) and post-placebo (p<.01, d=0.24), as well as a larger %Head during mutual gaze trials vs. activity gaze trials (p<.01 d=.53). There was no significant main effect of day of RG7713 administration and no significant interaction effects (p>.05). Results are illustrated in Figure 1.
Conclusions: These findings provide preliminary evidence of the ability of a novel V1a antagonist RG7713 to augment attention to others' heads in high functioning adults with ASD. When paired with preexisting response patterns to gaze behaviors of others, administration of RG7713 may result in an optimization of attention to others' heads. Although the administration of RG7713 did not alter the degree to which attention increased from activity to mutual gaze trials, administration of the compound was associated with an overall heightened amount of time spent attending to heads above both pre-infusion and placebo levels, with attention optimized in post-RG7713 mutual gaze trials. Furthermore, this study suggests that eye tracking may be a useful tool for developing and monitoring treatment effects of novel pharmacological interventions in ASD.

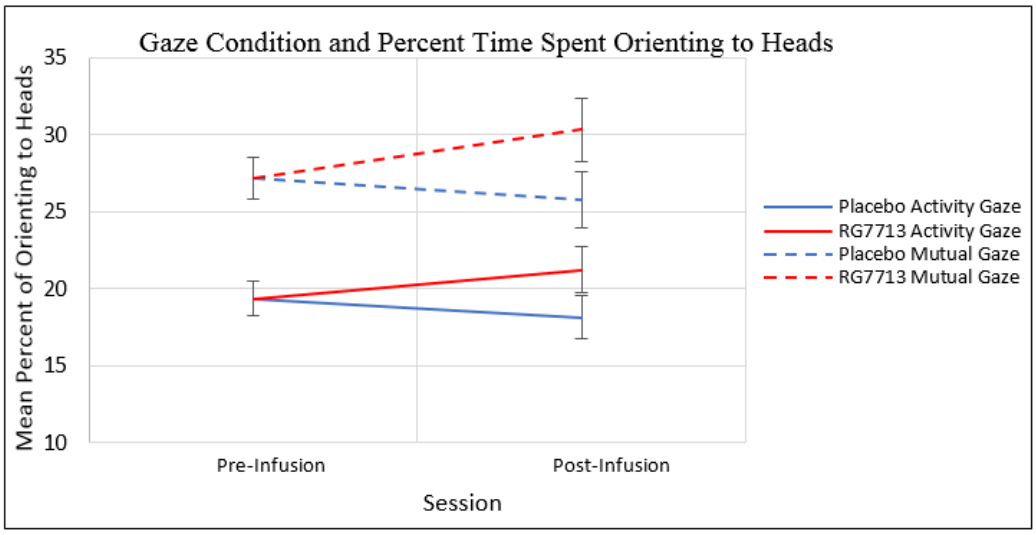

Figure 1. Gaze condition and the mean percent of time spent orienting to heads during activity monitoring, in pre- and post-placebo and RG7713 infusion trials. Error bars – 1 SE

191 - Overlooked Academic and Language Issues in the Treatment of ASD
1:45 PM - 2:35 PM - Room 309

1:45 **191.001** Technology-Based Intervention to Teach Mathematics Skills to Students with Autism

G. Yakubova[1], *E. M. Hughes*[1] *and M. Shinaberry*[2], *(1)Duquesne University, Pittsburgh, PA, (2)Duquesne University, Pittsburgh, PA*

Background:
Research examining video-based interventions and other instructional strategies to determine evidence-based practices for students with autism spectrum disorder has been limited to social, behavioral, communication, and daily living skills. Limited attention to teaching academic skills necessary for independent life can be disadvantageous given the necessity of at least basic academic skills to perform daily life activities, such as purchasing, managing the budget, and others. Students with autism spectrum disorder (ASD) face many challenges learning mathematics yet limited research supporting interventions exist in this area. Additionally, the economic development in the 21st century and rise of jobs that require at least some level of academic skills necessitate teaching of academic skills necessary for various aspects of post-school adult life. The presentation describes the results of the study examining the effectiveness of technology-based concrete-representational-abstract sequencing instruction in teaching mathematics skills to students with ASD.
Objectives:
The purpose of this study was to determine the effectiveness of video modeling intervention with concrete-representational-abstract (CRA) instructional sequence in teaching mathematics concepts to students with ASD.
Methods:
A multiple baseline across skills design of single-case experimental methodology was used to determine the effectiveness of the intervention on the acquisition and maintenance of mathematics skills for students with ASD. Three different mathematics skills were targeted for each participant based on their individual education goals. Students participated in a minimum of five baseline sessions, 11 intervention sessions, and three maintenance sessions during a three-week follow-up period. Data were analyzed using the recommended approaches for single-case experimental data: visual analysis analyzing for trend, level, variability, magnitude of effect and effect size calculation to determine the existence and magnitude of a causal relationship between an intervention and target skills (Kratochwill et al., 2013).
Results:
Results demonstrated that each student solved mathematics problems with improved accuracy during intervention compared to baseline levels. The intervention had a strong effect on students' skill acquisition and maintenance. Students' response accuracy improved from the mean of as low as 0 to 3% to as high as 61 to 100% accuracy. Two main findings were found: (1) increase in students' responses on addition, subtraction, and number comparison problems from baseline to intervention phases, suggesting the effectiveness of a technology-based intervention and (2) continued response accuracy at a three-week follow-up assessment for all skills for three of four students. Students and teachers also held positive perceptions on the effectiveness and practicality of the intervention.
Conclusions:
The findings of the study contribute to interventions on teaching mathematics skills necessary for further success in school and post-school life via technology-based instruction in a student-centered manner. This can provide valuable contributions for research and practice in the education of students with ASD. Findings offer potential for future research in examining this under-researched area of using CRA with technology in teaching students with ASD. It also offers implications for practice in using technology combined with other strategies to improve skill acquisition and learning outcomes of students with ASD.

1:57 **191.002** Teaching Reading Skills to Minimally Verbal School-Aged Children with Autism Spectrum Disorders with a Serious Game. a Controlled Study

S. Serret[1], *S. Hun-Billiaut*[1], *S. Thümmler*[2] *and F. Askenazy*[3], *(1)Autism Resource Center, Nice, France, (2)University Child and Adolescent Psychiatry Department, Autism Research Centre, Children's Hospitals of Nice CHU-Lenval, Nice, France, (3)University Child and Adolescent Psychiatry Department, Children's Hospitals of Nice CHU-Lenval, Nice, France*

Background: School-aged children with Autism Spectrum Disorders (ASD) and minimally verbal skills are usually judged "low-functioning" in accordance with poor performance on conventional assessment of global cognitive skills. However, recent studies suggest that some of these children have spared non-verbal cognitive abilities despite failing to acquire spoken functional language. As reading instruction for these children are limited by the traditional phonics approach, we developed the serious game SEMA-TIC based on non-verbal cognitive skills. SEMA-TIC is a computer-based intervention with 10 series of 10 games, progressively teaching reading skills based on specific learning strategies adapted to the autistic profile and without verbal instructions.
Objectives: The study investigates the efficiency of SEMA-TIC for the improvement of reading skills of minimally verbal school-aged children with ASD. It also compares the results with basic reading skills of typically developing children after formal academic reading training.
Methods: Twenty five ASD children (6 -11 years) with no functional language were recruited. Two groups were constituted: (1) ASD intervention group (n=12) who received four thirty-minute SEMA-TIC sessions per week over an average of 22 weeks; (2) ASD non-intervention group (n=13). The two groups completed at baseline and after the follow-up period five experimental reading skill tasks (alphabet knowledge, words reading, words / non-words discrimination, sentences reading and words segmentation)

and two standardized reading tasks (ALOUETTE and ODEDYS). Furthermore, a group of 16 typically developing children (TD group) from 6 to7 years schooled at the end of the first year of primary school and already readers were assessed by means of the same tasks.
Results: The two ASD groups showed no significant difference concerning clinical characteristics and results on experimental tasks at baseline. Results revealed significant main effects of group (ASD intervention versus ASD non- intervention group, ANOVA; $F(1,23)=256$; $p<.001$) and session (ANOVA; $F(1,23) = 301$; $p<.001$) on experimental tasks. A significant group x session x experimental tasks interaction was also found (ANOVA; $F(4,92) = 4.6$; $p<.01$). Post-hoc analysis revealed that ASD intervention group significantly improved in 4 out of 5 experimental tasks after training compared to ASD non-intervention group. Results also showed a main effect of group (ASD intervention versus TD group) on experimental tasks (ANOVA; $F(1,26) = 11$; $p<.01$). However and most importantly for the purpose of this study, results of post-hoc analysis (Tukey tests) show no significant difference between ASD intervention and TD group on each experimental task. Moreover, SEMA-TIC training enabled 25% of ASD intervention group to complete standardized tasks (ALOUETTE and ODEDYS) and to become decoding readers.
Conclusions: The present study shows that minimally verbal school-aged children with ASD are able to be instructed reading skills by means of a specific intervention using non-verbal cognitive skills. We therefore suggest that teaching reading skills to ASD children is not ineluctably linked to spoken language. The development of specific serious games as SEMA-TIC will be a major advance for these children.

2:09 **191.003** The Secondary School Success Checklist (SSSC): A Transition Planning Tool for High School Students on the Autism Spectrum

T. E. Regan[1], *S. Kucharczyk*[2], *K. Hume*[3] *and T. White*[1], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Arkansas, Fayetteville, AR, (3)University of North Carolina, Chapel Hlll, Carrboro, NC*

Background: Post high school, students with autism spectrum disorder (ASD) face a number of challenges, including lower rates of employment than graduating students with other disabilities (Shattuck et al., 2012). Effective and quality transition plans developed by high school Individualized Education Plan (IEP) teams are a contributor to positive postsecondary outcomes (Mazzotti et al., 2009). An important part of the transition planning process is using transition assessment to develop measureable postsecondary goals, transition services, and annual IEP goals (Szidon et al., 2015). To create effective and high quality transition plans, school personnel need a psychometrically sound and efficient transition assessment that addresses challenging areas for students with ASD, identifies strengths, gathers information from multiple sources, and provides data that translate into relevant goals for the transition plan.
Objectives: The Secondary School Success Checklist (SSSC) is a teacher-, parent-, and student-report tool designed to assess the unique skill profiles of high school students with ASD, identify priority skill targets, and compile this information across the stakeholders. Based on preliminary data from a sample of high school students with ASD, psychometric properties of the SSSC were evaluated in regard to (1)reliability of scores by assessment of internal consistency and (2)validity of scores by assessment of concurrent and criterion validity analyses.
Methods:
Development: The SSSC content and process is based on items and feedback gathered from measures already used and accepted in the field, pilot studies, focus group data across 7 stakeholder groups, and current literature. The SSSC was finalized after an 18-month development process. The SSSC was completed by 279 students, 111 staff members and 279 parents across 30 high schools as part of the Center on Secondary Education for Students with ASD, a large-scale RCT study of a comprehensive intervention model for high school students with ASD.
Data Analysis: Internal consistency reliability of each respondent version for domains and subdomains were examined by calculation of Cronbach's alpha coefficients. Concurrent validity was assessed by examining the correlations between student, parent, and teacher measures for each SSSC domain. Criterion validity was assessed by examining correlations between the teacher reported SSSC domain scores and the teacher completed subdomains of the Vineland Adaptive Behavior Scales.
Results:
1)Internal consistency was examined using Cronbach's alpha and was at least .60 across all subdomains via student, parent, and staff reporters.
2)Concurrent validity was found to be low in student ($r<.25$) correlations with either parents or teachers. Teachers and parents were moderately consistent with each other with correlations between .39 and .56.
3)Criterion validity in correlations between SSSC domains and the Vineland subdomains were consistent with a range of .40-.55 (.33-.66).
Conclusions: Based on the preliminary psychometric data, the SSSC is reliable and collects data from students, parents, and teachers, who each contribute unique and valuable information and perspectives to the transition planning process. The SSSC appears to be a valid tool that could be extremely useful for IEP teams seeking to develop relevant transition goals that address the postsecondary needs of high school students with ASD.

2:21 **191.004** A Randomized Control Trial to Evaluate the Efficacy of a Mobile Application to Treat Prosodic Deficits

E. Schoen Simmons[1], *C. A. Wall*[2], *M. Mademtzi*[3], *M. C. Lyons*[2], *R. Paul*[4] *and F. Shic*[2], *(1)Department of Psychological Sciences, University of Connecticut, Storrs, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (3)University of Birmingham, Bimringham, United Kingdom, (4)Sacred Heart University, Fairfield, CT*

Background: For those individuals with ASD who acquire spoken language, 50 – 80% will present with prosodic deficits (Baltaxe & Simmons, 1985). Emerging research suggests that mobile technology may be useful in treating these types of impairments; however, no randomized control trial has been conducted to validate their efficacy (Simmons, Paul & Shic, 2015).
Objectives: The purpose of this study was to assess the preliminary efficacy from a randomized control trial of an application, SpeechPrompts, for treating impairments in prosodic functioning.
Methods: Fifty-three students with prosodic deficits (Mean age = 8.64 years, SD = 3.06; Expressive language SS = 84.1, SD = 19.1) were recruited from school speech-language pathologists (SLPs; N = 22) and randomly assigned to either the experimental treatment condition (SpeechPrompts; n = 32) or treatment as usual (TAU; n = 21). For the experimental condition, SLPs used the SpeechPrompts software with their students 1x/week for 12 weeks. Those assigned to the control group continued receiving their speech and language intervention as usual. SpeechPrompts is an iOS application with four components that each target a prosodic construct (Intensity, Stress, Rate/Rhythm, Pitch). Students' prosody was rated pre- and post-treatment. Time spent using the application compared to time spent engaging in non-prosody related speech-language activities was measured.
Results: Global intonation ratings suggest there was no significant difference in prosody between groups at pre-treatment ($p=0.42$). The SpeechPrompts sessions had a mean length of 8.66 minutes (SD = 5) whereas non-SpeechPrompts sessions (e.g., sessions pertaining to non-prosody speech and language goals) had a mean length of 14.72 minutes (SD = 8.3). Following intervention, there was a trend for those assigned to the experimental group to be rated as more "typical" sounding in post-treatment prosody ratings of rhythm and intensity with moderate effect sizes; however, these results were not significant. Within-group analyses suggest that students in the SpeechPrompts condition were significantly more likely to be rated as more "typical" in Rate, Stress, Rhythm, Articulation, and Intonation ($p's<.05$) at study conclusion with moderate to large effect sizes. Conversely, students in the TAU condition, only showed significant improvements in Articulation ($p < .001$) with a moderate effect size.
Conclusions: This randomized controlled pilot was one of the first to evaluate an application to treat prosodic deficits in students with ASD. SLPs implemented the software with their students; however, usage data highlights that the software was implemented less than activities used to target social-communication and other language goals.

Given the complexity of ASD, it is unsurprising that prosody might not be on the top of a clinician's intervention priority list. Although no significant differences were observed in post-treatment ratings of prosody between treatment groups, trends in improvement of intensity and rhythm were emerging for the treatment condition. While SpeechPrompts may not be more effective than standard prosody interventions administered at greater intensity, its use appears to be associated with positive changes in prosody. These results suggest that SpeechPrompts might be an appropriate intervention option for those with prosodic deficits secondary to neurodevelopmental disorders.

Oral Session - 14B
192 - Issues in Treatment of Anxiety
2:40 PM - 3:30 PM - Room 309

2:40 **192.001** Maintenance of Intervention Effects of a Family-Focused Cognitive-Behavioral Treatment for Anxiety in Youth with ASD

S. Hepburn[1], *A. Blakeley-Smith*[2] *and J. Reaven*[3], *(1)Psychiatry & Pediatrics, University of Colorado / JFK Partners/Neurodevelopmental Behavioral Pediatrics, Aurora, CO, (2)Univ. of Colo. Denver-JFK Partners, Aurora, CO, (3)Univ. of Colorado Denver-JFK Partners, Aurora, CO*

Background: Empirical support for the efficacy of modified cognitive-behavioral interventions targeting anxiety symptoms in youth with ASD is building; however, there are few reports of maintenance of treatment gains beyond a 3-month follow-up period in the autism literature.
Objectives: To conduct a 1-year follow-up study of anxiety symptoms in 50 youth with ASD who participated in a randomized controlled trial of Facing Your Fears, initially reported in Reaven et al., 2012.
Methods: In the original study, 26 youth were randomly assigned to Treatment as Usual (TAU) and 24 to Active Treatment (Facing Your Fears, Reaven et al., 2010). Youth in the TAU condition were offered the opportunity to complete the intervention following completion of their post-TAU measures. Forty-seven youth, ages 7-11 with a confirmed diagnosis of ASD, completed the intervention and 35 families provided parent report of anxiety symptom severity in the youth 1-2 years after completing the 12-week intervention.
Results: *Preliminary Analyses.* Examination of differences between those families who provided follow-up data and those who did not yielded no significant differences in anxiety symptom severity (at baseline or at post-treatment), autism symptom severity, intellectual functioning, socioeconomic status (income and mother's level of education) or gender. There were also no differences in session attendance or parent/youth satisfaction ratings with the intervention. Anxiety symptoms were measured with the SCARED- Parent Version (Birmharer et al., 1999) at pre-treatment, post-treatment and at 1-year follow-up. The SCARED Total Score was used in this study, where scores of 25 or higher indicate greater risk of a clinically significant anxiety disorder. The mean number of days between post-treatment assessment and follow-up assessment was 378.06 (*sd* = 62.17).
Anxiety Outcomes 1 year post-treatment. Overall, parent report of anxiety symptom severity on the SCARED suggests that symptoms continue to maintain or decrease approximately one year after completing the Facing Your Fears Intervention. Mean SCARED scores were: Pre-treatment mean: 31.93 (*sd* = 11.85); Post-treatment mean: 27.36 (*sd* = 12.11); 1-year follow-up mean: 19.06 (*sd* = 10.34). At pre-treatment, 98% of youth obtained a clinically significant Total score on the SCARED (i.e, >25); at post-treatment, 51.4% obtained a score in the clinically significant range, and at 1-year follow-up, 17.1% obtained a score in the clinically significant range. Paired t-tests show statistically significant improvements at 1-year follow-up, relative to scores obtained immediately after completing the intervention (t (1,34) = 4.64, p = .000). Examination of responder characteristics and other intervening variables are underway.
Conclusions: These data are amongst the first reports of maintenance of intervention effects over a 1-2 year period for a cognitive-behavioral treatment for anxiety in youth with ASD. These findings add to the growing body of evidence supporting the potential impact of family-focused, cognitive-behavioral approaches to anxiety in ASD. Limitations include reliance on parent report of youth anxiety. Further research, utilizing more robust outcome measures, is warranted.

2:52 **192.002** Treatment Fidelity and Clinician Experience: Implementation of "Facing Your Fears" in Outpatient Settings

A. Blakeley-Smith[1], *L. G. Klinger*[2], *A. Keefer*[3], *A. Duncan*[4], *S. E. O'Kelley*[5], *E. Moody*[6], *S. Hepburn*[7] *and J. Reaven*[8], *(1)Univ. of Colo. Denver-JFK Partners, Aurora, CO, (2)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (3)Kennedy Krieger Institute, Baltimore, MD, (4)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)Psychology, University of Alabama at Birmingham, Birmingham, AL, (6)University of Colorado Anschutz Medical Campus, Aurora, CO, (7)University of Colorado / JFK Partners, Aurora, CO, (8)Univ. of Colorado Denver-JFK Partners, Aurora, CO*

Background: Clinician training and ability to implement a treatment program to fidelity are potential barriers to the transportability of evidenced based interventions (EBP) for youth with autism spectrum disorders (ASD) to outpatient clinics. When youth present with both ASD and anxiety, clinician training issues are even more relevant. Unfortunately, there are few clinicians with both ASD and anxiety experience. In efforts to increase training of new clinicians, it is important to determine the background or experience required to implement an EBP to fidelity, (e.g., experience with ASD or experience with anxiety). The role of clinician experience was examined in a study implementing one such EBP, Facing Your Fears (FYF; Reaven et al., 2011), a group cognitive behavior therapy for youth with ASD and anxiety, in outpatient settings.
Objectives:
(1) Examine whether clinician experience (i.e., years of ASD and/or anxiety experience) impacted fidelity ratings across three instructional conditions: *Manual* (manual only), *Workshop* (two-day workshop) and *Workshop Plus* (workshop plus bi-weekly consultation).
(2) Examine whether the quality of overall FYF delivery and the delivery of certain FYF components (i.e., psychoeducation, instruction on exposure, and implementation of exposure) varied across instructional conditions.
Methods: A three group parallel design was used to randomize eight teams of three clinicians, to one of the three training conditions. Four outpatient university clinics with 35 clinicians participated in delivering 24 groups of FYF across sites. Clinicians completed a questionnaire on treatment experience, reporting the number of years' experience with anxiety and/or ASD. Treatment fidelity was evaluated by two clinicians who rated 100% of videotaped sessions across all sites and conditions. Sessions were scored for absolute fidelity of all treatment components (absence/presence), quality of implementation (Likert scale, 1-5), and thoroughness of delivery of specified intervention components (i.e., Likert scale, 1-5).
Results:
(1) *Clinician Characteristics*. There were no significant differences across conditions in the number of years' experience clinicians had with ASD: F (2,31)=.053, p=.95. However, clinicians in the Manual condition had significantly more experience treating anxiety [F (2,31)=5.34, p=.95] . Greater ASD experience was associated with better fidelity (p = .039).(2) *Quality of Treatment Delivery and Treatment Components:* Quality ratings for the delivery of FYF was significantly greater for the Workshop/Workshop Plus conditions than for the Manual condition: F (2, 1374)=50.55, p<0001. There were no significant differences in the thoroughness by which clinicians implemented psychoeducational activities or instructional activities on exposure across conditions; however, Workshop Plus had significantly higher ratings of thorough implementation of in-vivo exposure activities, with the Manual condition faring significantly worse than chance (standardized residual 3.5 for fidelity=0).
Conclusions: Clinicians with greater ASD experience had significantly higher treatment fidelity ratings; however, clinicians across all three instructional conditions delivered FYF with good adherence. Clinicians in the Manual condition had significantly greater anxiety experience than clinicians in the Workshop conditions. Clinicians participating in the Workshop conditions provided significantly higher quality delivery of FYF and were more thorough in the implementation of all treatment components (including in-vivo exposure). These results will be discussed in light of child treatment outcome.

3:04 **192.003** Training Clinicians to Deliver Group Cognitive Behavior Therapy to Manage Anxiety in Youth with High-Functioning ASD: Results of a Multi-Site Trial

J. Reaven[1], *A. Blakeley-Smith*[2], *L. G. Klinger*[3], *A. Keefer*[4], *A. Duncan*[5], *S. E. O'Kelley*[6], *A. T. Meyer*[7], *C. Johnson*[8], *E. Moody*[9] *and S. Hepburn*[10], *(1)Univ. of Colorado Denver-JFK Partners, Aurora, CO, (2)Univ. of Colo. Denver-JFK Partners, Aurora, CO, (3)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (4)Kennedy Krieger Institute, Baltimore, MD, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Psychology, University of Alabama at Birmingham, Birmingham, AL, (7)University of North Carolina, Carrboro, NC, (8)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (9)University of Colorado Anschutz Medical Campus, Aurora, CO, (10)University of Colorado / JFK Partners, Aurora, CO*

Background: Children with ASD are at high risk for developing anxiety disorders (van Steensel et al. 2011). Cognitive-behavioral treatments (CBT) such as the Facing Your Fears (FYF) group treatment (Reaven et al., 2011) have demonstrated strong efficacy in the reduction of anxiety for youth with high-functioning ASD (Reaven et al. 2012; Ung et al. 2014). While it has been critically important to develop treatments for anxiety, it is equally important to facilitate the portability of these treatments to "real world" settings. Common efforts to disseminate treatments in the community consist of distribution of manuals, only *occasionally* paired with brief trainings (Rounsaville et al. 2005). A systematic comparison of clinician training methods for delivering CBT to children with ASD, tied to improved child outcomes, can provide guidelines for training real-world clinicians.
Objectives: (1) To identify an optimal training model to deliver FYF by comparing three instructional conditions: *Manual* (manual only), *Workshop* (two-day workshop) and *Workshop Plus* (workshop plus bi-weekly consultation); and (2) To examine the effectiveness of instructional method by assessing: a) clinicians' understanding of FYF (CBT Knowledge; Treatment Fidelity), and b) decreases in anxiety symptoms for youth participants (SCARED; ADIS-P).
Methods: A three group parallel design was used to randomize eight teams of three clinicians, to one of the three aforementioned conditions. Four outpatient clinics across the US, serving youth with ASD, participated in the study. Thirty-five clinicians delivered the 14-week FYF intervention across sites. A well-characterized sample (e.g., ADOS-2; SCQ) of 94 children with ASD ages 8-14 (and their parents) were randomized to condition; 80 children completed treatment. Fidelity and youth anxiety treatment outcome

(SCARED; ADIS-P) was examined across all sites and conditions.
Results: Clinicians in both *Workshop* conditions significantly increased CBT knowledge post-workshop F (1,18)=19.81, p< .0001. Excellent treatment fidelity (absence/presence of core components) was obtained across all conditions (*Manual* – 89.9%; *Workshop* – 92.8%; and *Workshop Plus* – 93.2%), although *Manual* was significantly lower than would be expected by chance X(2)=11.94, p=.003. Results of the intent-to-treat sample, yielded a significant interaction between time/condition in parent reported anxiety (SCARED) p=.04, with youth in both *Workshop* conditions demonstrating significant decreases in anxiety, and better than *Manual*. There was also a significant effect for time for child reported anxiety (SCARED), but not for condition, p=.04. Significant decreases in severity of Separation (p<.002), Specific (p<.0001), Generalized (p<.0001) and Social Anxiety Disorders (p<.0001), as derived from the ADIS-P, occurred for time. There was also a significant effect for time/condition, as youth with Social Anxiety Disorder in the *Workshop*condition, demonstrated significant improvements in symptoms relative to the other conditions p=.002.
Conclusions: Clinicians in all conditions delivered FYF with good adherence. Significant reductions in anxiety symptoms were apparent across conditions. While there may be an advantage to participating in the *Workshop* conditions, these results suggest that clinicians in *Manual* condition were able to read the Facing Your Fears manual, and achieve solid fidelity and youth outcome. Implications for implementation of evidenced based programs will be discussed.

3:16 **192.004** High Risk, High Gain: High-Anxiety Adolescents with ASD Make the Most Gains over the Course of Treatment

A. McVey[1]*, K. S. Willar*[1]*, B. Dolan*[1]*, S. Stevens*[2]*, A. M. Carson*[3]*, J. S. Karst*[4] *and A. V. Van Hecke*[1]*, (1)Marquette University, Milwaukee, WI, (2)University of Minnesota, Minneapolis, MN, (3)Autism Center & Psychology Service, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (4)Children's Hospital of Wisconsin, Wauwatosa, WI*

Background: Many individuals with ASD are characterized by high social anxiety (White et al., 2009). Social anxiety curtails initiation of social interaction, and may lead to further disruption of healthy social development. Social anxiety may limit positive outcomes for this population, especially in adolescence, when peer interactions become more heavily emphasized. Research has shown that social skills treatments are an effective treatment for ASD (Reichow, Steiner, & Volkmar, 2012), and that anxiety can decrease over the course of social skills treatments for ASD (Schohl et al., 2014). However, it is unknown whether adolescents with ASD, who also present with high levels of anxiety, show similar responses to social skills treatment, versus low-anxiety adolescents.
Objectives: Do treatment outcomes differ in high- and low-anxious adolescents with ASD?
Methods: 106 adolescents (mean/sd age= 13.5/1.5; 91 male; 88% Caucasian) with ASD and their caregivers were recruited. Participants had a verbal IQ > 70 (mean/sd=100/18.5) and diagnoses confirmed with the ADOS-G. A randomized controlled trial (RCT: immediate vs. waitlist control) of the PEERS® (Laugeson & Frankel, 2010) intervention was conducted. To examine the specific effects of anxiety on treatment outcomes, analyses were conducted with the 30 least anxious adolescents (lowest quartile, less than a score of 13) and the 27 most anxious adolescents (highest quartile, greater than a score of 23) on the *Social Anxiety Scale-Adolescent* (SADNEW subscale: self-report of fear and anxiety about unfamiliar peers; La Greca & Lopez, 1998). Data at pre- and post-PEERS® included: (1) the TASSK (adolescent report of PEERS®social skills knowledge; Laugeson, 2012), (2) the QSQ (adolescent report of social interaction frequency; Laugeson, 2012), and (3) the SRS-Parent Total score (ASD symptoms; Constantino, 2005).
Results: Multivariate ANOVAs indicated time (pre, post) by group (experimental, waitlist control) interactions for both High [$F(4, 15) = 7.26$, $p = .002$] and Low [$F(4, 16) = 7.83$, $p = .001$] anxiety groups. Follow-up univariate ANOVAs, separately for High and Low anxiety groups, indicated that only one outcome measure, the TASSK, showed a time by group interaction for Low anxious teens, $F(1, 19) = 30.70$, $p = .001$. In contrast, the High anxious teens showed significant time by group interactions for TASSK [$F(1, 18) = 19.25$, $p = .001$] and SRS [$F(1, 18) = 11.21$, $p = .004$], with QSQ approaching significance, $F(1, 18) = 3.82$, $p = .06$.
Conclusions: Both high- and low-anxious adolescents benefitted from the PEERS intervention, in the form of increased social skills knowledge. However, highly anxious adolescents showed more widespread improvement in outcomes than less anxious adolescents, specifically showing fewer symptoms of ASD and more social interactions with peers. These results highlight a unique opportunity and imperative to address social skills and friendships in a sub-group of adolescents with ASD who also have high levels of anxiety.

Oral Session - 15A
193 - Mechanisms/Correlates of Psychopathology
1:45 PM - 2:35 PM - Room 310

1:45 **193.001** Do Shared Mechanisms in Autism and Depression Underlie This Comorbidity?

K. Gotham[1]*, R. N. Crist*[2] *and J. W. Bodfish*[3]*, (1)Vanderbilt University, Nashville, TN, (2)Psychiatry, Vanderbilt University School of Medicine, Nashville, TN, (3)Vanderbilt University School of Medicine, Nashville, TN*

Background:
Depression is a leading form of clinical impairment for adults with autism spectrum disorder (ASD). Both depression and autism separately have been linked to deficits in social motivation and affect modulation (i.e., reflexive neurological responses to emotionally evocative stimuli).
Rumination is a robust predictor of depression in the general population (Robinson & Alloy, 2003) and conceptually similar to cognitive perseveration associated with ASD. Thus, social motivation, affect modulation, and rumination warrant study as indicators of potential mechanisms underlying depression in ASD.
Objectives:
(1) To assess the relation between mood, rumination, and social motivation in an adult ASD sample;
(2) To provide evidence of biomarkers of rumination and affect modulation while directly comparing adults with ASD, depression (DEP), and typical development (TD) on these constructs.
Methods:
Study 1 participants included n=50 adolescents and adults with ASD (16-35 years) and verbal IQ ≥ 70. For Study 2, ongoing data collection includes adults aged 18-35 with ASD (goal n=50), typically developing (TD) adults with current depression (goal n=30) or a previous, remitted depressive disorder (goal n=30), and TD never-depressed controls (goal n=30). See Table 1 for current Study 2 n's. Diagnoses were confirmed with the Autism Diagnostic Observation Schedule (ADOS-2) in both studies, as well as the Structured Clinical Interview for DSM-5 Disorders (SCID-5) in Study 2. A variety of psychometric instruments were used in both studies to assess social motivation (e.g., Social Interests and Habits Questionnaire [SIH; Gotham, Bishop et al., 2014]) and rumination (e.g., Ruminative Response Scale [RRS; Nolen-Hoeksema & Morrow, 1991]). Pupil diameter, measured through infrared videography on an eye-tracker, provides a quantitative index of neural reactivity to emotional stimuli, and was used to assess rumination and affect modulation in Study 2 (see Table 1 for task descriptions).
Results:
Neither rumination nor social motivation scores were significantly associated with age or verbal IQ in our ASD sample, nor were they associated with each other. Rumination scores, however, were strongly related to depressive symptoms (r=.662; p<.001) and to insistence on sameness (r=.545; p<.05). Pupillometry will be tested as a biomarker in which pupil wave amplitude operationalizes initial affect modulation, and latency has additional implications for rumination (Siegle et al., 2003). We expect to see sustained arousal (per pupil response to single stimuli) and attentional bias (per eye-tracking of paired stimuli) specifically to sad faces, images, and sentences in our three clinical groups compared to controls. We hypothesize that pupil response to positive facial stimuli will be related to self-reported level of social motivation.
Conclusions:
Creating evidence-based care for common and impairing comorbidities may be the most direct line to improving quality of life and reducing general health care needs for individuals with ASD as they age into adulthood. Ideally, treatment for depression in ASD should be guided by research into the multiple potential causes for these two disorders to co-occur, and the ways in which those mechanisms might interact. Studying this comorbidity may also provide a novel opportunity for discovery about the mechanisms themselves.

Table 1.
Eye-tracking and pupillometry tasks to assess shared mechanisms in depression and autism in Study 2

TASK	STIMULI	DURATION	TO ASSESS...
Pupil: Social Condition	• Faces (Happy, Sad, Angry, Neutral) • Scrambled mask	• 350 ms image • 8 second mask	Affect Modulation to Social Stimuli, Rumination
Pupil: Nonsocial Condition	• Positive (e.g., landscape) • Negative (e.g., caged animals) • Neutral (e.g., table)	8 seconds	Affect Modulation, Rumination
Pupil: Lexical Condition	Self-referential sentences (Positive, Negative, Neutral)	8 seconds	Affect Modulation, Rumination
Eye-tracking: Paired Preference	Neutral and Emotional (Happy, Sad, Angry) Pair	5 seconds	Attentional Bias

Note. We are collecting data on affect modulation from several tasks, some novel and some replicated, that involving passive viewing of single or paired presentations of emotional stimuli with social and nonsocial conditions. Continuously captured pupillometry data will be assessed at varying durations to indicate ruminative processing.

For Study 2, we currently have collected data from 15 participants (n=7 current depressed; n=2 depressed by history; n=6 typical controls) over the course of 6 weeks. We currently have 10 more participants scheduled, and will soon begin to recruit from our list of n=130 adults with ASD who have consented to be recontacted for research. In December 2015, we will begin co-recruitment and data collection with another ASD study inviting longitudinal participants back. We are on track to have robust preliminary data by May 2016 for a novel comparison of these two clinical populations.

1:57 **193.002** Infant Predictors of School-Age ADHD Symptoms in Siblings at High Familial Risk for ASD

E. Shephard[1], *B. Milosavljevic*[2,3], *T. Gliga*[4], *G. Pasco*[5], *E. J. Jones*[6], *F. Happé*[7], *M. H. Johnson*[8] *and T. Charman*[2], *(1)Institute of Psychiatry, Psychology, & Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Birkbeck College, London, United Kingdom of Great Britain and Northern Ireland, (5)Institute of Psychiatry, London, United Kingdom of Great Britain and Northern Ireland, (6)CBCD, Birkbeck College, University of London, London, United Kingdom, (7)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (8)Birkbeck, University of London, London, United Kingdom of Great Britain and Northern Ireland*

Background: Many children with autism spectrum disorder (ASD) also have symptoms of attention-deficit/hyperactivity disorder (ADHD), a developmental disorder characterised by impairing inattentiveness, hyperactivity, and impulsivity. The high co-occurrence rate, combined with evidence that ASD and ADHD share genetic and neurobiological pathways, suggests that infants who are at high familial risk for ASD may also be at increased genetic vulnerability to developing ADHD. Since ADHD is associated with significant school, social, emotional and behavioural problems, it is crucial to understand the development of ADHD in high-risk infants and, ideally, identify predictors of these symptoms early in life to facilitate timely intervention.
Objectives: The objectives were first, to assess school-age levels of ADHD symptoms in high-risk children prospectively studied since the first year of life, and second, to identify infant and early-life characteristics associated with school-age ADHD outcomes.
Methods: 42 infants with an older sibling with ASD (high-risk infants) and 37 infants with typically developing older sibling/s (low-risk infants) were enrolled in a prospective longitudinal study and completed assessments at 7-, 14-, 24-, 36- months and 7 years of age. At 7 years, parent-rated ADHD symptoms on the Conners 3 were compared between high-risk children who met DSM-5 criteria for ASD (HR-ASD; n = 15), high-risk children without ASD (HR-No ASD; n = 27) and low-risk controls (LR; n = 37). Early life (< 3 years) neurocognitive characteristics that were predictive of school-age ADHD symptoms in high-risk children were explored. Predictors were selected based on their robust association with ADHD in the literature. These were: saccadic RT and reaction time variability (RTV) measured at 7m, 14m and 36m on an attention shifting task, cognitive control performance (RT) on a Spatial Conflict task at 36m, and the temperament factors Surgency, Negative Affect, and Effortful Control measured at 7m, 14m, 24m, and 36m.
Results: 7-year ADHD symptoms were significantly higher in HR-ASD than HR-No ASD ($p < .05$, $d = .79$) and LR ($p < .01$, $d = 1.13$), but were low and comparable in the latter two groups ($p > .2$). Within the high-risk group, ADHD symptoms were significantly associated with earlier manual and saccadic RT and temperament, such that individuals with the slowest RTs and lowest Effortful Control in infancy and toddlerhood showed the highest levels of ADHD symptoms later in childhood (table 1). When the high-risk group was divided into those with elevated ADHD symptoms at 7 (Conners 3 T-scores > 60; HR-high-ADHD) and those with typical levels of ADHD at 7 (Conners T-scores < 60; HR-low-ADHD), the HR-high-ADHD children exhibited significantly slower RTs and significantly lower Effortful Control in infancy and toddlerhood than the HR-low-ADHD and LR control groups (figure 1). These effects remained when covarying for ASD symptoms at 7 years.
Conclusions: A proportion of high-risk infants, particularly those who develop clinically significant ASD, show high levels of ADHD symptoms at school-age. Slowed RTs and poor self-regulation in infancy and toddlerhood are associated with school-age ADHD symptoms in high-risk children, and may represent early risk-markers of later-childhood ADHD problems.

Table 1
Associations between 7-year ADHD symptoms and early-life predictors (RT and Effortful Control) in high-risk children

	Conners 3 Hyperactive/Impulsive T-score at 7-years	Conners 3 Inattentive T-score at 7-years
Saccadic RT at 7 months	$r\ (38) = .372,\ p = .02,\ r^2 = .14$	n/s
Manual RT (Conflict trials) at 36 months	$r\ (17) = .572,\ p = .016,\ r^2 = .33$	$r\ (17) = .530,\ p = .029,\ r^2 = .28$
Effortful Control at 14 months	$r\ (41) = -.349,\ p = .025,\ r^2 = .12$	n/s
Effortful Control at 24 months	$r\ (37) = -.419,\ p = .01,\ r^2 = .18$	$r\ (37) = -.423,\ p = .009,\ r^2 = .18$

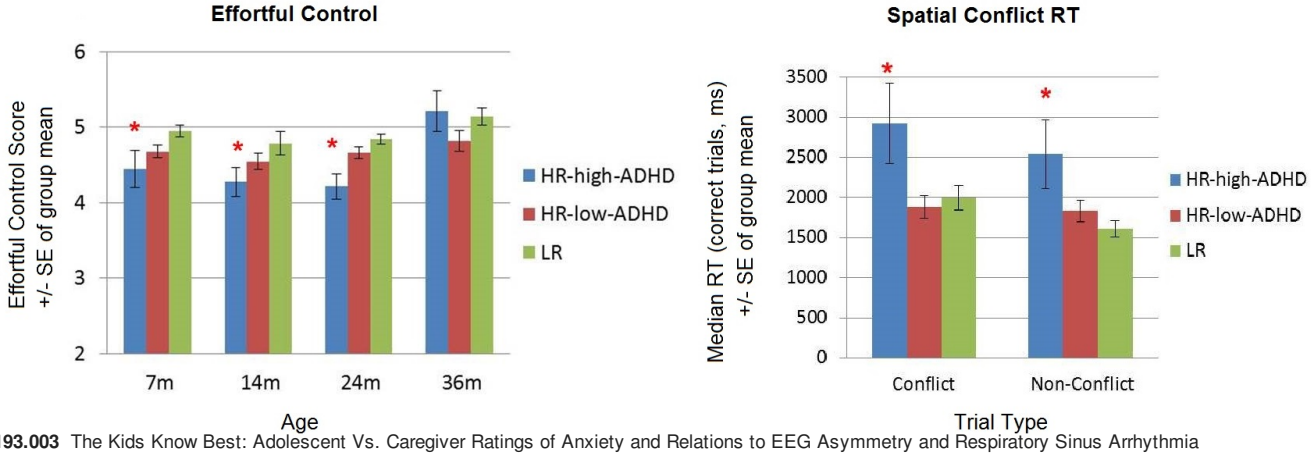
Effortful Control scores and manual RT in infancy and toddlerhood by 7-year ADHD outcome groups



2:09 **193.003** The Kids Know Best: Adolescent Vs. Caregiver Ratings of Anxiety and Relations to EEG Asymmetry and Respiratory Sinus Arrhythmia

B. Dolan[1], *K. A. Schohl*[1], *A. McVey*[1], *S. Stevens*[2], *A. M. Carson*[3], *J. S. Karst*[4] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)University of Minnesota, Minneapolis, MN, (3)Autism Center & Psychology Service, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (4)Children's Hospital of Wisconsin, Wauwatosa, WI*

Background: Measurement of anxiety in young people with ASD has often relied on caregiver or self-report checklists, but very few studies have examined the ecological validity of such approaches when compared to neurobiological or physiological measures of stress/ anxiety. Along with high social anxiety (White et al., 2009), many individuals with ASD present with right hemisphere asymmetry/dominance, and dysregulated physiological arousal (quantified as lower respiratory sinus arrhythmia, RSA), both of which may contribute to anxiety profiles in ASD (Van Hecke et al., 2009, 2013).
Objectives: 1) how strongly are self- vs. caregiver-rated measures of anxiety related, and 2) which, if any, of the anxiety ratings are related to RSA and EEG asymmetry in adolescents with ASD?
Methods: 106 adolescents (mean/sd age= 13.5/1.5 years; 91 male; 88% Caucasian) with ASD and their caregivers were recruited. Participants had a verbal IQ > 70 (mean/sd=100/18.5) and diagnoses were confirmed with the ADOS-G. Data included (1) resting-state frontal EEG gamma asymmetry; (2) resting-state RSA; and (3) the *Social Anxiety Scale- Adolescent* and *Caregiver* forms (SAS: La Greca & Lopez, 1998).
Results: Adolescent and caregiver ratings of adolescent anxiety on all subscales and total score on the SAS were significantly related, *rs* (83) = .21 - .47, *ps* = .05 - .0001. Higher left hemisphere frontal EEG asymmetry/dominance was related to higher anxiety as rated by adolescents on the SAS-SADNEW subscale (measures fear and anxiety about unfamiliar peers), $r\ (102) = -.20$, $p = .04$. Higher RSA was related to higher anxiety as rated by adolescents on the SAS-SADNEW, $r\ (104) = .20$, $p = .04$.
Conclusions: Although all self- and caregiver-rated measurements of social anxiety were related, only anxiety measures rated by adolescents were related to physiological and neurological measures. Further, these relations were not in the predicted direction. Adolescents with ASD, with higher physiological regulation (RSA) and higher relative left hemisphere asymmetry, also endorsed high levels of social anxiety. Results suggest a unique additive value of self-ratings when considering links amongst anxiety and neurophysiological measures, and a potential paradoxical effect, in that neurophysiological systems that support social approach may be linked with higher anxiety in adolescents with ASD.

2:21 **193.004** Exploring the Structure and Neurocognitive Correlates of Challenging Behaviour in Young People with Autism Spectrum Disorder

V. Carter Leno[1], *R. Kent*[2], *T. Charman*[2], *C. Jones*[3], *F. Happé*[4], *G. Baird*[5], *A. Pickles*[1] *and E. Simonoff*[2], *(1)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)School of Psychology, Cardiff University, Cardiff, United Kingdom, (4)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (5)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background:
Many young people with Autism Spectrum Disorder (ASD) exhibit 'challenging behaviour', characterised by severe non-compliance, aggression and self-injurious behaviour (SIB). The development of effective interventions requires greater knowledge of ASD-specific models of challenging behaviour. The collection of behaviours (non-compliance, aggression, SIB) subsumed under the term 'challenging behaviour' may be associated with different neurocognitive profiles.
Objectives:
A detailed exploration of the neurocognitive profile associated with different aspects of challenging behaviour. Structural equation modelling will be used to explore the relationship between SIB and aggression, and their associated neurocognitive profiles.
Methods:
This study involved 94 well-characterised adolescents (mean age 15.5 years) with a diagnosis of ASD from the Special Needs and Autism Project (SNAP), a longitudinal, population-based cohort. Parent-reported symptoms of SIB and aggressive behaviour were measured using items selected from the Profile of Neuropsychiatric Symptoms (PONS). Assessment of the neurocognitive profile included performance on tasks of executive functioning (inhibition, flexibility, sustained and selective attention) and social cognition (emotion recognition, theory of mind). Clinician-rated ASD ICD-10 symptoms and IQ were included as co-variates.
Results:
Initial analyses used bivariate regressions to explore relationships between aspects of challenging behaviour and neurocognitive task performance. FSIQ and then ASD symptoms were added as covariates to determine the specificity of the relationships. The final analyses will use SEM to build a comprehensive model.
Ratings of SIB and aggressive behaviour were explored in a varied sample of individuals with ASD (FSIQ: mean = 84.11 (17.46), range 50-119; clinician-rated ASD symptoms: mean = 8.04 (2.45), range 3-12).
Mean SIB = .57 (1.12), range = 0-5, and mean aggressive behaviour = 5.36 (4.61), range = 0-17.5. SIB and aggressive behaviour were significantly correlated (r=0.44,

p<0.01). SIB was associated with a greater number of ASD symptoms. No association was found with aggressive behaviour.
IQ: Aggressive behaviour was associated with lower FSIQ and performance but not verbal IQ. SIB was associated with a trend towards lower FS and verbal IQ.
Executive Functioning: Aggressive behaviour was associated with difficulties in flexibility, inhibition and sustained attention; however these did not remain after co-varying for IQ. SIB was not associated with any of these domains, but was associated with difficulties in selective attention. This became non-significant when co-varied for IQ.
Social Cognition: Aggressive behaviour was associated with specific difficulty in recognising fearful faces. This pattern of results remained when co-varied for both IQ and ASD symptoms. SIB was also associated with difficulties recognising fearful faces; however, this association became non-significant when co-varied for IQ. Neither aggressive behaviour nor SIB was associated with theory of mind ability.
Conclusions:
Although a useful clinical term, explanatory models of challenging behaviour may need to consider SIB and aggressive behaviour separately. There appeared to be differential associations of the two domains with respect to IQ, executive functioning and emotion recognition. Better characterisation of the neurocognitive profile associated with each domain may inform development of future interventions, and be used to tailor interventions dependent on which aspect of challenging behaviour is more problematic for a given individual.

Oral Session - 15B
194 - Eating Behavior in ASD
2:40 PM - 3:30 PM - Room 310

2:40 **194.001** Development and Validation of the Autism Eating Profile Questionnaire

E. Gal[1], *O. E. Stolar*[2] *and R. Gal-Mishael*[3], *(1)University of Haifa, Timrat, Israel, (2)Assaf Harofeh Medical Center, Ra'anana, Israel, (3)ALUT-The Israeli Society for Autistic Children, Giva'atim, Israel*

Background: Many children with autism spectrum disorders (ASD) exhibit a variety of eating/feeding problems, making eating a recurrent challenge. Despite recent research and developments in this area, there is a lack of thorough validated and reliable tools that specifically assess eating problems in children with ASD. The Autism Eating Problems and Patterns Questionnaire (AEPQ) was developed as a new and comprehensive assessment of children with ASD with the aim of better understanding the nature and sometimes the source of eating problems in this population.
Objectives: (1) To construct a questionnaire that will assess the eating problems and patterns of children with ASD (2) To determine the questionnaire's reliability and validity in two ways: a. examination of the internal consistency of the questionnaire's domains; and b. ascertaining its discriminative validity.
Methods: A 3-phase study was conducted: 1) construction of the questionnaire, including content validity and factor analysis 2) ascertaining internal consistency reliability, and 3) ascertaining discriminative validity by comparing the reports of parents of children with ASD to those of parents of typically developed children. Parents of 69 boys with ASD, mean age of 4 years and 10 months, and 85 typically developed children matched by age and gender, completed the AEPQ which includes three parts: (a) personal details and general information relating to eating habits, as well as medical and family history (b) a Likert scale part that addresses seven domains of eating problems, and (c) a food list aimed at assessing the actual diet of the child by means of types, variety of eaten foods. Cronbach's alpha coefficient was used to examine the domain scale's internal consistency. To test whether differences existed between the children with and without ASD, a Multiple Analysis of Variance (MANOVA) was conducted, followed by a series of ANOVA tests to investigate the differences between the two groups in the various questionnaire's domains.
Results: Factor analysis of the 46 items revealed seven factors that constructed seven different domains, namely: chewing and swallowing problems, food avoidance, eating selectivity, sameness and rigidity in eating, eating rituals, excessive eating and mealtime behavior problems. Internal consistency reliability of the AEPQ's seven domains range from a high to very high (Cronbach's alpha of r=.82 to .94).The MANOVA showed significant differences between the groups in their eating habits)F (6,69) =24.13 ,p<0.001, η^2=.65**(;** scores of children without developmental disabilities were significantly lower than the scores of children with HFASD in all of the questionnaire's domains, thus establishing the questionnaire's discriminant validity
Conclusions: The AEPQ presents a clear factor structure and is a reliable and valid tool for the assessment of eating problems, specifically various kinds of food selectivity of children with ASD. By generating a thorough profile of eating habits and problems that specifically relate to the characteristics of ASD, it may support clinical decision-making regarding interventions aimed at improving the eating problems of children with ASD.

2:52 **194.002** Continuous and Extreme Autistic Trait Ratings Are Associated with Avoidant Restrictive Food Intake Disorder

G. Wallace[1] *and N. L. Zucker*[2], *(1)The George Washington University, Washington, DC, (2)Duke Center for Eating Disorders, Duke University, Durham, NC*

Background: From its earliest description, autism spectrum disorder (ASD) has been linked with feeding-related problems. Dietary abnormalities are very common in ASD, including food selectivity, food refusal, and insistence on sameness while eating. Moreover, food selectivity is not limited to childhood, but clearly persists into the adolescent and adult years in ASD. With the adoption of DSM-5, a new eating/feeding disorder was introduced, avoidant restrictive food intake disorder (ARFID). ARFID is characterized by clinically significant difficulties with eating/feeding, including areas of likely phenotypic overlap with ASD, such as food avoidance based on sensory characteristics. In spite of this, no study to date has linked these two conditions. The present study seeks to fill this gap in knowledge.
Objectives: Examine continuous and extreme autistic trait ratings within a large group of participants oversampled for issues related to selective eating, including ARFID.
Methods: A large group of 1,992 adults (1,445 females) completed online surveys including self-ratings of autistic traits utilizing the original 50-item Autism-Spectrum Quotient (AQ) and eating-related behaviors (e.g., limitations in dietary intake, weight loss connected to limited dietary intake, sensory-related food sensitivities, etc.) validated to assess features of ARFID. The degree to which these eating related problems interfered with broader social and job functioning was also assessed.
Results: Individuals with symptoms consistent with ARFID (n=1,390), had higher overall autistic trait ratings (M=21.28, SD=7.38) than those without ARFID (n=602; M=20.16, SD=7.50; t=3.08, p=.002). More specifically, the ARFID group had elevated autistic traits in the areas of social skills (M=4.42, SD=2.76 vs. M=4.08, SD=2.78), attention switching/flexibility (M=5.35, SD=2.25 vs. M=4.94, SD=2.31), and communication (M=3.48, SD=2.28 vs. M=3.19, SD=2.23) compared to the non-ARFID group (ts>2.44, ps<.02). In turn, participants with extreme autistic trait ratings (total AQ score>31; n=160) were more likely to rate themselves as having ARFID (X^2=3.45, p=.036, one-tailed), than individuals with subthreshold scores. Finally when comparing how eating-related problems affected broader functioning, participants with both ARFID and elevated autistic traits (n=121) reported greater interference with their jobs than did those with ARFID alone (n= 1,268; X^2=3.39, p<.05, one-tailed) and greater anxiety and avoidance of social situations involving food (ts>2.25, ps<.025).
Conclusions: This is the first study to examine phenotypic overlaps of ASD and ARFID. Perhaps unsurprisingly, there were relatively strong associations between both continuous autistic trait ratings and extreme levels of autistic traits and ARFID. More specifically, the social-communication and inflexibility components of the ASD phenotype appeared most closely linked with ARFID. The inflexibility component of the ASD phenotype is particularly striking given conceptual connections drawn between it and selective eating in ASD. Additionally, elevated autistic traits appeared to exacerbate interference with everyday social and occupational functioning among individuals with ARFID. Much more work is needed to understand the shared and unique mechanisms driving eating-related idiosyncrasies that disrupt daily life among individuals with ASD and/or ARFID, which will serve to inform future intervention development.

3:04 **194.003** Changes in Food Selectivity over 6 Years in Children with Autism Spectrum Disorder

L. G. Bandini[1], *C. Curtin*[1], *S. Philips*[2], *S. E. Anderson*[3], *M. Maslin*[4] *and A. Must*[5], *(1)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Charlestown, MA, (2)Dept. of Public Health & Community Medicine, Tufts University School of Medicine, Boston, MA, (3)Division of Epidemiology, The Ohio State University College of Public Health, Columbus, OH, (4)E.K. Shriver Center – UMass Medical School, Charlestown, MA, (5)Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA*

Background: Food selectivity is a common problem in children with autism spectrum disorder (ASD) and is of concern because of its impact on nutrient adequacy and family mealtimes. Despite recent research in this area, few studies have addressed whether food selectivity present in early childhood persists into adolescence in children with ASD.
Objectives: To determine if food selectivity and the characteristics/presentation of foods that affect food selectivity persist in in children with ASD.
Methods: We re-contacted children who participated in the Children's Activity and Meal Patterns Study which examined dietary patterns, mealtime behaviors, and food selectivity in typically developing children and children with ASD aged 3-11 years. At the initial time point and on average 6.5 years later, a parent-completed food frequency questionnaire was used to measure food refusal and consumption of fruits, vegetables, snacks, and beverages; a 3-day food diary was used to determine the number of unique foods eaten; a diet interview with parents assessed refusal by the child based on food characteristics and presentation of the food (e.g., texture, foods mixed together). Food refusal was defined as the percentage of foods offered that were not eaten.
Results: Seventeen of the 53 (32%) children in the original study participated in the follow-up study. Those who participated in the follow-up study did not differ in age or in measures of food selectivity at baseline compared to those who did not participate. The mean (SD) age at baseline was 6.9 (2.4) years; mean (SD) age at follow-up was 13.4 (2.6) years. Mean (SD) food refusal at baseline was 46.8% (22.4), compared to 32.2% (19.4) at follow-up (p<0.01). The number of unique foods eaten decreased an average of 2.1 foods between baseline and follow-up (borderline significance, p=0.08). We found no statistically significant changes in the servings of beverages, fruits and vegetables, or snacks consumed between baseline and follow-up (all p>0.05). At baseline, 94% of parents indicated that their child currently refused food based on

consistency, compared to 41% of parents at follow-up ($p<0.01$). We observed no significant change in food refusal based on temperature, whether foods were mixed together, or whether foods were touching each other.
Conclusions: Our examination of the change in food selectivity as children become adolescents found that some aspects of food selectivity improved while others persisted. While food refusal improved overall, we did not observe an increase in food repertoire (number of unique foods eaten). Larger longitudinal studies are required to determine the extent of the persistence of food selectivity and the impact on nutritional status in children with ASD.

3:16 **194.004** Mealtime Behavior Problems and Spousal Stress Among Children with ASD

C. Curtin[1], *S. Philips*[2], *A. Must*[3], *S. E. Anderson*[4] *and L. G. Bandini*[1], *(1)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Charlestown, MA, (2)Dept. of Public Health & Community Medicine, Tufts University School of Medicine, Boston, MA, (3)Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, (4)Division of Epidemiology, The Ohio State University College of Public Health, Columbus, OH*

Background: Children with ASD are reported to have atypical eating behaviors and problematic mealtime behaviors. It has been suggested that mealtimes provide structure and promote family unity, and that stressful mealtimes can contribute to family disharmony. Emerging evidence suggests that mealtime behavior problems exhibited by children with ASD contribute to parental stress at mealtimes.
Objectives: To describe changes in children's mealtime behaviors and parental stress over time and to determine whether spousal stress is associated with mealtime behavior problems in children with ASD.
Methods: We re-contacted parents of children with ASD (n=53) who participated in the Children's Activity and Meal Patterns Study (CHAMPS). The original CHAMPS study included children with ASD and typically developing children ages 3-11 years. The average follow-up period was 6.5 years. Both the original CHAMPS study and the follow-up study included a parent questionnaire about family mealtimes that contained questions about mealtime behavior problems (score range 0-40) and spousal stress at mealtimes (score range 0-20).
Results: Seventeen of the 53 (32%) children with ASD who took part in the original CHAMPS study participated in the follow-up study. Those who participated in the follow-up study did not differ in age or prevalence of mealtime behavior problems at baseline compared to those who did not participate. However, parents who participated in the follow-up study were more likely to report higher levels of spousal stress than those who did not participate ($p<0.001$). The mean (SD) child age at baseline was 6.9 (2.4) years; mean (SD) age at follow-up was 13.4 (2.6) years. The mean (SD) score for spousal stress at baseline was 13.7 (4.0), which decreased to 10.1 (5.0) at follow-up ($p<0.05$). The mean (SD) mealtime behavior problem score was 21.8 (5.9) at baseline, which declined to 15.6 (4.9) at follow-up ($p<0.01$). At baseline, spousal mealtime stress was significantly correlated with mealtime behavior problems ($r=0.67$; $p=.005$); at follow-up this association weakened and was no longer statistically significant ($r=0.37$, $p=0.17$).
Conclusions: Our findings suggest a high prevalence of mealtime behavior problems and spousal stress at mealtimes among families of children with ASD and an association between the two. Over time, however, both mealtime behavior problems and spousal stress appear to improve. Given that mealtimes are important for family cohesion, the challenges that children and families face at mealtimes may be important clinical targets. Larger studies that examine the nature of and course of these relationships is warranted.
