Conclusions: This study found that even amongst a group of health professionals who often provided services to adults on the Autism spectrum, while they felt competent in providing care, they still wanted more training specific to caring for adults on the Autism spectrum, particularly in the areas of behaviour management and mental health.

229 **125.229** Using Community Partnerships to Better Understand the Barriers to Using an Evidence-Based, Parent Mediated Intervention for ASD in a Medicaid System

K. Pickard *and B. Ingersoll, Michigan State University, East Lansing, MI*

Background: Within the autism spectrum disorder (ASD) field, service use disparities have been noted to impede under-resourced, ethnic minority families’ ability to access high quality services for their child with ASD. Service access barriers and rates of attrition in ASD services are particularly relevant for parent-mediated interventions, and may suggest a lack of fit between evidence-based, parent-mediated interventions as they are presently being implemented in underserved community settings. However, no research to date has explicitly examined this fit.
Objectives: The present study used Roger’s Diffusion of Innovations theory to guide the understanding of the variables that might influence parent and provider use of an evidence-based, parent-mediated program (Project ImPACT) in a Medicaid system. The longterm goals are to use this understanding to enhance the fit of Project ImPACT for Medicaid systems.
Methods: Community-based partnerships were formed with 3 Medicaid systems to better understand the perceived compatibility, complexity, and relative advantage of using Project ImPACT within a Medicaid eligible population. As part of the community partnerships, 3 focus groups were conducted with 16 Medicaid eligible parents, and 3 focus groups were conducted with 16 ASD providers operating within a Medicaid system (i.e. see Tables 1 and 2). Groups were designed to elicit participants’ perceptions of Project ImPACT and feedback on adaptations that would enhance the fit of the Project ImPACT program within the Medicaid system.
Results: Across all groups, parents’ and providers’ reported general interest in using the Project ImPACT program. However barriers and suggestions consistently emerged regarding the need to: 1) reduce the complexity of all written materials; 2) include more visuals and metaphors in teaching; 3) ensure a strong alliance between the therapist and parent; 4) involve the extended family; and 5) have specific strategies to help families practice the intervention within their chaotic environments and within their pre-existing resources.
Conclusions: Results from the present study suggest that Project ImPACT is generally viewed as an important intervention by Medicaid parents and providers. However, parents and providers specify a number of perceived barriers centering on Project ImPACT’s compatibility, acceptability and relative advantage that would likely impede its use within this setting. Future directions are thoroughly discussed regarding next steps in designing and testing an adapted Project ImPACT program geared for the Medicaid system.

230 **125.230** Using Quality Improvement Collaboratives to Improve Early Identification of Autism By Primary Care Providers Serving Low Resource Urban Communities

M. Siller[1], *E. R. Hotez*[2] *and M. R. Swanson*[3], *(1)Hunter College of the City University of New York, New York, NY, (2)The Graduate Center of the City University of New York, New York, NY, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:
Almost a decade ago, the AAP (2006, 2007) published a groundbreaking policy statement on surveillance and screening of autism spectrum disorder (ASD). These guidelines recommended that all children be screened for ASD using formal screeners during pediatric well-child visits at 18 and 24 months. Although limited, available data suggest that only a minority of primary care providers (PCPs) has successfully implemented the AAP's recommendations (Volkmar & Reichow, 2014).
Objectives:
To investigate the preliminary efficacy of quality improvement collaboratives (QICs) for improving (1) ASD-specific screening rates during well-child visits at 18 and 24 months, and (2) self-reported knowledge/attitudes about early identification of ASD among primary care physicians.
Methods:
This research was conducted in collaboration with two urban PCPs in the Eastern US: a network of five clinics (PCP#1), and a clinic affiliated with a hospital center (PCP#2). The communities served by these PCPs were primarily African American (28% and 41%, respectively) and Hispanic (31% and 49%, respectively). The QICs were implemented over a 4-month period. Activities were guided by a multi-disciplinary leadership team comprised of the researchers and three individuals from within the clinic. The team met monthly to develop, evaluate, and refine an office-wide implementation system that addresses clinic-specific barriers. In addition, the leadership team determined the content of monthly training workshops offered to the clinic staff. Both PCPs chose to implement the M-CHAT (Robins et al., 2001).
To evaluate increases in screening practices and physician knowledge/attitudes, two kinds of outcome measures were collected: 1) Monthly chart reviews were completed for a period of about 6 months, starting one month prior to the QIC. Using a random sampling approach, medical charts of children from 17-25 months at the time of well-child visit were reviewed for documentation about ASD-specific screening and referrals. For PCP#1 and PCP#2, we abstracted data from 250 and 140 charts, respectively. 2) Before and after the QIC period, physicians completed a questionnaire evaluating knowledge/attitudes about screening, communicating with families, and referral practices.
Results:
A total of 15 physicians completed the pre- and post-questionnaire measures (female: 72%; racial/ethnic minority: 80%; years in practice: M=26, SD=12.5). Results revealed significant increases in physicians' knowledge/attitudes about screening measures, $t(14)=2.7$, $p < .05$. No significant increases were found with regard to physicians' knowledge/attitudes about early diagnosis, strategies for communicating with families, and effective referral practices. In addition, chart review results indicated that ASD-specific screening rates increased from 16% to 76% at PCP#1, and from 24% to 39% at PCP#2. Across both PCPs, ASD-specific screening measures identified a total of 10 children at high risk for ASD. Four of these were referred by the treating physician to the local early intervention program to determine eligibility for services.
Conclusions:
Despite advances in early identification of ASD, significant challenges persist in moving screeners from academic centers to the "real world". The current research demonstrates the preliminary efficacy of QICs for implementing ASD-specific screening measures by PCPs in ethnically diverse and low resource communities. Future directions for optimizing this learning system will be discussed.

231 **125.231** Using Technology to Create Sustainable Systems of Support for Toddlers at Risk for Autism Spectrum Disorder

S. K. Fuhrmeister[1], *E. Brooker Lozott*[2], *K. Resua*[1], *T. Ryan*[1], *M. Costo*[1] *and J. L. Stapel-Wax*[3], *(1)Marcus Autism Center, Atlanta, GA, (2)EIs for Autism Foundation, Jensen Beach, FL, (3)Emory University School of Medicine, Atl, GA*

Background:
The National Research Council (2001) found that early detection and 25 hours per week of active engagement promoted optimal success for young children with autism spectrum disorder (ASD) in kindergarten. Although intervention has the greatest impact on ASD if it begins before age three, 80% of children who need early intervention are missed (CDC, 2009; Filipek et al., 1999; NRC, 2001; USDOE, 2011). NRC (2001) along with Wong et al. (2014) of the Autism Evidence-Based Practice Review Group and the National Standards Project (2015), emphasize that evidence-based practices, such as naturalistic and parent-implemented interventions meet the criteria of "established treatments" for individuals with ASD. However, families with access to early intervention often find that the available systems are ill prepared in the specific skills and methods needed to effectively collaborate and coach parents/caregivers (Friedman & Woods, 2012). Therefore, more innovative methods for providing support and coaching to early intervention providers (EIPs) is necessary to ensure development of knowledge and skills and translation into practice (Bransford et al., 2000). However, there is a paucity of research on the effectiveness of coach-the-coach models supporting EIPs with the use of technology.
Objectives:
This ongoing project aims to improve collaborative coaching proficiencies of EIPs across Georgia via implementation of a novel, coach-the-coach model utilizing innovative and community-viable mobile coaching technology focused on increasing knowledge of adult-learning strategies, early red flags for ASD, and supports to promote active engagement for toddlers at risk for ASD.
Methods:
This study is tracking the progress of 25 EIPs across Georgia, coached to coach caregivers on increasing active engagement in toddlers at risk for ASD. Coaching of EIPs is

conducted in-person quarterly, with all other weekly coaching sessions occurring via technology. Effectiveness of the coach-the-coach model is assessed using SEE-KS™ (Rubin, E. et al., 2014) three-point rating scales to determine supports coached to caregivers by the EIPs to foster engagement and support understanding and expression in toddlers at risk for ASD. SEE-KS™ is a coaching framework based on Universal Design for Learning encompassing the principals of SCERTS® (Prizant et al., 2005).

Results:

Friedman's Tests were used to examine differences in support ratings over time due to the small sample size. Results from the current five EIPs indicate a significant increase from baseline in supports coached to caregivers to foster engagement (p<0.0001) and to support understanding (p=0.0060) and expression (p=0.0034) during the first three months of the project (see Table 1 and Figure 1). Mean changes represent approximately 30% increase in supports coached to caregivers from Time 1 to Time 2. Baseline scores of supports represent "treatment as usual" from the EIPs.

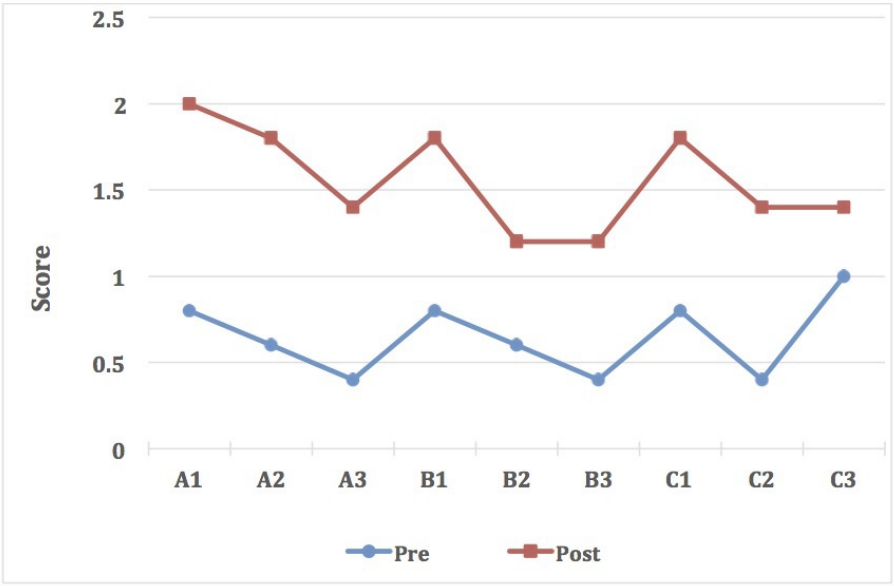
Conclusions:

These data indicate that the current coach-the-coach model resulted in caregivers providing increased supports to promote engagement, understanding, and expression in toddlers at risk for ASD. Through the use of innovative technology within the coach-the-coach model, EIPs learned to effectively coach an increase in caregiver-implemented supports within three months, empowering caregivers to utilize evidence-based supports in a short amount of time.

Table 1. Descriptive Statistics on Pre/Post Scores (Per Activity/Segment)

Activity/Segment	Pre Score*	Post Score*	p-values
A. Fostering Engagement	0.6 (0.51)	1.7 (0.46)	<0.0001
B. Presenting information in multiple ways	0.6 (0.51)	1.4 (0.74)	0.0060
C. Allowing students to act and express themselves in multiple ways	0.7 (0.46)	1.5 (0.83)	0.0034

Figure 1. Mean Score Comparison Per Question - Pre vs. Post



Practice

***C. M. Harker**, L. V. Ibanez, S. R. Edmunds, E. A. Karp and W. L. Stone, Department of Psychology, University of Washington, Seattle, WA*

Background: State-implemented early intervention (EI) programs are a first line of treatment for many children with, or at risk for ASD, making them an ideal setting for implementing ASD-specialized evidence-based interventions (EBIs) such as Reciprocal Imitation Training (RIT). However, sustained use of EBIs requires that the setting supports their delivery (Chambers et al., 2013). *Implementation climate,* the extent to which users perceive an intervention as supported and rewarded in their work setting (Klein & Sorra, 1996), is associated with intervention use (e.g., Dingfelder, 2012), as are the intervention's *acceptability* and *feasibility* (Proctor et al., 2011). Little is known about how these factors change over time, and how these changes influence providers' use of EBIs. One-day professional development workshops are the norm in training community-based providers; however, few studies track provider use of interventions after trainings are delivered. Even fewer track providers' sustained use of interventions over time.

Objectives: The specific objectives were to examine changes in ratings of RIT acceptability, feasibility, and implementation climate over three time points (post-training, 3-month follow-up, and 6-month follow-up) between providers who are and are not using RIT at follow-up.

Methods: EI providers attended one-day RIT workshops. Providers (n=116) rated the acceptability and feasibility of RIT and the implementation climate of their work setting (Usage Rating Profile-Intervention, selected items; Chafouleas, 2009) at three time points: immediately post-training and at 3- and 6-month follow-ups. Providers also reported at the 6-month follow-up whether they had used RIT (Use Group=79). Report of RIT use at 3-months was used when 6-month data were missing.

Results: Three hierarchical linear models were conducted to examine changes in provider ratings of RIT acceptability, feasibility, and implementation climate over time (see Table 1 for raw means) and handle missing data using Maximum Likelihood estimation. RIT use at follow-up was a predictor of the intercept for acceptability, B_{01} =. 29, p <. 01, feasibility, B_{01} = .22, p = .03, and implementation climate, B_{01} = .31, p <. 01. RIT use was also a predictor of linear change for acceptability, B_{11} = .13, p < .01, feasibility, B_{11} = .12, p < .01, and implementation climate, B_{11} = .11, p < .01. Ratings declined for all providers between post-training and follow-up, but declined *more* steeply for providers *not* using RIT at follow-up.

Conclusions: These findings suggest that though providers find RIT to be acceptable and feasible and rate their work climate as supportive immediately after the workshop, real world application of the intervention may present challenges that temper these ratings and providers' subsequent use of RIT. Community providers may require additional support within their work settings (e.g., supervisor encouragement, resources, incentives) in order to facilitate their use of EBIs with children in their caseload.

Table 1
Descriptives for feasibility, acceptability, and implementation climate

Variable	All Providers *M (SD)/n*	Use Group** *M (SD)/n*	No-Use Group** *M (SD)/n*
Acceptability*			
Post-training	3.45 (.48)/99	3.53 (.45)/71	3.26 (.50)/28
3-month follow-up	3.09 (.63)/87	3.29 (.49)/64	2.52 (.61)/23
6-month follow-up	3.02 (.73)/53	3.28. (.61)/40	2.23 (.44)/13
Feasibility*			
Post-training	3.37 (.45)/97	3.43 (.47)/70	3.23 (.38)/27
3-month follow-up	3.25 (.62)/80	3.42 (.49)/59	2.75 (.66)/21
6-month follow-up	3.04 (.81)/54	3.28 (.69)/41	2.28 (.71)/13
Implementation Climate*			
Post-training	3.43 (.43)/98	3.51 (.40)/70	3.23 (.42)/28
3-month follow-up	3.27 (.62)/82	3.46 (.47)/61	2.70 (.67)/21
6-month follow-up	3.15 (.69)/54	3.41 (.57)/40	2.43(.46)/14

Notes. * Scores range from 1-4, with 4 indicating more optimal ratings. Data reported are raw means. **Use Group = providers who reported using RIT with their caseload at 6-month follow-up; No-Use Group = providers who reported not using RIT with their caseload at follow-up (3-month data were used when 6-month data were not available).

233 **125.233** When Should Next Generation Sequencing be Used in Children at High-Risk for Autism Spectrum Disorder?

T. Yuen[1,2], *W. Ungar*[3], *P. Szatmari*[4] *and M. T. Carter*[5], *(1)Technology Assessment at Sick Kids, Hospital for Sick Chidlren, Toronto, ON, Canada, (2)Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, (3)Hospital for Sick Chidlren, Toronto, ON, Canada, (4)Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)Hospital for Sick Children, Toronto, ON, Canada*

Background: Next generation sequencing (NGS) is a novel but costly genetic testing technology that is currently reserved for syndromic children with autism spectrum disorder (ASD) who failed to receive a genetic diagnosis from traditional genetic testing. Using NGS earlier in the diagnostic pathway could generate information to aid diagnosis and lead to earlier treatment, but its optimal position in the diagnostic pathway remains unknown.
Objectives: The objective of this study was to construct a model of the diagnostic pathway from birth to age 6 in children at high risk for ASD to predict the health consequences of introducing NGS at different time points.
Methods: The diagnostic pathway for children at high-risk for ASD was modeled using discrete event simulation to predict age at diagnosis, wait time for treatment, and total costs. Clinical progression was structured in consultation with clinicians and current Canadian guidelines. The model incorporates ASD risk factors, recognized phenotypes of genetic mutations and developmental trajectories based on two prospective cohort studies (the Infant Sibling Study and Pathways to ASD Study) and published literature.
Results: The model accounts for heterogeneity in clinical pathway associated with individual characteristics such as gender, family history, congenital anomalies, ASD

symptom severity and developmental milestones. Moreover, the model can simulate queues for health services and predict wait times for clincial assessment and treatment. In turn, the average age at diagnosis and age at treatment initiation can be estimated when NGS was introduced at different time points along the diagnostic pathway. Conclusions: The simulation model from this study can generate much needed information for clinicians and decision-makers on how to integrate NGS in clinical settings. This model will be used in economic evaluations to help decide whether NGS can replace cheaper but less effective genetic tests. Reduction in unnecessary testing could also reduce delays in diagnosis and wait times for ASD services, which are critical issues in improving long term outcomes in ASD.

Speaker: G. Feng, MIT McGovern Insitute for Brain Research, Boston, MA

Recent genetic studies have identified a large number of candidate genes for autism spectrum disorder (ASD), many of which encode synaptic proteins, suggesting that synaptic dysfunction might be a key pathology in ASD. In addition, recently, genetic studies have revealed a significant overlap of risk genes for ASD and schizophrenia. However, it is not clear how different mutations of the same gene could contribute to the manifestation of different diseases. One such example is the Shank3 gene. The Shank3 gene encodes a postsynaptic scaffolding protein critical for the development and function of glutamatergic excitatory synapses. Disruption of the Shank3 gene is thought to be the cause of the core neurodevelopmental and neurobehavioral deficits in Phelan-McDermid Syndrome, an autism spectrum disorder. Using various Shank3 mutant mice as a model system, I will discuss (1) recent findings on synaptic and circuit mechanisms underlying autistic-like behaviors in Shank3 mutant mice; (2) the reversibility of synaptic, circuit and behavioral abnormalities in adult mutant mice; and (3) molecular and synaptic mechanisms that may explain how different alleles of the same gene lead to distinct synaptic and behavioral phenotypes in mice. Together, these findings may inform exploration of neurobiological mechanisms of ASD in human patients.

9:00 Dissecting Synaptic and Circuitry Mechanisms of Autism
***G. Feng**, MIT McGovern Insitute for Brain Research, Boston, MA*

Panel Session
137 - Recent Advances in Genetics and Neurobiology of Autism
10:30 AM - 12:30 PM - Hall B

Panel Chair: Guoping Feng, *MIT McGovern Insitute for Brain Research, Boston, MA*

Both genetic and environmental factors play important roles in the pathogenesis of autism spectrum disorder. The four panel members, each at the forefront of their respective fields, will discuss recent advances in large-scale genetic studies, neuro-immunology crossroad, and iPS cell technologies in the effort to unravel the etiology and neurobiology of autism spectrum disorder.

10:30 **137.001** Emerging Genetic Analyses of Autism Spectrum Disorders: Insights from Common and Rare Variation
***B. Neale**, Broad Institute, Cambridge, MA*

Background: The genetic analysis of autism spectrum disorders (ASDs) is accelerating. Increasing sample sizes are revealing risk factors across the allele frequency spectrum.
Objectives: Review genetic influences on ASD across the allele frequency spectrum from common variation through to spontaneously arising variation.

Methods: Genome-wide association analysis has been performed on over 10,000 cases of ASDs. Whole exome sequencing has been performed on ~5,000 cases of ASDs. We also incorporated frequency information from Exome Aggregation Consortium to refine and strengthen the evidence for association.
Results: For common variation, substantial increases in sample size have led to the identification of genome-wide significant loci. For rare variation, aggregation efforts to exome sequencing have sharpened our ability to identify significant genetic risk factors.
Conclusions: These studies highlight the importance of taking a comprehensive view of genetic risk and the need to continue increasing sample sizes to build the foundation for understanding the biological mechanisms that drive ASD in the population.

11:00 **137.002** A Multi-Omics Analysis of the Autism Brain

***D. Arking**, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Despite recent advances in identifying a number of genes involved in autism spectrum disorder (ASD) through identification of large effect de novo mutations, the vast majority of ASD risk remains unexplained. Moreover, while common genetic variation is expected to explain >50% of the variance in liability for ASD, no large/moderate genetic effects have been identified, and current studies are underpowered to identify common variants of small effect.
Objectives: Understanding the etiology of ASD is critical to identifying potential therapeutic targets. Given the limited success relying solely on genetic studies, we focus on a multi-omics approach, incorporating genome-wide association study (GWAS) results along with transcriptomic and methylation data from the primary affected tissue in ASD, human brain. The goal is to combine these different layers of genome-wide data to identify key pathways in the development of ASD.
Methods: GWAS results are available through the Psychiatric GWAS Consortium Autism Working Group on ~6,500 parent-affected child trios. Gene expression and methylation data were generated in up to 47 (32 unique individuals) ASD samples and 57 (40 unique individuals) controls, including multiple brain areas for gene expression studies.
Results: Gene expression studies identify microglial genes robustly dysregulated in ASD cortical brain, pointing to M2-activation as a common feature of ASD brains. Notably, these genes are not enriched for genetic variants associated with ASD (common or rare). Instead, a set of neuronal genes that are not differentially expressed are enriched for the genetic signal. Thus, combining GWAS with transcriptomics suggests a model in which the gene expression changes are secondary to the primary genetic defects, raising the question of whether M2-activation is a common causal pathway for ASD symptoms, or instead, a response to changes occurring during neurodevelopment. The incorporation of genome-wide methylation data is ongoing.
Conclusions: Combining multiple genome-wide level datasets (GWAS, transcriptomics, methylation) provides key insights into the etiology of ASD that cannot be gleaned from any of the datasets in isolation, and is likely to prove critical in identifying potential therapeutic targets.

11:30 **137.003** The Maternal Interleukin-17a Pathway in Mice Promotes Autism-like Phenotypes in Offspring

***G. Choi**, MIT McGovern Insitute for Brain Research, Cambridge, MA*

Background: Accumulating evidence points to a central role for immune dysregulation *in utero*as as a risk factor in Autism Spectrum Disorder (ASD). Human studies suggest that maternal viral infections early in pregnancy correlate with an increased frequency of ASD in the offspring. This observation, coined maternal immune activation (MIA), has been modeled in rodents by inducing inflammation in pregnant dams. However, The immune cell populations critical in the MIA model have not been identified.
Objectives: Based on previous observations suggesting their involvement in ASD, we tested whether TH17 cell population and its cytokine are necessary for MIA phenotypes.
Methods: N/A
Results: Using both genetic mutants and blocking antibodies targeting their activities, we have recently found that Th17 cells are critical mediators working in pregnant mice to induce behavioral abnormalities in MIA-affected offspring. T cell-specific inactivation of RORgt in mothers (thus selectively removing Th17 cells in pregnant mothers) protected from induction of MIA-dependent behavioral phenotypes in offspring. In addition, we found that maternal inflammation leads to abnormal cortical phenotypes in offspring and this malformation is fully rescued by inhibiting the maternal IL-17a pathway. We also found that the receptor for IL-17 (IL-17R) is expressed in the developing fetal brain and its expression is increased in the cortex upon MIA.
Conclusions: These observations suggest a hypothesis that uncontrolled activation of IL-17R expressed in fetal brain induces abnormal cortical development and these structural abnormalities may be an underlying cause of the MIA-dependent behavioral phenotypes.

12:00 **137.004** From Cortical Development to Cortex in the Dish: Modeling Human Neurodevelopmental Disease

***P. Arlotta**, Harvard, Cambridge, MA*

Background:
Brain imaging approaches have allowed for a low-resolution understanding of network abnormalities in living human brains of patients with neurodevelopmental and neuropsychiatric disorders, however a deeper understanding of pathologies affecting neural network behavior are only possible when abnormalities in cell connectivity, network activity and transcriptomes can be directly interrogated and correlated in an experimental system amenable to manipulation, phenotyping and high-throughput analysis.
Objectives:
We aim to generate a high-throughput in vitro model of the human developing brain to investigate the effect of disease-linked mutations on brain development and circuit function.
Methods:
I will present recent work on the development and long-term culture of 3D cerebral organoids derived from human pluripotent stem cells. This will include analysis of the developmental trajectory, cellular diversity and neuronal network features that mature within this human brain organoid model.
Results:
I will show that phenotypic abnormalities observed in patients carrying genetic mutations linked to neurodevelopmental disease can be reproduced within cerebral organoids.
Conclusions:
The work provides initial proof-of-principle demonstration that selected aspects of human neurodevelopmental disease can be modeled in high-throughput using 3D cerebral organoids.

Panel Session
138 - Growing Older with Autism; Cognition, Comorbidity and Quality of Life.
10:30 AM - 12:30 PM - Room 307

Panel Chair: Dermot M. Bowler, *City University London, London, United Kingdom*

Discussant: Laura Klinger, *Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC*

Although it has been known for several decades that autistic individuals grow older, it is not until the last few years that there has been any research into the effects of ageing in this population. This is surprising given that ageing in typical as well as other atypical populations carries with it a considerable burden for the individual in terms of cognitive and adaptive changes, and for society in terms of increased demands on systems of care provision. The four presentations in this panel report on age-related, later lifespan differences in cognition, quality of life and psychiatric comorbidities. These studies, although cross-sectional in nature, will lay the groundwork for future longitudnal follow-up investigations.

10:30 **138.001** The Association Between Cognitive Ability and Psychiatric Problems in Adults with ASD

***P. Howlin**[1] and P. Moss[2], (1)King's College London, Institute of Psychiatry, London, England, United Kingdom of Great Britain and Northern Ireland, (2)Kings College London, London, England, United Kingdom of Great Britain and Northern Ireland*

Background: Data on rates of mental health problems in adults with autism vary widely, from 20%-25% in some studies to over 70% in others. The relationship with cognitive level is also uncertain, with some studies suggesting mental health problems are more likely to occur in individuals of higher IQ who are more exposed to social pressures and/or are more aware of their social and other difficulties than individuals with intellectual impairments.
Objectives: The aim of the present study was to explore the association between mental health and cognitive functioning in a cohort of adults with autism who have been systematically followed up over several decades
Methods: Participants were 58 individuals who were first diagnosed with autism as children (mean age 6 years); current age mean age is 45 years. All were of average non-verbal IQ when seen as children. Adult measures included IQ assessments and self and informant measures of psychiatric difficulties
Results: Most individuals were able to complete formal cognitive tests as adults and in this group cognitive ability had remained very stable since they were first seen in childhood (mean child IQ 85,5, sd 14.2; mean adult IQ 87.3, sd.20.1). However, ability levels in 15 individuals could be assessed only indirectly; in this group cognitive levels

(based on Vineland proxy estimates) had declined significantly (mean 20.5; sd 2.1). Among the total cohort, 44% of adults were rated as having no mental health problems but 28% had mild to moderate difficulties and a further 28% had severe psychiatric problems. Overall there was a small but statistically significant correlation between IQ and ratings of adult mental health (r=-.32, p=.015). Significantly more individuals in the group showing a decline in cognitive ability were rated as showing moderate to high levels of psychiatric morbidity than those whose IQ remained within the average range (Fisher exact test .03). Thus, two thirds of individuals in the "cognitive decline" group had moderate to high levels of psychiatric disturbance compared with 28% of those with an IQ in the average range.
Conclusions: In this cohort of individuals seen over many years, there was no evidence that higher IQ was associated with a higher risk of psychiatric morbidity; in contrast individuals who had shown an apparent decline in cognitive functioning over the years seemed more likely to experience psychiatric disturbance. However, whether the findings reflect a true decline in cognitive ability, or whether poor test performance was due mainly to psychiatric and behavioural problems remains unclear. Other issues related to the assessment of IQ and mental health changes in long-term follow-up studies will also be discussed

10:55 **138.002** ASD-Related and Psychiatric Symptomatology Across the Adult Lifespan

A. G. Lever[1] *and H. M. Geurts*[2,3]*, (1)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam, Amsterdam, Netherlands, (2)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam; Dr. Leo Kannerhuis, Amsterdam, Netherlands, (3)Dept. of Research, Development & Innovation, Dr. Leo Kannerhuis, Doorwerth, Netherlands*

Background:
Although autism spectrum disorder (ASD) is considered a lifelong neurodevelopmental disorder, knowledge on the condition in middle and late adulthood is still limited. A steadily increasing number of studies suggest that some behavioral symptoms might abate over time, even though outcome is rather poor and the diagnosis is rarely waived. Psychopathology frequently co-occurs with ASD, but whether psychiatric symptoms and disorders, representing an important target for treatment, also diminish across the adult lifespan remains largely unknown.
Objectives:
The aim of this cross-sectional study is to investigate the relationship between age and ASD symptomatology (including social-emotional reciprocity and sensory sensitivity), and psychiatric symptoms and disorders.
Methods:
We administered self- and proxy-reported questionnaires (Autism-spectrum Quotient, Interpersonal Reactivity Index, Sensory Sensitivity Questionnaire, Symptom Checklist-90) and a neuropsychiatric interview (Mini International Neuropsychiatric Interview) to 435 adults with and without ASD (age range 19-79 years, IQ>80).
Results:
Self-report was poorly concordant to proxy-report, suggesting that both measures reveal different aspects of ASD symptomatology. Moreover, although age-related differences in social-emotional reciprocity were not observed, general and sensory symptoms increased in middle adulthood and decreased in late adulthood. High levels of depression, anxiety, and psychological distress characterized individuals with ASD across adulthood. More specifically, 79% experienced a psychiatric disorder at least once in their lives, and depression and anxiety disorders were most common. Nevertheless, older adults with ASD less often met criteria for any psychiatric diagnosis and, specifically, for social phobia.
Conclusions:
The high number of self-reported ASD symptoms and the persistence of these symptoms across the adult lifespan, underline the lifelong nature of this neuropsychiatric condition. However, despite consistently high levels of psychological distress, lifetime diagnoses for any psychiatric disorder occurred less often in older adults than in younger adults, suggesting reduced psychopathology in late adulthood.

11:20 **138.003** Ageing and Autism Spectrum Disorder: Symptom Severity, Life Outcome and Additional Mental Health Conditions in Adults Coming for First Diagnosis

E. Zivrali[1]*, F. Happé*[1] *and P. Howlin*[2]*, (1)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, London, England, United Kingdom of Great Britain and Northern Ireland*

Background: Recent studies suggest the prevalence of Autism Spectrum Disorder (ASD) in adults equals that found in children, approximating 1% in the last UK ONS Household survey (Brugha et al., 2011). Although ASD is assumed to be a lifelong condition, the majority of research studies focus on children or young adults (Mukaetova-Ladinska et al., 2011), and very little is known about changes in old age in ASD (Happe & Charlton, 2010; Perkins & Berkman, 2012).
Objectives: To gather more information about the pattern of autism symptom severity, life outcome and additional mental health conditions in older versus younger adults with ASD receiving first-diagnosis in adulthood.
Methods: Clinical case records were analysed from adults (N=100; aged 18 to 70, mean= 40 years) referred to an adult ASD diagnostic clinic to be assessed for a possible ASD diagnosis. Group comparisons between younger (aged 18 to 38, mean= 24 years) and older adults (aged 50 to 70, mean= 56 years) were made, for those individuals who did and those who did not receive an ASD diagnosis. ASD symptoms, life outcome (i.e. education, employment, independence, close relationships, and friendship), and additional psychiatric disorders were compared for younger and older adults, and in relation to age across the group.
Results: A third of adults with ASD had fair or poor life outcome, despite all having at least average intellectual functioning.Old adults with ASD had better close relationships, employment, and independence compared to the younger group, whereas ASD symptom severity, friendship, and educational outcome did not differ by age. The same pattern of age differences was seen in the non-ASD group except for employment. Additional psychiatric problems were common in both age groups with ASD, while there was a higher incidence of anxiety (56%) and depression (42%) in the old group compared to young adults. Other additional psychiatric conditions seen in old adults with ASD were OCD, ADHD, personality disorders, bipolar disorder, and harmful use of alcohol. Among the young individuals with ASD those who had OCD as an additional diagnosis had more severe rigid and repetitive behaviours and interests than those without additional mental health conditions.
Conclusions: This study represents an exploratory and preliminary step to fill the huge gap in the ASD literature concerning ageing. Limitations, implications and future research will be considered.

11:45 **138.004** Ageing with Autism: Memory and Quality of Life

A. Roestorf[1]*, P. Howlin*[2] *and D. M. Bowler*[3]*, (1)City University London, London, United Kingdom of Great Britain and Northern Ireland, (2)King's College London, Institute of Psychiatry, London, England, United Kingdom of Great Britain and Northern Ireland, (3)Psychology, City University London, London, United Kingdom*

Background: Longitudinal studies of ageing in autism spectrum disorder (ASD) report poorer outcomes for the majority of individuals, and that intellectual disability predicts later life outcomes (Howlin et al., 2013; Howlin & Moss, 2012). Cross-sectional studies paint a slightly different picture, reporting fewer age-related differences in relational processing (Ring et al., 2015), executive function and memory (Geurts & Vissers, 2012, Lever & Geurts, 2015). Whilst more longitudinal work is necessary, the time needed to complete such studies means that cross-sectional evaluations of age-related differences will continue to be important, albeit needing cautious interpretation. It remains largely unknown how the severity of autistic traits such as repetitive behaviours, and cognitive skills such as language and everyday memory, which are crucial in maintaining independence and quality of life in healthy ageing (Maylor, 1996; Henry et al., 2004), are affected by growing older with autism.
Objectives: (i) To identify cross-sectional age-related differences in language, intellectual functioning, repetitive behaviours and memory, between younger and older adults with ASD; (ii) Identify how these factors affect quality of life in older ASDs.
Methods: Our study includes 48 younger (YA) and older (OA) adults diagnosed with ASD and 44 non-autistic (non-ASD) adults, matched on age (18-80) and IQ (>70). Participants completed a series of tasks assessing IQ (WAIS), language ability (CREVT), autistic traits and repetitive behaviours (AQ; SRS;OCI-R), memory (CVLT) and Quality of Life (PWI; WHOQOL-BREF).
Results: Our preliminary data on (i) memory and (ii) Quality of Life show the following age-related differences in ASD (max n analysed to date = 21) and comparison participants (max n analysed to date = 11):
(i) Memory – no differences in recall were observed between younger and older ASDs (all $p > .1$), whereas older non-ASD comparison participants had significantly poorer recall than younger participants across short and long-delays (all $p < .05$).
(ii) Quality of Life was significantly worse overall for all ASDs compared to non-ASDs (all p's $<.02$). Older ASD participants reported significantly more satisfaction than younger ASDs with *personal relationships* ($p = .02$) and *future* ($p = .005$) Quality of Life domains, but the comparison participants showed no age-related differences in any domain.
In comparison participants, long-delay recall significantly correlated with receptive language ($p < .05$), negatively correlated with overall Quality of Life ($p < .05$), and all recall negatively correlated with age ($p < .05$). However, in ASD participants, recall and learning across trials was significantly associated with Quality of Life in *physical*, *standard of living*, *safety* and *future* domains (all $p < .05$), whilst recall across short delays was associated with receptive language and comprehension ($p < .05$) and the *community* Quality of Life domain.
Conclusions: Our preliminary findings on memory and Quality of Life both confirm and extend existing cross-sectional comparisons of older and younger adults with ASD (Lever & Geurts, 2015; Ring et al., 2015). However, these findings need to be complemented by robust longitudinal investigations, which will emerge from on-going follow-up of the sample studied here.

Panel Session

139 - What Is Different about Females with Autism: Where Are We and Where Do We Need to Go?

10:30 AM - 12:30 PM - Room 308

Panel Chair: Allison Ratto, *Children's National Medical Center, Silver Spring, MD*

Discussant: Julia Bascom, *Autistic Self Advocacy Network, Washington, DC*

Autism spectrum disorder (ASD) occurs significantly less often in females than in males, particularly among those without comorbid intellectual disability. Consistent with these discrepant prevalence rates, ASD research has often focused primarily on males, limiting our knowledge of the ASD profile in females. Increasingly, research examining gender differences in ASD has found that females may be affected differently than males by this disorder. Prior research has indicated that there are differences in symptom profiles, delays in diagnosis, and differential impacts on daily functioning, but the direction of effects differs notably across studies. The presentations in this panel will focus on the unique presentation of ASD symptoms in females, particularly those without intellectual disability. A meta-analysis of existing research will review findings over the past several decades regarding gender differences in symptom profiles across the range of intellectual disability. Other presentations will discuss gender differences in adaptive behavior, executive functioning, and core ASD symptoms, with a focus on females without intellectual disability. Implications of these findings for better understanding the diagnosis of ASD among females, as well as long-term impacts on daily functioning, will be discussed.

10:30 **139.001** A Systematic Review and Meta-Analysis Reveals Sex Differences in Rrbis in School Age Children with ASD without ID

K. Register-Brown[1], *A. B. Ratto*[2], *C. E. Pugliese*[3], *A. Verbalis*[3], *C. Rothwell*[4,5], *J. L. Martucci*[6], *E. I. White*[7], *G. Wallace*[8] *and L. Kenworthy*[9], *(1)Child and Adolescent Psychiatry, University of Maryland, Baltimore, MD, (2)Children's National Medical Center, Silver Spring, MD, (3)Children's National Medical Center, Rockville, MD, (4)Center for Autism Spectrum Disorders, Children's National Medical Center, Rockville, MD, (5)Catholic University of America, Washington, DC, (6)Neuropsychology, Children's National Health System, Rockville, MD, (7)NIMH, Bethesda, MD, (8)The George Washington University, Washington, DC, (9)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: The consensus that autism spectrum disorders (ASDs) are found four times as often in males as females has remained strikingly consistent despite evolving diagnostic criteria. The possible reasons for this sex difference in prevalence of ASDs are a topic of vigorous debate. First, although typical social, communication, and play behavior develops differently in boys and girls, the ASD diagnostic criteria are not sex-specific, and may systematically underdiagnose girls. Second, the higher prevalence of externalizing behaviors in boys may lead to an ascertainment bias, with boys more frequently taken for diagnostic evaluation due to their disruptive behavior. Finally, biological and environmental factors including genetics, hormones, and neuro-immune processes may act differentially in boys and girls, leading to true phenotypic differences by sex.
Objectives: Quantify sex differences in social, communication, and repetitive behavior and restricted interests (RRBI) symptom severity in individuals diagnosed with ASDs, and the potential mediating impacts of age and IQ.
Methods: PubMed was searched for relevant peer-reviewed articles published before September 29, 2015. Included studies reported core (social, communication, and/or RRBI) ASD symptom severity by sex in subjects diagnosed with ASDs. Meta-analyses were performed using random effects models. To account for measurement heterogeneity, separate meta-analyses were run by symptom domain for studies using the ADOS vs. the ADI vs. any other instrument. The effects of age and IQ were examined by rerunning meta-analyses stratified by subject age (in 5 year increments) and IQ (≤70 and >70).
Results: A total of 39 studies providing data on 9,005 subjects were included (Table 1). Males had significantly higher RRBI on all instruments, including the ADI and ADOS (OR 1.92, 95% CI 1.32-2.87, p=0.001; Table 2). Neither the ADI nor the ADOS, which were used in approximately two-thirds of the studies of social symptoms, revealed sex differences for social problems, although other instruments (eg. AQ, RBQ II, BISCUIT, and DASH-II) did indicate more social symptoms in males than females (OR 1.30, 95% CI 1.01-1.67, p=0.044). The ADI, but not the ADOS or other instruments, revealed more severe communication problems in males (OR 1.40, 95% CI 1.07-1.83, p=0.014). As only RRBI analyses were stable by measurement instrument, and as numbers of studies were inadequate to stratify by both age/IQ and instrument, only RRBI results were stratified by age and IQ. Boys aged 11-15 had significantly worse RRBI symptoms (OR 2.82, 95% CI 1.45-5.48, p=0.002), as did males with IQ>70 (OR 1.83, 95% CI 1.26-2.37, p=0.001).
Conclusions: This meta-analysis did not find any consistent sex differences in social deficit severity. Males had significantly worse communication deficits on parent report measures, and RRBI intensity on all measures. Early adolescent boys, and boys without intellectual disability (ID), showed higher RRBI severity than corresponding girls. These findings indicate that in non-ID school-aged children with ASD, current measurement tools are capturing more severe RRBI difficulties in boys. Whether this reflects inadequacy of the tools to comprehensively capture RRBI in girls, or relatively lower RRBI severity in girls, is a question for future research.

10:55 **139.002** Sex Differences in Real-World Executive Functioning and Adaptive Behavior in Children and Young Adults with Autism Spectrum Disorder

E. I. White[1], *A. B. Ratto*[2], *A. C. Armour*[3], *K. Register-Brown*[4], *H. S. Popal*[1], *G. Wallace*[5], *A. Martin*[1] *and L. Kenworthy*[6], *(1)NIMH, Bethesda, MD, (2)Children's National Medical Center, Silver Spring, MD, (3)Children's National Medical Center, Arlington, VA, (4)University of Maryland, Gaithersburg, MD, (5)The George Washington University, Washington, DC, (6)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Females with Autism Spectrum Disorder (ASD) are diagnosed less frequently (Rivet & Matson, 2011) and later (Begeer et. al., 2012), on average, than males. Questions surround whether these differences could be due to a distinctive profile of behavioral deficits for females with ASD as compared to males.
Objectives: The present study is the largest to date examining executive function and adaptive ability in females with ASD. The aim was to utilize parent ratings of real-world

executive functioning and adaptive behavior to better understand whether females present differently from males in areas of everyday functioning.
Methods: This analysis included a group of 81 females (mean age = 12.21, *SD* = 2.74; mean IQ = 106.88, *SD* = 20.15) and 162 males (mean age = 12.70, *SD* = 2.43; mean IQ = 106.88, *SD* = 18.84), ranging in age from 7-18 years, who met criteria for ASD on the Autism Diagnostic Interview-Revised (ADI-R) and/or Autism Diagnostic Observation Schedule (ADOS). Two male participants were matched to each female to within 4 years of age and 11 IQ points. Groups were equivalent on ADOS, ADOS-2, and ADHD symptom ratings for the subset of the group that had each. All participants were assessed using the Behavior Rating Inventory of Executive Function (BRIEF) and a subset of 57 females and 133 males were assessed using the Vineland Adaptive Behavior Scales-II (VABS-II). Two repeated measures ANOVAs were conducted to compare sex differences across scales on the BRIEF and VABS-II and, when appropriate, post-hoc independent *t*-tests were used to assess differences on specific domain scores.
Results: A mixed-model ANOVA with Sex (male, female) as the between subjects factor and BRIEF scale (8 scales) as the within subjects factor revealed a main effect of sex (F=5.035; p=.026, η_p^2=.020) with females rated as exhibiting greater executive function problems. The Sex (male, female) x VABS-II Domain (3 domains) ANOVA yielded no main effect of sex, but an interaction between VABS-II domain and sex (F=5.834; p=0.003, η_p^2=.030). Post-hoc *t*-tests revealed significantly greater impairments (i.e., lower standard scores) for females with ASD in the domain of Daily Living Skills (p=0.003).
Conclusions: Our results indicate relative weaknesses for females compared to males diagnosed with ASD on non-social executive function and daily living skills. These differences occur in the context of equivalent: clinician ratings of core autism symptomatology, parent ratings of ADHD symptoms and parent-reported social and communication adaptive skills. If these findings are confirmed, they have important implications for treatment targets in females with ASD.

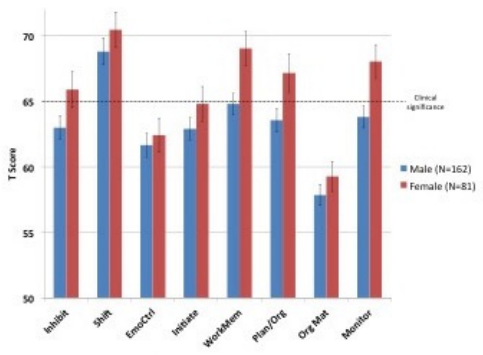

Figure 1. BRIEF profile T scores by sex

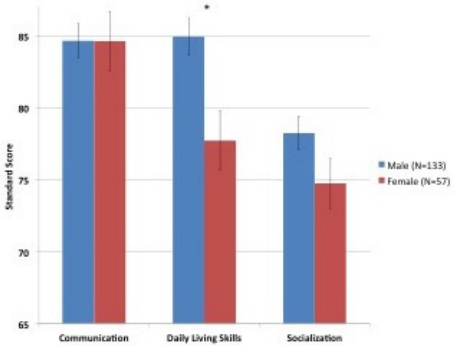

Figure 2. VABS-II domain standard scores by sex

11:20 **139.003** Gender Differences in Parent-Reported and Clinician-Rated Autism Symptoms

A. B. Ratto[1], *G. Wallace*[2], *C. E. Pugliese*[3], *J. L. Martucci*[4], *K. Register-Brown*[5], *E. I. White*[6], *H. S. Popal*[6], *C. Rothwell*[7,8], *A. Martin*[6] *and L. Kenworthy*[9], *(1)Children's National Medical Center, Silver Spring, MD, (2)The George Washington University, Washington, DC, (3)Children's National Medical Center, Rockville, MD, (4)Neuropsychology, Children's National Health System, Rockville, MD, (5)Child and Adolescent Psychiatry, University of Maryland, Baltimore, MD, (6)NIMH, Bethesda, MD, (7)Catholic University of America, Washington, DC, (8)Center for Autism Spectrum Disorders, Children's National Medical Center, Rockville, MD, (9)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Females are diagnosed with autism spectrum disorder (ASD) at significantly lower rates than males, with particularly discrepant rates among those without intellectual disability (Kirkovski, Enticott, & Fitzgerald, 2013). Prior research has found indications of differences in core ASD symptoms, including peer relationships, play, communication, and restricted/repetitive behaviors and interests (Kirkovski et al., 2013). Some have questioned whether high-functioning females may actually be under-diagnosed with ASD, due to differences in symptom presentation (Halladay et al., 2015). However, specific symptom profiles and patterns of impairment differ significantly across studies and by the particular measure used.
Objectives: The aim of the present study was to investigate differences in core symptoms of ASD by gender on gold standard measures using both clinician observation and parent report.
Methods: Participants included 129 children (n=43 females, n=86 males) with a confirmed ASD diagnosis, ages 4-14 years, with IQ>70 recruited from research and specialty clinic samples. Female participants were double-matched (i.e., two males to every one female) on IQ within 10 points. There were no significant differences in age (t= -.42, *ns*) or full-scale IQ (t=.25, *ns*) by gender. All participants were assessed using Module 3 of the Autism Diagnostic Observation Schedule (ADOS; Lord, Rutter, DiLavore, & Risi, 2002) or its recent revision the ADOS-2 (Lord et al., 2012), the Autism Diagnostic Interview-Revised (ADI-R; Rutter, Le Couteur, & Lord, 2003), and the Social Responsiveness Scale (SRS; Constantino & Gruber, 2004) or its recent revision, the SRS-2 (Constantino & Gruber, 2012).
Results: Chi-square analyses were used to examine differences on individual items on the ADOS. Overall, males and females performed similarly on ADOS items. However, females received significantly more severe scores for “Compulsions/Rituals” (χ^2=8.29, p<.02), and males performed worse on “Offers Information” at the trend level (χ^2=5.08, p<.07). Gender differences in parent-reported ASD symptoms were compared on subscales and total scores of the SRS and the ADI-R using t-tests (Table 1). Parents reported statistically significant differences on the SRS in Social Cognition (t= -1.99, p<.05), Social Communication (t= -2.71, p<.008), and Restricted/Repetitive Behavior (t= -2.67, p<.009) and approaching significant differences in Social Awareness (t= -1.87, p<.07), with females rated as more impaired than males on all subscales. In contrast, ADI-R scores showed males as more impaired in Social Interaction (t=1.98, p<.05) and Communication (t=2.25, p<.02).
Conclusions: Parent report measures showed greater impairment in current functioning for females, while greater impairment was reported for males during the crucial historical period for diagnosis (preschool years). This pattern of findings suggests that females with high-functioning ASD are at risk for delays in diagnosis and consequently are more impaired than their male peers during school-age years, perhaps due to related delays in access to services. Importantly, males and females performed similarly on clinician observation, with no significant differences on ADOS algorithm items, suggesting those who meet criteria for a diagnosis present similarly to expert clinicians during middle childhood and early adolescence. This may indicate a need for sex-normed early screening measures to increase access to early diagnosis for females with high-functioning ASD.

Table 1. Demographics and ASD Symptoms by Gender.

	Females (n=43)	Males (n=86)	Significance
Age	9.66 (1.83)	9.48 (2.40)	t =-.42 (*ns*)

11:45 **139.004** Gender Differences on the Newly Proposed ADOS-2, Module 4 Algorithm in ASD without ID: A Multi-Site Study

*L. G. Anthony[1], L. Kenworthy[2], G. Wallace[3], B. E. Yerys[4], B. B. Maddox[5], S. W. White[6], A. C. Armour[7], J. Miller[8], J. Herrington[9], R. T. Schultz[10], A. Martin[11] and **C. E. Pugliese**[1], (1)Children's National Medical Center, Rockville, MD, (2)Children's Research Institute, Children's National Medical Center, Rockville, MD, (3)The George Washington University, Washington, DC, (4)The Center for Autism Research, Philadelphia, PA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)Virginia Polytechnic Institute and State University, Blacksburg, VA, (7)Children's National Medical Center, Arlington, VA, (8)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (9)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (10)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (11)NIMH, Bethesda, MD*

Background: There has been increased interest in possible differences in symptomatology in females with ASD without ID as compared to males (Van Wijngaarden-Cremers et al., 2014). Traditionally, females with ID were thought to be more severely affected than males. Current research questions whether this is a true discrepancy or a methodological manifestation of mis- or under-diagnosis in females with ASD without ID (Halladay et al., 2015). The algorithm for the ADOS Module 4, appropriate for verbally fluent adolescents and adults, has been recently updated (Hus & Lord, 2014), though gender differences in the algorithm and items have not yet been explored.
Objectives: The purpose of this study was to investigate gender differences in core symptoms of ASD on gold-standard diagnostic measures via parent interview, parent report, and clinician observation.
Methods:
Participants included 255 individuals (n=53 females) across four research-reliable sites with a confirmed ASD diagnosis, ages 11-61 years, with either a full-scale (M=107.23, SD=17.71) or verbal (M=109.14, SD=17.93) IQ>70. There were no significant gender differences in age or full-scale or verbal IQ. All participants were assessed using Module 4 the Autism Diagnostic Observation Schedule (ADOS; Lord, Rutter, DiLavore, & Risi, 2002) or its recent revision the ADOS-2 (Lord et al., 2012). A subsample received the Autism Diagnostic Interview-Revised (ADI-R; Rutter, Le Couteur, & Lord, 2003) (n=33 females, n=157 males) and the Social Responsiveness Scale (SRS/SRS-2; Constantino & Gruber, 2004; Constantino & Gruber, 2012) (n=33 females, n=144 males).
Results:
There were no significant gender differences on any ADI-R subscales, but females scored significantly higher than males on the SRS total score (t= -2. 39, p<.01). On the ADOS, there was a trend towards males being rated as more impaired on the updated algorithm (t= 1.92, p=.06). Chi-square analyses were used to examine differences on individual items on the ADOS. Ratings of "3" were converted to "2" and ratings of "7/8" were converted to "0." Males were rated as significantly more impaired on the following items: "Stereotyped/Idiosyncratic Use of Words of Phrases" (χ^2=9.37, p<.01), "Descriptive, Conventional, Instrumental or Informational Gestures" (χ^2=7.12, p<.05), "Communication of Own Affect" (χ^2=8.51, p<.01), and "Empathy" (χ^2=9.40, p<.01).
Conclusions:
Historical parent report of ASD symptoms via the ADI-R did not reveal gender differences in the present sample. However, parents rated concurrent ASD symptoms on the SRS as more impaired in females than males. Males and females performed similarly on the majority of ADOS items though males were rated as having more severe ASD symptoms in several social communication skills, including two items on the newly proposed ADOS algorithm. Findings from this study indicate that although females look the same as (or better than) males on a few key symptoms on gold standard diagnostic measures, parents observe more social problems in the real world. This may be due to our societal expectations of greater social skills from cognitively able females or because our diagnostic tools are built for and standardized on a majority male population

and may not adequately capture ASD in females.

Panel Session
140 - Perspectives on Pain in ASD: Perception, Physiology, and Behavior
10:30 AM - 12:30 PM - Room 309

Panel Chair: Michelle Failla, *Vanderbilt University, Nashville, TN*

Discussant: Carissa Cascio, *Vanderbilt University School of Medicine, Nashville, TN*

Despite the common assumption that individuals with ASD are less sensitive to pain, empirical evidence is scarce and inconsistent. This panel will explore the available evidence, beginning with a systematic review of clinical behavioral studies suggesting that measurement approaches (e.g., facial affect, pain ratings, parent/self-report) heavily influence the presence and direction of reported differences in pain perception in individuals with ASD. This will be followed by three presentations that represent a range of these approaches, including clinical/caregiver report, psychophysics, functional neuroimaging, peripheral biopsy, and facial affect coding. The relation between pain and self-injurious behavior in ASD will be considered, and a summary discussion will synthesize the work presented with animal model and pharmacological perspectives. The goal of this panel is to provide an overview of available evidence for a severely under-studied aspect of sensory atypicality in ASD, and to encourage collaborative efforts integrating several of these approaches within the same population to clarify the emerging story of differences in pain perception in ASD. Given the potential for communication deficits to mask altered pain perception in verbal or nonverbal measures, creative approaches to understanding pain perception and processing are highly important for improving quality of life for individuals with ASD.

10:30 **140.001** An Overview of Pain in Autism: Investigating Differences in Sensation, Feeling and Behaviours

***D. J. Moore**, Natural Sciences and Psychology, Liverpool John Moores University, Liverpool, United Kingdom*

Background: In contrast to the well-known and extensively studied social communication challenges that characterize ASD, sensory atypicalities, which are also included in the core diagnostic criteria, are not well understood. In DSM-V criteria insensitivity to pain is cited as an example of these sensory atypicalities, however there is limited research evidence or consideration of what aspects of pain perception are measurable in this population.
Objectives: In a systematic review, a comprehensive search was utilized to identify research articles addressing the topic of pain in ASD.
Methods: Studies were identified using a range of relevant search terms including '(pain OR noxious OR nociception OR nociceptive OR C-fibers) & (Autism OR Asperger syndrome OR ASD OR Autistic)', in addition, hand searches from relevant journals, screening the reference sections of articles considered, and consultation from other experts in the field. Articles were eligible for inclusion if they included a well-defined sample of individuals with ASD, were written in English, and included a quantifiable measure of pain response or perception. Included articles used a variety of methods to assess pain sensitivity, including self-report, observations of behavioural changes in response to pain, and response to experimental pain models.
Results: The findings of the review show that both self/parent report and clinical observations appeared to report hyposensitivity to pain, whereas observations of medical procedures and experimental manipulation suggested normal or hypersensitive responses to pain.
Conclusions: The current state of the research leaves a large number of questions unanswered and fails to consider the reasons for or implications of altered pain perception in ASD. This introductory talk and the symposium at large will begin to address these core concerns. Further, in consideration of these limitations, we will also report preliminary data from our lab, which systematically considers response to a range of experimental pain models and motivational aspects of pain in individuals with ASD.

10:55 **140.002** Decreased Thermal Sensitivity in Adolescents with Autism Spectrum Disorder

***E. G. Duerden**[1], M. J. Taylor[2], M. Lee[3], P. A. McGrath[4], K. D. Davis[5] and W. Roberts[6], (1)The Hospital for Sick Children, Toronto, ON, Canada, (2)Diagnostic Imaging, The Hospital for Sick Children, Toronto, ON, Canada, (3)Hospital for Sick Children, Toronto, ON, Canada, (4)Pain Innovations Inc., London, ON, Canada, (5)Toronto Western Research Institute, University Health Network, Toronto, ON, Canada, (6)University of Toronto, toronto, ON, Canada*

Background: Autism spectrum disorder (ASD) is characterised by a range of behavioural, communication and social difficulties, as well as sensory abnormalities. While much research and clinical attention has focused on communication and socialization deficits, relatively less research has focused on sensory abnormalities, particularly altered pain reactivity, which may contribute to children's withdrawal behaviours and corresponding psychosocial difficulties.
Objectives: To assess sensitivity to thermal (cool, warm, heat pain, cold pain) stimuli in adolescents with ASD.
Methods: 20 adolescents with ASD (15 boys, mean age=14.6, SD=1.9, IQ > 70) and 55 typically-developing adolescents (27 boys, mean age=15.7, SD=1.1) were recruited for the study. Warm and cool detection thresholds (WDT and CDT) and heat and cold pain threshold (HPT and CPT) levels were assessed using a method-of-limits quantitative sensory testing protocol.
Results: Adolescents with ASD demonstrated reduced sensory function for thermal detection ($p<0.001$, both WDT and CDT), but not pain thresholds ($p<0.05$, both HPT and CPT) in comparison to controls, with no evidence for significant age or sex effects ($p>0.05$). Loss of warm and cool detection and heat pain threshold was significantly associated with impaired cognitive ability and autism symptom severity ($p<0.05$).
Conclusions: The association between thermal sensitivity and cognitive impairments and may reflect alterations in central processing of somatosensation, cognition and salience detection in adolescents with ASD. Further research using neuroimaging methods is needed to assess the neural underpinnings of thermal perceptual deficits in adolescents with ASD.

11:20 **140.003** Temporally Distinct Neural Responses to Pain in ASD: Evidence for Altered Cognitive Pain Modulation and Relationships to Self-Injurious Behaviors

***M. D. Failla**[1], E. J. Moana-Filho[2], G. K. Essick[3], G. T. Baranek[4], B. P. Rogers[1] and C. J. Cascio[5], (1)Vanderbilt University, Nashville, TN, (2)School of Dentistry, University of Minnesota, Minneapolis, MN, (3)School of Dentistry, University of North Carolina, Chapel Hill, NC, (4)UNC Chapel Hill, Chapel Hill, NC, (5)Vanderbilt University School of Medicine, Nashville, TN*

Background: There is a prevalent assumption that individuals with autism spectrum disorders (ASD) are less sensitive to pain. Yet, this assertion is not well supported by empirical evidence. Importantly, communication deficits make assessing pain through verbal reports particularly challenging in ASD. Objective markers of pain, such as neural responses obtained with neuroimaging, have been suggested as a means of clarifying the pain experience in vulnerable populations. Previous work has identified a neural pain signature (somatosensory cortices, insula, anterior cingulate) using functional magnetic resonance imaging (fMRI) that differentiates pain from innocuous stimulation.
Objectives: The goal of this study was to determine whether the temporal or spatial properties of the neural pain signature differ in individuals with ASD, and if so, what possible modulators outside the identified neural pain signature contribute to these differences. We also sought to explore whether differences in the signature relate to self-injurious behaviors that are thought to arise from aberrant pain processing in ASD.
Methods: Participants included 16 adults with ASD and 16 adults without ASD in a typical comparison group. Self-injurious behaviors were assessed with the Repetitive Behavior Scale-Revised; participants with ASD were categorized by presence or absence of self-injurious behaviors. Neural response to sustained heat pain was assessed with fMRI using a block design. For each trial, heat was applied to the right lateral calf for 21 seconds (15 seconds at target temperature, 3 second ramp up/down) followed by 39 seconds rest period.
Results: The two groups had similar pain ratings and pain thresholds, in addition to similar neural pain signature responses during acute pain. Yet, there was a highly exaggerated suppression of the neural pain signature in ASD during intermediate and late phases of sustained pain ($Z>2.3$, $p<0.001$, corrected). Direct group contrasts revealed greater response in the typical comparison group compared to ASD in dorsolateral prefrontal cortex and posterior cingulate regions during intermediate and late phases. Additionally, this widespread, late suppression of the neural pain signature in ASD was more prominent in the subgroup of individuals with self-injurious behaviors.
Conclusions: Late suppression of the neural pain signature may indicate aberrant pain processing in ASD associated with self-injurious behavior. Altered activity in areas thought to modulate the pain experience (dorsolateral prefrontal cortex and posterior cingulate) suggests a wider potential selection of coping strategies available to the typical comparison group than the ASD group during sustained pain. The contrast between equivalent pain ratings and striking differences in the neural pain response suggests individuals with ASD may have an altered experience of pain that is not reflected in their subjective pain ratings. Future studies will need examine functional connectivity within the neural pain signature in ASD and in connection with modulating regions in order to understand the mechanism of this altered processing.

11:45 **140.004** Severe Self-Injury in Persons with Autism and Related Neurodevelopmental Disorders: Differences in Sensory, Autonomic, and Immune Markers Suggest Hyperalgesia

***J. W. Bodfish**[1], M. Garrett[2], G. Wendelschafer-Crabb[3], W. Kennedy[3] and F. J. Symons[3], (1)Vanderbilt University School of Medicine, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)University of Minnesota, Minneapolis, MN*

Background: Self-injurious behavior (SIB) is a costly and treatment resistant form of repetitive behavior seen in the context of neurodevelopmental disorders such as autism. Physiological mechanisms regulating SIB have been understudied. Conventional wisdom surrounding self-injurious behavior is that persons who engage in SIB are

insensitive to pain; however, studies directly examining sensory function and relevant biomarkers are needed.
Objectives: We provide a survey of a series of studies that we have conducted designed to test this pain insensitivity hypothesis of SIB.
Methods: 81 consecutively recruited cases with a clinical diagnosis of ASD were evaluated using research diagnostic criteria for ASD (ADOS, ADIR, & expert clinical opinion), and were then subgrouped based on nonverbal IQ (> 90; < 70) resulting in samples of n = 30 cases with ASD + cognitive impairment (ASD+ID), n = 41 cases with ASD and no cognitive impairment (ASD-only), and 10 excluded cases. Cases were evaluated for the presence and severity of SIB using a mulitmethod phenotypic battery that included a set of SIB measures (RBSR, Clinical Interview for Repetitive Behaviors, YBOCS, observational coding of repetitive behaviors). In a sample of 34 cases with severe SIB (occurred at least daily, persisted at least 12 months, was the focus of active intervention) and 17 non-SIB cases matched on age and IQ, measures from quantitative sensory testing (heat, cold, pin prick, deep pressure), saliva samples (cortisol, alpha amylase), and 3mm epidermal punch biopsies taken from non-SIB sites (ENF density/morphology, neuropeptide content, mast cell degranulation) were analyzed.
Results: SIB occurred in ASD+ID (63%) and ASD-only (24%) subgroups, but severity was significantly greater in the ASD+ID subgroup ($p = .002$), and only occurred frequently during sampled direct observations in the ASD+ID subgroup. Analysis of a separate severe SIB subsample compared to matched ID controls indicated: (1) that cases with chronic SIB were characterized by increased behavioral markers of sensory reactivity during quantitative sensory testing (facial action coding of pain signs - sham trials < sensation trials [$p < .05$] SIB > non SIB [$p < .03$], (2) that sensory reactivity (magnitude of facial action units in response to sensation trials) was correlated with ENF innervation [$r = 0.47$, $P < .001$], (3) that substance P (SP) positive fiber counts tended to be greater in SIB cases, and (4) that peripheral innervation of epidermal nerve fibers in SIB cases was marked by differences in nerve morphology (density, distribution) and increased evidence of altered immune system activity in the form of degranulated mast cells [$p < .01$].
Conclusions: Taken together, our work suggests that at least a subgroup of individuals with chronic repetitive SIB may be in a physiological state similar to neuropathic pain / hyperalgesia associated with alterations in inflammatory, immune, and nociceptive systems. If so, this may provide a set of accessible, objective biomarkers of altered sensory function that may help identify the need for treatment and perhaps also mark the course of treatment response in this vulnerable but under-researched subgroup.

Panel Session
141 - But It Worked so Well in the Lab! Measuring Implementation of Evidence-Based Practices for Children with Autism in Community Settings

10:30 AM - 12:30 PM - Room 310

Panel Chair: Jill Locke, *University of Washington Autism Center, Seattle, WA*

Discussant: David Mandell, *University of Pennsylvania School of Medicine, Philadelphia, PA*

Implementation science comprises the study of methods to understand factors associated with successful integration of evidence-based interventions into community practice. There is evidence suggesting that it takes an average of 17 years for autism evidence-based interventions (EBI) to enter community practice settings. EBIs for children with autism often include complex and resource-intensive strategies that address different clinical outcomes that must fit with the resources and mission of the organizations in which they are implemented, and with the training and abilities of the practitioners using them. Research on use of EBIs in community settings must focus on implementation outcomes. These include the extent to which EBIs are: 1) implemented in the way they were designed (fidelity); 2) integrated within a service system (penetration); and 3) sustained once initial implementation efforts end (sustainment). We will present data from a: 1) randomized school-based implementation trial of a social engagement EBI for children with autism; 2) randomized school-based effectiveness trial of autism behavioral EBIs in public schools; 3) large-scale effectiveness trial of an autism behavioral EBI in publicly-funded mental health agencies; and 4) prospective, observational study of multiple EBIs implemented in a large-scale mental health system reform in which children with autism were served.

10:30 **141.001** A Little Goes a Long Way: A Randomized Controlled Implementation Trial of a Social Engagement Intervention for Children with Autism Spectrum Disorder in Public Schools

J. J. Locke[1], *W. I. Shih*[2], *J. Caramanico*[3], *C. Oh*[3] *and D. S. Mandell*[4], *(1)University of Washington Autism Center, Seattle, WA, (2)UCLA, Monrovia, CA, (3)University of Pennsylvania, Philadelphia, PA, (4)University of Pennsylvania School of Medicine, Philadelphia, PA*

Background: Children with autism have poorer social inclusion than do their classmates throughout elementary school. While several interventions have been developed and tested to address this challenge, few evidence-based social engagement interventions for children with autism are successfully implemented in schools. This disconnect may occur because these interventions are not feasible to implement in many public schools. To address this challenge, we partnered with public school personnel to adapt existing social inclusion interventions to increase their feasibility and acceptability, and to develop a set of implementation strategies that can support school personnel in using the intervention.
Objectives: To examine the implementation, child outcomes and sustainment of an evidence-based social engagement intervention for children with autism in public schools.
Methods: Thirty-one elementary-aged children with autism (87% male; mean age=8.8 (SD=2.0) years; 48% white) and 28 school personnel (86% female, mean age=39.5 years; 61% white) from 12 public schools in five districts participated. A stepped-wedge randomized controlled design was used in which data were taken at baseline, second baseline, exit and follow-up. Schools were randomized to: 1) training in Remaking Recess, a social engagement intervention for children with autism; or 2) training in Remaking Recess plus implementation support. Intervention implementation occurred during recess (30-45 minutes) for 12 sessions over six weeks. Implementation support was provided to school administrators three times over 12 weeks and entailed consultation in implementation strategies. School personnel rated their attitudes about evidence-based practices, acceptability, and implementation climate at exit. Children completed sociometric ratings while blind observers recorded playground peer engagement and implementation fidelity at each time point.
Results: There were no significant differences in attitudes about evidence-based practices, acceptability, or implementation climate between school personnel in either condition. Fidelity of implementation was low in both conditions. On average, school personnel in both conditions improved in some components of Remaking Recess (assessment ($p=.02$), set up ($p=.045$), accuracy ($p<.001$), and understanding ($p<.001$)) but not others (transition, participation and feasibility). There were no significant differences in the rate of improvement between the two groups of school personnel from entry to exit. Multilevel models where time was nested within children and children were nested within schools were used to test differences in social outcomes between schools that were randomized to Remaking Recess or Remaking Recess plus implementation support. There was a significant main effect of time for solitary ($p<.001$) and joint engagement ($p<.001$), where children in both conditions spent significantly less time in solitary engagement and more time in joint engagement after the intervention and at follow-up. There was a significant time by condition interaction ($p=.01$) where children with autism in the Remaking Recess plus implementation support condition had significantly more improvement in social network salience than in the Remaking Recess alone condition after the intervention ($p=.002$) and at follow-up ($p=.05$).
Conclusions: These data suggest that implementing some components of an evidence-based intervention with fidelity may lead to improved child outcomes; however, organizational-level implementation support may be necessary to improve child outcomes in public school settings.

10:55 **141.002** Scaling up Fidelity Measurement of Autism Interventions in Schools

M. Pellecchia[1], *M. Seidman*[1] *and D. S. Mandell*[2], *(1)University of Pennsylvania, Philadelphia, PA, (2)University of Pennsylvania School of Medicine, Philadelphia, PA*

Background: Most evidence-based interventions for children with autism were developed in highly controlled laboratory settings, as were the fidelity measures that accompany them. A growing body of research describes the importance of determining the best ways to scale up evidence-based practices in communities so that they are effective and sustain; less attention has been paid to the challenges and opportunities in measuring intervention fidelity on a large scale. Inexpensive, regular fidelity measurement is an important component of any effort to test intervention effectiveness or to engage in quality improvement and assurance efforts
Objectives: To present scalable strategies to measure common components of behavioral interventions for children with autism; describe direct observation fidelity measures used to assess implementation fidelity on a large scale, and; discuss methods to improve fidelity measurement and barriers to measuring implementation fidelity in real-world settings.
Methods: Direct observation fidelity measures were developed to assess the implementation fidelity to common components of comprehensive behavioral treatment packages for children with autism (discrete trial training, pivotal response training, visual schedules, positive reinforcement, and data collection) within a large community-based randomized trial. Implementation fidelity of each behavioral component was measured by direct observation bimonthly in 73 classrooms for an academic year by trained research assistants. Observers were trained to 90% reliability with a master coder, with continued field-based reliability checks throughout the year. Inter-rater reliability data also was collected at least 3 times throughout the year for each observer as an additional validity check.
Results: Data collection and analyses are ongoing. Research assistants achieved and maintained reliability estimates of at least 90%, following a brief half-day training and practice with coding videos. Qualitative comparisons with more intensive fidelity measures indicate that reliability was achieved faster using these measures. Field-based direct observation fidelity measurement for each component was conducted quickly, using a brief 10-minute sample of the targeted intervention, with high rates of validity.
Conclusions: Preliminary data indicate that implementation fidelity for complex behavioral interventions can be measured accurately in natural settings using inexpensive and brief measures, and that it is relatively easy to train novice staff on these data collection procedures. Accurate field-based fidelity measurement is a critical step for measuring the effectiveness and sustainability of evidence-based interventions delivered within community-based settings. The procedures described offer a model for accurately measuring intervention fidelity in large scale that can be replicated for use in other large-scale community-based implementation trials.

11:20 **141.003** Training Mental Health Providers to Deliver Evidence Based Interventions for Autism Spectrum Disorders (ASD): Training Predictors and Outcomes

C. Chlebowski *and L. Brookman-Frazee, Autism Discovery Institute at Rady Children's Hospital – San Diego, San Diego, CA*

Background: Publicly-funded mental health (MH) services play an important role in caring for school-age children with ASD. Previous research indicates that therapists providing routine MH service have limited ASD training and do not deliver strategies consistent with evidence-based (EB) interventions. To address this gap, the AIM HI ("An Individualized Mental Health Intervention for ASD") clinical intervention and corresponding therapist-training model were developed. AIM HI is a package of EB behavioral strategies targeting challenging behaviors in children with ASD designed specifically for the mental health services context for delivery by providers who do not specialize in ASD. The training model consists of an introductory workshop, 6 months of structured consultation with an expert trainer with performance feedback. It is currently being tested in a large-scale effectiveness/implementation trial in publicly funded community and school-based MH programs in two large counties in Southern California. Examining the process and outcomes of training community providers is a key aim of this large-scale study. Understanding factors associated with successful training is essential to inform community implementation efforts.
Objectives: This presentation will report preliminary data on therapist training outcomes and factors associated with these outcomes from community providers participating in the AIM HI training condition of the ongoing community effectiveness/implementation study.
Methods: Participants include the first 122 therapists enrolled in the training condition of the AIM HI trial. Multiple methods, measures and informants were used to assess training outcomes: *Training Completion* measures included consultation attendance and whether the therapist met eligibility for AIM HI certification. *Protocol Adherence* was measured by a Trainer-Rated Treatment Planning rating. *Session Fidelity* was measured by Observed In-Session Fidelity (rated by observers blind to the training condition). The Evidence-Based Practice Attitudes Scale (EBPAS) was used to measure therapist attitudes towards EB practices.
Results: *Training Completion* was high with 100% of therapists attending the introductory workshop. Therapists attended an average of 9.55 of the 11 consultations (*SD* = 2.98; Range: 0-11). Seventy-four percent of enrolled therapists received AIM HI certification after the 6 month training period. *Protocol Adherence* was high with the average Treatment Planning Fidelity score of 25.99 (*SD*=4.77; Range: 0-29). Sixty percent of therapists with complete observational coding data had *Session Fidelity* scores (averaged across the training period) in the acceptable range. Therapist baseline attitudes towards EBPs were associated with consultation attendance, Treatment Planning Fidelity, and Session Fidelity scores. The impact of previous training in different types of manualized intervention strategies on AIM HI training outcomes will be reported.
Conclusions: Preliminary data indicate that training MH providers to implement an ASD intervention is feasible; however, provider attitudes and previous experiences with EB approaches impact training success. These findings are especially relevant for an ASD population due to their complex and heterogeneous needs and the limited ASD experience of community MH providers. Future work is needed to refine training and implementation interventions to further increase the impact of implementing EB interventions in community settings.

11:45 **141.004** Service Use Patterns of Youth with Autism Spectrum Disorder within a Large-Scale Implementation of Evidence-Based Practices Fiscally Mandated in Children's Mental Health Services

N. Stadnick[1,2]*, A. Lau*[3] *and L. Brookman-Frazee*[2,4]*, (1)Psychiatry, University of California, San Diego, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)Psychology, University of California, Los Angeles, Los Angeles, CA, (4)Autism Discovery Institute at Rady Children's Hospital – San Diego, San Diego, CA*

Background: Children with autism spectrum disorder (ASD) receive care in multiple public service systems (Brookman-Frazee et al., 2009). The mental health (MH) service system plays an important role in caring for children with ASD (Mandell et al., 2005) given that the estimated rates of psychiatric comorbidity for youth with ASD are greater than 70% (Leyfer et al., 2006; Simonoff et al., 2008). There are a growing number of large-scale, system-driven implementations of evidence-based practices (EBPs) in publicly-funded MH systems for children but little is known about the specific types of services and intervention practices delivered to youth with ASD receiving MH care within these implementation efforts.
Objectives: To address this gap, this study examined MH service penetration and sustainment patterns of children and transition-aged youth with ASD receiving care in the largest public MH system in the United States within the context of a fiscally-mandated implementation effort of multiple EBPs.
Methods: In 2009, the Los Angeles County Department of MH (LACDMH) launched the Prevention and Early Intervention Transformation. Within this system reform, multiple EBPs were mandated through reimbursement reorganization, with initial implementation support (e.g., costs for therapist training) provided for six practices (Child Parent Psychotherapy [CPP], Cognitive Behavioral Intervention for Trauma in Schools [CBITS], Managing and Adapting Practice [MAP], Seeking Safety [SS], Trauma Focused Cognitive Behavioral Therapy [TFCBT], and Triple P) that address a range of child MH problems. Administrative claims data from LACDMH for these six practices from fiscal years 2009/2010 – 2014/2015 were extracted. Data from over three million claims for 87,100 clients from 94 agencies were used to characterize service utilization patterns for a subset of youth with ASD receiving specific practices.
Results: Preliminary analyses indicate that the total number of MH claims billed for youth with a primary ASD diagnosis was 12,690 from initial implementation to the current time of early sustainment. These claims represent 680 unique providers who delivered services to 499 unique children (76% male; *M* = 8.25 years, *SD* = 4.38). The majority of claims (75%) were for psychotherapy, followed by evaluation and assessment (13%), medication management (6%), and case management (6%). At the child-level, 40% of total claims were for Triple P followed by MAP (31%), CPP (11%), TFCBT (11%), SS (6%), and CBITS (<1%). Children with ASD in this sample were ethnically and culturally diverse (65% reported as Latino and 34% whose primary language was Spanish). A matched case-control design will be used to compare penetration and sustainment patterns between youth with ASD and those with non-ASD diagnoses to inform potentially unique implementation considerations for children with ASD. Children will be matched on sociodemographic and service context (e.g., provider type, setting type) characteristics.
Conclusions: This study is one of the first to use administrative claims data to characterize penetration and sustainment patterns of MH services for youth with ASD served within a large-scale system driven EBP implementation. Study findings provide direction on targeted implementation efforts to evaluate MH services delivered to children with ASD within a public MH system care reform.

Poster Session
142 - Innovative Technology Demonstrations
10:00 AM - 1:30 PM - Hall A

225 **142.225** Using Tablet-Based Gameplay for the Identification of Autism-Related Movement Patterns

A. Anzulewicz[1]*, D. Czajak*[2]*, J. T. Delafield-Butt*[3]*, P. Jarmolkowicz*[2]*, M. Mnich*[2]*, A. W. Paciorek*[4]*, K. Sobota*[2] *and D. A. Zaremba*[2,3,5]*, (1)Psychology, Jagiellonian University, Krakow, Poland, (2)Harimata, Krakow, Poland, (3)University of Strathclyde, Glasgow, United Kingdom, (4)Institute of Modern Languages, Pedagogical University of Krakow, Krakow, Poland, (5)Jagiellonian University, Krakow, Poland*

Background:
We would like to demonstrate a solution which automatically assesses the risk that a child might have ASD, by analyzing movements using smart gameplay. Disruption of normal movement patterns is a cardinal feature of ASD, however, it has recently been proposed that abnormalities in the development of intentional movements, including prospective planning and execution of movements, can be considered as one of the early markers of ASD. Crucially, such deficiencies can be observed before manifestations of syndromes typically associated with autism, *i.e.,* deficiencies in social interaction or reading emotions (Trevarthen and Delafield-Butt, 2013). Modern technology provides unprecedented access to motor information about the user. Inertial motion sensors coupled with gyroscopes and magnetometers have been miniaturised and integrated into consumer microelectronics such as smart phones, tablets, and wearable devices, opening new possibilities for their application in autism research and diagnosis.
Objectives:
To assess whether children with ASD can be distinguished from typically developing ones, and those with other developmental disorders on the basis of movement analysis conducted during a smart device gameplay
Methods:
Participants: 46 children with ASD, 20 with other developmental disorders (*i.e.*,. Down Syndrome, intellectual impairment, aphasia) and 369 typically developing children. The sample size of the control group was significantly larger than the experimental group to reflect the population structure, thus allowing precise calibration of the computer learning algorithms used for the data analysis.
Two mobile game-like applications for children aged 2-5 were used. In the first, a child's goal was to share a piece of food and distribute it evenly among four children depicted on the screen. In the second game, a child's task was to outline a shape (*e.g.* a squirrel or a snail) and fill it with colour. The materials were designed in collaboration with developmental psychologists. There was a 2-minute training and a 5-minute test session for each application. During the gameplay, touch data and data from tablet's sensors (gyroscope and accelerometer) were collected.
Results:
Data were analyzed by means of computer learning algorithms. 10-fold cross validation technique was used to ensure the models would not be prone to overfitting. Movement patterns of children with ASD and typically developing children were investigated by means of Random Greedy Forest (RGF) algorithm. Area under the receiver operating characteristic curve (AUC) was selected to be the metric, as it does not require a fixed classification threshold. The results demonstrated that AUC was relatively

high in case of both applications. The algorithms performed with 72% sensitivity and 88% specificity for differentiation of ASD from typically developing children. To assess whether the models successfully differentiate children with ASD from those with other developmental disorders simple models, namely, SVM and logistic regression were used because the latter group was relatively small (N=20). The models achieved 65% specificity and 79% sensitivity, suggesting that it is possible to differentiate ASD from other disorders.
Conclusions:
We provide evidence that ASD has a prominent motor component that can be identified by smart device gameplay, which should be taken into account in early assessment.

226 **142.226** The Effects of Video-Modeling on the Oral Hygiene of Children with Autism: A Promising Paradigm

M. Mademtzi[1], *B. Popple*[2], *C. A. Wall*[1], *L. Flink*[3], *J. Dikansky*[4], *D. Do*[4] *and F. Shic*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)White Oak Pediatric Dentistry, Newnan, GA, (3)Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, (4)Yale New Haven Hospital, New Haven, CT*

Background: Oral health is important for a person's general health as well as psychological wellbeing. However, individuals with autism often face difficulties with their self-care skills and therefore there is a need for improved dental hygiene routines for these individuals (Pilebro & Backman, 2005). One promising method to achieve this is through the use of video-modeling. Video-modeling is an evidence-based intervention that has various areas of application including self-care skills (e.g. Charlop-Christy, Le & Freedman, 2000; McLay, Carnett, van der Meer & Lang, 2015).

Objectives: The objective of this study was to investigate whether video-modeling can be an effective method for children with autism to learn how to brush their teeth.

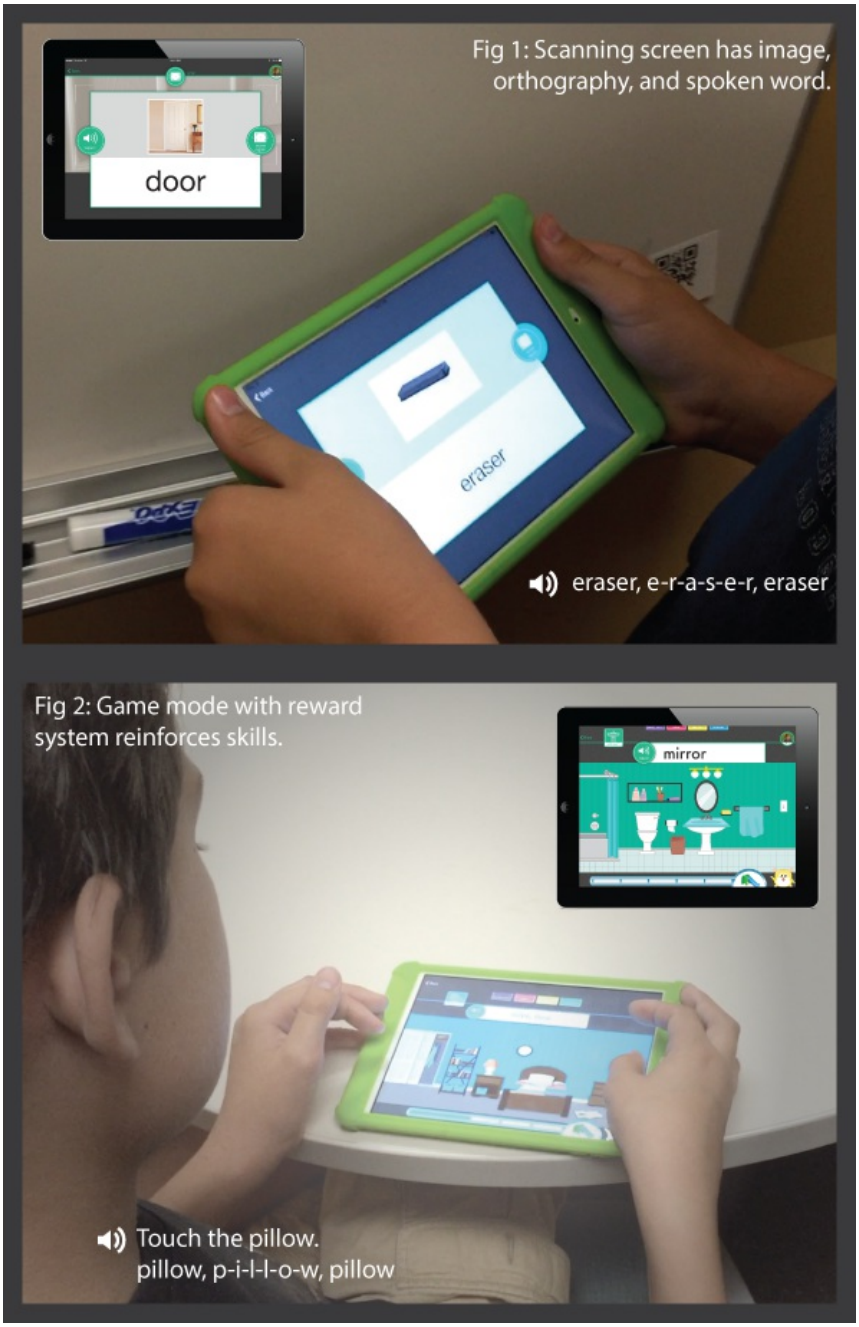
Methods: A pilot study was conducted with eight children diagnosed with autism recruited from a pediatric dental clinic (Mage= 8.75 years). Assessments included clinical examinations and survey data completed by the children's caregivers. Additionally, the Social Responsiveness Scale-2, Parent Report (SRS-2; Constantino & Gruber, 2002) was also completed. Participants were randomly assigned to either the experimental (N=4; 3 boys and 1 girl) or control (N=4; 2 boys and 2 girls) group. Parents received a link twice a day for three weeks prompting them to watch a video with their child before tooth brushing. The experimental group watched a video of a girl brushing her teeth with spoken instructions and the control group watched a video with moving fractal shapes and with symbolic background music (demo).
Results: Before the intervention both groups had visible plaque and did not differ in dental hygiene as measured by plaque index results (Cohen's d= 0.14). After the intervention the experimental group showed greater improvements in the same measures compared to the control group (Cohen's d= 1.17). The survey data completed by the children's parents revealed a significant increase of oral hygiene for the control group (Cohen's d= 2) but no differences for the experimental group (Cohen's d= 0). Also, low correlation was found between autism severity and SRS-2 scores with plaque index results (r=0.22 and r=0.11 respectively).

Conclusions: Although this study was conducted with a small number of participants, it holds a great potential for future applications on children's with autism oral hygiene. Future directions should include larger sample sizes, greater selection of videos (e.g. different languages, gender of the children actors) and also participants with various cognitive skills levels. The current study involved higher functioning children with autism that they might not deal with the same self-care skills difficulties as lower functioning ones. Results from the current study will help us inform the next steps of the video-modeling for oral hygiene. Our aim is to make the videos applicable to a larger number of participants, with different cognitive and cultural backgrounds and also make them more easily accessible by caregivers, practitioners and individuals with autism themselves. A prototype of this new system will be presented.

227 **142.227** Development of a Mobile Application for Early Literacy and Language Intervention in Children with Autism Spectrum Disorder

N. J. Rasche[1] *and O. Wendt*[2], *(1)Computer Graphics Technology, Purdue University, West Lafayette, IN, (2)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN*

Background: Children with autism spectrum disorders (ASD) exhibit deficits in both expressive and receptive language development. Substantial delays in literacy skills, specifically comprehension abilities, are influenced by these deficits. These children struggle with reading for meaning and lack the ability to comprehend text (Randi, 2010). Identification of letters and recognition of sight words are inconsistent. An intervention strategy to improve comprehension must put "an emphasis on their ability to understand language as well as working on their expressive language and communication skills" (Weismer, 2010). One possible intervention approach is multi-skill language instruction using a visual representation of an object with the orthography while teaching expressive communication. In order to assess this type of intervention and test its validity as a tool to improve early language and literacy, a mobile application was developed.
Objectives: The objective was to design a mobile application that will target the delay in literacy skills, specifically comprehension, by teaching expressive and receptive language together. The goals for the application are listed below.
1) Use the early literacy skill of labeling to teach receptive and expressive language skills while monitoring any improvement in learning the meaning of new words. A prototype was piloted in a university speech and language clinic with a 13-year-old participant with severe-moderate autism and minimal speech.
2) Utilize the mobile application to provide opportunities for repetition of learned skills and the customizable settings to accommodate user needs. During formative evaluations, we evaluated the usability of the game modes and tested the customization of the user defined settings.
Methods: An innovative mobile application, Literacy LABELS©, was created on the iOS platform that utilizes QR code technology. The application scans the QR codes on the printed labels that are placed on actual physical objects (Fig 1). New labels can be created within the application to customize the intervention for the participant's needs. The application has games that provide repetition of skills learned during the scanning of the physical labels (Fig 2). A more elaborated single case, A-B design study is underway replicated across three children who have severe-moderate autism to measure the identification of previously unknown words before and after intervention. Maintenance data will be collected on the retention of word identification skills. As an ancillary measure, we will document oral ability to attempt spelling and/or speaking newly learned words. This will produce empirical evidence documenting the benefits of intervention with Literacy LABELS©.
Results: Preliminary results from the formative evaluation suggest that the application has positive effects on receptive and expressive language development. Initial feedback from parents and clinicians has been favorable praising the ease of customization to learner needs and the engaging and motivating nature of the game-play mode. Further development of this technology will make an early literacy curriculum more accessible to students impacted by ASD and resulting language delays.
Conclusions: N/A

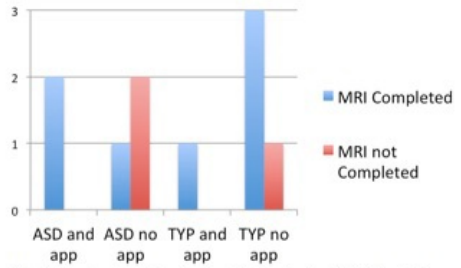


228 **142.228** Using an Ipad Application to Prepare Children with ASD for Research MRI

N. L. Johnson[1], *N. Salowitz*[2], *M. Van Abel*[3], *A. V. Van Hecke*[3], *S. I. Ahamed*[3] *and R. A. Scheidt*[4], *(1)College of Nursing, Marquette University, New Berlin, WI, (2)Marquette University, Franklin, WI, (3)Marquette University, Milwaukee, WI, (4)Marquette Univeristy, Milwaukee, WI*

Background:
Undergoing an MRI for a research study can be stressful for children with ASD and their parents. Many children have trouble staying still in the scanner due to the overwhelming sensory experience, including noise. There is limited research on technology to prepare children for the new experience of research study MRIs in order to decrease their stress and gain their compliance. Our past research found that ill children with ASD and their parent had less anxiety (than the control group that received typical care) and challenging behaviors and better compliance with diagnostic imaging when they were prepared with an iPad application (app) that foreshadowed the imaging process and appropriate behavior.
Objectives:
(1) To assess the experience of undergoing research study MRI for a child with ASD or a typically developing child (TYP) and an accompanying parent.
(2) To evaluate the feasibility, efficacy and acceptability of the 'Going to MRI for a Research Study' iPad app consisting of research task, mock scanner and MRI photographs and audio recording.
Methods:
We recruited 10 English-speaking parent/child dyads [(n=5 male children with ASD) (aged 14.8 ± 1.2 years)] and n=5 TYP [(4 male, 1 female) (aged 14.2 ± 3.2 years)] who were offered the option of using the app before the MRI in an interdisciplinary study on neural correlates of goal directed movement. Diagnosis of ASD or TYP was confirmed by the Autism Spectrum Screening Scale, and the Autism Diagnostic Observation Schedule, along with normal or corrected normal vision, and Intelligence Quotient > 70. Frequencies were calculated for app use and MRI completion rates and demographics were collected to describe the sample. Qualitative data were collected by individual, one-time, question guide facilitated, audiotaped telephone interviews. Audiotapes were transcribed into a Word document. Two researchers discerned themes via an iterative process, guided by the Family Self Management Theory, for participant experience with the research MRI, and the feasibility, efficacy and acceptability of the app for those that chose to use it.
Results:
Seven of the 10 children (70%) completed the MRI (n=2 ASD with app; n=1 no app but prior MRI experience; n=1 TYP with app; n=3 TYP no app). Three children (30%) did not complete the MRI (n=2 ASD no app; n=1 TYP claustrophobic) (see Figure). All parent/child dyads (N=10 parents and 10 children) were white, and the majority of parents were college educated with a Bachelor's degree or higher (n=8, 80%). Two themes emerged from the transcripts: (1) Desire to help others with autism (2) ASD child/parent without app had trouble with expectations for MRI. Participants described the iPad app's feasibility, efficacy, and acceptability (see Table).
Conclusions:
The results demonstrate the effectiveness of the app for preparing ASD children and their parent for completion of research study MRI. Use of the app could strengthen the protective factors that positively impact the child experience with MRI and family experience during research MRI. Results of the study will guide the development of interdisciplinary intervention studies of ASD parents and children undergoing MRI.

Figure. *Frequency of MRI Completion by Diagnosis and App Use*



ASD= Autism Spectrum Disorder, App= iPad application, MRI=Magnetic Resonance Imaging, TYP = Typically developing

Table. *Evaluation of iPad*

	ASD	TYP
Feasibility Ease of use?	Parent 6- *"very straight forward"*	Parent 7-*"I thought it was very good that she was able to comprehend it and do very well."*
Efficacy Helpful? Challenges?	Child 3- *"pictures helpful....it (MRI) was pretty long, but it wasn't all that bad"*	Parent 7-*" The actual test (research task with joystick) was more challenging as it got harder, but other than that, actually it went well."*
Acceptability What went well?	Parent 6- *"I thought it was great because she is very such a visual learner."*	Child 7- *"I signed up for everything because I was interested in trying new things."*

229 **142.229** Evaluating the Usability of a Social Skills Training App for Children with ASD

B. G. Kinsella[1]*, A. Kushki*[2] *and S. Chow*[1]*, (1)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Bloorview Research Institute, Toronto, ON, Canada*

Background:
Deficits in social communication are defining features of autism spectrum disorder (ASD). These deficits negatively have been associated with long-term negative outcomes such as unemployment and under-employment, low rates of independent living, and increased risk of psychiatric disorders. While prognosis can be significantly improved with intervention, few evidence-based interventions exist for social skill deficits in ASD. Existing interventions are resource-intensive, their outcomes vary widely for different individuals, and they often do not generalize to new contexts.
Technology-aided intervention is a motivating, low-cost, and versatile approach for social skills training in ASD. It can provide a safe and controlled venue for rehearsal of skills in a self-paced and personalized manner, allow for treatments to be implemented with high precision and fidelity, and reduce the cost, resource, and other accessibility barriers to existing treatments. Although early studies support the feasibility and potential effectiveness of technology-aided intervention for social skills training in ASD, existing approaches have been criticized for teaching skills based on human-computer interaction. This can paradoxically lead to further social isolation and hinder skill generalizability.
Objectives:
A Google Glass-based application ("app") was developed to help guide children with ASD through social interaction. The Glass is a head-mounted wearable technology that uses a microphone to listen to its environment and an optical heads-up display (HUD) to prompt and interact with the user. The app coaches a child through human-to-human interaction by listening to the conversation and providing appropriate responses as prompts on the HUD. Before testing clinical efficacy, the objective of this study was to determine the technology's viability as an appropriate medium.
Methods:
10 children (mean age=13.2 σ=1.5, verbal IQ=104.4 σ=20.9, Social Communication Questionnaire score=19 σ=3.5) with ASD were recruited to be participants. During each session, the participant used the app while engaging in a structured restaurant-themed interaction with a research assistant. The app was evaluated on its effectiveness (i.e. how accurately the app responds), efficiency (i.e. how quickly the user and the app), and user satisfaction (based on a post-session questionnaire that includes a 5-point Likert scale).
Results:
The application's detection accuracy (i.e. how often it detected a participants' utterances) was 97%, and recognition accuracy (i.e. how accurately it recognized the participants' phrases) was 89%. The users' average response time after being prompted was 2.5 seconds, and the system's average response time to recognize the user's speech was -0.25 seconds. User feedback on perceived experience of system use was collected and compiled. Notable responses include the participants believe the app can help them in daily life (4.0/5), the app was fun to use (4.4/5), and the app can help children communicate to people (4.0/5).
Conclusions:
To the best of our knowledge, this system is the first technology-based intervention for ASD that employs human-to-human coaching in naturalistic settings, and the results show that the device is an appropriate medium for treatment delivery. Future directions will include improvements to the prototype by incorporating relevant usability feedback, and a study to evaluate the clinical effectiveness of the app as a social skills intervention.

230 **142.230** An Investigation into the Effectiveness of an Arabic AAC Solution for Minimally Verbal Children with Autism

M. Habash[1]*, F. Alnemary*[2] *and F. Alnemary*[2]*, (1)A Global Voice for Autism, Ottawa, ON, Canada, (2)UCLA, Los Angeles, CA*

Background: Despite receiving interventions, about 20-30% of children with autism spectrum disorder (ASD) might be unable to use spoken language as they are classified as minimally verbal[1]. Thus, reliance on other means of communication becomes the alternative option. Several studies reported the successful use of augmentative and alternative communication (AAC) methods for children with ASD. As such, AAC solutions have become very common over the past few years, particularly with the availability of many devices and application for the English-speaking people; however, there have not been any equivalent AAC solutions for their Arabic-speaking counterparts. This is primarily due to the lack of institutional or corporate development interest and the complexity of the Arabic language when it comes to using text-to-speech engines and to the many dialects used in different countries. The "***Kalami***" pilot project developed as an icon-based AAC solution with multiple dialect and natural language.
Objectives: The purpose of this paper is to investigate the effectiveness of "Kalami" on facilitating communication, helping on developing language, and supporting positive behaviour of children with Autism in Arabic speaking families in the Middle East countries.
Methods: Ten children with minimally or non-verbal children with autism are participating in this investigation. Quantitative data collected through the application itself. Qualitative data is collected from families using weekly reporting schedule and parent survey.
Results: This is an ongoing investigation, which is expected to be complete in March 2016. Results will be published upon completion
Conclusions: The results from this study are expected to highlight the potential benefits and the challenges and barriers to bringing an Arabic AAC solution to families and their children

231 **142.231** An Investigation into an Internet of Things (IoT) Framework for Improving the Quality of Life of People with Autism in Low Income Countries

M. Habash*, A Global Voice for Autism, Ottawa, ON, Canada*

Background: With the immense developments of smart technologies and improvement in digital communication methods, the “Internet of Thing” has become a new standard for the design and development of connected devices and smart environments. There has been progress in utilizing the IoT framework for assistive technologies in different fields such as inclusion and independent living for seniors. Such smart environment (and associated devices) could have great potential for delivering and serving as means of assistive technologies for people with autism and their families as well. Furthermore, the low costs for such technologies could make them available for regions with low income, potentially helping improving the lives of people with autism and their families in underserviced and economically challenged regions of the world.
Objectives: The purpose of this paper is to investigate the potential of an Internet of Things (IoT) framework in delivering services and improving the quality of lives of people with autism and their families in low-income countries. In particular, this work aims to define the areas in which such framework can help, the services that can be delivered, the associated costs, and the possible challenges.
Methods: A framework is developed based on existing literature, available technologies, and needs assessments of people with autism and their families. Detailed design and associated components are discussed through panels of experts and volunteer families in multiple countries. Qualitative data is collected and presented based on discussions, surveys, and feedback.
Results: This is an ongoing investigation. The framework and associated approaches, devices, and outcomes of the assessment are expected to be complete in February 2016.
Conclusions: The results from this study are expected to highlight the potential benefits of the Internet of Things Framework for serving as means of delivering services and improving the quality of life of people with autism and their families

232 **142.232** App for Autism: Identifying Trends in the App Market

L. Hart[1], *S. Valencia*[2], *M. Mademtzi*[3] *and F. Shic*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale University School of Medicine, New Haven, CT, (3)University of Birmingham, Bimringham, United Kingdom*

Background: Apps for autism” are not only a fraction of the price of the devices that predated them (e.g. DyanaVox $10,000 plus), but are also non-stigmatizing and multi-functional (Parette & Scherer, 2004). However, llittle to no effort has been made to characterize the current state of this market of “apps for autism.” This represents a pressing issue as parents of children with autism and practitioners in the field can quickly become overwhelmed by the thousands of “apps for autism” and thousands more apps that could be useful but are not explicitly labeled for autism.
Objectives: To characterize the current state of apps for autism and explore current trends within this market by 1) creating an up-to-date database of apps for autism following Goodwin et al.’s classification scheme for interactive technologies for autism, with 2) Priori Data’s download, revenue, and app user ratings metrics for 55 countries, that will 3) be capable of automatically retrieving this information from Priori Data’s websites and compiling it within excel.
Methods: Apps are from two sources: databases listing apps for autism, and ongoing autism specific key-word search within Priori Data based on the “Domain” dimension of Goodwin et al.’s classification scheme (i.e., the technology’s focus area relevant to autism). Key words and terms included in the search were chosen that would expand the positive results returned of each of the label 6 labels comprising this dimension (e.g. social/emotional skills, language/communication, life/vocational skills, etc.). The current sample is comprised of 620(something) apps fitting the study’s inclusions/exclusion criteria. Priori Data’s app metrics for the past 13 months were then used to run the following analyses: 1) Global downloads – to 1.1) identify top 20 downloaded apps, 1.2) rank the 6 Domains areas according to their global downloads; 2) User Ratings, to 2.1) rank domains average user rating, 2.2) compare these average user rating of each domain to the all time average user rating for Priori Data’s primary app category; 3) App revenue, to identify 3.1) the top 20 individual apps with the highest revenue, 3.2) the rank the domains by mean total revenue, and 3.3) use app install revenue divided by app download revenue to determine the 50 apps with the highest unit price/the domain with the highest unit price.
Results: the data collected provides a picture of the most downloaded apps around the world, their revenues, the best rated apps and the number of user ratings. academic skills, language and communication and life and vocational skills are the most popular domains with biggest amount of downloads. The most user rated domains (user rated number> 100 ratings) are again Life/Vocational Skills and Academic Skills respectively.
Conclusions: Two distinct indicators of app success emerged within total downloads and revenue as metrics of success, one characterized by highly specific apps (e.g. AAC apps) with a high initial install cost but relatively low overall downloads, and another with a less specific focus that might appeal to broader audience (e.g. Life and vocational skills and apps that could be classified as “edutainment”).

233 **142.233** Using Technology to Promote the Implementation of Evidence-Based Practices in the United States and Internationally for Learners with ASD

A. Sam[1], *A. W. Cox*[2], *O. Alhaqbani*[3] *and S. L. Odom*[4], *(1)Frank Porter Graham Child Development Institute, University of North Carolina, Chapel Hill, Carrboro, NC, (2)Frank Porter Graham Institute, University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)Center For Autism Research, Riyadh, Saudi Arabia, (4)University of North Carolina, Chapel Hill, NC*

Background:
There is a national need for preparing teachers and other educational staff to implement evidence-based practices (EBP) with students with ASD. A new report from the National Professional Development Center on Autism Spectrum Disorder (NPDC) details 27 evidence-based practices, supported by research, that are effective for individuals with ASD (Wong et al., 2014). However, selecting and implementing EBP for individuals with ASD poses challenges for practitioners in special education and related fields. The US Department of Education recently funded a new, e-learning resource, AFIRM (http://afirm.fpg.unc.edu/), for 2 years. AFIRM is developing online, self-paced learning modules on these 27 practices for teachers of students with ASD. To assess the effectiveness of AFIRM, users complete surveys on the usefulness, relevance, and quality of the online modules.
Objectives:

1. Describe the demographics of the users who access the AFIRM modules (nationality, profession).
2. Examine the usability, relevance, and quality of AFIRM modules through collected survey data.
3. Compare survey ratings of international users and users from the United States.

Methods:
Users complete a survey with Likert-type questions on a four point scale with 4 being the highest possible rating. The survey addresses the usability, relevance, and quality of the AFIRM modules. Descriptive statistics and analyses will be used to examine similarities and differences in the ratings among international users and users from the United States.
Results:
Collection of data is ongoing as the number of modules expands and more users complete modules. Currently, the AFIRM website has over 2,600 users of the current 7 modules, representing more than 40 countries world-wide. The **quality** of the current modules were rated highly ranging from a mean of 3.33 for the Reinforcement module (n=96) to 3.70 for the Social Narrative module (n=13). Users rated the AFIRM modules as **relevant** to the work they do ranging from a mean of 3.35 for Time Delay (n=34) to 3.62 for Visual Supports (n=206). Users found the modules **useful** ranging from a mean of 3.32 for Time Delay (n=34) to 3.54 for Social Narratives (n=12). As development continues, an additional 10 modules are scheduled for release before March 2016. Data collected through March 2016 will be used to describe findings.
Conclusions:
Initial findings indicate that teachers, practitioners, and professionals (in more than 40 countries) who complete the AFIRM modules find them relevant to their work, useful, and the quality of the modules high. Further analyses will determine differences in how international users and users in the United States rate the usefulness, relevance, and quality of the modules.
Both the AFIRM and NPDC websites are in English. Recently, NPDC entered into a partnership with the Center for Autism Research, King Faisal Specialist Hospital, Riyadh, KSA to translate resources and materials into Arabic *(cfar.kfshrc.edu.sa/HomeEnglish.aspx).* Once the translation is underway, links will be added between the CFAR and AFIRM websites to facilitate access to the materials by Arabic speaking communities.

234 **142.234** User-Centered Design for Research Data Management Software: Evaluating and Improving Designs By Testing with Users (Early and Often)

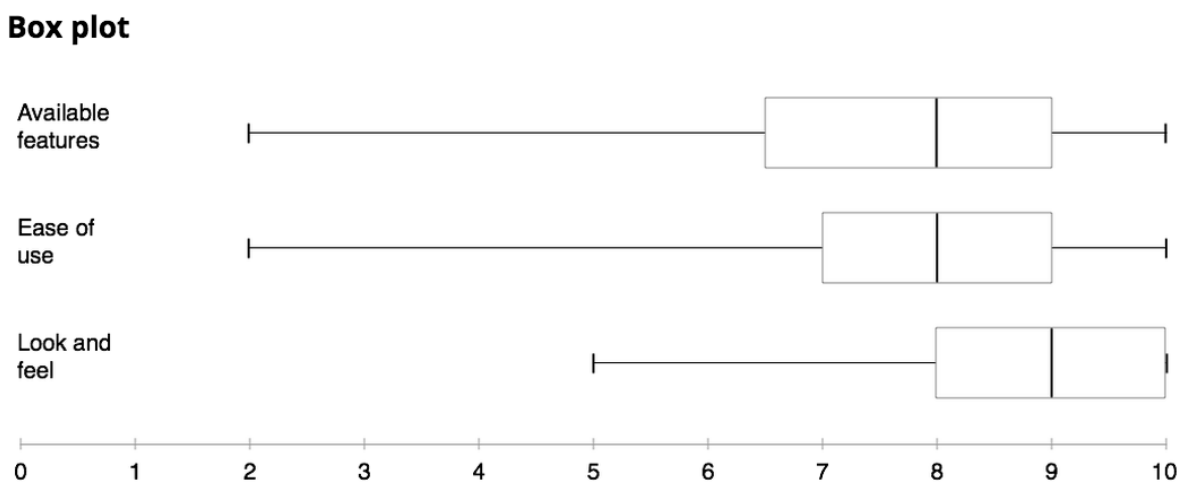
H. Agnew[1], *J. A. Salim*[2], *T. Schantz*[1] *and L. Rozenblit*[1], *(1)Prometheus Research, LLC, New Haven, CT, (2)Marcus Autism Center, Atlanta, GA*

Background: The Marcus Autism Center uses RexDB, an open-source platform for data management, to collect, organize, and analyze research data. Marcus sought to tailor their RexDB application to support specific needs regarding participant enrollment and visit tracking.
Objectives: The design team identified several constraints: (1) a short development schedule, (2) a modest budget, and (3) an established technology framework. We sought to design a technically feasible user interface that was demonstrably (a) useful (exclusive of unnecessary features, and inclusive of all necessary features), (b) usable (as measured by efficiency, learnability, memorability, error prevalence, and user satisfaction) [Nielsen, J. (2012) Usability 101: Introduction to Usability. http://www.nngroup.com/], and (c) appealing to users.
We aimed to be confident in the design's probability of success by testing prototypes before beginning the more costly and less flexible programming phase.
Methods:
After defining the client's needs, we brainstormed potential screen layouts and interaction patterns. We generated several alternative designs using inexpensive paper drawings, selecting the most promising based on their technical feasibility and similarity to previously validated design patterns. We converted the selected designs into

digital prototypes.
We then conducted user testing [Nielsen, J. (1994) Usability inspection methods. Conference Companion on Human Factors in Computing Systems, p.413-414.], in which eventual users completed realistic tasks with the prototypes. We observed interactions and asked questions to better understand their mindset and expectations (e.g., "What do you think you can do here?"; "What would you do next?"). We noted the frequency and cause of user errors.
At the end of each session, we asked:

1. How useful is this workflow to you?
2. Is there anything missing?
3. Is there anything here that you don't need?
4. How would you rate the application's ease of use?

Following each round, we updated our design and repeated the testing process until we believed the design was strong enough to move to the programming phase.
Results:
After programming and launching the interface, we measured perceptions of the application's usefulness, usability, and appeal ("look and feel"). We asked 52 users to rate the following three aspects on a 0 (worst) to 10 (best) scale (average responses shown):
1. Available features (Does it have the features you need?) 7.5 / 10
2. Ease of use 7.7 / 10
3. Look and feel 8.6 / 10
Conclusions:
By iterating and testing with users, we designed a useful and usable interface. The application was successfully launched and adopted without the need for a costly redesign. The final design was substantially different from the initial version. For example, some screens were removed completely because they were found to be unnecessary. The application's navigation was re-designed from scratch.
Teams designing complex web applications for domain-specific uses, such as autism research data management, may benefit from the user testing approach described here.



The box plot shows the minimum and maximum response (left/right tick marks), the first and third quartiles (left/right edges of the box), and the median (vertical line in the box).

235 **142.235** Stakeholder Perspectives on the Utility of the Web-Based Occupational Resource Kit (W.O.R.K.): An Interactive Curriculum to Support Students with Mild Intellectual Disabilities with and without ASD in the Successful Transitioning to Employment

***K. Adkisson**, D. Childress, K. Melillo, C. Hehman, I. Coleman, T. Phillips and J. Chin, 3C Institute, Durham, NC*

Background: Employment is essential for helping individuals with intellectual disabilities (ID) achieve independence, financial security, self-sufficiency, and to be active members in the community as well as foster a higher quality of life more generally (Test, Aspel, & Everson, 2006). However, only 25% of individuals with ID are employed two years after high school (Wagner et al., 2005). Additionally, 25% of students with ID also have a diagnosis of an Autism Spectrum Disorder (ASD), further impacting employment outcomes (Shea, 2006). While teachers often provide the first exposure to work and help students determine the type of job or employment they would like to pursue after high school, only 31.6% of high school classes focus on preparing students for employment (Guy et al., 2009).
Objectives: To develop and conduct usability and feasibility testing of an internet accessible, interactive employment preparation program, the Web-based Occupational Resource Kit (W.O.R.K.), keyed to the learning and adaptive needs of students with ID with and without ASD who are entering the workforce.
Methods: Following prototype development of the W.O.R.K. program, usability and feasibility testing was conducted. Students with ID and their parents (n=21 dyads, 11 with ASD) reviewed W.O.R.K. at home for two weeks. Educators of these students (n=30) also reviewed the program. Prototype content focused on communication skills with didactic instruction in the form of brief videos and interactive exercises to test understanding and application. Following this open review period, usability and feasibility testing of the program, online delivery platform, and student understanding of issues related to the successful transition to employment was assessed via survey and semi-structured interviews.
Results: All stakeholder groups found the program components to be of high quality and value as well as a highly usable intervention package (5-point Likert scale, 1=Strongly Disagree to 5=Strongly Agree; mean ratings > 4). Parents reported W.O.R.K. to fill a need for students with ID (M=4.57, SD=0.51) and believed the program would be effective in helping students transition to employment (M=4.33, SD=0.86). Educators rated W.O.R.K. of high overall feasibility and indicated W.O.R.K. would be a useful tool for supplementing lesson plans. Students reported the program was easy to use and engaging. Students with just ID (no ASD) enjoyed the content that contained humor and recommended more in future development. Student with ASD and ID provided comments focused more on the details of the video production (i.e., scenes recorded on green screen) and concrete applications of the presented strategies. Students with ASD and ID recommended videos about different work settings that applied more to their interests.
Conclusions: These data provide evidence for the usefulness and need of the W.O.R.K. program for students with ID with and without ASD preparing for employment. Gathered data is being used to create a blueprint of modifications and additions needed to key the intervention to the needs of students with ID with and without ASD (e.g., different blends of instructional elements and methods, customized graphic design, tailored activities). Future steps include fully developing the instructional content, followed by a pilot efficacy study.

Table 1. Student and parent ratings Construct	Students Mean (SD)	Parents Mean (SD)
Will be useful in a high school setting	4.43 (0.65)	4.43 (0.51)
Would be valuable to schools	4.54 (0.66)	4.64 (0.63)
Will help students transition into work	4.42 (0.69)	4.33 (0.86)
Content organized in a way that made sense	4.43 (0.76)	4.57 (0.51)
I (my child) learned something	4.46 (0.78)	4.43 (0.83)
Overall experience was positive	4.26 (0.74)	4.62 (0.50)
Innovative way to learn job skills	4.35 (0.75)	4.43 (0.63)
Would recommend further development	4.14 (0.77)	4.64 (0.50)
Content complements skills learned at school.	N/A	4.57 (0.51)

236 **142.236** Development of the Postsecondary Resilience Education Program (PREP): An Interactive, Web-Based College Readiness and Resilience Skills Building Program for Students with High Functioning Autism Spectrum Disorder

***D. Childress**, K. Melillo, K. Adkisson, A. Sam, I. Eremeev, B. Cassell, P. Allen and S. Rothman, 3C Institute, Durham, NC*

Background: Despite cognitive strengths, individuals with high functioning autism (HFA) pursue college at much lower rates than their typically developing peers with approximately 24% of individuals with ASD without intellectual disability reporting no regular educational or employment activities following high school (Taylor & Seltzer, 2011). Further, when these intellectually capable students pursue college, they tend to drop out prematurely (Glennon, 2001). A growing literature underscores the crucial role of resilience strategies for academic and social-emotional adjustment as well as persistence in postsecondary education (Walton & Carr, 2012). The lack of well-designed and accessible interventions to support students with HFA transitioning to postsecondary education contributes to the marked under-education and under-employment experienced by these individuals, thereby, negatively impacting their overall quality of life.
Objectives: To iteratively develop and conduct testing of a dynamic, customizable college readiness and resilience program. The *Postsecondary Resilience Education Program (PREP*) is keyed to the unique learning and social-emotional characteristics of students with HFA.
Methods: Usability and feasibility testing of *PREP* and semi-structured interviews were conducted. High-school students preparing for the entry to postsecondary education and their parents (n=13 pairs), as well as educators (n=25) reviewed *PREP* in their homes for 2 weeks. The online platform allows the user to view each unit addressing a specific skill domain with instruction provided through a combination of video presentation styles, including motion graphics, animation, illustration, and video modeling. Interactive exercises provide individualized feedback and reports based on user responses. Following the review of the program, participants met with research staff individually or in small groups to give feedback on the usability of the program, online delivery platform, and their understanding of issues related to the successful transition to college. Data sources included Likert scale responses about the program design, usability, qualitative responses on the usefulness of the program and the family's and educator's experiences with PSE transition.
Results: Overall, parents and students found *PREP* to be of high quality and value as well as a highly usable software (5-point Likert scale, 1=Strongly Disagree to 5=Strongly Agree; mean ratings > 4). Parents reported that they thought *PREP*would likely be effective in facilitating the transition from high school to postsecondary education for students with HFA (M=4.64, SD=.50). Students rated the program as likely to enhance the transition and preparation skills of students who are transitioning to college (M=4.27, SD=.65). Professionals reported the program fills a need for helping high school students with HFA transitioning to college (M=4.53, SD=.61). Qualitative comments supported Likert ratings.
Conclusions: These data provide preliminary evidence for the usefulness of the *PREP* program for students with HFA considering postsecondary education. Gathered data from the usability and feasibility testing was used to create a blueprint of course content and interactive styles needed to key the intervention to the needs of students with HFA (e.g., new instructional elements and methods, tailored activities). A subsequent pilot efficacy study of PREP for enhancing resilience and transitioning skills needed for successful transition to postsecondary education is underway in regional high schools.

237 **142.237** Using the Language Environmental Analysis System (LENA) to Evaluate a Community Based Pivotal Response Treatment (PRT) Parent Coaching Model for Autism Spectrum Disorder

M. Stolte *and V. Smith, University of Alberta, Edmonton, AB, Canada*

Background: Though evidence-based practices (EBP) for autism spectrum disorder (ASD) intervention exist, adoption is low in community practice (Dingfelder & Mandell, 2011). There is a need to partner with service providers and evaluate community based interventions as there is often a loss of quality when EBP is disseminated into real world settings. Additionally, there is a need to evaluate new technologies, such as the Language Environmental Analysis System (LENA), to determine if they may expedite efficient, reliable and valid embedded program evaluation, as a means of providing feedback on program effectiveness.
Objectives:

1. To provide a comprehensive description of a community based Pivotal Response Training (PRT) parent coaching model including teaching topics and format.
2. To evaluate the effectiveness of the model on child, parent and parent-child interactional communication patterns using the LENA.
3. To evaluate the use of LENA as a new technology to measure program effectiveness in a real world setting.

Methods: Using a single-subject research design matched with new digital language processor technology (i.e., LENA) and through partnership with a large accredited autism service provider in Western Canada, a community based PRT parent coaching model was evaluated. Eighteen independent video and audio recordings of baseline, intervention and follow-up data were evaluated on child, adult, conversational turns, and ratio of child initiated conversational turns for one parent-child dyad over a 16 week period. Detailed descriptive information, fidelity of PRT implementation, PRT content validity, and hypothesized relationships between coaching condition and communication patterns are appraised.
Results: Good content validity and program description of the coaching model was obtained. A functional relationship between adult language and coaching condition was identified. Hypothesized relationships between conversational turns and coaching condition could not be evaluated due to high variability in child vocalizations across conditions. PRT fidelity improved though was not fully achieved. Advanced LENA analysis of 29,469 communication blocks suggest balanced child and adult initiations also improved as a result of the coaching, though did not sustain once the coach was no longer present.
Conclusions: The PRT parent coaching model is an EBP that holds promise for community based implementation and the LENA is a useful adjunct evaluation measure, allowing for more in depth analysis of longitudinal communication patterns. However, given PRT fidelity was not achieved by the parent and child vocalization data was variable, interpretation of results is limited. Further research on this coaching model is needed. Positively, a clear description of the model in community practice was obtained including teaching format, topics and procedures. Additionally, parent-child ASD communication patterns were identified in a reliable, valid and user friendly manner over time, using new technologies, as they participated in this EBP coaching model. This study demonstrates the importance of evaluating EBP in community settings and how new technologies, such as LENA, can support this objective.

238 **142.238** Inhome: A Multimodal Bio-Behavioral Data Capture System for Autism Research

I. Riobo[1]*, O. O. Wilder-Smith*[2]*, J. C. Sullivan*[2]*, C. Cumpanasoiu*[2]*, C. Kim*[1]*, Y. Liu*[1]*, G. D. Abowd*[1]*, J. M. Rehg*[1] *and M. S. Goodwin*[2]*, (1)Georgia Institute of Technology, Atlanta, GA, (2)Northeastern University, Boston, MA*

Background: The majority of existing research in Autism Spectrum Disorder (ASD) relies on parent- or informant-report measures and/or behavioral assessments collected at a limited number of time points, often in unfamiliar settings (laboratory, clinic). Recent advances in commercially available multimodal recording technology make it possible to move beyond reliance on both approaches and collect intensive longitudinal video and physiological data in home-based settings. These technologies have the potential to provide greater statistical power, measurement precision and sensitivity, and enhanced ecological validity.
Objectives: (1) Develop a multimodal bio-behavioral data capture system to unobtrusively, efficiently, and accurately record and analyze behavior and physiology in individuals with ASD in home settings for up to 1 contiguous month. (2) Evaluate usability, feasibility, and data quality of our system in a sample of children with ASD and their families.
Methods: We developed *inHome* (In-Home Observation Measurement Equipment), an integrated system consisting of commercially available cameras, laptop computers, electrodermal activity sensors (Q Sensor), sleep sensors (AMI), and tablet computers that provide video review and annotation capabilities. *inHome* is currently configured to collect up to 30 days (5 hours per day) of continuous video, audio, physiological, physical activity, sleep, and informant-report data that is automatically synchronized and recorded to a central repository.
Results: To-date, 10 children with ASD (age 4-14 years) and their families have completed trialing the system in their homes for 2-4 weeks, for a total of 27 weeks of data collection, and approximately 900 hours of video, audio, physiological, and physical activity data. Installation of the system in a family's home and training on its use can be

completed in less than 90 minutes. Parent feedback from post-deployment interviews indicates that the system is easy-to-use, unobtrusive, and able to capture data that they believe is representative of their children's behavior.
Conclusions: We have successfully developed a novel system for collecting intensive longitudinal multimodal data on behavior, physiology, physical activity, and sleep, in individuals with ASD in home settings. The data obtained thus far represents a first-of-its-kind, long-term intensive longitudinal dataset of bio-behavioral data from children with ASD in home settings. In addition to complementing traditional survey and lab-based measures, enabling parents to efficiently gather high quality quantitative assessments of their children's behavior and physiology in the home over time could enhance intervention and clinical trials by establishing more sensitive and detailed outcome measures. It may also facilitate more basic research to the extent that our systems' measures can be associated with other biological indices (genetic, metabolic, proteomic, immunologic, neurologic, psychiatric, etc.) obtained from a large number of individuals on the autism spectrum. Our demonstration will include opportunities to try out and interact with the inHome system, as well as review examples of data collected from our end-user deployments.

239 **142.239** Assessment of the Olfactory Trait in Children with Autism Spectrum Disorders Using an Olfactory Software Application

H. Kumazaki[1,2], *T. Muramatsu*[2], *M. Miyao*[3], *T. X. Fujisawa*[1], *H. Kosaka*[1], *A. Tomoda*[1] *and M. Mimura*[2], *(1)University of Fukui Research Center for Child Development, Yoshida-gun, Japan, (2)Keio University, Tokyo, Japan, (3)DONGURI clinic for children with developmental disorders, Tokyo, Japan*

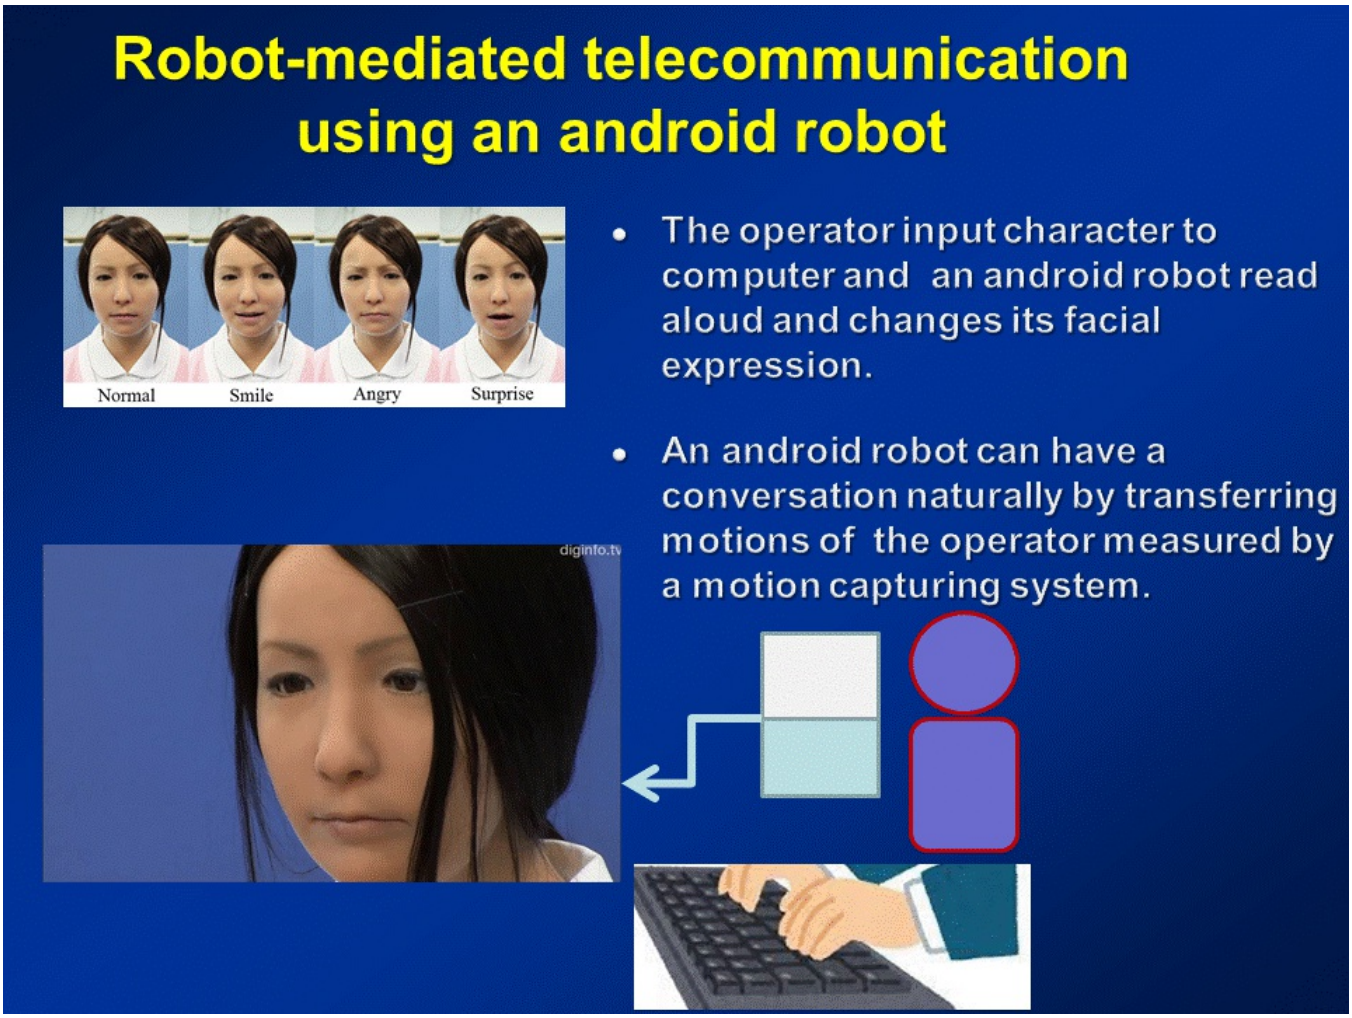
Background: Olfaction is regarded as one of the most important diagnostic or prognostic markers in a number of neuropsychiatric disorders. Abnormal reactions to olfactory stimuli in children with autism spectrum disorder (ASD) have been described in several clinical studies using sensory questionnaires. However, laboratory-based sensory psychophysical studies to investigate the olfactory trait in children with ASD using olfactory testing have produced inconsistent results. Previous research has failed to show significant correlations between autism severity and laboratory data. Adaptation is an important process, allowing individuals to adjust to changes in their environment. Few studies measure olfactory adaptation in children with ASD. Olfactory laboratory tests have provided limited information about such abnormalities in those with ASD.
Objectives: In this study, we used an olfactory measurement that uses a pulse ejection system as well as olfactory application software, which we developed. Previous olfactory measurement techniques cause problems with scents scattering and lingering in the air, making accurate measurements impossible. We have attempted to resolve these problems by using a display with a pulse ejection system to present a scent for a short duration at the picoliter level. Using very small quantities of scent reduces lingering scents during measurement and makes it more difficult for olfaction to adapt compared to existing measurement techniques. We also developed an olfactory application software that can measure the adaptation to changes in odor. This study examined adaptation to changes in odor using a pulse ejection system and this new software application in a sample of children with ASD.
Methods: The inclusion criteria were chronological age of 10 to 16 years and previous diagnosis of high-functioning ASD. All participants satisfied the diagnostic criteria for ASD in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (American Psychiatric Association, 2013). To exclude other psychiatric diagnoses, the Mini-International Neuropsychiatric Interview for Children and Adolescents was conducted by a licensed pediatric psychiatric clinician. Thirteen children with ASD participated. Adaptation to changes in odor was assessed using the olfactory measurement system with olfactory display, which uses a pulse ejection system, and the new software application. We used isoamyl acetate and ethyl butyrate flavor for the odorants. The odors of isoamyl acetate and ethyl butyrate flavor were released for 20 seconds each by the display using a pulse ejection system. We investigated whether participants were able to recognize the change of the odorants using touch panel display controlled by the olfactory software application. We used the Childhood Autism Rating Scale (CARS) to measure the severity of the autistic trait. Statistical analysis was performed using the Statistical Package for the Social Sciences, version 15.0.
Results: Seven participants passed, and six did not. The total score and the "Taste, Smell, and Touch Response and Use" score on the CARS were lower in the group who passed than in the group who did not ($p < 0.01$).
Conclusions: Adaptation to changes in odor may be connected with the severity of autism. Implications for further research are discussed.

240 **142.240** Robot-Mediated Interventions for Social Anxiety in Individuals with Autism Spectrum Disorder

H. Kumazaki[1,2], *Y. Yoshikawa*[3], *Y. Matsumoto*[4], *M. Miyao*[5], *H. Ishiguro*[3], *T. Muramatsu*[2] *and M. Mimura*[2], *(1)University of Fukui Research Center for Child Development, Yoshida-gun, Japan, (2)Keio University, Tokyo, Japan, (3)Osaka University / JST ERATO, Osaka, Japan, (4)National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, (5)DONGURI clinic for children with developmental disorders, Tokyo, Japan*

Background: In some cases, social anxiety is considered to be difficult to treat in individuals with autism spectrum disorder (ASD), and a variety of therapeutic and educational approaches have been attempted. Any of these may have educational benefits in some but not all individuals with ASD. Considering the present situation, there is an urgent need for the development and application of novel and more efficacious treatment strategies. Given recent rapid technological advances, it has been argued that technology, especially in the field of robotics, could be effectively harnessed to provide innovative clinical treatments for individuals with ASD. An android robot designed to look human can be used as a telecommunication medium for distant inter-human communication. Robot-mediated telecommunication using an android robot may encourage children with ASD to exhibit social communication.
Objectives: We propose the initial application of robot-mediated telecommunication using an android robot for targeted interaction to improve communication skills in individuals with social anxiety and ASD.
Methods: The inclusion criteria were chronological age of 18 to 24 years and previous diagnosis of high-functioning ASD (IQ ≥ 70) and social anxiety. This experiment was conducted in a familiar room that was used often by the participants for various activities. The participants typed on the keyboard, and the android spoke. The android was

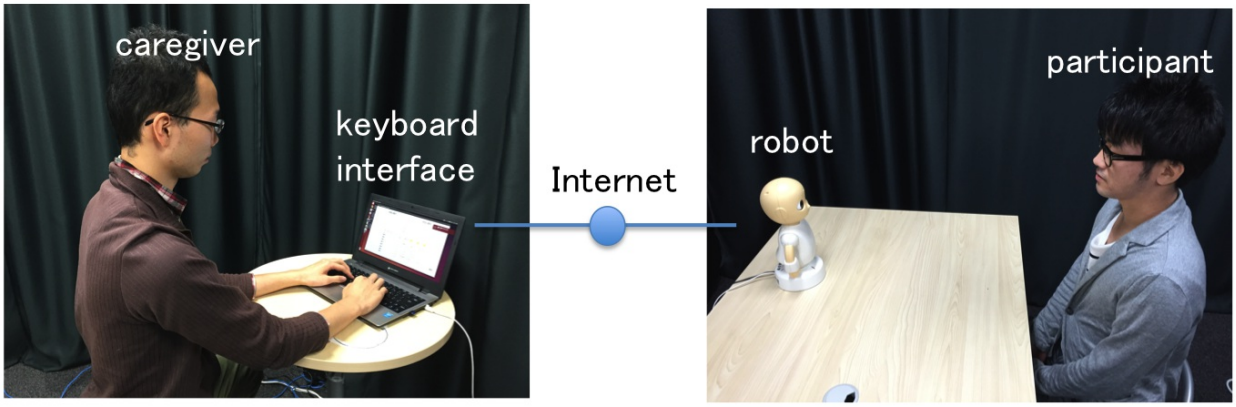
positioned at one end of the room within plain view of the participants. There was a camera image before the participant, which the participant was able to watch. The android robot used in this study was ACTROID-F (Kokoro Co. Ltd.), a female-type humanoid robot with an appearance similar to that of a real person. Its artificial body has the same proportions, facial features, hair color, and hairstyle as a human. At first sight and from a distance, it is difficult to distinguish this android robot from a live adult. ACTROID-F is capable of a range of movements (moving limbs up and down and turning the head from side to side). We adopted the remote control system conventionally used in robotics studies in covert ways. ACTROID-F is tele-operated to perform semi-structured conversations with a person for consultation. Emotion was measured using the Stress Response Scale (SRS).
Results: Twenty-three individuals diagnosed with ASD and social anxiety participated. Based on video recordings of the interactions, quantitative and qualitative analyses were conducted. All participants were able to respond and type in any situation. In all cases, when they typed on the keyboard, their expressions became soft. Before they typed, “enter,” they were stiff, but after they typed, “enter,” they were relieved. They seemed to be deep in conversation. Total score and some item scores on the SRS (i.e., become irritable, mind everything, sink deeply, and cannot concentrate on something) improved from before to after intervention ($p < 0.01$).
Conclusions: Despite the limited effectiveness of the intervention, it is suggested that intervention using an android could be used as a tool for the development of communication. Future research needs to examine the issue using a larger, more diverse sample and multiple levels of analysis of behavioral change.



241 **142.241** Advantages of Robot-Assisted Counseling: Can Caregivers Better Address the Concerns of Children with Autistic Spectrum Disorders Via a Small Humanoid Robot?

J. Shimaya[1], *Y. Yoshikawa*[1], *M. Miyao*[2], *Y. Matsumoto*[3], *H. Kumazaki*[4], *M. Nakano*[5] *and H. Ishiguro*[1], *(1)Osaka University / JST ERATO, Osaka, Japan, (2)DONGURI clinic for children with developmental disorders, Tokyo, Japan, (3)National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, (4)University of Fukui Research Center for Child Development, Yoshida-gun, Japan, (5)National Center for Child Health and Development, Tokyo, Japan*

Background: Children with ASD may experience difficulties communicating concerns to caregivers (e.g., clinical psychotherapists, special education teachers, etc.) due to deficits in social communication ability. Previous research indicates that children with ASD may be able to communicate effectively with robots; this possibility is partially supported by certain positive response tendencies in non-verbal communication (e.g. Cabibihan et al., 2013). Nonetheless, these tendencies do not confirm whether robots may facilitate therapeutic communication in a counseling context.
Objectives: Tele-operated robots’ potential to assist caregivers in indirectly counseling children with ASD was examined. We provided caregivers with opportunities to talk with participating children via a small humanoid robot; we subsequently qualitatively and quantitatively analyzed the conversations, which concerned the children’s concerns.
Methods: Three female teenagers (referred to as “A,” “B,” and “C”) with ASD participated. The participants’ caregivers had been unable to address their problems with human relationships. All participants directly and indirectly talked with their caregivers. The conversation times ranged from one to four In the indirect phases, participants talked with a 30-cm-height humanoid robot.. The caregiver could remotely control it to utter the caregiver’s messages using a keyboard interface. We qualitatively and quantitatively examined counseling achievements throughout the series of conversations.
Results: The average total time of conversation was 17.0 and 5.5 minutes in the indirect and direct phases, respectively. The utterance ratio (UR) was calculated as the ratio of normalized time spent on utterances by participants in the indirect phase, compared to in the direct phase. The average UR across all participants was 2.2 (SD = 1.1), indicating that participants uttered more in the indirect phases than in the direct phases. All participants were able to discuss concerns that had not previously been disclosed to their caregivers; however, counseling achievements varied among participants. A and B were able to discuss previously undisclosed worries; specifically, A disclosed the names of people she disliked, and B disclosed circumstances under which she felt uncomfortable interacting with her friends. By contrast, C was able to inhibit excessive aggression toward particular classmates; previously, she had been unable to avoid panicking even when merely encountering these classmates, and no caregiver had been able to adequately manage her panic reaction. C conversed with the caregiver for a particularly long time through the robot regarding these classmates, although she had previously experienced difficultly discussing that topic directly with the caregiver. As she promised to the robot in conversation, she successfully met one of these classmates while keeping calm. Significantly, the caregiver reported that C had been able to keep calm in the presence of these classmates including when she met him two weeks after the experiment.
Conclusions: The caregivers generally succeeded in counseling children with ASD via a small humanoid robot. This result encourages us to develop and introduce a robot-assisted counseling environment into the treatment and education of children with ASD, although the sample size has been limited. Long-term follow-ups and investigation of customization of the technique to reflect individual care needs are important issues for future research.



242 **142.242** Robot-Led Intervention for Improving Emotional Cognition in Children with ASD

S. A. Koch[1], *J. B. Lebersfeld*[1], *C. D. Clesi*[1], *C. E. Stevens*[1], *M. E. McNew*[1,2], *A. G. Parker*[1], *F. J. Biasini*[1] *and M. I. Hopkins*[1], *(1)Psychology, University of Alabama at Birmingham, Birmingham, AL, (2)Psychology, Florida International University, Miami, FL*

Background:
Mounting research supports the use of technology, including social robotics, to improve social communication in individuals with Autism Spectrum Disorder (ASD). Robot-assisted therapy has been shown to increase engagement and promote novel social behaviors (i.e., turn-taking, imitation, joint attention) during human-led sessions. However, increased value would be achieved by a robot-led intervention that could be duplicated and more easily accessed. SAM (Socially Animated Machine) was designed to independently lead a social skills intervention aimed at improving emotional cognition in children with ASD.
Objectives:
The aims of this study were to examine whether the robot-led intervention 1) improves task-specific emotion recognition skills, 2) improves generalized social perception skills, and 3) elicits an enjoyable and engaging environment.
Methods:
13 children with ASD and average cognitive skills (ages 5-11) completed this study. Participants were randomly assigned to treatment (n=7) and control (n=6) groups. Participants in the treatment group completed eight sessions with SAM involving several games designed to teach children to identify emotions using pictures, drawings, and social scenarios. Participants in the control group completed pre- and post-intervention sessions with SAM, but were otherwise assigned to a waiting list. Social perception skills, including emotion-matching accuracy and scores on the NEPSY-II Affect Recognition and Theory of Mind subtests, were compared across groups at pre- and post-intervention. Self-reported levels of enjoyment while interacting with SAM were also obtained.
Results:
Analyses were performed using a series of univariate ANCOVAs with adjustment for pre-intervention scores. Although participants in the intervention group improved in their percent accuracy for matching SAM's emotions from pre- to post-intervention (M=80.95 to M=93.45) and control participants did not (M=79.17 to M=81.94), the difference between groups was not significant, $F(1,10) = 3.106$, $p = .108$. On the NEPSY-II, there were no significant differences in post-intervention scores between the groups on Affect Recognition, $F(1,10) = .826$, $p = .385$, or Theory of Mind, $F(1,10) = 4.171$, $p = .068$. Descriptive statistics were used to examine enjoyment ratings at post-intervention. All participants, regardless of group placement, reported feeling very happy (M=9.31, SD=1.18) and comfortable (M=9.09, SD=1.80) while talking with SAM, and were eager to have additional interactions (M=8.23, SD=2.86).
Conclusions:
Preliminary findings suggest that children who completed the robot-led intervention improved in their ability to match SAM's emotional expressions; we expect this trend to reach significance with a larger sample size (estimated N=20). Children in the intervention group did not show improved performance on a measure of social perception compared to the control group. Notably, many of the participants achieved scores at or above the average range on this measure at pre-intervention, and as such had less room for improvement following intervention. Overall, participants enjoyed working with SAM and requested additional interactions. These findings suggest that SAM's robotic design fits the needs of this population and the intervention succeeds at teaching task-specific emotion recognition skills. Future research will be collected to assess the efficacy of the intervention and effect on generalized social perception skills in a group of children with lower cognitive and emotional functioning.

243 **142.243** Emotiplay - a Virtual Environment for Emotion Recognition and Expression Learning

S. Fridenson-Hayo[1], *S. Berggren*[2], *O. Atzmon*[3], *A. Lassalle*[4], *N. Meir-Goren*[3], *S. Tal*[1], *S. Newman*[3], *S. Baron-Cohen*[4], *S. Bolte*[2] *and O. Golan*[1], *(1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden, (3)Compedia, Ramat-Gan, Israel, (4)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom*

Background: Children with Autism Spectrum Disorders (ASD) experience difficulties communicating their own emotions and recognizing the emotions of others. It has been shown that virtual computerized environments can produce simplified versions of the socio-emotional world, reduce sensory stimulation, and support a featured-based learning style of socio-emotional cues, gradually integrating them into a holistic picture. EmotiPlay is a technology initiative that draws on the results of a 3-year EU-funded project called ASC-Inclusion, aimed at developing a virtual world for emotion learning.
Objectives: (1)To demonstrate the advancements of the technology of the virtual environment designed to teach children with ASD how to understand, recognize, and express emotions. (2) To present results of three clinical trials evaluating the environment in the UK, Israel and Sweden.
Methods: The program is embedded in a virtual world and includes highly engaging elements, aimed at enhancing the child's motivation, including games, animation, video and audio clips, rewards, a child's avatar, and communication with smart agents and peers. The system combines several state-of-the art technologies in one comprehensive environment, including computerized analysis of users' gestures, facial and vocal expressions. The evaluations included 6-9 year olds with high functioning ASD who used the environment for 8-12 weeks. Evaluations included face, voice, body, and integrative emotion recogntion tasks, as well as SRS and vineland socialization measures. In the UK, 18 children were tested before and after using the sytstem. In Israel (n=40) and Sweden (n=32) children were either allocated into a treatment or a delayed treatment control group.
Results: The current demonstration will show:

1. How virtual worlds can be harnessed for autism therapy and treatment
2. How the system operates, the user interface, various modalities and rewarding system.
3. Results of the clinical trials and their effects on the product development.

Conclusions: EmotiPlay project offers children with ASD and their families the benefit of state of the art educational technology for enhancement of their socio-emotional communication skills. Clinical trials provide support for its efficacy and call for future randomized controlled trials of the environment.

244 **142.244** 3-D Social Attention Training for Young Children with ASD

Z. Zheng, ***Z. Warren****, H. Zhao, Q. Fu, A. S. Weitlauf, A. Swanson and N. Sarkar, Vanderbilt University, Nashville, TN*

Background: As we unravel ASD's complex neurogenetic origins and environmental influences, there will be increasing need for technological tools that help us better understand symptom profiles for detection and potentially for intervention/prevention. A poor response to one's name being called, in children with adequate hearing has consistently been identified as an early red-flag for ASD in infancy and toddlerhood and is included as part of standardized, widespread screening checklists and diagnostic instruments. We therefore designed and tested a novel technological system that tracks children's visual attention and responds independently in order to measure and scaffold an exemplary social attention task for young children, namely, response to their names being called.
Objectives: The ultimate objective of this study was to empirically test the feasibility and usability of an adaptive technological learning environment, capable of intelligently

administering early social orienting prompts and adaptively responding based on within system measurements of performance.
Methods: This system was comprised of name prompting and attention tracking sub-systems, an animated attractor (a bouncing ball), and a reinforcing feedback mechanism. Eight toddlers with ASD and eight infants and toddlers without developmental concerns participated in a pilot study. Each participant completed a single experimental session consisting of 10 trials of response to name training. During the trials, when a child did not respond to his or her name being called on the target monitor, a bouncing ball appeared on the monitor closest to the child's current gaze. This ball then bounced across monitors to direct the child's gaze toward the target monitor. If the child looked away or failed to follow the attractor, then additional motion and sound effects were added to the bouncing ball to heighten the attractor's effect. If the child looked at the target screen (target hit) in response to his/her name, the attention tracking sub-system recognized the success and promptly delivered praise with a firework animation.
Results: All participants tolerated the system well. No sessions were terminated due to participant distress or engagement challenges. All participants in the ASD group eventually hit the target (turned toward their name) across all trials. On average, children in the ASD group averaged 3.07 seconds between initial prompt and success. TD children, an average of 10 months younger than ASD children, also performed with a high level of accuracy. The average time required for TD children to hit the target was 1.19 seconds.
Conclusions: We studied the application of an innovative closed-loop adaptive technological system with potential relevance to core areas of vulnerability related to ASD in infancy and toddlerhood. The proposed computer system was extremely well tolerated by the children. Toddlers with ASD and typically developing infants and younger toddlers were able to ultimately respond accurately to prompts delivered by the technological system within the standardized protocol. Further, the system was capable of attracting and pushing toward correct performance autonomously without user intervention.

245 **142.245** The Potential of Collaborative Virtual Environments for ASD Intervention

*L. Zhang, H. Zhao, Q. Fu, A. Swanson, A. S. Weitlauf, **Z. Warren** and N. Sarkar, Vanderbilt University, Nashville, TN*

Background:
Over the past decade researchers have explored traditional virtual reality (VR) environments as potential intervention platforms for children with autism spectrum disorder (ASD). Such systems, however, have often been limited by the programming burden of attempting to realize fluid social communication and meaningful conversation within system as well as restraints in the flexibility of employing confederate partners. Collaborative Virtual Environments (CVEs), distributed and multiplayer involved virtual environments, may be have considerable more potential to overcome these barriers for more realistic deployment as ASD intervention tools. Specifically, CVEs can be developed to offer children with ASD opportunities to interact and communicate with peers in a safe and flexible communication environment that may also be more intrinsically motivating and easier to access than traditional forms of social intervention.
Objectives:
We designed and evaluated a CVE where children with ASD and their typically developing (TD) peers engaged in a series of collaborative games. We evaluated the feasibility and tolerability of the system as well as the impact of the CVE on within system performance and metrics of social communication skill.
Methods:
Our CVE was developed with Unity3D game engine (http://unity3d.com/). Three different types of puzzle games were designed, including turn-taking, color-sharing, and enforced collaboration games, to foster different kinds of collaborative interactions and communications. The CVE was designing to be accessed by two users from different locations through internet. The distributed users communicated by voice in real time in the CVE. Seven ASD/TD pairs, and seven TD/TD pairs completed the one visit experiment which involved pre/post-test evaluation as well as an extended period of interaction within the CVE. The pre- and post-test were composed with turn-taking game and enforced collaboration games requiring sharing color for estimation of changes in interactions and communications of participants.
Results:
When examining the interaction pairs, the task-related performance of ASD/TD pairs and TD/TD pairs improved across the CVE interaction session. There was a significant increase in the success frequency as well as a significant decrease in time duration of both turn-taking and enforced collaboration from pre-test to the post-test. The number of the task-oriented spontaneous utterance in ASD/TD pairs and the number of the task-oriented questions utterance in TD/TD pairs significantly increased.
Changes were also seen in examining individual performance metrics. Specifically, the task-related performance of children with ASD, TD children in the ASD/TD pairs, and TD children in the TD/TD pairs improved. TD children in both groups increased in the word frequency, with the number of social utterances of individual children in the TD pairs decreasing.
Conclusions:
CVEs may have the ability to foster collaborative interaction and communication skills for children with ASD. Such environments could yield interesting metrics of social communication and/or potential modalities for intervention. Planned future work will modify the system to add feedback as well as verbal and nonverbal (eye gaze) contingencies to develop potential intervention platforms for peer mediated intervention.

246 **142.246** Customizable, Interactive Toy Platform to Enable Motivation-Driven Cognitive and Physical Development in Children Diagnosed with Autism or Developmental Disorders

K. T. Johnson[1] *and R. W. Picard*[2]*, (1)MIT Media Lab, Massachusetts Institute of Technology, Cambridge, MA, (2)Massachusetts Institute of Technology, Cambridge, MA*

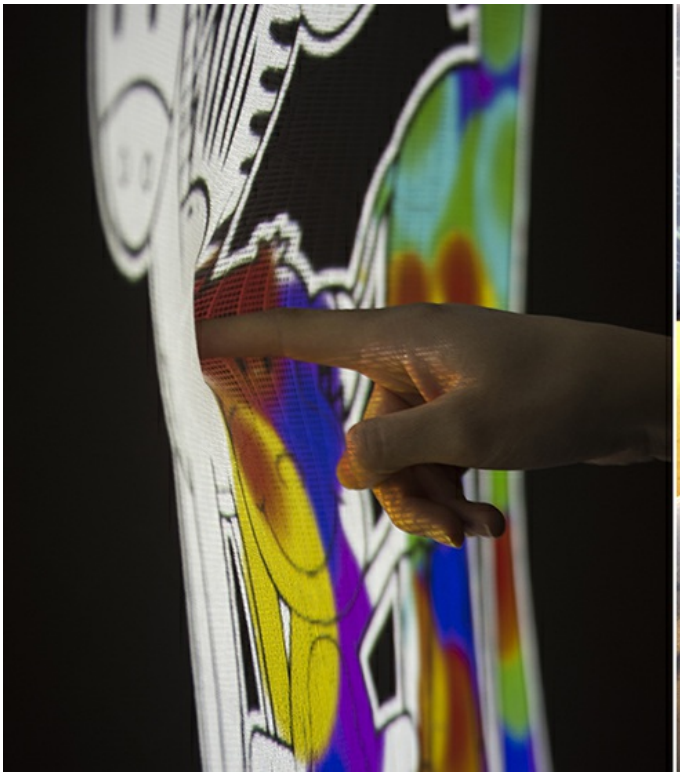
Background: Most typically-developing children are motivated to learn and explore intrinsically, often driven by curiosity or pursuits of mastery and independence (Ryan & Deci, 2000). For many children with neuro-differences, however, this intrinsic motivation may be insufficient to overcome environmental distractions, sensory demands, or motor challenges required to focus, learn, or complete a task. Yet, children diagnosed with Autism Spectrum Disorder (ASD) and/or other developmental disorders often show intense, specific affinities for particular items or topics that can be leveraged to teach skills or ideas (Mancil & Pearl, 2008). Indeed, well-established therapy techniques utilize highly-motivating personal rewards to achieve ambitious therapeutic goals, including increased attention, physiological regulation, and social engagement (Vismara & Lyons, 2007). Ideally, these goals can extend beyond the therapy setting, integrating seamlessly within daily play activities. Technology has the capability to bridge this divide; yet, current devices lack the individualization and dynamic adaptation necessary to teach and engage many atypical learners.
Objectives: To enable independently-initiated play experiences with therapeutic benefits -- including increased engagement, learning, and psychophysiological regulation -- while simultaneously collecting quantitative measures of this progress during play.
Methods: We have developed a customizable, interactive toy platform that can be rapidly tuned to align with a child's intrinsic interests and potential sensitivities, enabling new opportunities for regulation, social engagement, and comprehensive data collection. This self-contained physical smart toy has a removable, modular center piece that allows us to adapt the challenge of the task to the needs of the child by inserting different modules, including shape sorting, ring stacking, and pincer grasp development activities. In addition, embedded digital sensors capture data quantifying a child's engagement and behavior while interacting with the toy. An integrated smartphone allows user-friendly customization of the motivating reinforcement mechanism, such as favorite video clips, music samples, or light displays. In this way, the toy can also become a vehicle to provide controlled stimuli capable of presenting other experimental paradigms in a flexible, ambulatory, and ecologically valid environment.
Results: Preliminary data from three children (age 2-4) with ASD using an early prototype of the toy indicated that individualized reinforcement was highly motivating, increasing the children's abilities to attend to and achieve challenging tasks. We also found a correlation between the challenge level of the task and the necessary preference level of the reward, confirming a need for a tunable device that can match the "just right challenge" to the "just right reward." Our IMFAR demonstration will include opportunities to interact with our next-generation prototype, as well as to discuss additional data from neuro-diverse children engaging with the toy platform.
Conclusions: We have created a new customizable toy platform designed to elicit increased cognition, self-regulation, and social engagement for children with complex neurological needs through a highly-motivating, self-driven play environment. Early results suggest that the toy's personalized reinforcement can help a child achieve ambitious cognitive and motor goals at an accelerated pace, underscoring the promise of innovative technologies for ASD research and intervention and warranting the need for further studies.

247 **142.247** Technologies for Tactile Multi-Sensory Environments

***S. Ahlquist**, University of Michigan, Ann Arbor, MI*

Background: (Category: Technology Demo) Children with autism spectrum disorder (ASD) often face an array of sensory challenges resulting in delayed abilities in fine motor skills and quality of movement. Re-imagining the interface with technology as both a large tactile surface and a physical environment, the senses beyond just the visual can be engaged as a part of the grading of movement and fine motor skill-building process. Deep pressure is often used to provide sensory regulation for those with dysfunctioning tactile, vestibular and proprioceptive sensory systems. Using a highly stretchable textile as a pressure-sensitive responsive interface suggests that deep-pressure can be provided as a part of activities aimed at developing fine motor skills.
Objectives: To improve the grading and quality of fine motor movements.
Methods: The technology utilizes custom knitted textiles as highly stretchable, pressure-sensitive interfaces. The Microsoft Kinect is used to measure the amount of pressure being applied at any point on the textile.Two prototypes have been developed, StretchCOLOR and StretchPLAY, to test the efficacy of activities using large-scale textile interfaces for improving quality of movement. StretchCOLOR acts as a large-scale coloring book where increasing pressure on the textile changes the hue of the color being used, for instance an initial touch outputs a red color, changing to orange and yellow as the amount of pressure applied increases. StretchPLAY is a large-scale play structure where climbing along and through the stretchy textile surface triggers various sounds clips to play and animations to be projected onto the textile.
Results: Diagnostics in the software are measuring aspects of interacting with the textile interface such as frequency of touches to determine pace of movement, depth of touch to determine range of pressures being applied, and location of touch to determine amount of task being completed. Data is currently being collected with the prototypes

being used regularly as a part of the ABA program of several children at a local therapy center.
Conclusions: The development and application of this technology involves collaboration between architecture, psychiatry and kinesiology. It looks to create a robust multi-sensory experience of technology, providing activities aimed at developing fine motor skills. Through anecdotal evidence, the technology has shown to be engaging, rather than engrossing, allowing children to enjoy the activities while secondarily encouraging social interaction.



248 **142.248** The Sensory Toy Box: An Interactive Game-Based Technology As an Assessment Tool

S. Valencia[1], *P. Perez Fuster*[2], *M. Mademtzi*[1], *L. Hart*[1] *and F. Shic*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Autism Research Group. Robotics Institute, University of Valencia, Valencia, Spain*

Background: The diversity of sensory styles in individuals with ASD has been widely reported in the literature (Bogdashina, 2003). These diverse sensory profiles have a direct impact on the individual's response to the environment and their perceptual experience. Available evidence suggests that perceptual alterations, independent from social function, can be present in many individuals with ASD (Behrmann et al., 2006). Learning about each individual's sensory profile can help identify sensory strengths and weaknesses that can assist in the selection of appropriate methods for teaching and treatment (Bogdashina, 2003). Current assessment tools to determine sensory profiles are questionnaire based and typically completed by parents. Collecting data on sensory preferences directly from individuals with ASD seems to be challenging, especially from minimally verbal children. An Interactive game-based technology was developed to help children with visual impairments learn about touch perception and to promote their sensory abilities (Valencia & Uribe, 2014). This device presents visual, auditory and tactile features that can also be beneficial for children with ASD and can provide a framework for data collection on individual sensory preferences.
Objectives: the objective of this study is to present a novel interactive technology based on the Valencia & Uribe (2014) prototype that can be used as an assessment tool for the evaluation of sensory preferences in children with ASD.
Methods: The sensory toy box for children with ASD is a device that recognizes different tangible inputs using Radio-frequency identification (RFID) technology. The device is also linked to an app, used for stimuli presentation on a tablet. The tangible inputs, figurines or shapes, have RFID tags that can be programmable through RFID writer devices to create a desired response on the toy box. The user selects tangible objects based on auditory and visual prompts he or she receives from the box or tablet. The system allows data collection on the: 1) frequency of selection of each object and 2) the order in which each object is placed on the box according to each stimulus presented.
Results: In Valencia & Uribe's study, participants included children with visual disability (1 male, 4 females; Mage=7±0.82) and children without visual disabilities (2 males, 1 female; Mage=7.33±0.57). Through different game modes (i.e. storytelling, letters, and musical) and the use of auditory cues, visual rewards and tactile stimulation, the children in this study interacted positively with the toy box. Difficulties in concept associations to physical objects were identified in 3 of the participants. This result opens the way to explore the potential of using different sensory stimuli targeting the auditory, tactile and visual systems to discover strengths and weaknesses in sensory processing in children with ASD.
Conclusions: In this work we have developed an interactive technological tool to assist in the evaluation of sensory preferences in children with ASD. Data collection is ongoing, and by May of 2016 we expect to present on the interactions of 4-6 minimally verbal children with ASD on the toybox.

Poster Session
143 - Animal Models
11:30 AM - 1:30 PM - Hall A

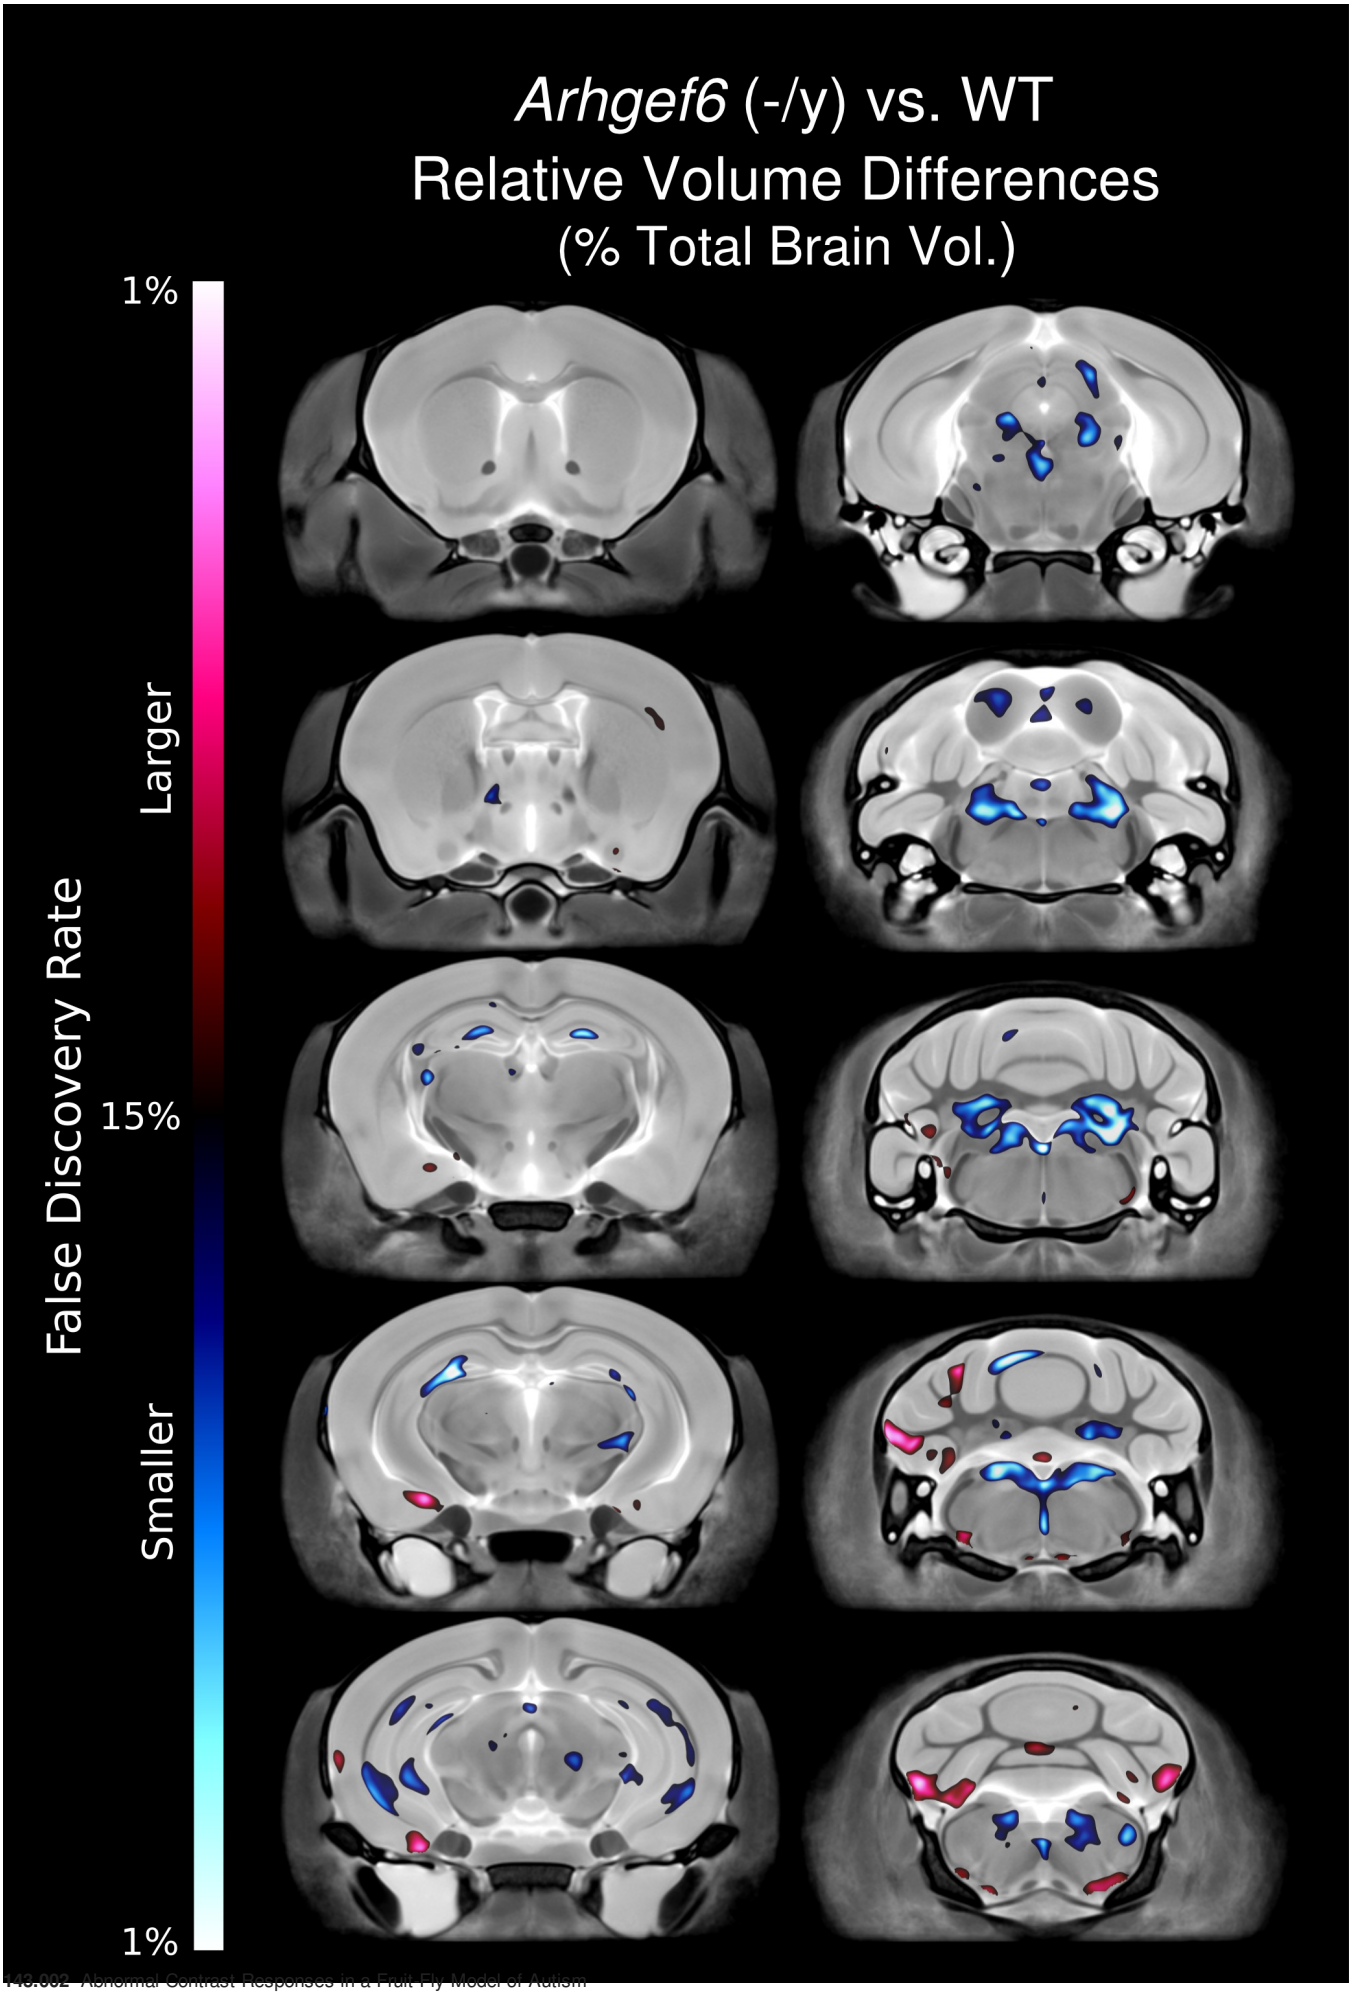
1 **143.001** A Novel Arhgef6 Mouse Model Shows Focal Volume Loss in the Hippocampus and Deep Cerebellar Nuclei

J. Ellegood[1], *R. Yuen*[2], *A. Creighton*[3], *L. Spencer Noakes*[1], *B. J. Nieman*[1], *L. Nutter*[3], *S. W. Scherer*[2] *and J. P. Lerch*[1], *(1)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (2)Centre for Applied Genomics (TCAG), Hospital for Sick Children, Toronto, ON, Canada, (3)Canadian Mouse Mutant Repository, Toronto Centre for Phenogenomics, Toronto, ON, Canada*

Background: Mutations in the *ARHGEF6* (Rac/Cdc42 Guanine Nucleotide Exchange Factor (GEF) 6) gene have been previously linked to non-specific X-linked mental retardation (Kutsche et al. 2000). A null-mutant was previously created and characterized using histology and electrophysiology (Ramakers et al. 2012). That study found that the gross brain structure appeared normal; however, Golgi staining revealed an increase in both dendritic length and spine density in the hippocampus. Mutations in *ARHGEF6* haven also been recently found in autism (Jiang et al. 2013).
Objectives: To assess the neuroanatomical differences in a novel autism gene candidate, *ARHGEF6* with high-resolution structural MRI.
Methods:
A novel *Arhgef6* loss-of-function mouse model was produced from targeted-trap C57BL/6N ES cells (*Arhgef6*$^{tm2e.1(EUCOMM)Wtsi}$/Tcp) and maintained on a C57BL/6N background. As a first screen 31 fixed mouse brains were examined. Sixteen of which were *Arhgef6*(tm1e.1/y) mice and the other 15 were WT controls (C57BL6/N). The mice were P60 ± 2 days.
MRI Acquisition – A multi-channel 7.0 Tesla MRI scanner was used to acquire anatomical images of the brain. A T2-weighted, 3-D fast spin-echo sequence was used (restricted sampling to a circular region in the two phase encode dimensions). This sequence yielded an image with 40 µm isotropic voxels (3D pixel) in ~14 h.
Data Analysis – To visualize and compare any differences the images from each group are registered together. The goal of the registration is to model how the deformation fields relate to genotype (Lerch et al., 2008). Volume differences are then calculated either in individual voxels or for 159 different segmented regions (Dorr et al. 2008, Ullmann et al. 2013, and Steadman et al. 2014). Multiple comparisons were controlled for using the False Discovery Rate (FDR) (Genovese et al., 2002).

Results: The total brain volume was unchanged (432 ± 6 mm^3 for *Arhgef6*(-/y) and 432 ± 14 mm^3 for WT); however there was a significant difference in the variability in the groups (p=0.02, Levene's test). After normalizing for total brain volume, 11 of the 159 regions were found to be significantly different at an FDR of <5%. Notable decreases were found in the hippocampus (-2.57%, FDR<1%), the inferior and superior colliculi (-3.74 and -3.36, respectively, both FDR <1%), and all three deep cerebellar nuclei, namely the dentate nucleus (-2.65%, FDR=6%), nucleus interpositus (-4.81, FDR <1%), and fastigial nucleus (-4.05, FDR <1%). These findings can also be seen voxelwise in Figure 1.

Conclusions: Ramakers et al. reported that *Arhgef6* was primarily expressed in the hippocampus, where we also identify significant volume losses. In addition, we also identified focal alterations in the deep cerebellar nuclei, supporting recent evidence implicating cerebellar outputs in autism and mental retardation.

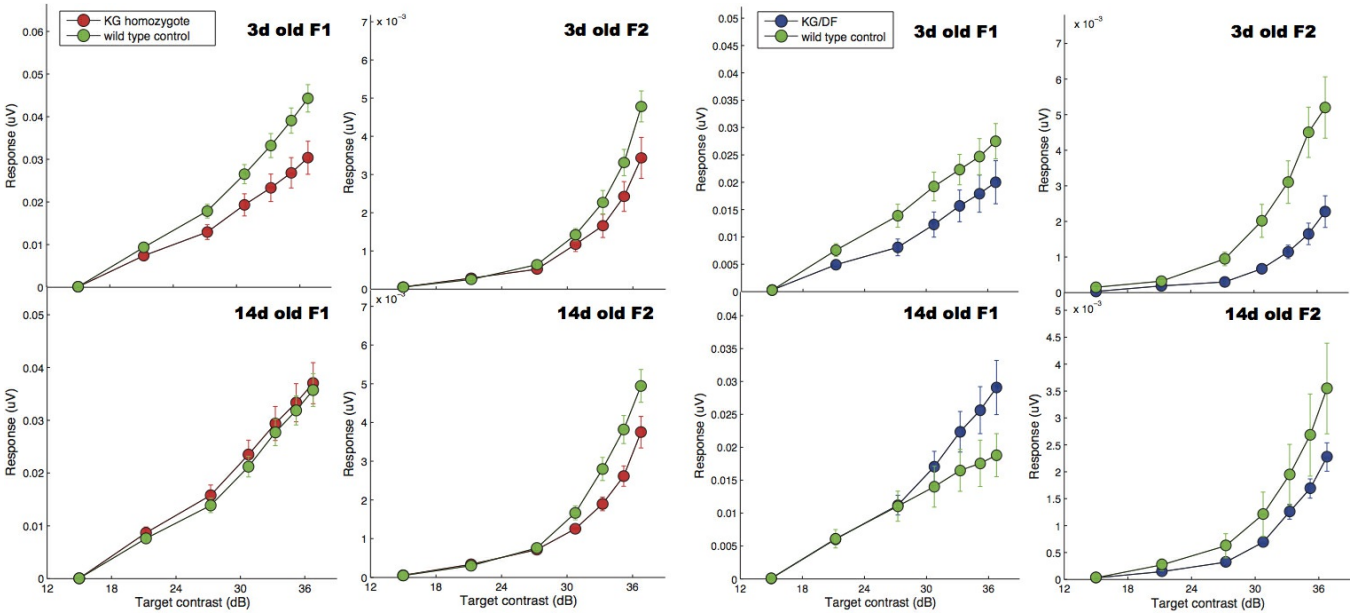


T48.002 - Abnormal Contrast Responses in a Fruit Fly Model of Autism

G. Vilidaite[1], *D. H. Baker*[2], *A. R. Wade*[3] *and C. J. Elliott*[4], *(1)University of York, York, England, United Kingdom, (2)Department of Psychology, University of York, York, United Kingdom, (3)Department of Psychology, The University of York, York, United Kingdom, (4)Department of Biology, The University of York, York, United Kingdom*

Background:

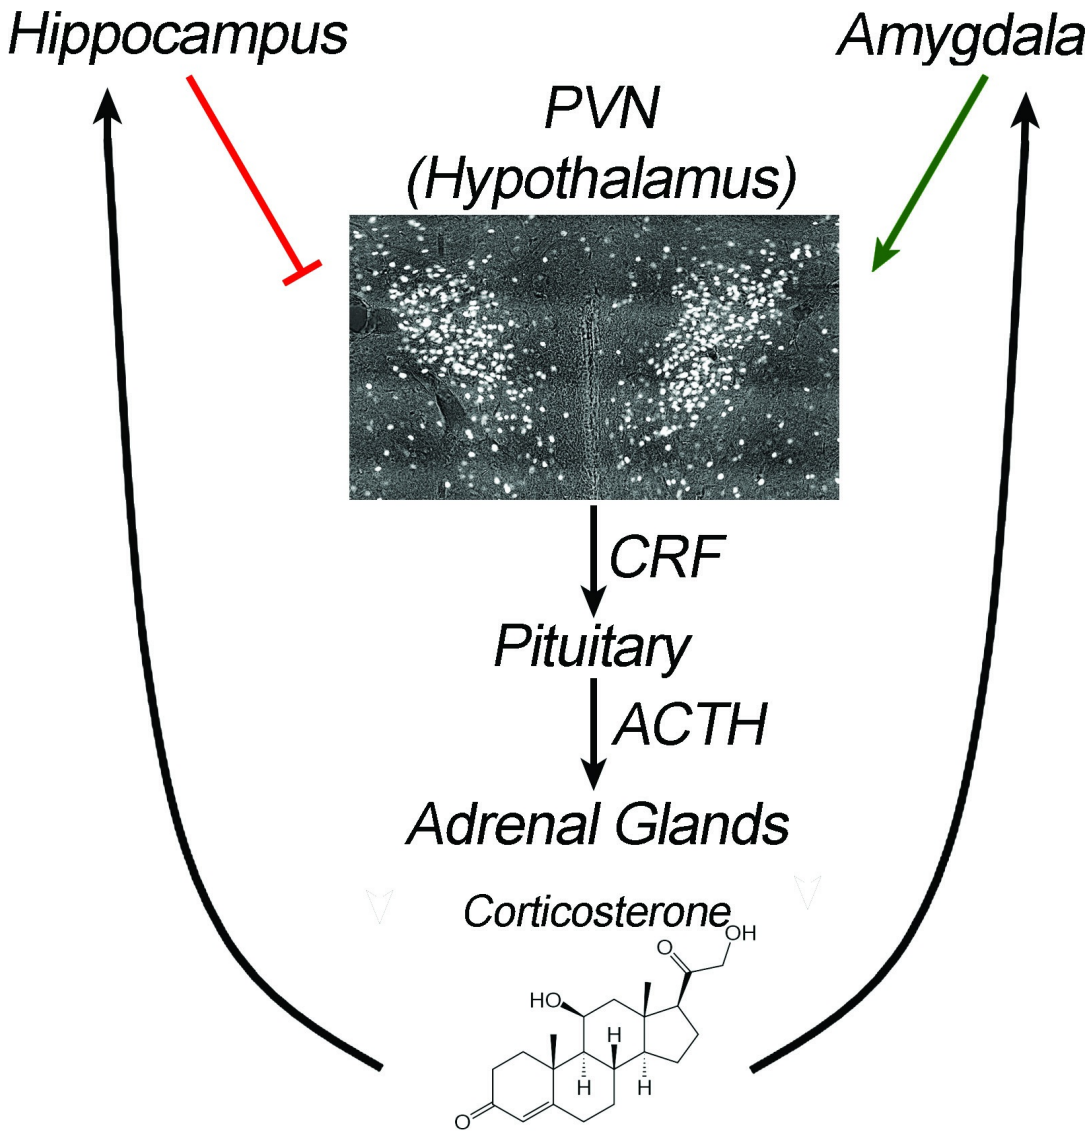
Sensory abnormalities, such as hypersensitivity to bright lights and loud sounds, are a common symptom in human autism spectrum conditions (ASC). Here we investigate a potential biological and genetic underpinning of these effects using a fruit fly model of autism. Mutations in the sodium-hydrogen exchanger gene Nhe9 have been linked with ASC in humans (Morrow et al, 2008), and the fly homologue is the Nhe3 gene.
Objectives:
We investigated whether Nhe3 mutations affect visual responses in Drosophila.
Methods:
Two stocks of *Drosophila* were used: a mutant (KG) and a gene deficiency (DF). Matched eye-colour controls were used. SSVEP (Steady State Visual Evoked Potential) electroretinograms (Afsari et al, 2014) were recorded at 3 and 14 days old (i.e. juvenile and adult flies). The stimulus was a flickering blue LED, with 12Hz temporal frequency and 7 contrast levels (0-69%). The mean amplitudes for each contrast level for the target frequency (1F, primarily the photoreceptor response) and second harmonic (2F, primarily post-retinal neural responses) were calculated. We tested at least 12 flies of each genotype and age, and averaged amplitudes across all individuals.
Results:
All Nhe3 mutant genotypes differed substantially from wild type controls and heterozygotes (mutant-wild type crosses). The key finding is that young (3-day-old) KG homozygote flies show reduced response amplitudes at 1F and 2F (both 30% less than wild types). This was confirmed by testing the KG/DF cross: at 3 days these also had lower response amplitudes at both 1F and 2F. Older (14 days) KG and KG/DF flies had still had reduced 2F responses but their 1F responses were bigger than the controls. The 1F responses of 14-day-old flies were bigger than the 3-day-old flies.
Conclusions:
ERG response amplitudes differ between ASD model fruit flies and wild type controls at both 3 and 14 days of age. Fourteen-day-old mutants show increased sensitivity in photoreceptors as indicated by higher 1F amplitude but decreased response from more complex cells (lamina neurons) as evidenced by their lower 2F amplitudes. This suggests that the transfer from photoreceptors to neurons higher up in the visual stream is reduced. Our results demonstrate that the Nhe3 gene has a critical impact on multiple stages of the visual pathway, and may also mediate neuronal health and function more widely throughout the nervous system. In a companion study, we report analogous effects in EEG data from human adults with a clinical ASD diagnosis (compared with age-matched controls), and in the normal population as a function of autistic traits. The fly data therefore provide a possible genetic model for sensory abnormalities in human autism.



3 **143.003** Autism Mouse Model Exhibits Dysregulated Norepinephrine Innervation and Neural Activity in the Limbic System

C. C. Peng[1,2], *J. Lunden*[1], *M. Genestine*[3], *V. Mirabella*[4], *S. Prem*[5] *and E. DiCicco-Bloom*[6], *(1)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (2)Rutgers University, New Brunswick, NJ, (3)UMDNJ, Piscataway, NJ, (4)Child Health institute of New Jersey, New Brunswick, NJ, (5)Neuroscience, Graduate School of Biomedical Sciences, Piscataway, NJ, (6)Rutgers University - Robert Wood Johnson Medical School, Piscataway, NJ*

Background:
Autism Spectrum Disorder (ASD) is characterized by abnormalities in social interaction and restricted/repetitive behaviors. *Engrailed-2 (En2)*, a gene associated with ASD, is a neural patterning transcription factor involved in the development of the embryonic mid-hindbrain region, where norepinephrine (NE) producing neurons emerge. Previous studies indicate that *En2* knockout (*En2*-KO) mice display ASD-like deficits in social interactions, fear conditioning, and depression-related tasks (forced swim, tail suspension), which implicate abnormal stress responses. Environmental stressors elicit physiological responses by increasing Hypothalamus-Pituitary-Adrenal (HPA) axis activity, which initiate in the paraventricular nucleus of the hypothalamus (PVN). HPA axis activation, specifically PVN activity, is modulated by projections from limbic structures, including the amygdala (stimulatory) and the ventral hippocampus (VH) (inhibitory) (Figure 1). While dorsal forebrain structures in the *En2-KO* exhibit reduced NE levels and fiber innervation, innervation patterns into the ventral limbic system, including amygdala and PVN, are undefined.
Objectives:
Characterize NE fiber innervation into the basolateral amygdala (BLA) and PVN using biochemical and anatomical approaches, and determine whether neural activity, indicated by c-Fos immunohistochemistry, in BLA, PVN, and VH following swim-stress correlates with NE innervation.
Methods:
In postnatal day 60-70 wild type (WT) and KO mice (N=4-6/genotype), western blot analysis was performed to determine protein levels of norepinephrine transporter (NET) and tyrosine hydroxylase (TH). NET-containing fibers in BLA and PVN were assessed on tissue sections using immunohistochemistry. To measure stress response, animals were given 10 minutes of swim stress followed by PFA fixation via cardiac perfusion at 120 to 140 minutes. All perfusions occurred between 2:30 to 4:30 PM EST.
Results:
En2-KO mice exhibited increased NET (1.7-fold, $p<0.02$) and TH (1.5-fold, $p<0.002$) protein levels in the amygdala. NET fiber counts were also increased in BLA (2.3-fold, $p<0.0007$) and PVN (1.7-fold, $p<0.016$). Following swim stress, *En2*-KO mice exhibited increased c-Fos nuclei in PVN (2.25-fold, $p<0.006$), suggesting an increase in neural activity. However, c-Fos nuclei were decreased in VH (50%, $p<0.02$) of the same animals following swim stress, suggesting decreased post-stress neural activity in VH.
Conclusions:
Our observations indicate that *En2*-KO mice are hyperinnervated by NE fibers in the PVN and BLA. Additionally, neural activity in the PVN is increased >2 fold under stress conditions, changes that parallel fiber innervation. Conversely, in the hippocampus, where NE levels and fibers are reduced (Genestine et al, 2015), there is a 50% decrease in c-Fos activity. Given that the amygdala plays a stimulatory role and the VH elicits inhibition in the PVN, the changes we detect in fiber patterns and neural activity would be predicted to exaggerate stress circuit activation and responses, which in turn likely contribute to the *En2*-KO deficits in social interactions, fear conditioning, and depression-related tasks. More generally, these studies of the *En2*-KO mouse model provide insights into neurobiological mechanisms by which common genetic variants associated with neurodevelopmental disorders alter the balance of neural pathways. Consequently, these structural and functional differences may increase subject vulnerability to other genetic and environmental factors in disease causation.



4 **143.004** Autism-Associated Gene Engrailed-2 Plays a Cell Autonomous Role in Regulating Proliferation and Cell Death in Hippocampal Neural Stem Cells in Vitro

***M. Durens**, S. Chung and E. DiCicco-Bloom, Rutgers University - Robert Wood Johnson Medical School, Piscataway, NJ*

Background: *Engrailed-2 (En2)* is a homeodomain transcription factor important in the proper development of the cerebellum and midbrain. Two intronic single nucleotide polymorphisms were shown to be over-transmitted to individuals with autism spectrum disorder (ASD) compared to unaffected siblings. Similar neuropathology is observed in the cerebellum of *En2* knockout (*En2*-KO) animals and some ASD patients, including reduced cerebellar vermis size, decreased Purkinje neuron numbers, and defects in foliation. More recently, there is increased attention to changes in the forebrain, in part because ASD-related behavioral phenotypes in the *En2*-KO, such as deficits in social interactions, fear conditioning and learning, depend on forebrain circuits. These behaviors are accompanied by structural changes, including reduced weight, size and cell number in several areas including hippocampus, likely reflecting abnormalities in neurogenesis. Indeed, *En2*-KO exhibits ~2-fold increases in stem cell proliferation and immature neuron apoptosis in the dentate gyrus, which implies that En2 activity in the brain can regulate proliferation and cell survival in the hippocampus. While these differences have been attributed to reductions in norepinephrine innervation, very low levels of *En2*are detected in the hippocampus, raising the possibility of cell autonomous functions.
Objectives: This study seeks to examine cell autonomous roles for *En2* in regulating hippocampal neurogenesis by showing that (1) stem cells cultured in vitro as neurospheres express *En2*, and (2) the absence of *En2*in cultured cells leads to increased proliferation and apoptosis.
Methods: Hippocampi from P7 *En2*-KO and WT mice were dissociated and cells were plated in defined media containing 2% B27 supplement, 20 ng/ml EGF and 10 ng/ml FGF. *En2* mRNA expression was assessed using quantitative PCR. Primary neurospheres were assayed for neurosphere numbers and size after 7 days in culture. Immunofluorescent labeling of whole neurospheres was performed to determine rates of proliferation (BrdU incorporation) and apoptosis (cleaved caspase-3, pyknosis). Experiments were performed at least 3 times, with each experiment consisting of at least one WT and *En2*-KO culture.
Results: Expression of *En2* mRNA as well as its homolog *Engrailed-1* was detected in WT neurospheres. While primary neurosphere assays revealed no change in numbers of primary spheres, measurement of sphere diameter showed increased frequency of larger spheres in *En2*-KO, suggesting potential effects on proliferation and/or survival. Compared to WT neurospheres, the *En2*-KO exhibited a 2-fold increase in BrdU labeling ($p<0.005$) as well as apoptosis ($p<0.05$).
Conclusions: This study suggests that *En2* plays a role in regulating proliferation and apoptosis in hippocampal neural stem cells. While evidence of *En2* expression in hippocampal dentate gyrus cells *in vivo* remains uncertain, we were able to show expression of *En2* in neural precursor cultures. Furthermore, increased proliferation and cell death observed in *En2*-KO neurosphere cultures recapitulates what is observed *in vivo*, suggesting that *En2* may inhibit proliferation and promote survival in a cell autonomous manner. More broadly, these studies indicate how the activities of developmental regulatory genes in diverse brain regions impact brain structure and function, and may contribute to our understanding of how ASD-related behaviors occur in the *En2*-KO mouse.

5 **143.005** Bioinformatics Analysis of Phenotypic Data of ASD Rodent Models

*I. Das, **M. A. Estevez** and S. B. Basu, MindSpec, Inc., McLean, VA*

Background: The Autism Database (AutDB) is a publicly available, manually annotated, modular database that serves as an ongoing collection of genes linked to Autism Spectrum Disorders (ASD). The animal model module of AutDB catalogues over 600 ASD-related rodent models, extracted from primary literature.
Objectives: Although there have been other comparative analyses of ASD rodent models, they have been limited in scope, both in terms of the number of animal models and the extent of phenotypic assessments used. By looking at the total data sets of rodent models that is available in AutDB, we are expanding our analysis to more than 600 ASD rodent models, and about 375 phenotypic parameters, divided in 16 larger categories. A bioinformatics analysis of this scope can be used to elucidate ASD research trends and etiology
Methods: All data is extracted from published, peer-reviewed primary reports. The metadata is standardized in a phenotypic database, which is a routinely updated comprehensive list of phenotypic terms (pheno-terms) and experimental paradigms. These pheno-terms reflect the actual research and are divided into categories that align with human ASD phenotypic features. For each individual model, annotated pheno-terms contain a given value (e.g. *increased*, *decreased*, *no change*, *abnormal*). Using the aggregate of these pheno-term values, models are clustered into functional groups.
Results: ASD rodent models cluster based on phenotypic data that reflect neurophysiological, behavioral and developmental complexity. By looking at a broad genetic and environmental model set we are able to ascertain common underlying biological mechanisms in ASD etiology.
Conclusions: The AutDB animal model module serves as a detailed repository of rodent model phenotypes reported in the ASD field. The scientific standardization of phenotypic parameters allows for data mining and bioinformatics analysis. Our present analysis provides a glimpse of the complexity of ASD etiology, and allows us to visualize the contribution of both genetic and environmental factors by using animal models.

6 **143.006** Characterization of Four ASD Mouse Models Reveals Common Behavioral Phenotypes and Transcriptional Networks in the Striatum

*O. Oron[1], S. Shohat[2], E. Reuveni[1], S. Shifman[2] and **E. Elliott**[1], (1)Faculty of Medicine, Bar Ilan University, Safed, Israel, (2)Hebrew University of Jerusalem, Jerusalem, Israel*

Background:
In recent years, multiple mouse models have been produced to study autism. In order to gain high-impact information from these mice models, we propose that the parallel behavioral and molecular phenotyping of several mouse models will help to identify behaviors and molecular mechanisms that are in common, and are therefore more likely to be directly involved in autistic behavior.
Objectives:
In our current study, we looked at locomotor function, anxiety, and risk assessment behaviors in four well-established autism mouse models. In order to discover common molecular pathways that are dysregulated in all mouse models, we did whole transcriptome sequencing (RNA-seq) of the striatum of these mice models. By comparing the behavior of these multiple models and the transcriptome dysregulation in the striatum, a brain area highly involved in these behaviors, we can determine specific molecular mechanisms that are directly responsible for the relevant behavioral dysfunctions.
Methods:
We performed motor-related and risk- assessment related behavioral and molecular experimentation on four mouse models of ASD: Shank3 KO, CNTNAP2 KO, Chr16p11.2del, and BTBR mice. We performed Open Field (OF), rotorod, Dark Light (DL), and Elevated Plus Maze (EPM) on all mouse models. We used this data to quantify locomotor function, anxiety-levels, and risk assessment behaviors. RNA was extracted from the striatum of all four mouse models, and their controls, and performed whole throughput RNA sequencing (RNA-seq) on all samples. RNA-seq data was analyzed by both differential expression and WGCNA (Weighted Gene Correlation Network Analysis) to identify genes that are dysregulated in all models and that correlate with the behavioral phenotypes.
Results:
We found that all four mouse models showed either hyperactive or hypoactive behaviors (Shank3 KO was hypoactive, and the others are hyperactive), and all mouse models showed differential behavior in the anxiety/risk assessment tests. Of interest, we found that all genetic mouse models displayed a decrease in risk assessment behavior. Striatal gene expression analysis found that three of the four models share 31 genes that are commonly upregulated, including IGF2, IGFBP2, and Sema3b. WGCNA analysis, followed by protein-protein interaction networks, found that specific gene expression networks, such as networks including HDAC genes, could be correlated to the dysregulated risk assessment behavior in the autism mouse models.
Conclusions:
Common dysfunctions in risk assessment and locomotor behaviors are found in multiple autism mouse models. In addition, we can correlate these behaviors to distinct gene expression networks. This study provides evidence that we can discover novel molecular pathways involved in the autism-related behavior through the parallel molecular and behavioral phenotyping of multiple autism mouse models.

7 **143.007** Conserved GABA/GAMMA Coupling Is Seen in a Translational Preclinical Model That Recapitulate a Key Aspect of ASD

***R. G. Port**[1], G. C. Carlson[2] and T. P. Roberts[3], (1)Neuroscience Graduate Group, Biomedical Graduate Studies, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (2)Psychiatry, University of Pennsylvania, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA*

Background:
Autism spectrum disorders (ASD) have been hypothesized to arise from an imbalance of excitation and inhibition (E/I imbalance). In both clinical and preclinical studies, E/I imbalance has been repeatedly observed using a wide range of techniques. One result of E/I imbalance could be altered gamma-band activity (GAMMA), which is thought to be heavily reliant on inhibition for its generation. Accordingly, concurrent to the E/I imbalance findings, alterations to GAMMA are present across modalities in ASD, being recapitulated by multiple independent groups. These GAMMA deficits are also present in preclinical models recreating key aspects of ASD.

In healthy adults GAMMA is related to GABAergic tone in both motor and visual systems, though not without controversy. Preliminary work suggests this is also true for the auditory system, and that concomitant decreases in both GABA and GAMMA are present in ASD within the same participants. Furthermore, the biological coupling of neurochemistry and neuronal GAMMA activity is conserved is ASD. What remains to be known is if this GABA/GAMMA coupling seen in humans translates to pre-clinical phenotypes (as with E/I imbalance and GAMMA activity separately).
Objectives:
Determine if the GABA/GAMMA coupling seen in the auditory system of both typically developing participants and participants with ASD, is recreated in an animal model that recreates a key aspect of ASD.
Methods:
Magnetoencephalography (MEG) and magnetic resonance spectroscopy (MRS) was used to record neuronal activity and GABAergic tone (respectively) in both typically developing participants and participants with ASD. This was contrasted to translational pre-clinical findings from an animal model that recapitulates key aspects of ASD (Protocadherin 10 heterozygous mice [PCDH10 +/-]) and their wild-type counterparts. In-vivo electroencephalography (EEG) and high performance liquid chromatography (HPLC) recorded neuronal responses and inhibitory tone in these mice respectively. To allow for comparison of electrophysiological data, near identical analyses are implemented for both clinical and pre-clinical data.
Results:
GABA and GAMMA are correlated in both typically developing participants and participants with ASD (R^2_{TD}=0.31, $p<0.05$; R^2_{ASD}=0.13, p<0.05), with no difference between group level regression slopes (difference in slope of regression $p>0.1$). While separating based on genotype was not possible due to insufficient sample size, GABA and GAMMA appear correlated in PCDH10 +/- and their wild-type counterparts (R^2 =0.41, $p<0.05$).
Conclusions:
Typically developing participants and participants with ASD demonstrate an association between GABA and GAMMA, with the coupling conserved between groups. A pre-clinical murine model of ASD and their wild type counterparts also demonstrated such a relationship, suggesting this phenotype is conversed across species. Further study is needed to determine if within group associations of GABA and GAMMA differ between PCDH10 +/- mice and their wild type counterparts.

8 **143.008** Effects of Pargyline and Para-Chlorophenylalanine on Mouse Social Behavior

***G. G. Gould**[1], N. Witt[2], J. Allen[2] and A. Sanchez[3], (1)The University of Texas Health Science Center at San Antonio, San Antonio, TX, (2)Biology, University of Texas at San Antonio, San Antonio, TX, (3)Biology, St. Mary's University, San Antonio, TX*

Background: Impaired social behavior is a core symptom of autism that also appears in other psychiatric disorders like schizophrenia, bipolar disorder and depression. It has proven to be among the most treatment-resistant of psychiatric illness symptoms. Serotonin (5-HT) is a monoamine neurotransmitter that regulates mood balance in the brain, it is also a strong shaper of social behavior. For example in some patients and in mice sociability deficits in behavior tests worsen with decreases in 5-HT availability, but improve following administration of the selective serotonin reuptake inhibitor (SSRI) fluoxetine, which enhances 5-HT neurotransmission.
Objectives: The purpose of this study was to determine if increasing serotonin availability in the brain would correspond with improvements in sociability. Conversely we predicted that reducing serotonin availability in the brain would worsen sociability in either innately gregarious or socially deficient mice.
Methods: To test this hypothesis, we performed social interaction, social novelty, locomotor and repetitive behavioral tests on BTBR mice, a socially deficient s inbred strain, and C57BL/6 mice, which display normal social behaviors. Before testing, adult males of both strains were given either a single injection of 100 mg/kg pargyline, a monoamine oxygenase inhibitor, to block the metabolic breakdown of 5-HT in the brain, or 300 mg/kg over 3 days of para-chlorophenylalanine (PCPA), a tryptophan hydroxylase inhibitor to block 5-HT synthesis in the brain. Controls were treated with vehicle on the same schedule with the drug treatments. The behavioral tests employed

were mouse three-chamber sociability and marble burying as an index of restrictive repetitive behavior.
Results: We observed in social interaction preference tests that PCPA treatment enhanced PCPA increased locomotor activity in C57BL/6, but not BTBR mice. More critically PCPA reduced social interaction preference in both strains, with little effect on social novelty preference. On the other hand, pargyline enhanced social interaction preference in C57BL/6 and social novelty preference in both strains. Marble burying was unchanged by either PCPA or pargyline treatments.
Conclusions: Findings from our study demonstrate that pargyline likely induced increases in brain serotonin concentrations that enhanced social behavior in both socially impaired mice, and normal mice. Conversely they also show that PCPA induced-decreases in available brain serotonin generally suppressed mouse sociability. Overall, these findings lend further support to the hypothesis that sociability is shaped by central 5-HT availability.

9 **143.009** Efficacy of Risperidone in an Insulin-Resistant Mouse Model of Hyperactivity and Deficient Sociability

***V. R. Garbarino**, UTHSCSA, San Antonio, TX*

Background: Many patients with autism are given risperidone, an atypical antipsychotic, to control restrictive-repetitive behaviors, impulsivity and aggression. Risperidone has tranquilizing properties, mediated primarily by its actions as an antagonist at dopamine D_2 receptors, and risperidone does little to promote social interaction behavior in most patients. Unfortunately, long-term use of risperidone often produces serious metabolic side-effects including increased appetite, obesity, and early onset of type II diabetes. In doing so, risperidone may also modify the dopaminergic response of patients by elevating their insulin levels. This is because insulin enhances the function of dopamine transporters, making them more efficient at removing dopamine from brain extracellular fluid.
Objectives: We hypothesize that elevated insulin levels will enhance the expression and function of dopamine transporters and D_2 receptors, and mute behavioral responses to risperidone treatment. This hypothesis was tested in mice with natural mutations that alter circulating levels of insulin. Since autism is 5x more prevalent in males than in females, and because insulin levels in male mice were more responsive to these genetic modulators, only male mice were used in this study.
Methods: Black-and-tan Brachyury Tufted (BTBR T+Itpr^{3}tf/J mice, crossed with C57BL/6 mice yield F1 hybrid offspring that are socially impaired and insulin resistant. The F1 mice have increased abdominal adiposity, and elevated insulin levels relative to either parent strain by 10 weeks of age. Levels of insulin are greatest in F1 hybrids > BTBR > C57BL/6 mice. These mice were treated acutely with risperidone (0.01 mg/kg) or vehicle and behaviorally tested in three-chamber sociability and marble burying tests. Their social dominance was also compared in a tube test. Brains from naïve mice were also used in-vitro in radioligand binding and uptake studies for the dopamine transporter and D2 receptor to compare binding site density and functional response in mice within a physiologically-relevant range of insulin levels.
Results: F1 mice were socially deficient in three-chamber tests, and were more impulsive than either parent strain in a social dominance test. Their social and repetitive behavior was not improved by risperidone administered acutely. In fact, risperidone treatment was less effective in BTBR and F1 hybrid mice at reducing marble burying than it was in C57BL/6 mice. [^{3}H] WIN 35,428 binding to dopamine transporters was similar among strains, but [^{3}H] dopamine uptake was significantly increased in BTBR mice. [^{3}H] dopamine binding sites were higher in BTBR and F1 hybrids than in C57BL/6 mice.
Conclusions: Dopamine transmission may be suppressed in F1 and BTBR mice by elevated insulin levels, which may alter their responsiveness to risperidone. As evidence of this, marble burying in F1 mice was unaffected by an acute risperidone treatment, while the same dose of risperidone reduced this in C57BL/6 mice. The BTBRxBL6 F1 mouse appears to be a useful physiological model for investigation of long-term drug treatment effects on the social brain and on glucose metabolism.

10 **143.010** Estrogen Receptor Î² Protects Against ASD-like Behavior in Mice

***A. M. Crider**, Georgia Regents University, Augusta, GA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder affecting 1 in 68 children in America and approximately 1% of the population worldwide. Although the underlying neurobiological mechanism for ASD pathophysiology is not clear, recent studies have suggested the role of endoplasmic reticulum stress in ASD. Moreover, our recent study has shown that ER stress induces ASD-like behavior including communication deficits, social deficits, depressive behavior, and repetitive behavior mechanism in mice. ASD is generally thought to be gender-specific with 5 times more males diagnosed with the disorder than females suggesting a potential role of female sex hormones in ASD. We recently showed that estrogen receptor β (ERβ) is reduced in the prefrontal cortex of ASD subjects as compared to age- and gender-matched control subjects. However, the mechanisms behind this deficit are not known.
Objectives: This study aims to determine whether estrogen receptor β signaling can protect against endoplasmic reticulum (ER) stress induced behavioral deficits in mice.
Methods: ER stress was induced by administering tunicamycin (1mg/kg I.P.) to mice. Protein levels were measured by western blot analysis whereas RT-PCR was used for gene expression analysis. Behavioral tests were performed including ultrasonic vocalization recordings, social interaction test, grooming test, marble bury test, forced swim test, tail suspension test, and open field test. The role of ERβ was examined by pharmacological as well as genetic manipulations in mice.
Results: We found that ER stress in mice reduces ERβ signaling in mouse frontal cortex. ER stress induced ASD-like behavior such as social deficits, depressive-like behavior, increases in obsessive behaviors, and communication deficits. Moreover, boosting ERβ signaling could reverse ER stress-induced deficits in ASD-like behavior in mice.
Conclusions: ERβ is a possible target for treatment of ASD and related neurodevelopmental disorders.

11 **143.011** Exposure of Juvenile Mice to High-Dose Acetaminophen Confers Elevated Serum Cytokine Levels and Sociability Impairments in Adulthood

***M. T. Edwards**[1], G. G. Gould[1], S. T. Schultz[1] and R. Alvarez[2], (1)Physiology, The University of Texas Health Science Center at San Antonio, San Antonio, TX, (2)Naval Medical Research Unit, JBSA Fort Sam Houston, TX*

Background: Epidemiological evidence suggests that exposure of children younger than 5 years old to acetaminophen may be problematic for social brain development if it can't be properly metabolized. Conjugative disposition pathways may be underdeveloped or compromised in some children treated with acetaminophen. Oxidative degradation pathways for acetaminophen are capable of triggering immune responses. We hypothesized that immune system activation could potentially disrupt juvenile brain development to produce autism-like behaviors in mice. However, the specific factors mediating these effects have not been described, although parallels have been described for mice treated with valproic acid. We have used high dose acetaminophen exposures in juvenile mice (P18-21) to explore mechanisms that might compromise sociability in this population of acetaminophen sensitive children.
Objectives: The hypothesis underlying this study was that high-dose (>100 mg/kg) acetaminophen exposure in weanling (PD 18-21) mice might trigger unique and enduring immune responses that correspond with impairments in the social behavior of C57BL/6J mice, or worsening of them in socially deficient BTBR mice. These enduring changes in the immune system may persist and serve as biomarkers of such exposures.
Methods: Male C57BL/6 and BTBR mice were exposed for 4 days to injections of acetaminophen (400 mg/kg) or vehicle (saline + 10% DMSO), and matured to adulthood (PD 80). Three chamber sociability tests of C57BL/6 mice revealed a significant ($p<0.05$) reduction in social interaction relative to vehicle controls that was comparable to prenatal treatment with valproic acid. However, the social behavior of BTBR mice was unaffected. We postulated that persistent adverse immune responses might have contributed to this outcome. Serum collected after the behavior tests was used for cytokine and chemokine measurements performed using the Bio-plex mouse cytokine 23-plex panel on the Bio-plex 200 suspension array system.
Results: Eotaxin levels were significantly higher in C57BL/6 adults treated as juveniles with high dose of acetaminophen. These mice also had high levels of TNF-α and G-CSF, both of which act as stimulation factors for granulocytes. In contrast, in BTBR mice, eotaxin levels were low and along with G-CSF, they remained unaffected by acetaminophen. TNF-α expression was reduced in acetaminophen treated BTBR relative to controls. Eotaxin can inhibit neurogenesis, particularly in the hippocampus. We therefore looked for evidence of reduced hippocampal serotonergic neuronal density based on saturated serotonin transporter binding by quantitative autoradiography, but we found no difference from control treatment values. However, the elevated eotaxin levels in C57BL/6 treated as juveniles with high-dose acetaminophen and differences among strains in their levels may relate in other ways to their sociability phenotypes.
Conclusions: The strain of mouse used in immune system challenge studies strongly influences the outcome of such studies and must be carefully considered. BTBR mice have impaired sociability that was not influenced by high dose acetaminophen. However, in C57BL/6 mice, social behavior was impaired and elevated eotaxin levels may be biomarkers of acetaminophen induced oxidative stress endured during juvenile development that can be measured in adulthood.

12 **143.012** Gestational Valproic Acid Alters Polyamine Metabolism in the Mouse Placenta: Implications for Autism Spectrum Disorders Causation

***A. Sokoloff**[1] and S. M. Mimche[2], (1)Emory University Physiology, Atlanta, GA, (2)Physiology, Emory Uiversity, Atlanta, GA*

Background: Currently ~40% of Autism Spectrum Disorders (ASD) risk is attributed to non-genomic factors. Gestational use of the antiepileptic drug valproic acid (VPA) is one such factor that is associated with substantial increase in offspring risk of ASD. In the mouse, mid-gestational administration of VPA results in ASD-like anatomy and behavior in offspring. Although ASD-promoting effects of VPA are commonly considered to operate by histone deacetylase inhibition, VPA impacts many signaling pathways leaving unresolved the molecular mechanism(s) by which VPA promotes an ASD phenotype.
Objectives: We have realized that many maternal risk factors for ASD correlate with dysregulation of polyamine (PA) metabolism (e.g., rheumatoid arthritis, diabetes) implicating PA dysregulation in ASD causation. To our knowledge it is not known whether VPA can disrupt PA metabolism and thus whether the effects of gestational VPA might be mediated by dysregulation of PA metabolism. As a first-test of a VPA-PA link we here ask whether gestational administration of VPA in the mouse can cause dysregulation of placental PA metabolism.
Methods: Pregnant CD1 mice were injected subcutaneously with 600 mg/kg VPA or with equivalent volume physiological saline on gestational days 12, 13 and 14 and

tissue was harvested ~4 hours post-final treatment. Placentas were dissected and assigned to analysis by (1) qRT-PCR of mRNA of polyamine pathway enzymes ornithine decarboxylase 1 (ODC), adenosylmethionine decarboxylase 1 (AMD1) and spermidine/spermine N1-acetyltransferase 1 (SAT1), (2) SDS-PAGE-Western of ODC protein or (3) Hematoxylin-Eosin histochemistry for determination of placenta mid-sagittal cross-sectional area (following cryostat sectioning).
Results: Compared to controls, mRNA of all PA enzymes was elevated by 1.38±0.09x (ODC, average±SD), 1.90±0.10x (AMD1) and 1.59±0.57x (SAT1) by VPA. By Western, ODC protein was elevated 1.6x by VPA. Placenta cross-sectional area was decreased following VPA treatment (10.8± 2.2 mm^2 VPA versus 14.4± 2.0 mm^2 Control).
Conclusions: These results demonstrate that gestational VPA can alter placental PA metabolism with morphological consequence. Whether VPA impacts PA metabolism in maternal and fetal compartments and in the placenta at other developmental time points awaits further investigation.

13 **143.013** Modulating Excitation: Inhibition Imbalance in ASD As a Means of 'Fractionating the Spectrum'; An In Vivo, Clinical [1H]-MRS Assay

L. A. Ajram[1], *J. Horder*[2], *R. H. Wichers*[3], *S. C. Williams*[4], *R. A. Edden*[5], *C. M. Murphy*[3], *D. G. Murphy*[3] *and G. M. McAlonan*[6], *(1)Institute of Psychiatry, London, United Kingdom, (2)Institute of Psychiatry, King's College London, London, England, United Kingdom of Great Britain and Northern Ireland, (3)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (4)Centre for Neuroimaging Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (5)Johns Hopkins University School of Medicine, Baltimore, MD, (6)Department of Forensic and Neurodevelopmental Science, IoPPN, KCL, London, United Kingdom*

Background: There are no pharmacological treatments for the core symptoms of Autism Spectrum Disorder (ASD). However, accumulating evidence suggests an imbalance between excitatory (E) glutamate and inhibitory (I) GABA in ASD; and may explain the early promise of proGABA and anti-glutamate drugs such as riluzole. Here we tested the hypothesis that, compared to unaffected controls, individuals with ASD have differences in the E/I response to a riluzole drug challenge.
Objectives: There are no pharmacological treatments for the core symptoms of Autism Spectrum Disorder (ASD). However, accumulating evidence suggests an imbalance between excitatory (E) glutamate and inhibitory (I) GABA in ASD; and may explain the early promise of proGABA and anti-glutamate drugs such as riluzole. Here we tested the hypothesis that, compared to unaffected controls, individuals with ASD have differences in the E/I response to a riluzole drug challenge.
Methods: Subcortical Glx was significantly lower in men with ASD compared to controls at baseline (placebo, p=0.03). Riluzole significantly increased the inhibitory index in the subcortex of both groups (p = 0.04). However, in the prefrontal cortex, riluzole increased the inhibitory index in the ASD group only (p=0.04). Post-hoc testing suggested that increases in inhibitory indices in both groups were driven by increased GABA. Differences in frontal lobe connectivity in ASD appeared normalized by riluzole. The difference in the effect riluzole has on E:I balance in the ASD cohort is significantly associated with baseline E:I levels and symptom presentation.
Results: Subcortical Glx was significantly lower in men with ASD compared to controls at baseline (placebo, p=0.03). Riluzole significantly increased the inhibitory index in the subcortex of both groups (p = 0.04). However, in the prefrontal cortex, riluzole increased the inhibitory index in the ASD group only (p=0.04). Post-hoc testing suggested that increases in inhibitory indices in both groups were driven by increased GABA. Differences in frontal lobe connectivity in ASD appeared normalized by riluzole. The difference in the effect riluzole had on E:I balance in the ASD cohort was significantly associated with baseline E:I levels and symptom presentation.
Conclusions: Individuals with ASD have differences in E/I balance (lower subcortical Glx in ASD) and responsivity (Riluzole increases inhibition in the cortex of ASD patients only), at regional (shown by MRS) and whole-brain levels (shown by fMRI). Thus, the glutamate-GABA system may be a tractable treatment target in ASD. This MRS/rs-fMRI approach may provide a safe means to fractionate the ASD sample into more biologically homogeneous sub-groups, for example prior to clinical trial. Baseline E:I levels are potentially predictive of E:I 'responsivity', therefore this approach may also help predict who will be responsive to glutamate-GABA treatments (such as riluzole).

14 **143.014** Neurobehavioral Abnormalities Relevant to Autism Spectrum Disorders Are Detected in Mice with Selective Expression of Mutant DISC1 in Purkinje Cells of Anterior Cerebellum

A. V. Shevelkin[1,2], *B. N. Abazyan*[1], *C. Yang*[1], *O. A. Mychko*[1], *G. L. Rudow*[3], *J. C. Troncoso*[3] *and M. V. Pletnikov*[1,4], *(1)Departments of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, (2)P.K.Anokhin Institute of Normal Physiology, Moscow, Russia, (3)Departments of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD, (4)Solomon H. Snyder Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Disrupted-In-Schizophrenia-1(DISC1) and its variants have been associated with neurodevelopmental disorders, including schizophrenia and autism spectrum disorders (ASD). Purkinje cells (PC) express DISC1. We generated a mouse model of inducible and selective expression of mutant DISC1 in PC of anterior lobuli of the cerebellum (II-V and internal side of VI).
Objectives: We sought to analyze the brain and behavioral alterations in this mouse model.
Methods: We evaluated volume of the cerebellum and PC in mice at postnatal (P) day 21 and 150 after assessing behavioral phenotypes in male and female mice in novelty-induced activity, elevated plus maze, Y maze, object and place recognition, fear conditioning and rotarod. Conventional western blotting and electrophysiological technics were used in the experiments. All protocols were approved by the Animal Care and Use Committee at Johns Hopkins University.
Results: We found a significant decrease in PC size at P21 but not at P150. Analysis of soma PC size showed small and big soma PC in the anterior cerebellum of control mice, but only small soma PC size in mutant DISC1 mice at P21. Neither total number of PC nor volume of the cerebellum were significantly altered in mutant DISC1 mice. No up-regulation of cellular markers of inflammation was observed in mutant mice. Mutant male but not female mice demonstrated abnormal social interaction, hyperactivity and deficient novel object recognition. We observed no group differences in elevated plus maze, spontaneous alteration or spatial recognition in Y maze. Preliminary electrophysiological experiments found higher frequency and amplitude of mEPSCs, but no changes in excitability and R_{input} of PC in mutant DISC1 mice. Mutant DISC1 mice had comparable expression of NR1 and NR2A but significantly more expression of SNAP-25 and PSD-95 in the cerebellum but not in the cortex.
Conclusions: Our findings indicate that mutant DISC1 affects PC morphology at P21 and produces cognitive and social abnormalities in adult mice. This may have the potential to advance our knowledge of the role of DISC1 in maturation and function of the cerebellum related to neurodevelopmental disorders.

15 **143.015** Peri-Conceptionnal Exposure to Sulphonamide Antibiotic Increases Anxiety and Reduces Social Interactions in Wistar Rat Offpring

S. Degroote, *D. Hunting and L. Takser, Université de Sherbrooke, Sherbrooke, QC, Canada*

Background: There is a growing body of evidence that gut microbiota characteristics might be closely related to mental dysfunctions. However, no studies are available on maternal gut microbiota and fetal brain development, despite large use of antibiotics in obstetric practice.
Objectives: To determine how periconceptional exposure to SuccinySulfaThiazole (SST), a non-absorbable antibiotic, can affect behavior in rat offspring.
Methods: Females Wistar rats were divided in two groups: control, or exposed during one month before breeding until Gestational Day 15 to a diet containing 1% SST. Behavioral tests were then administered to offspring: nest-seeking behavior, open field, marble burying, elevated plus maze, and test of social interactions.
Results: Both males and females offspring exposed peri-conceptionnally to SST showed reduced social interactions. Male offspring showed altered olfactory discrimination of maternal odour in the nest-seeking behavior test and reduced exploration of the open arm in the elevated plus maze test.
Conclusions: Periconceptionnal exposure to SST provoke alterations in offspring's behavior without any maternal infection, and given the fact SST is a non-absorbable antibiotic, we speculate that these neurobehavioral alterations are related to gut microbiota alterations.

16 **143.016** Resveratrol Prevents Behavioral Changes in the Valproic Acid-Induced Animal Model of Autism, Modulating Excitation/Inhibition Balance in Mpfc and Hippocampus

G. Della Flora Nunes[1,2], *M. F. Dutra*[1,3], *V. Bambini-Junior*[1,4], *W. S. Nunes*[1,3], *M. M. Hirsch*[1,3], *G. Z. Staevie*[1,3], *G. B. Negrini*[1,3], *J. S. Terra*[1,3], *G. B. Schwingel*[1,3], *T. Quadros*[1,3], *T. Gonchoroski*[1,3], *R. Riesgo*[1,5] *and C. Gottfried*[1,3], *(1)Translational Research Group in Autism Spectrum Disorder (GETTEA), Porto Alegre, Brazil, (2)SUNY at Buffalo, Buffalo, NY, (3)Research Group in Neuroglial Plasticity, Porto Alegre, Brazil, (4)Oswaldo Cruz Institute, Oswaldo Cruz Foundation, Laboratory on Thymus Research, Rio de Janeiro, Brazil, (5)Child Neurology Unit, Clinical Hospital of Porto Alegre (HCPA), Porto Alegre, Brazil*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disability characterized by sociability impairments accompanied by communication deficits and stereotyped behavioral patterns. Although ASD etiology is still not known, there is growing evidence that an imbalance between excitation and inhibition is a prominent characteristic at the neuronal circuitry level. One of the known risk factors for ASD is maternal use of valproic acid (VPA) during gestation. Based on this observation, VPA is commonly used to generate an ASD-like condition in rodents.
Objectives: Considering the neuroprotective, antioxidant and anti-inflammatory effects of resveratrol (RSV), we aimed to investigate the influence of prenatal RSV treatment on a set of social behaviors. In addition, we assessed the influence of this treatment on mRNA and protein expression levels of excitatory (PSD-95 and neuroligin-1) and inhibitory (gephyrin and neuroligin-2) synaptic proteins in medial prefrontal cortex (mPFC) and hippocampus.
Methods: Pregnant females were randomly divided into four groups: Control, RSV, VPA and VPA + RSV. Valproic acid (600 mg/Kg) was injected intraperitoneally on embryonic day 12.5 (E12.5). Resveratrol (3.6 mg/kg) was administered subcutaneously every day from E6.5 to E18.5. Control group received only vehicle. Social behavior was assessed through social transmission of food preference (STFP) in young male rats and by three chamber and empathy tests in adults. Two animals per litter of at least 4 litters were tested. Levels of synaptic proteins were determined using qRT-PCR and Western blot analysis. Statistical analysis was performed using the SPSS 20 Software. Two-way ANOVA was used for all tests, except the three-chamber, which was analyzed by a generalized estimating equation (GEE).
Results: In the three-chamber test, VPA rats presented no preference between a new object and a new rat and no preference for social novelty. Prenatal administration of resveratrol prevented these VPA-induced social impairments. In the STFP, VPA animals showed impaired communication, as indicated by the absence of preference for the flavored food consumed by the demonstrator rat. RSV treatment again averted VPA action, but interestingly switched the preference toward the new flavor. The empathy test

revealed that VPA rats have a delay in the first opening of the restrainer to release the trapped conspecific to in comparison to controls. However, once they start opening the restrainer, they opened it in the subsequent days. Resveratrol did not change this pattern. For the expression analysis, we found that RSV led to a trend of decrease in the level of protein PSD-95 in the mPFC of the VPA+RSV group animals compared to the VPA group (p=0,092), probably exerting its actions at the translation level. In addition, RSV increased gene expression of gephyrin in both mPFC and hippocampus.
Conclusions: Therefore, the present study demonstrates a successful prenatal intervention able to prevent social alterations induced by VPA in rats. In addition, we identified possible mechanisms by which RSV could diminish neuronal excitability. This can be the basis for the phenotypic prevention exerted by RSV and adds evidence to the growing body of findings that behavioral alteration can be mediated by excitation/inhibition regulation in ASD.

17 **143.017** Resveratrol Prevents Sensory Deficits in Animal Model of Autism Induced By Prenatal Exposure to VPA

M. F. Dutra[1,2], *G. Della Flora Nunes*[1,2], *M. M. Hirsch*[1,2], *W. S. Nunes*[1,2], *G. Z. Staevie*[1,2], *G. B. Negrini*[1,2], *G. B. Schwingel*[1,2], *J. S. Terra*[1,2], *R. S. Riesgo*[2,3], *C. Gottfried*[1,2] *and V. Bambini-Junior*[2,4], *(1)Research Group in Neuroglial Plasticity, Porto Alegre, Brazil, (2)Translational Research Group in Autism Spectrum Disorder (GETTEA), Porto Alegre, Brazil, (3)Neurology Unit, Clinical Hospital of Porto Alegre, Porto Alegre, Brazil, (4)Oswaldo Cruz Institute, Oswaldo Cruz Foundation, Laboratory on Thymus Research, Rio de Janeiro, Brazil*

Background: Autism spectrum disorder (ASD) is classified as a neurodevelopmental disorder, presenting impairments in social communication and sociability, as well as stereotyped behavioral patterns. Although the etiology remains unknown, there is growing evidence suggesting a complex interplay between genetic and environmental risk factors during pregnancy. Many CNS impairments are related to ASD (e.g. multisensory alterations) and recent data were pointing out to an unbalance between excitation and inhibition with high predominance in excitation compound, particularly in cortical and limbic areas related to sensory processing. Prenatal exposure to valproic acid (VPA) is an environmental risk factor to ASD development and it has been widely used to induce autistic-like behaviors in rodents. We previously showed that a prenatal treatment with resveratrol (RSV) was able to prevent the social deficits induced by VPA in male offspring rats.
Objectives: The present work aimed to investigate the effects of prenatal exposure to RSV and VPA in rats' sensory behaviors. In addition, we aimed to evaluate the gene expression of key synaptic components for the excitatory and inhibitory balance in the amygdala region.
Methods: Female rats were treated at 12.5 days of pregnancy, with VPA (600 mg/kg, i.p.) or vehicle. A low dose of RSV (3.6 mg/kg, s.c.) were administered from E6.5 to E18.5. Male pups from different litters of experimental groups were used for behavioral and molecular experiments. Two sensory behaviors were performed, at PN10 (Nest Seeking Behavior) and PN30 (Whisker Nuisance Task). After 30 days, male rats were euthanized and the relative gene expressions for synaptic proteins were evaluated. All data were analyzed by SPSS statistical program applying one-way ANOVA followed by Tukey's test.
Results: Regarding the nest seeking behavioral test, VPA group presented reduced number of correct choices to the nest, which is in accordance to the literature data. RSV was able to prevent this behavioral impairment (in RSV+VPA group). However, the time to reach any shavings was increased in both VPA and RSV+VPA group. The WNT showed the same pattern of prevention by prenatal administration of RSV. The VPA group presented higher score values (higher nuisance) compared to RSV and RSV+VPA groups. Therefore, the prenatal treatment with RSV was capable to reduce the score values when compared to VPA group. The present work showed for the first time, significant alterations at the genic expression of synaptic proteins related to excitatory and inhibitory synapses in the amygdala region, an important brain structure related to attachment behavior and emotional features in sensory processing integration, known to be altered in ASD. RSV increased the genetic expression level of Gephyrin in the amygdala of RSV group. Also, RSV decreased the genetic expression levels of Synaptophysin in RSV+VPA group. There were no changes in genetic expression of PSD95 among groups.
Conclusions: These data highlights RSV as an important preventive molecule in the study of autistic-like sensory behaviors in VPA model, as well as an important tool for seeking etiological targets and physiopathology studies in TEA.

18 **143.018** Sulforaphane Improved Social Communication Impairment in Valproate Induced Autistic Mice with up-Regulation of BDNF and NR2B in Cerebral Cortex

K. F. Chau, W. Yang, A. Y. T. Choi, W. N. Leung and ***C. W. Chan****, School of Chinese Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background:
Autism (ASD) is a neurodevelopmental disorder in which the etiology remains speculative. There are various causative agents to trigger the onset of ASD. The histone deacetylase inhibitor, valproic acid (VPA) has been linked with the etiology of ASD. Rodent models with autistic features induced by VPA have been widely used in many researchers in the past decade. Various treatments have been applied to these ASD models but there is no remarkable method to ameliorate the autistic behavior. A recent clinical study has showed that sulforaphane (SFN) enriched broccoli extract could improve social communication of autistic children. However, the mechanism behind remains inconclusive. SFN has been reported to involve in various mechanisms such as DNA acetylation and counteracting oxidative stress. In this study, the effect of sulforaphane on VPA-induced mouse model of ASD and the mechanism behind was investigated.
Objectives:
This study aimed to investigate the effects of SFN toward the amelioration of autistic feature in ASD using a VPA-induced mouse model. Besides, the mechanism of SFN-related pathway will be studied in respect to the pathogenesis of ASD.
Methods:
Pregnant BALB/c albino mice were injected intraperitoneally with VPA (600 mg/kg) on embryonic day 12.5, the mothers were allowed to give birth. The sham group mice were prepared by giving the mothers PBS intraperitoneally. The autistic feature of male pups were verified on postnatal day 28 by three-chambers sociability test. Mice with autistic feature were randomly assigned into SFN treatment group and control gorup.The SFN treatment group (VPA-SFN) mice was given with SFN (3.854 mg/kg/day) by oral gavage; while the control group were fed with saline (VPA-SAL). Both groups were fed daily for 22 days. The three-chambers sociability test was performed on postnatal days 35, 42 and 49 to assessthe sociability and social novelty of mice. On postnatal day 50, the mice were euthanized and the cerebral cortices were harvested to perform quanitative PCR analysis ofASD-related genes such as brain-derived neurotrophic factor (BDNF), NMDA receptor subunit2B (NR2B).
Results:
From the results of three-chambers sociability test, VPA-SAL mice spent less time with the stranger mice, showing impaired sociability (Fig 1A and B.); also, less time preference were showed towards the novel mice, demonstrating a lack of social novelty (Fig. 1C and D). At PND 49, after 3-weeks SFN treatment, VPA-SFN mice spent significantly more time than VPA-SAL mice with the stranger mice by 66.9% (p<0.01) in the first 10 minutes of the test (Fig. 1A), and they showed more time preference towards novel mice by 44.4% (p<0.01) (Fig. 1D). Moreover, from quantitative PCR results (Fig. 2), BDNF and NR2B expressions were significantly lower in VPA-SAL mice when compared with the sham group. SFN treatment significantly increased the expressions of BDNF and NR2B by 2.40 (p<0.01) and 2.68 (p<0.05) folds respectively.
Conclusions:
Sulforaphane ameliorated the social communication impairments in valproic acid-induced autistic mice with up-regulations of BDNF and NR2Bin the cerebral cortex.

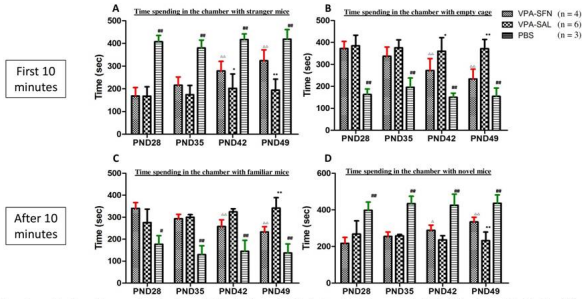


Fig.1. Comparison of the three mice groups in 3-chambers sociability test. In the first 10 minutes of the test, compared with the VPA mice treated with saline, VPA mice treated with sulforaphane showed improvement in sociability in which they preferred staying in the chamber with stranger mice (A) rather than the chamber with an empty cage (B); also, VPA-SFN mice showed improvement in social novelty as compared with VPA-SAL mice. When a novel mice is introduced to the empty cage after ten minutes, they showed more preference to stay in the chamber with the novel mice (D) rather than with the more familiar mice (stranger mice) (C). * $p < 0.05$ ** $p < 0.01$ VPA-SFN vs VPA-SAL by Two-way repeat measure ANOVA *post hoc* Bonferroni Tests; # $p < 0.05$ ## $p < 0.01$ VPA-SAL vs PBS by Two-way repeat measure ANOVA *post hoc* Bonferroni Tests; Δ $p < 0.05$ ΔΔ $p < 0.01$ comparison of various postnatal days (PNDs) vs PND28 within each mice group by One-way repeat measure ANOVA *post hoc* Tukey's test; VPA-SFN: VPA mice fed with sulforaphane; VPA-SAL: VPA mice fed with saline; PBS: sham mice group which had been prenatally injected with PBS.

19 **143.019** Targeting Glia with N-Acetylcysteine Modulates Excitation/Inhibition Balance, Neural Activity and Rescues Behavioural Deficits in BTBR Mice

A. Durieux[1], *M. M. Petrinovic*[2], *M. D. Saxe*[2], *M. von Kienlin*[3], *D. G. Murphy*[4], *B. Künnecke*[5] *and G. M. McAlonan*[6], *(1)Kings College London, London, United Kingdom, (2)F. Hoffmann-La Roche, Basel, Switzerland, (3)2Roche Pharma Research & Early Development, Neuroscience, Roche Innovation Center, Basel, Switzerland, (4)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (5)Neuroscience, Roche Pharma Research & Early Development, Neuroscience, Roche Innovation Center, Basel, Switzerland, (6)Department of Forensic and Neurodevelopmental Science, IoPPN, KCL, London, United Kingdom*

Background:
Although the causal mechanisms of autism spectrum disorder (ASD) are poorly understood, recent advances suggest that an imbalance between excitatory (E) glutamate and inhibitory (I) GABA neurotransmission is a prominent feature of the condition and may be contribute to social impairments and repetitive behaviours. Targeting E/I balance pharmacologically may therefore be a promising approach for drug discovery in ASD. Multiple factors converge to modulate E/I balance *in vivo*, including synaptic and glial mechanisms. For instance, ASD is associated with synaptic gene anomalies that directly disrupt glutamate and GABA signalling; however increasing evidence suggests that glial dysfunction also contributes to E/I imbalance in ASD. N-acetylcysteine (NAC), an FDA approved mucolytic drug which has shown some clinical benefits to treat severe stereotypies in ASD, is thought to modulate glutamate levels through activation of the cystine-glutamate antiporter located on glia.
Objectives:
In this study we tested the hypothesis that acute administration of NAC alters E/I balance, and causes related changes in neural activity patterns and behaviour in BTBR mice, an inbred strain which exhibits behavioural and neuro-morphological phenotypes reminiscent of ASD.
Methods: By combining translational neuroimaging modalities, i.e., perfusion-based functional magnetic resonance imaging (fMRI) and quantitative spectroscopy (MRS), with behavioural assessments we investigated the effects of acute NAC treatment on social and repetitive behaviours, as well as their underlying neurochemistry and circuitry in BTBR and control C57BL/6J mice.
Results: Striatal activity and glutamate levels were elevated in BTBR mice, whereas basal neural activity in the mPFC was comparable with that of C57BL/6J mice. BTBR mice also exhibited severe stereotypies and reduced social interactions, as documented previously. Acute NAC treatment reduced cortical glutamate in both strains, though this was not significant in BTBR mice. NAC normalised abnormal repetitive behaviours as well as social interaction duration in BTBR mice, while concomitantly decreasing striatal neural activity to control levels. Similar modulation of neural activity and decrease in stereotypies were also observed in C57BL/6J mice. Notably, locomotor activity was not affected by NAC.
Conclusions:
NAC treatment normalises social and repetitive behaviour in BTBR mice, likely through modulation of E/I balance which has functional consequences on corticostriatal circuitry. This provides evidence that pharmacological modulation of glial mechanisms can shift E/I balance acutely, with associated neuro-functional and behavioural consequences. Glial metabolism may be a potential drug target for the development of new therapies for ASD. Additionally, our findings warrant further investigation into the potential therapeutic use of NAC in individuals with ASD.

20 **143.020** The Contribution of Reduced TrkB Signaling to Autistic-like Behaviour in the Valproic Acid-Induced Mouse Model

C. Nicolini[1], *V. Aksenov*[2], *E. Rosa*[1], *C. D. Rollo*[2], *J. A. Foster*[1], *F. M. Longo*[3] *and M. Fahnestock*[1], *(1)Dept. of Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada, (2)Dept. of Biology, McMaster University, Hamilton, ON, Canada, (3)Dept. of Neurology & Neurological Sciences, Stanford University, Stanford, CA*

Background: The molecular mechanisms underlying autistic-like behaviour remain to be elucidated. Mutations in autism-linked genes adversely affect molecules, such as brain-derived neurotrophic factor receptor TrkB and Akt/mTOR pathway components, which regulate dendritic spine formation, function and plasticity. In line with these findings, we previously demonstrated reduced TrkB/Akt/mTOR protein and signaling in human idiopathic autism and in the valproic acid (VPA)-induced rodent model of autism. These results support the hypothesis that defective TrkB/Akt/mTOR pathway signaling is a molecular substrate of autistic behaviour and identifies this pathway as a potential therapeutic target for autism. Promisingly, decreased TrkB signaling via Akt has been rescued by administration of the TrkB partial agonist LM22A-4 in an animal model of Rett syndrome, a monogenic disorder associated with high rates of autism.
Objectives: To better establish the contribution of decreased TrkB/Akt/mTOR pathway signaling to autistic behaviour, we aimed to examine whether systemic treatment with the partial TrkB agonist LM22A-4 would restore TrkB/Akt/mTOR signaling and ameliorate autistic-like behaviour in the offspring of VPA-injected mothers.
Methods: Pregnant CD1 mice received a single intraperitoneal (i.p.) injection of 500 mg/kg VPA on gestational day 12.5, while controls were injected with only saline. Pups were weaned on postnatal day (PD) 21 and received an i.p. injection of either saline or LM22A-4 (0.05mg/g) once daily from PDs 21-35. Sociability and repetitive/stereotypic behaviour were evaluated on PDs 29-34 using the three-chambered social approach task and marble-burying test, respectively. Litters were killed and brain tissue harvested on PD 35. Protein expression and phosphorylation levels of the serine/threonine protein kinase Akt, a key downstream effector of TrkB, were measured by Western blotting in the temporal/parietal neocortices of saline- and LM22A-4-treated VPA and control mice.
Results: Behavioral results were dependent on sex, with female VPA-exposed mice displaying a lack of sociability and male VPA-exposed mice displaying increased repetitive behaviour compared to controls. Contrary to VPA-exposed saline-treated females, LM22A-4-treated VPA-exposed female mice displayed normal sociability. Also, VPA-exposed male mice treated with LM22A-4 buried fewer marbles than saline-treated VPA-exposed males, consistent with a decrease in repetitive behaviour. Lastly, both LM22A-4-treated VPA-exposed females and males had higher levels of phosphorylated Akt than saline-treated VPA-exposed mice, similar to untreated controls.
Conclusions: Our results support the hypothesis that reduced TrkB/Akt/mTOR signaling contributes to autistic behaviour and that this pathway might have a therapeutic role in treating idiopathic autism. Indeed, promisingly, we show that systemic treatment with the partial TrkB agonist LM22A-4 appears to restore the reduction in TrkB signaling and improve social and repetitive behaviours in the VPA mouse model of autism.

21 **143.021** Touchscreen Learning in the Shank3B Mutant Mouse Model of Phelan-Mcdermid Syndrome and Autism Spectrum Disorder

N. A. Copping, G. M. Foley, E. L. Berg, B. L. Onaga, J. L. Silverman and ***M. Yang****, Psychiatry and Behavioral Sciences, MIND Institute, Sacramento, CA*

Background: Translocation and breakpoint mutations in *SHANK3* have been implicated in autism spectrum disorder (ASD), Phelan-McDermid Syndrome (PMS) and intellectual disabilities (Betancur & Buxbaum, 2013; Gauthier et al., 2009; Leblond etal., 2014; Moessner et al., 2007), leading to the hypothesis that reduced SHANK3 expression may impair basic brain functions that are important for social communication and cognition (Durand et al., 2007). Shank3 is a synaptic scaffolding protein, localized in the postsynaptic density. Mutant mouse and rat models have been generated to evaluate the biological and behavioral consequences of *Shank3* gene mutations (Bozdagi et al., 2010; Peca et al., 2011; Bangash et al., 2011; Wang et al., 2011; Kouser et al., 2013).
Objectives: The present experiments were designed to evaluate cognitive phenotypes in *Shank3B* mice. The touchscreen pairwise discrimination task was chosen by virtue of its: (a) conceptual and technical similarities to the CANTAB test battery used for testing cognitive functions in humans, (b) minimal demand on motor abilities, and (c) translational validity for future clinical trial outcome measures (Silverman et al., 2013).
Methods: Breeding pairs were purchased from The Jackson Laboratory (JAX catalogue #017688). Mice were bred in a conventional mouse vivarium at the University of California Davis School of Medicine in Sacramento. Pairwise visual discrimination was tested in the automated Bussey-Saksida touchscreen system for mice (Campden Instruments Ltd/Lafayette Instruments, Lafayette, IL, USA), using a procedure slightly modified from the methods described previously (Brigman & Rothblat, 2008; Bussey et al., 2012; Brigman et al., 2013; Silverman et al. 2013). Mice were trained to discriminate two novel images (spider and plane) displayed side-by-side in two windows on the screen in a spatially pseudo-randomized manner. To examine simple learning under a stringent definition, acquisition was assessed with a performance criterion of >80% correct responses (excluding correction trials) over two consecutive sessions and with a minimum of 30 trials completed. Days to reach criterion, number of total trials, number of incorrect responses, and number of correction trials were compared between genotypes.
Results: As compared to *Shank3* wildtype (+/+), *Shank3* heterozygous mutant (+/-) mice exhibited impaired learning in the visual discrimination of luminescent-balanced stimuli. Wildtype controls displayed normal learning typical of the C57BL/6J background strain on all measures. Shank3 +/- mice required more training days to reach criterion and exhibited trends toward making more errors. Both genotypes reached criterion within the 30-day cutoff.
Conclusions: We detected a significant deficit in higher-order cognitive functions in the *Shank3B* mutant mouse model of PMS and ASD, suggesting that this mouse model is a useful preclinical tool for studying neurobiological mechanisms behind cognitive impairments in PMS and ASD. The current findings are the starting point of our future research in which we will investigate multiple domains of cognition and explore pharmacological interventions.

22 **143.022** Transgenerational Transmission and Modification of Behavioral Deficits Induced By Prenatal Immune Activation

U. Meyer[1,2], *U. Weber-Stadlbauer*[1] *and J. Richetto*[1], *(1)Institute of Pharmacology and Toxicology, University of Zurich-Vetsuisse, Zurich, Switzerland, (2)Physiology and Behavior Laboratory, ETH Zurich, Schwerzenbach, Switzerland*

Background: It has been demonstrated that environmentally induced brain dysfunctions are not solely expressed by the individuals directly exposed, but can also be transmitted to the offspring, sometimes across multiple generations.
Objectives: Here we explored whether such transgenerational effects can be induced by prenatal infection, an environmental risk factor of autism and related neurodevelopmental disorders.
Methods: We used a well-established mouse model of prenatal immune activation, which has been shown to induce multiple behavioural deficits relevant to autism and related disorders. Pregnant mice (F0) were injected with the viral mimetic poly(I:C) (5 mg/kg) or control solution in early pregnancy (gestation day 9), and the behavioral effects were tested in the F1 generation. To examine whether such deficits can be transmitted to subsequent generations, we generated F2 and F3 offspring by inter-crossing F1 and F2 offspring, respectively. We performed behavioral testing in adult F1, F2 and F3 offspring and exploited transcriptional profiling to determine gene expression in the prefrontal cortex (PFC) and amygdala (AMY) of F1 and F2 mice using next generation sequencing.
Results: Behavioral analyses in F1, F2 and F3 offspring revealed that deficits in social interaction and cued fear, which emerge in F1 offspring, are also present in the F2 and F3 generation. F1 offspring also showed increased sensitivity to the psychostimulant drug amphetamine. Interestingly, the F2 and F3 generation displayed the opposite pattern, namely reduced amphetamine sensitivity. Deficits in sensorimotor gating, which are typically observed in the F1 generation, were not present in F2 and F3 offspring. RNA-sequencing analysis revealed a total number of 227 genes that are differentially expressed in F1 PFC poly(I:C) versus controls, 359 in F2 PFC poly(I:C) versus controls

and 1226 genes in F1 Amy as well as 1665 genes in F2 Amy poly(I:C) versus controls. Out of the differentially expressed genes in F1 and F2 PFC, a total number of 12 genes are affected in both F1 and F2 brains. In the Amy, 415 genes are overlapping between F1 and F2 brains.
Conclusions: Our findings demonstrate that behavioral deficits induced by prenatal infection can be transmitted and modified across subsequent generations. Furthermore, analysis of the transcriptome in F1 and F2 Amy and PFC revealed differential gene expression in poly(I:C) versus control animals in F1 as well as F2 animals. Future experiments will examine the possibility that the behavioral abnormalities and the differences in gene expression following prenatal immune activation are transmitted to subsequent generations via modifications in the epigenetic machinery.

23 **144.023** 22q11.2 Duplication Syndrome: Assessment of Autism Spectrum Disorder, Other Neuropsychiatric Symptoms, and Adaptive Skills

C. C. Clements[1], *L. M. DePolo*[2], *A. de Marchena*[2], *D. M. McDonald-McGinn*[3], *E. H. Zackai*[4], *B. Emanuel*[3], *R. T. Schultz*[5], *J. Miller*[2] *and T. L. Wegner*[2,6], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Pediatrics, Seattle Children's Hospital, Seattle, Seattle, PA*

Background: Past research suggests that individuals with 22q11.2 Deletion Syndrome (22q11.2DS) have elevated rates of autism (~15%), ADHD (>50%), and schizophrenia (~25%). Recently widespread use of microarrays has identified duplication of the identical 2.54Mb region in a growing number of patients (22q11.2DupS). Case reports suggest heterogeneous medical and neuropsychiatric profiles, but there has not yet been systematic assessment of ASD and other neuropsychiatric symptoms.
Objectives: To characterize the prevalence of ASD and the presentation of psychiatric symptoms and adaptive skills in individuals with 22q11.2DupS.
Methods: Youth with 22q11.2DupS or 22q11.2DS were recruited from a genetics specialty clinic at the Children's Hospital of Philadelphia, and matching groups of ASD and typically developing controls (TDC) were formed form other studies at the Center for Autism Research. 22q11.2DupS participants (n=28) were matched 1:3 on age and sex, with 1:1 matching for children younger than four years, to participants in all three comparison groups: 22q11.2DS (n=62), ASD (n=70), and TDCs (n=73). Parents of all participants completed measures of social communication skills, psychiatric symptoms, and adaptive behavior skills (SCQ, SRS or SRS-2, CASI-4R, and Vineland-II). Parents of youth with 22q11.2DupS (but not deletions) also completed the ADI-R (n=20). A subset were also administered the ADOS (n= 8). All participants in the ASD comparison group were evaluated with both instruments.
Results: Five of 20 individuals with 22q11.2DupS met research diagnostic standards and clinical judgment for a diagnosis of ASD (25%). All 5 carried a community diagnosis of ASD, as did 7 of the 15 participants who did not meet research diagnostic standards. Parent report questionnaires found that both the 22q11.2DupS and 22q11.2DS groups showed greater impairment than the TDC group on all social indices (all p's < 0.001; d's > 1.80). Duplication and deletion groups did not differ on any social measures. Both duplication and deletions showed impairment on the Vineland-II Adaptive Behavior Composite that was intermediate between TDCs and ASD. The ASD, 22q11.2DS, and 22q11.2DupS groups each demonstrated significantly elevated neuropsychiatric impairments compared to TDCs.
Conclusions: This report is the first study to assess ASD symptoms in a sample of individuals with the 22q11.2DupS. One quarter met gold-standard diagnostic criteria for ASD and showed similar levels of social communication impairment (SCQ and SRS/SRS-2) to children with idiopathic ASD. The estimated 25% rate of ASD observed in children with 22q11.2DupS is much higher than the population prevalence estimates of 1-2%, and is among the highest of any genetic syndrome associated with ASD.

24 **144.024** A Comparison of Polygenic Contribution to Autism Spectrum Disorder Using Common, Rare and Copy Number Variants

K. Benke[1], *B. Sheppard*[2], *K. M. Bakulski*[3], *A. B. Singer*[3], *C. Shu*[4], *C. Ladd-Acosta*[5], *C. J. Newschaffer*[6] *and M. D. Fallin*[7], *(1)Mental Health, Johns Hopkins School of Public Health, Baltimore, MD, (2)Johns Hopkins School of Public Health, Baltimore, MD, (3)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)A.J. Drexel Autism Institute, Philadelphia, PA, (7)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: Current evidence suggests that the genetic contribution to autism spectrum disorder (ASD) is polygenic, consisting of small, accumulating effects of many variants. While some of the contribution may come from rare single variant mutations or rare copy number variation, the summation of modest effects among common variants is still likely to be important.
Objectives: To create polygenic risk scores (PRS) using large sample results from the Psychiatric Genomics Consortia (PGC) mega-analysis for ASD using genome-wide genotype data from the Study to Explore Early Development (SEED), a multi-site case-control study and compare the performance of these PRS to scores calculated from copy number variant burden, rare variant burden, or other combined metrics.
Methods: We have created a polygenic risk score, derived from discovery results available from the PGC for ASD, using measured genotypes in SEED to investigate the interplay of genetic and environmental risk factors that underlie disease risk. We will further create a score reflective of the burden of rare variation (using 1000 genomes imputed data) and rare copy number variation burden (using Penn CNV calls). Correlations among the three scores, their potential interactions, and their ability to classify membership into case status will be explored.
Results: The association of the common variant PRS with ASD status was significant, but appeared to be due to confounding by genetic ancestry. We will present results adjusted for ancestry as well as comparisons with rare-variant based scores.
Conclusions: This is the first effort to our knowledge to investigate multiple polygenic scores in ASD. Our results can shed light on whether rare, common and CNV burden are correlated or represent independent contributions to the risk of autism.

25 **144.025** A SHANK3 Point Mutation with Phelan-Mcdermid Phenotype, Notably without Autism Spectrum Disorder or Intellectual Deficits

C. Samango-Sprouse[1,2], *P. Lawson*[1] *and O. Goker-Alpan*[3], *(1)The Focus Foundation, Crofton, MD, (2)George Washington University, Washington, DC, (3)Genetics, O and O Alpan, LLC, Fairfax, VA*

Background: The *SHANK3* gene encodes a scaffolding protein in the cortex and cerebellum that plays a role in synaptic signal transmission. *SHANK3* is disrupted in Phelan-McDermid Syndrome (PMS or 22q13.3 deletion syndrome), which is characterized by variable central nervous dysfunction including speech and motor delays, hypotonia, Intellectual Deficits (ID), and Autism Spectrum Disorder (ASD). Expressive language is typically more impaired than receptive language. There is evidence larger deletions correlate with greater developmental dysfunction and higher rates of ASD. As many as 84% of individuals with PMS are also diagnosed with ASD. *SHANK3* haploinsufficiency is also implicated in ASD, and is present in 0.5% of ASD cases (one of the largest monogenic causes of ASD) and 2% of moderate-to-profound ID cases.
Objectives: N/A
Methods: N/A
Results: We present a 5 year-old girl with a single point c.2265+3 A>T variant in intron 19 in the *SHANK3* gene.
She has a history of developmental regression, limb asymmetry, advanced bone age, and coordination difficulties. Feeding disturbances and speech delay with intermittent regression of skills were noted at 18 months. She is diagnosed with Childhood Apraxia of Speech (CAS) with facial and truncal hypotonia, motor difficulties, balance problems, oculomotor apraxia, and visual perceptual deficits (SS=74 on VMI). GARS-2 and GADS scores are below the first percentile, however,the SRS-2 revealed mildly atypical scores in social cognition and social awareness with T-scores of 63 and 62, respectively, compared to a Total T-Score of 56. Intellectual function tends to be in the average range (90-109), with a Fluid Reasoning (FR) of 93, Working Memory Index (WMI) of 103, and a Verbal Comprehension Index (VCI) of 81 (low average). Expressive and receptive vocabulary scores were 97 and 103 on EOWPVT-R and ROWPVT-R, respectively.
Her phenotypic profile including facial dysmorphisms and neurodevelopmental profile are characteristic of PMS, while she does not meet criteria for ASD.
Conclusions: This report highlights the first case –to our knowledge– where a single-point mutation in the *SHANK3* gene has resulted in a constellation of findings associated with PMS, supporting that *SHANK3* is critical to the PMS phenotype, and that smaller deletions/ mutations correlate with more normalized neurocognitive function. Critically, this case supports higher intellectual capability than has been previously reported in patients with *SHANK3* mutations (typically ranging from moderate to severe ID).
Also significant, while the majority of patients with *SHANK3* mutations and deletions have ASD, this patient shows no significant ASD features but does have some social language issues. This fits with the literature showing that smaller deletions/mutations correlate with lower rates of ASD diagnosis, as well as the fact that ASD is not inherent in cases of *SHANK3* mutation.
Lastly, this case is novel in that the patient is diagnosed with CAS. While language delay (especially expressive) is consistently reported in PMS, diagnosed CAS is unreported. Further investigation is merited to evaluate whether CAS is more prevalent in PMS than is currently documented, as well as its potential contribution to the phenotype, especially the delayed speech, expressive language disorder, and any oral motor deficits.

26 **144.026** A System for Gene Ranking through Integrative Variant Annotation in Autism Spectrum Disorders

E. Larsen[1], *I. Menashe*[2], *M. N. Ziats*[3], *W. Pereanu*[1] *and S. B. Basu*[4], *(1)MindSpec Inc., McLean, VA, (2)Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Baylor*

College of Medicine, Houston, TX, (4)MindSpec, Inc., McLean, VA

Background:
The search for genetic factors underlying autism spectrum disorders (ASD) has led to the identification of hundreds of genes containing thousands of variants that differ in mode of inheritance, effect size, frequency and function. These data are summarized in our Autism Database (AutDB; also known as SFARI Gene), an open-access database for genetic variation associated with ASD. However, a major challenge in the field of ASD biology involves assessing the collective genetic evidence in an unbiased, systematic manner.
Objectives: Here, we describe a scoring algorithm for prioritization of candidate genes based on the cumulative strength of evidence from each ASD-associated variant in AutDB.
Methods:
A total of 928 annotated research articles were analyzed to generate a dataset of 2187 rare variants and 711 common variants distributed across 461 ASD-associated genes. Each individual variant was manually annotated with multiple attributes extracted from the original report, followed by score assignment using a set of standardized scoring parameters that were summed up to yield a single score for each gene in the database.
Results: There were remarkable variations in gene scores resulting in a log-normal distribution of scores with a mean gene score of 16.65 ± 29.57. Interestingly, there were 12 genes with scores deviating more than two standard deviations (SDs) from the mean score of all genes, with very high scores for three genes (*SHANK3*, *CHD8*, and *ADNP*). Importantly, the gene scores generated by our approach were significantly correlated with that in the SFARI Gene scoring module (Spearman r = -0.63; *P<0.0001*) indicating a strong agreement between gene prioritization using our approach and the expert-mediated SFARI Gene scoring initiative. We further validated our scoring strategy using two recently published ASD risk gene lists and prioritized a new set of genes with cumulative evidence.
Conclusions:
Our scoring algorithm provides a framework for assessment of diverse types of genetic variants associated with ASD that are likely to be important for defining the genetic risk architecture in ASD.

27 **144.027** Association Between Copy-Number Variations and Savant Skills Among People with Autism Spectrum Disorder

H. Rosenthal *and I. Menashe, Ben-Gurion University of the Negev, Beer Sheva, Israel*

Background: Savant skills, which are defined as “outstanding skills in individuals with otherwise intellectual impairment,” are significantly more common in individuals with autism spectrum disorders (ASD) than in any other group of people examined to date. The existence of such a considerable and well-defined group of extremely talented people within the autism spectrum suggests common underlying mechanisms that require further exploration. We hypothesized that copy-number variations (CNVs), which are thought to play a role in ASD susceptibility, may also underlie these exceptional skills among people with ASD.
Objectives: To study the association between CNVs and savant skills among individuals with ASD.
Methods: We studied 1108 children diagnosed with ASD from the Simons Simplex Collection (SSC) database. Savant skills were determined based on five designated questions regarding exceptional talent in visuospatial ability, memory ability, musical ability, drawing ability, and computational ability from the autism diagnostic interview revised (ADI-R) questionnaire. CNV data were retrieved from a genome-wide analysis of CNV in these children.
Results: Of the 1108 children with ASD in this study, 467 (42%) had one or more savant skills. This prevalence is significantly higher than the observed 31% of savant skills among children with ASD that did not undergo CNV analysis in the SSC cohort ($P<0.001$). It is also higher than the typically 10%-30% reported prevalence of savant skills among children with ASD in other studies. Similarly to other reports, savant skills in our study were associated with a higher IQ (93.0±24.2 vs. 79.1±25.5; $P<0.001$), and a larger head circumference (HC) (54.3±2.55 vs. 53.8±2.60; $P = 0.003$) among children with ASD. Interestingly, we found association between savant skills and a lower count of rare CNVs among children with ASD (14.0±5.54 vs. 14.8±6.2 for children with and without savant skills respectively; $P = 0.03$). This association mainly reflected differences in copy-number deletions, rather than copy-number duplications, and was particularly noticeable among children with exceptional computational ability (9.1±4.61 vs. 10.1±4.97; $P= 0.02$) even after accounting for their higher IQ and larger HC. We also examined whether certain talents are predisposed by specific ASD susceptibility CNV loci, but no such associations were found.
Conclusions:
Our findings suggest that CNVs contribute to the presentation of exceptional talents among children with ASD.

28 **144.028** Association of Dysfunctional Polymorphisms in Acetylserotonin O-Methyltransferase with Insomnia in ASD

O. J. Veatch*, Z. Warren, J. S. Sutcliffe, M. H. Potter, A. L. Palmer and B. A. Malow, Vanderbilt University, Nashville, TN*

Background: Insomnia, defined as difficulty initiating or maintaining sleep, is a commonly observed comorbidity in autism spectrum disorder (ASD). Dysfunctional polymorphisms in genes encoding enzymes in the melatonin synthesis pathway contribute to risk for both ASD and insomnia. An important gene in this pathway, acetylserotonin O-methyltransferase (*ASMT*), encodes the ASMT enzyme which catalyzes the final step in melatonin biosynthesis. Presence of risk variants in the promoter element of *ASMT* are related to reduced expression of *ASMT*. Reduced expression of *ASMT* has been correlated with reduced enzymatic activity and a reduction in subsequent melatonin production in ASD. Evidence suggests that reduced levels of *ASMT* enzymatic activity relate to comorbid sleep onset insomnia in ASD. However, most previous studies have not looked specifically at the potential contributions of polymorphisms in *ASMT* to insomnia risk in ASD.
Objectives: To examine the hypothesis that polymorphisms in the *ASMT* gene are associated with insomnia in ASD.
Methods: We genotyped three known risk SNPs (rs44469096, rs5989681, rs6644635) shown to relate to reduced expression of the *ASMT* gene. SNPs were genotyped in 120 children (ages 2-13 years) diagnosed with ASD whose parents had completed the Children’s Sleep Habits Questionnaire (CSHQ). These individuals were enrolled in research studies related to sleep in children with ASD, as well as broader autism genetics studies. We initially examined associations of genotypes at each SNP and presence of an insomnia-related problem as indicated by the parent. We additionally evaluated the associations of genotypes at each SNP with sleep onset delay, night wakings, and sleep duration (estimated from parent-reported bedtimes and wake times) to refine the potential relationship of SNPs in *ASMT* with symptoms of insomnia.
Results: There were 84 children with ASD whose parent indicated a problem in an insomnia-related question on the CSHQ and 36 children with no insomnia-related problems reported. There were no associations between the dysfunctional SNPs genotyped in *ASMT* and presence of a problem in an insomnia-related domain, however genotypes in rs6644635 were trending toward significance (p=0.058). Upon further examination of specific CSHQ questions, SNP rs6644635 was associated with shorter sleep duration (β= -14.74, p=0.032), and, interestingly, fewer problems with night wakings (OR=0.43, p=0.027). No SNPs were associated with sleep onset delay problems in this dataset (p≥0.238).
Conclusions: The presence of dysfunctional alleles at SNP rs6644635, in the 5’-UTR of the *ASMT* gene, was associated with short sleep duration. The lack of association of SNP rs6644635 with sleep onset delay and the paradoxical finding of fewer reported problems with night wakings require further examination, including studies that also assess SNPs in genes involved in the metabolism of melatonin (e.g., *CYP1A2*). Examination of melatonin pathway genes in larger datasets appears warranted.

29 **144.029** Autism Pathway Network Analyses Identify Overlaps with Other Disease Groups, Involve Many Functions and Converge upon MAPK and Calcium Signaling

Y. Wen[1,2,3]*, M. Alshikho*[1,3] *and M. R. Herbert*[1,2,3]*, (1)Neurology (Pediatric), Harvard Medical School, Boston, MA, (2)Higher Synthesis Foundation, Cambridge, MA, (3)Neurology, Massachusetts General Hospital, Charlestown, MA*

Background: Autism spectrum disorders (ASDs) encompass many etiologies and heterogeneous phenotypes brought together by common behavioral features and emergence during early development. As of December 2014, the SFARI (Simons Foundation Autism Research Initiative) Gene-Human Gene Module recorded 667 human genes implicated as relevant to ASDs whose diversity challenges efforts at identifying coherent biological mechanisms.
Objectives: Identifying convergent molecular pathways in which multiple candidate genes are involved may be an effective way to gain insight into the underlying molecular bases of ASDs. We sought to combine information from several existing and well-established databases to contextualize autism-associated genes in relation to the functions of gene products, the networking of reactions, pathway-pathway and gene-pathway interactions, and disease-disease relationships.
Methods: We first investigated enrichment within the Human Gene Module of SFARI Gene, by computing overlaps between SFARI genes and MSigDB (Molecular Signatures Database, v4.0) gene set derived from KEGG (Kyoto Encyclopedia of Genes and Genomes) Pathway Database. This allowed us to generate a ranked list of the top 50 pathways within which the ASD genes were enriched. We then applied Redundancy Control in Pathway Databases (ReCiPa) to the enriched pathway list, to minimize the impact of potential redundancy caused by some highly overlapped pathways, which were merged as collections, yielding a final list of 40 pathways, grouped in Disease and Function categories. KEGG pathway maps were used to identify the interactions among pathways, which were fully depicted in a pathway network map. The relative frequencies of representation of components of the pathway network were quantitatively ranked and assessed by tabulating the number of interactions each pathway had within the network. No weighting was applied as there were no standard methods available.
Results: “Calcium signaling pathway”(p-value 2.84E-29) and “neuroactive ligand-receptor interaction” (p-value 2.87E-29) were the most enriched, statistically significant pathways from the enrichment analysis. Pathways were grouped into 10 disease pathways: cancer (4/10), neurodegenerative (3/10), cardiac (2/10) metabolic diseases (1/10); and 30 functional pathways: cell signaling (9/10), cell structure/transport (5/30), immune (3/30), neural (5/30) metabolism (8/30). Perturbations associated with KEGG’s category of environmental information processing were common. The two most interactive pathways, MAPK signaling pathway and calcium signaling pathways, interacted with 20/40 and 12/40 pathways respectively.

Conclusions: Our key findings, derived from methods free of a priori assumptions regarding relevance to autism, demonstrate marked overlap between ASD genes/pathways and those associated with other diseases, and indicate that environmental information processing is broadly impacted. Findings converged upon MAPK signaling and calcium signaling pathways—which impact a large range of biological processes involved in many functions and diseases—as interactive hubs in the autism pathway network. These findings support the idea that, based upon potential compromise of many types of biological output, autism-associated genes may contribute not only to core features of autism themselves but also to vulnerability to other chronic and systemic problems potentially including cancer, metabolic conditions and heart diseases. ASDs may thus arise, or emerge, from underlying vulnerabilities related to pleiotropic genes associated with pervasively important molecular mechanisms, perturbed environmental information processing and multiple systemic co-morbidities.

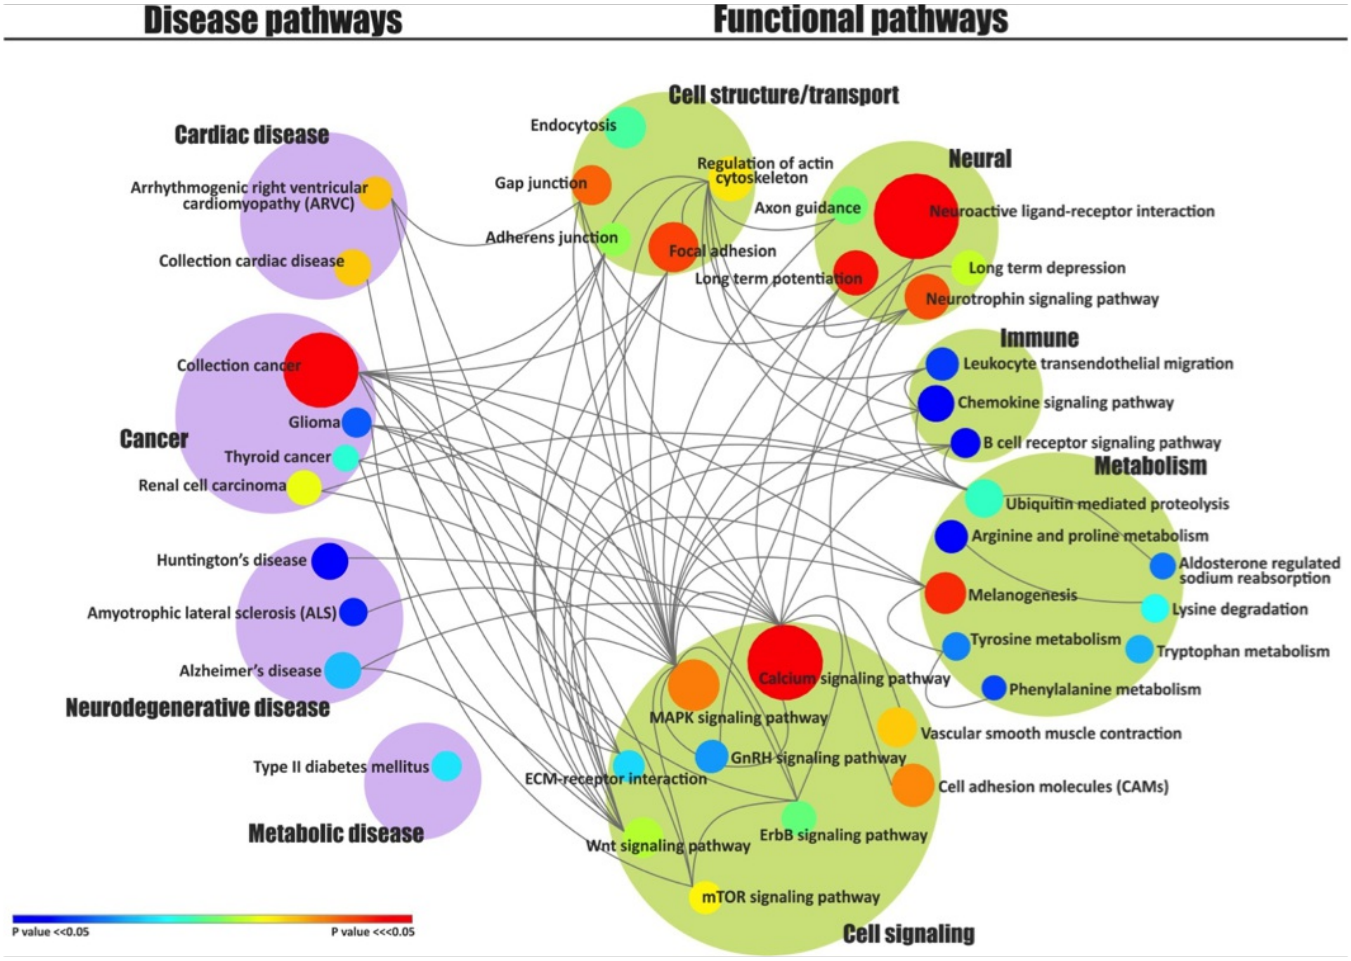

Figure 1 Autism pathway network. Pathways are grouped vertically under two classes, Disease and Function. The color of each node within the groupings represents the p-value of that pathway. The size of each node represents the number of ASD genes in that pathway. Interactions between pairs of pathways are indicated by edges.

30 **144.030** Autism Spectrum Symptomatology in Children with 7q11.23 Duplication Syndrome

B. P. Klein-Tasman[1] *and C. B. Mervis*[2]*, (1)Department of Psychology, University of Wisconsin - Milwaukee, Milwaukee, WI, (2)Dept. of Psychological and Brain Sciences, University of Louisville, Louisville, KY*

Background: Recent findings from studies of *de novo*copy number variants (CNVs) in a large sample of children in the Simons Simplex Collection identified a strong association between duplication of the Williams syndrome region (Dup7q11.23) and autism (Levy et al., 2011; Sanders et al., 2011).
Objectives: Gold-standard diagnostic assessments of ASD symptomatology were conducted for a group of children with Dup7q11.23 who participated in a specialty research clinic for individuals with this syndrome.
Methods: Participants were 63 children with genetically confirmed Dup7q11.23 (25 girls, 38 boys), ranging in age between 4 and 17 years (M age = 8.64 years, SD = 3.77). A comprehensive battery assessing cognitive, language, and psychosocial functioning was administered by a multidisciplinary team, including autism spectrum diagnosis by a Licensed Psychologist with specialized training in the diagnosis of ASD. Parents were interviewed about ASD-related symptomatology with the Autism Diagnostic Interview – Revised (ADI-R). The appropriate module of the Autism Diagnostic Observation Schedule – 2 was administered (ADOS-2; Mod 1 n = 9, Mod 2 n = 21, Mod 3 n = 33).
Results: Based on the ADI-R diagnostic algorithm, which heavily weights retrospective accounts of functioning, 25 participants (39.6%) were classified "autism." Based on the ADOS-2 algorithm, 16 (25.4%) were classified "autism spectrum (AS)" (5 "AS", 11 "autism") and 47 children (74.6%) were classified as "nonspectrum" (NS). Of the children classified "NS," 29 had severity scores of 1 (minimal to no evidence), ten had severity scores of 2, and eight had severity scores of 3. Based on a combination of the ADI-R, ADOS-2, and clinical judgment, 12 participants (19.0%) were clinically diagnosed with ASD. All 12 were classified "AS" or "autism" on the ADOS-2; 9 were classified "autism" on the ADI-R. Of the remaining 47 participants, 16 were classified "autism" on the ADI-R and 4 were classified "AS" or "autism" on the ADOS-2.
Conclusions: Careful characterization of ASD-related symptomatology using gold-standard ASD assessment measures combined with clinical judgment indicated that about 19% of children with Dup7q11.23 showed symptomatology consistent with an ASD clinical diagnosis. This rate indicates an elevated risk in comparison to the general population but also suggests that the presence of Dup7q11.23 by itself is not strongly indicative of the presence of an ASD. Reliance on retrospective parental report alone results in a higher rate (39.7%) of identified ASD-related symptomatology. The potential contribution of the history of language delays coupled with extreme social anxiety and/or shyness characteristic of the syndrome to parental observations of sociocommunicative challenges will be discussed. Additionally, implications of these findings for clinical management of children with Dup7q11.23 and for genotype-phenotype investigations will be addressed.

31 **144.031** Blood-Based Transcriptomic Mega-Analyses Comparing Individuals with Autism Spectrum Disorder and Unaffected Comparison Subjects

D. S. Tylee*, J. L. Hess, T. P. Quinn, R. Barve and S. J. Glatt, SUNY Upstate Medical University, Syracuse, NY*

Background: Microarray technology has been applied in the study of Autism Spectrum Disorders (ASDs) for more than a decade. Blood-based studies offered a promising source of non-invasive biomarker signal and shed light on differences in immune cell functions. However, the collective body of blood-based ASD microarray literature suffers from some inconsistencies.
Objectives: In order to summarize the existing literature, we performed a mega-analysis of all available microarray whole blood and lymphocyte studies that comparing ASD cases (n = 647) and unaffected, non-family member comparison subjects (n = 468).
Methods: We modeled covariate effects and adjusted regression models per gene to remove non-significant covariates, providing best-estimates of transcripts dysregulated

in ASD. We also performed permutation-based gene set and co-expression network analyses. Our results provide the best available characterization of dysregulated gene transcripts and emergent functions in ASD blood samples.
Results: Our results were consistent with diminished interferon-, EGF-, PDGF-, PI3K-AKT-MTOR-, and RAS-MAPK-signaling cascades, and increased ribosomal translation and NK-cell related activity in ASD. We explore evidence that distinct subgroups of ASD cases may contribute to observed effects for different gene sets and network modules. We also explore evidence for sex-differences in the transcriptomic signature of ASD; more studies of female samples will be required to confirm these findings. Finally, we constructed generalizable machine-learning classifiers using the blood-based microarray data.
Conclusions: We contrast our results with respect to blood- and brain-based RNA and protein biomarker (e.g. cytokines, growth factors) studies and we discuss the ways that blood transcriptomic signals implicate some pathways known to play causal roles in syndromic ASDs.

32 **144.032** Brain Structure and Quantitative Trait Shifts in 16p11.2 De Novo Deletions Relative to Non-Carrier Siblings

A. M. Michael[1,2], *D. W. Evans*[3], *A. Moreno De Luca*[1,4], *C. C. Dougherty*[1] *and G. J. Moore*[1,2,4], *(1)Autism and Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA, (2)Institute of Advanced Application, Geisinger Health System, Danville, PA, (3)Department of Psychology, Bucknell University, Lewisburg, PA, (4)Radiology, Geisinger Health System, Danville, PA*

Background: The 16p11.2 deletion syndrome is a copy number variation (CNV) resulting in the deletion of 29 genes. It may be inherited or occur as a *de novo*event, and has been associated with a range of neurodevelopmental and neuropsychiatric disorders (NDPSs) including autism spectrum disorders (ASD) (Moreno-De-Luca 2013; Maillard 2014). The 16p11.2 deletion is found in up to 1% of individuals with ASD, and is associated with increased total intracranial, gray, and white matter volumes as well as volumetric increases in the cerebellum, thalamus, fusiform and superior temporal gyri, precuneus, and insula (Qureshi 2014, Maillard 2014). Recent studies indicate that the 16p11.2 deletions carriers exhibit a 'shift' (delta between the non-carrier sibling) toward greater impairment on a range of phenotypic traits (Moreno-De-Luca 2014). It remains unclear, however, whether similar shifts, relative to non-carrier relatives, also apply to key brain structures.
Objectives: Here, we aim (1) to replicate findings that reveal phenotypic shifts in 16p11.2 deletions relative to non-carrier siblings on a variety of quantitative phenotypic traits; (2) to examine whether deletions exhibit volumetric shifts in brain regions relative to non-carrier siblings; (3) examine whether observed phenotypic shifts in deletions may be explained by corresponding shifts in brain volumes.
Methods: Fifteen families with 16p11.2 de-novo deletions (12.6±4 years) and non-carrier siblings (12.1±5.6 years) from the Simons Variation in Individuals Project (Simons VIP Consortium, 2012) were included in this study. Verbal and non-verbal IQ, CBCL-Internalizing and CBCL-Externalizing, SRS, Purdue Pegboard Test scores and high resolution brain MRIs were examined. Volumes of cortical and subcortical brain structures were computed using FreeSurfer, adjusted for age, sex and BMI and were normalized by each subject's total brain volume.
Results: As noted previously, phenotypic scores of deletion were shifted toward greater impairment relative to their siblings (percentages of families out of 15 and P-values are within parenthesis) in the following domains: verbal IQ (87%, 0.006), non-verbal IQ (80%, 0.02), CBCL Internalizing (87%, 0.006), SRS (100%, 6E-5) and Pegboard (87%, 0.006); see Figure 1. In 11 of 15 families (73%), deletions had larger total brain volume compared to their siblings. But in all 15 families (P<6E-5) deletions' cortical gray matter volume when calculated as a percentage of total brain was smaller compared to siblings (Figure 2). Deletions' ventricles were negatively correlated with both verbal (P<0.02) and non-verbal (P<0.004) IQ; corpus callosum volume was positively correlated with CBCL-Internalizing (P<0.03). In non-carrier siblings, thalamic volume correlated positively to non-verbal-IQ (P<0.02), and the ventral-DC was negatively correlated to CBCL-Internalizing (P<0.03) and CBCL-Externalizing (P<0.02). The shift in ventricular volume predicted shift in verbal-IQ (P<0.04) and non-verbal-IQ (P<0.02).
Conclusions: This study shows that *de novo* 16p11.2 deletions show deleterious phenotypic shifts relative to non-carrier siblings and shifts in brain volume of key structures implicated in ASD and other NDPDs. We show that shifts in certain phenotypes can be mirrored by shifts in brain structures. These findings highlight the importance of considering family background when examining the deleterious impact of the 16p11.2 and other CNV syndromes that are implicated in NDNPs.

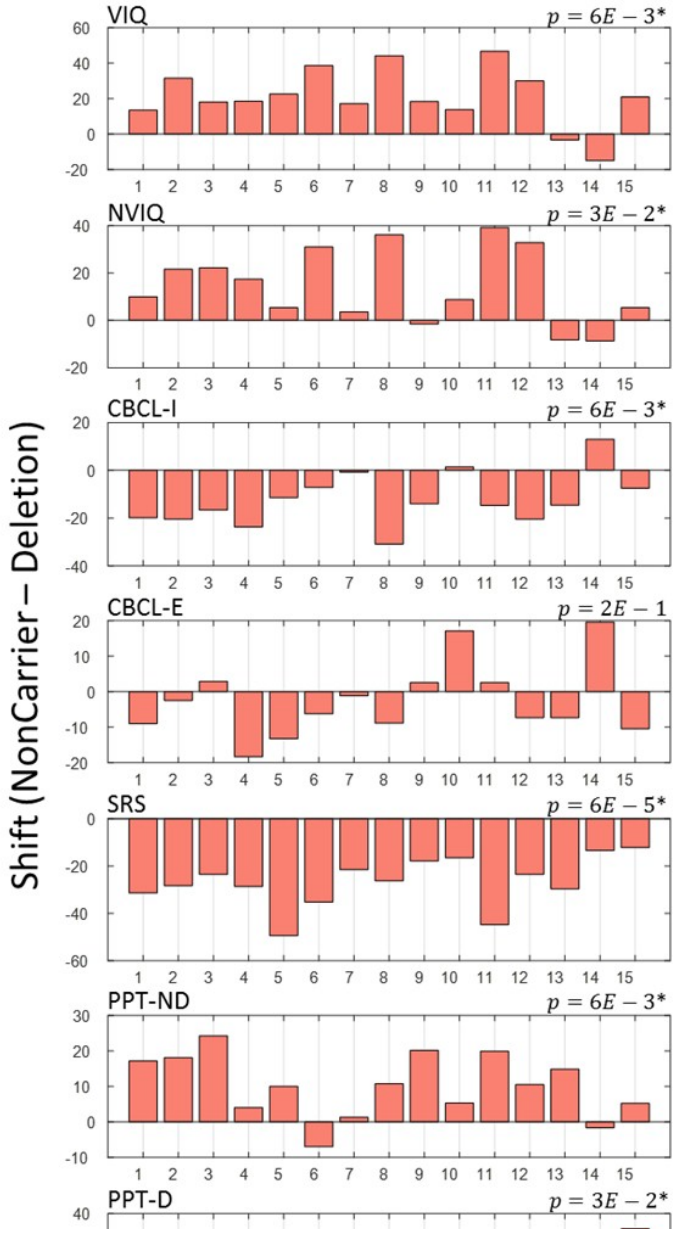

Figure 1: Phenotypic Shift (= NonCarrier – Deletion) for Each Individual Family

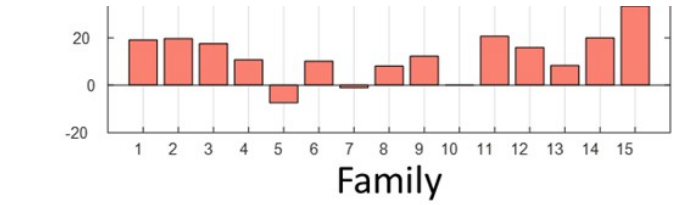
Compared to non-carrier siblings, deletions exhibit deleterious phenotypic shifts in cognitive, social and motor domains. Except CBCL-E, the direction of all other test scores are statistically significant at the family level. VIQ = Verbal IQ, NVIQ = non-verbal, CBCL-I = child behavior checklist – Internalizing, CBCL-E = CBCL



checklist Internalizing, CBCL-E = CBCL-Externalizing, SRS = social responsive scale, PPT-ND = Purdue Pegboard Test (PPT) non-dominant hand and PPT-D = PPT dominant hand.

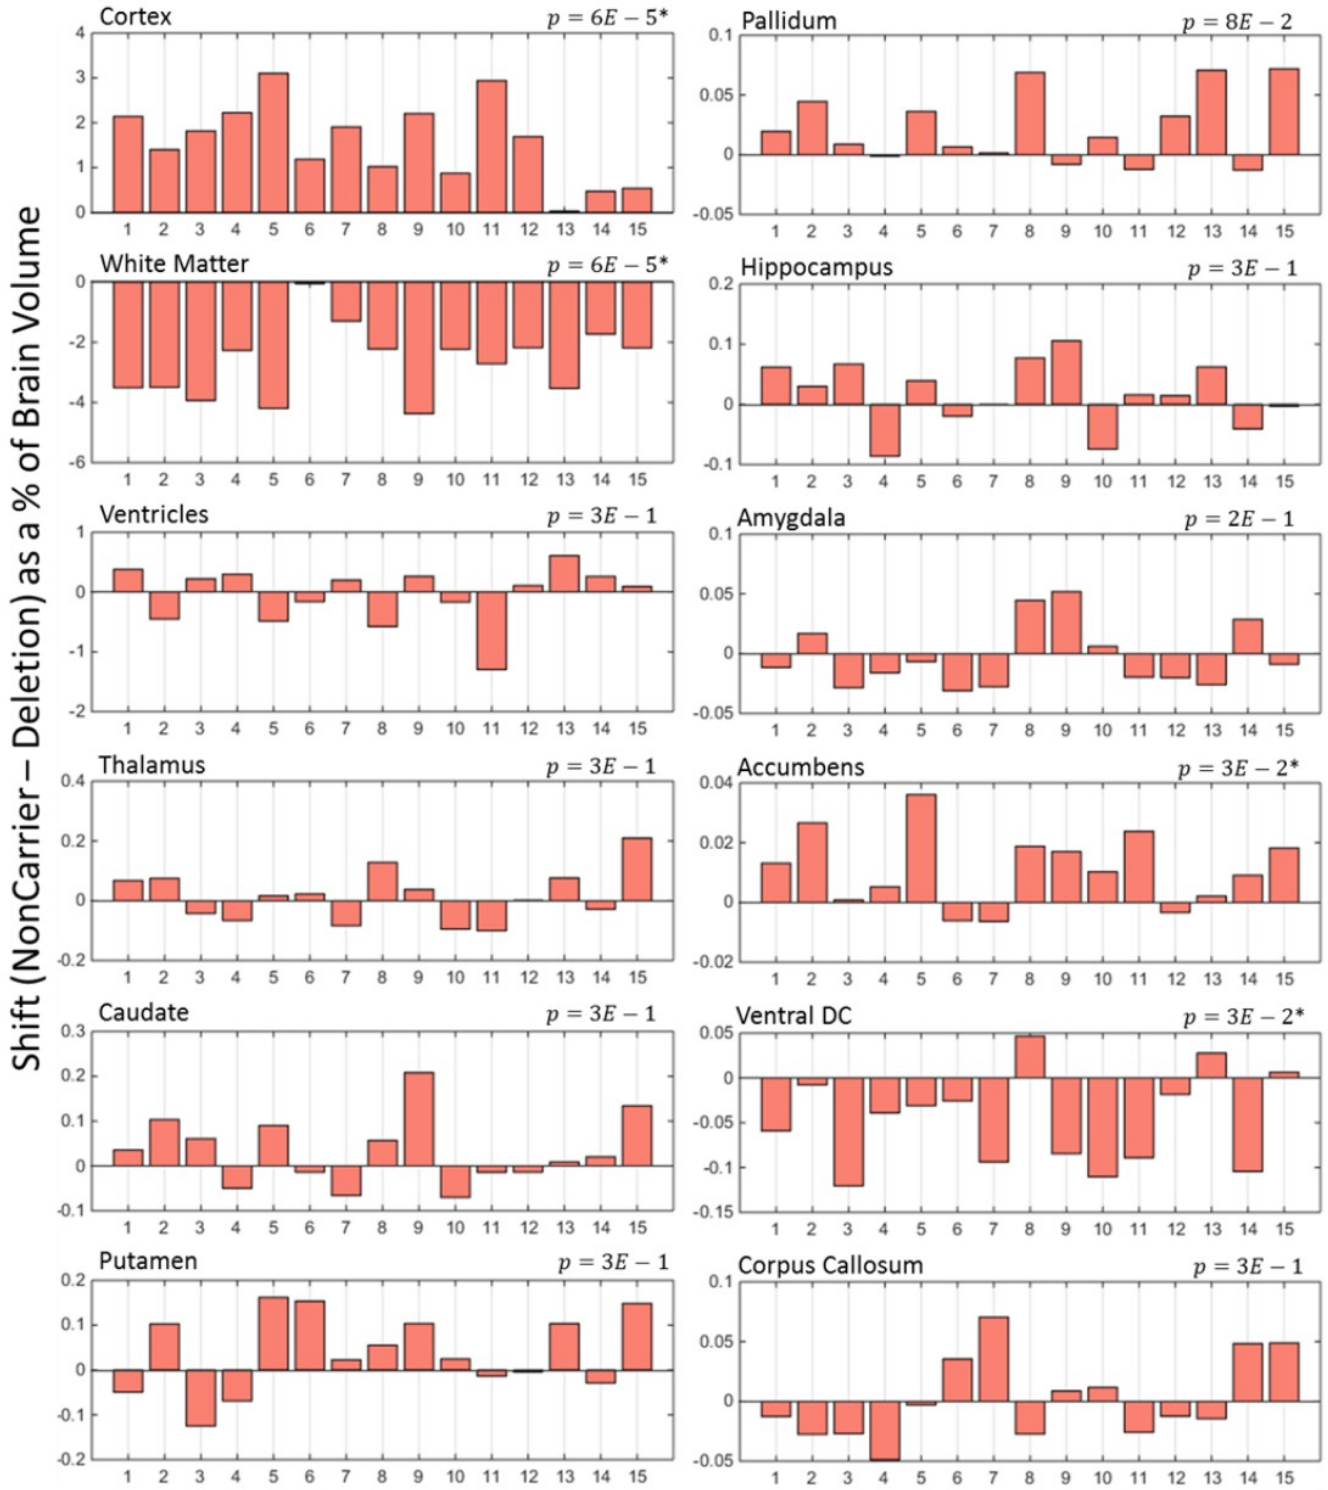


Figure 2: Brain Structure Volume Shift (= NonCarrier – Deletion) for Each Individual Family. Brain structure volume differences between non-carrier siblings and deletion carriers are presented as a percentage of brain volume. Compared to siblings, deletions exhibit lower cortex volume (up to 3%) and larger white matter volume (up to 4%) in all 15 families. Accumbens and ventral diencephalon volumes were significantly larger and smaller respectively in siblings.

33 **144.033** Building the Open Information Commons for Autism Research and Discovery: The Hartwell Autism Research and Technology Initiative (iHART)

J. Y. Jung[1], *L. Perez-Cano*[2], *M. Duda*[1], *D. Kashef-Haghighi*[1], *J. Kosmicki*[1], *J. K. Lowe*[2], *E. K. Ruzzo*[2], *S. Sharma*[1], *D. H. Geschwind*[2] *and D. Wall*[1], *(1)Department of Pediatrics, Stanford University, Stanford, CA, (2)Department of Neurology, UCLA, Los Angeles, CA*

Background: The search for markers and therapeutic targets has been hampered by the complexity of autism as an integrated system of behaviors, genetics, and environment. This highlights the urgent need for an increasingly larger collection of shared data for open investigations both within and across autism's systems.
Objectives: We have created the first openly available, cloud hosted "sandbox" of autism data. This sandbox is grounded in a foundation of whole genomic DNA sequence of nearly 5000 individuals enriched for multiplex families, twins, and females, coupled with rich phenotypic information. This sandbox has already begun to complement the large collection of autism exomes in the field to enable identification of de novo variants, large structural variants, and the effect of non-coding region variants with large-scale whole genome data. Ultimately, we hope this database as an openly accessible and cloud hosted resource will enable the field to together define the forms of autism and begin making faster gains towards the development of robust diagnostic tools and targets for therapy.
Methods: We have built a cloud resource that utilizes the massively parallel and distributed computing capabilities of Google to integrate genetic markers with phenotype within biological networks. We have also enabled a system for easy queries of the data as well as a universal interface for sharing and integration of new datasets, with the goal of both growing and sharing the data openly now and in the future.
Results: The iHART now contains nearly a petabyte of data including Illumina HiSeq X10, 30X whole genomic sequences of ~5000 individuals that we intend to grow to over 10,000 individuals spanning roughly 2500 families by 2017.
Conclusions: The iHART represents a primary example of what is both possible and necessary to reach, through interdisciplinary collaboration, a truly open "Information Commons" for autism. The effort involves collaborators from Stanford, UCLA, the Simons Foundation Autism Research Initiative (SFARI), and New York Genome Center. In our talk at IMFAR, we will describe the progress on the initiative, demonstrate the user interface to iHART, showcase the preliminary discoveries, and announce its availability for use by our growing community of open access autism researchers.

34 **144.034** CNV Analysis and Exome Sequencing in Japanese Autism Spectrum Disorder Subjects

K. Nakamura[1], *I. Thanseem*[2], *M. Tsujii*[3] *and N. Matsumoto*[4], *(1)Hirosaki University Graduate School of Medicine, Aomori, Japan, (2)Hamamatsu University School of Medicine, Hamamatsu, Japan, (3)Chukyo University, Toyota, Japan, (4)Yokohama City University Graduate School of Medicine, Yokohama, Japan*

Background: Linkage and candidate gene association studies have implicated several genes and chromosomal regions in autism. However, consistent picture of a common susceptibility loci in autism is still lacking. Hence there is paradigm shift away from the previously held "common disease – common variant" hypothesis to a "common disease – rare variant" model, for the genetic architecture of autism. There is a growing consensus among geneticists that rare structural variants including genomic copy number variations (CNVs) may contribute to the autism etiology. Most recently, exome sequencing (ES) studies have also revealed the importance of rare single nucleotide variations (SNVs).
Objectives: In this study, we have examined the global CNV, with special emphasis on rare *de novo* and inherited CNVs in Japanese samples. We have also sequenced the exomes of individuals which include patients with sporadic autism and their parents, reasoning that these families with no previous history of ASD or related phenotypes would be enriched for *de novo* mutations.
Methods: The 203 families were recruited on collaboration with a non-governmental organization, Asperger Society Japan (http://www.as-japan.jp/) in central Japan. The Affymetrix Genome-Wide Human SNP *Nsp*/*Sty* 6.0 array was used to screen the samples. PennCNV and Birdsuite package were used to identify autosomal CNVs from the genome wide SNP data. We have also sequenced the exomes of 60 individuals which include 20 patients with sporadic autism and their parents. For exome sequencing, Genomic DNA was captured using SureSelect Human All Exon v5 kit, and sequenced on HiSeq2000. Image analysis and base calling were performed by sequence control software real-time analysis and CASAVA software v1.8. Single-nucleotide variants and small indels were identified using the GATK UnifiedGenotyper and filtered according to the Broad Institute's best-practice guidelines v3.
Results: Among a total of 7305 CNVs detected in affected children after all QC corrections, 3728 were found to be affecting genes. Among the remaining 378 CNVs, 17 novel/ultra-rare *de novo* events were identified through a series of filtering and validating strategies. Among the *de novo* events, there were four novel, five partially novel and eight ultra-rare CNVs; many of these regions has genes involved in neurodevelopmental pathways. Among the inherited CNV, we found 53 ultra-rare events. All of the ultra-rare/novel CNVs were re-confirmed by relative qPCR. A total of 32 rare novel *de novo* events were observed though ES. This includes 15 missense mutations, a nonsense mutation, 2 frameshift mutations caused by indels, one splice site mutation, and 7 synonymous mutations. 25 de novo events had occurred within the coding sequences, while the remaining 7 de novo events were located within 20 bp of the exon/intron boundary. Majority of these mutations were predicted (PolyPhen or SIFT) to have a damaging effect on the respective protein structure/function. Several of these genes have been implicated in neural functions.
Conclusions: We discovered several novel/ultra-rare *de novo* and inherited CNVs and SNVs, many of them are potentially deleterious; further highlighting the genetic heterogeneity of the disorder. Many of these variations affect genes that play major roles in crucial neurodevelopmental processes.

35 **144.035** Chinese Control Sample Collection for Genetic Studies of Autism Spectrum Disorder

S. An[1], *W. Zhou*[2], *Q. Wu*[2], *J. Zhang*[1], *C. Yang*[1], *H. Zhao*[1], *B. Zhao*[1], *S. Wang*[1], *X. Zheng*[1], *X. Yang*[2], *J. Li*[2], *H. Gao*[2], *Y. Dou*[2], *L. Yan*[2], *M. Wang*[2], *Y. Ye*[2] *and L. Wei*[1,2], *(1)National Institute of Biological Sciences, Beijing, Beijing, China, (2)Center for Bioinformatics, School of Life Sciences, Peking University, Beijing, China*

Background: Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder characterized by deficits in social communication and social interaction, and repetitive behaviors and restricted activities. Family and twin studies of ASD showed that genetic factors contribute to the etiology of ASD.
Objectives: To promote the genetic studies of ASD in Chinese population, we collected blood samples and personal information from typically developed Chinese adults.
Methods: Sample collection was approved by international review board. Informed consent was obtained from each participant before sample collection. We collected personal information of each participant from three aspects. Firstly, we collected their basic information including gender, age, born city, ethnic group, and education level. Secondly, we collected the history of ASD and other neurological and psychiatric disorders (such as intellectual disability, schizophrenia and depressive disorder) of all the participants and their relatives including their children, parents, siblings, and second and third degree relatives. Thirdly, broader autism phenotype of each participant was evaluated using autism spectrum quotient(AQ), which is a widely used self-report questionnaire used to quantify autistic traits of adults with average intelligence. The Chinese version of AQ has 35 items

and was generated using data from Taiwanese (Lau, W. Y., et al. (2013)).
Results: In total, we collected 10 ml whole blood from 776 males and 261 females. The ratio of males to females is 2.96:1. Their ages ranged from 18 to 59 years, with an average of 29.67. Participants were from 21 provinces, 3 municipalities, and 4 autonomous regions. 53.62% of participants were from north of China. Percentages of participants whose own bachelor's degree or high school diploma, respectively, were 21.60% and 32.01%. Both were higher than the levels from nationwide survey. 92.2% of participants were from Han ethnic group. For 9.45% of participants, they or their relatives were diagnosed with or suspected of neurological and/or psychiatric disorders. The total AQ scores of males (77.52645 ± 9.458683) were higher than that of females (76.1341 ± 9.656864) (two sided t-test, p-value=0.04), which was consistent with previous studies.
Conclusions:
We collected control blood samples from typically developed Chinese adults with detailed personal information, which will greatly contribute to the genetic studies of ASD in China.

36 **144.036** Clinical Characterisation of Neurexin1 Deletions and Their Role in Neurodevelopmental Disorders

J. E. Fitzgerald[1], *J. Hall*[2], *M. van den Bree*[2], *R. Delorme*[3], *T. Werge*[4], *A. C. Tabet*[5,6], *L. T. Duong*[7], *H. Peeters*[8], *I. Noens*[9], *N. Cosemans*[8], *S. Esteba*[10], *M. Al-Shehhi*[11], *R. Novell*[10], *S. Lynch*[11], *A. Green*[12], *S. Shen*[13] *and L. Gallagher*[14,15], *(1)Trinity College Dublin, Dublin, Ireland, (2)Cardiff University, Cardiff, Wales, (3)Child and Adolescent Psychiatry, Robert Debre Hospital, Paris, France, (4)University of Copenhagen, Copenhagen, Denmark, (5)Robert Debre Hospital, Paris, France, (6)GHFC unit, Pasteur Institute, Paris, France, (7)Forensic Psychiatry of Zeeland, Mental health of the Region of Zeeland, Slagelse, Denmark, (8)Center for Human Genetics, KU Leuven, Leuven, Belgium, (9)Parenting and Special Education Research Unit, KU Leuven, Leuven, Belgium, (10)Institute for Health Assistance (IAS) and Julia Martin Park Hospital, Girona, Spain, (11)National Centre for Medical Genetics, Dublin, Ireland, (12)Our Lady's Children's Hospital, Crumlin, National Centre for Medical Genetics, Dublin, Ireland, (13)REMEDI, National College of Ireland Galway, Galway, Ireland, (14)Psychiatry, Trinity College Dublin, Dublin, Ireland, (15)Linndara Child and Adolescent Mental Health Services, Dublin, Ireland*

Background:
The Neurexin1 (NRXN1; 2p16.3) gene has been identified as a rare but significant genetic risk factor for a number of neurodevelopmental disorders including autism spectrum disorder (ASD), schizophrenia, intellectual disability and bipolar disorder. NRXN1 encodes neurexins, presynaptic neuronal adhesion molecules that bind to postsynaptic neuroligins to stabilise synapse formation and facilitate neuronal transmission. Common clinical features are associated with NRXN1 deletions but these have not been deconstructed using in-depth neuropsychological, neurocognitive and neuroimaging techniques.
Objectives:
This European-wide collaboration aims to deep phenotype individuals and characterise the clinicopathological features of NRXN1 deletions in order to establish diagnostic biomarkers and targeted therapeutic interventions.
Methods:
Individuals with NRXN1 deletions are currently being identified and recruited through clinical genetic services at each site. All consented participants are completing a battery of semi-structured neuropsychological assessments and questionnaires to probe for existing and/or sub-threshold psychiatric disorders or symptoms. A comprehensive cognition battery (CANTAB), which includes tests of reaction time, attention, executive functioning, working memory, cognitive flexibility and social cognition are administered to all participants to assess neurocognitive functioning. Abnormal brain structure and function is investigated using both MRI and EEG techniques. High resolution T1, diffusion weighted, magnetic resonance spectroscopy and resting state functional data are acquired using MRI. EEG measured brain activity is probed during resting state in addition to visual and auditory oddball paradigms. Parallel investigations of patient derived iPSCs are also ongoing.
Results:
To date, 117 individuals from 61 families have been identified with NRXN1 deletions across 6 European sites and recruitment is ongoing. Neuropsychological assessments have been administered to 26 individuals (8 de novo, 8 inherited and 10 familial carriers). From these, 12 individuals have met criteria for ASD, 7 for intellectual disability (3 mild ID and 4 severe ID), 5 for epilepsy, 5 for an anxiety disorder, 3 for a psychotic disorder, 3 for ADHD and 2 for a mood disorder. Neurocognitive assessments to date (n=6) indicate that poor attention and executive dysfunction are most characteristic of individuals with NRXN1 deletions. Preliminary MRI data (n=6) suggests individuals with NRXN1 deletions have an altered cortical structure, characterised by reduced cortical thickness, greater surface area and disrupted white matter organisation.
Conclusions:
Although the study data are preliminary, interesting clinical characteristics of NRXN1 deletions are emerging. NRXN1 deletions are an important risk factor for neurodevelopmental disorders. Additional clinical and neurobiological phenotyping in addition to mapping of the NRXN1 genotype may elucidate the underlying neurobiological processes contributing to neurodevelopmental disorders.

37 **144.037** Comprehensive Autism Spectrum Screening for Infants (CASS-i): A Screening Tool for Autism Spectrum Disorder (ASD) and Developmental Learning Delay (DLD) and the Incidence of Copy Number Variance (CNV)

C. Samango-Sprouse[1,2,3], *C. Keen*[1], *K. Haskell*[1], *F. Aliabadi*[4], *C. Parmele*[5] *and A. Gropman*[6], *(1)The Focus Foundation, Crofton, MD, (2)George Washington University, Washington, DC, (3)Molecular Genetics, Florida International University, Miami, FL, (4)The Pediatric Group, Crofton, MD, (5)Annapolis Pediatrics, Annapolis, MD, (6)Neurodevelopmental Disabilities and Neurogenetics, Children's National Medical Center, Washington, DC*

Background: The CDC estimates ASD occurs 1:88 children, and an increased incidence of CNV in ASD and DLD has been documented [Roberts et al., 2014]. The earlier at-risk infants with ASD or DLD and the associated CNV are detected, the sooner the infant can receive targeted interventions to reduce the impacts of these disorders and improve outcome. The CASS-i is based on previously published findings on a combination of early indicators of motor, social and physical attributes associated with ASD and DLD [Samango-Sprouse et al., 2015].
Objectives: To develop a screening tool that identifies salient biomarkers for efficient, easy, quick and effective utilization by primary care providers (abbreviation not used again so deleted to save space). To identify infants prior to 12 months of age for ASD and DLD, and to use Chromosomal Microarray (CMA) to quantify the incidence of CNV.
Methods: Two large pediatric groups located in suburban Maryland assessed 4 biomarkers at 9-month well baby visits (WBV). These biomarkers were: head tilt reflex (HTR), accelerated head growth and increased head circumference (HC), pulls to sit (PTS), and turns to name (TTN). The Pervasive Developmental Disorders Screening Test (PDDST) was given at 30 months as an exit screening test to identify infants who may have been missed during 9 month WBV. An absence of any of the 4 biomarker screeners, or an abnormal PDDST were indicated as "red flags" and followed up with a neurodevelopmental evaluation. Institutional Review Board approval for the study was given and updated annually.
Results: A total of 339 typical developing infants with no known history of ASD or neurogenetic disorders were enrolled in the study. Of the 339, 302 had appropriate responses on all 4 biomarkers. 37 had abnormal results in 1 or more of the biomarkers or the PDDST. Of the 37 with abnormal results, 23 came in for neurodevelopmental evaluations, 7 declined, 5 gave no response, and 2 did not show. From the 23 who came in for evaluations, 10 infants (43%) were identified at risk for ASD or DLD; specifically, 5 infants were identified to be at risk for ASD and 5 were identified to be at risk for DLD. So far, CMAs were completed on 11 of the 23 infants (not all in 'at risk' group, 8/10 at risk had CMAs completed – chart below) and 2 had CNVs (18%). Both with CNVs were part of the 'at risk' cohort (20%). One of the CNVs found is associated with ASD, and the other CNV places the infant at risk for an autosomal recessive genetic condition and is associated with DLD.
Conclusions: CASS-i is an expansion of earlier findings and further supports that it's a quick, easy and effective screening tool to identify at risk infants for ASD and DLD prior to 12 months [Samango-Sprouse et al., 2015]. The incidence of CNVs within our 'at risk' DLD infant population support previous findings and is supplementary to existing research of the increased incidence of CNV and ASD [Roberts et al., 2014].

38 **144.038** Effect of Autism Risk CNVs on Autistic and Neuropsychiatric Traits in a Population Based Adolescent Sample

E. Loth[1], *R. Toro*[2], *J. B. Poline*[3], *G. Huguet*[4], *G. Schumann*[5] *and T. Bourgeron*[6], *(1)Institute of Psychiatry, King's College London, London, England, United Kingdom, (2)Institut Pasteur, Paris, France, (3)Berkeley University, Berkeley, CA, (4)Génétique médicale, CHU St Justine, Montréal, QC, Canada, (5)SGDP Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Institute Pasteur, Paris, France*

Background: Like many neurodevelopmental and neuropsychiatric disorders, Autism Spectrum Disorder (ASD) is viewed as lying on a continuum that shades into sub-clinical traits in the 'normal' population. Current estimates suggest that 10-20% of cases are caused by one or more copy number variants (CNVs) in the genome (see Simons Foundation Autism Research Initiative, SFARI). However, it is not known whether these same CNVs also affect autistic and related social-affective traits in the 'general population'. Furthermore, possible sex differences are indicated by recent findings suggesting that the increased male:female ratio in ASD may be due to a 'protective' effect in females, who may require a greater burden of CNVs. Finally, our understanding of potentially mediating neural and neurocognitive mechanisms is still incomplete.
Objectives: To investigate in an adolescent sample from the general population (1) the effect of ASD-risk CNVs (as compiled by SFARI) on ASD symptoms and other neuropsychiatric traits (overall, and stratified by sex); and (2) to examine whether differences in cognitive profile, brain structure and/ or function in CNV-carriers mediate the link between genetic risk factors and clinical symptoms.
Methods: Participants are 1,713 adolescents (841 males, 872 females) from the IMAGEN cohort. CNV detection was performed based on the Illumnia 610/660 arrays, using two different algorithms (QuantiSNP and PennCNV) on samples that passed Quality Control to minimize the number of potential false discoveries. For each participant we computed the number of intronic and exonic deletions/ duplications in SFARI risk-genes. In a first step, SFARI risk-gene carriers were compared to no-risk gene carriers on ASD symptoms (Social Responsiveness Scale); emotional, conduct, peer, hyperkinetic and overall problems impacting daily adaptive functioning (Strength and Difficulties Questionnaire), and IQ (WASI). In a second step, we plan to compare the groups on a number of a) neurocognitive domains: empathy/ perspective-taking, impulsivity, reward processing, attention, and working memory; (b) cortical thickness/ surface area, and (c) and strength of functional connectivity.
Results: 1,369 adolescents carried no deletion/duplication in SFARI risk genes, 297 one, 32 two, 6 three, and 9 four deletions/ duplications. We found that boys carrying one or more ASD-linked CNVs had nominally significantly higher ASD symptoms than no-risk carriers (p=.036). This effect was not observed in girls. At age 13-14 years, both male and female SFARI risk gene-carriers also had significantly more peer problems (p=.001), emotional problems (p=.028), and overall problems that impacted daily functioning (p=.00001). However, SFARI-risk gene carriers did not differ from non-carriers in terms of IQ.
Conclusions:
In a population-based sample, boys carrying one or more ASD-linked risk genes exhibited higher ASD traits than non-carriers. However, these CNVs also increased broader emotional and social (peer) problems, and overall problem impact in boys and girls at a similar rate. Consistent with findings from clinical groups, this indicates that these CNVs may not map onto a 'specific' vulnerability for ASD but a broader range of (sub-clinical) social-emotional dysfunctions. We will also report findings from ongoing analyses on the potentially mediating role of brain structure and function, and neurocognitive profile in these associations.

39 **144.039** Familial Contribution to Clinical Variability in Social Responsiveness for Individuals with Disruptive Mutations to CHD8 and CHD8 Target Genes

R. K. Earl*, C. M. Hudac, J. Gerdts, E. E. Eichler and R. Bernier, University of Washington, Seattle, WA*

Background:
Chromodomain helicase protein 8 (*CHD8*) is one of the most frequently identified *de novo* likely gene disrupting mutations (LGDM) occurring in simplex ASD (Iossifov et al, 2014; O'Roak et al, 2012). *CHD8* is a key regulator for a network of associated ASD risk genes involved in neurodevelopment (Cotney et al, 2014). Distinct phenotypic patterns have emerged for *CHD8*, yet considerable variability in ASD presentation remains (Bernier et al, 2014). Considering this variability in observed phenotype, the impact of *CHD8* and associated LGDMs may be better captured by the extent that observed performance deviates from expected outcomes. Given high familial heritability of phenotypic traits such as social behavior (Constantino, 2005), parental functioning serves as a measurement of expected outcome and informs penetrance of *de novo* gene variants (Moreno-de-Luca et al, 2014). This promising approach can help quantify genetic contribution to phenotypic variability for mutations to *CHD8* and *CHD8*-target genes.
Objectives:
First, to explore the genetic impact of disruptive events to *CHD8* and *CHD8*-targets on phenotypic variability in social functioning by quantifying observed-expected (e.g., proband-parent) discrepancy. Second, to assess the observed-expected discrepancy for *CHD8* and *CHD8*-targets relative to other ASD-associated gene-disrupting mutations and idiopathic ASD.
Methods:
Participants were simplex families of children who met strict criteria for ASD and either: (1) a *de novo* mutation of *CHD8* and *CHD8*-target genes (via Cotney et al, 2014, n=45(9 female)), (2) other non-*CHD8*-related LGDM (n=313(53)), or (3) no known gene event (i.e. idiopathic, n=2073(264)). Identified families were participants of the Simons Simplex Collection, the Autism Simplex Collection, and an ongoing study of individuals with identified ASD-risk gene events. Social behavior was measured by the Social Responsiveness Scale (Constantino, 2005) for both probands and non-carrier parents. One-way ANOVAs compared group differences in observed-expected discrepancy between proband and parents for raw SRS scores.
Results:
Overall, participants with *CHD8* and *CHD8*-target mutations had greater discrepancy in proband and paternal SRS than those with a non-*CHD8* LGDM and those with no gene event. More specifically, children with *CHD8* and *CHD8*-target mutations showed a decrement in social ability relative to expected ability as assessed by mean parental social ability (standard deviation, *SD* = 3.01), father social ability (*SD* = 2.71), and mother social ability (*SD*= 2.86). Preliminary analyses indicated that groups differed significantly in proband-father SRS difference score ($F(2, 2411) = 3.25$, $p = 0.039$, see Figure 1), but not in proband-mother or proband-parental average difference score.
Conclusions:
Individuals with *CHD8* and *CHD8*-target gene events show greater impairment in social responsiveness relative to expected (based on parental ability) than individuals with a non-*CHD8* LGDM or no gene event. The presence of this effect for paternal but not maternal comparisons may indicate a differential genetic contribution to social behavior. Overall, findings suggest a unique pattern of penetrance for *de novo CHD8*-related events compared to other LGDMs, which may enhance understanding of symptom

severity and treatment.

40 **144.040** Genome-Wide ASD Phenotype-Genotype Association Study in Two Large Data Sets

A. Yousaf[1], *R. Waltes*[1], *D. Haslinger*[1], *S. Lindlar*[1], *S. M. Klauck*[2], *E. Duketis*[1], *M. Sachse*[1], *A. Voran*[3], *M. Biscaldi*[4], *M. Schulte-Rüther*[5], *S. Kupferschmid*[6], *S. Cichon*[7,8,9,10], *M. Noethen*[7], *J. Ackermann*[11], *I. Koch*[11], *C. M. Freitag*[1] *and A. Chiocchetti*[1], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Johann Wolfgang Goethe-University Frankfurt/Main, Frankfurt, Germany, (2)Cancer Genome Research Group, German Cancer Research Center (DKFZ), Heidelberg, Germany, (3)Department of Child and Adolescent Psychiatry, Saarland University Hospital, Homburg, Homburg, Germany, (4)Department of Child and Adolescent Psychiatry, University Hospital Freiburg, Freiburg, Germany, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (6)University Hospital of Child and Adolescent Psychiatry, University of Bern, Bern, Switzerland, (7)Institute of Human Genetics, University of Bonn, Bonn, Germany, (8)Department of Genomics, University of Bonn, Bonn, Germany, (9)Division of Medical Genetics, Department of Biomedicine, University of Basel, Basel, Switzerland, (10)Institute of Neuroscience and Medicine (INM-1), Research Center Juelich, Juelich, Germany, (11)Molecular Bioinformatics, Institute of Computer Science, Johann Wolfgang Goethe-University Frankfurt am Main, Frankfurt, Germany*

Background:
Autism spectrum disorders (ASD) are a group of genetically and phenotypically heterogeneous neurodevelopmental disorders. Approximately 49% of ASD heritability can be attributed to common variants (Gaugler et al.,2014) which are also suggested to contribute to phenotypic variability (Devlin et al., 2011, Anney et al.,2011, Davis et al.,2012). Only few studies have reported association of specific genetic variants with quantitative ASD phenotypes. Latest research shows that a system-wide analysis of genetics of ASD phenotypes has an important role in understanding the heterogeneity of this disorder.
Objectives:
Here, we aimed at discovering associations of common variants with Autism Diagnostic Interview-Revised (ADI-R) items. We thus performed a whole-genome analysis on ADI-R scores of ASD patients. To interpret the findings in their biological context we mapped significant variants to their genes and tested for enriched pathways. Our approach aims at identifying potential pathomechanisms that modulate ASD symptoms.
Methods:
Using the “1000 Genomes” data containing ~79 million variants as reference, we imputed whole genome data of two large Datasets, the Autism Genome Project (AGP) and a newly genotyped German data set (Illumina 770K OmniExpress). We defined independent ASD phenotypes based on factors extracted from ADI-R scores following the approach of Liu et al. (2011) implementing exploratory and confirmatory factor analysis. SNPs overlapping in both cohorts with a minor allele frequency above 0.05 were included and tested for association with each of the 5 factors extracted using fixed effect linear regression models. Models were corrected for ethnicity, collecting center and gender. Nominally significant SNPs identified in both, the AGP and the German data set, were subjected to downstream analyses including gene mapping, GO-term enrichment as well as identification of co-regulatory gene modules of brain-development significantly associated with each phenotype.
Results:
We generated five Eigen-phenotypes (EP) from the ADI-R factor analysis labeled as Joint Attention, Social Interaction and Communication, Non-verbal Communication, Repetitive Sensory-motor Behavior and Compulsion/Restricted Interests. Ancestry analysis showed that distribution of ethnicities is similar between AGP and German data. In a preliminary approach using 163,136 tagging SNPs only, we identified for each EP more than 400 SNPs that were nominally associated in both cohorts. GO-term analysis revealed that genes associated with EPs were enriched for phenotype specific biological processes including “Neuron projection and development” for Joint Attention or “Locomotor behavior” for Repetitive Sensory-Motor Behavior.
Conclusions:
Our preliminary study showed that the genetic architecture of the individual EPs is specific, suggesting, that the different phenotypic aspects of ASD might have a distinct underlying genetic basis. We expect that our additional analysis including all imputed SNPs will refine our findings and increase our understanding of mechanisms modulating ASD phenotypes.

41 **144.041** Genotype-Phenotype Correlations of Phelan-Mcdermid Syndrome Based on Neurodevelopmental Gene Expression Patterns of the 22q13 Region

L. P. Grosvenor[1], *M. N. Ziats*[2] *and O. M. Rennert*[3], *(1)NIMH, NIH, Washington, DC, (2)NICHD, NIH, Bethesda, MD, (3)NICHD, NIH, Bthesda, MD*

Background: Phelan-McDermid Syndrome (PMS), also known as 22q13 deletion syndrome, is a rare genetic disorder that results from gene deletions on chromosome 22. Hundreds of different deletions of varying size have been reported in this gene-rich region, which contains ~100 coding mRNAs as well as other, poorly characterized non-coding RNAs (ncRNAs). The clinical phenotype of PMS is similarly heterogeneous, characterized by intellectual disability, autism spectrum disorder (ASD), hypotonia, severe delays or absence of speech, and dysmorphic physical features. Investigations into the molecular mechanisms linking deletions on 22q13 to the clinical phenotype have focused on the synaptic scaffolding protein *SHANK3*, despite observations suggesting the phenotype of PMS is dependent on gene deletion size. It is important to understand what role other RNAs on 22q13 may play in human neurodevelopment, and how their disruption may contribute to features of the PMS phenotype.
Objectives: This work attempts to (i) comprehensively assess in an unbiased manner the functional genomic landscape of the 22q13 region and then (ii) to interpret these discoveries in the context of genomic location on 22q13 and the phenotypic features of PMS.
Methods: We used the Allen Brain Atlas database to assess the brain expression patterns of genes on the 22q13 region across typical neurodevelopment (16 brain regions; 2nd trimester through 40 years of age). We identified a subset of genes in the 22q13 region with enhanced expression in early development and in autism-related brain regions, and then analyzed the interactions of these genes and their roles in molecular pathways using the Ingenuity Pathway Analysis (IPA) software.
Results: Surprisingly, we found the majority (38/69; 55%) of genes on 22q13 are not expressed in the brain at all. Furthermore, we found that 9/24 (38%) of *SHANK3* exons do not have detectable expression during human neurodevelopment. The spatio-temporal expression profiles of individual genes vary across development, and multiple trends emerge, such as a decrease in expression during early childhood (ages 2-4 years). In particular, we found *SHANK3* is not expressed in brain prenatally compared to postnatally. In addition to *SHANK3*, we identified 4 genes on 22q13 as critical to typical neurodevelopment based on their expression: *ATXN10*, *MAPK8IP2*, *MLC1*, and *SULT4A1*. Network analyses of these genes revealed significant interactions with *SHANK3* and consistent enrichment on molecular pathways critical to synaptic development, cell-to-cell signaling, and plasma membrane transport.
Conclusions: Our results provide insight into the genomic landscape of the 22q13 region and the role these genes play in neurodevelopment. Most of the genes in this region are not expressed in the brain at all, and the expressed genes exhibit highly variable expression across development. Similar variation and unexpected lack of expression also exist for *SHANK3* exons. We show *SHANK3* is expressed significantly less prenatally compared to postnatally, which has potential implications for developing treatments of PMS. We identified four additional genes on 22q13 that have very high neurodevelopmental expression, play critical roles in cell-to-cell signaling, membrane transport, and synaptic scaffolding pathways, and which may be additional strong candidates for genes underlying the PMS phenotype.

42 **144.042** Glutamatergic Signalling and Autism: A Family Based Association Study on the Glutamatergic Neurotransmitter System

A. Yousaf[1], *H. S. Bour*[1], *D. Haslinger*[1], *E. Duketis*[1], *T. Jarczok*[1], *M. Sachse*[1], *A. Voran*[2], *M. Biscaldi*[3], *S. Kupferschmid*[4], *M. Schulte-Rüther*[5], *F. Degenhardt*[6,7], *S. Herms*[6,7,8], *S. Cichon*[6,7,8,9], *I. Koch*[10], *R. J. Anney*[11,12], ***A. Chiocchetti***[1] *and C. M. Freitag*[1], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Johann Wolfgang Goethe-University Frankfurt/Main, Frankfurt, Germany, (2)Department of Child and Adolescent Psychiatry, Saarland University Hospital, Homburg, Homburg, Germany, (3)Department of Child and Adolescent Psychiatry, University Hospital Freiburg, Freiburg, Germany, (4)University Hospital of Child and Adolescent Psychiatry, University of Bern, Bern, Switzerland, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (6)Institute of Human Genetics, University of Bonn, Bonn, Germany, (7)Department of Genomics, University of Bonn, Bonn, Germany, (8)Division of Medical Genetics, Department of Biomedicine, University of Basel, Basel, Switzerland, (9)Institute of Neuroscience and Medicine (INM-1), Research Center Juelich, Juelich, Germany, (10)Molecular Bioinformatics, Institute of Computer Science, Johann Wolfgang Goethe-University Frankfurt am Main, Frankfurt, Germany, (11)Trinity College Dublin, Dublin, Ireland, (12)Institute of Psychological Medicine and Clinical Neurosciences, Cardiff University,, Cardiff, United Kingdom*

Background:
Common single nucleotide polymorphisms (SNPs) can explain up to 50% of ASD risk. In a previous study we showed that common functional SNPs of genes implicated in Fragile X Syndrome (FXS) are associated with ASD risk (Waltes et al., 2014). Interestingly, the FXS associated protein FMRP is regulated by the glutamatergic system, a pathomechanism discussed for ASD.
Objectives:
Here we tested if functional common SNPs of glutamatergic genes are also associated with ASD risk or ASD specific symptoms in two large ASD family cohorts (Autism Genome Project/AGP set, N=2734 families; German data set N=578 families). Since the genetic architecture between individuals with High IQ (HIQ= IQ>70) and Low IQ (LIQ= IQ≤70) differs (Vieland et al., 2010), we also split the two cohorts into high and low functioning (HIQ, LIQ) individuals.
Methods:
207 functional SNPs of 124 glutamatergic genes with a minor allele frequency over 5% were tested using Plink v 1.9 (DFAM) in the cohort with HIQ, LIQ and the combined cohorts, respectively. Phenotype association was tested using logistic ordinal regression correcting for gender, IQ and clinical site. Phenotype measures were taken from the Autism Diagnostic Interview-Revised (ADI-R) scores for Social Interaction (Domain A), Verbal Communication (B1-B4; verbal individuals only), Non-Verbal Communication (Domain B2;B3; all individuals), Repetitive Behavior (Domain C) and Abnormal Development (Domain D). Variants significant in both cohorts with effect sizes in the same direction were considered as replicated. Similarly, genes with any nominal significant variant in both cohorts were considered as replicated hits.
Results:
We identified nominal significant associations of variants rs7206796 and rs3790112 (*GNAO1*) as well as rs3742926 (*AKAP6*) in both the German and the AGP LIQ cohort. In addition, significant but not overlapping SNPs of *AKAP2* were identified (LIQ only). rs2178865 (*GRIK1*) was associated with Abnormal Development, and rs731826 (*AKT1S1*) was associated with Non Verbal Communication in the HIQ cohorts. In addition, we report 24 genes that are nominally associated with ADI-R scores in both cohorts. Genes that were involved in all five phenotypes tested were strongly related to the TOR Pathway (e.g. genes *MTOR* and *TSC2*) or the second messenger system (e.g. G-proteins GNAS, phospholipases PLCB, protein phosphatases *PPP1CA*). A subset of genes was specific to each phenotype or significant in one of the subgroups (HIQ and LIQ) only. For example *AKAP13* or *RPS6K* are associated with Verbal Communication in Low Functioning Individuals.
Conclusions:
We suggest that variants of genes that are associated with glutamate signaling, and specifically the mTOR pathway are modulators of ASD symptoms. Genes such as *TSC1* or *RPS6K* are known to mediate glutamatergic signaling through mTOR, whereas AKAP proteins are important interactors of glutamate receptors (Sanderson et al., 2011). Both, the mTOR pathways and AKAP proteins have previously been associated with ASD (Chen et al ., 2014; Poelmans et al., 2013). Further functional analyses of glutamatergic variants are thus recommended to elucidate ASD etiology.

43 **144.043** Identification of Convergent Molecular Pathways during the Development of Neurons Derived from Patients with Idiopathic Autism Using Rnaseq Analysis

D. Dykxhoorn[1], *B. A. DeRosa*[2], *M. A. Pericak-Vance*[3], *K. Belle*[1], *J. M. Vance*[4], *C. Garcia-Serje*[1], *D. Van Booven*[5], *M. L. Cuccaro*[3] *and H. N. Cukier*[5], *(1)University of Miami Miller School of Medicine, Miami, FL, (2)The Hussman Instute for Human Genomics, Miami, FL, (3)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, (4)Hussman Institute for Human Genomics, Miami, FL, (5)John P Hussman Institute for Human Genomics, University of Miami, Miami, FL*

Background: Recent studies have shown that genes harboring ASD risk loci are highly enriched in sets of genes expressed during early neocortical development and genes encoding proteins that function in specific biological pathways involving regulation of transcription, chromatin remodeling, cell adhesion, signaling complexes, and synapse function. However, the impact that these genetic variants have on ASD pathophysiology remains largely unknown. This is due in large part to a lack of genetically-relevant human disease models. The advent of human induced pluripotent stem cell (iPSC) technology and advances in neural differentiation techniques, have made it possible to study the molecular mechanisms that underlie ASD pathology. These stem cell-based differentiation approaches mimic in vivo neurogenesis and, as such, provide the opportunity to study the neurodevelopmental nature of ASD.
Objectives: Patient-specific induced pluripotent stem cells (iPSCs) present a unique opportunity to examine the hypothesis that heterogeneous ASD loci converge on specific molecular pathways during the early neural development.
Methods: Therefore, we generated patient-specific iPSC lines from 6 unrelated ASD individuals bearing rare variants identified through exome sequencing in extended multiplex families. The patient-specific iPSCs, in addition to iPSCs derived from unrelated control individuals, were differentiated into cortical neurons and transcriptome analysis using RNAseq was performed on the neurons at three time points over a 135 day time course of their *in vitro* development. Pathway and gene ontology (GO) analysis was performed on the set of identified differentially expressed (DE) genes.
Results: Transcriptome analysis implicate disturbances in the regulation of transcription, WNT signaling, chromatin remodeling, cell adhesion and migration, and synapse development across all time points analyzed. Over the course of neuronal differentiation, we observe key changes in gene associated with neural development and synaptic functionality. The greatest number of differentially expressed genes occurred at the earliest time point. To highlight some of these findings, specific pathways enriched in early neurons (day 35 *in vitro*) were identified that include WNT/MET signaling (p = 4.9510-36) and collagen catabolism (p = 7.41-09). Diffferentially expressed genes in midpoint neurons (day 85 *in vitro*) map to pathways involving cell migration (p = 1.34-06) and GABAergic neuron signaling transmission (p = 2.86-09). In later time point neurons (day 135 *in vitro*), differentially expressed genes are enriched in pathways involving WNT-mediated axon guidance (p = 4.71-05), calcium signaling (p = 8.92-20), and chromatin remodeling (p = 1.49-24).
Conclusions: The findings of this study show that common molecular etiologies underlie pathogenesis in subsets of individuals with idiopathic autism, including neuronal differentiation, axon growth, and synapse function.

44 **144.044** Increased Frequency of TSC2 Missense Mutations in Non-Syndromic Autism

L. Kalsner[1], *B. Manwani*[2], *J. Twachtman-Bassett*[3], *E. Cornell*[4], *L. Derynioski*[5], *A. Milanese*[6], *T. Dumont-Mathieu*[7], *C. Stanley*[8] *and S. Chamberlain*[9], *(1)Connecticut Children's Medical Center, Hartford, CT, (2)Neurology, University of Connecticut Health Center, Farmington, CT, (3)Connecticut Children's Medical Center, Colchester, CT, (4)Research, Connecticut Children's Medical Center, East Hartford, CT, (5)Neurology, Connecticut Children's Medical Center, Farmington, CT, (6)Divison of Developmental and Rehabilitation Medicine, Department of Pediatrics, Connecticut Children's Medical Center, Farmington, CT, (7)Division of Developmental and Rehabilitation Medicine, Department of Pediatrics, Connecticut Children's Medical Center, Farmington, CT, (8)Courtagen Life Sciences Inc, woburn, MA, (9)Genetics and Genome Sciences, University of Connecticut Health Center, Farmington, CT*

Background: Tuberous sclerosis complex (TSC) is a neurogenetic disorder caused by heterozygous loss-of-function mutations in either the TSC1 or TSC2 genes. Classically the condition is diagnosed based on a constellation of clinical findings including hypomelanotic macules, angiofibromas, retinal hamartomas, cortical dysplasias, subependymal nodules, cardiac rhabdomyomas, and renal angiomyolipomas. It is also recognized that autism spectrum disorder is common in children with TSC, affecting roughly 50% of patients. TSC genes operate by inhibiting the mammalian target of rapamycin complex 1 (mTORC1), a complex pathway that controls translation and cell growth. Autism spectrum disorder (ASD) is neurodevelopmental disorder, characterized by impairments in social interaction, social communication and restricted or repetitive patterns of behavior. Numerous genes have been identified in which mutations cause or contribute to autism risk. Though mutations in TSC2 are known to cause tuberous sclerosis complex which is commonly associated with autism, mutations have not been known to independently increase risk for autism in the absence of clinical manifestations of TSC. We hypothesized that missense mutations in the TSC2 gene may contribute to risk for ASD, in the absence of classic signs of tuberous sclerosis complex.
Objectives: The objective of this study was to compare the frequency of TSC2 missense mutations in children with autism spectrum disorder to that found in the general population.
Methods: Peripheral blood samples were collected from 50 children diagnosed with non-syndromic autism at the Connecticut Children's Medical Center (CCMC) in the autism spectrum assessment program (ASAP) after obtaining consent according to protocols approved by the Institutional Review Board at CCMC. TSC2 sequencing was performed by Courtagen Diagnostics Laboratory as part of a multi gene panel using the Illumina MiSeq sequencing system. Variants identified were compared with reported variants in the Exome Aggregation Consortium (ExAC) database, using chi-square test.
Results: In our patient population, 8 out of 50 patients (16%) with non-syndromic autism were found to have non-synonymous missense mutations in the TSC2 gene. This is significantly higher than the reported prevalence of 1.3% in the general population, with 766 missense and loss-of-function TSC2 variants found in approximately 60,000 individuals as reported in the ExAC database, $p < 0.01$.
Conclusions: Our study concludes that patients with missense mutations in the TSC2 gene, but no clinical manifestations of tuberous sclerosis complex, may be at higher risk of autism. This may be due to the disruption of neuronal function through effects on the mTORC1 pathway and may raise the possibility of novel therapeutic targets for treatment of autism in the future.

45 **144.045** Integrating Expression Quantitative Brain Loci in ASD GWAS Analyses

C. Shu[1], *C. Ladd-Acosta*[2], *A. Jaffe*[3], *J. L. Daniels*[4], *C. J. Newschaffer*[5], *A. M. Reynolds*[6], *D. E. Schendel*[7], *L. A. Schieve*[8] *and M. D. Fallin*[9], *(1)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Lieber Institute for Brain Development, Baltimore, MD, (4)University of North Carolina, Chapel Hill, NC, (5)A.J. Drexel Autism Institute, Philadelphia, PA, (6)University of Colorado - Denver, Aurora, CO, (7)Aarhus University, Aarhus, Denmark, (8)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, (9)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: Autism Spectrum Disorder (ASD) is highly heritable and there is evidence that common genetic variation plays a major role in this variability. However, genome-wide association studies (GWAS) thus far have had limited success. Genetics studies of other psychiatric disorders have shown enrichment for genetic variants that control brain expression, i.e. brain expression quantitative trait loci (eQTLs). Limiting genome-wide single nucleotide polymorphism (SNP) analyses to subsets known to be brain eQTLs (denoted "eSNPs"), and/or located in genes known to show developmental brain expression patterns, can reduce the search space allowing important association signals to separate from signals simply due to millions of tests performed.
Objectives: To perform genome-scale SNP association analyses for ASD, limited to SNPs known to be brain eSNPs or known to be located in genes expressed in early neural development. Further, to compare patterns of genome-wide association among SNP subsets defined by expression in specific brain regions.
Methods: Brain eSNPs and their proxy SNPs, based on linkage disequilibrium (LD) in 1000 genomes, were obtained from 6 published brain eQTLs studies, with annotation for 11 different brain tissue types. GWAS was performed on all SNPs, subsets of brain eSNPs, and brain tissue specific eSNPs after LD-based SNP pruning, using SNPs data from the Study to Explore Early Development (SEED) from 584 ASD cases and 725 non-ASD controls drawn from the general population. Similar annotation-based subsetting of Psychiatric Genomics Consortium (PGC) ASD SNP results are planned. Comparisons were made by examining the patterns of QQ plots.
Results: A total of 288,675 brain eSNPs were obtained after LD pruning, along with brain tissue specific eSNPs in cerebellum(3,027), frontal cortex(1,450), hippocampus(764), inferior olivary nucleus(659), occipital cortex(695) , pons(440), putamen(425), substantia nigra(359), temporal cortex(1,420), thalamus(636), and intralobular white matter(1,034). GWAS based on brain eQTLs revealed SNPs (rs7625872, rs73861956) that separated from expectation in QQ plots, while no separation was observed in the overall GWAS analysis of SEED data. The QQ patterns were also differential by subset in analyses based on eSNPs for specific brain tissues, where only QQ plots of cerebellum, frontal cortex and temporal cortex eSNP subsets showed positive separation from expectation.
Conclusions: The findings reported here are consistent with literature on the key brain regions involved in ASD etiology, namely cerebellum, frontal cortex and temporal cortex. Subsetting GWAS analysis to brain eSNPs can provide further insight on the ASD common variant signals.

46 **144.046** Maternally Acting Gene Alleles Contribute to Autism

W. G. Johnson[1], *E. S. Stenroos*[2] *and S. Buyske*[3], *(1)661 Hoes Lane, Rutgers University, Piscataway, NJ, (2)Neurology, Rutgers-RWJMS, Piscataway, NJ, (3)Rutgers University, Piscataway, NJ*

Background:
Environmental, genetic and epigenetic factors contribute to fetal development. Genetic factors acting prenatally include maternal genes acting in maternal tissues, i.e., maternally acting gene alleles (MAGAs). MAGAs act independently of whether or not they are inherited by the fetus. From the mother's perspective, MAGAs are genetic factors, producing gene products that influence intrauterine environment. From the fetus's perspective, MAGAs are environmental factors since they act independently of any

inheritance from mother to fetus and since their effects result from gene action in the mother not in the fetus.
Maternally acting gene alleles, MAGAs, act in the mother during pregnancy to change the intrauterine environment. MAGAs produce gene products that may influence intrauterine environment. Maternal genes may have greatest effect when ratio of maternal to fetal mass is greatest, especially early in gestation. Certain anatomic effects in autism reflect changes in very early development. The role of MAGAs is less well understood than that of fetal genes.
Objectives: To assess the current data on maternal alleles in autism.
Methods: We identified reports of prenatal maternal effects and excluded those resulting from: Parent of origin effect, mitochondrial DNA variations and acute maternal environmental exposures. Methods and results for all publications were evaluated and compared.
Results: Among reports of candidate genes we found 11 reports of maternal alleles implicating 7 genes that altered the risk of autism. Five reports were of immune related alleles including *C4B* and *HLA-DRB1*. Three of these reported increased risk when mothers had the allele *HLA-DRB1*04.* A non-inherited maternal allele, NIMA, *HLA-DRB1*1302* is also a risk factor for autism. Four reports were of alleles of folate / 1-carbon metabolism, (*MTHFR, SLC19A1 and CBS*). Three of these showed altered risk based on maternal pre-natal vitamin intake. One report was of a maternal haplotype in *GSTP1,* ahaplotype made up of 2 missense polymorphisms not in high Linkage Disequilibrium with each other. Last, a maternal association of MAOA is contingent on male offspring having the same allele.
Conclusions: Maternal alleles in autism reported so far act in immune pathways, folate / 1-carbon metabolism, oxidative stress / detoxification pathways and monoamine metabolism, all of which are important in maintaining a proper environment for fetal development. Since MAGA's play an important role in autism but one less well studied then fetal genetic factors in autism, additional study is needed. A large study considering environmental influence, fetal alleles and interactions between mother and fetus and possibly epistasis is needed to better understand maternal allelic contributions to autism.

47 **144.047** Meiotic DNA Repair and Epigenetic Remodeling of the X and Y Chromosomes Could Contribute to the 'gender Bias' in Sex-Linked Autism Spectrum Disorders

***J. L. Hopkins**, M. Jamabo and P. W. Jordan, Biochemistry and Molecular Biology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background:
Autism Spectrum Disorders (ASD) exhibit a strong gender bias, whereby males are up to four times more likely to develop ASD than girls. Sex chromosome mutations have been associated with ASD, and children with sex-chromosomal aneuploidies, such as Turner [XO] and Klinefelter's [XXY] syndromes have an increased risk of developing ASD. The majority of errors that give rise to sex-chromosome abnormalities in progeny are derived from the paternal germline during meiosis I. Therefore, genomic instability during male meiosis may represent a causal factor for genetic and/or epigenetically-linked ASD pathogenesis and its increased prevalence in males.
In order for homologous chromosomes to accurately segregate during meiosis, they must first pair, synapse, and undergo crossover recombination. During male meiosis, the X and Y chromosomes remain largely unsynapsed and lack a homologous template to facilitate canonical DNA double-strand break repair, and therefore repair and segregation of the sex chromosomes is inherently error-prone. To ensure meiotic progression, the sex chromosomes are epigenetically silenced and compartmentalized into a peripheral nuclear subdomain known as the "sex body" in a process known as "Meiotic Sex Chromosome Inactivation" (MSCI). This process is initiated and maintained by accumulation of DNA damage response proteins (DDR) on the XY chromatin-wide domains. Sex chromosome silencing persists beyond meiosis and can influence imprinting and embryonic development in the next generation.
Objectives:
We hypothesize that the Polo-like kinase4 (PLK4) plays a novel role in DNA repair and epigenetic reprogramming of the sex chromosomes during male meiosis, and that failure to regulate these mechanisms in the paternal germline can lead to aberrations in imprinting and/or increased de-novo mutations in sex-linked genes. These events are likely to contribute towards the molecular etiology of sex-chromosome linked ASD.
Methods:
We have utilized a mutant mouse model (*Plk4*$^{I242N/+}$) to elucidate the meiotic role of PLK4 in male germline-quality, with emphasis on MSCI. Short-term spermatocyte culture, chromosome spreads, protein, and mRNA analysis were performed using purified germ cells from *Plk4*$^{I242N/+}$ and littermate control mice. qPCR and immunofluorescence microscopy were used to assess transcriptional silencing and condensation of the sex chromosomes in spermatocytes. Paternal X-chromosome (X_p) imprinting will be assessed at the 2-16 cell stages in WT pre-implantation embryos by using Cot1 and Xist-RNA FISH, and X-chromosome paint.
Results:
PLK4 localizes to the sex chromosomes during prophase I in males, resembling the localization patterns of DDR proteins known to be involved in MSCI. Meiotic progression, DNA damage repair, and sex-body organization and silencing is abnormal in *Plk4*$^{I242N/+}$spermatocytes.
Conclusions:
PLK4 regulates epigenetic remodeling and DNA repair of the sex chromosomes during MSCI. Ongoing studies will determine whether defective MSCI initiation and maintenance in spermatocytes can give rise to abnormal X_p chromosome imprinting. The precise mechanism by which these abnormalities lead to impaired brain development is not well understood. GWAS will be useful to determine whether any associations exist between parental meiosis-specific genes and increased mutations on the sex chromosomes in children. Assessment of paternal sperm quality might also be considered.

48 **144.048** Mssng - Combining Open Science and 10,000 Whole Genome Sequences to Speed the Delivery of New Understandings in Autism

***M. T. Pletcher**, Autism Speaks, Boston, MA*

Background: Genetics have been successfully leveraged to provide critical insights into the molecular pathology and heterogeneity of Autism Spectrum Disorder (ASD). Yet, there are critical gaps in our understanding of the disorder that prevent efficient diagnosis and treatment. In an effort to speed the delivery of new discoveries and therapeutics, Autism Speaks, along with its key partners, Google and the Hospital for Sick Children have initiated the MSSNG program.
Objectives: Through MSSNG, we have endeavored make available to a broad community of researchers, clinicians, diagnostic laboratories, and educators at least 10,000 whole genome sequences from members of families with ASD, the associated clinical and phenotypic data, and the tools necessary to fully explore and analyze that data.
Methods: After completion of the sequencing, raw genome sequences are placed on Google Cloud Platform where they are reviewed for quality and processed through a annotation pipeline that runs off the Google Genomics API. As soon as this process is completed and permission is received from the appropriate institutional review board or research ethics board, the annotated genomes are published for use by approved investigators. Any investigator with a legitimate research question can gain access to the MSSNG database by applying through a process that is managed by an independent Data Access Compliance Office and is consistent with the donors' informed consent.
Results: Nearly 5000 genomes have been completed to date and all 10,000 genomes are anticipated to be available to approved researchers by the spring of 2016. A track for the UCSC browser has been created so that even those that have not gone through the MSSNG access process can still view the variants identified in the MSSNG dataset and their associated frequencies. Although not originally available, approved researchers can now download BAM files so that they might be able to do custom analyses locally. MSSNG has also provided a web-based interface to allow individuals to identify specific variants, generate gene-specific variant lists, conduct statistical analysis, and browse individual phenotype data. Although still early, investigation of the MSSNG dataset has led to important insights into the role of de novo mutations in ASD and has identified novel genetic variants as potential causative factors in the disorder.
Conclusions: MSSNG provides an open and flexible environment to study the largest genomic resource of its kind. It provides a critical reference dataset for genetic investigations in any number of unrelated diseases while powering efforts to define discrete but clinically meaningful subcategories of ASD. Ultimately, the success of MSSNG will be determined by the value it brings to the families that made MSSNG possible through their donation, by impacting their journey with ASD and improving outcomes.

49 **144.049** Multivariate Analysis of Insomnia-Related Behaviors Profiled in the Simon's Simplex Collection

***O. J. Veatch**, J. S. Sutcliffe, Z. Warren, M. H. Potter and B. A. Malow, Vanderbilt University, Nashville, TN*

Background: Autism spectrum disorder (ASD) is a phenotypically heterogeneous condition with diverse symptomatology and expression of multiple comorbidities. The wide variability in clinical manifestations may be explained by underlying genetic heterogeneity. Incorporating evidence related to expression of comorbidities may identify clinically meaningful subgroups. For example, sleep disorders such as insomnia are common in individuals with ASD, suggesting involvement of shared molecular pathways with sleep or circadian regulation. Identifying subgroups of individuals with co-occurring insomnia may allow detection of clinically relevant genetic mechanisms conferring large effects.
Objectives: We tested the hypothesis that applying multivariate statistical approaches to analysis of insomnia-related questions available in medical histories from individuals in the Simon's Simplex Collection would effectively identify subgroups of individuals with ASD expressing comorbid insomnia.
Methods: We conducted cluster analysis evaluating parent responses on five questions specific to insomnia included in the medical histories of 2,708 children ages 4-17 years with ASD. Input variables included parent responses related to whether their children had ever had difficulty going to bed, difficulty falling asleep, frequent or prolonged awakenings at night, sleepwalking or frequent nightmares, and/or needed their parents to lay down with them in order to sleep. We determined differences between the mean sleep duration reported for individuals between identified clusters. We also evaluated differences in the proportion of individuals with parents reporting problems in sleep-related behaviors, and other comorbidities including seizures, attention deficit disorder and constipation. We also assessed whether the proportion of individuals with exonic mutations in two melatonin pathway genes (*ASMT* and *CYP1A2*), implicated in risk for both ASD and insomnia, were different between clusters.
Results: Clustering algorithms identified two distinct groups of individuals with ASD. Cluster 1 (the non-insomnia cluster) included 1,898 individuals and Cluster 2 (the

insomnia cluster) included 810 individuals. The largest difference in the clusters was related to difficulty falling asleep, followed by whether or not the child needed a parent in order to fall asleep, difficulty going to bed, and frequent or prolonged awakenings. The presence of sleepwalking or nightmares also defined some of the cluster differences; however, differences were substantially less than other questions of interest to insomnia. Individuals in Cluster 2 also had shorter sleep durations than those in Cluster 1. Furthermore, more individuals in Cluster 2 had attention deficit disorder and constipation. There was no difference between the proportions of individuals with mutations in either candidate gene between clusters.
Conclusions: Our clustering algorithm, based on five insomnia-related symptoms assessed in the SSC medical histories, was effective in allowing us to determine the most common sleep concerns in children with ASD. In addition, presence of insomnia was related to the presence of two other important comorbidities in ASD, ADD and constipation. While we did not observe a difference in mutations in the two candidate genes assessed, it is possible that these clusters represent genetically distinct ASD subsets. In order to fully evaluate potential genetic differences between clusters it will be necessary to evaluate more genes that affect sleep patterns, including circadian and melatonin receptor genes.

50 **144.050** NLGN2 Haploinsufficiency Causes a Distinctive Neurobehavioral Phenotype Characterized By Anxiety, Autism, Intellectual Disability, and Obesity

M. Shinawi[1], *D. Baldridge*[2], *G. Douglas*[3], *C. Garriga*[4] *and M. T. Cho*[3], *(1)Pediatrics, Washington University School of Medicine, St. Louis, MO, (2)Washington University School of Medicine, St. Louis, MO, (3)GeneDx, Gaithersburg, MD, (4)St. Louis Children's Hospital, St. Louis, MO*

Background: Dysregulation of synaptic function is considered a common pathophysiological mechanism for a variety of neurobehavioral phenotypes and mutations in several synaptic proteins have been implicated in these disorders. Animal and *in vitro* studies have shown that neuroligin 2 (NL2) clusters in inhibitory postsynaptic membranes and induces, through the mediation of collybistin and gephyrin, an inhibitory postsynaptic specialization by localization of the glycine and $GABA_A$ receptors. These functions are essential for the maintenance of excitatory/inhibitory balance in the brain. Deletion of *nlgn2* in mice leads to changes in the molecular make-up of inhibitory synapses and inhibitory synaptic transmission, and increases anxiety-like behaviors. Conditional knockout (KO) of *nlgn2* in the medial prefrontal cortex of mice causes deficits in anxiety, fear memory and social interaction. The conditional *nlgn2* KO in the basal amygdala, a brain region with prominent effect on fear and anxiety behaviors, leads to a robust anxiety phenotype upon exposure to an anxiogenic environment. In humans, missense variants in *NLGN2* have been implicated in a few cases of schizophrenia.
Objectives: Investigation of the molecular basis of a distinctive neurobehavioral phenotype in a 14-year-old Caucasian male.
Methods: The proband exhibited global developmental delay since early infancy. He was diagnosed with PDD-NOS at age 3 years but later his phenotype has been dominated by short attention span, severe anxiety and obsessive-compulsive behaviors. His other problems included hypotonia, some dysmorphic features, macrocephaly and obesity, which was associated with hyperphagia, food-seeking behavior, and diet-related obsession. His previous work-up has been negative and included chromosomal microarray analysis, molecular testing for fragile X syndrome, and methylation studies for Prader Willi syndrome. Exome sequencing was performed using Agilent Clinical Research Exome kit and Illumina HiSeq 2000 100 bp paired-end reads. GeneDx's XomeAnalyzer was used to evaluate sequence changes between the proband, parental samples and reference. Sanger sequencing was used to confirm positive exome findings.
Results: Exome sequencing revealed a heterozygous *de novo* variant in *NLGN2*designated as c.441C>A (p.Y147X; p.Tyr147Ter), which has not been reported previously as a disease causing mutation nor as a benign polymorphism. It is predicted to cause loss of normal protein function either through protein truncation or nonsense-mediated mRNA decay.
Conclusions: This is the first report of a truncating variant in *NLGN2* that recapitulates the anxiety phenotype in mice. We provide evidence that the *de-novo* loss-of-function variant in our proband is pathogenic. Our data add to the accumulating evidence implicating synaptic proteins in the etiologies of a spectrum of neurodevelopmental phenotypes and demonstrate the power of exome sequencing in psychogenetics. The genetic data may have implications for the treatment of the psychological findings in our proband.

51 **144.051** Placenta Methylation and Autism Risk in the Early Autism Risk Longitudinal Investigation (EARLI)

S. V. Andrews[1], *K. M. Bakulski*[1], *J. Feinberg*[2], *R. Tryggvadottir*[3], *K. D. Hansen*[4], *S. C. Brown*[5], *L. A. Croen*[6], *I. Hertz-Picciotto*[7], *C. Ladd-Acosta*[8], *C. J. Newschaffer*[9], *A. P. Feinberg*[2] *and M. D. Fallin*[10], *(1)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Johns Hopkins University, Baltimore, MD, (3)Johns Hopkins University, Center for Epigenetics, Baltimore, MD, (4)Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Mental Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (8)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (9)A.J. Drexel Autism Institute, Philadelphia, PA, (10)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: Epigenetic mechanisms are of increasing interest in Autism Spectrum Disorder (ASD) etiology. Previous studies have established an association of altered epigenetic marks in brain and lymphoblastoid tissues of ASD cases compared to controls, including DNA methylation (DNAm) and histone 3, lysine 9 trimethyl (H3K9me3) modifications. The placenta is an important mediator of stress and environmental exposures during the gestational period, shown to be a critical risk window for neurodevelopmental disorders, and is therefore of interest for etiologic investigations of ASD. However, to date, there have been no previous genome-wide studies of placenta DNAm and ASD.
Objectives: We measured DNAm across the genome in placenta tissue to identify genomic regions at which DNAm differed according to autism risk as quantified by the Autism Observational Scale for Infants (AOSI) administered at 12 months.
Methods: We isolated genomic DNA from the fetal side of 133 placenta samples from the Early Autism Risk Longitudinal Investigation (EARLI), an ongoing autism-enriched pregnancy cohort which enrolls families with a previously diagnosed ASD child during a new pregnancy. Families are followed throughout the gestational period and infants are followed from birth through 36 months. Recruitment was carried out at 4 sites: Drexel University School of Public Health & Children's Hospital of Philadelphia, University of California Davis & MIND Institute, Johns Hopkins Bloomberg School of Public Health & Kennedy Krieger Institute, and Northern California Kaiser Permanente. Sequencing libraries were prepared using the NEBNext Ultra DNA Library Prep Kit for Illumina by New England BioLabs Inc. Whole-genome bisulfite sequencing at 13x coverage used 125 base pair, paired-end reads with the Illumina HiSeq 2500. We are currently performing alignment using Bowtie2, calculating methylation at single-nucleotide resolution, and searching for differentially methylated regions (DMRs) according to AOSI score, adjusting for ancestry and sex using the BSmooth algorithm as implemented in the R package 'bsseq'.
Results: AOSI score was available on 115 of the 133 children with available placental samples (range 0-19, mean [sd] = 5.25 [3.86]). We will report at the meeting the top-ranked DMRs and explore their implicated regions for their potential functional relevance to ASD and towards placenta functionality more generally.
Conclusions: This study comprises the largest and most comprehensive survey of the placenta methylome in the context of ASD to date. Discovered regions may help define the role of placenta methylation in ASD etiology and may support the development of a placenta-based DNAm biomarker for autism risk.

52 **144.052** Prevalence of Prenatal and Perinatal Birth Complications in Individuals with and without ASD-Associated Copy Number Variants

J. Han[1], *A. Wolken*[2], *S. Barber*[1] *and R. Bernier*[1], *(1)University of Washington, Seattle, WA, (2)Seattle Children's Hospital, University of Washington, Seattle, WA*

Background: Although the etiology of ASD is unknown, both genetic and environmental factors have been implicated in autism spectrum disorder (ASD) risk. Recent advances in identifying ASD associated genetic events, such as copy number variation (CNV), underscore the role of genetics in the etiology of ASD (Sanders et al., 2015). Studies have also found that prenatal and perinatal birth complications are associated with increased risk for ASD (Gardener et al., 2009, 2011). However, the relationship between pre- and perinatal birth complications and genetic events associated with ASD is not well understood.
Objectives: The objectives are: 1) To examine the prevalence rates of birth complications in individuals diagnosed with ASD with an ASD associated CNV and those with idiopathic ASD. 2) To examine whether rates of birth complications differ between individuals with deletion versus duplication CNVs. 3) To assess the prevalence of prenatal and perinatal birth complications separately within these groups.
Methods: Participants included 285 individuals with at least one CNV (178 duplications, 107 deletions) and 2083 individuals without CNVs from the Simons Simplex Collection (SSC), none of whom had likely gene disrupting mutations (Iossifov et al., 2014). ASD associated CNVs were identified by Girirajan et al., 2013. We obtained prenatal and perinatal data from the Medical History Interview completed with parents. As defined by Froehlick-Santino et al., 2013, prenatal complications included vaginal bleeding, low gestational age, and maternal medication usage and perinatal complications included low birth weight (<2500g), jaundice, and "markers of hypoxia". We performed chi-square analyses to assess prevalence rates of birth complications for individuals with ASD associated duplications, deletions or no-CNVs.
Results: 70 (65.4%) of cases with a deletion had reported pre- or perinatal complications, while 104 (58.4%) of cases with a duplication and 1252 (60.1%) of the no-CNV group had birth complications. Non-parametric analyses examining the relationship between genetic status (presence of a deletion CNV, duplication CNV or no CNV) and presence of birth complications revealed no differences in rates of birth complications: X^2 (2, N = 2368) = 1.458 p= 0.482. When pre- and perinatal complications were examined separately, rates of perinatal complications were higher (50.5% of the total sample) than prenatal complications (20.4% of the total sample) but no significant differences between groups were observed.
Conclusions: Our results show that children with ASD associated deletions and duplications have similar rates of birth complications compared to children without any CNVs. The rate of perinatal complications was higher than the rate of prenatal complications, but no significant differences between groups were found. These findings provide strong evidence that there is no relationship between ASD associated CNVs and birth complications; however, an alternative explanation is that this may be due to study exclusion criteria, which eliminated individuals with serious birth complications and restricted sample variability. Previous work has identified the presence of specific phenotypic patterns (e.g. head circumference) related to duplications and deletions at the same locus (Jacquemont et al., 2011). Therefore, future work to investigate the

interactions of environmental factors and CNVs on birth complications is needed.

53 **144.053** Quantification of FMRP in Human and Mouse Tissues By Capture Immunoassays

W. T. Brown[1], *T. Adayev*[2], *R. Kascsak*[2], *R. Kascsak*[3], *C. Dobkin*[4], *S. Nolin*[2] *and G. LaFauci*[2], *(1)Human Genetics, Institute for Basic Research in DD, Staten Island, NY, (2)Institute for Basic Research in DD, Staten Island, NY, (3)New York State Institute for Basic Research, Staten Island, NY, (4)NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY*

Background: The Fragile X syndrome is a leading inherited cause of ASD. The Fragile X syndrome is due to mutations of the FMR1 gene that result in the absence of fragile X mental retardation protein (FMRP).
Objectives: To develop a screening test for FMRP.
Methods: We have developed a rapid, highly sensitive method for quantifying FMRP from dried blood spots and lymphocytes. This assay uses two new antibodies mAb 6B8 (Biolegend) and R477, a bacterially expressed abbreviated FMRP standard, and a Luminex platform to quantify FMRP.
Results: The assay readily distinguishes between samples from males with fragile X full mutations and samples from normal males. It also differentiates mosaic from non-mosaic full-mutation male samples. We have employed the assay to screen 2000 newborn dried blood spots (DBS) and present their distribution. We also applied the assay in a retrospective study of 76 newborn DBS that had been stored for an extended period and included full mutation males as well as normal individuals. We were able to correctly identify all 5 known male fragile X positive cases among samples stored up to 47 months.
Using mAb 5C2 (Biolegend) and R477, we have also developed a similar immunoassay for the quantification of Fmrp in mouse tissues. This assay was used to quantify Fmrp in brainstem, cerebellum, hippocampus, and cortex strains of mouse (C57 BL and FVB) in seven and ten week-old animals, showing developmental variation.
Conclusions: This sensitive assay allows for the quantitation of FMRP for purposes of newborn screening. The assay will also allow studying the developmental variation of mouse Fmrp expression in different organs.

54 **144.054** Risk Pathways to Autistic Traits and Autism Spectrum Disorder in Tuberous Sclerosis Complex (TSC)

F. S. McEwen[1], *C. R. Tye*[1], *H. Liang*[1,2], *E. D. Barker*[3], *E. L. Woodhouse*[4], *L. Underwood*[1], *F. Sheerin*[5], *N. Higgins*[6], *M. Clifford*[1], *.. Tuberous Sclerosis 2000 Study Group*[1], *J. R. Yates*[7,8] *and P. F. Bolton*[1,9], *(1)Child & Adolescent Psychiatry / Social, Genetic & Developmental Psychiatry Centre, King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (2)Southwark Child & Adolescent Neurodevelopmental Service, South London & Maudsley NHS Foundation Trust, London, United Kingdom, (3)Department of Psychology, King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (4)Forensic & Neurodevelopmental Sciences, King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (5)Department of Neuroradiology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom, (6)Department of Radiology, Addenbrooke's Hospital, Cambridge, United Kingdom, (7)Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom, (8)East Anglian Medical Genetics Service, Addenbrooke's Hospital, Cambridge, United Kingdom, (9)South London & Maudsley NHS Foundation Trust, London, United Kingdom*

Background: Tuberous sclerosis complex (TSC) is an autosomal dominant genetic condition caused by mutation of either the TSC1 or TSC2 gene, and characterised by tumour-like lesions in the skin, brain and other organs. The majority of children with TSC have epilepsy and around half have autism spectrum disorder (ASD) and/or intellectual disability. While the risk for ASD is elevated in TSC, there is marked variability in outcome, from autism, through the broader autism phenotype, to unaffected. It is not clear what causes this variability in outcome or what the underlying mechanisms might be. A number of risk factors have been associated with ASD, such as mutation, number of tubers in the cerebral cortex, and epilepsy. However, it is not known how these risk factors act together to influence the risk for ASD.
Objectives: To investigate how multiple risk factors, including mutation (TSC1 vs. TSC2), cortical tuber load, and type and severity of epilepsy, act together to increase the risk for ASD.
Methods: TS2000 is the first UK population-representative, prospective longitudinal study to chart the development of TSC throughout childhood. All cases identified as newly diagnosed during 2001-2006 were recruited (N=125) and have been followed for up to 14 years. Genotyping was carried out to determine the causal mutation; cortical tuber load was determined using brain MRI or CT scans; detailed seizure history was taken from parents and supplemented with information from medical records to rate seizure severity (Early Childhood Epilepsy Severity Scale, E-Chess); children were assessed with the Autism Diagnostic Interview-Revised (ADI-R) and the Autism Diagnostic Observation Schedule (ADOS-2) to characterise ASD outcomes.
Results: Forty-three percent of participants met criteria for ASD on both ADI-R and ADOS-2, and a further 25% met criteria on one instrument. Thirteen percent showed subthreshold autistic traits. A minority (20%) did not meet criteria on either the ADI-R or ADOS-2. Mutation (TSC1 vs. TSC2) was not significantly associated with ADI-R or ADOS-2 scores ($t(64)=0.34$, $p=.72$; $t(62)=0.51$, $p=.61$). Higher ADI-R and ADOS-2 scores were associated with: higher cortical tuber load (ADI-R rho=.23, p=.048; ADOS-2 rho=.24, p=.038); epilepsy severity in the 1st and 2nd years of life, at age 3+ years and age 7+ years (rho .25-.48, all p<.03); and a history of infantile spasms (d=0.73, p<.001; d=0.81, p<.001). Structural equation modelling suggested a risk pathway from mutation to cortical tuber load (TSC2 predicted higher tuber load), to epilepsy severity in the first two years of life, to ASD risk.
Conclusions: Children with TSC are at very high risk for ASD, as well as social/communication difficulties that fall short of diagnosis of ASD but might nonetheless be clinically important. Epilepsy in the first two years of life, especially that characterised by infantile spasms, early onset, and greater severity, leads to a high risk of ASD. The prompt diagnosis and treatment of seizures in infancy may improve the prognosis in these high risk children.

55 **144.055** Sexual Dimorphism of Regulatory Small Non-Coding RNAs in the Superior Temporal Gyrus Brain Region of Autism Spectrum Disorders: A Pilot Study

B. Stamova[1], *B. P. Ander*[1], *F. R. Sharp*[1] *and C. M. Schumann*[2], *(1)Department of Neurology, University of California, Davis, School of Medicine, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA*

Background: Autism spectrum disorders (ASD) are more common in boys than girls. The bases for sex differences in ASD are poorly understood. It is theorized that higher etiologic load, including genetic and/or environmental load, is needed for females to develop ASD. Though sex differences in ASD neuropathology have been reported, sex differences in ASD brain transcriptomes remain largely unexplored. Male and female ASD subjects could have different molecular mechanisms for normal regional patterning in the brain which could contribute to sex differences in ASD. Thus, we investigated differential expression of small non-coding RNAs (sncRNA, including microRNA) in the superior temporal gyrus (STG) of male and female brains of ASD compared to typically developing (TD) controls. We investigated the superior temporal sulcus (STS) and primary auditory cortex (PAC) within the STG. STS is an association cortex involved in social perception, joint attention, face perception and speech perception and is implicated in ASD. PAC is a primary sensory cortex modulating auditory processing.
Objectives: To assess sncRNA expression in STS and PAC in postmortem male and female human brains of ASD compared to TD controls.
Methods: Affymetrix miRNA 3.0 arrays were run on 34 samples (5 ASD Female, 5 ASD Male, 2 TD Female, 6 TD Male; two brain regions – STS, PAC; 4-58 years of age; 2 of the 18 subjects had only one brain region available). ANOVA was used to identify sexually dimorphic differentially expressed sncRNA ($p<0.005$, $|\text{fold-change}|>1.2$). REML variance estimate suitable for unbalanced designs was used. To account for normal sexual dimorphism, we compared ASD female to TD female and ASD male to TD male, and overlapped the differentially expressed sncRNA to identify sexually dimorphic sncRNA expression specifically in ASD (Fig.1).
Results: We found sexually dimorphic sncRNA expression in the ASD postmortem brain, with a higher number of sncRNA being dysregulated in females compared to males (Fig.1). There were 27 sexually dimorphic sncRNA in ASD STS (7 in male and 20 in female), 9 in ASD PAC (2 in male, 7 in female), and 71 regionally dysregulated (between STS and PAC) (31 in male, 39 in female, and 2 common) (Fig. 2). The predicted mRNA targets of the mature miRNAs are over-represented in different pathways in male and female in STS and PAC. Axonal Guidance Signaling was the most over-represented canonical pathway in the regionally dysregulated (STS vs PAC) mature miRNAs both in male (FDR-corrected p=3.1E-12) and female (FDR-corrected p=2.4E-09). However, most of the predicted dysregulated target mRNAs were different in males compared to females. A number of predicted targets have been implicated in ASD, such as MET (in female), NTRK3 (in male), and SHANK2 (in both).
Conclusions: The sexually dimorphic sncRNAs in male and female ASD brains likely contribute to aberrant development and function of STS and PAC and likely contribute to some of the sexually dimorphic features of ASD. Future studies will need to confirm these findings.

56 **144.056** Social Visual Engagement—a Putative Autism Endophenotype—Exhibits Marked Variation and Striking MZ Twin Concordance in Typical Infants

J. N. Constantino[1], *A. Klin*[2], *A. Glowinski*[3], *S. Kennon-McGill*[3], *C. Weichselbaum*[3] *and W. Jones*[2], *(1)Washington University School of Medicine, Saint Louis, MO, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (3)Washington University in St. Louis, St. Louis, MO*

Background: Diminished eye contact has long been described as a classic symptom of autism spectrum disorder, and abnormalities in eye tracking measurements of social visual engagement (SVE) have been shown to predict autism spectrum disorders (ASD) among infants in ASD-affected families, by as early as 6 months of age (Jones and Klin, 2013). Because ASD is among the most heritable of all neuropsychiatric disorders (Geschwind and State, 2015), with most of its genetic risk attributable to common (polygenic) factors, and since a majority of polygenic influences on ASD overlap with those influencing normal variation in social competency in the general population (Robinson et al., 2011), it is additionally important to examine the genetic structure of candidate developmental endophenotypes of the disorder in the general population.
Objectives: This is the first attempt to explore specific SVE predictors of ASD in an epidemiologically-ascertained sample of infants, here encompassing 56 monozygotic (MZ) twins and 112 dizygotic (DZ) twins.
Methods: We capitalized upon the availability of a unique epidemiologically-ascertained infant twin cohort, which has been previously reported (Marrus et al., 2015), and acquired precisely the same eye tracking indices which predicted ASD among infants at risk in Jones and Klin (2013), in order to explore the distribution and genetic structure of these risk indices in the general population. Full description of the eye-tracking methods can be found in Jones and Klin, 2013.
Results: Quantitative SVE measurements exhibited striking MZ twin-twin concordance (on the order of 0.90) and only moderate DZ twin-twin concordance (on the order of 0.30,) indicating extremely high heritability, minimal measurement error, and wider-than-expected variation among typically-developing twins in the 18-24 month age range. This is shown in Figure 1 (attached). To address the fact that not every child is attentive to every section of every video clip presented, we repeated the analysis incorporating only those segments for which both members of a twin pair were visually engaged. The results were unchanged. Finally, we conducted detailed analyses of moment-to-moment twin-twin correlation, which revealed striking homology in tracking of eye movement in X and Y coordinate space between the members of MZ twin pairs, again in contrast to DZ twin pairs, as shown for representative twin pairs in the attached Figure (2) for gaze location in X-coordinate space over time.
Conclusions: SVE measurements in these epidemiologically-ascertained twins reflected remarkable MZ twin-twin concordance and robust biological/ecological validity for the measurement method. By comparison, substantially lower DZ concordance confirmed that familial influence on SVE—which has been proposed as an autism endophenotype—is largely genetic in origin. We commonly (i.e. in over one third of this normative sample) observed patterns of visual fixation which predicted the occurrence of autism among infants at high familial risk. How SVE interacts with other neurodevelopmental liabilities in the ontogeny of ASD warrants intensive subsequent study.

Social Visual Engagement—A Putative Autism Endophenotype—Exhibits Marked Variation and Striking MZ Twin Concordance in Typical Infants

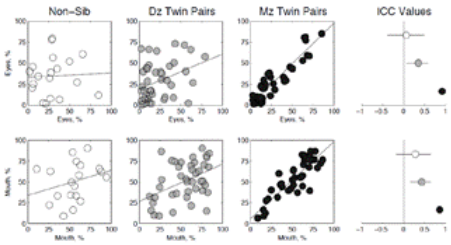

Figure 1. Scatter plots of Child 1 (x-axis) - Child 2 (y-axis) correlations for total proportion of time spent with eye gaze fixated on eyes (upper row) and mouths, for pairings of unrelated children (left column), dizygotic twins (middle column), and monozygotic twins (right column), followed by specification of intra class correlation coefficients. This depicts striking homology in fixation time for identical twins, and marked heritability of the trait, given successive erosion in ICC for DZ twins and unrelated children.

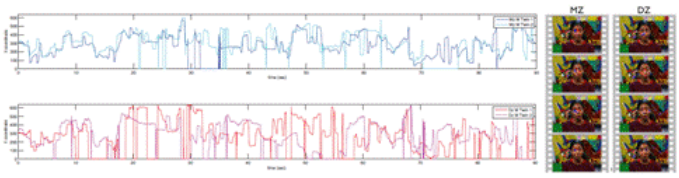

Figure 2. Representative tracing of eye gaze position in X-coordinate space plotted as a function of time for pairings of identical (MZ) twins (upper plot on the left) and non-identical (DZ) twins (lower plot on the left) during the viewing of a dynamic social scene.

57 **144.057** Temporal Gene Expression Profiles and Behavioral Regression in Children with ASD with Postsynaptic Density Gene Disruptions

S. Trinh[1], *R. P. Goin-Kochel*[2] *and R. Bernier*[1], *(1)University of Washington, Seattle, WA, (2)Baylor College of Medicine, Houston, TX*

Background: Approximately one-third of children with an autism spectrum disorder (ASD) experience developmental regression within the first three years of life. However, the mechanisms underlying this behavioral phenotype remain unknown. Recently, disruptions in postsynaptic density (PSD) genes have been found to result in higher rates of developmental regression in language and social engagement skills (Goin-Kochel et al., under review). PSD genes play a role in regulating synaptic function in human neocortex (Bayés et al., 2011) and show differential timing in expression, with some genes preferentially expressed during synaptic formation and others during synaptic remodeling and differentiation (Swulius et al., 2010). Thus, disruptions in PSD genes preferentially expressed later in synaptic development may lead to normal initial behavioral development followed by onset of abnormal development and/or behavioral regression. Understanding the relationship between developmental gene expression timing and phenotypic ASD profiles may elucidate mechanisms of behavioral regression in ASD.
Objectives: To explore the following correlations in individuals with ASD who have PSD gene disruptions: 1) gene expression timing and presence of behavioral regression and 2) gene expression timing and age of ASD symptom onset.
Methods: Participants were 33 children from the Simons Simplex Collection with PSD gene disruptions (as defined by Iossifov et al., 2014) who meet strict criteria for ASD. Age of typical maximum expression for each PSD gene was extracted from the BrainSpan transcriptome exon microarray data (http://www.brainspan.org). Eight children with parentally reported history of developmental regression in language and social engagement skills were compared to 25 children without regression. First, groups were compared using independent samples t-test on the age of typical maximum expression of disrupted genes observed between the first prenatal trimester and third postnatal year. Second, age of typical maximum expression was used to predict regression groups using logistic regression. Finally, for all participants, using regression analysis, age of typical maximum gene expression was used to predict parentally reported age of ASD symptom onset.
Results: Age of maximum expression did not predict regression group (p=.46), and regression groups did not differ significantly in age of maximum expression ($t(37)$=.72, p=.48). However, age of maximum expression significantly predicted age of ASD symptom onset ($F(1, 37)$=5.02, p=.03, R^2=.119) such that the later the age of maximum expression, the later the age of reported onset of ASD symptoms. That is, participants with disruptions in PSD genes typically expressed later in development tended to have later reported ages of ASD symptom onset.
Conclusions: The observed relationship between age of ASD symptom onset and age of maximum gene expression in individuals with likely gene-disrupting mutations to PSD genes suggests the importance of gene expression timing in symptom expression timing. Previous mouse model studies demonstrate preferential expression of PSD genes in different phases of synaptic development (Swulius et al., 2010); these findings suggest that the differential phases of expression can impact symptom onset. Better understanding of the normal developmental timing of gene expression in genes disrupted in individuals with ASD may aid in explaining the phenotypic variability regarding symptom onset among children with ASD.

58 **144.058** The Autism-Associated Long Noncoding RNA MSNP1AS Regulates a Network of Genes Involved in Neuronal Process Stability

J. DeWitt[1], *N. A. Grepo*[2], *B. Wilkinson*[1], *K. Morris*[3], *J. A. Knowles*[1] *and D. B. Campbell*[1], *(1)University of Southern California, Los Angeles, CA, (2)USC, LOS ANGELES, CA, (3)The Scripps Research Institute, San Diego, CA*

Background: From genome-wide association studies (GWAS), a novel gene was discovered that has a highly significant association with autism spectrum disorder (ASD). The gene is a long non-coding RNA (lncRNA) designated *MSNP1AS* (moesin pseudogene 1, antisense). Expression of *MSNP1AS* was increased in the cerebral cortex of individuals with ASD and individuals with the ASD-associated genetic marker. Overexpression of *MSNP1AS* in human neuronal cells caused decreased expression of moesin (*MSN*) mRNA and moesin MSN protein, which is involved in neuronal process stability and immune response. These data indicate one aspect of the potential contribution of increased *MSNP1AS*expression in ASD. However, there are likely to be additional transcriptomic impacts of this lncRNA.
Objectives: To examine the transcriptomic impacts of the lncRNA, *MSNP1AS.*
Methods: To determine the effects of altered *MSNP1AS* expression on the neuronal transcriptome, we transfected human neuronal progenitor cells with constructs that overexpressed *MSNP1AS* or transcriptionally silenced *MSNP1AS*.
Results: RNA-Seq analysis indicated altered expression of multiple genes that contribute to altered neuronal process stability and immune response, including *MSN*.
Conclusions: Our data indicate several genes that are impacted by *MSNP1AS* dysregulation more significantly than *MSN*, suggesting a network of genes that contribute to ASD risk. Ongoing experiments seek to define the role of the *MSNP1AS* gene network in neuronal process stability.

59 **144.059** The Kaiser Permanente Autism Family Biobank: A Resource for Research on Autism Spectrum Disorders

M. L. Massolo, *C. K. Yoshida, Y. Qian, A. N. Anderson and L. A. Croen, Division of Research, Kaiser Permanente, Oakland, CA*

Background:
While specific causes of autism spectrum disorders (ASD) have not been identified, the genetic contribution to ASD etiology is strongly supported by twin and family studies. A growing body of evidence also supports the role of environmental factors, especially those occurring during the gestational or early postnatal period.
Objectives:
To collect biological specimens from 5,000 trios comprised of a child (minor or adult) with ASD, and his/her two biological parents, with the ultimate goal of creating a resource that will promote and facilitate research on genetic and environmental influences of ASD and response to treatment.
Methods:
To be eligible the affected child must be a Kaiser Permanente Northern California (KP) member with an ASD diagnosis recorded in the electronic medical record, while parents need not be KP members. Prior to launching recruitment, a focus group explored concerns regarding use of genetic information in clinical care, use of genetic information in research, and biospecimen collection. Recruitment involves sending by mail or email monthly batches of invitation letters, with intensive follow-up by phone, email, and/or mail. Adults with ASD receive an individual letter, independent of their parents. Parents and adult children consent online or by phone; parents consent for minor or incapable children. Upon consenting, participants choose to donate blood or saliva. Blood is drawn at KP facilities, and saliva kits are mailed to participants' homes. Two instruments will be collected online, the SRS-2 (from all three family members) and a Family History Questionnaire. Biospecimen and survey data will be combined with longitudinal clinical and phenotypic data stored in the electronic medical record. After one year of recruitment, qualitative interviews with parents of affected children will take place to find out barriers and facilitators to study participation, and recruitment materials will be modified as needed. Recruitment is scheduled to take place from 2015 to 2018.
Results:
At the start of recruitment in July 2015 we identified 17,370 KP members with an ASD diagnosis recorded in their medical record. In terms of age and sex, 8% were <4 years of age, 40% between 5-14 years, and the rest 15 years and older; 80% are male. Almost half are white, 21% Hispanic, 17% Asian, and 8% African American. By November 2015, 684 individuals consented to participate, representing 248 unique families (192 trios, 52 duos, and 4 singles). The majority of those who consented chose saliva over blood: 82% of children, 79% of fathers, 74% of mothers. A total of 323 biosamples have been collected to date - 108 from children, 111 from mothers, and 104 from fathers.
Conclusions:
The KP Autism Family Biobank will serve as a resource to promote and facilitate autism research and will be available to researchers around the world. An access review committee will be formed to vet proposals for use. In addition, genetic data generated from the specimens and selected phenotypic data will be shared without identifiers with the Simons Foundation and deposited in the National Database for Autism Research (NDAR).

60 **144.060** The Quantitative Autism Score (QAS): A Tool to Unravel Genetic Associations

S. Luzi[1], *M. L. Cuccaro*[1], *E. R. Martin*[2], *M. A. Pericak-Vance*[1], *A. J. Griswold*[3], *J. R. Gilbert*[1] *and J. P. Hussman*[4], *(1)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, (2)John P Hussman Institute for Human Genomics, University of Miami, Miami, FL, (3)University of Miami, Miami, FL, (4)Hussman Institute for Autism, Inc., Catonsville, MD*

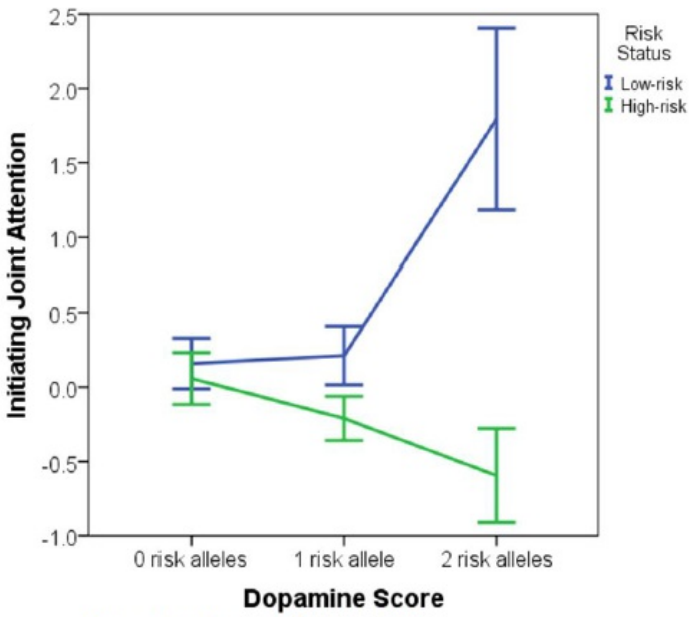
Background: The clinical diagnosis of ASD has changed considerably since its introduction into the formal nomenclature, reflecting conceptualization of ASD as a multi-dimensional phenotype. We hypothesize that genetic variants modify the expression of ASD symptomatology within subjects diagnosed with ASD, and specifically that variation in ASD candidate genes will lead to an increased number of core autism features. To evaluate this hypothesis, we developed a quantitative autism score (QAS) using variables on the ADI-R which reflect ASD features that have remained consistent throughout the changing diagnostic criteria (core ASD features).
Objectives: To identify genes that explain variation in the number of core ASD features.
Methods: The QAS was developed using the ADI-R, the semi-structured informant interview used to classify individuals for research studies in ASD. The QAS was defined using ADI-R algorithm items which consistently distinguish ASD from non-ASD or are present in early development and persist. The 25 QAS items are scored as present/absent and summed to yield a total score (0-25). Individuals with higher scores are those with more core features of ASD. The score was then calculated in 1118 ASD subjects from the Hussman Institute for Human Genomics (HIHG) and the Simons Simplex Collections. These individuals also had DNA sequence data available from a 17Mb custom capture covering 681 genes within regions identified by GWAS of ASD (Hussman et al 2013). SKAT-O (Li et al 2012) was used to conduct gene-based and single-variant tests for association with QAS as a quantitative trait. We examined combinations of synonymous, non-synonymous, missense, stop, loss-of-function and splice variants in different hypothesis tests. A Bonferroni correction for the number of genes tested was used as a significance threshold for each hypothesis with an experiment-wise significance level of 0.05.
Results: Values for the QAS in the 1118 subjects ranged from 4 to 25 with a mean value of 18.06 (sd=3.942). We found significant association for the gene *CDH4* (p= 9.20E-06) when all exonic variants were included in the gene-based test. This gene is a neuronal cell adhesion molecule known to play a role in brain segmentation and neuronal outgrowth and is a member of the cadherin family of genes, many of which have previously identified as ASD candidate genes and have been implicated by genetic association and sequencing for rare variants. We also found a significant association for the LGR5 gene when all exonic variants were included (p=3.59E-05) and when only missense variants were included (p=7.67-05). LGR5 is known to be implicated in neuronal specification in the nervous system. Single-variant tests within these two genes identified two synonymous variants in *CDH4* and two variants (1 synonymous and 1 missense) in *LGR5* associated (p<0.05) with QAS.
These results are in the process of being tested in three different replication samples.
Conclusions: Our study identified two genes, *CDH4* and *LGR5*, associated with the number of core ASD features. Our findings add support to the importance of genes involved in neurogenesis as well as to the role of phenotypic variations within ASDs.

61 **144.061** The Role of Dopaminergic Variants in Initiating Joint Attention in High- and Low-Risk Siblings

D. N. Gangi[1], *D. S. Messinger*[2], *E. R. Martin*[3] *and M. L. Cuccaro*[4], *(1)MIND Institute, University of California, Davis, Sacramento, CA, (2)Psychology, University of Miami, Coral Gables, FL, (3)John P Hussman Institute for Human Genomics, University of Miami, Miami, FL, (4)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL*

Background: The capacity to use gaze and gesture to share experiences or events with a social partner, initiating joint attention (IJA), typically emerges during the first year of life. Deficits in IJA are a core impairment in children with Autism Spectrum Disorder (ASD), and IJA may be a particularly important skill for infants at risk for ASD (high-risk siblings; younger siblings of children diagnosed with ASD). Levels of IJA at 8 months have predicted later ASD symptom severity at 30 months in high-risk siblings (Ibañez, Grantz, & Messinger, 2012). This suggests that the ability to share attention with a social partner before one year is particularly important for high-risk siblings in the development of ASD symptomatology. However, high-risk siblings exhibit substantial behavioral heterogeneity, both in early levels of IJA and in later ASD symptomatology.
Objectives: We aimed to explain variability in early levels of IJA by examining the role of common dopaminergic genes, *DRD4* and *DRD2*—variants that have been associated with attention problems in children.
Methods: High-risk siblings (n = 55, 35 male) and low-risk siblings (n = 38, 16 male) were genotyped for *DRD4* and *DRD2*. Each infant was assigned a dopamine gene score (ranging from 0-2) reflecting the number of genotypes associated with less efficient dopaminergic functioning (7-repeat allele of *DRD4* and A allele of *DRD2*) (Pearson-Fuhrhop, Minton, Acevedo, Shahbaba, & Cramer, 2013). Infants were administered the Early Social Communication Scales (ESCS) at 8, 10, and 12 months, a semi-structured interaction with an examiner during which a series of toys are presented and activated. Rates per minute of IJA were calculated for each assessment age; a mean was then calculated from the standardized values of each assessment age to provide a measure of IJA in the first year for analyses.
Results: A regression model indicated a dopamine score*status interaction effect, b = -0.81, t = -3.09, p = .003. Regression analyses by risk group indicated that in high-risk siblings, IJA levels decreased as dopamine scores increased (indicative of less efficient dopaminergic functioning), b = -0.31, t = -2.03, p = .047, while in low-risk siblings, IJA levels increased as dopamine scores increased, b = 0.50, t = 2.35, p = .03 (see Figure 1).
Conclusions: Higher dopamine scores, indicative of less efficient dopaminergic functioning, were associated with lower early levels of IJA in high-risk siblings. Low-risk siblings exhibited the opposite pattern, suggesting differential susceptibility. In the presence of familial risk for ASD, less efficient dopaminergic function was associated with lower IJA levels. Links between common genetic variants and behavioral phenotypes can aid in understanding developmental heterogeneity within high-risk siblings. Knowledge of genotypes in high-risk siblings associated with areas of difficulty relevant to ASD, such as IJA, may aid in assessing risk and identifying siblings at the greatest potential need for early interventions.

Figure 1. Mean levels of initiating joint attention (IJA) by group.



Note. Error bars reflect +/- 1 SE.

62 **144.062** Tissue-Specific Expression Quantitative Trait Loci (eQTL) in GI Symptomatic ASD Children

S. J. Walker[1], *A. Krigsman*[2] *and C. D. Langefeld*[3], *(1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Far Rockaway, NY, (3)Center for Public Health Genomics and Department of Biostatistical Sciences, Winston Salem, NC*

Background:
Previously, we characterized, via whole transcriptome analysis of ileocolonic biopsy tissue, an IBD-like condition that occurs with high frequency in autism spectrum disorder (ASD) children. Using gene expression data from that study, together with whole genome single nucleotide polymorphism (SNP) data on DNA from the same individuals, we are exploring genome-wide expression quantitative trait loci (eQTL).
Objectives:
The immediate goal of this study is to test the hypothesis that SNPs that influence gene expression (eQTL) in the colon and terminal ileum identified in our ASD population are associated with Crohn's disease (CD), ulcerative colitis (UC) and inflammatory bowel disease (IBD).
Methods: Gene expression data (generated from Agilent whole genome microarrays) and SNP data (generated at 23&me on custom Illumina SNP chips) from 64 individuals were used for the eQTL analyses. Standard quality control was completed for association studies (e.g., SNP call rate, Hardy-Weinberg Equilibrium). Analyses were computed separately for colon and terminal illium samples and by ASD^{IC} (ASD with ileocolitis). For each transcript and tissue type, we computed a genome-wide association analysis using linear regression on single nucleotide polymorphism (SNP) *cis* (within 500kb) to the probe's gene. In this eQTL analysis, we regressed the SNP's genotype and the first principal components onto $\log_2$ expression for the transcript. Given the modest sample size, only the dominant genetic model was computed. A fixed effect meta-analysis and the corresponding test for heterogeneity of effects were computed across disease groups. Significance of an eQTL effect was measured as p-value <1x10E-6 and expression fold change of at least 1.5. We cross referenced these eQTLs (or SNPs in linkage disequilibrium (LD: r-squared>0.7) with lists of SNPs associated with CD, UC and IBD obtained from the UCSC Genome Browser GWAS catalog.
Results:
The number of children analyzed varies by tissue. There were 18 ASD^{IC+} with colon samples and 22 ASD^{IC+} terminal ileum samples. In total, 189 eQTL SNPs had p<1x10E-6. Comparing these eQTL SNPs or their proxies (SNPs in high LD) to known published GWAS results failed to identify any known loci associated with CD, UC and IBD. Previously we reported eQTLs on chr 7q11.23 with known links to Williams Beuren Syndrome and ASD, RYR2 (colon: rs10802598, and 1q43, $p=2.25x10^{-8}$) and EPHB1 (colon: rs10512944, 3q22, $p=1.88x10^{-12}$) related to ASD and/or ASD-phenotypes through other studies and approaches. Examination of the region about rs10512944 on 3q22 region appears to show high trans-mammalian species conservation and is in proximity to a region of high taxonomic class (Mammal, Aves, Pisces) conservation. The cause of this high trans-species conservation is not known, however, as there are limited known regulatory (DNase I Hypersensitivity Clusters, transcription factors) elements in the region.
Conclusions:
These data show no evidence that eQTL from the colon and terminal ileum, identified in our ASD population, are known CD, UC and IBD risk loci. However, eQTLs identified in this sample are associated with ASD and/or ASD-phenotype and are in areas of evolutionary high trans-species conservation.

63 **144.063** Using Whole Exome Sequencing to Investigate the Genetics of Sensory Processing Disorders

E. J. Marco[1], *G. Da Gente*[2], *S. Thomas*[3], *A. Brandes-aitken*[4] *and* ***E. Sherr***[4], *(1)University of California in San Francisco, San Francisco, CA, (2)Neurology, UCSF Brain Development Research Program, San Francisco, CA, (3)Epidemiology and Biostatistics, UCSF, San Francisco, CA, (4)Neurology, UCSF, San Francisco, CA*

Background:
While genetic causes of Autism Spectrum Disorders (ASD) have been extensively investigated, there has yet to be a focus on the genetics of Sensory Processing Disorders (SPD), either as a part of the ASD phenotype or in isolation. Heritability rates for sensory sensitivity have been estimated to be as high as 54% for tactile sensitivity and 38% for auditory sensitivity. In addition, there are several genetically mediated neurodevelopmental disorders with evidence of sensory sensitivity such as Fragile X and 16p11.2 deletion syndrome.
Objectives:
Firstly: to determine whether de novo pathogenic mutations are found in candidate neurodevelopmental genes in a small SPD cohort (N=11). Our second objective is to determine if in this SPD cohort there is a higher prevalence of rare potentially pathogenic variants in ASD associated genes than in the overall pool of genes interrogated by exome sequencing.
Methods:
We enrolled 11 children (ages 8-16 years) with SPD, but who do not meet clinical criteria for ASD, and their biological parents from the UCSF Sensory Neurodevelopment and Autism Program Registry. Probands and their biologic parents underwent sensory assessments and genetic testing using whole exome sequencing using the Agilent sure select platform and an in house analytic pipeline based on the current GATK best practices workflow (https://www.broadinstitute.org/gatk/guide/best-practices). Missense, nonsense, splice site, frameshift and indel mutations that were not present in dbSNP or the exome variant server (http://evs.gs.washington.edu/EVS/) were included in the downstream analysis of both de novo and inherited mutations. Mutations in ASD-linked genes were tested for association with the SPD phenotype through analysis of a bionomial distribution, accounting for gene length and correcting for multiple comparisons using Bonferroni.ASD linked genes were selected from the SFARI gene collection (genes.sfari.org).
Results:
First, our analysis identified a *de novo* premature stop codon mutation in the MBD5 gene of a single female child in our cohort. MBD5, located at 2q23.1 has previously been implicated in mental retardation autosomal dominant type 1. Affected individuals are reported to have microcephaly, intellectual disabilities, severe speech impairment, ASD and seizures but there is no mention of sensory processing differences. Second, inherited mutations in genes repeatedly linked to ASD are found in children with SPD more frequently than would be expected in a random model. However, given our small sample size, this finding only reached trend level (p=0.068).

Conclusions:
While further studies with a larger sample size are required, this preliminary study showing that both de novo and inherited ASD related mutations are found in an SPD only cohort suggests that SPD is mediated by similar deficits as ASD and that a similar clinical genetic investigation is warranted for children with SPD who may not meet other DSM based labels.

64 **144.064** Whole Exome Sequencing in Extended Families Identifies Shared and Unique Likely Gene-Disrupting Alterations

H. N. Cukier[1,2], *S. Luzi*[1], *L. Gomez*[1], *J. M. Lee*[1], *P. L. Whitehead*[1], *I. Konidari*[1], *W. Hulme*[1], *J. Haines*[3], *M. L. Cuccaro*[1,4], *J. R. Gilbert*[1,4] *and M. A. Pericak-Vance*[1,2,4], *(1)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, (2)Neurology, University of Miami, Miami, FL, (3)Case Western Reserve University, Cleveland, OH, (4)Dr. John T. Macdonald Foundation Department of Human Genetics, University of Miami, Miami, FL*

Background: Autism spectrum disorders (ASDs) encompass a constellation of neurodevelopmental conditions and studies to date demonstrate that the underlying etiology is extremely heterogeneous. With the advent of whole exome sequencing (WES), studies have been implicating genes across many disorders. Thus far, autism exome studies have primarily focused either on simplex families to discover *de novo* alterations or consanguineous families that carry recessive mutations.
Objectives: Our study performs exome sequencing in extended, multiplex families with affected cousin pairs to identify potential ASD genetic factors. Our initial analysis focused on identifying identical by descent (IBD) variants that could contribute to ASD risk. This study extends these results and combines the results with also more severe alterations which may not be shared across families.
Methods: We performed WES on at least two affected cousins across 40 multiplex ASD families. A total of 164 individuals were captured with the Agilent SureSelect Human All Exon kit, sequenced on the Illumina HiSeq 2000, and the resulting data processed and annotated with BWA, GATK, and SeattleSeq. We have previously identified alterations that were inherited from a common ancestor and identical by descent. In this analysis, we focused on heterozygous alterations that were predicted to result in stop-gain or stop-loss mutation, or potentially interfere with splicing, collectively called “likely gene-disrupting” (LGD) variants. The LGD alterations that were both shared and unique within were evaluated families. We also determined whether any of these alterations fell within 142 ASD candidate genes; these included syndromic ASD genes and genes with relatively high confidence (as defined by the SFARI gene database).
Results: Following exome sequencing, each extended family was identified to carry approximately 90,000 variants. When we filtered each of the families for potential LGD alterations, we decreased the variants of interest to a few hundred per family. We then culled the data to determine if our variants intersected any previously reported ASD candidate genes; we identified a unique a stop-gain alteration in *NRXN3*, a gene already identified in ASD patients with copy number variants. Furthermore, potential splicing alterations were recognized, including in the ASD candidate genes *CC2D1A*, a gene also connected to intellectual disabilities, as well as *VPS13B*, a gene first reported to cause Cohen syndrome and since linked to ASDs, developmental disorders, epilepsy, and intellectual disabilities.
Conclusions: By studying these extended, multiplex families, we hope to reveal how inherited and unique alterations in may be acting in concert to result in ASDs.

65 **144.065** Whole Genome Sequencing and Identical By Descent Filtering of Autism Spectrum Disorder Extended Families Reveals Novel ASD Risk Variants

A. J. Griswold[1], *H. N. Cukier*[1], *D. Van Booven*[1], *P. L. Whitehead*[2], *N. K. Hofmann*[1], *J. M. Lee*[2], *E. R. Martin*[1], *M. L. Cuccaro*[2], *J. R. Gilbert*[2], *J. P. Hussman*[3] *and M. A. Pericak-Vance*[2], *(1)John P Hussman Institute for Human Genomics, University of Miami, Miami, FL, (2)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, (3)Hussman Institute for Autism, Inc., Catonsville, MD*

Background: Massively parallel sequencing in autism spectrum disorder (ASD) has focused primarily on whole exome (WES) or whole genome sequencing (WGS) in trio cohorts for identification of *de novo* loss of function protein coding variants. These studies have only used simplex families and the available WGS analyses have reported largely only on protein coding portions of the genome.
Objectives: Our study applies WGS to extended, multiplex families with at least two affected cousins likely to carry rare, partially penetrant inherited alterations. We hypothesize that identical by descent (IBD) filtering in these large, multiplex pedigrees would define genomic regions of shared ASD risk and allow identification of coding variants missed by exome sequencing, functional variants in the 98% of the genome that is noncoding, as well as structural variation, to identify potential new ASD loci.
Methods: We performed WGS on at least two affected cousins across six ASD extended families (15 individuals). Sequencing was performed on the Illumina HiSeq2500 and analyzed through pipelines including BWA-MEM alignment, quality recalibration by GATK, and variant calling with the GATK HaplotypeCaller. Structural variants (SVs) were called with the SWAN algorithm. Annotations were applied with ANNOVAR including functional predictions for noncoding variants (GWAVA, CADD, FATHMM-MKL). We determined IBD regions using whole genome genotyping data and the MERLIN package and used these regions to filter variations for each family. Variants were prioritized by sharing in all affected individuals per family, rarity of the variant in the population (< 1%), and evidence of functionality from computational predictions.
Results: We sequenced each genome to ~40X coverage and identified more than four million single nucleotide variants (SNVs) and small indels and more than 100 SVs per individual. IBD and sharing filtering within each family limited the total number of SNVs for analysis to 289-655,355, depending on family structure. Among coding SNVs, ~94% concordance was found with existing WES (Cukier, et al, 2014), however WGS identified ~10% more coding variant calls. These include a family with a rare missense mutation in the neurogenesis growth factor *GDF11* and another with a frameshift in the axonal development gene *SLAIN1*. Impact of noncoding variation is continuing to be evaluated, and has identified two shared likely functional variants in the putative promoter of the ASD candidate gene *CNTN4* in one family and a two others upstream of potassium channel *KCTD1* in another. Finally, rare copy number variants disrupting the promoter of the neurodevelopmental *WWOX* gene as well as deleting an exon of the lincRNA *FIRRE* involved in chromosomal organization were found in single families.
Conclusions: By studying these unique pedigrees, applying cutting edge sequencing and analysis methods, and employing using IBD filtering we establish that WGS in extended families can be used to identify ASD risk alterations. Such methods extend the scope of ASD genetic risk beyond *de novo* protein coding variants to functional noncoding SNVs, SNVs not captured by WES, and SVs that might be conferring ASD Taken together, WGS identifies new ASD candidate genes and pathways.

Poster Session
145 - Interventions Non-Pharmacologic - School Age, Adolescent, Adult
11:30 AM - 1:30 PM - Hall A

66 **145.066** A Brief Behavioral Sleep Intervention Improves Sleep Onset Delay and Sleep Efficiency in Adolescents with Autism Spectrum Disorders

W. A. Loring[1], *R. Johnston*[1], *L. Gray*[2], *S. E. Goldman*[3] *and B. A. Malow*[1], *(1)Vanderbilt University, Nashville, TN, (2)Neurology, Vanderbilt University Medical School, Nashville, TN, (3)Vanderbilt University, franklin, TN*

Background: Sleep problems affect many individuals with autism spectrum disorders (ASD). Many studies of sleep problems in ASD have focused on young children, with less understood about the treatment of sleep problems in adolescents with ASD. Treatment of sleep problems with medications is not always successful and often has negative side effects. Behavioral treatment of sleep concerns for adolescents with ASD is an understudied area with many potential benefits regarding its use. In this study, we are assessing the impact of an education-based program on nighttime sleep and daytime functioning for adolescents with ASD.
Objectives: Objectives of this study are to: 1) develop a manualized education program for adolescents with ASD and their parents and 2) assess the impact of this program on nighttime sleep and daytime functioning for adolescents with ASD.
Methods: We delivered a brief sleep intervention to 20 adolescents, ages 11-18 years, and their parents. Adolescents had sleep onset delay and/or night wakings as measured by actigraphy. The program consisted of 2 education sessions with a psychologist, the adolescent, and his/her parent, followed by 2 follow-up phone calls. These sessions focus on previously researched components of successful sleep, including daytime habits, bedtime routines, sleep timing, and sleep environment as well as the addition of strategies related to relaxation and distraction. Actigraphy provided objective data concerning the adolescent’s pre- and post-program sleep. The parent and adolescent also completed pre- and post-program self-report measures. Final study results are presented here from actigraphy, parent and adolescent sleep measures, and satisfaction measures. The sleep measures include parent and adolescent report of the Adolescent Sleep Wake Scale (ASWS), Adolescent Sleep Hygiene Scale (ASHS), and Modified Epworth Sleepiness Scale (M-ESS).
Results: Of those enrolled, 63% were male and 22.2% were female. The average age was 14.77 years (SD=1.769), the average full scale cognitive score was 102.48 (SD=14.65), and the average ADOS-2 calibrated severity score was 7.33 (SD=2.176). Through actigraphy, significant improvement was observed in sleep latency ($p=0.007$) and sleep efficiency following treatment ($p=0.030$). In both parent and adolescent report of the ASWS, a significant improvement was seen with treatment in total score ($p<0.001$ and $p=0.006$) and all subscales. In both parent and adolescent report of the ASHS, a significant improvement was seen in total score ($p<0.001$) and 4 of 5 subscales. A significant improvement in total score was seen in adolescent report of the M-ESS ($p=0.002$), but not parent report. 50% of the sample was able to be contacted 3 months following completion of the study and gains were maintained for all contacted based on parent and/or adolescent report. Parents reported high satisfaction and were able to implement session recommendations at a high rate of understanding and comfort level.
Conclusions: Through this brief format of behavioral sleep education, significant improvements were detected in reported overall sleep behaviors and objectives measures of sleep latency and efficiency. These findings offer promising results in improving sleep for adolescents with ASD through a brief intervention.

67 **145.067** A Manualized Program to Support Transitions within Classroom Routines for Students with ASD: Child and Teacher Outcomes

S. Iadarola[1], *T. Smith*[2], *W. I. Shih*[3] *and T. AIR-B Network*[4], *(1)University of Rochester Medical Center, Rochester, NY, (2)Division of Neurodevelopmental and Behavioral*

Pediatrics, University of Rochester Medical Center, Rochester, NY, (3)UCLA, Monrovia, CA, (4)AIR-B Network, Los Angeles, CA

Background: Over the past decade, children with autism spectrum disorder (ASD) have been included in public education settings at swiftly increasing rates (National Center for Education Statistics, n.d.). Students in these settings frequently experience difficulties with transitions that occur during their daily routines. Transition-related difficulties often result in challenging behavior, including disruption, noncompliance, tantrums, aggression, and self-injury (Schreibman, Whalen, & Stahmer, 2000). Specific behavioral techniques to support transitions have been identified through single-subject research studies, but this research should be extended to include packaged interventions that are easily implemented in school settings and that are associated with more global child and teacher outcomes.
Objectives: This project aimed to develop and evaluate the Schedules, Tools, and Activities for Transitions (STAT) program, a short-term, manualized package intervention of behavioral supports relevant to facilitating successful transitions within the daily routine for students with ASD (K-5) in self-contained educational settings.
Methods: Across three sites (UCLA, University of Pennsylvania, University of Rochester), a cluster-randomized group comparison design with matched pairs was used to assign self-contained classrooms to treatment (STAT program) or waitlist control. STAT involved a 12-16 session, collaborative, coaching model between research staff and school staff that encouraged educators to use 9 steps to facilitate successful classroom transitions, thereby resulting in a teacher-mediated intervention program. Intervention components included antecedent-based strategies (e.g., warnings, visual supports), teaching strategies (e.g., prompt hierarchies), and reinforcement. Student outcomes included academic engagement, independence (ABAS self-direction domain) and problem behavior (School Situations Questionnaire) during school routines, and teacher-nominated target problems. Teacher outcomes included fidelity and generalization. Data on intervention implementation and buy-in were also collected.
Results: n total, 153 students and 76 educators participated. No group differences were noted for academic engagement, as baseline academic engagement was quite high (.80%) at baseline across sites. For teacher-nominated target problems, STAT showed a significant positive effect over waitlist, with a larger proportion of classrooms indicating improvements in the identified behaviors (χ^2=13.996, p=0.003). Positive effects of the STAT program were also found on the SSQ (SSQ; $M_{control}$ = .67; $M_{treatment}$ = .72), but not on the ABAS (ABAS; $M_{control}$ = 4.51; $M_{treatment}$ = 4.32).
Conclusions: The use of a teacher-mediated, behavioral intervention program was successfully implemented in self-contained classrooms across three under-resourced school districts. The results preliminarily suggest the utility of implementing a behavioral intervention package that can be beneficial for aspects of student behavior, feasible for educators to implement with high fidelity, and perceived as sustainable in real-world settings.

68 **145.068** A Pilot Investigation of Classroom-Based Music Therapy for Individuals with ASD and Other Disabilities

J. Mendelson[1], *Y. White*[2], *L. Hans*[3], *R. Adebari*[3], *J. Riggsbee*[4], *A. Goldsmith*[3], *K. Buehne*[3], *S. Jones*[3] *and G. Dawson*[5], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Greensboro, NC, (2)Voices Together, Durham, NC, (3)Duke University, Durham, NC, (4)Education, Duke University, Durham, NC, (5)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC*

Background: Research supports the efficacy of music therapy for improving communication skills in children with autism and related disabilities (Gold, Wigram, & Elefant, 2010 Srinivasan & Bhat, 2013). Neuroscience research suggests that music as a treatment modality may be uniquely well-suited to the information processing strategies employed by individuals with ASD (Stanutz, Wapnick, & Burack, 2014). Given early findings suggesting its efficacy (Braithewaite & Sigafoos, 1999; Brownell, 2002; Buday, 1995), classroom-based music therapy may be an especially time and cost efficient means of treatment delivery for children with various developmental disabilities. However, little is known about the efficacy of music therapy delivered in a classroom
Objectives: This was an initial pilot investigation of the efficacy of a classroom-based music-based intervention, Voices Together®, for improving communication skills in children with autism and developmental disabilities.
Methods: Four local public elementary school special education classrooms serving 5 children with a classification of autistic disorder and 32 children with intellectual disability without autism were randomly selected to receive one of two levels of exposure to *Voices Together®* music therapy "Long-Term" (15 weeks beginning in January 2105 (Time 1), n=14) or "Short-Term" (7 weeks beginning 7 weeks later in February (Time 2), n=17). Using observational ratings, Duke University researchers reliably scored participants live in terms of their level of verbal responsiveness to prompts during three songs (Hello, Feel, and Topic) featured each week of the program. Data were collected at three time points: baseline (T1), then in 7-week increments (T2 and T3).
Results: Independent *t*-tests investigating between-group (short vs. long term) differences in verbal responses at Times 2 and 3 were not significant. Both groups demonstrated increases in verbal responses over time, however, only the long-term group demonstrated significant within-group increases. Repeated measures ANOVA from Time 1 to Time 3, indicated improvement in mean verbal response during the *Feelings song* $F(2, 28)= 3.32$, $p<.05$ Significant change was found between Time 1 and Time 2 ($t(14)= 2.63$, $p<.05$). There were also significant improvements in verbal responses to *All Songs* between Time 1 and Time 2, $t(14)=2.47$, $p<.05$, and between Time 1 and Time 3, $t(14)=2.46$, $p<.05$ (Figure 1). Results showed a shift, on average, from 'one word' to 'partial sentence' responses to the prompts from the therapist.
Conclusions: Findings from this initial pilot investigation suggest that music therapy delivered in a classroom can result in improvements in verbal abilities among individuals with autism and other developmental disabilities. The finding that improvements were achieved during 45-minute weekly sessions in a classroom-based, public school setting suggests that structured music therapy programs such as *Voices Together®* may be a time efficient and cost effective modality of treatment. These preliminary findings warrant conducting a randomized controlled trial to further investigate the efficacy of classroom-based music therapy for improving speech development in children with autism and other disabilities.

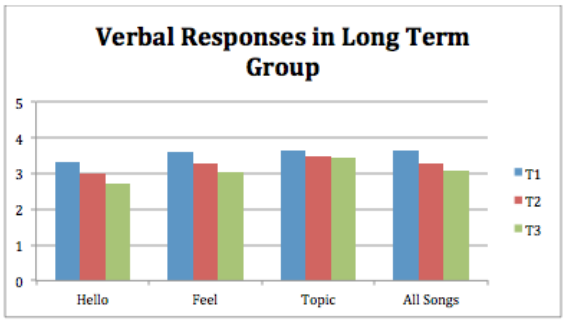


Figure 1. Mean verbal responses to three songs over time in the Long Term Therapy Group. Lower scores reflect more advanced verbal responses.

69 **145.069** A Pilot Test of Adult Social Knowledge (ASK) Workshop: An Intervention to Improve Outcomes in Young Adults with ASD

T. Oswald[1], *L. Gilhooly*[2], *J. B. McCauley*[3], *L. Libero*[4], *R. Hansen*[5], *P. C. Mundy*[6], *A. M. Iosif*[7], *S. J. Rogers*[4], *A. C. Stahmer*[3], *P. Schetter*[8], *S. Ruder*[8], *R. May*[9] *and M. Solomon*[10], *(1)2825 50th Street, University of California at Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Davis, CA, (3)University of California at Davis MIND Institute, Sacramento, CA, (4)University of California at Davis, Sacramento, CA, (5)Pediatrics and the MIND Institute, University of California Davis, Davis, CA, (6)Education and Psychiatry, University of California at Davis, Sacramento, CA, (7)Public Health Sciences, University of California Davis, Davis, CA, (8)MIND Institute, UC Davis, Sacramento, CA, (9)Alta California Regional Center, Sacramento, CA, (10)MIND Institute, Sacramento, CA*

Background:
Adult outcomes are alarmingly poor for people with Autism Spectrum Disorder (ASD). Over 50% of these individuals were not pursuing post-secondary education or gainfully employed in the 2 years after high school (Shattuck et al., 2012). Adults with ASD, compared to other disability groups, have the worst social and vocational outcomes, experience a higher burden of health and mental health issues and report low levels of life satisfaction (Howlin et al., 2004; Taylor & Mailick, 2014). Half a million children with ASD will enter adulthood in the coming decade (CDC, 2014). Services for adults with ASD that assist with this life transition are urgently needed.
Objectives:
To develop and pilot test the curriculum for Adult Social Knowledge (ASK) Workshop—a 19-week, 1 ½ hours/week intervention to improve functional outcomes for young adults with ASD (18-24 years of age). The ASK curriculum was adapted from the Functional Adaptive Skills Training (FAST; Patterson et al., 2006) and the Social Adjustment Enhancement intervention (Solomon et al., 2004), using Android technology, to target three pivotal areas of adult functioning: (1) Planning & Organization, (2) Social Skills & Interpersonal Communication, and (3) Communication in the Work Place & Community Engagement. Parents attended a concurrent support group that also provided information about community resources

Methods:
Analyses are for nine (2 female) adults with community diagnoses of ASD without intellectual disability. Pre-test and Post-test assessments were conducted using the ASEBA Adult Self-Report (ASR; Achenbach & Rescorla, 2003) subscales of "Attention Problems" (measuring planning and organization problems) and "Depression", as well as the WHO Quality of Life BREF Self-Report "Social Relationships" subscale (WHOQOL-BREF; WHOQOL Group, 1997). Univariate statistical tests were used.
Results:
A paired samples t-test revealed a statistically significant reduction in planning and organization problems from pre-test (M = 70.13; SD = 12.65) to post-test (M = 65.25; SD = 7.70), based on the ASR Attention Problems subscale, $t(7)$ 2.41, $p < .05$, with a large effect size (Cohen's d = .85). Though not statistically significant, a medium effect size (Cohen's d = *.72)* was found for the reduction in ASR depression levels from pre-test (M = 66.75; SD = 11.76) to post-test (M = 62.38; SD = 7.96), $t(7)$ 2.05, $p = .08$. Additionally, a medium effect size (Cohen's d = .56) for improvements in social relationships as measured by the WHOQOL-BREF were found for pre-test (M = 53.13; SD = 35.06) to post-test (M = 61.46; SD = 28.50), although this was not statistically significant, $t(7) = -1.60$, $p = .15$. High levels of satisfaction also were reported by young adults and their parents during a focus group at the conclusion of the trial.
Conclusions:
Given that participants in the ASK Workshop reported fewer planning/organization problems and depressive symptoms and greater social relationships after the intervention and expressed high satisfaction with the program, we are refining the curriculum in preparation for a wait list controlled experimental therapeutics trial, that will test improvements in cognitive control as a mechanism of therapeutic change, to begin shortly.

70 **145.070** A Simulated Driving Intervention for Young Adults with Autism Spectrum Disorder: Attention, Perceptual, and Motor Considerations

L. E. Mash[1,2]*, M. Samano*[2]*, N. Suarez*[2]*, S. Yu*[2]*, J. Townsend*[2] *and L. Chukoskie*[3]*, (1)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (2)Department of Neurosciences, University of California, San Diego, La Jolla, CA, (3)The Institute for Neural Computation, University of California, San Diego, La Jolla, CA*

Background: Obtaining a driver's license is an important milestone for most teenagers. In many parts of the United States, driving is critical for adults to function independently; the inability to drive can be an obstacle to education, employment, and routine errands such as grocery shopping. Although many high-functioning individuals with autism spectrum disorder (ASD) plan to drive, research has shown that many in this population experience deficits in attention, motor, and perceptual skills that are crucial for safe driving (Miller, Chukoskie, Zinni, Townsend, & Trauner, 2014; Townsend, Keehn, & Westerfield, 2011). Prior driving simulation research suggests that these features may, in fact, impact the ability of teens with ASD to drive (Reimer et al., 2013). However, the extent of the relationship between these basic functions and driving ability in ASD remains unclear. Furthermore, it is unknown whether teenagers on the autism spectrum may benefit from training on a driving simulator, and how individual differences in basic processing affect driving outcomes. By allowing teenagers with ASD to practice in a low-risk environment, we expect that both their overall confidence and driving proficiency will improve.
Objectives: Our goal was to assess the effectiveness of driving simulation training, and to relate basic perceptual, attention, and motor skills to driving ability in individuals with ASD.
Methods: 18 teenagers and young adults with ASD trained on a driving simulator for 45-60 minutes each week, for six weeks. Simulations included 1) simple drives, 2) divided attention drives that required responses to visually peripheral stimuli while driving, and 3) "challenge" drives that included unexpected obstacles. Divided attention and challenge drive performance was compared pre- and post-intervention. Our personalized six-week training program allowed participants to master progressively more complex driving environments at their own paces. Additional pre- and post-training assessments included a visual-motor integration task, an attention-orienting task, a general motor assessment, and a balance test. Participants' parents also completed the Social Responsiveness Scale-2. Changes in driving, attention, and sensorimotor function over the course of the intervention were assessed, as well as the role of pre-training basic processing skills as predictors of intervention success.
Results: Overall, driving skills improved over the course of the six-week intervention. Of the 18 participants, two have since become fully-licensed drivers; follow-up of the remaining participants is pending. Analysis of supplementary tasks is under way to determine whether and how driving ability and improvement with training is related to basic attention, perceptual and motor function.
Conclusions: Our six-week training appears to have been effective in improving performance on specific driving simulation tasks. Pending data analysis will shed light on the mechanistic involvement of perceptual, motor, and attention functions in moderating this change. These data will inform future research on the added benefit of training these general skills as part of a driving intervention; developing the best possible training resources for potential drivers with ASD will help to ensure optimal independence and quality of life as these individuals transition to adulthood.

71 **145.071** A Summer Intervention Targeting the Acquisition of Fundamental Movement Skills Among Children with ASD

K. Staples*, A. Bellerive, K. Collins and S. Lautenslager, University of Regina, Regina, SK, Canada*

Background: Having the confidence and competence to perform fundamental movement skills plays a critical role in development, providing the foundation for participation in physical activity and sport. Many children with ASD have difficulty performing the fundamental movement skills needed to participate successfully in what are often group-based activities. These movement skill difficulties become more obvious with increasing age and more children with ASD are left on the sidelines. During the summer months, opportunities to practice and improve these skills are further constrained because children with ASD are not receiving regular physical education.
Objectives: Over the summer months, Sports Camps are offered on many university campuses, yet very few have the structure and support for children with ASD to participate successfully. The purpose of this research was to examine the effectiveness of an intervention for children with ASD that followed the format of a summer Sports Camp. Following best practice guidelines (Smith et al., 2007), the intervention was based on 4 hours of instruction per day for a total of 20 hours per week; athletes participated in at least 4 of the 8 weeks of instruction. The delivery of the intervention was based on the 8 key components of pivotal response teaching (PRT) that are grouped into antecedent and consequence strategies. The coaches were undergraduate students in kinesiology who were trained to deliver quality instruction using PRT strategies to their teams of 1 to 3 children.
Methods: 10 children (7 boys, 3 girls) with ASD (7 to 10 years; FSIQ = 45 to 117) participated in the intervention targeting the acquisition of fundamental movement skills. The curriculum was based on the 13 skills included in the *Test of Gross Motor Development* (*TGMD-3*) a criterion referenced assessment that examines the performance of both locomotor and object control skills. Multiple performance criteria allow children to receive credit for any aspect of the movement they are able to perform and scoring is based on 46 and 54 possible performance criteria for the locomotor and object control subtests, respectively. The effectiveness of the intervention was determined by examining the change in the number of criteria met during the performance of the locomotor and object control subtests before and after participation.
Results: Following 4 to 8 weeks of participation in the intervention, children with ASD improved their performance on the locomotor subtest from a mean score of 17.2 to 27.10 (p = .008) and on the object control subtest from 20.9 to 31.3 (p = .001). These improvements reflect an increase of 24% and 22% in the number of performance criteria met for locomotor and object control skills.
Conclusions: This research demonstrates the effectiveness of PRT strategies in the acquisition of movement skill for children with ASD. The mastery of fundamental movement skills is integral to promoting active participation among children with ASD and the summer months are an opportune time when intensive instruction can occur.

72 **145.072** A Synthesis Review of Employment Support Interventions in ASD

D. B. Nicholas*, University of Calgary, Edmonton, AB, Canada*

Background: Evidence suggests that adults with ASD are at risk for poor employment outcomes. Of those who obtain employment, underemployed or being employed in positions that are not meaningful or rewarding may limit employment engagement. These challenges can negatively impact individual quality of life and self-esteem, and potentially impose gaps in labor market productivity. A relatively small body of literature explores employment support interventions for individuals with developmental and/or intellectual disabilities. While some models and interventions show promise, little is known about their use and effectiveness with the ASD population.
Objectives: This synthesis review explored employment support interventions applied in ASD, along with respective outcomes.
Methods: A synthesis review of ASD employment support interventions was implemented. The peer-reviewed literature on vocational interventions in ASD was reviewed. A librarian trained in Cochrane collaboration synthesis/systematic review methods conducted the search, exploring Cochrane, Scholar's Portal, CINAHL, EMBASE, ERIC, Medline and PsycINFO databases, and the gray literature. Studies were included if they identified a vocational intervention in ASD and outcome data.
Results:
This search yielded 501 articles targeted to adults with ASD (18 years of age or older); however, only 10 studies were included due to meeting inclusion criteria of evaluating an ASD employment support intervention. Two broad categories of interventions were identified: supported employment (community placement and job coaching) and technology-based applications (media and online use). It is important to note that the literature disproportionately reported on the cognitively-able ASD population, with less consideration of diversities relative to variability across the ASD spectrum, gender or other social determinants of health.
Supported employment literature in ASD tended to favor positive outcomes from interventions when protracted, commenced earlier in life, and tailored to the needs of the individual. Supported employment was identified as potentially offering positive impacts on cognitive performance. A community placement model was shown to offer better outcomes than a sheltered work approach. Job coaching was often viewed as integral to employment access. Interventions that utilized technology were perceived to yield positive outcomes, as was video-modeling which was posited to teach modeled skills, with some participants replicating these in work settings. The use of personal digital assistants (PDAs) was also shown to nurture work-related behaviors.
It is important to note that the reviewed studies were generally limited by methodology limitations including design, small sample size and imprecise outcome measurement, leading to concerns over the generalizability of this literature.

Conclusions: There is a need for research with stronger empirical designs as well as inclusion of diversities in ASD and the social determinants of health. Addressing both access *and* retention of employment is critical in evaluation and practice, as is building employer engagement and community capacity.

73 **145.073** A Systematic Review of Employment Outcomes for Adults with ASD

B. M. Di Rezze[1], *H. Viveiros*[2], *R. I. Pop*[3] *and G. Rampton*[3], *(1)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (2)CanChild Centre for Childhood Disability Research, McMaster University, Hamilton, ON, Canada, (3)McMaster University, Hamilton, ON, Canada*

Background:
Employment services or interventions for individuals with neurodevelopmental disabilities (NDD), including ASD, have been described in the literature to include counseling, job skill training, coaching and training of supports. In the employment disability literature, outcomes are often measured based on dichotomous approaches (e.g., whether an individual is employed), as well as continuous metrics (e.g., tenure and compensation over time). These outcomes are unable to evaluate what is specifically going well/poorly in multi-service employment interventions for individuals with ASD. To identify the outcomes measured in employment and ASD research, a comprehensive search across NDDs could identify measures that better evaluate existing or novel interventions.
Objectives:
To review studies describing standardized employment-focused measures and assessment procedures in ASD.
Methods:
The review targeted employment outcomes using standardized measures or procedures for adults with neurodevelopmental disabilities, based on DSM-5 criteria. One reviewer (HV) conducted the search of ERIC, MEDLINE, CINAHL, HaPI, and PsycINFO databases. Our search generated 2,151 citations, and after duplicate removal we screening in two stages. Reviewers used a predetermined list of eligibility criteria, with a key focus on finding articles that looked at employment outcomes beyond typical metrics (i.e., employed/unemployed, wages, and hours). For the first stage, two reviewers (HV and RP) conducted independently title and abstract screening of 2,075 articles, with all disagreements adjudicated by the senior advisor (BDR). For the second stage both reviewers conducted full text screening and eliminated all but 54 articles. Both reviewers conducted data extraction using a standardized form for population, recruitment setting, standardized measures, and employment outcomes. A descriptive examination of the studies was conducted to identify the population characteristics, construct of outcome measures, and measurement properties.
Results:
Among the 54 articles included, the majority focus on persons with intellectual disability (ID) (35 papers), and the next largest focus is on persons with ASD (14 papers). From the ASD studies, seven focused exclusively on individuals with ASD; four included both individuals with ASD and others with NDD; and three examined individuals with a combined diagnosis of ASD and ID or other NDD. ASD studies included standardized measures and job skill evaluation procedures. Two ASD-specific measures included the Autism Work Skills Questionnaire and the Vocational Index for Adults with ASD. Measurement constructs in ASD involved mainly six person-focused outcomes such as job satisfaction, preference, performance, as well as, work personality, motivation and readiness. Three constructs were represented by measures related to the work environment, such as workplace culture, supports (e.g., co-worker involvement) and social integration.
Conclusions: This review demonstrates the breadth of research measuring a variety of employment outcomes for adults with ASD - detailing both person and work environment-focused measures. ASD measures could serve as potential examples of new directions for research across other NDDs and conversely, constructs of measures identified in NDD could be areas of consideration in future ASD research.

74 **145.074** Adapting an Evidence Based Intervention Using an Implementation Science Framework

A. D. Rodgers[1], *L. A. Ruble*[1], *M. W. Jackson*[2], *C. Snell-Rood*[3], *W. H. Wong*[1], *Y. Yu*[4], *J. ". A. Odom*[1] *and J. H. McGrew*[5], *(1)University of Kentucky, Lexington, KY, (2)Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (3)Behavioral Sciences, University of Kentucky, Lexington, KY, (4)Indiana University-Purdue University, Indianapolis, IN, (5)Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background: This pilot research responds to the 2012 Interagency Autism Coordinating Committee for studies that utilize “implementation science to test methods to improve implementation of evidence-based treatments.” Applying the Consolidated Framework for Implementation Science (Damschroder, et al., 2009), we collected stakeholder perspectives on the experience of students with autism spectrum disorder (ASD) transitioning out of school and stakeholder recommendations for improvement. Findings were employed to adapt an evidence-based implementation strategy for schools called the Collaborative Model for Promoting Competence and Success (COMPASS). COMPASS, a teacher-parent consultation intervention based on a transactional framework (Ruble, Dalrymple, & McGrew, 2012), has been tested in two randomized controlled trials for young children with ASD.
Objectives: To use an implementation science framework to identify the critical factors impacting quality implementation and intervention effectiveness in COMPASS with the long-term goal of applying this information to understand, adapt, refine, and pilot the parent-teacher consultation.
Methods: Ten focus groups were conducted with 42 participants including individuals with ASD, parents, school service providers, school administrators, adult service providers, and state policy makers from the Kentucky offices of Vocational Rehabilitation, Special Education, Medicaid, and Developmental Disabilities. Each hour-long session was recorded and transcribed. The research team performed qualitative content analysis through composing a codebook of themes derived from the literature on transition and cross-checked all codes with themes appearing in a preliminary reading of all transcripts. Codes were discussed and refined within the team to finalize the codebook. Team members worked in pairs to test and apply codes; all codes were tested until reaching 80% agreement in inter-rater reliability. Then, each pair of coders applied codes line by line to all transcripts. Researchers reviewed coded content code-by-code to identify specific aspects of COMPASS to be adapted and revised to meet the needs of transition-age youth.
Results: Stakeholders identified several crucial points of intervention to improve transition for young adults with ASD including (a) adding or developing new measures of quality of life, self-determination, activation, and social support; (b) incorporating student goals for vocational and independent living skills and parent goals for obtaining services; (c) developing psychoeducational handouts on the transition process, state services, and a transition planning timeline with descriptions of different roles; (d) assessing parent perception of openness of IEP team to curricular changes; (e) involving student in completion of COMPASS forms and in the consultation; (f) inviting certain players, such as the vocational rehabilitation counselor, to consultation and coaching sessions, and offering different methods for involvement (e.g., in person, phone), (g) assessing current services prior to the consultation and assessing student interests, strengths, and skills; and (h) adapting interests questionnaires based on student abilities, such as use of visuals, and adapting COMPASS questions for age appropriateness.
Conclusions: Focus group data were used to adapt and revise the COMPASS model for transition age youth by improving assessment, communication between key players, and involvement of students and key players in planning. Our qualitative, stakeholder-centered process may be helpful for other implementation science studies adapting autism interventions to fit specific contexts.

75 **145.075** Adaptive Changes in Anxiety and Arousal Following a Randomized Control Trial of a Theatre-Based Intervention for Youth with Autism Spectrum Disorder

B. A. Corbett[1], *S. D. Blain*[1], *S. Ioannou*[2] *and M. Balser*[3], *(1)Vanderbilt University, Nashville, TN, (2)Psychology and Counseling, Lipscomb University, Nashville, TN, (3)Wake Forest University, Winston-Salem, NC*

Background: Increased anxiety and stress are frequently found in children with autism spectrum disorder (ASD) and often associated with social challenges. Following a randomized control trial of a peer-mediated, theatre-based intervention, significant treatment effects were shown across several areas of social competence including increased group play with novel peers.
Objectives: Elevated anxiety and physiological arousal are often associated with peer interaction in youth with ASD. Peer-mediation has been shown to facilitate positive social effects. Furthermore, participation in theatre games and social play in the treatment setting may generalize to other settings, leading to higher quality, less distressing interactions during social play. Thus, the purpose of the current study was to examine the impact of the intervention on reducing anxiety and stress.
Methods: Participants included 30 high-functioning (IQ >70) youth with ASD (8-to-14-years of age) randomly assigned to the Experimental (EXP, N = 17) or Wait-list control (WLC, N = 13) group. Participants were exposed to the Peer Interaction Paradigm (PIP) before and after the treatment to assess duration of play with novel peers, self-reported anxiety, and cortisol levels. A series of Analysis of Covariance (ANCOVA) models were used to test the between-group differences for the anxiety and stress variables. Specifically, the variables included the STAIC anxiety scale (Trait and State), as well as baseline and social stress cortisol collected during group play with peers. Pearson product moment correlations were conducted between anxiety, cortisol, and Group Play.
Results: Significant pre-test-adjusted between-group differences at posttest were observed on Trait-anxiety ($F(1, 27)=9.16$, $p=0.005$) showing lower Trait-anxiety in the experimental group. However, no group differences were observed for State-anxiety ($F(1, 27)=0.03$, $p=0.86$). Additionally, there were no between group differences on the diurnal or stress based cortisol values. There was a significant negative correlation between Group Play and Trait-anxiety ($r=-.362$, $p=0.05$) showing a self reported reduction in anxiety following the intervention for the EXP group. Playground cortisol was positively correlated with Group Play, for the experimental group ($r=0.55$, $p=0.03$) showing higher arousal for more engagement with peers.
Conclusions: The theatre-based, peer-mediated intervention not only results in improvement in social competence in youth with ASD, but also contributes to reductions in trait-anxiety associated with more social interaction with peers. In SENSE Theatre, peers serve as models for reciprocal social exchange. It is feasible that social engagement during the intervention may facilitate positive appraisals of peer interaction thereby reducing perceived anxiety during subsequent social exchange. Positive correlations between cortisol and Group Play in the EXP group suggest that increased physiological arousal may facilitate social engagement with peers. Optimal performance on demanding tasks requires greater arousal and for children with ASD, engaging with peers may be conceived of as challenging. Therefore, some degree of

physiological arousal is essential for social interaction and may be adaptive for individuals with ASD.

76 **145.076** An Examination of Predictors of Social Intervention Response for Elementary Aged Children with Autism

K. O'Connor[1], *M. Herzog*[2] *and J. P. Stichter*[3], *(1)University of Missouri, Columbia, MO, (2)Special Education, University of MIssouri, Columbia, MO, (3)Department of Special Education, University of Missouri, Columbia, MO*

Background:
The autism spectrum is unique due to the significant heterogeneity in both onset as well as presentation observed in diagnosed individuals. Interventions, especially those that target social skills, are not universally effective across the autism spectrum due in part to the heterogeneity of symptom severity. Although previous research has identified several characteristics that may be predictive of improved treatment outcomes, this research does not distinguish phenotypically distinct subtypes and may not inform treatment decisions. Given the limited information on targeting social competency interventions for autism, the purpose of this study was to examine behavioral phenotypes present in the subtype of individuals with high functioning autism within the context of an established social program (Social Competency Intervention for Elementary Aged Children: SCI-E).
Objectives:
The objectives of this study were to examine the extent to which characteristics of elementary aged participants with autism predict treatment responsivity as well as to identify possible distinct behavioral phenotypes present in the study sample that can support intervention responsivity and treatment needs.
The following research questions were investigated:

1. To what extent do pre-intervention characteristics predict treatment responsivity?
2. What are the specific characteristics associated with children with autism who demonstrate differing levels of responsiveness?
3. To what extent do pre-intervention behavioral phenotypes predict treatment responsivity?

Methods:
This quasi-experimental study investigated the characteristics of a group of children with autism that may be predictive of treatment responsivity within the context of the SCI-E program. Participants included 13 males and 5 females (n=18) with an autism spectrum diagnosis between the ages of 6 and 11 years (*M*= 8 years 9 months) with estimated full scale IQ's ranging from 77 to 132 (*M*= 99). The program consisted of a ten-week program with hour-long sessions twice per week targeting conversation, emotion regulation and problem solving skills.
Behavioral phenotypes were identified through analyses of participant profiles based on pre-intervention characteristics as well as following intervention based on treatment responsivity. Intervention outcomes were determined through the use of pre/post assessments including both direct participant performance measures and parent report measures.
Results:
The results of this study indicate that low pre-treatment ASD specific impairments (symptom severity scores) and Theory of Mind abilities were predictive of intervention outcomes. An initial exploration into behavioral phenotypes within the context of the SCI-E program yielded four distinct groups of participants that significantly differed based on overall level of intelligence as well as on measures of symptom severity.
Conclusions:
This study identified a complex and varied profile of characteristics and responsivity within the sample of children with autism that will inform researchers as to the efficacy of the SCI-E program as well as assist with treatment decisions for participants. The use of specific research examining responsivity and behavioral phenotypes throughout the stages of efficacy research has the potential to increase the specificity of social intervention research and improve outcomes for individuals on the autism spectrum.

77 **145.077** Building a Summer Transition Program for Autistic College Students That Has Replicable Benefits: A Participatory-Action Model

C. Shane-Simpson[1], *R. Obeid*[2], *D. DeNigris*[3], *M. Siller*[4], *E. R. Hotez*[5], *J. Pickens*[6], *M. Alicea*[6], *A. Massa*[7] *and K. Gillespie-Lynch*[8], *(1)The Graduate Center & College of Staten Island, New York, NY, (2)CUNY Graduate Center, New York, NY, (3)The Graduate Center & College of Staten Island, CUNY, New York, NY, (4)Hunter College of the City University of New York, New York, NY, (5)The Graduate Center of the City University of New York, New York, NY, (6)CUNY, Staten Island, NY, (7)CSI; CUNY, Staten Island, NY, (8)CUNY Graduate Center, Brooklyn, NY*

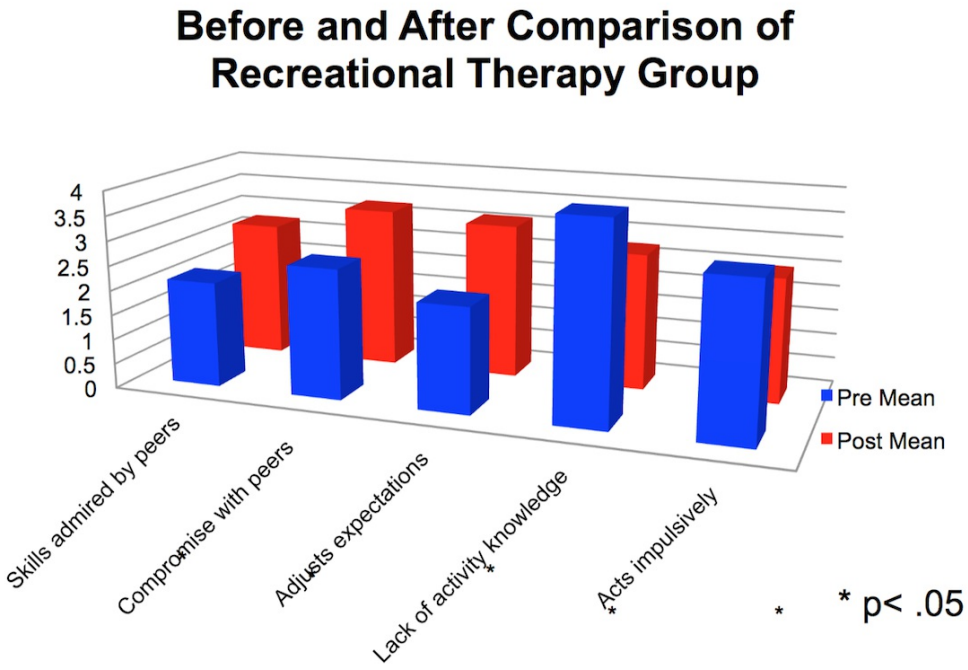
Background:
As more autistic students enter college, many face difficulties with self-advocacy, social interaction, and self-regulation (Gelbar et al., 2014; Van Hees et al., 2014). Few specialized supports are available for autistic college students (Barnhill, 2014). We used a participatory-action design to develop a summer transition program for incoming autistic college students. Participation in our first week-long program was associated with improvements in self-reported autism symptoms and anxiety (Oral presentation; IMFAR 2014). After adapting the curriculum using feedback from autistic and non-autistic students, we ran a second transition program in 2015 to determine if findings from the first program replicated.
Objectives:
1. Determine if autistic symptoms are more closely related to other challenges than intelligence (as they were in the first program);
2. Compare self-reported and parent-reported symptoms;
3. Evaluate benefits of participating in our second program.
Methods:
We developed a curriculum manual by revising materials from our first program to increase multimodal learning opportunities and assess fidelity more effectively. Through focus groups and individualized meetings, autistic and non-autistic students from our mentorship program helped adapt the curriculum.
Ten students (2 women) enrolled in a free week-long transition program (3 were in high school). All students self-identified as autistic, exceeded the parent-reported SRS cut-off for autism, and provided IEP documentation of disability (2 IEPs did not specify a diagnosis). Doctoral students led programming while undergraduate mentors (2 with a documented ASD and 4 without) helped model effective behaviors.
Pre-/Post-tests assessed autism symptoms (SRS-2; Constantino & Gruber, 2012), anxiety (Spielberger et al., 1983), autism knowledge (Gillespie-Lynch et al., 2014), disability identity (Darling, & Heckert, 2010), and academic self-efficacy (Hoover-Dempsey & Sandler, 2005), and included interviews and role-plays. Nonverbal intelligence was assessed with the TONI (Brown et al., 1997).
Results:
Autism symptoms positively correlated with orientation towards the social model (p=.008), but were unrelated to other measures. Nonverbal intelligence negatively correlated with trait anxiety (p=.025) and perceived support from friends (p=.033). Parental reports of participants' autism symptoms (M=95.3, SD=23.0) were higher than participants' self-reports (M=67.0, SD=28.1, p=.024).
Participation in the program was associated with decreased self-reported autism symptoms (p=.05) and increased autism knowledge (p=.012). Participants reported that they enjoyed meeting people, practicing social and self-advocacy skills, and learning college-related skills. One said, "it made me aware about other people with disabilities have a voice." Another said, "I really liked how I got to learn things that will prepare me for the future in college." Autistic mentors enjoyed meeting participants and sharing their self-knowledge with them.
Conclusions: Associations between symptoms, intelligence, and challenges were different in the current sample (which had higher average intelligence) relative to our first program. Improvements in symptoms replicated from the first program (wherein a trend was observed) to the second. Reduced anxiety did not replicate in the current program, but improvements in autism knowledge, which is essential for self-advocacy, were apparent during this program. Findings suggest that programming has replicable benefits that should be evaluated in larger samples.

78 **145.078** Comparative Effectiveness of Two Non-Pharmacological Approaches to Self-Efficacy and Social Skills

E. Kemeny *and D. A. Hutchins, Recreational Therapy, Slippery Rock University, Slippery Rock, PA*

Background: Adolescents with autism spectrum disorders (ASD) need effective non-pharmacological approaches that impact self-efficacy and social skills (Dattilo & Rusch, 2012; Obrusnikova & Miccinello, 2012). Garcia-Villmaser et al. (2010) found that preliminary evidence that recreation improves quality of life. However, no research compares the impact of goal-directed individualized recreational therapy and non-goal directed recreation for youth with ASD.
Objectives: This research concerns the question: Which intervention is the most effective in improving the social skills and self-efficacy?
Methods: A convenience sample of 24 participants, ages 13-19, with ASD were divided into equal groups (age and gender) to participate in a 4-week repeated measures design that compared two conditions (goal-directed individualized with non-goal directed recreation). Three outcomes were measured before and after the weekly 2 hour sessions in both conditions: parent-report of Home Community-based Social Scale (HCSBS), Self-efficacy Scale (Dishmann et al., 2005), and researcher observation (OARS smart tablet application) of six social skills. The same recreational activities (such as social games and horseback riding) were used in both conditions. Only participants in condition A received an individualized assessment and treatment plan.
A series of paired sample t-tests were used on each dependent variable to determine if there were significant differences within each group before and after the programs. Next, a factorial ANOVA with repeated measures was used to compare the differences between the conditions (goal-directed vs. non-goal directed recreation participation).

Results: The t-test revealed a difference pre to post (p <. 05) in the goal-directed condition on the parent-reported HCSBS, the self-efficacy scale, and OARS in eight different areas: a decrease in impulsive behavior, an improvement in admiration by peers, compromise with peers, adjusting to expectations, overall social competence score, knowledge of recreational options, and responsiveness to mentor. A descriptive analysis revealed that social games were more effective in promoting responsiveness to mentor/peer and the outdoor equine-assisted activities were more effective in supporting initiating conversation. Based on the repeated measures ANOVA, the areas of significant difference (p<. 05) between the individualized-goal and non-goal directed were found in the self-report of self-efficacy: 1) perceiving physical activity as fun and enjoyable, 2) knowledge of activity, and 3) increased positive mood regarding activity.
Conclusions: Individualized goal-directed recreational therapy appears to be more effective in targeting self-efficacy for community participation than general recreation programs. Participants in both groups received an opportunity to participate in the same recreational interventions over the same time period with the same frequency. Therefore, the main difference in the groups was that the recreational therapy (RT) condition had a goal-directed intervention based upon the assessment and goal planning. The individuals in the RT condition had input into their goals and intentionally worked toward improving their own social and physical skills while participants in the other condition only received the recreational program itself. Just providing a recreational program is not enough. For more effective community integration, intentional targeting and inclusion of the adolescent with ASD in goal planning may have a greater impact on self-efficacy for social recreational and leisure participation.



79 **145.079** Current Inclusion Practices for Students with ASD in Under-Resourced Schools

L. Huynh[1], *M. Dean*[2], *S. Iadarola*[3] *and T. AIR-B Network*[4], *(1)UCLA, Los Angeles, CA, (2)California State University, Channel Islands, Camarillo, CA, (3)University of Rochester Medical Center, Rochester, NY, (4)AIR-B Network, Los Angeles, CA*

Background: In response to federal mandates, children with ASD are included in general education classrooms at increasing rates(Smith 2012), and many school districts have identified “best practices” for teachers to support inclusion of children with ASD. However, little is known about teachers’ views on the feasibility, acceptability, and utility of these inclusive practices. Teachers’ views are important because they could exert a significant influence over whether and how new interventions are adopted and implemented. Furthermore, evidence suggests that empirically supported inclusion practices are often implemented inconsistently and without fidelity (Hunt, Soto, Maier, & Goetz, 2002).
Research in these areas is timely, given the emphasis in ASD research on developing interventions and practices that can be successfully adopted in real-world settings. Factors related to the implementation of services, such as capacity, buy-in, and “barriers to the ‘fit’ between social context and intervention” (Dingfelder & Mandell, 2011) can significantly affect how new interventions are adopted and carried out.
Objectives: The purpose of the study is to use qualitative research methodology to examine the barriers and facilitators to inclusive practices and perceived child outcomes in three socio-economically disadvantaged schools in a large urban school district.
Methods: Using a purposive sample of 3 schools, we facilitated 9 focus groups with teachers (4), paraprofessionals (3), and parents (2) of children with ASD, and 7 key informant interviews with administrators (3), parents (1), and related service providers (3). Under a phenomenology framework, transcripts were analyzed using thematic analysis.
Results:
Two themes permeated the school and neighboring community climate. Financial hardships and perceived discrimination created daily stressors that hindered interpersonal relations within and across community and school settings. The extent to which these stressors caused communication breakdowns directly related to perceived child outcomes. Financial burdens affected the hiring of support staff, caseload management, training opportunities for teachers, parents, and paraprofessionals, and a general lack of access to instructional materials and resources. Children were often placed in ASD programs at schools outside of their neighborhood, and a lack of transportation or childcare, or the inability to take off work made parent involvement difficult.
Perceived discrimination was reported by educators and parents. Special education teachers were perceived as being a lower priority than general education teachers, and children with ASD often received little support in inclusive environments. The extent to which adults facilitated a climate of inclusion was positively related to the perceived acceptance of a child with ASD. Parents reported being rejected because of their child with ASD, leading to feelings of isolation. There was a relationship between level of school and community support for parents, and the perceived quality of inclusion programs.
Conclusions:
Our findings suggest that there is a tension between federal mandates and school policy, and actual school practices. Financial hardships and perceived discrimination reveal a lack of infrastructure to support the implementation of best practices for inclusion in socioeconomically disadvantaged communities. Interpersonal communications related to the barriers had a direct effect on perceived child outcomes, such that healthier communication was associated with greater acceptance.

80 **145.080** Deconstructing the Literature on the Treatment of Anxiety in Youth with ASD

B. M. Marro[1], *R. J. Weber*[1], *L. Bungert*[1], *S. Sommer*[1], *C. M. Kerns*[2], *L. J. Moskowitz*[3], *E. Cohn*[4] *and M. D. Lerner*[1], *(1)Stony Brook University, Stony Brook, NY, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)Psychology, St. John's University, Queens, NY, (4)Center for Health Innovation, Adelphi University, Garden City, NY*

Background: Anxiety symptoms in Autism Spectrum Disorders (ASD) are highly prevalent (Simonoff et al., 2008). Interventions aimed at treating ASD and anxiety include different elements, each defined as a "discrete clinical technique or strategy" (Chorpita et al., 2005). Characterizing interventions by their base elements streamlines terminology, and illuminates variation and overlap amongst interventions, which may be particularly diverse when targeting comorbid syndromes. No study has reviewed discrete elements in the literature on treating anxiety in ASD. Doing so provides a uniquely informative bird's-eye view of current evidence-based treatment in this literature. Further, as only two treatment approaches, Cognitive Behavioral Therapy (CBT) and Applied Behavioral Analysis (ABA), are considered "empirically supported" for anxiety in ASD, it is useful to see whether patterns of their use can be discerned by examining distributions of their discrete components.
Objectives: (1) To explore which elements are used most commonly in the empirical literature treating anxiety in ASD youth. (2) To categorize those elements that are best characterized as CBT or ABA strategies. (3) To examine how participant age and gender relate to element distribution.
Methods: Researchers reviewed PubMed, PsycINFO, and Web of Science. This process yielded excellent agreement (ICC(1,2)=.957), and N = 40 articles. They were coded for elements compiled by a research consortium as representing common evidence-based practices in the field, and for participant age/gender. Inter-rater reliability for these codes was excellent (ICC(2,5)=.792). In order to classify elements as CBT or ABA, we grouped elements based on the published definitions (Gosch et al., 2006; National Autism Center, 2015), then employed an iterative backwards stepwise inclusion strategy to achieve acceptable internal consistency. We examined frequencies of individual elements in the literature, as well the presence of ABA and CBT strategies; paired-sample *t*-tests and χ^2 tests were used to compare strategy frequency and associations with age & gender.
Results: The most common elements, appearing in ≥40% of articles, were Graduated Exposure, Cognitive Restructuring, and Homework; conversely, Meditation, Prompt Fading, and Time Out were not present (Figure 1). CBT was comprised of Cognitive Restructuring, Homework, Relaxation/Deep Breathing, and Self-Awareness Bodily Response (Cronbach's α=.661). ABA was comprised of Prompting, Priming, Games and Activities Involving Social Interaction, Shaping, Stimulus Control, and Video/Audio Modeling (Cronbach's α=.688). The number of CBT elements used was significantly greater than the number of ABA elements (*t*=2.06, *p*=.046; CBT: *M*=1.4, *SD*=1.37; ABA: *M*=0.7, *SD*=0.46). No significant association was found between gender or age and the presence of CBT or ABA elements (all *p*>.190).
Conclusions: That Graduated Exposure is the most commonly implemented element suggests that the research literature strongly relies on well-supported approaches to anxiety in ASD. The use of more CBT strategies in this review may reflect a differential preference for representing internal (i.e. cognitive aspects of anxiety) symptoms in CBT, relative to purely external (i.e. visible behavior) symptoms in ABA. Future work is warranted to similarly characterize interventions implemented in the community and to explore variation in treatment techniques on that larger scale as a function of age, gender, or other characteristics.

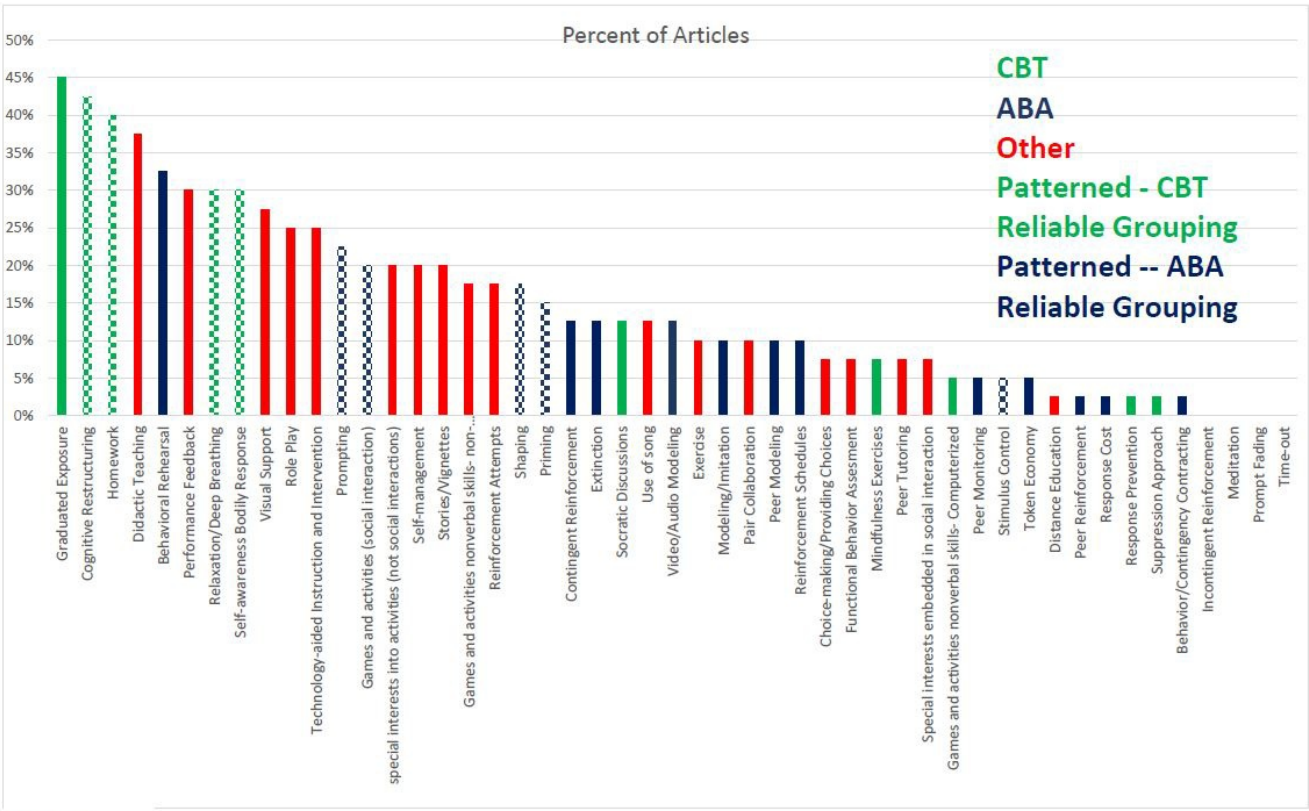


Figure 1

81 **145.081** Effectiveness of a Novel Outdoor Behavioral Health Treatment Intervention for ASD: A Single Subject Design

*M. E. Villalobos[1], **S. Semcho**[2], D. Schuler[3] and S. Lewis[3], (1)TEACCH Autism Program University of North Carolina Chapel Hill, NC, Asheville, NC, (2)Psychiatry, TEACCH UNC Chapel Hill Autism Program, Asheville, NC, (3)CReATE: Center for Research, Assessment, and Treatment Efficacy, Asheville, NC*

Background: Recent estimates have indicated that autism spectrum disorder (ASD) affects approximately 1 in 68 children (Baio, 2014); epidemiological data suggests that this figure represents a marked increase in prevalence rates observed over the past decades (Duchan, & Patel, 2012). Social behavior deficits, a core diagnostic criterion of ASD, negatively impact youth's functioning in many ways. Struggles to develop relationships, rigid behavioral routines, affective dysregulation, and hyperactivity reduce social learning opportunities and compound functional difficulties (Bauminger, Shulman, & Agam, 2003). Thus, there has been a renewed interest in the development of comprehensive, psychosocial treatment for youth with ASD. The current feasibility study explored the effectiveness of a multi-modal, intensive, residential treatment program, delivered in a naturalistic wilderness setting, for adolescents with ASD. Quasi-experimental data has supported the use of similar programming for adolescents with psychiatric disorders (e.g., Russell, 2002; Lewis, 2013); however, this is the first study of its kind to examine the effectiveness of such programming for youth with ASD.
Objectives: The purpose of the current research was to conduct a feasibility study, investigating the therapeutic response of a single subject to a novel treatment intervention for youth with ASD. It was hypothesized that the participant would evidence improvements in overall psychological functioning and social skills, as well as associated behavioral excesses and deficits during 8-weeks of intensive residential treatment.
Methods: A 15-year-old male with diagnoses of ASD and ADHD was enrolled in a residential treatment program, delivered in the naturalistic setting of the NC national forest. Data were collected pre- and post-treatment, as well as weekly throughout the duration of the program; data included standardized, normative instruments completed by therapist and youth (i.e., Treatment Outcome Package [TOP; Kraus et al., 2005] and Social Skills Improvement System [SSIS; Gresham and Elliot, 2008]), behavioral documentation conducted by trained staff, and partial-interval behavioral recording, conducted weekly by staff trained in behavior analysis.
Results: Results supported primary hypotheses. Clinically meaningful reductions in externalizing behaviors, ADHD symptoms, internalizing problems, and overall ASD-related behavioral symptoms were observed, from baseline to discharge. Comparisons of pre- to post-treatment therapist ratings indicate that the participant demonstrated significant, clinically meaningful improvements in adaptive social skills (13th percentile, baseline; 55th percentile discharge) and significant reductions in problem behaviors (99th percentile, baseline; 77th percentile, discharge). Specifically, improvements were noted in communication, responsibility, empathy, social engagement, and self-control. Further, behavioral observation data indicated greater frequency of positive social behaviors (e.g., contributing to group discussion, helping peers, starting/joining a conversation) and decreased frequency of negative social behaviors (e.g., verbal impulsivity) over 8-weeks of treatment.
Conclusions: The results indicate that in the current single-subject feasibility study, the participant evidenced significant improvements in functioning broadly— including psychological symptomatology, social skills, prosocial behavior, peer relatedness— from baseline to post-treatment. These results offer encouraging preliminary evidence for the effectiveness of a novel, multi-modal, intensive treatment for adolescents with ASD and comorbid behavioral and mental health disorders.

82 **145.082** Effects of Therapeutic Horseback Riding for Youth with Autism Spectrum Disorder

Z. Pan[1], *D. A. Granger*[2], *J. Lucas*[3], *B. Dechant*[4] *and R. Gabriels*[5], *(1)Pediatrics, University of Colorado Denver school of medicine, Aurora, CO, (2)Institute for Interdisciplinary Salivary Bioscience Research, Arizona State University, (3) Johns Hopkins University School of Nursing, Bloomberg School of Public Health, and School of Medicine, Phoenix, AZ, (3)Psychiatry, University of Colorado, Aurora, CO, (4)University of Colorado - Denver, Aurora, CO, (5)Children's Hospital Colorado, Aurora, CO*

Background:
In a randomized clinical trial, (Gabriels et al., 2015; NIH/NINR 1R01NR012736) demonstrated that therapeutic horseback riding (THR), as compared to a no horse activity control, benefitted children with autism spectrum disorder (ASD) on measures of irritability, hyperactivity, social cognition and social communication, along with the total number of words and new words spoken during a standardized language sample.–
Objectives: To examine whether results reported by Gabriels and colleagues (2015) can be replicated,, determine the feasibility of collecting saliva samples from children with ASD, and explore the effect of THR on individual differences in children's cortisol levels
Methods: Sixteen participants, 6-16 years old with a diagnosis of ASD were randomized with 1:1 ratio into either THR or no-horse barn activity control group (BA). Other inclusion criteria include a combined score of 11 points or higher on the Irritability and Stereotypic Behavior subscales of the ABC-C and nonverbal IQ ≥ 40. Exclusion criteria included physical or behavioral issues that would prevent participation, a history of animal abuse or phobia to horses, more than two hours of EAAT experience within the past six months, or taking steroid medications. Pre- and post-intervention evaluation of Systematic Analysis of Language Transcripts (SALT) were conducted by a speech therapist blinded to intervention condition. A designated caregiver for each participant completed the ABC-C and Social Responsiveness Scale (SRS). Salivary samples were collected pre- and 20 minutes post- THR group sessions and later assayed for cortisol
Results:
THR-related behavior response patterns are presented in Figure 1 and Table 1. The effect of THR, as compared to BA control, was significant on hyperactivity ($p<0.05$) and marginally significant ($ps<0.1$) on irritability and social communication. Pre- and post-intervention saliva cortisol were successfully collected in 90% and 40% of the interventions sessions respectively for THR and Barn groups] Linear mixed effects model analysis indicated that greater irritability was associated with greater post-intervention reduction in cortisol in the THR group ($p=0.05$) and in the Barn group (each $p=0.10$); Greater hyperactivity is associated with greater cortisol reduction in THR group ($p<0.05$) but not in the barn group.
Conclusions:
The effects observed in the prior THR RCT were partially replicated. It was feasible to collect saliva from children with ASD at the riding center. Although this preliminary study did not have sufficient statistical power to evaluate effects on salivary cortisol as outcome for assessing immediate effects of the THR intervention on HPA activity, results suggest that salivary cortisol may be a promising measure for future investigations to explore the mechanisms of THR as having a sensory/calming effect on children with ASD.

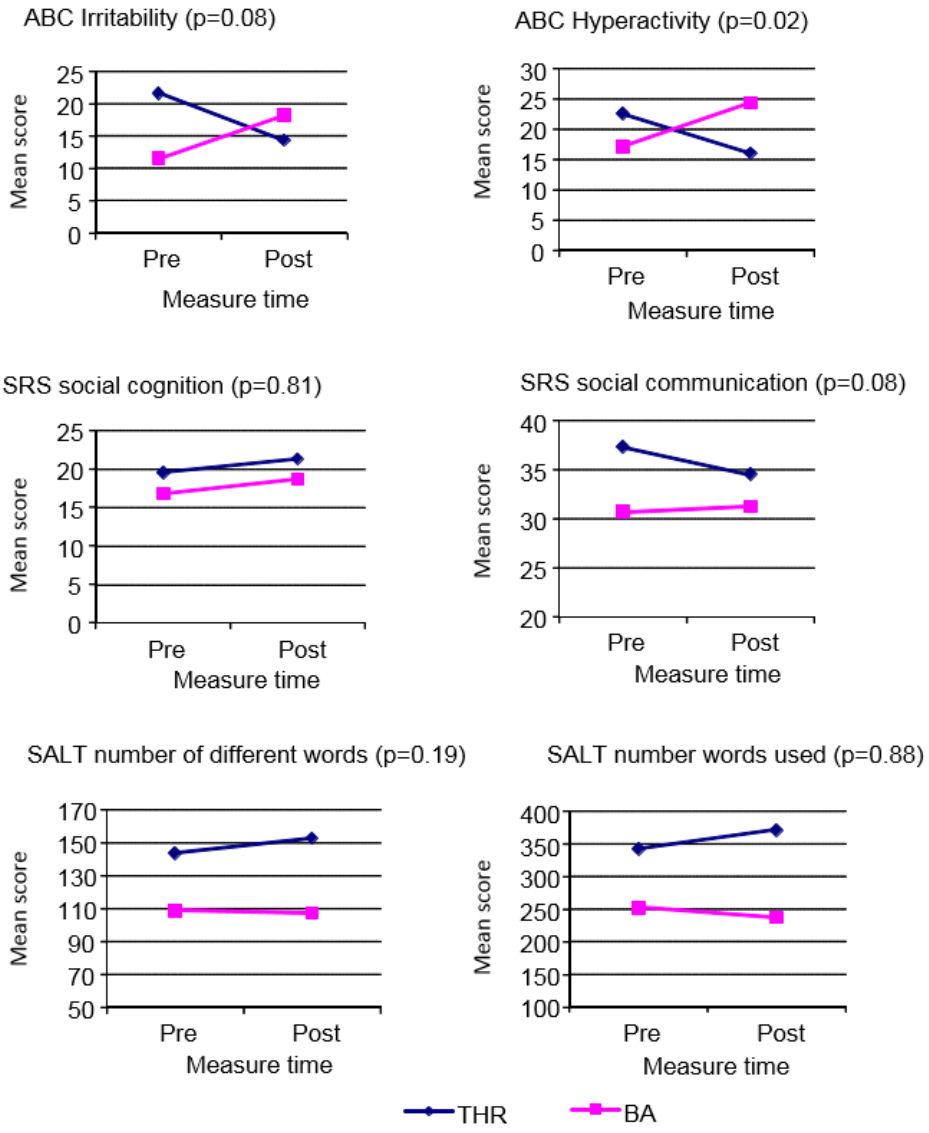

Figure 1 : Results replicated 5 out of 6 outcomes observed between two groups in a previously published, larger RCT (n=127).

83 **145.083** Electrophysiological Assays of Multisensory Integration and Sensory Processing in Autism Spectrum Disorders

S. Molholm*, Neuroscience and Pediatrics, Albert Einstein College of Medicine, Bronx, NY*

Background:
The development of ordered interactions among inputs to the different sensory systems is a necessary component of normal functioning and plays a fundamental role in our ability to successfully navigate the environment. Examples of multisensory influences on normal perception are manifold. For example, seeing someone speak can have

profound effects on what is heard, and the perceived location of a sound is affected by the location of a co-occurring visual event. It has been proposed that failure to develop normal integration of sensory inputs is at the root of some childhood neuro-behavioral disorders, a notion that has been especially applied to autism. This notion led to the formulation of the Sensory Integration Theory in the late 70's, a theory that has attracted a large following over the intervening years.
Psychometric tests and questionnaires indicate profound differences in sensory processing in individuals with autism. However, the neural underpinnings of these sensory processing differences remain elusive. One promising line of research suggests that differences in connectivity may be involved. It has been argued that in autism, perhaps as a consequence of reduced long-range connectivity, typical perception and cognition are disrupted when information must be integrated across sensory and cognitive domains. A breakdown in long-range connectivity would of course lead to impoverished integration of sensory information across modalities.
Objectives:
1) To use objective neural and behavioral metrics of sensory processing and multisensory integration (MSI), in order to probe the integrity of multisensory integration processes in ASD.
2) To develop biomarkers that can be used to assay normalization of function due to treatment.
Methods:
High-density electrophysiological scalp recordings served to measure the brains response to unisensory and multisensory stimuli (basic visual, auditory, and somatosensory stimuli presented alone or simultaneously). Parallel behavioral reaction-time measures assessed perceptual enhancement due to multisensory stimulation. In an additional, purely behavioral paradigm, the consequence of impaired MSI for speech processing was examined. Here participants identified spoken words-in-noise that were sometimes accompanied by videos of the speaker saying the word. Improved performance on the auditory-plus-video condition compared to the auditory-alone condition indexed MSI.
Results:
Basic unisensory processing was relatively intact in ASD, especially for somatosensory and visual stimulation. In contrast, integration of audiovisual multisensory inputs was significantly impaired in this group, as evinced by both neurophysiological and behavioral measures. The audiovisual speech-in-noise task further revealed profound MSI deficits in children with autism that impacted their ability to discern words in a noisy environment.
Conclusions:
The ability to integrate multiple sensory cues incurs major advantage to decoding the social and communicative milieu. The impaired MSI that we observe in children with an ASD puts them at significant disadvantage in such complex situations where a fine weighting of multisensory cues is required. The protracted development of MSI offers a window of opportunity for intervention to remediate MSI. Here we present measures of MSI that can be used to assess the impact of interventions on these fundamental processes.

84 **145.084** Enhancing Joint Attention Skills in Children with Autism Spectrum Disorder through an Augmented Reality Technology-Based Intervention

P. Perez Fuster[1], *G. Herrera*[1], *A. Ferrer*[2], *M. Mademtzi*[3] *and F. Shic*[3], *(1)Autism Research Group. Robotics Institute, University of Valencia, Valencia, Spain, (2)Educational and Developmental Psychology, School of Psychology, University of Valencia, Valencia, Spain, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Joint attention (JA), defined as the ability to coordinate attention with an interactive social partner to share awareness of an object or event, has been identified as a key deficit among children with ASD (Mundy et al., 1986). In particular, children with ASD do not engage in responding to JA (RJA) behaviors, such as gaze following and pointing, in the same way as typically developing individuals (Mundy, 2003). Because these skills are crucial for child development and learning (Charman, 2003), previous behavioral interventions have been implemented (Kasari et al., 2006). Also several studies have used technology as a mediating tool to improve RJA skills, leading to significant overall improvements in some children (Cheng & Huang, 2012).
Objectives: The objective of this study was to enhance the RJA skills of gaze following and pointing in children with ASD through an intervention based on the use of *Pictogram Room*. This technology is a Kinect-based Augmented Reality (AR) system comprised of multiple educational video games designed for enhancing a variety of skills including RJA in children (Herrera et al., 2012).
Methods: Two males and one female of 3, 5 and 8 years old with ASD participated in the study. ADOS-2 (Lord et al., 2012) and ESCS (Mundy et al., 2003) standardized tools were used to assess participants' RJA skills. A single-subject multiple-baseline design was used over twelve weeks. The intervention consisted of six sessions of 30 minutes: 15 minutes for the intervention (i.e. participants used *Pictogram Room* to learn how follow the gaze of a virtual dummy and touch the object of shared attention in an AR environment) and 15 minutes for the assessment (i.e. the dependent variable was measured as the number of times that participants gaze followed a real dummy by pointing out the object of shared attention in the physical world). Maintenance was evaluated through follow up assessments. Another assessment in which the students had to respond to a person's gaze was used to evaluate generalization.
Results: ADOS-2 and ESCS assessments identified students' difficulties for RJA, which made them to be eligible for participating in the study. For measuring the dependent variable, two blind raters independently coded the videos and an inter-observer reliability of >90 was reached. The *Percentage of All Non-Overlapping Data* was 96% and Pearson *Phi* statistic analysis showed an effect size of 0.92 ($p < .01$), which indicated that the intervention was highly effective for improving the RJA skills of gaze following and pointing of the three students. Improvements were maintained after one month and generalized to a person's gaze.
Conclusions: This study suggests that a novel AR technology-based intervention can be effective for the improvement of RJA skills in children with ASD. Although the intervention has been implemented for only three children, the findings are significant and promising. Therefore, it would be desirable as future work to evaluate the impact of this intervention on a larger sample. Also a randomized controlled trial would help to explore its full efficacy.

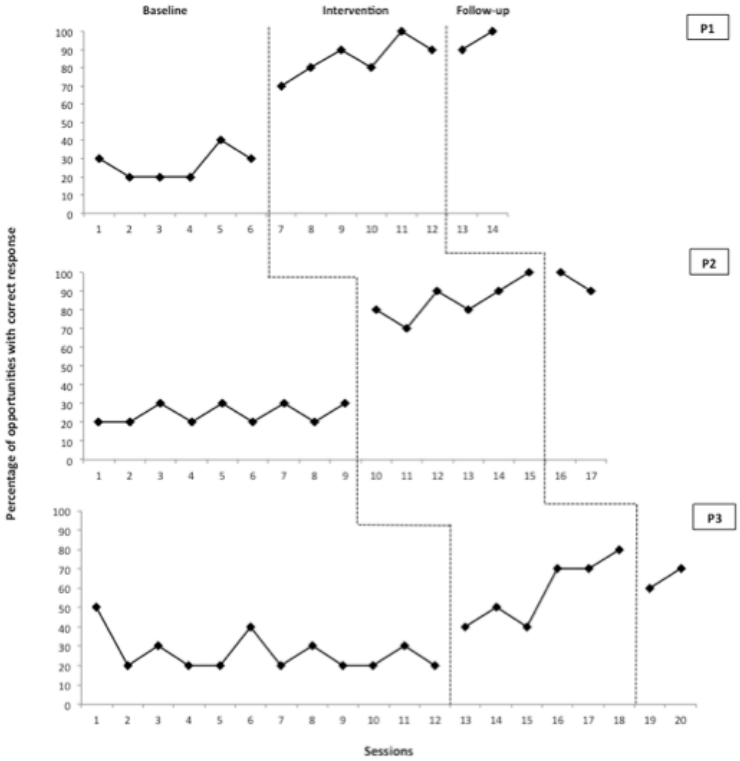

Fig. 1 Percentage of opportunities in which the participant correctly gaze followed and pointed the target object of shared attention

85 **145.085** Evaluating the Summer Treatment Program for Children with Autism Spectrum Disorders

B. Aaronson[1,2], *D. Campa*[1,2], *A. Compton*[1,2], *E. Baumler*[1] *and A. M. Estes*[1,3], *(1)University of Washington Autism Center, Seattle, WA, (2)Department of Educational Psychology, University of Washington, Seattle, WA, (3)Department of Speech and Hearing Sciences, University of Washington, Seattle, WA*

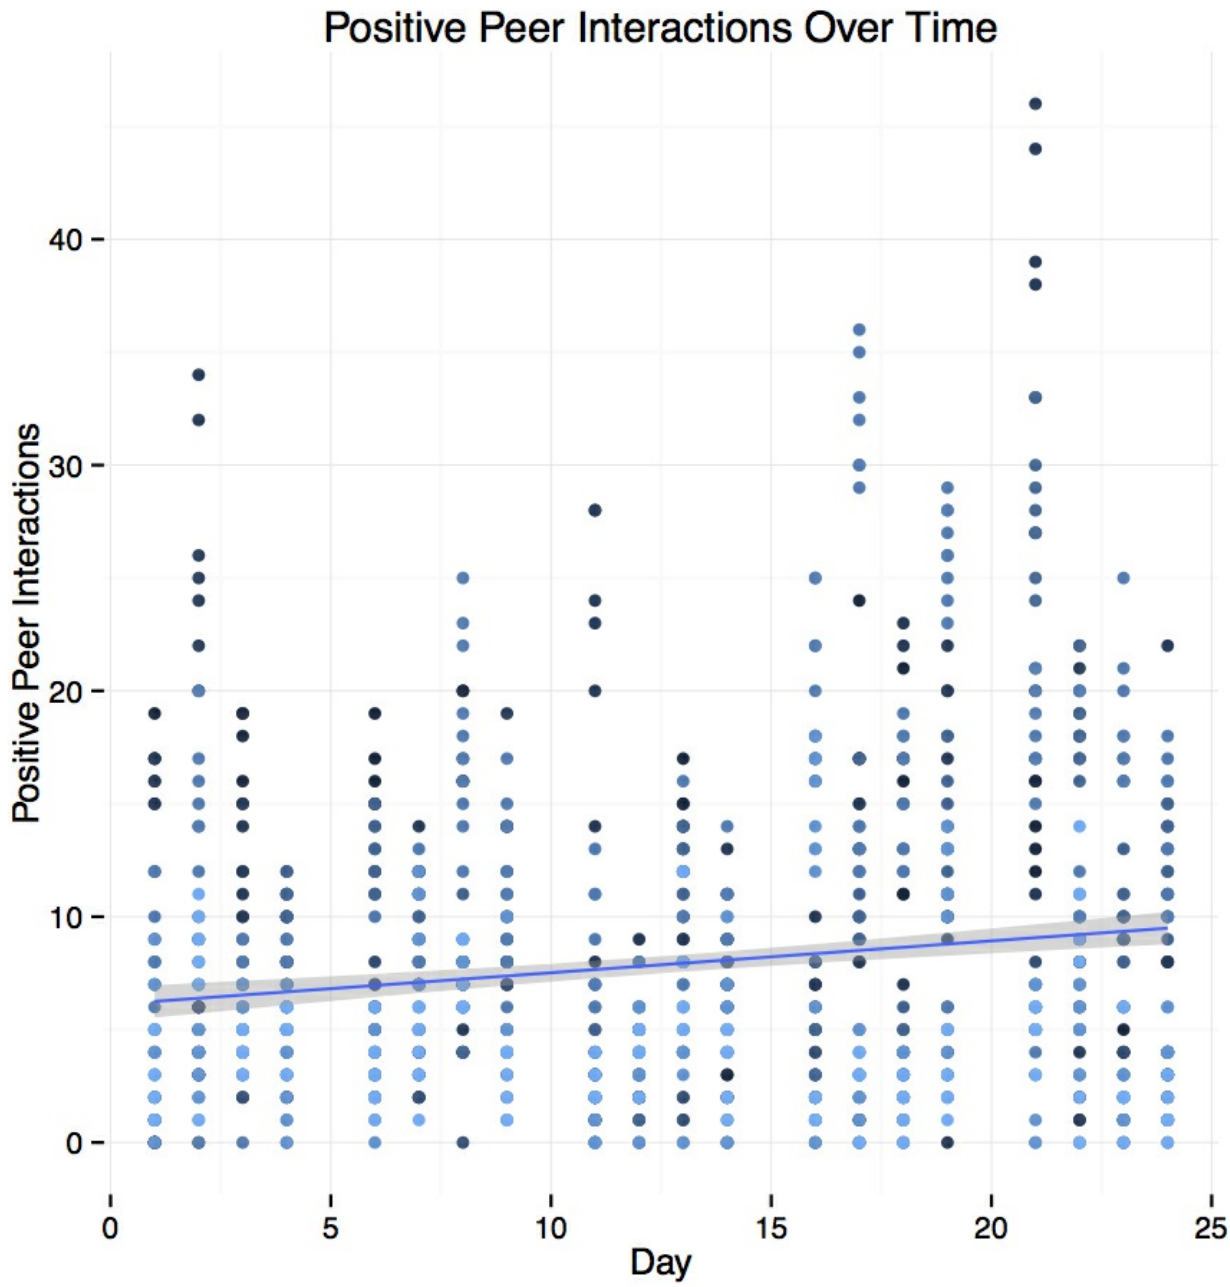
Background: The Summer Treatment Program (STP) was developed by Pelham and colleagues to provide behavioral and social skills intervention for children with attention-deficit hyperactivity disorder (Pelham, Greiner, Gnagy, 1985; 2014). Children participate in structured recreational activities, while a detailed token economy promotes adaptive behaviors. Behavior management is a prominent program objective, along with a detailed social skills curriculum. There are around a dozen programs in the United States that use the STP methodology. It is becoming increasingly common for children with autism spectrum disorder (ASD) to enroll in these summer programs due to their explicit structure, focus on social skills, and limited alternative summer options. To our knowledge, there has been no report of the effectiveness of the STP in promoting social skills for children with ASD.

Objectives: To evaluate the effectiveness of the Summer Treatment Program in increasing positive peer interactions for children with autism spectrum disorder.

Methods: The UW Autism Center adopted the Summer Treatment Program to provide children with ASD an opportunity for structured development of behavioral and social skills during the summer. Minor modifications to the program for children with ASD are described, including a modified time-out procedure. Graduate and undergraduate students were recruited to implement the program, completing 2 weeks of training in the STP model, including intervention techniques and behavioral coding. Behavioral data were collected continuously during the program, including measures of attention, compliance, and positive peer interactions. The frequency of positive peer interactions over time was reviewed for 59 participants of the 5-week program during the summer of 2015 with a documented diagnosis of autism spectrum disorder.

Results: Preliminary analysis of 59 participants with ASD included calculating a simple linear regression to examine the relationship between days of participation in the Summer Treatment Program and the number of positive peer interactions. A significant regression equation was found $F(1, 1178) = 27.19$, $p < .001$, with an $R^2$of 0.022. Positive peer interactions increased 0.14 for each day of attending the program.

Conclusions: For children with ASD who participated in the Summer Treatment Program, an increase was observed over time in the number of positive peer interactions, which includes helping others, sharing with others, and ignoring provocation. The Summer Treatment Program methodology may be an effective tool for increasing social skills in children with ASD. Future research might examine the program's impact on other specific behavior and autism symptomology.



86 **145.086** Evaluation of the Client-Therapist Relationship in an Emotion Regulation Intervention for Children with Autism Spectrum Disorder

P. Burnham Riosa *and J. A. Weiss, York University, Toronto, ON, Canada*

Background:
Evidence-based practice (EBP) involves integrating the current best available research literature with clinical expertise and client characteristics, values, and preferences (American Psychological Association, 2005). An understudied yet important facet of EBP is the therapeutic alliance (TA), or collaborative therapist-client working relationship. Across treatment modalities, TA is a predictor of treatment success in both child and adult populations (Horvath & Symonds, 1991; Martin et al., 2000; Wampold et al., 1997). Researchers have described the need to evaluate TA in interventions for children and youth with ASD (Brown et al., 2014). Empirically supported treatments designed to address co-occurring emotional and behavioral problems of children with ASD are emerging; however, relatively little work has been done to examine TA in interventions for this population.
Objectives:
The objective of the current study was to examine the therapist-client relationship and its relation to client satisfaction ratings and child treatment outcomes in a cognitive behavior therapy (CBT) intervention, the *Secret Agent Society: Operation Regulation* (Beaumont, 2013).
Methods:
As part of an ongoing randomized waitlist controlled trial, 20 children (19 males) ages 8 to 12 years (M = 9.8; SD = 1.29) with ASD and their parents completed the 10-session CBT intervention and detailed measures of therapeutic alliance. Parents and children completed child ER (*Emotion Regulation Checklist* (Shields & Cicchetti, 1997; *Children's Emotion Management Scale*, Zeman et al., 2010) and psychopathology (*Behavior Assessment System for Children, 2nd Edition*, Reynolds & Kamphaus, 2004) measures pre- and post-intervention. Two trained coders rated early (Session 2), middle (Session 5), and late (Session 9) therapy sessions using the *Therapy Process Observational Coding System–Alliance Scale*(McLeod, 2005; McLeod & Weisz, 2005). Coders established excellent reliability (ICC = .95). Parents and children completed post-intervention program satisfaction measures.
Results:
Forty-nine unique video-recorded sessions were coded across 20 participants for child-therapist and parent-therapist alliance (ICC = .95). Observational ratings of these alliances were correlated (r = .48, p= .04), with ratings of child-therapist alliance and parent-therapist alliance high across early, middle, and late sessions.
Early session child-therapist alliance was not related to child psychopathology, ER, or satisfaction ratings; however, high early parent-therapist alliance was related to low parent-reported internalizing problems post-intervention (r = -.69, p =.002). High middle session child-therapist alliance was correlated with low externalizing symptoms (r = -.68, p =.004) and emotional lability/negativity (r = -.73, p =.001). High middle session parent-therapist alliance was also correlated with low in externalizing problems (r = -.51, p =.05) and higher child-reported overall coping (r = .61, p =.02). Finally, high late session child-therapist alliance was correlated with child-reported satisfaction with the program (r = .80, p =.001) and child-reported coping (r = .69, p =.003) post-intervention. Late parent-therapist alliance was not correlated with any post-intervention measures (p> .05).
Conclusions:
Our study highlights the importance of examining therapeutic relational processes to understand client satisfaction and treatment outcomes of children with ASD. The implications of understanding relational processes on the delivery of empirically supported treatments in this population will be discussed.

87 **145.087** Examining the Effectiveness of the PEERS Program on Social Skills and Anxiety in Adolescents with Autism Spectrum Disorder

T. L. Hill[1], *S. Gray*[1], *K. Boggs*[2], *C. Johnson*[2], *E. J. Carey*[2], *C. N. Baker*[1] *and R. E. Varela*[3], *(1)Psychology, Tulane University, New Orleans, LA, (2)Children's Hospital, New Orleans, New Orleans, LA, (3)Loyola University New Orleans, New Orleans, LA*

Background: Poor social functioning is a hallmark feature of Autism Spectrum Disorder (ASD). As such, recent research has focused on developing social skills interventions for individuals with ASD. Research indicates that the Program for the Enhancement and Enrichment of Relational Skills (PEERS), a manualized social skills intervention for high functioning adolescents with ASD, is efficacious. However, to date, no studies have examined the effectiveness of the PEERS program in community settings. Moreover, high functioning youth with ASD often present with comorbid anxiety. Social skills interventions may increase participants' self-efficacy in social interactions, thereby reducing the anxiety that participants may feel in social interactions, yet only one study (Schohl et al., 2014) has sought to extend the current findings linked to PEERS by examining the program's effects on participants' anxiety.
Objectives: This small-scale pilot study aimed to evaluate the effectiveness of the PEERS program not only on improving social skills but also on reducing anxiety.
Methods: Participants included 5 high functioning adolescents ages 13 to 15 with ASD and their parents. The intervention consisted of 90-minute, weekly parent and teen sessions over the course of 14 weeks. Pre and post measures were completed by the parents and adolescents and included the Social Skills Improvement System (SSiS), the Social Responsiveness Scale (SRS-2), the Test of Adolescent Social Skills Knowledge (TASSK), the Quality of Play Questionnaire (QPQ), and the Screen for Child Anxiety Related Disorders (SCARED). Pre- to post-intervention improvement was examined using paired samples t-tests.
Results: Results from the paired samples t-tests are presented in Table 1. There was significant improvement in adolescents' knowledge of the specific social skills taught during the intervention. Autism symptomatology and internalizing symptoms (measured by the SSiS Internalizing scale) showed a significant decrease from pre- to post-intervention. While the paired-samples t-test failed to reveal a significant decrease in pre- to post- anxiety as measured by the SCARED, SCARED Total scores generally decreased for most participants (Fig. 1). Furthermore, the two participants with clinical levels of anxiety (SCARED Total score > 25) prior to intervention reported non-clinical levels of anxiety at post-test. For the variables of interest, the strength of the effect sizes for the mean change scores on the outcome variables in this study were small to large, and most were comparable to the effect sizes for the mean change scores calculated from the published PEERS efficacy studies (see Table 1).
Conclusions: This independent and community-based small-scale pilot study supports the effectiveness of the PEERS program in community-based care for improving the social functioning of high functioning adolescents with ASD. Although reducing anxiety is not a direct target of the PEERS program, our findings are consistent with the findings of Schohl et al. (2014), which indicate that participation in the PEERS program also leads to reductions in anxiety.

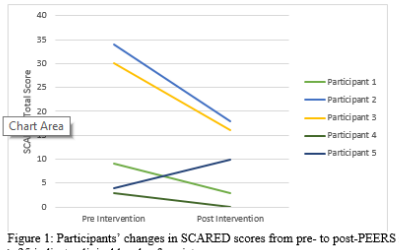


Figure 1: Participants' changes in SCARED scores from pre- to post-PEERS intervention; scores > 25 indicate clinical levels of anxiety.

Mean pre- and post-intervention scores, standard deviations, and effect sizes for outcome variables (N = 5)

88 **145.088** Examining the Efficacy of Teacher Training Models for Pivotal Response Treatment: A Comparison of in-Person Coaching and Video-Feedback

J. K. Randolph[1], *K. O'Connor*[2] *and S. M. Kanne*[3], *(1)Thompson Center, Columbia, MO, (2)Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (3)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Pivotal Response Treatment (PRT) is an evidenced-based practice of naturalistic behavioral principles that enhances social-communication and engagement behaviors of children with autism spectrum disorders (ASD). Traditionally delivered in-person, access to PRT training remains a challenge for regions without immediate access to an expert coach. The use of video-feedback may provide access to high-quality training to meet the needs present in rural areas and regions that traditionally have difficulties with access to care.
Objectives: This presentation will review initial data from a nonequivalent quasi-experimental between-group design on the comparison of an in-person training model and video-feedback training model for teachers and paraprofessionals of children with autism and emergent social-communication skills.
Methods: This study is a nonequivalent quasi-experiment between-group examination of PRT training models comparing an in-person training model group and a video-feedback training model group. Both treatment groups were provided an in-person dyadic initial overview training of PRT principles. The in-person treatment group was then provided weekly 25-minute in-person sessions of independent implementation, coached practice, and feedback, while the video-feedback treatment group was provided weekly typed feedback after reviewing videos of independent implementation. Both treatment groups were considered at fidelity when the teacher achieved at least 80% fidelity of implementation across 3 consecutive feedback sessions. Collection of maintenance and generalization data is on-going. Participants included children with ASD and significant language delays, ages 3-10 years who are eligible for special services in public school settings. Dependent measures include structured behavior observations of teachers' fidelity of implementation and children's social-communication and engagement behaviors.
Results: To date, 40 teacher-child pairs have completed. Data collection is ongoing with an estimated n=76 (41 in-person feedback and 35 video feedback) to be completed by March 2016. Preliminary data has been analyzed for 18 participants (n=9 per training group). There were no statistically significant differences between the two training groups in regard to teachers' baseline ability or children's characteristics. Initial data analysis indicates there is no statistically significant difference between the average number of sessions to obtain fidelity whether the training was conducted in-person or via video feedback. Children in both treatment groups acquired similar levels of increases in social-communication and engagement skills as fidelity of PRT implementation was achieved by teachers. No statistically significant differences were observed between training groups in regard to their maintenance levels of PRT fidelity.
Additional analyses will be conducted to examine the potential relationship between teacher fidelity, child response to intervention and child characteristics in the domains of: cognition, communication, social engagement, toy play, self-stimulatory behavior, avoidant behavior and maladaptive behavior. Analysis regarding social validity for both training models will also be included.
Conclusions: These preliminary data suggests promise in reaching remote sites with high quality training through the use of video feedback. Potential benefits and challenges of video-based feedback training models and areas in need of future research will be discussed.

89 **145.089** Examining the Efficacy of a Family Peer Advocate Model in Reducing Caregiver Stress in Black and Hispanic Caregivers of Children with Autism Spectrum Disorder

E. Fourie[1], *J. M. Jamison*[2], *P. M. Siper*[3], *P. Trelles*[4], *M. Gorenstein*[4], *J. Krata*[5], *E. Holl*[5], *D. Halpern*[4], *A. Kolevzon*[2], *J. D. Buxbaum*[6], *B. Hernandez*[5], *L. Mitchell*[5] *and J. Shaoul*[5], *(1)Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, New York, NY, (2)Psychiatry, Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, New York, NY, (3)Seaver Autism Center, New York, NY, (4)Icahn School of Medicine at Mount Sinai, New York, NY, (5)YAI, New York, NY, (6)Psychiatry, Seaver Autism Center at Mount Sinai, New York, NY*

Background: Studies show that caregivers of children with developmental disabilities, and especially those with autism spectrum disorder (ASD), experience higher levels of caregiver strain than caregivers of typically developing children. Family peer advocates (FPA; often referred to as parent advocates) have been utilized across child service delivery systems to facilitate engagement in care and minimize the challenges that caregivers face. Peer-delivered advocacy services have been found to reduce isolation, normalize distress, and de-stigmatize child and family needs. Because the majority of research to date has examined caregiver strain in a largely Caucasian sample, there is a need to examine the FPA model within a more ethnically diverse population. Black and Hispanic children are experiencing disproportionately increasing rates of ASD diagnoses and are a frequently underserved population.
Objectives: To examine the impact of focused contact with an FPA on family stress and caregiver strain.
Methods: Sixty-seven children of Black or Hispanic descent, between the ages of 5 and 12, were screened for this study. Thirty-nine children met research eligibility criteria for ASD using the DSM-5, the Autism Diagnostic Observation Schedule (ADOS-2) and the Autism Diagnostic Interview-Revised (ADI-R) and were included in the analysis. This study used a single-blind randomized controlled design, in which caregivers were randomized to a Family Peer Advocate (FPA) group or a community care control group (control group). Caregivers in the FPA group had phone contact with a trained FPA at least twelve times over a six-month time period. Caregivers in the control group received treatment as usual within the community. All caregivers completed the Parenting Stress Index (PSI)—Short Form and Caregiver Strain Questionnaire (CSQ), both validated in autism populations, at three time points (baseline, month 3, and month 6).
Results: There was a significant two-way time x group interaction on the PSI for total score (p<.001), as well as each subscale. The FPA group showed significant improvement in parental stress over time on PSI total scores and all subscales, while the control group did not significantly improve on any PSI subscale. There was also a significant two-way time x group interaction on the CSQ (p<.001), indicating that the FPA group showed significantly less caregiver strain over time as compared to the control group.
Conclusions: Our results demonstrate that caregivers who were paired with an FPA over a six month time period were more likely than the caregivers in the control group to report decreased stress and strain on two separate measures. This evidence supports the efficacy of this FPA model in alleviating stress levels for Black and Hispanic families of children with ASD. Future studies should include larger samples, an active treatment comparator, and a follow-up time point to see if contact with an FPA had sustained effects on parental stress levels.

90 **145.090** Examining the Impact of the PEERS® Social Skills Intervention on Females with ASD

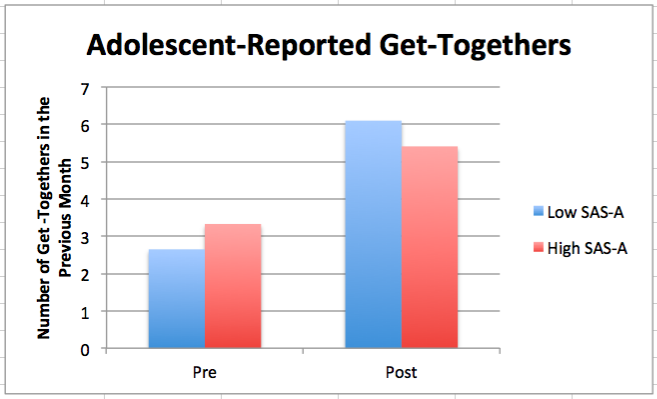
A. McVey[1], *B. Dolan*[1], *A. G. Meyer*[1], *J. S. Karst*[2], *S. Stevens*[3], *K. A. Schohl*[1], *C. Caiozzo*[1], *E. Vogt*[1], *S. Potts*[1] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Children's Hospital of Wisconsin, Wauwatosa, WI, (3)University of Minnesota, Minneapolis, MN*

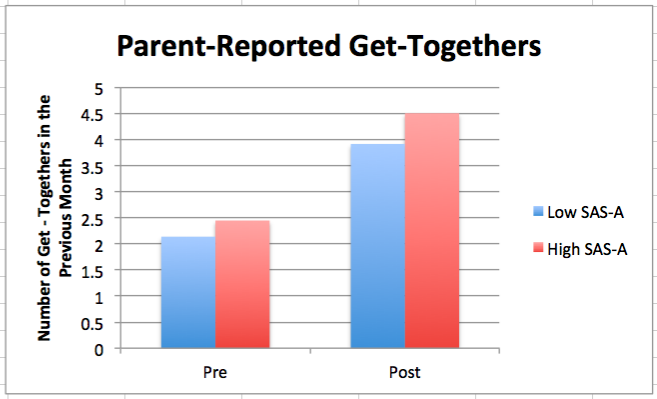
Background: A paucity of research has been conducted to examine the effect of social skills interventions on females with autism spectrum disorder (ASD). Broadly, literature on social skills interventions for this population has focused on males alone or males and females in aggregate (Chan et al., 2009).
Objectives: The primary objectives of this study were to examine if changes in social skills knowledge and social responsiveness among female adolescents and young adults with ASD differed from males who underwent the same social skills intervention.
Methods: One hundred and eleven adolescents (n = 111; 15 female) between the ages of 11 and 16, and 48 young adults (n = 48; 9 female) between the ages of 18 and 28 with ASD participated in this study. Two comparable social skills interventions, specifically the Program for the Education and Enrichment of Relational Skills (PEERS®) for adolescents and PEERS® for Young Adults, were conducted based on age. Both PEERS® interventions focus on improving friendship quality and social skills among young adults with higher-functioning ASD (Laugeson, Frankel, Gantman, Dillon, & Mogil, 2012; Gantman, Kapp, Orenski, & Laugeson, 2012). Participants were high-functioning individuals with ASD, who comprised the Experimental Treatment Group (n = 56 adolescents, n = 23 young adults) and the Waitlist Control Group (n = 55 adolescents, n = 25 young adults). Pre- and post-intervention measures included the *Test of Adolescent Social Skills Knowledge* (Laugeson and Frankel, 2010) for adolescents, the *Test of Young Adult Social Skills Knowledge* (Gantman et al., 2012) for young adults, which are self-report measures, and the *Social Responsiveness Scale* (Constantino et al., 2003), a parent-report measure.
Results: Preliminary results include available data from males and females from the experimental treatment and waitlist control groups; ongoing analyses will include additional participants for both groups. When analyzed by group, males and females do not differ significantly on their improvement within these areas, as measured by the TASSK/TYASSK (F = .748, p = .388) and SRS (F = .494, p = .483). Both groups demonstrate significant improvement on both the TASSK/TYASSK (F = 121.2, p < .01) and SRS (F = 10.8, p < .01) from pre- to post-intervention.
Conclusions: Our results suggest that the PEERS® intervention is as effective for females with ASD as males with the disorder. Research shows that males and females often demonstrate differing presentations of the disorder (Dean, 2013), and females may be thought to be more “socialized” than males (Goldman, 2013; Solomon et al., 2012). Our findings indicate that, despite these differences in presentation, females show similar patterns of improvement in social skills to males. This has important implications for understanding how females with ASD respond to social skills intervention.

91 **145.091** Examining the Relation Between Social Anxiety and Social Engagement Outcomes Among Adolescents with Autism Spectrum Disorder Following the UCLA PEERS® Intervention

A. V. Dahiya[1,2], *E. Veytsman*[3], *R. Ellingsen*[4] *and E. A. Laugeson*[3], *(1)UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Behavior, Los Angeles, CA, (3)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (4)University of California Los Angeles, Los Angeles, CA*

Background:
Deficits in social skills, including impaired social-emotional reciprocity, poor nonverbal communicative behaviors used for social interaction, are common hallmarks for those with autism spectrum disorder (ASD) (Otero et al. 2015). As a result, adolescents with ASD often have difficulty understanding their peers and establishing social reciprocity with others (Volkmar 2011). These social skill deficits, in combination with elevated physiological arousal, can lead to the development of social anxiety, which is significantly associated with increased social avoidance (Bellini 2006). Previous research on the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®), an evidence-based social skills intervention for adolescents with ASD, demonstrates increases in social engagement following treatment (Laugeson et al. 2012). While research suggests that social anxiety is associated with social avoidance, the extent to which social anxiety is related to frequency of social engagement in adolescents with ASD following PEERS®has yet to be examined.
Objectives:
The present study examines the relationship between social anxiety at baseline and social engagement in adolescents with ASD following the completion of a 14-week parent-assisted social skills intervention.
Methods:
One hundred adolescents (males=84; females=16) with ASD ranging from 11-18 years of age (M=14.02; SD=1.81) and their parents participated in the study. Adolescents and their parents attended an evidence-based, parent-assisted social skills intervention, PEERS®. They attended 90-minute group treatment sessions over a period of 14-weeks to learn guidelines of social behavior related to the development and maintenance of social relationships. In order to assess social anxiety and social avoidance at baseline, adolescents and parents completed the Social Anxiety Scale (SAS; La Greca, 1999) pre-intervention. To assess change in frequency of social engagement, adolescents and parents completed the Quality of Socialization Questionnaire (QSQ; Frankel & Mintz 2008) which assesses the frequency of hosted and invited get-togethers with peers in the previous month at baseline and post-intervention. Pearson correlations were calculated to examine the relationship between social anxiety at baseline and change in social engagement from pre- to post-treatment.
Results:
Results reveal that 49 percent of participants (n=49) reported social anxiety in the clinical range at baseline, as measured by the SAS total score (≥50). While social engagement increased over the course of treatment for the full sample, as measured by adolescent and parent-reported hosted (p<.001) and invited (p<.05) get-togethers on the QSQ, overall social anxiety at baseline on the SAS was not associated with improvement in social engagement following intervention. However, higher scores on the SAS subscale of General Social Avoidance and Distress were significantly correlated with an increase in parent-reported hosted get-togethers (p<.05) following treatment.
Conclusions: Although there was no significant relationship between adolescents' overall social anxiety at baseline and change in social engagement following PEERS®, there was a significant treatment effect for adolescent and parent-reported hosted and invited get-togethers. Greater general social avoidance and distress prior to treatment may be related to better treatment outcomes through improved social engagement. These findings suggest that social anxiety may not influence treatment outcomes related to social engagement for adolescents following the PEERS® intervention.





92 **145.092** Examining the Role of Social-Communication in Explaining Treatment Gains for Adolescents with ASD Following the PEERS® Social Skills Intervention

C. C. Bolton[1], *E. Veytsman*[1], *Y. Bolourian*[2] *and E. A. Laugeson*[1], *(1)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)University of California - Riverside, Riverside, CA*

Background: Social communication skills, including social interaction, social competence, speech style and language pragmatics, are strongly associated with long-term outcomes for youth with autism spectrum disorder (ASD) (Howlin et al. 2004; Ingersoll, 2011). Deficits in social communication are often the earliest identifiable indicators of ASD, and several early intervention models target this domain (Ingersoll, 2013; Kasari, 2015). However, research has not previously examined the influence of social communication on the development of social skills in adolescence.
Objectives: This study examines the role of social communication in predicting social skills ratings following the implementation of the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®), an evidence-based social skills curriculum in both school-based and outpatient mental health settings.
Methods: Participants included 186 adolescents with ASD referred for social skills training in outpatient and school settings. Among the outpatient sample, participants included 80 adolescents (males=68; females=12) 11-18 years of age (*M*=13.8, *SD*=2.25) School based participants included students (*n* = 80 males; *n* = 26 females) in 6th – 12thgrades attending a non-public school for students with ASD. Adolescents, parents, and teachers completed pre and post-test measures, including the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008) and the Social Responsiveness Scale (SRS; Constantino & Gruber, 2005). Following the completion of baseline measures, adolescents participated in a 14-week manualized teacher-facilitated intervention then completed post-test measures. A linear regression analysis was conducted to examine the relation between baseline measures of social-communication (SRS) and the SSIS post-treatment.
Results: Data analysis shows that social communication (SRS) at baseline is significant in explaining the variance in social skill acquisition (SSIS) following intervention. Adolescent social communication scores (SRS) both significantly predicted b = -.61, t(70) = -6.92 *p*<.000 and explained a significant proportion of variance in social skills as rated by parents R^2 = .41, *F*(1,70) = 47.92, *p*£.000 in the school-based sample. In the same sample, social communication both significantly predicted b = -.82, t(104) = -6.89, *p*<.000 and explained a significant proportion of variance in social skills R^2 = .32, *F*(1,104) = 47.34, *p*£.000 as rated by teachers following intervention. Social communication also significantly predicted social skills scores as rated by parents in the clinic sample, b = -.37, t(80) = -3.51, *p*<.001 and also explained a significant proportion of the variance R^2 = .14, *F*(1,78) = 12.32, *p*<001. However, social communication was better able to account for outcomes in the school-based sample than the clinic sample.
Conclusions: Data analysis revealed that social communication significantly predicted social skills scores and also explained a significant proportion of variance in social skills scores following intervention in both school-based and outpatient settings. This research demonstrates the importance of social communication in the acquisition of social skills following intervention and should be further evaluated. These results may provide additional support for early intervention targeting the domain of social communication to support social skills intervention and boost treatment outcomes for social skills acquisition.

Table 1

Summary of Simple Regression Analyses of Social Communication on the SRS in Predicting Post-Treatment Results on the SSIS

	School-based Participants				Outpatient Participants			
Outcome Variables	*B*	*SE B*	*β*	R^2	*B*	*SE B*	*β*	R^2
SSIS-Parent *(N = 70)*	-.61	.09	-.64***	.41	--	--	--	--
SSIS-Teacher *(N = 104)*	-.82	.12	-.56***	.32	--	--	--	--
SSIS-Parent *(N = 80)*	--	--	--	--	-.37	.12	-3.51	.14

Note. p<.05, **p<.01, ***p<.001; Listwise deletion was used in the regressions resulting in small decreases for the sample sizes across the measures included in this analysis. SSIS = Social Skills Improvement System (Gresham & Elliot, 2008); SRS = Social Responsiveness Scale (Constantino & Gruber, 2005).

93 **145.093** Examining the Treatment Efficacy of the PEERS in Japan: Towards Improving Social Skills of Children with Autism Spectrum Disorder

T. Yamada[1], *Y. Miura*[2] *and M. Oi*[3], *(1)Osaka University, Osaka, Japan, (2)Kanazawa University, Kanazawa, Japan, (3)Kanazawa University, United Graduate School of Child Dev., Kanazawa, Japan*

Background: Children with autism spectrum disorder (ASD) are characterized by social communication and interpersonal disabilities, repetitive behaviors, and restricted interests. These characteristics affect important aspects of their lives, like making friends and maintaining good relationships. As a result, these individuals experience difficulties in social adjustments, especially because adolescents focus more on themselves and social relationship with others.
Objectives: The need for social skill training programs to support social adjustment is increasing, but many of these programs are targeted at young children. PEERS (Program for the Education and Enrichment of Relational Skills) is parent-assisted social skills training organized as a group session. PEERS utilizes the principles of cognitive behavior therapy to improve social functioning for teens with ASD. For both teens and parents, each session (once a week) lasts 90 min and continues for 14 weeks. Although PEERS has been shown to improve the social skills of adolescents with ASD in North America, cross-cultural trials have only just started. The objective of

this research was thus to examine the treatment efficacy of PEERS in Japan for improving social skills.
Methods: The PEERS treatment manual was translated into Japanese, and the curriculum contents necessary for cultural adjustments were modified with the permission of the developer of PEERS. Modifications included examples of peer groups, places where teens can find new friends, humorous material that could be understood in terms of Japanese culture, and activities teens enjoy together. Participants included 28 teens between 6th and 9th grade diagnosed with ASD and a verbal intelligence score >70 on WISC-IV. Eligible teens were assigned to a treatment group (TG) or a delayed control group (CG). Primary outcome measures included questionnaires quantifying social ability and communication skills and behaviors related to ASD. Secondary outcome measures included depressive symptoms and behavioral problems. All participants including their mothers and teachers completed these outcome measures three (pre-treatment, post-treatment, follow-up) or four times (a baseline assessment was added for the delayed control group).
Results: Comparison of pre- and post-intervention questionnaires indicated that teens receiving PEERS showed improved social skill knowledge according to the Test of Adolescent Social Skills Knowledge (TASSK) and social skills in the area of social communication. The measures parents reported suggested that teens showed decreased ASD symptoms relating social responsiveness by the end of the 14-week intervention, according to the Social Responsiveness Scale. Also, in the social skills area of Vineland II, interpersonal relationship, play/leisure time, and coping skills scores differed significantly before and after treatment. According to Vineland II, scores in the area of maladaptive behaviors also decreased. Besides these scores, high levels of parent, child, and staff satisfaction were reported, in addition to high attendance rates.
Conclusions: Teens receiving the PEERS treatment showed increased social skills knowledge and improved interpersonal relationship skills. The PEERS intervention appears effective for teens with ASD in Japan after small cultural adjustments.

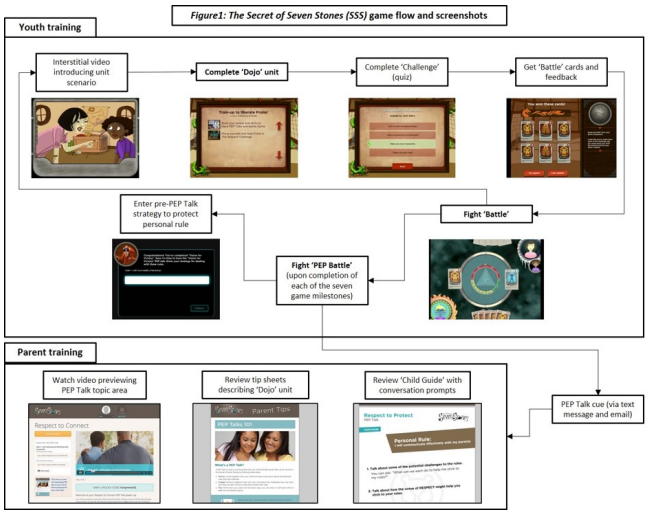
94 **145.094** Exploring the Feasibility of an Innovative Inter-Generational Computer Game for Sexual Health Education in Youth with Autism Spectrum Disorder and Other Neurodevelopmental Disabilities: A Mixed-Method Case Study

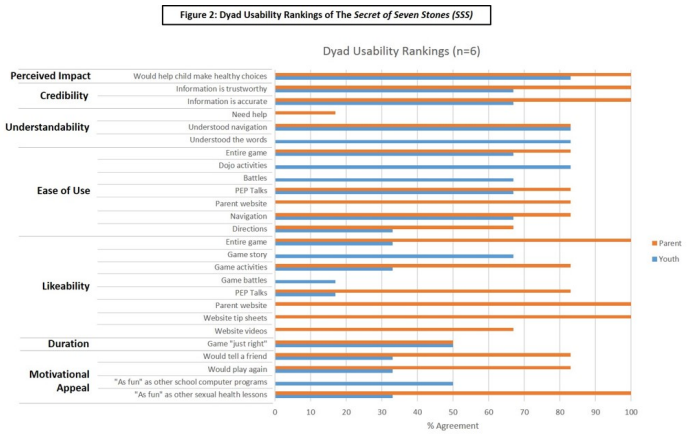
P. Chaudhary[1], *S. M. Dube*[2], *L. N. Ceglio*[2], *D. A. Pearson*[3], *H. Y. Song*[4], *A. M. Spencer*[5], *C. Markham*[2], *M. Peskin*[6], *D. Santa Maria*[7], *J. McLaughlin*[8], *J. M. Wilkerson*[5], *R. Addy*[5] *and R. Shegog*[2], *(1)Health Promotion and Behavioral Sciences, University of Texas School of Public Health, Houston, TX, (2)Center for Health Promotion and Prevention Research, University of Texas School of Public Health, Houston, TX, (3)Psychiatry & Behavioral Sciences, University of Texas Medical School at Houston, Houston, TX, (4)University of Texas School of BioInformatics, Houston, TX, (5)University of Texas School of Public Health, Houston, TX, (6)Center for Health Promotion and Prevention Research, Houston, TX, (7)Nursing Systems, University of Texas School of Nursing, Houston, TX, (8)Radiant Creative Group, LLC, Houston, TX*

Background: Although youth with Autism Spectrum Disorder (ASD) and other Neurodevelopmental Disabilities (NDD) experience deficits in communication and social skills, the onset of puberty and sexual development is not equally delayed. Yet, their sexual and relationship needs are often neglected. Moreover, barriers to effective peer and parental communication experienced by these individuals, limit the educational impact of traditional sexual health interventions. As the individuals with ASD/NDD are often visual learners, technology based serious intergenerational games represent a salient strategy to fulfil this gap. Hence, this study aims to explore the potential of an innovative, home-based intergenerational computer game, *The Secret of Seven Stones (SSS)*,to promote sexual education and parent-youth communication in this population.
Objectives:

1. To explore the usability of SSS for sexual health education in ASD/NDD youth.
2. To explore the feasibility of using SSS in the home setting.
3. To explore the feasibility of SSS to promote parent-youth communication.

Methods: This study is a mixed methods multiple case study of six parent-youth dyads (11-14 years) in a large metropolitan area in Texas. This study is a subset of a larger, randomized control efficacy trial, to evaluate the 18-level home-based SSS computer game and parent website (Figure 1). A stepped development framework, Intervention Mapping, informed the theoretical and empirical foundation of SSS. Parent and youth self-reported data were collected via Questionnaire Development System (QDS™) survey assessing pre-sexual and sexual behaviors, intentions towards sex and parent-youth communication about sex, and gaming behaviors at baseline and 3-month follow-up. Game progress and time-on-task data were collected from the SSS data base. Usability rating surveys and in-depth semi-structured exit interviews were conducted with parents and youth at 3-month follow-up.
Results: The youth sample (n=6) was male (50%), Caucasian, of mean age 13.04 ± 1.49 years, and with diagnosis of Autism Spectrum Disorder (ASD) (33%) and/or had other Neurodevelopmental Disabilities (NDD) (67%). Youth were sexually inexperienced (100%) but engaged in some pre-sexual behavior (50%) and intending to have sex in next year (33%). Some had ever talked to their parent about sexual topics such as birth control (50%), condoms (33%), HIV/AIDS (50%), and STIs (33%). Parents were female, 46.1 ± 2.43 years old, and Caucasian. By 3-month follow-up most youth had either completed SSS (57%) or completed over half of SSS (14%). Youth and parents rated the game as captivating (67-100%), easy to use (67-83%), understandable (50-100%), credible (67-100%), and helpful for making future healthy choices (83-100%) (Figure 2). SSS rated lower on uniqueness, attractiveness, and motivational appeal (33-67%). Youth reported length and technical difficulties as barriers to game play. Qualitative findings highlighted higher acceptability of the game and website among parent-youth dyads, particularly for ease of navigation, website resources, and parental involvement. Parents indicated benefits of SSS in mediating parent-youth communication regarding sexual health.
Conclusions: Our exploratory analysis indicated that an intergenerational game offers an acceptable and feasible strategy to address the socio-sexual needs of youth with ASD/NDD. These exploratory results suggest that further research with larger samples is indicated.





95 **145.095** Family Support Interventions for Young Adults with ASD

L. E. Smith[1], *J. S. Greenberg*[1] *and M. R. Mailick*[2], *(1)University of Wisconsin-Madison, Madison, WI, (2)Waisman Center, University of Wisconsin-Madison, Madison, WI*

Background: Autism spectrum disorders (ASDs) are developmental disabilities that affect approximately 1 in 68 children in the US. Although there is evidence of some abatement of autism symptoms and behavior problems over time (Esbensen et al., 2008; Seltzer et al., 2004; Shattuck et al., 2007; Woodman et al., 2015), ASD is a chronic disability which presents multiple challenges for individuals and their families at each stage of the life course. Further, improvements in behavioral functioning slow down following high school exit (Taylor & Seltzer, 2010) and there is a significant loss of services for individuals with ASD upon exiting the school system (Howlin et al., 2005). Given the dearth of *formal* services for young adults with ASD, it may be all the more imperative to offer interventions that increase a family's capacity to find and create *informal* supports and activities. Thus, interventions that help adults with ASD and their family members learn new skills and enhance the effectiveness of their advocacy are necessary. However, currently there are no empirically-based interventions designed for the family (Schultz et al., 2011; Taylor, Dove et al., 2012). To address this gap we have developed a multi-family psychoeducation model, *Working Together*, designed for disengaged young adults with ASD and their families. The *Working Together* model adapts an approach commonly used in research and practice with individuals with varying mental health conditions (e.g., schizophrenia, bipolar disorder) and applies it to families of individuals with ASD. This model is unique with its emphasis on supporting the family system to increase engagement of individuals with ASD in employment and educational activities.
Objectives: We will report on the process of development of a family-centered intervention model, including data from focus groups and a feasibility pilot.

Methods:
A comprehensive review of the literature was conducted to develop intervention content. Three focus groups were completed to gain feedback on the proposed model from key stakeholders including young adults with ASD, family members, and service providers. The model and curriculum content were further refined based on this input. Finally, a feasibility pilot study was conducted with 4 families. Feedback from the feasibility pilot was used to create the final model to be evaluated in a 12-month randomized control trial.
Results:
Based on a comprehensive literature review, a model was developed that involved 8 weekly group sessions, 2 individual family sessions, and a method for ongoing resources and referrals. Focus group data confirmed the need for family-centered supports for individuals with ASD during adulthood and suggested that the curriculum should also include an emphasis on coping strategies and safety. Results from the feasibility pilot suggested a need for the model to include additional opportunities for individualized support and a high family interest in ongoing booster sessions.
Conclusions: The finalized *Working Together* model is currently being evaluated in randomized control trial with 54 families.

96 **145.096** Functional Score Changes in a Group of Patients with Autistic Spectrum Disorders (ASD) with Interdisciplinary Treatment

***S. L. Baetti**, Pediatrics Mental Health, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*

Background:
In the Italian Hospital of Buenos Aires there is an interdisciplinary team (ASD team) that provides treatment to patients with developmental disorder. It works with clinicians, music therapists, psychologists, speech therapists, occupational therapists, physical therapists and pedagogical professionals The team uses the IDEA (Inventory autistic spectrum) as a qualitative tool for evaluating the severity and responses to treatment of the patients. The IDEA is a behavioral observation scale that evaluates 12 aspects of development. It also estimates the severity of autistic characteristics, and provides targets for intervention, and gives tips for monitoring the evolution. No studies have been found in Argentina to validate this tool in monitoring patients with ASD. Population: pediatric patients between 2 and 17 years old, diagnosed with ASD who have at least 2 assessments of IDEA in a minimum interval of time of 6 months between each other. (Inclusion criteria)
Objectives: To make a description about the progress and give a score to this progress of patients who are in treatment with an ASD Team.
Methods: It is a retrospective and descriptive study. We include all patients founded in the ASD team treatment between 2008 and 2014. The description of the patients' evolution was done through the analysis of the IDEA score. Items evaluated were: age, sex, result of the first IDEA scores (IDEA 1) and the second IDEA score measured after 6 months of evolution (IDEA 2). Also an IDEA partial score of each dimension evaluated. The IDEA scale measures disorder or dysfunction. Each dimension of IDEA presents a range of 8 points, from 0 to 8. 8 correspond to a maximum level of involvement in each dimension and 0 as skill without disorder. The total score is the result of the sum of the 12 dimensions (range 0 to 96). The score decline implies improvement in patients' functionality. The cutoff points below 50 are considered with good prognosis and below 25, with high functionality.
Results: From a total of 50 patients, 39 met the inclusion criteria. 85% were male and the median age was 5 years (IQR 4-6). After two evaluations made with IDEA The results shows a score decrease in 31 patients (79%).
Conclusions: A statistic significant difference is observed between the initial IDEA (median 36 RIC 28-50) and final IDEA (median 31, IQR 25-40).An statistical analysis is done in two groups of patients: better prognosis n: 29 (With initial scores: less than 50) and worse prognosis n: 10 (with initial scores : higher than 50) and it is observed that the difference between scores of groups 1 and 2 was statistically significant test result. (p less than 0.005)

97 **145.097** Identification of Sensitive Outcome Measures of Functional Skills

***E. Ridgway**, Rose F. Kennedy Children's Evaluation and Rehab Center (CERC) at Montefiore, Albert Einstein College of Medicine, Bronx, NY*

Background: Clinicians and researchers have an obligation to evaluate the effectiveness of the interventions they provide. Patient-reported outcome measures are an important component of outcome measurement and effectiveness research and these have gained increase recognition and status with the advent of the Patient-Centered Outcomes Research Institute and initiative (PCORI, 2014); however, they may be subject to response bias. In regard to occupational therapy using sensory integration, a frequently requested and utilized intervention for children with ASD, there is now pilot data showing that this intervention improves the child's participation in functional activities and that the children show increased independence in activities of daily living and socialization via parent-report measures. To further explore the evidence for this intervention and others that target these outcomes, valid, reliable, performance-based outcome measures are needed to supplement parent-rated measures.
Objectives:
The objective of this presentation is to present the findings from a study funded to identify psychometrically sound, suitable, performance-based outcome instruments to measure functional skills and socialization in children with ASD that could be used in future studies.
Methods:
This study used mixed methods to identify performance-based measures of daily living skills and socialization, test their feasibility when applied to children with ASD ages 6-9, and explore their discriminant validity. Systematic review of the literature was completed to identify currently available performance-based assessments of activities of daily living and socialization for children with ASD. Inclusion criteria included that the measure 1) evaluates daily living skills and/or socialization; 2) is appropriate for use with children with ASD ages 6-9 years of age; 3) is performance-based; 4) and is norm referenced for use with ASD. A panel of experts in Autism and/or outcome measurement rated measures using a quality indicator scale that rates psychometric rigor, sensitivity, and appropriateness for ASD. Top-rated measures were then subject to a modified Delphi Process. In the next stage of this research a feasibility trial of the top-rated measures with 20 ethnically diverse children with ASD will be conducted at an urban clinic.
Results: Eight performance-based outcome measures of Activities of Daily Living or Socialization were identified from the literature review. Quality indicator ratings showed that the top-rated instruments that met most criteria were The Assessment of Motor and Process Skills (AMPS – Fisher & Jones, 2012) and the Evaluation of Social Interaction (ESI - Fisher and Griwold, 2010). These assessments will be used in the feasibility trial that will be conducted during January and February 2016.
Conclusions:
The AMPS is a performance-based, standardized assessment of daily living skills that has strong reliability and validity as an outcome measure and has norms for use with ASD. The ESI is a reliable, valid, performance-based assessment that shows strong promise as an outcome measure of social interaction for children with ASD. Discriminative validity and feasibility data will also be presented. This final phase will determine their discriminative validity and utility for use as an outcome measure in a comparative effectiveness trial.

98 **145.098** Implementation Outcomes of a Coach-Based Transition Program for Students with ASD in Urban Educational Settings

***C. Aponte**[1], K. Zanibbi[1], T. Smith[2], J. J. Locke[3] and T. AIR-B Network[4], (1)University of Rochester Medical Center, Rochester, NY, (2)Division of Neurodevelopmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (3)University of Washington Autism Center, Seattle, WA, (4)AIR-B Network, Los Angeles, CA*

Background: There is a gap between behavioral interventions developed within a university-based laboratory and the settings within which the interventions are likely to be executed. Barriers in school systems may impede the consistency and quality with which an evidence-based intervention can be executed. Engaging in community-partnered research to develop interventions addresses the needs and goals of the key community stakeholders with consideration to barriers that are present in the community setting. In addition to the content and outcomes of treatments, an important aspect of this type of intervention development is the evaluation of the degree to which implementers in community settings accept the intervention, and the degree to which they adhere to the components of the intervention.
Objectives: We aimed to: a) evaluate the fidelity with which teachers executed the components of the Schedules, Tools, and Activities for Transitions (STAT) program; and b) determine the acceptability and feasibility of the STAT program in under-resourced public schools.
Methods:
Along with our community partners, we developed the STAT program to address transition-related problem behavior commonly observed in students with ASD in self-contained classrooms. STAT was implemented in three urban school districts in Rochester NY, Los Angeles, and Philadelphia. Participating classrooms were randomized to immediate treatment (n = 73) or waitlist control (n = 77). Blind observers collected teacher Fidelity at baseline, exit, and 3-month follow-up. Teachers who received immediate treatment also completed the Implementation Climate Survey, and a Buy-in Measure at post-treatment and follow-up.
For the Buy-In Measure, teachers rated the degree to which they agreed with 21statements about the importance of the intervention on a Likert scale (1 = strongly agree; 7 = strongly disagree).
For Implementation Climate, teachers used a Likert scale (1 = not true; 5 = true) on 17 items designed to assess program quality, school support, and global perceptions of climate.
Results:
Although preliminary results indicated that, at baseline, teachers assigned to either group were already implementing STAT components with high (88%) fidelity, there was a slight post-treatment advantage for the experimental condition. Teachers in immediate treatment improved their average fidelity score to 93% (exit), and 97% (follow-up); fidelity scores for teachers in waitlist control maintained at 89% (post) and 87% (follow-up). Teachers' average buy-in scores were 1.73 at exit and 1.71 at follow-up, indicating high levels of intervention acceptability. For the Implementation Climate Questionnaire, teachers indicated that the STAT program was important and a priority in their schools.
Conclusions: Given the time and resource barriers in many urban schools, implementing evidence-based interventions poses significant challenges. Preliminary results from

this study suggest that, although many teachers already implement components of behavioral interventions, their performance can be enhanced through additional intervention. These effects were maintained over time, with participants continuing to adhere to the transition program. Additionally, teachers found the intervention valuable, and generally reported feeling supported by supervisors and classroom teams. This information supports the ongoing use of coach-based, packaged behavioral intervention and suggests that this model can be sustainable in public school settings.

99 **145.099** Implementation of Interventions in Under-Resourced Public Schools: Teacher and Administrator Perceptions of Programs for Students with ASD

E. Reisinger Blanch[1], *J. J. Locke*[2], *D. S. Mandell*[3] *and T. AIR-B Network*[4], *(1)University of Pennsylvania, Philadelphia, PA, (2)University of Washington Autism Center, Seattle, WA, (3)University of Pennsylvania School of Medicine, Philadelphia, PA, (4)AIR-B Network, Los Angeles, CA*

Background: Moving evidence-based practice from research clinics into under-resourced community settings requires considerable effort and resources. ASD interventions rarely are developed with the skills and resources of end user in mind, and rarely take into account the organizational context that will support (or not support) intervention implementation. Working in partnership with community practitioners and the organizations in which they work could enhance the effectiveness and sustainability of autism interventions (Locke, Kratz, Reisinger, & Mandell, 2014).
Objectives: To determine, after one year of implementation without outside support, if administrators and implementers (teachers & aides) feelings change regarding a) whether the intervention sustained, b) how school staff feelings change regarding the acceptability of the intervention and c) whether staff identify new barriers to implementation.
Methods:
The programs of interest are the Schedules, Tools, and Activities for Transitions (STAT) program, a behaviorally based classroom intervention for children with ASD, and the Remaking Recess (RR) intervention, a social engagement intervention for included children with ASD. The STAT and RR interventions were implemented in three urban school districts in Philadelphia, Rochester, and Los Angeles. Including all sites, 78 teachers and 157 students were enrolled in STAT and 106 teachers/aides and 95 students were enrolled in RR. Participating schools were randomized to immediate treatment or a waitlist control. Study staff collected program fidelity by rating staff adherence to program components throughout treatment. Measures of implementation climate and buy-in were collected at post-treatment and follow-up.
One year after support ended, 7 school administrators and 35 program implementers (classroom aides or teachers) were interviewed using a semi-structured interview protocol. One interview protocol was developed per intervention. Separate forms were developed to target the experience of implementers or supervisors. Each protocol contained between 14- 23 questions and each interview was audio recorded and later transcribed for analysis. Each interview averaged between 30- 60 minutes and was conducted at the participating school or by phone.
For the buy-in measure, teachers rated the degree to which they agreed with statements about the importance of the intervention on a Likert scale (1 = strongly agree; 7 = strongly disagree). For implementation climate, teachers used a Likert scale (1 = not true; 5 = true) on items designed to assess program quality, school support, and global perceptions of climate. Qualitative data are analyzed using NVivo. Codebook was created through consensus across members of the study team. Quantitative analysis included descriptive stats of measures of buy-in and implementation climate.
Results: Data analyses are ongoing. Teachers report that intervention fidelity and buy-in continue to be relatively high after one year. Qualitative responses suggest ongoing and new barriers that emerge in the course of the year.
Conclusions: Study results suggest that targeted modular interventions for children with ASD can be implemented and sustained in under resourced public schools. The data also suggest that barriers to implementation must be taken into account when looking to improve community practice.

100 **145.100** Improvement in Reciprocal Conversation Skills and Maladaptive Behaviors in Young Adults with ASD

C. A. Paisley[1], *A. Dutton*[1], *D. R. Oosting*[1], *R. Doggett*[2], *R. Tillman*[3] *and P. E. Ventola*[1], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Department of Child and Adolescent Psychiatry, The Child Study Center at NYU Langone Medical Center, New York, NY, (3)University of Maryland, College Park, MD*

Background: Many young adults with ASD are under- or unemployed and struggle with social relationships. Despite these difficulties and the significant challenges faced during the transition into adulthood, there are few evidence-based treatment options for young adults with ASD. Pivotal Response Treatment (PRT) is a naturalistic behavioral treatment that focuses on increasing skills in pivotal areas. PRT has been adapted for use in adolescents with a focus on self-monitoring (Doggett et al., 2013), but no study, to date, has used this model with young adults.
Objectives: Using a multiple baseline design, we sought to determine if a four-month treatment based on principles of PRT could improve reciprocal conversation skills and decrease maladaptive behaviors (e.g. skin picking, odd vocalizations) in young adults with ASD.
Methods: Three young adults between the ages of 18 and 21 years (Mean IQ = 106.67, S.D. = 11.93) participated in four months of treatment targeting reciprocal conversation skills and maladaptive behaviors. The sessions were 90 minutes, twice a week. The treatment followed principles of PRT, adapted for use with young adults (Doggett et al., 2013). Using a multiple baseline design, participants were randomized into a baseline condition (between 3 and 7 probes spanning 6 to 14 weeks). Specific targets included number of conversational turns and maladaptive behaviors. During the treatment phase, data on targeted behaviors was collected every two weeks. Additionally, to provide a measure of day-to-day functioning following treatment, the parents of the participants completed a Vineland Adaptive Behavior Scale-Second Edition (Vineland-II) before and after treatment.
Results: Following the start of intervention, participants rapidly increased their reciprocal conversation skills and the frequency of their maladaptive behaviors decreased. These improvements were maintained over time. Furthermore, the participants made notable gains in adaptive communication and social skills based on parent report. Specifically, participants made the equivalent of at least one year of gains in expressive and receptive communication skills and two years of gains in interpersonal relationship skills over the course of the 4-month intervention.
Conclusions: Young adults with ASD are a vastly underserved group with few options for evidence-based treatment and often limited access to care. Young adults can, though, dramatically benefit from behavioral treatment targeting reciprocal conversation skills and maladaptive behaviors following a short-term behavioral treatment based on principles of PRT adapted for young adults. Improvements are evidenced in the context of a clinical setting but also within their daily lives.

101 **145.101** Improving Autism Outcome Measures: An Integrated Home and Clinic Protocol with Novel Technologies

R. M. Jones[1], *C. Carberry*[1], *A. Hamo*[1], *H. Rao*[2], *U. Gupta*[2], *A. Albin*[2], *R. Pawar*[2], *I. Kleckner*[3], *O. O. Wilder-Smith*[4], *M. S. Goodwin*[4], *M. Clements*[2] *and C. Lord*[1], *(1)Weill Cornell Medical College, White Plains, NY, (2)Georgia Institute of Technology, Atlanta, GA, (3)University of Rochester Medical Center, Rochester, NY, (4)Northeastern University, Boston, MA*

Background: Sensitive, standardized, reliable outcomes for clinical trials attempting to change behavior in children and adults with Autism Spectrum Disorder (ASD) have been limited to date. Previous clinical trials often rely on a single behavior to quantify change (Findling et al., 2014) or determine change in one context (i.e. solely parent report or assessments only in the clinic) or use a measure with limited capability for replication (Bolte & Diehl, 2013), thus reducing the scope of the research. Outcomes in clinical trials that combine multiple domains to measure behavior and use multiple contexts to collect data offer the greatest success of capturing change in individuals with ASD.
Objectives: 1) To identify and evaluate social communication and physiological arousal measures that may be sensitive to change; 2) To determine an integrated clinic, smartphone/online and home protocol that is cost effective, unobtrusive and maximizes participant retention. No treatment intervention is part of this study, as the aim is to test the scalability of measurements that track behavior over time.
Methods: 16 children and adolescents with ASD (5-17 years of age), with at least 2-3 word phrases, completed a 1-week protocol. Data collection is ongoing in 20 children and adolescents in an 8-week protocol measuring behavior in both the clinic and the home. In both settings, electrodermal activity (EDA) data were collected via wrist sensors (Q sensors) and natural language data were recorded via LENA digital language processors. Caregivers completed momentary questions about their child's behavior on a smartphone.
Results: All families completed the protocol, including answering daily smartphone questionnaires and using the LENA devices and Q sensors in their home. As we predicted, there is substantial variation across children in behavior across contexts in amount of language produced and occurrence of problem behaviors. Novel voice detection procedures correctly identified the child's voice at approximately 90% accuracy as well as affective vocalizations (laughing), providing an automated alternative for time intensive transcriptions and replacing current LENA supported algorithms not suited for children above 5 years of age. As predicted, EDA data from the clinic visit demonstrates increased physiological arousal during mildly frustrating tasks in 63% of the participants. Home EDA data are considerably more variable and changes in EDA do not consistently correspond to increased screaming detected from the LENA recordings, confirming established findings that EDA is complicated to interpret without additional contextual information. Parent momentary reporting demonstrates some consistency with standardized questionnaires (negative mood PANAS) and events identified on the LENA, but are also variable across time and parents.
Conclusions: Caregivers of children and adolescents with autism are motivated to use novel technologies in a daily home and clinic protocol to measure their child's behavior. Children's behavior does vary across contexts and there is variability in parental styles in reporting their child's behavior. The research provides an important foundation to inform future outcome protocols that measure caregiver-reported, behavioral, and physiological changes in children undergoing medical and behavioral interventions.

102 **145.102** Improving Impressions of Social Competence: Results from an RCT of the START Social Skills Program for Adolescents with ASD

J. Ko, *A. Miller, S. Solomon and T. Vernon, University of California, Santa Barbara, Santa Barbara, CA*

Background: There has been a growing interest in targeting the social vulnerabilities of adolescents with ASD. Outcomes of these efforts have primarily consisted of a variety of parent and self-report measures (Miller, Vernon, Wu, & Russo, 2014). These measures, while serving as useful indicators of improvement, have notable limitations related to social desirability and other reporting biases (McMahon et al., 2013; Moskowitz, 2006). There is a need to determine if purported social improvements endorsed on parent and self-rating scales are also reflected in impression ratings of social competence made by one's peers. Blind peer ratings of social competence (made after watching conversation probes of each participant) present a novel method for understanding if everyday observers are able to discern noticeable improvements in social aptitude.
Objectives: The current study measures social skills improvement using social impression ratings following participation in a randomized controlled trial (RCT) of a social intervention for adolescents with ASD.
Methods: Participants consisted of 35 adolescents with ASD (ages 12-17; 31% female) who were enrolled in an RCT of the Social Tools And Rules for Teens (START) program. Adolescents were randomized to either a treatment group or a waitlist control group. The treatment group completed the 20-week curriculum; each 2-hour session consisted of an individual therapeutic check-in, unstructured socialization with typically developing high school and undergraduate facilitators, structured social activity, discussion of a weekly social topic, and a check-out session with the parents. Two 5-minute video conversations with two unfamiliar similar-aged students (one male and one female who were unaffiliated with the study) were recorded in naturalistic settings at both intake and 20-week time points. Undergraduates unfamiliar with the aims of the project or the disability status of the individuals (total n=131) were recruited to watch these videos and provide social ratings along numerous dimensions, including social skills, comfort, awkwardness, perceived quality of existing relationships. The same undergraduate completed a rating for a given participant at both intake and 20-week time points. Videos were counterbalanced among raters, so a rater was not always viewing videos in the same order. Every participant video was rated five times by different raters to ensure consistency of ratings.
Results: A series of dependent t-tests were performed for both the treatment and waitlist control groups. Pre- and post-intervention ratings demonstrated meaningful change in the treatment group (p=.001), but no significant improvement was noted in the control group. While participants varied in their total change scores over the course of their START program enrollment, 97% of the immediate treatment participants experienced improvement in overall ratings from their pre-intervention to post-intervention (20-week) time point.
Conclusions: Overall, observer ratings of social impressions provide favorable evidence regarding the social validity and significance of the START program. This method offers a real world indication of improved social competence that is not adequately captured by survey measures alone. The START model appears to positively impact the use of pivotal conversation strategies, which in turn creates more favorable social impression ratings among one's peers.

103 **145.103** Kids Love Musicals!: Social and Emotional Learning Outcomes in Special Education Environments

O. Zyga[1], *H. Meeker*[2], *J. Kirk*[2] *and S. W. Russ*[1], *(1)Psychological Sciences, Case Western Reserve University, CLEVELAND, OH, (2)The Musical Theater Project, Cleveland, OH*

Background: Children with autism spectrum disorders (ASD) show deficits in ability to process and express appropriate emotions and interact in social situations. Previous research has shown that the use of theater and music in the context of therapy have been beneficial in producing gains in socio-emotional functioning for individuals with ASD (Corbett et al., 2015). In the present study, the researchers examined the effects of the *Kids Love Musicals!* (KLM) residency program on children who either had a diagnosis of ASD or some type of learning or developmental disorder. The KLM program employs musical theater as a way to teach children skills relating to expressing emotions, engaging in cooperative learning, and imagination development through performing the "Wizard of OZ." Within this study, students engaged in a 4-week intervention, delivered once a week for 30 minute sessions.
Objectives: The main aim of this study was to provide empirical support for the KLM musical theater program. The authors wanted to better understand if students were able to make gains in socio-emotional skill development during the program. A secondary aim of the project was to understand if the intervention program could be tailored to various ages and ability levels.
Methods: The KLM residency program was delivered to 5 schools across the greater Cleveland area to children ranging from 1^{st}-12^{th} grade. The intervention sessions were video recorded and student's ability on variables of Eye Contact, Turn Taking, Sharing & Cooperative Learning, Engagement, Social Awareness & Self-Confidence, Symbolic Flexibility, and Emotional Understanding were coded by trained research assistants and interrater reliability was establish. Each variable was assigned a score on a likert scale based on a coding scheme adapted from previous research. Qualitative notes were also taken of student functioning. In total, 52 students were coded for the variables listed above. All students had previous diagnoses of either ASD or other developmental or learning disorders or delays.
Results: Results showed that across all schools and ability levels, students made gains in Eye Contact ($p < .001$, $t = -4.156$), Turn taking & Cooperative Learning ($p < .001$, $t = -5.020$), Engagement ($p < .001$, $t = -5.054$), Social Awareness & Self-Confidence ($p = .003$, $t = -3.188$), Symbolic Flexibility ($p = .001$, $t = -3.609$), and Emotional Understanding ($p = .009$, $t = -2.710$) from session one to the end of the residency program. Further analysis also showed a significant main effect of school setting on variables of Turn taking & Cooperative learning, Social Awareness & Self-Confidence, and Emotional understanding, suggesting that ability level may play a role in gains possible during the intervention.
Conclusions: Overall, these findings suggest that engagement in a musical theater program does support the building of socio-emotional skills in children with ASD and other developmental disorders. Next steps include independent pre and post-assessments of measures of interest and delayed follow-up to understand the stability of these gains and their generalizability outside of the musical theater intervention.

104 **145.104** Let's Move Your Body! Physical Activity to Treat Anxiety in Adults with Autism Spectrum Disorders

N. Brondino[1], *L. Fusar-Poli*[1], *E. Codrons*[2], *L. Correale*[2], *C. Panisi*[1], *P. Politi*[1] *and M. Vandoni*[2], *(1)Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, (2)Laboratory of Adapted Motor Activity, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy*

Background: Anxiety is a common comorbidity in autism spectrum disorders (ASD). Particularly, during adolescence and adulthood, people with ASD may experience a worsening in anxiety symptoms as a result of entering more complex social situations and of becoming more aware of their interpersonal difficulties. To date, pharmacological treatments (such as antidepressants) have showed preliminary efficacy, but data are still sparse and medications can be burdened by side effects. On the other hand, cognitive-behavioral therapy seems promising, but, presently, there are no empirically supported treatments for anxiety in ASD. It is well-known that physical activity is associated with a wide range of health benefits. In particular, aerobic exercise seems to exert an anxiolytic effect on healthy controls as well as on patients with generalized anxiety disorder or panic disorder.
Objectives: the present randomized study aimed to evaluate the effect of physical activity on anxiety levels in a sample of adults with ASD
Methods: Our study planned to recruit 20 participants who were randomly assigned to treatment or waiting list. Treatment consisted in one and a half hour per week of aerobic physical workout. Exercise sessions lasted for three months and subjects were required to attend at least 10 sessions. Heart rate and activity counts have been recorded during treatment sessions. Anxiety was evaluated using self-report questionnaires (i.e. Zung Self-Rating Anxiety Scale) as well as clinician-rated instruments (i.e. Hamilton Anxiety Scale). Additionally, cortisol diurnal variation was measured before and after treatment.
Results: all patients in the treatment arm experienced improvement in symptoms and there was a significant decrease in self-report anxiety ($p<0.05$).
Conclusions: physical activity may represent an alternative effective treatment for anxiety in this patient group.

105 **145.105** Measuring the Generalization of Skills in Response to Treatment in Minimally Verbal Children with ASD

R. Grzadzinski[1], *C. Dick*[2], *N. Hong*[3] *and C. Lord*[4], *(1)Center for Autism and the Developing Brain, New York, NY, (2)Center for Autism and the Developing Brain, White Plains, NY, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (4)Weill Cornell Medical College, White Plains, NY*

Background: Measuring the generalization of skill acquisition and treatment response is crucial for the maintenance of learned behavior. For children with Autism Spectrum Disorder (ASD), generalizing specific skills across contexts can be particularly challenging (Klinger & Dawson, 2001). Given this challenge, researchers and clinicians often rely on a clinical judgment of improvement because there are few standard measures that capture changes seen outside of the intervention setting. Using the Brief Observation of Social Communication Change (BOSCC) may be one way to assess generalization of skills acquired during the clinician-child interactions to a broader context, such as parent-child interactions.
Objectives: This study aims to explore the relationship between clinicians' ratings of behavioral improvements observed during treatment of a child with ASD and blind raters' observations of behavioral improvements during play sessions with a parent. The BOSCC, a novel, objective measure, is used to assess whether children with ASD are generalizing improvements made in intervention to interactions with a parent.
Methods: Data from 150 families participating in adaptive interventions for minimally verbal children with ASD will be presented. Children have a diagnosis of ASD, are between 4.5 and 8.5 years old, and used fewer than 20 spontaneous words during a 20-minute naturalistic language sample. The BOSCC is applied to 10-minute parent-child semi-structured play videos gathered across three time points (baseline, mid-intervention, post-intervention). The BOSCC is then coded by researchers blind to video time point and intervention status. Decreases in BOSCC scores, indicating symptom improvement, from baseline to mid-intervention and from mid- to post-intervention are compared in responders and non-responders defined by Clinical Global Impression ratings of Improvement (CGI-I) from the same time points. Analyses compare children who are able to generalize to other contexts (defined by decreases of >1 SD on the BOSCC) to the remaining children. Analyses also explore whether cognitive level, adaptive skills or ASD symptoms as measured by the Vineland Adaptive Behavior Scales (VABS) and the Autism Diagnostic Observation Schedule (ADOS) predict decreases on the BOSCC.
Results: Analyses of a subset of data show that approximately 60% of children are defined by CGI-I as responders to treatment and 25% decrease >1 SD on the BOSCC.

These results suggest that although children are able to make improvements within the context of treatment with an individual interventionist, these changes may not be seen in other contexts, such as interactions with parents. No significant differences in cognitive level, VABS domains, or ADOS symptom severity were found between children who were defined as responders on the CGI-I and children who decrease >1 SD on the BOSCC. Additional analyses within a larger dataset will aid in elucidating these results. Conclusions: It is important for researchers to recognize the potential limitations of specific skill acquisition seen in singular research contexts. This may be particularly relevant for minimally verbal children with ASD. Consistent with other work, our findings suggest that generalization is a particular challenge for children with ASD and needs to remain a focus of intervention research.

106 **145.106** Neural Validation of Sensory Subtypes in Autism Spectrum Disorder

ABSTRACT WITHDRAWN

Background:
Distinct sensory subtypes in ASD have been identified (Ausderau et al, 2014; Lane et al, 2014). Sensory subtypes have been posited as a means of identifying clinically meaningful subgroups within ASD. In one subtype model, two dimensions of sensory function have been proposed to underlie sensory subtypes – sensory reactivity and multisensory integration (MSI; Lane et al, 2014). This model is based on parent-report of sensory symptoms. Further elucidation and validation of dimensions underlying sensory subtypes in ASD is needed using neural and behavioural measures. In doing so, hypotheses relating to the mechanisms of sensory disturbance in ASD will be further refined and a new framework for the application of customised therapies will be developed.
Objectives:
In this paper, findings from preliminary studies will be discussed to address the question: do children with ASD classified using Lane et al's sensory subtype model differ in their neural response profiles to sensory paradigms assessing sensory reactivity and multisensory integration?
Methods:
Findings from four preliminary studies investigating the neural correlates of Lane et al's sensory subtype model will be summarised. The studies include the following: 2 x event-related potential studies assessing brain activation response to an auditory oddball paradigm (total ASD n=60), 1 x event-related potential study assessing steady state EEG response to an auditory-tactile multisensory integration paradigm (ASD n=10), and 1 x cardiac study assessing heart rate variability in response to a novel sensory challenge protocol (n=42). All studies included children with ASD aged between 3-15 years. ASD participants were classified initially using Lane et al's sensory subtype model based on parent ratings of sensory function on the Short Sensory Profile (McIntosh et al, 1999). This model classifies children into one of four sensory subtypes: Reactive High/MSI Low, Reactive High/MSI High, Reactive Low/MSI High, Reactive Low/MSI Low. Analyses were then conducted to examine differences between groups on each of the neural measures and for each of the sensory paradigms.
Results:
Preliminary findings indicate that brain activation potentials of children with ASD classified as Reactive High display a sustained positive shift in later (post-400ms) processing of novel auditory stimuli. Children with ASD classified as Reactive Low display no differences in brain activation potentials in the later processing of novel and standard auditory stimuli. Further, children with ASD classified as Reactive High, show increased cardiac sympathetic activity (as measured by pre-ejection period) throughout a novel sensory challenge protocol. Data from the event-related potential study examining response to a MSI protocol is currently being collected.
Conclusions:
On balance, the findings of these preliminary studies provide support for the hypothesis that neural profiles in response to sensory protocols assessing sensory reactivity vary on the basis of sensory subtype classification. Further study is required to confirm these differences particularly in response to sensory protocols assessing MSI. Neural validation of the sensory subtype model in ASD provides an important link between the 'bench and the ball pit' by establishing a framework for both mechanism discovery and clinical practice.

107 **145.107** Occupational Therapy Using Sensory Integration to Improve Functional Skills in Children with Autism Spectrum Disorders – Results of a Randomized Trial

***R. Schaaf**, Thomas Jefferson University, Phildalphia, PA*

Background: Sensory features (hyper and hypo-reactivity to sensation and unusual sensory interests) are a common occurrence in children with Autism Spectrum Disorders (ASD) and are now included in the DSM5 as one manifestation of the 'restricted, repetitive patterns of behavior, interests, or activities' diagnostic criteria. Given the recognition of sensory difficulties as a key feature of the autism diagnosis, interventions that address these sensory features may be an important component of a comprehensive treatment program for ASD. Families indicate that sensory features are among the most debilitating symptoms limiting participation in daily activities for them and their children. Currently, interventions that target these sensory features are controversial and have been criticized due to lack of evidence. This session reports on a randomized control trial aimed at investigating an occupational therapy intervention that targets these sensory features and measures its outcomes.
Objectives: The objective of this session is to report on findings of a randomized trial of occupational therapy using sensory integration to improve adaptive behaviors and functional skills in children with ASD.
Methods: Thirty-two children with a confirmed diagnosis of ASD between the ages of 6-9, matched on mental age and autism severity were randomized to either occupational therapy intervention or usual care for 30 sessions over a 10 week period. The intervention followed a manualized protocol based on the principles of sensory integration that was tested in a previous feasibility study. A random selection of 15% of the sessions was tested for fidelity using a validated measure. Pre-post scores on Goal Attainment Scales (primary outcome measure) and the Pediatric Evaluation of Disabilities Inventory (PEDI - secondary outcome measure - Haley, et al, 2011) – a measure of the child's participation in activities of daily living and socialization were compared.
Results: Children in the intervention arm scored significantly higher on Goal Attainment Scales ($p = 0.003$, $d = 1.2$) and showed improvements in independence in self-care ($p= 0.008$ $d = 0.9$) and socialization ($p = 0.04$, $d = 0.7$) on the PEDI in comparison to the control group. Average fidelity rating was 82 on a scale of 100 indicating treatment adherence.
Conclusions: The study provides preliminary data that occupational therapy using sensory integration may be useful for children with ASD whose sensory features are impacting participation activities of daily living and socialization. The study shows rigor in its use of a manualized protocol, measurement of treatment fidelity, and matching of groups on IQ and severity of ASD. Groups were comparable at pre-treatment on a number of measures and at post treatment on "other services" utilized. This pilot work set the stage for a comparative effectiveness trial, funded by NIH, that will compare this intervention to behavioral intervention and further elucidate its potential effectiveness and utility.

108 **145.108** Omega 3 Fatty Acids and Children with Autism: Consumption and Supplementation in Community Settings

***S. L. Hyman**[1], B. L. Schmidt[2], A. Koehler[3], E. McDonnell[4], E. A. Macklin[5] and P. A. A. Stewart[6], (1)Pediatrics, University of Rochester School of Medicine, Rochester, NY, (2)University of Rochester, Spencerport, NY, (3)Medicine, University of Buffalo, Buffalo, NY, (4)Massachusetts General Hospital Biostatistics Center, Boston, MA, (5)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (6)Pediatrics, University of Rochester, Rochester, NY*

Background: Omega 3 fatty acids, eicosapentaenoic acid and docosahexaenoic acid (DHA+EPA), are commonly used nutritional supplements for children with autism spectrum disorders (ASD). It is unknown whether children with ASD who may be selective eaters meet their daily requirement for DHA+EPA from naturally occurring and/or fortified food sources, whether adequate or excessive amounts are provided through supplementation, or whether nutritional supplementation in community use reflects doses used in treatment trials examining symptoms including inattention and repetitive behaviors.
Objectives: To quantify reported intake of DHA+EPA from both diet and nutritional supplementation in a community sample of children with ASD and examine the demographic and behavioral characteristics of children who are/are not given DHA+EPA supplementation.
Methods: Autism Speaks Autism Treatment Network participants from 5 sites (n=286, 14% female) recorded 3 day diet records for food and supplements. Total intake was quantified using Nutrient Data for System © for EPA+ DHA and supplement manufacturer data. Analyses included T tests or Wilcoxon rank sum tests for continuous data and Fisher's exact tests for categorical data.
Results: Only 1 of the 286 participants (a nonsupplement user) met the daily requirement for DHA+EPA from diet alone. The major dietary sources of omega 3 intake in most children were eggs and chicken. Supplement users (n=43) were similar in age and IQ to nonsupplement users, but more likely to be female (p=0.029) with college educated mothers (p=0.02). The groups did not differ in DHA+EPA consumption from diet alone. Of supplement users, 7% met and 65% exceeded dietary requirements. Supplement users had lower scores on the Child Behavior Checklist for externalizing behaviors (mean 56.6 + 9.6 vs 60.6 + 11.2; p=0.038), on the Children's Sleep Habits Questionnaire (42.3 + 9 vs 45.4 + 9.3; p=0.028) and on the Repetitive Behavior Scale-Revised (26.2 + 17.3 vs 37.5 + 22.2; p<0.001). Doses used in clinical trials, greater than 1000 mg/d, were consumed by 28% of participants given supplements.
Conclusions: Children with ASD are deficit in their intake of Omega 3 Fatty acids from diet alone. Supplementation in the community is typically at a lower dose than the doses evaluated in clinical trials. This unadjusted, cross sectional data cannot determine whether the association of increased DHA+EPA intake with less externalizing behavior, better sleep scores and less repetitive behaviors is related to supplementation or whether children with lower scores are more likely to receive supplements. Future clinical trials might evaluate the impact of a range of doses.

109 **145.109** On Target for Life: An Executive Function Intervention for Adolescents with Autism Spectrum Disorders

S. Seese[1], *K. M. Dudley*[2], *L. Kenworthy*[3], *L. G. Anthony*[4], *M. A. Werner*[5], *L. Cannon*[5], *L. Mohamed*[6], *C. E. Pugliese*[4] *and J. F. Strang*[7], *(1)Center for Autism Spectrum Disorders, Children's National Medical Center, Rockville, MD, (2)Children's National Medical Center, Center for Autism Spectrum Disorders, Ellicott City, MD, (3)Children's Research Institute, Children's National Medical Center, Rockville, MD, (4)Children's National Medical Center, Rockville, MD, (5)Ivymount School, Rockville, MD, (6)Yale Child Study Center, New Haven, CT, (7)Children's National Medical Center, Silver Spring, MD*

Background:
Executive function (EF) skills are critical for young people as they progress through school. Students with ASD fall further behind their peers in EF skills as they enter middle school. Unstuck and On Target, an elementary school-based cognitive behavioral intervention, has been shown to improve EF skills, behavior and social skills in elementary school students. On Target for Life is an upward age extension of UOT, adapted to address the specific needs of adolescents in middle school. OTL was developed through a participatory process framework targeting EF skills in teens with ASD without intellectual disability. OTL uses scripts, engaging visuals, and in vivo experiments and games in order to apply and generalize EF skills to real world scenarios in the lives of teens with ASD.
Objectives:
1) Evaluate the change in executive functioning skills in adolescents before and after participation in On Target for Life.
Methods:
17 adolescents received the On Target for Life intervention delivered by school staff over the course of 22 sessions. OTL focuses on teaching adolescents how to set goals, be flexible, and learn how to plan and get what they want/need. Our pilot test of the study compared changes from pre-to-post intervention. Data was collected through standardized and experimental child measures. Observations from previous studies of UOT have indicated that with increased flexibility skills, children are more efficient at problem solving. As a measure of efficiency and problem solving, we calculated average problem-solving time on a visual problem solving task (Wechsler Block Design) items pre-to-post intervention. The Challenge Task (CT), an in-vivo observational method, challenges adolescents to be flexible and make organized plans. The CT yields scores on planning and flexibility. The DKEFS Verbal Fluency measure provides a standardized difference score between category and switching fluency, measuring the "cost" in efficiency that demands for flexibility/switching.
Results:
Adolescents who completed the On Target for Life intervention demonstrated significant improvement (faster time) solving Block Design items from pre to post intervention ($t(16)=2.71$, $p=.016$). Total Block Design t-scores did not improve, $t(16)=-.33$, $p=.744$. Students showed improved flexibility skills ($t(16)=3.49$, $p=.003$) and planning skills ($t(16)=4.89$, $p=.001$) on the Challenge Task from pre to post intervention. Scores on the DKEFS switch cost measure did not show improvement, $t(16)=-.71$, $p=.490$.
Conclusions:
These results suggest that most adolescents show some improvement after participation in On Target for Life. However, these results should be interpreted cautiously, as the current study represents only a small number of adolescents without a comparison group. A larger randomized controlled trial (N=36) of adolescents with ASD in main stream schools is currently underway to further evaluate the effectiveness of this intervention. This RCT also includes a companion parent manual and training program to be used in conjunction with the school-based intervention.

110 **145.110** Parent and Child Characteristics of Families Participating in Parent-Mediated Social Skills Interventions for Autism

R. Shalev[1], *M. L. Gordillo*[1], *K. Sullivan*[1], *B. Chen*[1], *R. Doggett*[1], *E. A. Laugeson*[2], *S. Kuriakose*[1] *and A. Di Martino*[1], *(1)Department of Child and Adolescent Psychiatry, The Child Study Center at NYU Langone Medical Center, New York, NY, (2)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background: A growing literature indicates that parent-mediated social skills interventions, such as *Children's Friendship Training* (CFT; Frankel & Myatt, 2003) and the *Program for the Education and Enrichment of Relational Skills* (PEERS®; Laugeson & Frankel, 2010) increase social competence and friendships among children with Autism Spectrum Disorder (ASD). In CFT and PEERS®, parents are trained to become active agents who provide social coaching to their children during and after treatment. Despite their central role in these interventions, parents' direct impact on their children's treatment outcomes remains unclear. Currently, at the NYU Child Study Center, we are conducting a pilot study on outcomes for children who complete CFT and PEERS® that involves measuring parent and child characteristics before and after intervention.
Objectives: In preparation for future investigations of treatment outcome, the current study examined baseline measures of parents' functioning and their relationships with baseline measures of their children.
Methods: To date, we have enrolled 11 children with ASD (8 males; 7-14 year-old; $M=11.9\pm2.3$) and 11 parents (one per child; 8 mothers, 41-55 year-old; $M=49.2\pm4.7$) undergoing CFT or PEERS®. Parents completed the Social Responsiveness Scale, Second Edition Parent Report (SRS-2-P) and the Child Behavior Checklist (CBCL), which were used to index children's autism severity and their internalizing and externalizing symptoms of psychopathology. Parents' autistic traits were assessed using the SRS-2 Adult Form (SRS-2-A), completed by their spouses. Each parent completed the Positive Affect Index (PAI), which assesses the quality of the parent-child relationship. Bivariate correlational analyses measured the relationships between the above parent and child measures.
Results: Parents did not show clinically significant elevations in autistic traits, as indicated by SRS-2-A Total T-scores (range: 38 – 59, $M=48.7\pm8.5$). Total scores on the PAI varied (range: 30 – 57, M 43.1±8.8). Notably, both measures indicated a wide range of functioning. Parents' scores on the SRS-2-A were positively correlated with their children's scores on the SRS-2-P ($r=.83$, $p=.04$). High relationship quality measured by the PAI was negatively correlated with scores of the Total Externalizing Problems scale ($r=-.85$, $p=.008$) and related subscales (e.g., Rule-Breaking Behavior; $r=-.85$, $p=.007$) on the CBCL. There was not a significant relationship between PAI and SRS-2-P scores.
Conclusions: The association between parents' and children's autistic traits indicates that the poorer children's social skills, the lower those in parents. In addition, higher quality relationships between parents and children were associated with fewer externalizing behavioral challenges in children. Given the centrality of parent-child interactions in CFT and PEERS®, it is important to understand whether parent characteristics or parent-child relationship quality affects treatment outcomes for children who participate in parent-mediated interventions. In future investigations, we will seek to clarify these relationships and to determine whether they serve as mechanisms of therapeutic change.

111 **145.111** Performance-Based Social Skills Intervention Improves Explicit Social Cognition in Children with Autism Spectrum Disorder

E. Kang*, A. Burns, L. Allegue and M. D. Lerner, Stony Brook University, Stony Brook, NY*

Background:
Individuals with autism spectrum disorder (ASD) exhibit deficits in theory of mind (ToM; Frith & Frith, 2003), emotion recognition (Lozier *et al.,* 2014), and social knowledge (Attwood, 2007), all of which are social cognition processes fundamental to social interactions (Kennedy & Adolphs, 2012). These involve explicit understanding of the correct information about a social situation and overt indication of such understanding is required for applying these skills to everyday life. Therefore, most social skills interventions (SSI) for ASD utilize didactic approach to directly and explicitly teach these target skills (e.g., Goldstein & McGinnis, 1997; Laugeson et al., 2009). These SSI have shown positive yet limited effects in social cognitive skills (White et al., 2007).
There is a growing empirical support for performance-based approaches in SSI that provide enriched, *in vivo* social learning and practice opportunities *without* explicit instruction (Lerner et al., 2011; Lerner & White, 2015). It is unknown, however, which (if any) explicit social cognitive processes may be affected directly by these interventions – that is, can explicit social understanding be learned via non-didactic, performance-based approaches?
Objectives:
This study examined the impact of a non-didactic SSI on social cognition processes not explicitly taught. We hypothesized that participating in a performance-based intervention would yield improvements in ToM, emotion recognition, and social knowledge.
Methods:
Children with ASD ($N=13$; $M_{age}=13.25$, $SD_{age}=2.14$) participated in a 6-week social performance-based summer intervention program. They completed measures of explicit social knowledge (Maedgen & Carlson, 2000) and facial emotion identification (Nowicki, 2004). Their parent completed a measure of explicit ToM (Hutchins, Prelock, & Bonazinga, 2012), assessing early, basic, advanced, and total ToM.
Results:
Bivariate correlations revealed negative association between early ToM and deficits in social knowledge, driven by the subscale indicating a tendency to believe passive responses to social situations as correct, and positive association between the subscale indicating a tendency to believe aggressive responses to social situations as correct and errors in emotion recognition (Table 1). Paired samples *t*-tests between pretest and posttest scores evinced improvement in total ToM ($t=2.920$, $p=.014$), which was driven by gains in advanced ToM ($t=2.695$, $p=.021$); improvement in explicit social knowledge regarding assertive behavior ($t=-2.185$, $p=.051$); and improvement in emotion recognition ($t=-2.462$, $p=.015$), which was driven by subtler faces ($t=-3.154$, $p<.001$).
Conclusions:
As measured by parent-reported, self-reported, and behavioral indexes, we found relations among social knowledge, ToM, and facial emotion recognition in children with ASD. More importantly, we found that participating in an SSI that does *not* teach via didactic instruction led to improvements in ToM, identification of emotion in faces, and

explicit social knowledge. Our results suggest that even with minimal didactic instruction or instrumental reinforcement of target skills (e.g., explicit training and feedback on face-emotion recognition or ToM activities), these social cognitive skills can be *implicitly* and *experientially* acquired in children with ASD via engaging in targeted activities. This provides additional support for intact implicit learning in ASD (Foti et al., 2014), and for social performance-based approaches to SSI that provide an enriched environment for children with ASD.

Table 1
Correlations among baseline scores of social knowledge, theory of mind, and emotion recognition

		CABS			ToMI				DANVA Faces
		Total			Total				Total Errors
			Aggressive	Passive		Early	Basic	Advanced	
CABS	Total	1	.46	.83**	-.37	-.57*	-.14	-.38	.17
	Aggressive		1	-.11	.13	.12	.17	.07	.67**
	Passive			1	-.49	-72**	-.26	-.48	-.23
ToMI	Total				1	.69**	.89**	.96**	.23
	Early					1	.45	.61*	.33
	Basic						1	.75**	.16
	Advanced							1	.20
DANVA Faces	Total Errors								1

*$p < .05$. **$p < .01$. CABS = modified Children's Assertiveness Behavior Scale, assessing social knowledge. ToMI = Theory of Mind Inventory, assessing theory of mind. DANVA = Diagnostic Analysis of Nonverbal Accuracy-2, assessing errors in reading nonverbal emotion cues in faces.

Notes. CABS and DANVA have negative direction of scale (higher scores mean greater deficits). ToMI has positive direction of scale (higher scores mean greater ability).

112 **145.112** Pivotal Response Treatment: An Examination of Educators' Maintenance and Generalization of Fidelity of Implementation

J. K. Randolph[1], *J. P. Stichter*[2] *and C. Schmidt*[3], *(1)Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (2)Department of Special Education, University of Missouri, Columbia, MO, (3)School of Human Services, University of Cincinnati, Cincinnati, OH*

Background: Pivotal Response Treatment (PRT) is an evidenced-based practice of naturalistic behavioral principles. The increase in social communication and engagement behaviors of children with autism as a result of the intervention is well documented. Most research demonstrates the benefits of PRT as a parent-based intervention, with emergent support for the use of PRT as a school-based intervention. Little is understood about the maintenance and generalization of PRT fidelity.
Objectives: This presentation will review data from a concurrent multiple-baseline design across four educator-student dyads on educators' fidelity of implementation and students' social-communication and engagement across educational contexts once initial fidelity of implementation has been achieved.
Methods: A concurrent multiple-baseline design across four educator-student dyads was employed in order to examine educators' maintenance and generalization of PRT across educational contexts and the subsequent impact on students' social-communication and engagement. Initial training on PRT occurred with each dyad separately over 12, thirty-minute sessions and consisted of modeling, coached practice, and performance feedback during play-based interactions (considered the primary training context). Then, during the two-month follow-up phase the educators' rates of fidelity were probed weekly to determine if they were maintaining adequate treatment fidelity and generalizing the use of PRT to untrained secondary and tertiary educational contexts.
Results: Visual inspection of the data indicates that three of the four educators who were trained to implement PRT were able to maintain the fidelity of implementation in the primary context in which they were trained during the follow-up phase. All four of the educators increased their percentages of implementation of the core behaviors of PRT across contexts during follow-up when compared to their natural rates of these behaviors at baseline. Additionally, one of the four educators was able to consistently generalize PRT with fidelity to an untrained context. Overall, increases in the level of fidelity in which the educators implemented PRT appear to have had an impact on the increased mean rates of the students' social-communication and engagement behaviors. It should also be noted that students' social-communication and engagement behavioral increases were observed in the untrained secondary and tertiary contexts.
Conclusions: These data indicate the potential for some educators to maintain the use of PRT with fidelity without additional consultative support after training has ended, but the results also indicate a need to consider other potential variables to increase the likelihood of treatment maintenance by all educators. Discussion includes the need to better understand the long-term impact on students who are supported by educators using PRT across contexts with fidelity versus the initial positive benefit that is achieved when educators initially reach fidelity. The need for more research on educator characteristics that may predict the need for follow-up consultation to maintain and generalize treatment fidelity is also discussed.

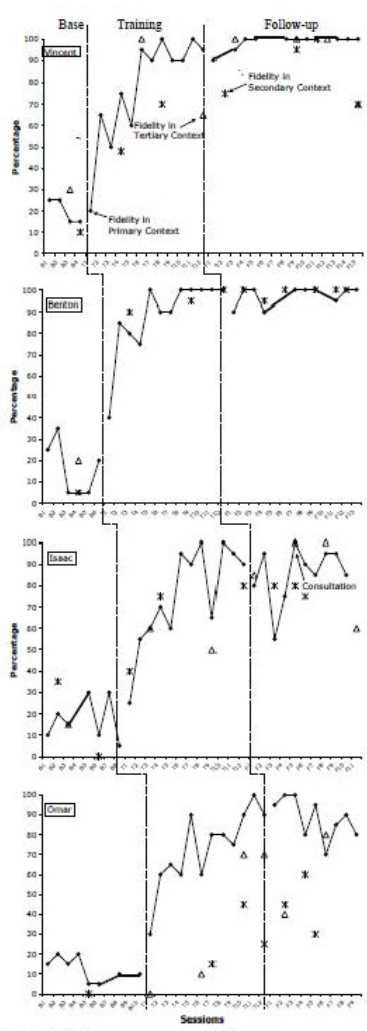

Figure 1. Practitioners' fidelity of PRT across contexts and phases.

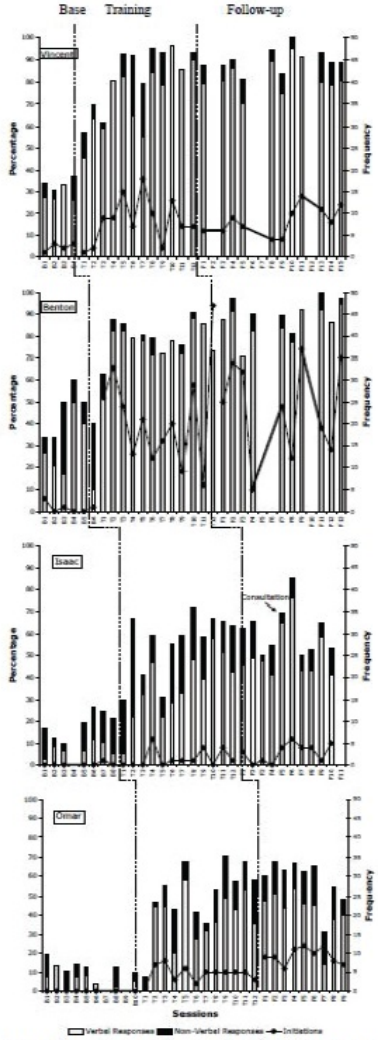

Figure 2. Students' percentages of responses and frequencies of initiations across phases.

113 **145.113** Preliminary Effectiveness of the Autism Life Care Model (ALCM) in Improving Comorbid Internalizing and Externalizing Symptoms in Adolescents with ASD

M. Murray[1], *A. Pearl*[2], *A. Heintzelman*[3], *A. Layton*[1] *and Z. Soulliard*[1], *(1)Penn State Hershey, Hershey, PA, (2)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hummesltown, PA, (3)Penn State College of Medicine, Hershey, PA*

Background: Successful transitions for individuals with ASD to adulthood are critically dependent upon the collaboration across care networks, as well as the inclusion of the individual in decision making. This has been difficult to accomplish for adolescents with ASD who have been poorly served through isolated treatment silos leading to inefficient use of resources and confusion about treatment needs. A PA Statewide Needs Assessment found that close to half of all caregivers of adolescents reported an unmet need for transition services, as well as related unwanted outcomes (e.g., inpatient hospitalization) as they age. The existing system promotes disjointed and narrowly focused care which leads to poor outcomes for adults with ASD. Frustration about this lack of synchrony and patient-centeredness led to the development of the Autism Life Care Model (ALCM) which targets transition-aged youth with ASD. This model provides a consistent, frequent assessment of strengths and needs, patient-centeredness in the establishment and monitoring of treatment goals, as well as collaboration and reinforcement of interventions across disciplines and environments.
Objectives: This study sought to examine the effectiveness of the ALCM pilot program at six months following enrollment in the program. Given the short duration of follow-up, it was expected that individuals enrolled in the program would demonstrate improvements in co-morbid internalizing and externalizing symptoms as a result of increase coordination of care related to treatment goals.
Methods: Twenty-one families participated in the ALCM pilot along with one ALCM Coordinator. Sessions were conducted in an outpatient psychiatry clinic specializing in treating individuals with ASD. Out of the 21 clients (M = 15.90; SD = 2.90) enrolled in ALCM, eight individuals and their parents completed the Child Behavior Checklist (CBCL), the Youth Self Report (YSR), and the Intolerance of Uncertainty Scale(IUS)/Intolerance of Uncertainty Scale for Children (IUSC) at an initial intake session, as well as at a six month follow-up session.
Results: Repeated-measures ANOVAs were completed to assess for significant changes in variables of interest. At the time of the follow-up, caregivers reported on average that their child's number of somatic complaints significantly decreased while their child's ODD problems and intolerance of uncertainty showed a trend toward significantly decreasing. At a six month follow-up session, the individuals with ASD reported a significant decrease in anxious/depressed symptoms, aggressive behavior, somatic problems, antisocial/conduct problems, internalizing problems, and externalizing problems. Additionally, the total amount of reported problems showed a trend toward significantly decreasing. The group means for the majority of these scales fell from the borderline clinically significant range to the normal range of symptomatology on the CBCL and YSR.
Conclusions: Results from the pilot of the ALCM program supported the hypotheses that following engagement in the program, individuals demonstrated decreased self- and caregiver-reported symptoms of comorbid internalizing and externalizing symptoms. Although further research needs to be done to rule-out alternative explanations for these results, the recorded improvements in behavior are promising in regards to the effectiveness of improved coordination of treatment efforts across individual's care networks.

114 **145.114** Preliminary Results of an Emotion Regulation RCT for Children with Autism Spectrum Disorder

J. A. Weiss[1], *P. Burnham Riosa*[1] *and C. S. Albaum*[2], *(1)York University, Toronto, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada*

Background:
Children with ASD frequently experience associated psychopathology, with approximately 70% meeting requirements for a psychiatric disorder (Leyfer et al., 2006). The heightened prevalence of these emotional problems may be linked to emotion regulation (ER) difficulties (Mazefsky et al., 2013). Cognitive behavior therapy (CBT) targeting ER has been found to be effective in children without ASD (Ehrenreich-May et al., 2013), but there is limited evidence of its efficacy for children with ASD.
Objectives:
To evaluate the efficacy of the *Secret Agent Society: Operation Regulation* (SAS:OR, Beaumont, 2013), a multi-component CBT program targeting ER difficulties in children with ASD.
Methods:
Thirty-three children with a confirmed ASD diagnosis (93.9% male) and their parents (78.8% female) participated in the program. Children were 8 to 12 years of age (M = 9.50, SD = 1.13) with at least average IQ (M = 103.19, SD = 14.18, Range: 79-140). Parents, children, and clinicians completed measures of child ER (*Emotion Regulation Checklist*, Shields & Cicchetti, 1997; *Emotion Regulation and Social Skills Questionnaire*, ERSSQ-P; Beaumont & Sofronoff, 2008;*Children's Emotion Management Scale,*

Zeman et al., 2010) and psychopathology (*Behavior Assessment System for Children, 2nd Edition*, BASC-2, Reynolds & Kamphaus, 2004; *Anxiety Disorders Interview Schedule: Parent Interview*; Silverman & Albano, 1996; *Clinical Global Impressions Scale*, Guy 1976) at pre-intervention (baseline), and post-intervention. Following baseline assessment, children were randomly assigned to either a treatment immediately (TI; $n = 16$) or waitlist control condition (WLC; $n = 17$). Groups were not significantly different on child age, gender, IQ, or ASD symptom severity at baseline ($p > .10$).

Results:

Using analysis of covariance to control for pre-intervention levels, parents of children in the TI condition reported significantly lower child negative affect compared to children in the WLC condition post-intervention ($p = .006$). After controlling for baseline levels, additional group main effects were found post-intervention in parent-reported child internalizing symptoms on the BASC-2 ($p = .04$) and socially-mediated emotion regulation on the ERSSQ-P ($p = .001$). Children in the TI condition self-reported greater overall emotion inhibition than children in the WLC condition at post-intervention ($p = .02$). An independent clinician blind to group allocation rated children on an overall improvement in clinical severity, and rated children in the TI condition to have significantly more improvement than those in the WLC condition ($p = .003$). Post intervention group main effects were also observed with regard to the number of psychiatric diagnoses ($p = .014$) and severity of clinical impairment ($p = .028$).

Conclusions:

Preliminary results of this RCT support the efficacy of SAS:OR in improving child psychopathology and ER outcomes according to parent, child, and clinician reports.

115 **145.115** Randomized Controlled Trial of a Technology-Based Intervention to Enhance Academic Organization and Planning in College Students with ASD and ADHD

T. Oswald[1], *A. M. Iosif*[2], *J. D. Hori*[3], *J. Wilson*[4] *and P. C. Mundy*[5], *(1)2825 50th Street, University of California at Davis MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Student Disability Center, University of California, Davis, Davis, CA, (4)Student Disability Center, UC Davis, Davis, CA, (5)Education and Psychiatry, University of California at Davis, Sacramento, CA*

Background:

Adults with autism spectrum disorder (ASD) and/or attention deficit hyperactivity disorder (ADHD) are less likely to attend or graduate from college than peers with other disabilities or typical development (Shattuck et al., 2012, Dvorsky & Langberg, 2014). Simonoff et al. (2008) found that ADHD was the second most common comorbid disorder in individuals diagnosed with ASD. Further, ADHD symptoms have been found to negatively correlate with study habits and academic adjustment in the college population (Norwalk et al., 2008), suggesting that ADHD symptoms (e.g., monitoring, organization, planning, prioritizing) may contribute to poor academic outcomes in college students with ASD and ADHD.

Objectives:

To examine the novel application of tablet technology, using an academic e-planner app, to help college students with ASD and/or ADHD monitor their assignment and exam due dates, prioritize and plan time for homework, and stay academically organized. The study included an active control group, which used an app that monitored daily water consumption rather than academics, to control for general tablet use and motivation.

Methods:

Participants consisted of 38 undergraduate college students, 28 with ADHD (19 male; 9 female) and 10 with ASD (7 male; 3 female) ranging in age from 18-50 years (M=23.90, SD=6.56). Participants were eligible for the study if they had provided medical documentation of their ASD and/or ADHD diagnosis to the UC Davis Student Disability Center (SDC) and were currently receiving academic accommodations through the SDC. All participants were loaned an iPad tablet for a term and, using stratified randomization based on diagnosis and gender, were assigned either the academic e-planner app or the hydration tracker app. Thirty-eight were randomized and 6 were lost to follow-up (2 with ASD; 1 in treatment and 1 in control), so 32 were included in the primary analyses. The primary outcomes were the subscales (Academic Organization/Monitoring and Hydration Monitoring) of a 15-item instrument developed by the research team.

Results:

For the Organization scale, the improvement at follow-up from baseline was significantly higher (p-value = .04) in the treatment group (follow-up vs. baseline difference = 0.43, 95% CI -0.06 to 0.92) than in the control group (follow-up vs. baseline difference = -0.20, 95% CI -0.60 to 0.20). There were no significant treatment vs. control differences in improvement at follow-up in Hydration Monitoring (p-value ≥ .15), although, as expected, the control group tended to have better improvement in Hydration (follow-up vs. baseline difference = 0.52, 95% CI 0.21 to 0.83) than the treatment group (follow-up vs. baseline difference = 0.14, 95% CI -0.32 to 0.61). The size of the ASD group was too small to allow formal subgroup comparisons, but 3 of the 4 ASD participants in the treatment group showed improvement in Organization that was consistent with the overall treatment group.

Conclusions:

Our study provides evidence that specifically using an app to monitor academics enables students to manage their school workload better. Future research should assess the effectiveness of an academic e-planner app in a broader college community of students with ASD and/or ADHD.

116 **145.116** Reducing Behavior Problems Among Students with Autism Spectrum Disorder: Coaching Teachers in a Mixed-Reality Setting

E. Pas[1], *S. R. Johnson*[1], *K. E. Larson*[1], *L. A. Brandenburg*[2,3], *R. Church*[4] *and C. Bradshaw*[5], *(1)Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD, (2)Special Education, Kennedy Krieger Institute, Baltimore, MD, (3)School of Education, Johns Hopkins University, Baltimore, MD, (4)Kennedy Krieger Institute, Baltimore, MD, (5)University of Virginia, Curry School of Education, Charlottesville, VA*

Background: The growing number of children diagnosed with an Autism Spectrum Disorder (ASD) indicates that school personnel need to be equipped with the appropriate skills to address the far-reaching needs of these students. Children with moderate to severe ASD are at risk for exhibiting behavior problems including aggression and self-injurious behaviors, which can interfere with learning and impact student safety (Munson et al., 2008; Sullivan & Bradshaw, 2012). These behavior problems prove to be challenging for teachers to manage; yet, relatively few teachers have training in the use of evidence-based interventions for educating students while addressing behavior problems in the classroom (Scheuermann et al., 2003; Shyman, 2012).

Objectives: This study aims to fill these gaps, by exploring the extent to which a teacher-tailored coaching approach that utilizes a state-of-the-art mixed-reality simulator was associated with increased teacher capacity to address the diverse behavioral needs of students with ASD. Targeting the practices of teachers serving these students is consistent with the public health approach to prevention (O'Connell et al., 2009) and is likely an effective and cost-efficient way of addressing the complex needs of multiple children with ASD simultaneously.

Methods: Specifically, 19 teachers in two non-public special education settings serving students with ASD were provided with the intervention. Coaches provided data regarding the amount of time they specifically engaged in each coaching activity. Both teachers and coaches provided ratings regarding the acceptability of the intervention. Classroom observations were conducted by an external observer three times (baseline, post-test, and follow-up). The *Assessing School Settings: Interactions of Students and Teachers*(ASSIST; Rusby et al., 2001) classroom observations were conducted by two research assistants. The ASSIST includes event-based tallies (i.e., counts of specific behaviors) for teacher use of classroom management strategies and student behavior. In addition, the observer provided responses to Likert-type items regarding teacher classroom management, student behavior, and the engagement of students in meaningful participation.

Results: A repeated measure MANOVA demonstrated a significant measure by time effect. Follow-up repeated measures ANOVAs revealed statistically significant improvements in teacher management over time, as well as some evidence of improvements in student behavior. Specifically, observers tallied increasing levels of teacher use of proactive behavioral expectations $F(2, 28) = 6.727$, $p = .004$ and use of approvals $F(2, 28) = 8.123$, $p = .002$. Decreases in student non-compliance were also tallied $F(2, 28) = 3.584$, $p = .041$. Observer ratings of the classroom environment, using Likert-type scales, also improved with regard to teacher proactive behavior management, $F(2, 28) = 6.921$, $p = .004$, teacher monitoring, $F(2, 28) = 14.096$, $p = .000$, teacher control, $F(2, 28) = 17.109$, $p = .000$, and teacher and student meaningful participation, $F(2, 28) = 9.814$, $p = .001$. There were also marginally significant improvement over time in student socially disruptive behaviors approached significance, $F(2, 28) = 3.188$, $p = .057$.

Conclusions: Implications for future research and the practice of teachers in special education settings serving students with an ASD are discussed.

117 **145.117** Social Skills Group Training in High-Functioning Autism Spectrum Disorder: A Pragmatic Multicenter RCT

N. Choque Olsson[1], *C. Coco*[1], *A. Rade*[2], *O. Flygare*[2], *Q. Chen*[2], *S. Berggren*[1], *K. Tammimies*[3] *and* ***S. Bolte***[4], *(1)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden, (3)Women's and Children Health, Center of Neurodevelopmental Disorders (KIND), Karolinska Institutet, Stockholm, Sweden, (4)CAP research center, Gavlegatan 22, Karolinska Institutet, Stockholm, Sweden*

Background: Despite the continuous need for evidence based interventions for individuals with higher functioning autism spectrum disorder (HFASD) few treatments have been comprehensively evaluated. Social skills group training (SSGT) is a widely applied method for school aged children and adolescents with HFASD. Reviews conclude that there is some evidence for the efficacy of SSGT, but that more rigorous research is needed to draw robust conclusions, and that more focus on external validity is required.

Objectives: This study sought to overcome several of the methodological shortcomings of previous randomized controlled trials of SSGT in HFASD, by examining the by far largest sample ever, using manual-based method, well-defined inclusion and exclusions criteria, psychometrically sound outcome measures, multiple informants including blinded raters, computerized randomization, monitoring of the standard care control treatment as well as personalized medicine and therapy genetics.

Methods: We conducted a pragmatic randomized controlled multicenter trial: Manualized SSGT "KONTAKT" (12 sessions) plus treatment as usual [TAU] versus waiting list TAU only at three points of assessment (baseline, post training, 3 months follow-up) in children and adolescents with HFASD. N=366 individuals aged 7 to 18 years were assessed for eligibility, of which 304 were randomized to SSGT treatment plus TAU (n=153) or TAU only (n=151). Participants have clinical ICD-10 diagnoses of ASD,

corroborated by ADOS, and IQ>70. They were trained at 14 regular health care units by 50 clinicians, in the majority certified in the manualized training. Parent and blind teacher report Social Responsiveness Scale ratings served as primary outcome measures.
Results: Preliminary analyses for parent SRS ratings show significant effects of SSGT "KONTAKT" on SRS social cognition scores at follow-up. Blind teacher SRS ratings show significant post treatment effects for social cognition and autistic mannerisms. Further analyses for age group yield that adolescents show significant symptom improvement for the SRS total score post training and at follow-up on the parent but not the teacher report form.
Conclusions: Findings indicate that SSGT "KONTAKT" (i) is feasible in naturalistic clinical settings, (ii) leads to various social communication symptoms improvements, (iii) and has higher effects in adolescents than in children. Furthermore, (iv) results indicate that parents report more improvements than teachers. Ongoing moderator analyses for sex, age, comorbidity, medication, severity, language, IQ and other variables, as well as genome-wide methods such as SNP microarrays and next generation sequencing will identify sets of predictors of individual SSGT response.

118 **145.118** Social Tools and Rules for Teens (The START Program): Results of a Randomized Controlled Trial of an Experiential/Didactic Socialization Program for Adolescents with ASD

***T. Vernon**, A. Miller, J. Ko, A. Barrett and E. McGarry, Koegel Autism Center, University of California Santa Barbara, Santa Barbara, CA*

Background: Experiential learning, or the process of learning through authentic experiences and subsequent reflection on those encounters, is an essential process in the development of core social competencies. There is a unique benefit to gaining exposure to the full range of dynamic variables associated with real-world social encounters, which cannot be replicated via secondhand accounts and instructional lessons. Unfortunately, adolescents with ASD often do not possess the prerequisite skillset and motivation to sustain the level of social immersion needed to benefit from this learning process. Additionally, these individuals may not have access to an accepting peer environment to facilitate acquisition of the very skills necessary to avoid future social rejection. Their persisting social vulnerabilities can limit their long-term relational success, warranting a need for comprehensive social programming. There may be significant benefit to a group socialization program that combines a safe experiential learning context (i.e. an environment that allows for social experimentation and skill development) with a didactic format that emphasizes traditional skill instruction.
Objectives: This RCT evaluated a multi-component socialization intervention to simultaneously target motivational, conceptual, and skill deficits using a hybrid experiential/didactic treatment approach. This investigation evaluated the impact of the 20-week START program on the social functioning of adolescents with ASD through the use of survey and conversational measures.
Methods: Thirty-six adolescent participants were randomized to immediate or delayed treatment conditions. The START socialization program consisted of 20 sessions offered once a week that placed equal emphasis on experiential social immersion and didactic social lessons. Participants engaged in individual therapeutic check-in sessions, free socialization periods, structured social activities, discussion of specific skills, and checkout sessions with parents. Program components included emphasis on creation of a club-like atmosphere, the inclusion of typically developing high school peer models, an individually identified target social skill for each participant (that was monitored, tracked, and updated every five weeks), use of self-management technology to discretely target these skills during the unstructured socialization time, skill depictions from popular television shows, and weekly social assignments. Participants in both groups were assessed at intake and after the 20-week duration of the program.
Results: Evidence of significant social competence improvements were observed exclusively in the immediate treatment group, including changes in Social Responsiveness Scale-2 (SRS-2) standard scores (pre=75.7, post=68.1, $p<0.05$), Social Skills Improvement System (SSIS) standard scores (pre=86.9, post=100.7; $p<0.05$) and Social Competence & Motivation Scale (SCMS) scores (pre=70.6, post=86.6; $p<0.001$). Notable improvements were also noted in coded live conversation probes recorded pre to post-treatment.
Conclusions: The results of this RCT suggest that there may be unique benefits to a socialization curriculum that offers both experiential and didactic training components within a single peer-facilitated intervention. These findings are an important step in identifying optimal strategies to simultaneously target the complex, intertwined factors that limit social progress in adolescents with ASD. Specifically, creating an experiential context may give adolescents the opportunity to finally become fully immersed and accepted by a peer group, which then becomes the ideal forum in which to practice and master critical social competencies.

119 **145.119** Special Education Autism Classification

***K. Sidwell**[1], D. Lincer[2], J. Solis[2], J. Shenouda[1] and W. W. Zahorodny[3], (1)Rutgers University, Newark, NJ, (2)Pediatrics, Rutgers University, Newark, NJ, (3)New Jersey Medical School, Westfield, NJ*

Background:
As increasing numbers of students are diagnosed with Autism Spectrum Disorder (ASD), schools are under greater pressure to provide appropriate special education services. Empirical evidence is needed to inform special education providers about the characteristics of students with ASD who are served under different eligibility classifications and to describe the placement and program characteristics associated with educational growth. Some recent studies suggest that severity of impairment due to ASD and intellectual capacity are associated with special education under the Autism classification. However, there is a paucity of information on this topic from recent studies in populous, diverse, regions.
Objectives: The purpose of this study is to describe the characteristics of ASD children associated with an Autism classification for special education services in metropolitan New Jersey.
Methods:
Study data were from the New Jersey Autism Study (NJAS), an ASD surveillance investigation conducted in Essex, Union, Hudson and Ocean counties, over 5 successive cycles (2000, 2002, 2006, 2008 and 2010). NJAS data were based on review, analysis and independent ASD case-determination derived from information contained in health and education records. Demographic information, level of impairment due to ASD, level of cognitive ability and other case-specific data, including the educational and program classification of children, was analyzed. Socioeconomic status (SES) was represented by a community-level index. Analysis was performed using descriptive statistics and Chi-square tests.
Results:
Among 1,985 ASD cases identified by multiple cycles of active surveillance, > 95% were receiving special education services. Forty four percent of these children (881 children) were served under the Autism classification, the most prevalent eligibility type accorded children with ASD. ASD diagnostic subtype (Autistic Disorder vs. PDD-NOS) was associated with Autism classification, with 76% of Autism-classified students meeting the diagnostic pattern of Autistic Disorder, as opposed to PDD-NOS (p<.001). Severity of impairment due to ASD was significantly associated with Autism classification, such that 75% of Autism classified students had moderate or severe levels of impairment (p=.001). Cognitive ability was also negatively associated with Autism classification, with 40% of Autism-classified students showing an intelligence quotient (IQ) below 70 (p=.001). Interestingly, ASD children with comorbidities—both Attention Deficit Hyperactivity Disorder (ADHD) and (other) psychiatric disorders—showed a lower likelihood of being Autism-classified (p=.001). Neither SES or race, nor socioeconomic status of ASD cases was associated with likelihood of being served under an Autism classification.
Conclusions:
The study findings suggest that the most significant factors contributing to an Autism classification for special education services are ASD diagnostic subtype, severity of impairment due to ASD and cognitive impairment. ASD students with co-morbid diagnoses usually received services under other eligibility classifications, including Other Health Impaired (OHI) and Emotionally disturbed. We did not identify significant associations between sex, race and SES and Autism classification, indicating apparent lack of obvious disparities in this regard. The findings are informative because they represent multiple large, complete ASD populations from a specific metropolitan region, but our findings may not be representative of Autism classification patterns in other states.

120 **145.120** Statewide Assessment of Teachers' Perceptions Related to Educating Students with Autism Spectrum Disorders

***S. E. Blumberg**[1], W. A. Loring[1], H. Huber[2], E. M. Kuntz[2], V. F. Knight[2], L. J. Garrett[1] and P. Juarez[1], (1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN*

Background: Students with Autism Spectrum Disorder (ASD) often receive services through state Departments of Education IDEA Programs. Federal legislation calls for educators serving these students to use evidence-based practices (EBPs). The process of identifying and correctly implementing EBPs has become increasingly demanding for educators working with students with ASD. As such, preparation and training in EBPs for educators is a pressing need.
Objectives: This program evaluation gathered educators' perceptions on the importance and level of preparedness across instructional areas, use of instructional practices, access to training or resources on EBPs for individuals with ASD and perceived comfort when implementing EBPs before and after training.
Methods: A survey was sent to special educators in Local Education Agencies across a state in the southeastern United States serving in Preschool through High School settings. Questions included frequency of usage of EBPs as defined by the National Professional Development Center on ASD, sources of training on these practices, factors influencing the selection of practices, and instructional skills. In an additional phase, educators attending ASD specific training sessions were instructed to self-report perceived comfort regarding implementation of specific EBPs, both before and after training.
Results:
A total of 535 special educators provided complete survey responses. Educators indicated the following non-academic areas were *very important* to teach - social skills (91.6%), communication (87.3%), daily living skills (86.7%), self-determination (75.5%), and vocational skills (72.7%). However, there was a notable decrease in the percent who indicated feeling *very prepared* to teach these subjects (social skills: 56.1%, communication: 42.4%, daily living skills: 55.3%, self-determination: 43.7%, and vocational skills: 24.1%).

Reported frequency of utilizing EBPs when teaching was variable ranging from 12.4% - 88.8% being used *at least weekly*. The most frequently reported were modeling (88.8%), Picture Exchange Communication System (68.6%), ABA-based interventions (67.8%), cognitive behavioral intervention (60.2%), and visual supports (61.1%). Despite reported use, participants reported having no access to training (e.g., live/online trainings, print/electronic resources) for those most frequently used EBPs – (modeling:42.8%, Picture Exchange Communication System: 56.1%, ABA-based interventions:49.0%, cognitive behavioral intervention:57.2%, and visual supports:54.2%). Additional data regarding EBPs educators reported using most and least will be presented.
Additional data on perceived confidence in implementing EBPs prior to and following receiving ASD specific training is under analysis. Preliminary results indicate participants reported higher confidence levels in implementing specific EBPs correctly before receiving training than they reported after receiving training.
Conclusions: The preliminary results of this project indicate educators statewide recognize the importance of students with ASD receiving instruction in core content areas and non-academic areas, however many feel they lack preparedness to do so. Teachers report implementing EBPs in classrooms but not having access to training and resources. Furthermore, reported levels of confidence were noted to decrease immediately after receiving training, indicating educators may not be implementing the reported EBPs with fidelity or fully comprehending accurate means of implementation. Therefore, the need to provide focused and ongoing training and support for educators in these areas is crucial.

121 **145.121** Sticking with It: Psychotherapy Outcomes for Adults with ASD in a University Counseling Center

E. Anderberg[1], *E. S. Neeley Tass*[1], *J. C. Cox*[1], *J. I. Cline*[1], *D. Petersen*[1], *D. M. Erekson*[1] *and M. South*[1,2], *(1)Brigham Young University, Provo, UT, (2)Psychology and Neuroscience, Brigham Young University, Provo, UT*

Background:
Young adults with autism spectrum disorders (ASD) experience high rates of comorbid mental health concerns as well as distress arising from the core symptoms of autism. Many adults with ASD seek psychological treatment in outpatient facilities in their communities that are not specifically geared towards individuals with ASD. However, few studies have looked at the effectiveness of standard psychotherapeutic care in adults with ASD.
Objectives:
This study aims to discover how individuals with autism spectrum disorders fare in psychotherapy within a college mental health care setting compared to their neuro-typical peers.
Methods:
Data for this study were pulled from a large data set containing information on 34874 clients that visited the Brigham Young University Counseling and Psychological Services (CAPS) center for psychotherapy from 1994-2015. Therapy case notes (N=271,343) were searched for terms associated with autism spectrum disorders ("autism," "Asperger's," "spectrum," etc.) and each flagged case note was coded for the diagnostic relevance of the term. Finally, each client's case note ratings were merged and a final diagnostic code was determined: Confirmed ASD (CASD)(N=95), Probable ASD but is not diagnosed (PASD)(N=109), or Does not have ASD (Neuro-typical, NT) (N=34670).
The CAPS uses the Outcome Questionnaire-45 (OQ) to track distress at each session. The well-validated OQ-45 is generally completed shortly before every session the client attends and has been shown to be sensitive to change across the course of therapy. Change in OQ scores across sessions was analyzed with a repeated measure mixed model using lag 1 autocorrelation to account for within subject correlation.
Results:
Clients with confirmed or probable ASD showed no difference in level of distress at intake compared to their neuro-typical peers (CASD, M = 68.1; PASD, M = 69.4; NT, M = 67.4; $p = .90$). However, clients with confirmed and probable ASD stayed in treatment for a significantly larger number of sessions than neuro-typical clients (CASD, M = 6.7; PASD, M = 6.0; NT, M = 4.2; $p < .001$). Clients with confirmed ASD also improved at a faster rate in therapy than neuro-typical clients, especially after the first five sessions. We are undertaking additional analyses to look at the relationship between OQ-45 scores at intake and eventual outcome.
Conclusions:
Overall, adult therapy clients with autism spectrum disorder appear to benefit from typical community psychotherapy approaches as much or even more than their neuro-typical peers. They also tend to stay in therapy longer than their peers, which may indicate that they do not feel relief of distress as quickly and require more sessions to feel as though therapy was successful. Results indicate that adults with ASD benefit greatly from psychotherapy the longer they stick with it, and should be encouraged to continue in therapy even if they do not feel immediately that it is helping.

122 **145.122** Stop. Breathe. be. Supporting Youth with Autism Spectrum Disorder Using Mindfulness Training

K. S. Thom *and J. Montgomery, University of Manitoba, Winnipeg, MB, Canada*

Background:
Youth with Autism Spectrum Disorder (ASD) with average and above average intellectual abilities have been identified as a particularly at-risk group. Persisting impairments in self-regulation, social communication and interaction, coupled with increasing awareness of social differences and limited services places these youths at significant risk of secondary social and emotional problems, including high rates of loneliness, victimization, and mental health problems. Mindfulness-based interventions (MBIs) have emerged in the literature as a promising approach for improving coping, social and emotional skills in a variety of adult and child populations, however, research in MBIs and ASD remains limited. By offering training in self-regulatory and self-awareness skills, MBIs may be particularly effective in improving the social and emotional well-being of youth with ASD.
Objectives:
The purpose of this study was to investigate whether mindfulness training is an acceptable and effective approach for improving social and emotional well-being in youth with ASD.
Methods:
Adolescents with ASD between the ages of 13 and 17 years, with a VIQ > 80, were recruited for this study. Adolescents meeting inclusion criteria (N= 14) participated in a 9-week, small group MBI which focused on training youth in self-awareness, stress management, and positive coping strategies. Participants completed pre- and post-training measures including: 1) a measure of emotional intelligence, the BarOn Emotional Quotient-Inventory: Youth Version; 2) a measure of emotional dysregulation, the Difficulties in Emotion Regulation Scale; 3) a social/emotional outcome measure, the Behaviour Assessment System for Children, Second Edition: Self-Report of Personality; and 4) a measure of mindfulness, the Cognitive and Affective Mindfulness Scale-Revised, in a randomized order. Parents of the adolescents completed 1) a screening instrument for ASD, the Autism Quotient: Adolescent Version (pre-training only); 2) a Participant Information Questionnaire assessing diagnostic and developmental history (pre-training only); 3) a social/emotional outcome measure, the Behaviour Assessment System for Children, Second Edition: Parent Rating Scale; and 4) a social skills measure, the Social Skills Improvement System: Parent Rating Scale. Parents and adolescents also completed a post-intervention feedback survey to assess acceptability and feasibility of the intervention.
Results:
Parents reported significant improvements in adolescents' social skills and reductions in problem behaviors following the 9-week MBI. Adolescents reported no significant changes in emotion dysregulation, emotional intelligence, and mindfulness. Quantitative and qualitative responses from the parent and adolescent feedback surveys indicated high ratings of program satisfaction and feasibility, as well as improvements in self-calming, self-management, and emotional skills. Results are considered exploratory and generalizability is limited by the study's small sample size and lack of control group.
Conclusions:
The results from this study add to emerging empirical support for mindfulness training in youth with ASD by providing evidence to suggest that this approach is engaging, acceptable, and effective in improving social and emotional skills and well-being. The results of this study also highlight important measurement considerations, including the utility of mixed-methods assessment strategies. Implications for group-based interventions, program evaluation, and future research will be discussed.

123 **145.123** Study of Effectiveness of the Emotion Regulation Training on Social Skills and Repetitive Behaviors in Children with High Functioning Autism

S. Rezaei Dehnavi[1], *S. Rashidi*[2] *and A. R. Bakhshashye*[3], *(1)Payame Noor university, Isfahan, Iran, (2)Islamic Azad University Yazd Branch, Isfahan, Iran, (3)Islamic Azad University Yazd Branch, Yazd, Iran*

Background: Emotional regulation education was recommended to improve social skills and reducing in repetitive behaviors in previos studies.
Objectives: The purpose of this study was study the effectiveness of the emotion regulation education on social skills and repetitive behaviors in children with High Functioning Autism(HFA).
Methods: The research was experimental Using a two Groups Pre and Post Test design . 28 children with HFA were selected and randomly assigned in two experimental and control groups The experimental group participated in emotion regulation training basis on manual of the Stress and Anger Management Program (STAMP) in nine sessions (two sessions per week) . Social Skills Rating Form of Triad Social Skills Assessment (TSSA) and Repetitive behaviors Inventory were applied to assess dependent variables. Covariance analysis was used to analyze the data
Results: The results indicated that social skills in experimental group had been significantly($p<0.00$) improved , but there was no difference in repetitive behavior in two groups.
Conclusions:

Basis on the results of this study. Emotional regulation education is recommended for improving the social skills in children with HFA.

124 **145.124** Summer Camps As Social Performance Intervention for Adolescents with ASD and Their Peers

J. Kaboski[1], *J. J. Diehl*[2], *K. E. Kawalec*[3], *K. Tang*[4], *H. N. Van Steenwyk*[5], *H. Miller*[6], *M. Prough*[7], *J. Riemersma*[7], *G. Ramos*[7], *D. Klee*[7], *L. T. Simon*[8], *J. Georgeson*[7] *and E. Tracy*[7], *(1)University of Notre Dame, Granger, IN, (2)LOGAN Community Resources, Inc., South Bend, IN, (3)University of Notre Dame, Hammond, IN, (4)Psychology, University of Notre Dame, Notre Dame, IN, (5)F.U.N. Lab at the University of Notre Dame, Brainerd, MN, (6)University of Notre Dame, Notre Dame, IN, (7)University of Notre Dame, South Bend, IN, (8)University of Notre Dame, Spring Lake, MI*

Background: For adolescents with ASD who have developed the requisite social *skills*, there are limited opportunities to improve social *performance*(Koegel et al., 2012). Koegel et al. (2012) tested the effectiveness of a social performance approach with elementary school-age children in their school setting with typically developing (TD) peers. This approach was unique from other peer-mediated models in that the participating peers were not selected or trained to work with children with ASD. Rather, the success of the approach relied on the shared interest of the children to facilitate natural social interactions. Whether such approach could successfully be adapted to adolescents with ASD is yet unclear.

Objectives: We provided a series of technology-related summer camps, which offered an engaging and supportive environment in which adolescents with ASD could practice appropriate social and collaborative skills with TD peers. Shared common interest was in one of two topics: robotics or computer game programming (CGP). The primary goal of the camp was to improve social anxiety and social skills.

Methods: We recruited 33 individuals with ASD and 36 TD peers, ages 10-17 years, who received general education science instruction at school, and expressed interest in either robotics or CGP. Participants completed a weeklong summer camp, during which they were trained in programming either a humanoid robot or computer games, depending on the type of camp in which they were participating. In all camps, participants had the opportunity to program a robot or computer game while collaborating in pairs (1 ASD: 1 TD). Participants were not labeled as having ASD. Social skills were taught indirectly through assigned technology-related exercises, such as programming the robot to make appropriate eye gaze and gestures to interact naturally with the audience. Pre- and post-treatment data were collected on participant-reported levels of social anxiety (Social Anxiety Scale) and parent-reported social skills (Social Skills Improvement System).

Results: The data from all camps were combined and a series of paired samples *t*-test were conducted to compare pre- and post-intervention data. The ASD group experienced a significant improvement on social skills and social anxiety from pre- to post-test. It should be noted that averages for the ASD never reached the standardized norm on the measures. While the TD group did experience some improvements in both measures, they never reached significance. This is to be expected considering their already desirable levels of social skills and social anxiety at the start of the camps (see Table 2). When the sample was analyzed separately by the type of camp, the ASD sample in the robotics camp showed improvements in both social skills and social anxiety while the ASD sample in the CGP camp showed improvements in only social anxiety. TD children, regardless of the type of camp, did not show any improvements.

Conclusions: These results provide a strong support for the effectiveness of social performance-based camps for adolescents with ASD. Whether there is something unique about programming humanoid robots that is more conducive to social skills learning needs to be explored further.

Table 1. Pre- vs. Post-Intervention Data for All Camps Combined

Measures	Pre-Test *M (SD)*	Post-Test *M (SD)*	*t*	*p*
ASD Group (*N*=32)				
SAS-A/SASC-R: Total score	47.73 (15.21)	42.91 (16.38)	4.12	.00**
SSIS: Social Skills Scale	81.53 (14.08)	85.78 (12.59)	-3.17	.00**
TD Group (*N*=27)				
SAS-A/SASC-R: Total score	37.33 (11.52)	35.38 (12.39)	2.30	.03*
SSIS: Social Skills Scale	102.46 (11.93)	104.03 (11.37)	-1.30	.20

Note. SASC-R = Social Anxiety Scale for Children – Revised; SAS-A = Social Anxiety Scale, the Adolescent adaptation; SSIS = Social Skills Improvement System.
*p<.05, **p<.01

Table 2. Robotics Camp vs. CGP Camp (Reporting on ASD participants only)

Measures	Pre-Test *M (SD)*	Post-Test *M (SD)*	*t*	*p*
Robotics Camp (*N*=24)				
SAS-A/SASC-R: Total score	46.88 (14.91)	41.25 (16.13)	3.65	.00**
SSIS: Social Skills Scale	81.33 (14.92)	86.33 (12.89)	-3.10	.01*
CGP Camp (*N*=9)				
SAS-A/SASC-R: Total score	50.00 (16.70)	47.33 (17.18)	2.63	.03*
SSIS: Social Skills Scale	82.13 (12.04)	84.13 (12.3)	-0.87	.42

Note. SASC-R = Social Anxiety Scale for Children – Revised; SAS-A = Social Anxiety Scale, the Adolescent adaptation; SSIS = Social Skills Improvement System.
*p<.05, **p<.01

125 **145.125** Surviving and Thriving in the Real World: A Daily Living Skills Intervention for Adolescents with ASD

A. Duncan[1], *C. L. Thomas*[1], *L. A. Ruble*[2] *and L. J. Stark*[1], *(1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Kentucky, Lexington, KY*

Background: Adolescence is a time of critical milestones, and those with autism spectrum disorder (ASD), even those who are high functioning (IQ >70), have difficulties successfully transitioning to the adult world in areas such as independent living and employment (Hume et al., 2014). In one study, 46% of parents reported that adults with high functioning ASD required "extensive help" completing activities of daily living, which impacted their ability to maintain employment (Farley et al., 2009). Daily living skills are everyday activities such as personal hygiene, cooking, cleaning, and managing money. Daily living skills were the only significant factor that predicted a positive outcome in adulthood for individuals with ASD, and have been linked to a more successful outcome in college, employment, and independent living (e.g., Klinger et al., 2015). Despite their importance, the daily living skills of adolescents with high functioning ASD fall far below what would be expected based on their IQ and chronological age (Duncan & Bishop, 2015). However, daily living skills can be taught using empirically-based strategies. Currently, there are no evidence based intervention packages that target the acquisition of daily living skills in adolescents with high functioning ASD.
Objectives: The primary aim of the current study was to develop and evaluate the intervention package, *Surviving and Thriving in the Real World (STRW)*, to increase critical daily living skills in adolescents with high functioning ASD. A pre-post trial was conducted in order to refine tools for measuring individual progress on targeted daily living skills (i.e., goal attainment scaling), maximize recruitment and retention strategies, finalize the intervention protocol, determine efficacy, and assess feasibility and

acceptability.
Methods: The pre-post trial consisted of 8 adolescents with ASD between 14-18 years and their parents. All participants had IQs>70 and met criteria for ASD on the ADOS-2. Information on daily living skills was collected using (1) the Vineland Adaptive Behavior Scales, 2nd Edition and (2) a goal attainment scale that was created for each adolescent from a parent interview that assessed skills in the goals targeted in the STRW intervention. STRW consists of 12 group sessions with adolescents and their parents that targets skills in the areas of hygiene, cooking, laundry, and money management. Data on factors such as acceptability, feasibility, and satisfaction were collected after each assessment. Daily living skills will be re-evaluated after completion of STRW.
Results: The pre-post trial for STRW is currently being conducted and will be completed by February. Statistical analyses will be conducted to examine predictors, primary outcomes, and feasibility, acceptability, and satisfaction.
Conclusions: The current study is the first step in the development and evaluation of a daily living skills intervention for high functioning adolescents with ASD. The results of the pre-post trial of STRW will determine initial efficacy and evaluate acceptability, feasibility, and satisfaction. A daily living skills intervention has the potential to directly affect current functioning and future adult outcomes in adolescents with high functioning ASD by increasing capabilities for skills that are needed to be successful in independent living, college, and employment.

126 **145.126** Teaching Emotion Recognition with the Transporters DVD

***P. LaCava**, Rhode Island College, Providence, RI*

Background: Facility with understanding, recognizing and responding one's own and others' emotions is at the core of social interactions (Baron-Cohen, 1995; 2003). In a variety of experimental tasks, children with Autism Spectrum Disorders (ASD) have shown delays in recognizing and understanding emotions (Golan et al., 2009). To improve emotion recognition skills several tactics have been successfully used. This includes more traditional approaches (i.e., direction instruction, ABA, etc.), computer programs such as Mind Reading (Baron-Cohen et al. 2003; LaCava et al., 2007; LaCava et al., 2010), or FaceSay (Hopkins et al., 2011), and the Transporters DVD (Golan et al., 2009). While experimental studies have shown the Transporters to be a motivating and effective way to teach emotions (Golan et al., 2009; Young & Posslet, 2012; Williams et al., 2012), no research to date has addressed the efficacy of the Transporters with American children.
Objectives: To complete a pilot study to assess if the Transporters DVD can improve emotion recognition of American children with ASD. We hope to use this study's findings to support a full clinical trial of the Transporters in the United States.
Methods: We are implementing a small pilot study using a one group pre-test post-test design with children ages 4 to 10. Currently 6 children have completed the study, with 3 more currently using the program; we intend to have between 10 to 15 participants in the final sample. 33% of our current sample is from a minority racial group. All participants will have an official diagnosis of ASD if diagnosed after DSM-5 2013 changes or a diagnosis of autistic disorder, Asperger syndrome or PDD-NOS, if diagnosed prior to 2013. At pre-testing parents are asked to complete the Social Emotional Evaluation Questionnaire (Wiig, 2008) and the Childhood Autism Spectrum Test. Children complete the Peabody Picture Vocabulary Test (Dunn & Dunn, 2007), the Social Emotional Evaluation Identifying Common Emotions and Identifying Emotional Reactions subtests (Wiig, 2008), and three researcher made computerized emotion recognition tasks (based on Golan et al., 2009). The intervention consists of 4 weeks of watching the Transporters DVD in either the home or school setting for at least 15 minutes a day/5 days a week. At post-testing we reassess children on the emotion recognition measures.
Results: We are still collecting data at this time but initial results suggest that the Transporters DVD is effective in helping about half of the participants to increase their emotion recognition performance from pre to post testing.
Conclusions: Final conclusions will be made once all participants complete the study. However, as no peer-reviewed publication currently exists about the Transporters efficacy in the United States, these initial findings will be important for families and practitioners making intervention decisions.

127 **145.127** Teaching Research Staff Implementation of a Social Skills Intervention: An Extension of Behavior Skills Training

***J. Day-Watkins**[1], A. Pallathra[2], J. E. Connell[1] and E. S. Brodkin[2], (1)Drexel University, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA*

Background: Behavior skills training (BST) is a parent and staff training package that includes verbal instructions, modeling, rehearsal, and feedback (Nosik, Williams, Garrido, & Lee, 2013). BST relies on the presence of a trainer throughout the training period. It may be advantageous to find training arrangements based on BST that reduce the reliance on a trainer (Giannakakos, Vladescu, Kisamore, & Reeve, in review). One such variation is video modeling with voiceover instruction (Vladescu, Carroll, Paden, & Kodak, 2012). This package includes voiceover instruction that describes the behaviors being modeled in the video.
Objectives: The present study sought to use BST to teach three adult participants (research staff) to implement a video modeling intervention aimed at teaching social skills to adult consumers with autism spectrum disorder (ASD). After training, we sought to assess generalization to three untrained social skills: transitioning conversation, listening to conversation, and empathetic responses. The overall goal of the study was to extend the BST literature to training social skills interventions.
Methods: Three participants were taught to provide a video model to teach a confederate to engage in one social skill (i.e., approach and greet others). During baseline trials, participants were given access to written instructions before role-play with the confederate. During role-play, the confederate engaged in a variety of scripted correct and incorrect responses. During treatment, participants were given a video model with voice-over instruction. The training video depicted how to teach social skills by introducing a video model in the presence of an error. The training video included written and auditory prompts that highlighted critical steps in the task analysis and where to input data collection. After access to the training video, participants repeated role-play trials. Following the role-play, feedback was provided to participants on steps completed correctly and incorrectly. Generalization probes were conducted with an adult with ASD who was not associated with training.
Results: All participant scores increased from baseline (*M=8%)* to treatment (*M=96%).* Participants met the training criterion for mastery within 2-3 treatment sessions. Generalization was demonstrated across novel skills from baseline (*M*=6%) to treatment (*M*=86%).
Conclusions: Following BST, participants demonstrated correct use of a video model to teach a social skill. Participants generalized use of the video model to teach as many as three additional novel social skills. These data indicate the efficiency of BST by demonstrating spontaneous skill acquisition when only a subset of skills is directly trained, in this case one social skill. Furthermore, the use of a video reduces the amount of direct training time for staff trainers. This study extends the BST literature in two ways. First, it uses BST to train staff to implement a social skills intervention. Second, in a separate study currently in progress, the same participants are training adult consumers with ASD to engage in the social skills described here. To our knowledge, this may be the first BST study to report effects on consumers' behavior.

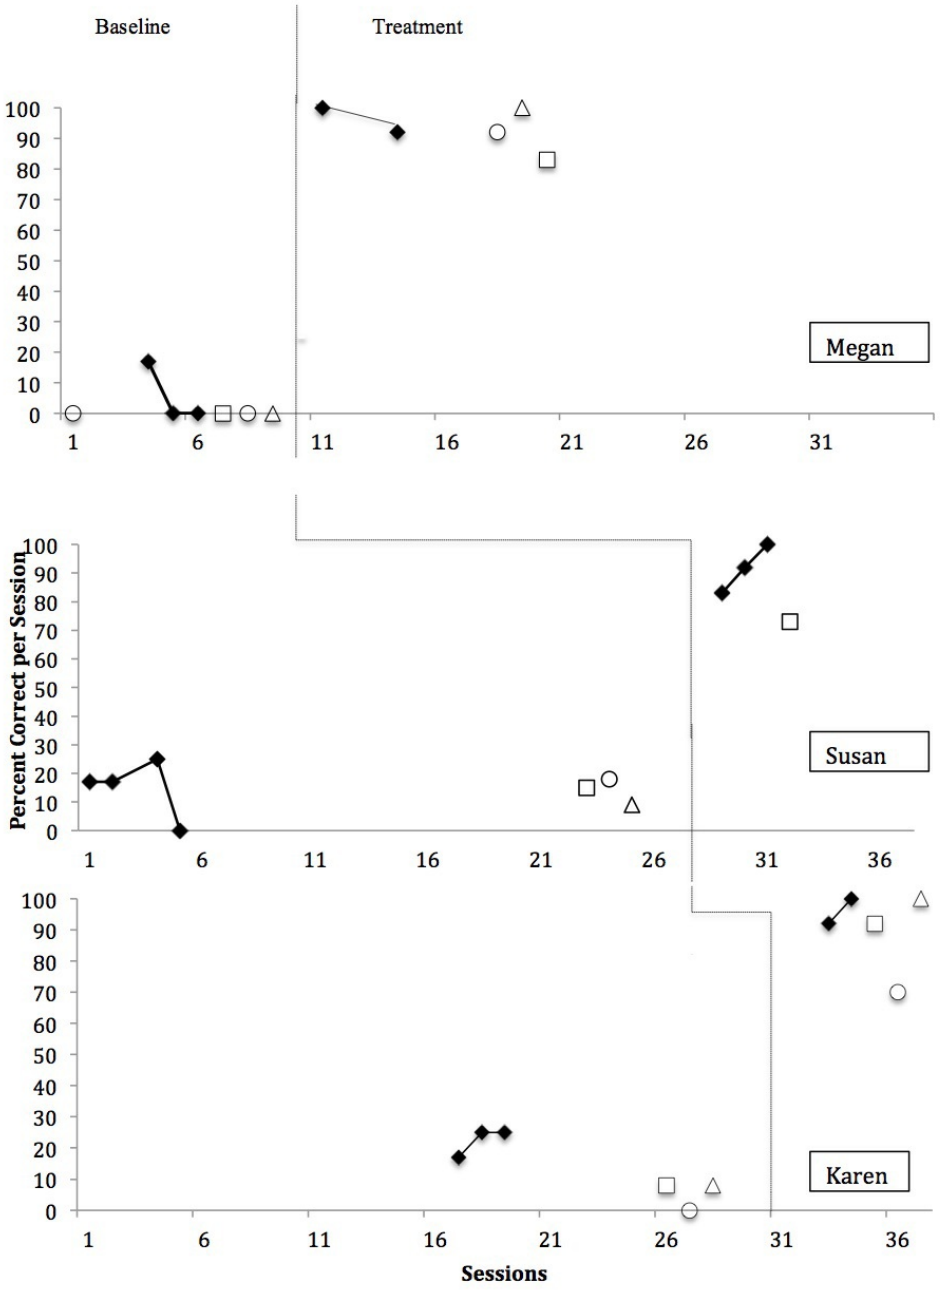

Figure 1. Percent of correct responses per session. Filled diamonds represent trained skill; open squares, circles and triangles are generalization skills 1, 2, and 3 respectively. Generalization conducted with an actual consumer not used in training.

128 **145.128** The Efficacy of Student-Assisted LEGO Therapy in Children with Autism Spectrum Disorders Using the Autism Impact Measure

J. Gehricke[1,2], *R. steinberg Epstein*[1], *L. Lam*[1], *A. Z. Chester*[1], *T. Thampipop*[1], *K. Pesterfield*[1], *R. Bisht*[1], *S. Quan*[1] *and J. H. Donnelly*[1,2], *(1)The Center for Autism & Neurodevelopmental Disorders, Santa Ana, CA, (2)University of California, Irvine, Santa Ana, CA*

Background: Since children with Autism Spectrum Disorders (ASD) are naturally drawn to repetitive and predictable patterns, LEGO Therapy is advantageous in attracting and motivating children with ASD due to its structured play, intrinsically enjoyable properties, and opportunities for originality. LEGO Therapy allows participants to practice verbal and nonverbal communication with an emphasis on social support, social problem solving, and conflict resolution; all of which are impairments associated with ASD. Behavioral interventions using LEGO aim to help children with ASD initiate and sustain higher quality interactions with peers.
Objectives: The present study was designed to examine the short-term effectiveness of LEGO therapy in improving ASD symptoms, including sensorimotor symptoms (e.g., fascination with looking and touching objects, avoiding sounds, textures and smells), social communication (e.g., social withdrawal, eye contact), and repetitive behaviors (e.g., repetitive body movements, lining things up).
Methods: Twelve children with ASD between the ages of 6 and 14 participated once per week for five weeks in one-hour LEGO Therapy sessions. During each session, participants were paired with a student assistant and engaged in LEGO play, taking turns as either a “builder” or an “engineer.” To monitor progress, parents were given the Autism Impact Measure (AIM), a 41-item parent survey shown to be a reliable measurement for tracking short-term improvements in ASD symptoms and impairments. Parents reported the frequency of ASD symptoms and their impact on daily functioning in their child over the last two weeks at baseline and after completion of the five-week period. The data processing and analysis was conducted with SPSS Statistics 21 using Wilcoxon tests at a one-tailed probability level of 0.05.

Results: Overall, LEGO Therapy significantly decreased the impact of ASD symptoms on daily functioning from baseline to study completion (p = 0.027). More specifically, LEGO Therapy significantly reduced the impact of sensorimotor symptoms (ps ≤ 0.021) as well as deficits in social communication (ps ≤ 0.017) on daily functioning.
Conclusions: The findings suggest that LEGO Therapy can significantly improve the daily functioning of children with ASD, particularly in symptoms associated with deficits in sensorimotor functioning and social communication.

129 **145.129** The Influence of Cognitive Empathy in Predicting Changes in Social Skills Improvement for Adolescents with ASD Following the UCLA PEERS® Program

L. Zhang[1], *J. W. Yang*[1], *E. Veytsman*[2] *and E. A. Laugeson*[2], *(1)The Help Group-UCLA Autism Research Alliance, Sherman Oaks, CA, (2)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background: Empathy involves the capacity to recognize, identify, understand, and experience the emotional states of others, and is essential to the development and maintenance of meaningful relationships (Davis, 1980). In particular, empathy requires both the ability to share the emotional experience of the other person (affective component) and an understanding of the other person's experience (cognitive component) (Decety & Jackson, 2004; Eisenberg & Eggum, 2009; Hodges & Klein, 2001). Baron-Cohen and Wheelwright (2004) characterize high functioning autism spectrum disorder (ASD) as an empathy disorder, arguing that those with ASD often lack empathy and are unresponsive to socio-emotional cues. The Program for the Education and Enrichment of Relational Skills (PEERS®) is an evidence-based, caregiver-assisted social skills training program (Laugeson & Frankel 2010), which has been shown to improve social skills and empathy in youth with ASD without intellectual disabilities. While improvements in empathy have been observed, the extent to which empathy at post-treatment is related to improvement in social skills following PEERS® has yet to be examined.
Objectives: The present study examines the relationship between post-treatment levels of empathy and the improvement in social skills for adolescents with ASD following the PEERS® social skills intervention.
Methods: Participants in this study included 90 adolescents (67 males, 23 females) with ASD ranging from 11-18 years of age (*M*=13.86, *SD*= 1.76) and their parents who presented for social skills treatment through the UCLA PEERS® Clinic. Adolescents and parents attended weekly 90-minute group treatment sessions over a 14-week period. Skills related to making and keeping friends and handling peer conflict and rejection were taught through didactic instruction using concrete rules and steps of social etiquette, role-play demonstrations of targeted skills, in-session behavioral rehearsal activities, and parent-assisted weekly socialization homework assignments.
In order to understand the relationship between empathy and social skills improvement following treatment, parents completed the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008) pre-and-post intervention. Empathy was assessed at post- intervention through parent reports on the Empathy Quotient (EQ; Baron-Cohen & Wheelwright, 2004), which assesses empathy levels among adolescents with ASD. Pearson correlation coefficients were calculated to examine the relationship between parent-reported EQ following treatment and the change in parent reported SSIS from pre- to post-test.
Results: Results indicate that cognitive empathy on the EQ following treatment was associated with improvement in Communication ($p<.05$), Assertion ($p<.01$), and Internalizing Problem Behaviors ($p<.05$) on the SSIS. No statistically significant correlations were observed between total scores on the EQ, SSIS, or other subscales.
Conclusions: These findings suggest that adolescents with ASD whose parents reported higher cognitive empathy following the PEERS® program were more likely to have better communication skills, assertion, and exhibit less internalizing problem behaviors following treatment. These findings are useful in understanding the relationship between empathy and improvement in social skills following treatment, and distinguishing those who may be more likely benefit from targeted social skills treatment.

130 **145.130** The Influence of Self-Esteem in Predicting Social Anxiety in Adolescents with ASD Following the UCLA PEERS® School-Based Curriculum

J. Albright[1], *C. C. Bolton*[2], *N. Rosen*[1], *L. C. Tucci*[3] *and E. A. Laugeson*[2], *(1)Psychiatry, UCLA, Los Angeles, CA, (2)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)The Help Group/UCLA Autism Research Alliance, Sherman Oaks, CA*

Background: As a result of social skill deficits and heightened social demands common to adolescence, teens with Autism Spectrum Disorder (ASD) are particularly susceptible to feelings of anxiety. In fact, 11% to 84% of adolescents with ASD report feelings of impairing anxiety (White et al., 2010). In typically developing adolescents, self-esteem has been linked to peer acceptance and social activity, which in turn impedes feelings of social anxiety. However, research has yet to explore the impact of self-esteem on social anxiety in this population. The Program for the Education and Enrichment of Relational Skills (PEERS®) School-Based Curriculum is a 16-week evidence-based social skills intervention that addresses social skill deficits by teaching students how to make and keep friends. While this program has been shown to improve social functioning, and decrease social anxiety in some cases, the relationship between self-esteem and social anxiety has yet to be explored.
Objectives: The present study seeks to examine how baseline self-esteem predicts changes in levels of self-reported social anxiety following a school-based social skills intervention for adolescents with ASD.
Methods: Participants included 106 adolescents, ranging from 11-18 years of age (M=15.08, SD=1.82). Participants received 30 minutes of daily social skills instruction in the classroom over a 16-week period. Teachers provided instruction on the PEERS® curriculum through didactic presentation, role-play demonstrations, behavioral rehearsal activities, and review of socialization homework assignments. In order to understand the relationship between self-esteem and social anxiety, students completed the Piers Harris Self-Concept Scale Second Edition (PHS2; Piers, Harris, and Herzberg, 2002) at pre-test to measure self-esteem, and the Social Anxiety Scale for Adolescents (SAS-A; La Greca, 1993) at post-test to measure social anxiety. Regressions were calculated to examine the relationship between PHS2 sub-scales and the SAS-A. T-tests were calculated to compare pre/post measures of overall self-esteem and social anxiety.
Results: Results indicated that higher youth-reported self-esteem on the PHS2 at baseline significantly predicted social anxiety as measured by the SAS-A ($p<0.001$) post-treatment. A two-factor model accounting for Intellectual Status ($p<0.001$) and Popularity ($p<0.001$) were able to account for 33% of the variance in social anxiety post-treatment. Results also indicated that overall self-esteem significantly increased from pre-test to post-test, $t(105)=-3.06, p=0.003$.
Conclusions: These findings suggest that adolescents with ASD who report higher levels of self-esteem prior to receiving the PEERS® intervention are less likely to report feelings of social anxiety following treatment. Specifically, adolescents who endorse more confidence in social functioning and intellectual ability prior to treatment are less likely to experience anxiety brought on by social interactions following the intervention. In addition, overall self-esteem improved, while overall social-anxiety decreased, following the PEERS® School-Based Curriculum. These findings provide useful information about who is most likely to benefit from treatment, allowing for more targeted intervention.

131 **145.131** The Relationship Between Friendship Quality, Companionship and Social Engagement in Adolescents with Autism Spectrum Disorder

J. W. Yang[1], *L. C. Tucci*[2], *Y. Bolourian*[3], *E. Veytsman*[4], *C. C. Bolton*[4] *and E. A. Laugeson*[4], *(1)The Help Group-UCLA Autism Research Alliance, Sherman Oaks, CA, (2)The Help Group/UCLA Autism Research Alliance, Sherman Oaks, CA, (3)University of California - Riverside, Riverside, CA, (4)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background:
Impaired social functioning among youth with Autism Spectrum Disorder (ASD) may lead to lack of social engagement, companionship, and poor friendship quality (Orsmond, Krauss, & Seltzer, 2004; Bauminger & Kasari, 2000). Greater friendship quality has been associated with fewer social problems, and less internalizing or externalizing problem behaviors. Having at least one close friend has been shown to be a protective factor against peer victimization and better overall adjustment in adolescents (Waldrip, Malcolm, & Jensen-Campbell, 2008). Children with ASD often report having friendships in school settings, but these friendships are often focused on circumscribed interests with little outside social engagement (Church, Alisanski, & Amanullah, 2000). Despite the growing research examining the social functioning of school-aged children with ASD, little is known about the friendship quality and social engagement in older youth (Macintosh & Dissanayake, 2006).
Objectives:
The present study seeks to address this research gap by examining the relationship between friendship quality and social engagement among adolescents with ASD in school settings.
Methods:
Participants included 106 adolescents (males=86; females=20) ranging from 12-18 years of age (*M*=15.08; *SD*=1.82) at The Help Group's Village Glen School, a nonpublic school for youth with ASD. Participants were involved in a larger treatment outcome study investigating the effectiveness of the PEERS® school based curriculum (Laugeson 2014). In order to examine the relationship between friendship quality and social engagement, adolescents completed the Friendship Quality Scale (FQS; Bukowski, Hoza, & Bolvin, 1994) at baseline, which assesses overall friendship quality along the domains of companionship, helpfulness, closeness, conflict, and security. Additionally, in order to assess social engagement, adolescents completed the Quality of Socialization Questionnaire (QSQ; Frankel & Mintz, 2008) prior to treatment. The QSQ measures the number of hosted and invited get-togethers and degree of conflict during get-togethers in the previous month. Pearson correlation coefficients were calculated to examine the relationship between friendship quality on the FQS and social engagement using the QSQ.
Results:
Results indicate that higher baseline total scores on the FQS are correlated with higher baseline scores on the QSQ frequency of invited get-togethers ($p<.05$), and with lower baseline scores on the QSQ conflict scale ($p<.05$). In addition to these findings, companionship on the FQS is correlated with higher baseline scores of frequency of invited get-togethers ($p<.001$) and hosted get-togethers ($p<.001$) on the QSQ. Higher baseline companionship scores on the FQS are also correlated with lower baseline scores on the QSQ conflict scale ($p<.002$). No other statistically significant correlations across the subscales of the FQS and QSQ were found.

Conclusions:
These findings suggest that adolescents with ASD that report greater friendship quality and demonstrate higher companionship are more likely to be social engaged with their peers, and experience less conflict within their friendships. These results suggest that when the treatment priority is to increase social engagement and decrease conflict, the need for more targeted interventions to improve friendship quality and companionship may be warranted.

132 **145.132** The Relationship Between Treatment Acceptability and Child Outcome in Group CBT for Youth with ASD and Anxiety

C. E. Walsh[1], *A. Blakeley-Smith*[2], *L. G. Klinger*[3], *A. Keefer*[4], *A. Duncan*[5], *S. E. O'Kelley*[6], *S. Hepburn*[7], *E. Moody*[8] *and J. Reaven*[9], *(1)3037247659, University of Colorado Denver, Denver, CO, (2)Univ. of Colo. Denver-JFK Partners, Aurora, CO, (3)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (4)Kennedy Krieger Institute, Baltimore, MD, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Psychology, University of Alabama at Birmingham, Birmingham, AL, (7)University of Colorado / JFK Partners, Aurora, CO, (8)University of Colorado Anschutz Medical Campus, Aurora, CO, (9)Univ. of Colorado Denver-JFK Partners, Aurora, CO*

Background: Children with ASD are at increased risk for developing anxiety and modified cognitive-behavioral therapy (CBT) interventions can be effective in reducing anxiety in this population (Lang et al., 2010). CBT for anxiety consists of psychoeducation (e.g., somatic management, attention to automatic negative thoughts) and graded exposure (facing fears a little at time) (Velting et al., 2004). However, client resistance is typically highest during exposure practice compared to psychoeducation (Abramowitz et al., 2002). Little is known about how children with ASD (and their parents) perceive the acceptability of treatment and in particular, exposure. In fact, it is important to understand whether clients must consider a treatment helpful (or acceptable) in order to improve. Currently, the relationship between treatment acceptability (e.g., perceptions about a treatment and whether it is deemed helpful; Kazdin et al., 2005) and treatment outcomes in CBT for youth with ASD is unknown. Gaining a better understanding of this relationship may allow researchers to refine intervention content and delivery. **Objectives:** (1) To examine overall ratings of acceptability for parents and children completing the Facing Your Fears (FYF) intervention (Reaven et al., 2011) (a group CBT treatment for youth with anxiety/ASD); and (2) To compare acceptability ratings for psychoeducation (sessions 1-6) and exposure (sessions 7-13) among parents and children; and (3) To determine the association between acceptability and child outcome (child and parent report on the SCARED). **Methods:** This study was part of a larger, multi-site study, investigating the impact of clinician training on treatment fidelity and youth anxiety treatment outcome. A three group parallel design was used to randomize eight clinician cohorts to one of the three training conditions. Acceptability ratings were collected from parents and children who participated in the 14-week FYF intervention at four outpatient clinics across the US. Acceptability was rated for each activity across sessions and rated on a 5-point-Likert scale (1=Not helpful; 5=Very helpful). A sub-sample of 63 children with ASD ages 8-14 (and their parents) were included in the analyses. **Results**: Mean acceptability ratings for children and parents were high for the overall treatment (Parent Overall: *M*=4.4, *SD*=.42; Child Overall: *M*=4.12, *SD*=.64) Children and parents did not differ on their ratings for psychoeducation (Parent: *M*=4.39, *SD*=.40; Child: *M*=4.07, *SD*=.63) and exposure (Parent: *M*=4.46, *SD*=.48; Child: *M*=4.19, *SD*=.76) sessions. However, ratings of child acceptability of the overall treatment were significantly related to child outcome (child report on the SCARED), *r*=.292, *p*<.05. More specifically, higher child acceptability ratings of exposure sessions were significantly related to a reduction in child anxiety symptoms, *r*=.355, *p*<.05. **Conclusions:** Overall, parents and children rated the FYF treatment as helpful in treating anxiety. However, children who rate exposure sessions as helpful were more likely to report a reduction in anxiety symptoms. Given that exposure is considered an “active ingredient” in anxiety treatment, acceptability of exposure may in fact be important for change to occur. Implications for the importance of measuring acceptability in treatment research will be discussed.

133 **145.133** The Use of an Online Intervention to Improve Emotion Identification in Clinical and Non-Clinical Young Adults with a Range of Autistic Behaviors

C. Dickter[1], *J. Zeman*[2], *J. Burk*[1], *C. I. Mitchell*[1], *K. Chaney*[3], *J. Ball*[4] *and M. Urbano*[5], *(1)College of William & Mary, Williamsburg, VA, (2)Psychology, College of William and Mary, Williamsburg, VA, (3)Rutgers University, New Brunswick, NJ, (4)EVMS, Norfolk, VA, (5)Eastern Virginia Medical School, Norfolk, VA*

Background:
Individuals with autism spectrum disorder (ASD) exhibit differences in selective attention and emotion identification compared to non-ASD individuals. Little research has developed interventions aimed at young adult individuals who display autistic behaviors, although this is a developmental period of critical transitions.
Objectives:
This study aimed to develop and evaluate novel, short-term, online training sessions to improve selective visual attention and emotion identification in young adults with a wide range of ASD behaviors. Changes in task performance over time were assessed, as were potential differences between participants with a clinical autism diagnosis and a group of non-diagnosed individuals with high or low degrees of autistic behaviors.
Methods:
Fifty-four individuals (28 males; *Mage* = 19.73) completed the training sessions. Autistic behaviors were assessed with the Autism Quotient (AQ; Baron-Cohen et al., 2001). Seventeen individuals clinically diagnosed with ASD were recruited from the autism clinic at a local medical school (M_{AQ} = 26.50; *SD* = 3.93). The remaining participants were recruited from a small liberal arts university, 20 of whom reported autistic traits in the clinical range (M_{AQ} = 30.14; *SD* = 4.38) and 17 who reported few autistic behaviors (M_{AQ} = 9.47; *SD* = 2.52). The training strategies included eight online sessions completed over the course of three weeks. The training sessions included: 1) an oddball task that trained participants to press a key on some trials while refraining from responding on others, 2) a classic Stroop task, 3) a task training participants to identify the emotions of faces varying in the ambiguity of the emotion, 4) a task that trained participants to switch between identifying emotions on faces and identifying the color of the backgrounds behind the faces, 5) an antisaccade task training participants to identify emotion faces on either side of a screen, and 6) a task in which participants were trained to identify the emotions displayed by faces in which only the eyes were presented.
Results:
Performance on the six training tasks was assessed with a series of 3 (Number of Training Sessions) x 3 (Group: Clinical, High AQ, Low AQ) mixed-model ANOVAs. Results revealed that there was a significant interaction on the eyes training task, $F(4, 102) = 4.12$, $p = .006$. Simple main effects analyses demonstrated that over the course of the three sessions, both the clinical sample (M_1 = 58.12; M_2 = 65.93; M_3 = 70.83), $F(2, 32) = 22.45$, $p < .001$, and the non-clinical High AQ sample (M_1 = 79.59; M_2 = 83.06; M_3 = 84.03), $F(2, 38) = 4.36$, $p = .029$, showed significant improvements. The low AQ sample did not show improvement. There were no differences in performance on the other tasks.
Conclusions:
These data indicate that an online intervention using a complex task involving the recognition of emotions might improve the ability of diagnosed individuals or those who report high levels of autistic behaviors to recognize emotional expressions.

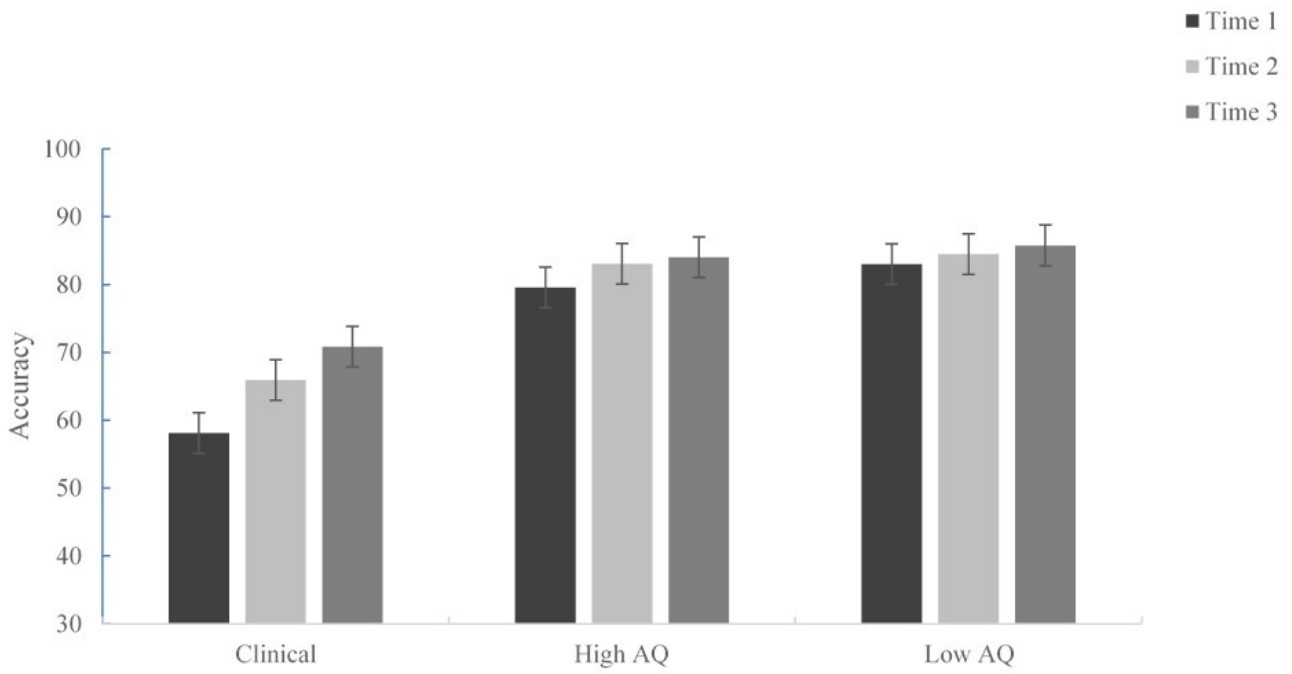

Figure 1. Accuracy on the eyes task as a function of group and training session.

Note. Error bars represent standard error.

134 **145.134** Training Teachers Implementing Reading Skills & Literacy Programming within Schools

K. Johnsen[1]*, J. Salt*[1] *and S. LaMontagne*[2]*, (1)Have Dreams, Park Ridge, IL, (2)Have Dreams, Evanston, IL*

Background:
While some students with ASD may proceed through literacy development at a typical pace, many students struggle with some aspect of literacy skills. Students with ASD may struggle with letter recognition, decoding, or reading comprehension. In addition, some characteristics of ASD, e.g. theory of mind and struggles with understanding social behavior, may affect the interpretation of a characters intentions or actions in a storyline. Teachers rarely receive specialized training in autism, and may encounter difficulties in their attempts to provide effective literacy opportunities for their students with ASD.
During our training, participants learn how to apply literacy interventions across a range of skill sets (early reading, emergent reading, fluent readers). The training is multi-modal. It includes lectures, real life examples, video demonstration, and opportunities to create adapted reading materials. At the end of training, participants must be able to create and teach reading activities; as well as provide multiple literacy opportunities for their pupils. The training incorporates structured teaching methodology which is specifically designed to accommodate the characteristic strengths, and neurological differences of individuals on the autism spectrum.
Objectives:
This study investigated the effectiveness of the training model to increase teacher competence in literacy programming. The study addressed (i) competence of literacy programming gained across the training period (ii) the implementation of specific reading strategies following training.
Methods:
(i) Participating teachers (n= 70) who attended the training workshop completed a structured questionnaire pre and post training.
The questionnaire was developed and piloted by the lead trainers to assess key aspects of literacy skills interventions. Each of three sections described a student with skills sets at the concrete level (pre-reader); intermediate level (emergent reader); abstract level (fluent reader). Participants answered four questions in each section regarding that child. The final questionnaire had 12 questions; maximum total score of 72.
(ii) 10-14 days following training, participants were contacted by email and asked to return a survey of literacy skills strategies they implemented in their schools.
Results:
i) T-test revealed that there was a significant (p<.01) increase in competence scores pre and post training at each level of literacy development (concrete, intermediate, abstract).
ii) A response rate of n= 42 (60%) was achieved for the follow up survey.
Follow up questions indicated that some aspect of the structured teaching training was implemented into practice by n=40 (95%) of responders. Direct observation of a small number of classrooms was achieved at follow up (n=10). Self-report and direct observation of implemented strategies was 100%, indicating that self-report was accurate in a small sample.
Conclusions:
By attending the training, participants increased their confidence in their ability to teach literacy, at any level of reading ability, to individuals with ASD. Furthermore, once they returned to their home schools they implemented a multitude of literacy techniques. Although satisfaction of training was very high, desire for ongoing consultation is an issue that could be addressed. These results indicate the effectiveness of our training program. The training is now being provided to other professionals in the field.

135 **145.135** Treatment Fidelity and the Mainstream Environment: Predictors of Successful Outcomes for ASD Youth

M. C. Wills[1]*, L. Kenworthy*[2]*, L. Cannon*[3]*, J. F. Strang*[4]*, C. Luong-Tran*[5]*, J. L. Sokoloff*[6]*, E. Bal*[7]*, A. C. Armour*[8] *and L. G. Anthony*[1]*, (1)Children's National Medical Center, Rockville, MD, (2)Children's Research Institute, Children's National Medical Center, Rockville, MD, (3)Ivymount School, Rockville, MD, (4)Children's National Medical Center, Silver Spring, MD, (5)Children's National Medical Center, Center for Autism Spectrum Disorders, Lorton, VA, (6)University of Missouri, Columbia, MO, (7)Kennedy Krieger Institute, Baltimore, MD, (8)Children's National Medical Center, Arlington, VA*

Background: Thirty-seven percent of students with an autism spectrum disorder (ASD) spend the majority of the school day in the mainstream environment, making inclusion classrooms the optimal setting for the delivery of ASD interventions (U.S. Department of Education, 2015). However, the increased executive and social demands present within this environment pose major challenges for the dissemination of evidence-based treatments (Humphrey & Lewis, 2008). Therefore, it is critical for researchers to measure the extent to which interventions are being delivered as intended within the school setting, and utilize this information to make treatment manuals more accessible, identify optimal levels of treatment fidelity, and enhance student outcomes.
Objectives: The purpose of this study is to 1) evaluate the role of treatment fidelity and interventionist characteristics on student behavioral outcomes; 2) examine the relationship between fidelity and the experience/training of the interventionist; and 3) determine group differences in fidelity, interventionist characteristics, and student outcomes.
Methods: All children had IQ>70 (*M*=108.45, SD=18.01), met ASD criteria on the ADOS or ADI, and were in the 3rd–5th grade (*M*=9.52, *SD*=1.02). Participating schools (N=14) were randomly assigned to either the UOT intervention (10 schools; 16 interventionists; 47 students) or a social skills training program (4 schools; 7 interventionists; 20 students).
Fidelity observations were used to evaluate the quality of treatment implementation across the 23 intervention groups (e.g., intervention adherence, group/time management, student engagement, etc.). Classroom observations were conducted to measure pre-post changes in real-world functioning (i.e., cognitive flexibility, planning, and social appropriateness). All observations were conducted by a blind evaluator 2-3 times throughout the school year (~15 minutes each). The Challenge Task (CT), an ADOS-like interview designed to measure executive functioning, was also used as a measure of pre-post change in flexibility, planning, and social appropriateness. Independent

samples t-tests were used to evaluate group differences. Correlational analyses were used to measure the relationship between fidelity and interventionist experience/training. Longitudinal linear models with random effects for school and student were used to measure the effect of fidelity on student outcomes.
Results: There were significant group differences in treatment fidelity (t=3.45, p<.01), acquired knowledge (t=-2.24, p<.05), years of experience (t=3.2, p<.01), with UOT interventionists demonstrating higher levels of acquired knowledge (M=70.31, SD=18.42) and SST interventionists adhering to higher levels of fidelity (M=86.92, SD=5.14) and having more years of experience (M=16.20, SD=12.04). In comparison to SST, UOT groups also demonstrated greater improvements in CO Plan (t=-6.97, p<.001), CO Flex (t=-11.02, p<.001), and CO Social (t=-6.44, p<.001). Treatment fidelity was correlated with higher levels of acquired knowledge, r=.40, p<.05. There was no significant effect of treatment fidelity, years of experience, or acquired knowledge on student outcomes.
Conclusions: Results suggest that high levels of treatment fidelity and professional experience are not required in order to achieve successful treatment outcomes in the mainstream educational setting. While additional research is needed in this area, these data provide support for the training of school personnel to implement evidence-based practices for students with ASD.

136 **145.136** Understanding Theory of Mind Improvements As a Result of Face Processing Instruction

C. A. Wall[1], *L. Rice*[2] *and F. Shic*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Moorpark Unified School District, Simi Valley, CA*

Background: *FaceSay* is a computer-based intervention that offers students simulated practice with eye gaze, joint attention, and facial recognition (Symbionica, LLC). Previous research has demonstrated that *FaceSay* improves emotion recognition and theory of mind (ToM) in school-aged children with ASD (Rice et al., 2014). ToM skills are not directly targeted with *FaceSay*, and the mechanism behind these improvements is not yet understood. In order to determine the specific components of ToM that are affected by this intervention, between-group differences in categories of items on the NEPSY-II ToM subscale were examined (Korkman, Kirk, & Kemp, 2007).
Objectives: To explore the components of ToM that are influenced by intervention with *FaceSay*. Potential differences were assessed using a: 1) theoretical approach to item grouping based on the NEPSY-II manual, and 2) statistical approach to item grouping.
Methods: Thirty-one school-aged children (M_{age}=7.76 years) meeting the educational criteria for ASD participated in a randomized-control trial studying the effects of intervention with FaceSay (Experimental group) versus an educational program (Control group) for 10 weeks. Students' ToM skills were assessed pre- and post-intervention using the ToM subtest of the NEPSY-II. Items were grouped into constructs using the NEPSY-II manual and exploratory factor analyses (EFA) with Varimax rotation. The Verbal Task and Contextual Task were treated separately for all analyses. Theoretical constructs were excluded if they were indexed by only one item. Factors were generated using pre-intervention data, and regression scores were calculated for each student at both time points using pre-intervention models. Repeated-measures ANOVAs were conducted to assess the effects of the intervention on each set of items.
Results: Results of the theoretical analyses indicated that groups differed on items assessing the understanding of false belief (F(29,1)=5.59, p<.05, partial η^2=.19), imitation (F(29,1)=8.55, p<.01, partial η^2=.28), and figurative language (F(29,1)=10.33, p<.01, partial η^2=.26), with those undergoing the intervention experiencing greater improvement. Results of the EFA recommended extracting five components, accounting for 63.7% of the variance. Repeated-measures ANOVAs resulted in a significant effect for the fourth factor (F(29,1)=7.86, p< .01, partial η^2=.21). This factor represented higher performance on items 4 (imitation/pretending) and 15 (understanding figurative language) of the NEPSY-II, with individuals in the the Experimental group seeing greater improvement. These items were similar, and unique, in that they both mentioned fingers and required students to think abstractly about this body part.
Conclusions: Results highlight two methods for assessing change in ToM as a result of intervention with *FaceSay*. There was some overlap in the items that were noted by both sets of analyses. Intervention with *FaceSay* led to improvements in imitation and figurative language items. The construct most closely targeted by *FaceSay* is imitation; the game "Follow the Leader" asks students to manipulate one avatar's face to match the facial expression of another. In addition, the game often offers instruction or reinforcement using figurative language, such as "Let's roll!" that offers students additional exposure to this manner of speaking. Future work should continue to explore the beneficial effects of *FaceSay* intervention.

137 **145.137** Understanding the Essential Elements of a Transition Program in Preparing Individuals with Autism Spectrum Disorder for Adulthood

G. Y. H. Lam[1], *J. C. Timmons*[2] *and A. Zalewska*[2], *(1)School Psychology Program, Department of Educational and Psychological Studies, University of South Florida, Tampa, FL, (2)Institute for Community Inclusion, University of Massachusetts Boston, Boston, MA*

Background:
There is an increasing number of individuals with Autism Spectrum Disorders (ASD) entering adulthood. They struggle through the post-school transition to attain promising adult outcomes, such as employment and postsecondary education. A 30-week multi-component community-based transition program provides these young adults with opportunities for self-exploration and career planning through activities such as classroom instruction, internship experience, and peer mentoring.
Objectives:
To understand stakeholders' experiences and to investigate the essential elements in a community-based transition program that aims to promote independence and support post-school outcomes in young adults with ASD.
Methods:
As a part of a program evaluation, 18 stakeholders were recruited to participate in individual semi-structured interviews. A purposeful sampling method was used to recruit a range of stakeholder groups, including program staff, peer mentors, community collaborators, students with ASD, parents, alumni with ASD who had graduated from the program, and alumni's parents. Stakeholders were asked to describe their experience in the program, how their experience contributed to students' growth and development, and recommendations for improvements. All interviews were transcribed verbatim and were subjected to thematic analysis using a constant comparative method, which involved generating themes and codes as well as memo writing.
Results:
Findings from the qualitative data analysis revealed a set of values that permeated all program components, including student-centeredness, strength-based perspective, customized and individualized supports, and organizational and professional development. These fundamental principles pervaded each of the main program components, namely knowledge about self and career, practice in real-world contexts, and support through a safe environment. Throughout the program, both students and parents underwent a period of personal growth and transformation, in which parent transformation was marked by learning to "let go," while student transformation manifested as an emerging confidence in terms of (a) self-awareness, (b) self-esteem, (c) independence, (d) preparedness, and (e) social competence. Stakeholders also identified program barriers and suggested areas of improvement, including (a) strengthening autism awareness training to external collaborators; (b) providing structured support to the internship experience; (c) building partnerships with the local community; (d) providing instructional support to students with diverse abilities; (e) explicating program mission and expectations; (f) providing support to families and peer mentors; and (g) building post-program student and family capacity.
Conclusions:
The present program evaluation revealed essential program features that support youth-to-adulthood transition for individuals with ASD. Poster participants will be able to learn about effective components of a transition program and to incorporate them within their current programs and future endeavors to improve adult outcomes of the ASD populations. Future research could further explore the evidence base of the abovementioned programmatic features with a more vigorous design.

138 **145.138** Using Multiple Informants to Assess Social Functioning and Treatment Outcome for Adolescents with ASD Following the UCLA PEERS® Program

E. Veytsman[1], *C. Ferrendelli*[1], *J. W. Yang*[2], *C. C. Bolton*[1] *and E. A. Laugeson*[1], *(1)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)The Help Group-UCLA Autism Research Alliance, Sherman Oaks, CA*

Background: Assessment of social functioning of youth with social challenges consistent with Autism Spectrum Disorder (ASD) is complicated by conflicting informant perceptions. For youth with ASD, self-report of symptoms of psychiatric diagnoses should be interpreted with caution (Mazefsky et al. 2011), as this population has shown poor diagnostic agreement with parents (Storch et al. 2012), underscoring the need for multiple informants, including teachers and therapists. Research shows concordance rates between parent and adolescent report are widely heterogeneous, dependent upon the instrument, the disorders under investigation, and the informant characteristics (Mazefsky et al. 2011). Understanding the discrepancy between parent, teacher, and self-report of social functioning and treatment outcome among youth with social challenges is critical for determining the most reliable informants.
Objectives: The current study examines perspectives from multiple informants following a 14-week evidence-based social skills intervention for adolescents with ASD in order to investigate perceptual differences of social skills functioning and changes over time.
Methods: Participants included 239 adolescents with ASD referred for social skills training in outpatient and school settings. Among the clinic sample, participants included 133 adolescents (males=110; females=23) 11-18 years of age (M=14.02, SD=1.79) with ASD who attended 14 sessions of a weekly 90-minute social skills group with their parents using the Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson & Frankel 2010). Within the school sample, participants included 106 adolescents (males=86; females=20) 11-18 years of age (M=15.08, SD=1.82) with ASD who received daily teacher-facilitated social skills instruction in the classroom using the PEERS®school-based curriculum (Laugeson 2014). In order to assess perceptual differences of social functioning, adolescents and parents completed the Social Anxiety Scale (SAS; La Greca 1999), Quality of Socialization Questionnaire (QSQ; Frankel & Mintz 2008), and Empathy Quotient (EQ; Baron-Cohen & Wheelwright 2004) at pre and post-test. Parents and teachers also completed the Social Skills Improvement System (SSIS; Gresham & Elliott 2008) and Social Responsiveness Scale (SRS; Constantino 2005) pre and post-treatment. Paired sample T-tests and Pearson product-moment correlations were conducted to examine informant perceptions of adolescent social functioning across settings, and Bonferroni adjustments were made.

Results: Results reveal moderate and significant correlations between parent, adolescent and teacher report for measures of social functioning. However, there were significant differences (*p's*<.001) between parent and adolescent report of social anxiety and engagement, and parent and teacher report of social skills and autism symptoms at baseline and post-treatment. These differences decrease at post-treatment across measures in both samples, signifying increased agreement between informants following intervention. Conversely, differences in adolescent and parent report of social engagement measured by the QSQ significantly (*p*<.001) increase at post-treatment in the school-based sample.
Conclusions: This study highlights the complexity of using multiple informants in the assessment of social skills across settings. Although significant differences between reporters decreased over time in the outpatient sample following treatment, the increase in differences in the school-based sample may be explained by less parent involvement in this setting. The results demonstrate the need for multiple informants in social skills assessments.

Table 1, *Concurrent Validity of Parent and Adolescent Report of Social-Engagement Post Treatment*

	QSQ Parent Report		
	r	*p*	*N*
Teen report: Hosted get-togethers (Clinic)	.31	< .001	111
Teen report: Invited get-togethers (Clinic)	.31	< .001	111
Teen report: Hosted get-togethers (School)	.44	< .000	76
Teen report: Invited get-togethers (School)	.18	.31	76

Note. Pairwise deletion was used in the calculation of bivariate correlation coefficients, resulting in small decreases for the sample sizes across the measures included in this analysis. QSQ=Quality of Socialization Questionnaire (Frankel & Mintz, 2008).

139 **145.139** Using Peers As Supports for Adult College Students with ASD

J. Hooker[1], *L. Morgan*[2], *T. Dasher*[2] *and A. Leatzow*[2], *(1)Communication Science and Disorders, Florida State University, Tallahassee, FL, (2)Florida State University Autism Institute, Tallahassee, FL*

Background:

As a result of the increased prevalence rate (CDC, 2014), a larger of population of individuals with autism spectrum disorder (ASD) and normal intelligence are transitioning into college. While 'high functioning' individuals have the intellectual capability to participate in postsecondary education, their success is often stymied by difficulties in the areas of executive functioning, social communication, and mental health. Currently, these challenges are met with a dearth of research examining the effectiveness of supports and programs designed to promote success (Gelbar, Smith, & Reichow, 2014), highlighting the need for systematic studies with this population.

Objectives:

This study seeks to evaluate the initial effectiveness of the *College Peer Coach Program* for adult college students with ASD. We hypothesize that adults who participate in the program will report positive gains on measures of well-being and executive functioning between baseline and post-intervention.

Methods:

Five adults diagnosed with ASD, currently enrolled at a local post-secondary institution, were initially recruited for the current study. Participants, all of whom are male, range in age (18 to 24) and academic rank (1 freshman, 3 sophomores, and 1 junior). A series of self-report measures related to well-being (e.g., WHOQOL-BREF, GAD-7, PHQ-9), executive functioning (BRIEF-A), and reported needs (College Student Needs Assessment) are administered at the start and conclusion of each semester. Participants were randomly assigned to a trained, undergraduate Peer Coach to meet on a weekly basis for 12 weeks each semester of participation. Peer Coaches were trained to support participants in areas related to social participation, communication, college adjustment, and independence using four strategies either evidence-based for children and adolescents with ASD or recommended for college students with ASD by experts in the literature: visual supports, role-playing, direct questioning, and environmental arrangements (Wong, et al., 2014; Wolf, Brown, & Bork, 2009; VanBergeijk, Klin, & Volkmar, 2008).

Results:

Preliminary analyses of baseline measures (N=5) confirm significant need in the areas of social participation, executive functioning, and well-being. WHOQOL-BREF scores indicated lower quality of life ratings in the social domain (mean domain score = 9.00) compared to averages of a larger sample of individuals with similar demographics (Skevington, Lotfy, & O'Connell, 2004). BRIEF-A scores highlight difficulties in the area of metacognition, (mean T-score= 62.00); with the greater difficulty reported on the initiating, shifting attention, and planning/organizing subscales (mean T-scores: 60.00 for all). Participants also endorsed an elevated number of depression symptoms according to PHQ-9 scores (mean= 5.8). An additional three to five participants will be recruited during the following semester. Pre-intervention and post-intervention score differences on all outcome measures will be presented.

Conclusions:

These preliminary results provide an indication of challenges reported by current college students with ASD. In concordance with the literature, this sample experiences particular difficulties in the areas of executive functioning and social participation. Future analysis of the relationship between peer support and outcome measures will be discussed.

140 **145.140** Using a Parent-Assisted Gaming Intervention to Improve the Social-Emotional Skills of Children with Autism Spectrum Disorders – a Randomized Controlled Trial

R. B. Beaumont[1]*, H. A. Walker*[2] *and K. Sofronoff*[3]*, (1)Social Skills Training Institute, St Lucia, QLD, Australia, (2)School of Psychology, University of Queensland, St Lucia, Australia, (3)School of Psychology, University of Queensland, Brisbane, QLD, Australia*

Background:

Families living in remote locations often have limited access to specialist Autism Spectrum Disorder (ASD) services. Tele-health services offer a cost-effective, practical solution to this problem. Few studies have evaluated the utility of this approach for parents of children with ASD, however, particularly in the domain of social-emotional skills training.

Objectives:

To evaluate the effectiveness of the Secret Agent Society Computer Game Pack (SAS) with weekly online/telephone group parent support in improving the emotion regulation and social skills of children with ASD.

Methods:

Seventy children with ASD (60 males, 10 females) aged between 7 and 12 years (M= 9.89, SD = 1.37) and their parents participated in the trial. All children had cognitive abilities at least within the average range and were recruited from three Australian states. Parents were primarily married, of European ethnicity and tertiary educated. Families were randomised to the SAS or CIA conditions. The SAS condition involved parents participating in a 150 minute group Skype introductory meeting with the lead trial researcher, followed by 10 weekly group phone or Skype informal support sessions. These sessions focused on helping parents to problem-solve challenges in helping their child to play the SAS computer game each week and to complete associated skills practice tasks ('Home Missions'), described in a brief program delivery guide. Computer game activities taught children how to recognise emotions and apply emotion regulation strategies when facing social challenges.
The CIA condition involved a comparable level of online/Skype group parent support provided by the same researcher, with parents helping their child to complete non-therapeutic activities from an online Central Intelligence Agency website for kids (described in a program delivery guide) over a 10 week period.

Results:

Intention to treat Mixed-Model ANOVAs showed that SAS participants made significantly greater improvements than CIA participants on parent report measures of emotion regulation and social skills (ERSSQ-P; $p < .0005$) and social skills (Spence Social Skills Questionnaire–Parent version (SSQ-P); $p<.0005$) from pre- to post-treatment. Children in the SAS group also showed greater improvements in their knowledge of anxiety management strategies than those in the CIA condition on a story-based task (James and the Maths Test; $p= .001$). There was no difference between SAS and CIA participants' improvements in knowledge of appropriate anger management strategies on a similar task (Dylan is Being Teased), however ($p =.18$). On teacher-report measures, there was no difference in the improvement made by participants in the SAS and CIA conditions ($p=.60$) on a measure of emotion regulation and social skills (ERSSQ-T). However, there was a greater improvement in teacher ratings on an independent social skills measure (SSQ-T) for the SAS group relative to the CIA group ($p = .04$). Results from analysing webcam footage of children's use of emotion regulation strategies when playing a frustrating computer game at pre- and post-treatment are pending, and will be presented.

Conclusions:

Results suggest that the parent-assisted gaming intervention may be an effective social-emotional skills training option for families of children with ASD who have limited access to services.

141 **145.141** Vocational Rehabilitation Service Use Among Youth and Young Adults with Autism: Comparing Students and Non-Students

J. Rast[1]*, P. Shattuck*[2] *and K. A. Anderson*[1]*, (1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Vocational rehabilitation (VR) provides a wide array of services (such as rehabilitation counseling, job skills training and job placement) to help facilitate employment among people with disabilities, including those with autism. Studies suggest that an individual's probability of employment varies by the types of VR services he/she receives. The types of services that a client receives through VR may differ between individuals who are and are not enrolled in school. Because the use of specific services during VR is known to be associated with an employment outcome, studying the pattern of service use in different types of users is important. Understanding patterns of service use may lead to a better understanding of the interaction of the VR system with different groups of VR users.
Objectives: We aim to identify service use patterns in VR users with autism, classifying separately those who enter VR as high school students, other students, and non-students.
Methods: Data came from the federal Rehabilitation Services Administration (RSA) 911 database which contains records for cases closed by state VR agencies. We analyzed data for 8531 clients with autism under the age of 25 who received services and had a case closed in 2013. We used latent class analysis to identify classes of individuals with autism with differing service use patterns, separating high school students, other students, and non-students at the time of VR application.
Results: Half of clients with autism under the age of 25 apply for VR while they are a student and of those, almost 75% are high school students. Among students, there are four clear types of VR service users: light users who receive one or two services, light users who receive mostly VR counseling and one or two other services, medium users who receive VR counseling and practical job assistance (such as placement and supports), and heavy users that often receive five or more services. The main difference between high school students and other students is that high school students more often receive information and referral services than other students. There are more differences in service use patterns between students and non-students. Non-students fall into three classes of users which share general characteristics of student users: light users who use one to three services, users who receive few services but do get VR counseling, and heavy users who receive five or more services.
Conclusions: The different patterns of service use between high school students, other students, and non-students may be linked to practices in place for different types of applicants. However, the variability within a single group may be related to differing levels of need or levels of unmet need in some of the users. In addition to seeing the variability in type and number of services provided, the presence of a pattern of light service use in all three groups suggests there is room for intervention to improve VR provision for all clients.

142 **145.142** Workplace Social Skills Program Evaluation for Young Adults with Autism Spectrum Disorder

H. Thomas *and T. P. Gabrielsen, Brigham Young University, Provo, UT*

Background: Social skills are among the primary deficits of young adults with autism spectrum disorder (ASD). The outcome of such social impairments not only hinders peer and familial relations, but also creates a difficulty in obtaining and maintaining employment. Those with ASD find it difficult to interview for job positions, socialize appropriately with coworkers and the public as well as adapt to changes in normal work environments. A wide range of studies have focused on interventions to improve

social skills; however, very few have specifically addressed social skills in the workplace. Located in Utah, Easter Seals Goodwill Northern Rocky Mountains (ESGW) has created a nine-week transition program called Peer Connections, designed to help young adults with disabilities gain skills and independence, as a direct response to individual needs in the disability community. Peer Connections seeks to improve workplace social skills of individuals with high functioning autism or other social communication disorders who are transitioning to adulthood in accordance with the Individuals with Disabilities Education Improvement Act (IDEIA).
Objectives: This study examines the effectiveness of Peer Connections' supported experience with peers, adult coaching, feedback, and self-evaluation in a volunteer work environment. Participants were paired with typical peers as "co-workers" and assigned a work site (e.g., Museum of Natural Curiosity) to combine natural social supports with instruction and practice in working with the public and meeting the demands of a job. Because ESGW is not a research institution, Peer Connections has never been evaluated and therefore partnered with BYU to obtain objective evidence regarding its effectiveness.
Methods: Participants in the program were predominantly male between the ages of 15-24. Participants underwent eight hours of extensive preliminary assessments, provided by ESGW, before the interventions were implemented. These assessments were used as baseline data and were compared with end of program assessments. Both a peer and site facilitator observed participants during their public interface time each week and completed an ESGW feedback form. Additional social skills assessments and self-reported inventories were used on a weekly basis to guide skill development goals. Participant performance was measured periodically using the SRS-2, SRSS, and self-report (SRS-2) in addition to weekly on-site observations. Participant assessments from past years were also analyzed. Follow-up measures and observational generalization probes were performed.
Results: Preliminary results suggest observable changes in coping skills, conversation initiation, maintaining conversations, and eye contact. Post-intervention assessments by self-report typically declined compared to pre-intervention, possibly an indication of increased insight into areas for improvement. Social validity assessment indicates that participants liked the intervention, felt they had improved, would recommend it, and would do it again. Generalization probes are ongoing to determine maintenance effects outside of the training environment.
Conclusions: Peer support, adult coaching, feedback, and self-evaluation in a real work environment may positively increase social skills in the workplace for individuals with ASD. Separate from vocational training, this study will fill a gap in the literature and in practice on social skills intervention for workplace conditions.

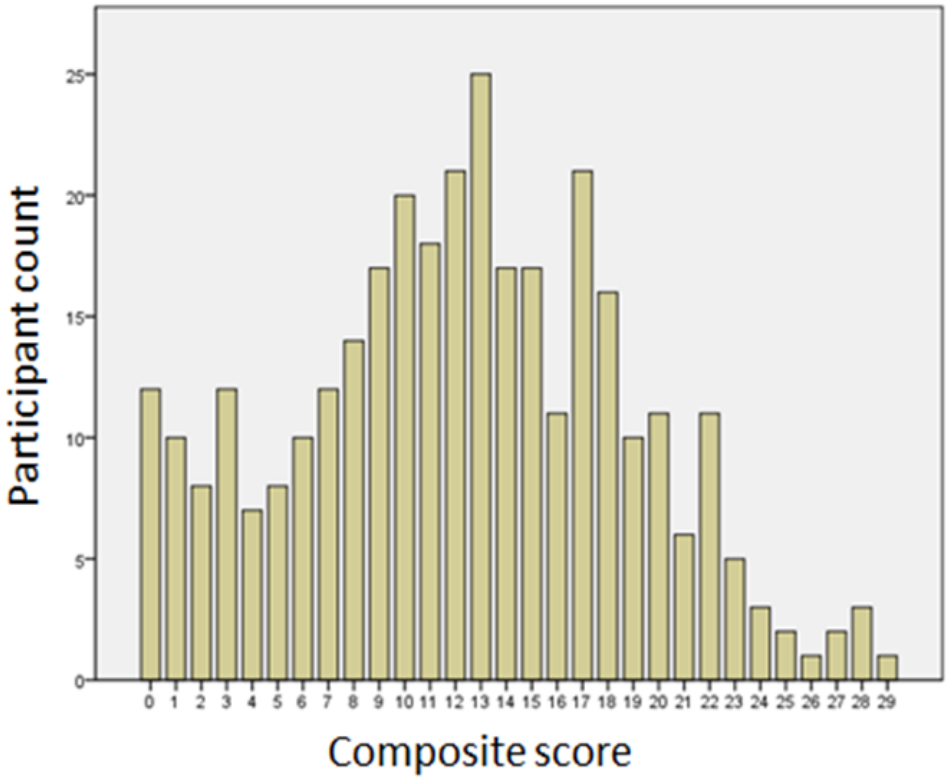
Poster Session
146 - Sensory, Motor, and Repetitive Behaviors and Interests
11:30 AM - 1:30 PM - Hall A

143 **146.143** A Parent-Report Measure of Restricted and Repetitive Behaviors for Early Childhood

J. J. Wolff[1], *B. Boyd*[2] *and J. T. Elison*[3], *(1)University of Minnesota, University of Minnesota, Minneapolis, MN, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)University of Minnesota, Minneapolis, MN*

Background: Restricted and repetitive behaviors (RRBs) are defining features of autism spectrum disorder (ASD) which emerge early in life and may differentiate children who do and do not develop the disorder during toddlerhood (Wolff et al., 2014; Elison et al. 2014). These behaviors also occur as part of typical early development, supporting the acquisition of more complex and goal-directed behavior (Evans et al., 1997; Thelen 1979). Existing paper and pencil measures of RRBs are largely anchored in pathological features seen in older children and adults. As a result, they and are not intended to capture individual differences in restricted and repetitive behaviors among young children.
Objectives: Our goals were twofold: 1) To adapt the Repetitive Behavior Scale, Revised (RBS-R; Bodfish et al., 2000) for use among typically and atypically developing children during early childhood; and 2) To collect pilot data on the measure from a large cohort of typically developing children.
Methods: We developed the Repetitive Behavior Scale for Early Childhood (RBS-EC), a brief (~10 minute) parent report measure consisting of 34 items. The measure is comprised of 4 subscales constituting categories of repetitive behavior congruent with existing measures and theoretical constructs: repetitive motor, self-directed/self-injurious, restricted, and ritual/routine. Unlike most existing measures, the RBS-EC focuses on frequencies (rather than severity) of behavior and yields both subscale and total scores for frequency and behaviors endorsed. Content validation was performed through feedback from outside experts in repetitive behavior and child development. Initial beta testing and feedback was obtained from parents of both typically and atypically developing children (infants through early school age). We performed preliminary psychometric analyses of 330 data sets collected from parents of 18 to 25 month-old children. The data were ascertained from a quasi-epidemiological sample recruited from the Institute of Child Development's research registry as part of a larger study investigating quantitative phenotypes in young children.
Results: The distribution of total repetitive behavior endorsed scores is presented in Figure 1. Internal consistency for the total RBS-EC was excellent ($\alpha = 0.91$). For subscales, internal consistency ranged from adequate to excellent (repetitive motor: $\alpha = 0.94$; self-injurious: 0.74; restricted: 0.81; ritualistic: 0.78). Test-retest reliability for total and subscale scores were in the excellent range (ICC > 0.90).
Conclusions: Initial results suggest that the RBS-EC is sensitive to individual differences in repetitive behaviors among typically developing toddlers, providing highly dimensional behavioral data. This is in contrast to the floor effects seen in the application of more clinically-oriented and less developmentally appropriate measures of repetitive behavior to typically developing young children. Next steps include examining the RBS-EC factor structure and psychometric properties in our full sample of 800+ children as well as expanding our sample to include children of different ages and children who are developing atypically.

Figure 1. Distribution of total repetitive behaviors endorsed for n = 330 toddlers



144 **146.144** A Study of Assessments: A Comparison of Bsiq and RBS-R Reported Rrbs

S. M. Attar, *P. C. Hickey and E. Hanson, Developmental Medicine Center, Boston Children's Hospital, Boston, MA*

Background: Restricted and repetitive behaviors (RRBs) include a broad category of behaviors which are considered core characteristics required for a diagnosis of Autism Spectrum Disorder (ASD) according to the Diagnostic and Statistical Manual (DSM-V; American Psychiatric Association, 2013). Parents have often reported that RRBs can be the most stressful aspect of ASD (Bishop, Richler, Cain & Lord, 2007). RRBs can be subdivided into repetitive and sensory motor behaviors (RSM) and Insistence on Sameness behaviors (IS). This study analyzes the difference between RRB IS, RSM, and Total composite scores as measured by two assessments: the Behavior and Sensory Interest Questionnaire (BSIQ) (Hanson et. al. 2015) and the Repetitive Behaviors Scale – Revised (RBS-R) (Bodfish, Symons & Lewis, 2000).
Objectives: This study aims to assess if the BSIQ and RBS-R report the same number of presenting RRBs.
Methods: A sample of 513 children with ASD (82% male) was drawn from the Simons Simplex Collection and the Boston Autism Consortium. Participant ages were between 24-216 months, (mean=92.3, SD=45). ASD diagnosis was verified with the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R). Parents were administered the BSIQ, designed to evaluate the number, type, and intensity of RRBs, by a trained clinician. The RBS-R, also designed to evaluate the number, type, and intensity of RRBs, is a parent report survey that parents completed independently. Preliminary analysis included descriptive statistics and a series of paired-T tests to determine if a significant difference exists between IS, RSM, and Total composite scores on the BSIQ and RBS-R within the same population. The severity scale on both measures (0-3) was collapsed to a Yes/No binary for all statistics.
Results: Preliminary analyses revealed a significant difference (.000) in the percent of behaviors reported on the BSIQ versus the RBS-R for RSM scores. 25% of respondents reported the presence of an RSM behavior on the BSIQ as compared to 29% on the RBS-R. Preliminary analyses revealed a marginally significant difference (.09) in the percent of behaviors reported on the BSIQ versus the RBS-R for IS scores. On average, 22% of respondents reported the presence of an IS behavior on the BSIQ as compared to 24% on the RBS-R. Preliminary analyses revealed that there is not a significant difference (.000) in the percent of overall behaviors reported on the BSIQ versus the RBS-R for Total Scores.
Conclusions: These preliminary analyses suggest that respondents are more likely to report a behavior on the RBS-R than on the BSIQ. It is possible that the BSIQ's specificity and clinical judgment results in less RRB quantity but a more accurate account of presenting RRBs and their severity. Further research should examine if a difference is reported specifically in the severity of behaviors on the RBS-R versus the BSIQ. As well, additional studies are required to determine which assessment method provides the most accurate measurement of presenting RRBs.

145 **146.145** An fMRI Investigation of Audiovisual, Auditory and Visual Processing in Autism Spectrum Disorder

P. Regener[1,2], *S. A. Love*[3], *K. Petrini*[4] *and F. E. Pollick*[5], *(1)School of Psychology, Glasgow University, Glasgow, United Kingdom, (2)Glasgow University, Glasgow, United Kingdom, (3)Institut de Neurosciences de la Timone, Marseille, France, (4)Department of Psychology, University of Bath, Bath, United Kingdom, (5)University of Glasgow, Glasgow, United Kingdom*

Background:
The ability to integrate auditory and visual information is crucial to everyday life. Behavioural results have predominantly shown that individuals with Autism Spectrum Disorder (ASD) have deficits in audiovisual integration. These findings have recently been supported by electroencephalography (EEG) studies (Brandwein et al., 2015).
Objectives:
There are limited data from functional magnetic resonance imaging (fMRI) studies investigating audiovisual processing in ASD. To address this issue and to reveal brain areas involved in audiovisual processing, the current fMRI study looked at audiovisual, unisensory auditory and unisensory visual processing in ASD. Two types of stimuli were used, complex social face-voice (FV) displays and simple non-social beep-flash (BF) displays.
Methods:
Participants included 13 adult males with ASD and age and 13 IQ-matched typically developed (TD) males. FV displays included an audiovisual condition of a face moving to say a single word and the voice saying the word, an auditory condition of a voice, and a visual condition a face moving to say a word. Similarly the BF displays included an audiovisual condition of a beep with a flashing circle, an auditory condition of a beep, and a visual condition of a flashing circle. The BOLD signal was obtained while participants were presented with blocks of audiovisual, auditory and visual conditions of FV and BF displays.
Results:
A random effects analysis contrasting groups revealed that processing of audiovisual as well as auditory and visual stimulus conditions in both the FV and BF displays was associated with reduced activation in ASD. Audiovisual, auditory and visual conditions of FV stimuli revealed reduced activation in ASD in regions of the frontal cortex, while BF stimuli revealed reduced activation in the lingual gyri. The inferior parietal gyrus revealed an interaction between sensory condition of BF displays and group.
A conjunction analysis was performed to show areas of audiovisual processing and revealed that the bilateral superior temporal cortex (STC) was sensitive to audiovisual information in ASD and TD for both types of displays. However, the activation regions of the STC were smaller in the ASD group. Additionally a superior frontal area was shown to be sensitive to audiovisual FV displays in the TD group, but not in the ASD group.
Conclusions:

Overall this study indicated differences in brain activity for audiovisual, auditory and visual processing of social FV and non-social BF displays in ASD compared to TD. These results were mainly characterized by the ASD group showing less activation than the TD group in auditory, visual and audiovisual regions. In addition, differences were found in frontal cortex for FV displays.

146 **146.146** Analyzing How Autism Severity Affects Motor and Social Skills: An Exploration Using the SFARI Base Dataset

A. M. Colombo-Dougovito[1] *and R. E. Reeve*[2]*, (1)University of Virginia, Charlottesville, VA, (2)University of Virginia, Earlysville, VA*

Background: Social skill deficits and repetitive behaviors are the defining features evaluated during autism spectrum disorder (ASD) diagnostic assessments. Assessment tools, such as the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2; Lord, Rutter, Di Lavore, & Risi, 2002; Lord et al., 1989), evaluate the level of impairment within these two characteristics to provide an understanding of the extent of the disorder. In addition to the typical deficits associated with ASD, a growing body of research suggests that gross motor deficits are also present in most children with ASD (Liu & Breslin, 2013; Lloyd, MacDonald, & Lord, 2013; Staples & Reid, 2010). However, little is known about the effect of severity has on social and gross motor skills in children with ASD.

Objectives: The purposes of this study are to determine: (1) What effect does the level of severity have on the motor skills and social skills in children with ASD?, and (2) If a difference exists between severity groups, which dependent variable has the greatest effect?

Methods: Utilizing a sub-sample from the SFARI base dataset, a MANOVA was used to understand differences among the multivariate means of social skills and gross motor skills of 483 children with autism and autism spectrum disorder. The present sample was divided into two groups based on ADOS-2 severity output: (a) those diagnosed with autism (i.e., more severe, $N = 444$), and (b) those diagnosed with autism-spectrum (less severe, $N = 39$). Average age of the participants was 66.27 months or about 5.6 years of age. Mean for participants diagnosed with autism was 66.48, and mean for participants diagnosed with autism-spectrum was 63.92 (group differences were non-significant, $t_{(481)}=1.152$, $p = 0.250$).

Results: Wilk's criterion indicated the combined dependent variables were non-significantly affected by severity of the autism diagnosis, multivariate $F_{(2, 480)} = 1.640$, $p = 0.195$. Analysis of the between-subject effects univariate test further revealed a non-significant difference between the groups on gross motor scores, $F_{(1, 201.883)} = 1.303$, $p = 0.254$. Participants in the less severe group (autism-spectrum) scored arithmetically higher ($M = 83.31$) than those in the more severe (autism) group ($M = 80.93$). This non-significant difference was also seen in the social skill univariate evaluation, $F_{(1, 4535.986)} = 2.242$, $p = 0.135$. While the less severe group ($M = 70.62$) again scored higher in social skills than the more severe group ($M = 59.37$), as would be expected, differences were non-significant. Effect sizes further demonstrate a weak association between the gross motor and social skill of the groups, partial $\eta^2 = 0.003$ and partial $\eta^2 = 0.005$ respectively.

Conclusions: Results suggest that little difference exists between severity groups on gross motor and social skills; however, results may be limited to the age range of the participants (about 5.6 years of age). Differences in groups may become greater as children age. This analysis suggests that at a young age (about 5 years of age) there is little difference between severity groups within ASD and the severity of gross motor and social skills.

147 **146.147** Anticipatory Gaze during Action Observation: Impact of Social Training on Children with ASD

J. L. Haworth[1], *K. Libertus*[2] *and R. Landa*[1], *(1)The Kennedy Krieger Institute, Baltimore, MD, (2)University of Pittsburgh, Pittsburgh, PA*

Background:
Anticipatory gaze in the context of goal directed hand actions are typically observed in children by their second year of life (Falck-Ytter, 2006; von Hofsten, 2004). Though, previous findings suggest that children with ASD tend to focus on mechanical properties of motion, with deficiency in social perception and attention to social activities (von Hofsten, 2009; Shic, 2011). With current intervention efforts to encourage social skills development (Kasari, 2012; Landa et al., 2011), it remains to be seen how goal-directed gaze is impacted by newly developed attentional biases (Chawarska, 2010).
Objectives:
Determine whether targeted social skills intervention improves social attention, without detriment to goal-directed attention and understanding of others' object interaction.
Methods:
Eighteen children with ASD participated in 5-months of parent-training (n=10), or 'combined'-training (n=8) where parent-training was augmented with classroom training to promote social interaction with targets including (a) face-processing: attention to faces, face recognition; (b) social-anticipation: attention to human motion, action and intention understanding; and (c) imitation: recognition of being imitated, imitation of others' actions. Groups were similar on age, ADOS combined severity score, and Hollingshead (*ps*>.05, independent-samples-t-test).
We examined children's anticipatory gaze while viewing a social agent (14-month-old toddler) moving a series of blocks across a table, with a cross-body motion, to a clear

bowl. In trial1 (movement of first block), the actor looked at the bowl immediately upon touching the block. In trial2, a social gaze occurred where the actor first looked to the left – away from the target bowl. Children viewed this video-sequence in a dimly lit room, monitored by remote eye-tracker (Tobii X-120). Arrival of participants' gaze to the bowl (target) in relation to arrival of the actor's hand was measured in milliseconds, to assess their ability to anticipate the outcome of the actor's action. Aggregate percentage of fixation times at the face and hand areas of interest (AOI) also were measured.
A three-way mixed ANOVA (Trial*Time*Group) assessed differences in anticipation times, with separate three-way mixed ANOVA (Time*Group*AOI) assessing differences in fixations to hand and face AOIs.
Results:
Missing data (T1Pre=1; T2Pre=2; T1Post=3; T2Post=4) was replaced by multiple-imputation with 10-iterations. We found a significant Trial*Time*Condition interaction, across all imputations (mean p=.011±0.0097). The Time*Group*AOI interaction was also significant (p=0.022, η_p^2=0.285).
Conclusions:
The Combined-training group progressed from a pre-intervention strong tendency to allocate attention to the moving hand in the scene to a post-intervention allocation of attention to socially relevant stimuli (the actor's face). This, without losing awareness of the actor's relocating of the blocks from the table to the bowl as indicated by preserved goal-directed anticipatory gaze. Thus, increased social interest does not impede the ability of children in the Combined-training group to attend to the task-relevant features in the dynamic scene (i.e., they still afforded attention to the bowl at the appropriate time to observe the block arrival). The Parent-training only group demonstrates *decreased* interest in the face AOI and *increased* attention to the hand from pre- to post-intervention, and increased degree of anticipatory gaze to the bowl from pre- to post-intervention.

Figure 1. Images to illustrate the Action Anticipation task

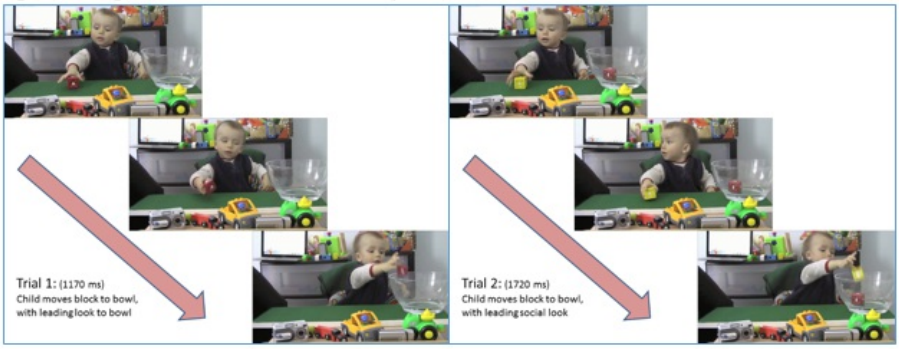

Figure 2. Gaze arrival to target location relative to block arrival (anticipatory look time), in milliseconds. More negative numbers indicate earlier arrival of gaze to the target, preceding block arrival. Pre-Post group means on trials 1 & 2 are plotted separately, and on separate plots for a) Combined-training and b) Parent-training only groups. Percent of time looking at each defined area of interest, c) Face and d) Hand during the Action Anticipation eye tracking task, plotted separately for each treatment group at pre- and post-intervention.

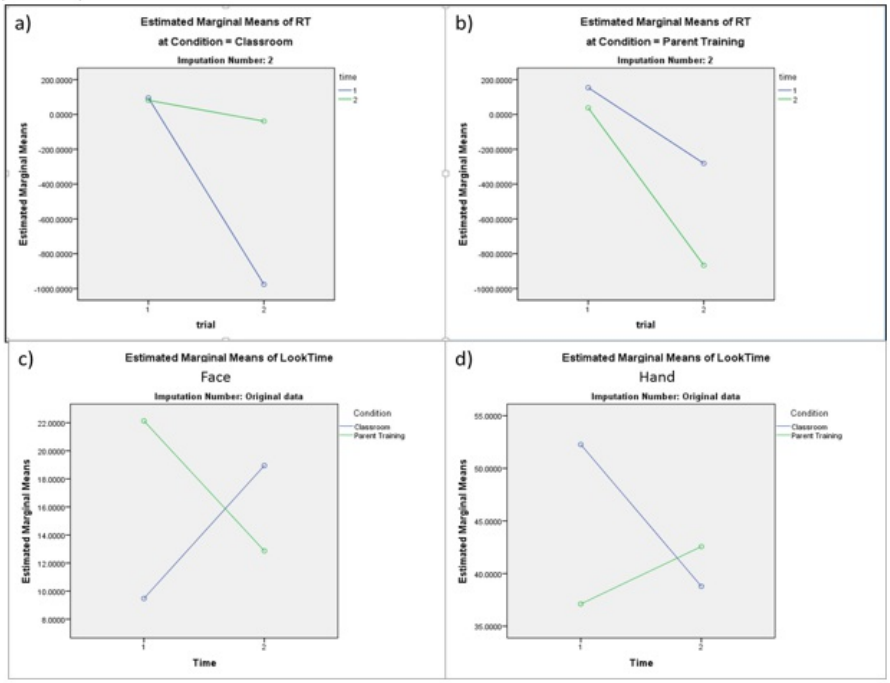


148 **146.148** Are Sensory Problems in ASD Really Sensory?

M. Zinni[1,2], M. Westerfield[3], L. E. Mash[1,4], S. Wee[1], L. Chukoskie[3] and ***J. Townsend***[1]*, (1)Department of Neurosciences, University of California, San Diego, La Jolla, CA, (2)Neuroverse, Inc., San Diego, CA, (3)The Institute for Neural Computation, University of California, San Diego, La Jolla, CA, (4)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA*

Background: Abnormal sensory responses are a commonly reported clinical feature of autism spectrum disorder (ASD). Sensory symptoms are assessed by a number of standardized questionnaires; studies based on these second-hand, self- or observational reports find increased rates of sensation seeking and/or sensation avoidance in all sensory modalities in ASD. Despite the general consensus that abnormal sensory function is an important clinical feature of autism, there is little or no understanding of the underlying mechanisms. Further, because the vast majority of evidence regarding these symptoms is based solely on behavioral descriptions, it is not clear if these symptoms are truly sensory in nature or if alternatively, they reflect abnormalities in general arousal or attention. Because our previous work suggests that abnormal sensory processing in ASD may be driven by impaired control of attention and arousal, we suggest that what appears to be abnormal sensory function in ASD may result from interactions of attention and arousal with sensory processing.
Objectives: Our goal was to investigate underlying sources of sensory symptoms by assessing critical components of sensory processing (e.g., sensory habituation and neural refraction) and the influence of attention and physiological arousal on sensory responsiveness.
Methods: Study participants were adults with ASD and a typically developing (TD) adult comparison group. Participants completed three experiments utilizing behavioral, event-related brain potential (ERP) and heart-rate (HR & HRV) measures to examine neural sensory responses to: auditory stimulation; changes in intensity of auditory stimulation; repeated auditory stimulation (refractory and habituation responses). During these experiments, we also examined the effects of physiological arousal and attention on brain responses to sensory stimulation.
Results: Adults with ASD reported significant sensory problems on the Sensory Profile Questionnaire (Brown & Dunn, 2002), suggesting that sensory difficulties persist

throughout the lifespan. Physiological measures, however, did not support a true sensory origin of these symptoms. ERP responses to auditory stimuli of varying intensity were similar in amplitude between ASD and TD groups. Also, ASD adults, like TD adults showed the expected refractory response to a repeated sensory stimulus (i.e., the sensory response to the second of a pair of stimuli was smaller). However, gradual habituation over time was atypical in ASD, but only when sensory stimulation was unattended. That is, response to irrelevant background sounds did not diminish over time in ASD adults; in TD adults there was little sensory response to these repeated background stimuli after only several minutes. Additionally, baseline arousal differed between groups as measured by HR & HRV, and greater arousal was observed in the ASD group during the presentation of auditory tones.
Conclusions: These findings suggest that in adults with ASD, sensory difficulties that are experienced in daily life may be a function of differences in the modulation of general arousal and the effects of attentional state rather than abnormalities in basic sensory response. Understanding the nature of sensory abnormalities and the processing level (sensory, arousal, attention) at which sensory behavior is perturbed can guide development of more specific treatment of these troublesome symptoms.

149 **146.149** Association of Somatosensory Difficulties with Behavioral Problems in Children with Autism Spectrum Disorder

W. Overcast[1], *A. Shui*[2], *A. R. Narayanan*[3], *J. Walton*[4] *and D. L. Coury*[3], *(1)The Ohio State University College of Medicine, Columbus, OH, (2)Massachusetts General Hospital, Boston, MA, (3)Nationwide Children's Hospital, Columbus, OH, (4)Pediatrics, Nationwide Children's Hospital, Columbus, OH*

Background: Somatosensory difficulties manifest as hyper- or hypo-reactivity across the senses and are found in the large majority of children with Autism Spectrum Disorder (ASD). Previous studies have demonstrated a relationship between sensory difficulties and problem behaviors. We sought to expand on these studies by examining multiple problem behavior measures and using a large cross-sectional sample.
Objectives: We sought to determine the relationship between somatosensory difficulties and problem behaviors in children with ASD, including investigation of the relation of individual somatosensory domains with specific problem behaviors.
Methods: This retrospective study used data collected through member centers of the Autism Speaks Autism Treatment Network. Our study included 6,902 children and adolescents under the age of 18 years who had been diagnosed with ASD. We analyzed the Short Sensory Profile (SSP) total score and subscale scores as measures of somatosensory difficulties and their associations with problem behaviors as measured by the total and subscale scores of the Child Behavior Checklist (CBCL) and Aberrant Behavior Checklist (ABC) and the Autism Diagnostic Observation Schedule (ADOS) Tantrums, Aggression, Negative or Disruptive Behavior item., Linear regression and polytomous logistic regression were used for continuous and categorical behavioral problems, respectively, adjusting for gender, age, DSM-IV diagnosis, IQ, race, ethnicity, primary caregiver education level, insurance status, any psychological problem status, taking stimulant, and taking SSRI. A Bonferroni correction was applied to account for analyzing multiple behavioral problems variables for each somatosensory domain.
Results: The majority of children in the sample were male, Caucasian, and had an IQ of 70 or more. Baseline psychological problems (ADHD, anxiety, disruptive behavior, other psychiatric problem) were reported in 15.5%. The mean age at informed consent was 6.2 years. After controlling for covariates, there were significant associations between behavioral and somatosensory problems. Children with fewer somatosensory symptoms had fewer behavioral problem symptoms as measured by CBCL and ABC. For each unit increase in SSP Tactile Sensitivity score (=less sensitivity), ABC Irritability score were lower (=less irritable) by 0.76 units. Hyperactivity and total aberrant behavior were higher in children with lower auditory filtering difficulties (ß=-1.11 and -2.94, respectively). Of the sensory difficulties, for each unit reduction in sensation seeking, rule breaking behavior score were lower by 0.05 unit. Lower conduct problems are associated most with higher auditory filtering and sensation seeking (ß=-0.05 for both). Average levels of aggressive behavior were higher among children with higher scores on tactile sensitivity, movement sensitivity, auditory filtering and sensation seeking (ß=-0.06 for all).
Conclusions: Our study demonstrates a strong relationship between somatosensory difficulties and problem behaviors in a cross-sectional sample of children with ASD. Our characterization of the relationship between individual sensory and behavioral domains may aid targeting of sensory therapies, with subsequent behavioral problem improvement.

150 **146.150** Attention Training in Children with Sensory Processing Disorder

J. A. Anguera[1], *A. Brandes-Aitken*[2], *C. Rolle*[3], *B. Wu*[4], *E. Martucci*[5], *J. Bower*[5], *A. Gazzaley*[6] *and E. J. Marco*[2], *(1)Neurology, UCSF SNAP, San Francisco, CA, (2)University of California in San Francisco, San Francisco, CA, (3)Stanford University, Palo Alto, CA, (4)Neurology, UCSF SNAP, San Francisco, CA, (5)Akili Interactive, Boston, MA, (6)Neurology, UCSF, San Francisco, CA*

Background:
Sensory Processing Disorders (SPD) negatively affect a child's ability to process incoming stimuli and can disrupt cognitive and social development. It has been estimated that 40% of children with SPD will meet diagnostic criteria for Attention Deficit and Hyperactivity Disorder (ADHD). Previously, we have documented baseline deficits in response time variability on measures of sustained attention in our SPD cohort.

Objectives:
In the current study, we aimed to determine if training with an interactive digital game-like tool (Project: EVO^{TM}, or EVO) would improve attention in children with SPD relative to age-matched controls.
Methods:
We recruited 19 neurotypical children (12 female; mean age 9.6 +/- 1.4), 17 children with SPD+ADHD traits (6 female; mean age 10.0+/- 1.5) and 13 children with SPD-only (6 female, mean age 10.5 +/- 1.5) through the UCSF Sensory Neurodevelopment and Autism Program. All children played EVO at least 20 times over a one-month period for approximately 30 minutes each session. During these sessions, children were required to steer their avatar through complex river-like paths while simultaneous shooting at targets while ignoring distractors. Pre and post play, we assessed measures of attention on a game-like platform (NeuroRacer), a well-recognized lab based assessment of attention (TOVA), a neurophysiological measure of cognitive control (Midline Frontal Theta using EEG), and a parent report measure of inattention (Vanderbilt).

Results:
Using an ANOVA analysis, we found a significant main effect by visit (pre and post training) for response time on NeuroRacer and response time variability on the TOVA (F= 21.46 p<.000 and F=6.04, p=.017, respectively), but no Group by Visit interaction. Midline frontal theta (MFT) power during NeuroRacer play did show a significant group by visit interaction, with follow-up tests revealing that only the children with SPD and ADHD traits showed increased MFT power following the month long training (F=5.72, p=.007). On the parent report measure of inattention (Vanderbilt), we also found a significant group by visit interaction (F=6.40, p=.004), with follow-up tests revealing that only the SPD+ADHD children demonstrated a reduction in symptoms of inattention. Critically, we observed a significant relationship between increased MFT power and improved inattention via the Vanderbilt measure (r=.427, p=.015).
Conclusions:
In conclusion, the Project: EVO^{TM} training study supports the benefit of dedicated attention based training for some children with SPD, with evidence of brain plasticity and impact on real world function. It highlights the importance of detailed cognitive assessment of attention in children with SPD and other neurodevelopmental conditions in order to personalize a treatment approach with cognitive training tools.

151 **146.151** Baseline Respiratory Sinus Arrhythmia Predicts Restricted Repetitive Behavior Severity

E. E. Condy *and B. H. Friedman, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Respiratory sinus arrhythmia (RSA) is a physiological phenomenon that indexes parasympathetic influence on cardiac activity. The *neurovisceral integration model* (Thayer & Friedman, 2004) posits that higher levels of RSA promote flexible behavior and better adaptive functioning, which are both impaired in autism spectrum disorder (ASD). The social communication deficits and restricted repetitive behaviors characteristic of ASD are inflexible by nature, paralleling the behaviors described by the neurovisceral integration model. For this reason, RSA could be valuable in assessing ASD symptomatology. Although studies have shown baseline RSA is lower in children with ASD than their typically developing peers, RSA has seldom been examined in relation to more specific symptoms. In the literature, higher baseline RSA has been associated with better social functioning in ASD (Patriquin, Scarpa, Friedman & Porges, 2013), but few studies have examined RSA in relation to restricted repetitive behaviors.
Objectives: This study aimed to replicate the between-group differences in baseline RSA seen in previous studies, and to establish a relationship between baseline RSA and the two symptom domains integral to an ASD diagnosis: social communication deficits and restricted repetitive behaviors.
Methods: A three minute baseline was collected in 10 children (ages 5-8; 9 male) with an ASD diagnosis (n = 5) and in typically developing children (n= 5). Parents completed the Social Responsiveness Scale-2 (SRS-2) and the Repetitive Behavior Scale-Revised (RBS-R). A Mann-Whitney U test was used to assess the difference in baseline RSA between groups, and correlations using the social communication index (SCI) score from the SRS-2 and the total RBS-R score were conducted to see how baseline RSA related to social communication and repetitive behaviors.
Results: A one-tailed Mann-Whitney U test revealed that children with ASD had lower baseline RSA (Mdn = 6.46) compared to their typically developing peers (Mdn = 8.86), U = 4.00, p = .048. One-tailed Spearman's correlations showed that baseline RSA was related to total restricted repetitive behavior severity on the RBS-R, $\rho(8)$ = -.644, p = .022; however, the relationship between baseline RSA and the SRS social communication index score did not reach significance, $\rho(8)$ = -.529, p= .058.
Conclusions: Group level differences in baseline RSA between children with ASD and their typically developing peers that characterize the literature and were replicated in this study. These differences can subsequently be related to specific symptoms seen in ASD. Specifically, lower baseline RSA was associated with more severe restricted

repetitive behaviors. The relationship between these should be further explored to determine whether RSA and parasympathetic functioning might be a possible mechanism of repetitive behaviors, whether differences in RSA relate to specific repetitive behavior subtypes, and if biofeedback paradigms utilizing RSA measurement can be developed to address repetitive behaviors in ASD.

152 **146.152** Brain System Abnormalities Associated with Reduced Control of Sustained and Repetitive Motor Behaviors

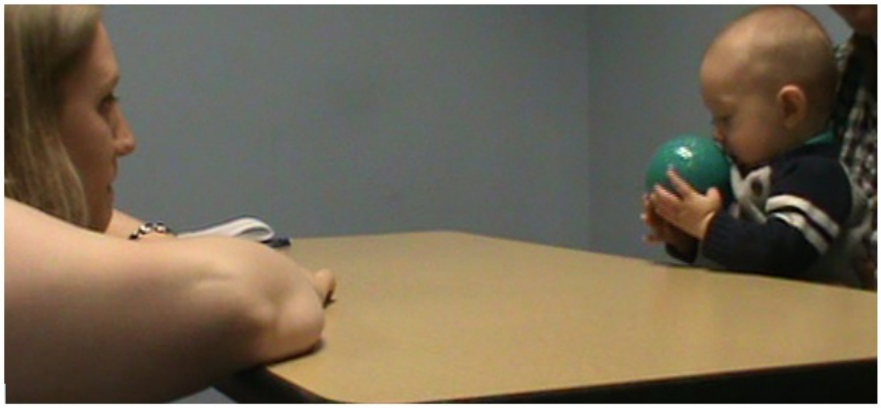
M. W. Mosconi[1], *L. M. Schmitt*[2], *S. P. White*[2] *and J. A. Sweeney*[2], *(1)University of Kansas, Lawrence, KS, (2)Center for Autism and Developmental Disabilities, University of Texas Southwestern, Dallas, TX*

Background:
A diverse set of sensorimotor impairments has been documented in autism spectrum disorder (ASD). We have found that patients show reduced control of manual motor behaviors when they attempt to maintain a constant level of force (sustained force), and when they produce rapid, repetitive action sequences (repetitive force). The severities of these two types of sensorimotor impairments are relatively independent across affected individuals. In the present study, we used functional MRI (fMRI) to identify brain systems contributing to sustained and repetitive motor impairments in ASD.
Objectives:
To identify the neural system abnormalities associated with dysmetria of sustained sensorimotor behaviors and repetitive sensorimotor behaviors in ASD.
Methods:
Twenty individuals with ASD and 15 healthy controls matched on age, IQ and handedness completed fMRI tests of precision grip force. During the sustained force test, participants pressed with their thumb and index finger on a force transducer while viewing a white FORCE bar on a screen that moved upwards with increased force toward a fixed green TARGET bar. Participants were instructed to maintain the FORCE bar at the level of the TARGET bar for 24 seconds. During the repetitive force test, participants completed 24 second blocks consisting of six repeated sequences in which they pressed on the transducer for 2 seconds and then relaxed for 2 seconds. Blocks for both tests were alternated with 24 sec rest blocks. Participants completed three blocks of each test at both 20 and 60% of their maximum force (12 force blocks total). The order of tasks and force level (20 and 60% of maximum force) were counterbalanced across participants.
Results:
Preliminary analyses were consistent with our published work (Mosconi et al., 2015; Wang et al., 2015) and indicated that individuals with ASD show increased force error relative to controls during the sustained force test, and less accurate initial force pulses compared to controls during the repetitive force test. During the sustained force test, individuals with ASD showed less activation in left superior temporal gyrus, bilateral posterior parietal cortex, supplementary motor cortex and bilateral cerebellum. During the repetitive force test, individuals with ASD showed less activation in supplementary motor cortex, contralateral primary motor cortex, right inferior parietal lobule and bilateral putamen.
Conclusions:
We report evidence that reduced accuracy of sustained motor behaviors in ASD is associated with reduced activation of parietal-cerebellar brain systems involved in transforming visual feedback into reactive motor adjustments. In contrast, reduced control of repetitive motor actions in ASD appears to reflect underactivity of frontal-striatal brain systems involved in initiating and terminating dynamic motor behaviors. These findings indicate that the diverse sensorimotor impairments that are evident in the majority of individuals with ASD reflect multiple distinct motor control and brain mechanisms. Our results also identify new brain targets for treatment development efforts aimed at reducing sustained sensorimotor dysmetria and repetitive behaviors in ASD. Further, this study shows that both cerebellar and striatal disruptions may represent significant components of the neurodevelopmental processes that cause ASD.

153 **146.153** Breadth and Continuation of Object Exploration Are Impacted By ASD Risk and Motor Ambition

M. B. Nebel[1,2], *J. L. Haworth*[3] *and R. Landa*[3], *(1)Department of Neurology, Johns Hopkins School of Medicine, Baltimore, MD, (2)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (3)The Kennedy Krieger Institute, Baltimore, MD*

Background:
School-age children with Autism Spectrum Disorders (ASD) exhibit particular difficulty with hand-eye coordination and appear to be less sensitive to visual feedback during motor learning. Estes et al. (2015) note that differences in sensorimotor behavior at 6-months-of-age between infants at high (HR) and low (LR) for autism are informative of continued developmental trajectory and later expressed autism phenotype. This echoes the importance of identifying early fine and gross motor deficits in children with ASD (Landa, 2008). Typically, self-initiated reaching leads to longer exploration of, more interest in, and more multimodal engagement with objects (Needham, et al., 2002). Motor deficits in infancy impacting self-initiated actions affect the extent of learning and growth which occurs during the active interaction (Gibson & Pick, 2000), in part because this quality of the interaction determines the kind of information (e.g., shape, texture, or weight) that can be obtained about the object (Bushnell & Boudreau, 1993).
Objectives:
Evaluate continued interest in object exploration expressed over trials of a novel ball catching task, assessed against autism risk and motor ambition (determined as anticipating ball arrival).
Methods:
Six-month-old infants (n=107, 64 HR and 43 LR) participated in the study. Video recordings of the ball rolling sub-task from the Autism Observation Scale for Infants (AOSI) were coded for the following object exploration behaviors: attempt to grasp, lift, anticipation of mouthing, mouthing (after lift or by leaning down), shaking, patting, banging, rolling, hand transfer, and dropping ball on table or floor. For each of 3-trials, we counted object exploration (OE, the total # of behaviors) and new behaviors (NB, those not previously performed). Anticipation was coded according to whether any manual action was expressed in response to the approaching ball on the first trial. A 3-way mixed-model MANOVA (Trial × Risk × Anticipation) was performed, with pairwise comparisons to identify where differences occurred (alpha=0.05).
Results:
No differences were found in the total number of OE behaviors, for any factor or interaction. For NB, a main effect of Trial was identified ($F_{2,206}$=40.0, p<0.001, η_p^2=0.280), with follow-up indicating fewer new behaviors on subsequent trials. Additionally, Risk × Anticipation ($F_{1,103}$=6.26, p=0.014, η_p^2=0.057) and Trial × Anticipation ($F_{2,206}$=5.24, p=0.006, η_p^2=0.048) interactions were found. Follow-up to the Trial × Anticipation interaction suggests that non-Anticipators showed more new behaviors on the second trial compared to Anticipators and then much fewer on the third. Follow-up to the Risk × Anticipation interaction indicates that HR non-Anticipators showed the fewest NB.
Conclusions:
Six-month-old infants sought to develop a robust repertoire of exploratory behaviors and continued to take advantage of new object exposures by adding new strategies on subsequent trials. However, across all children, the number of new strategies declined with each new opportunity. HR and LR infants who anticipated the ball displayed similar object exploration behavior across trials and showed more OE on the first trial than did non-anticipators. Interestingly, non-anticipating LR infants demonstrated more NB than anticipatory infants on the second trial, while non-anticipatory HR infants demonstrated consistently fewer new behaviors, especially on the first trial.



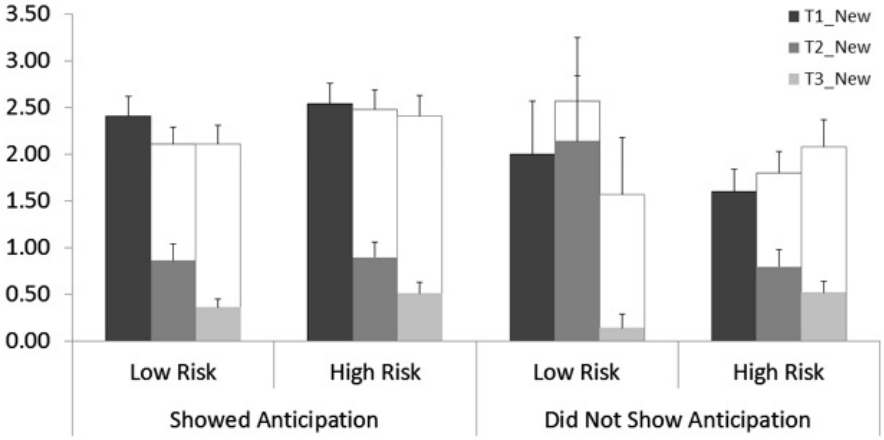


Figure 1: Mean count of expressed behavior across each of three trials, between risk group and whether anticipation behavior was observed. New behaviors (those not observed on any previous trial) are represented by filled-grayscale, and are overlain on the total count of behaviors (those observed on that given trial) which are represented by the gray-bounded bars. Error bars represent standard error.

154 **146.154** Can Timing Tasks Successfully Differentiate Children with ASD from Those with SLI?

ABSTRACT WITHDRAWN

Background: A perinatal disruption in cerebellar development has been proposed to be a direct cause of autism spectrum disorder (ASD; Wang, Kloth, & Badura, 2014). Adults with cerebellar lesions exhibit timing deficits, as indicated by increased timing variability on a finger tapping task (Schlerf, Spencer, Zelaznik, & Ivry, 2007). Much like children with ASD, children with specific language impairment (SLI) show deficits in language, and also motor development. However, discrete timing is not implicated, since children with SLI do not show deficits in variability during single-effector timing tasks (Zelaznik & Goffman, 2010). Timing tasks that involve coordination of multiple effectors (e.g., clapping) are impaired in SLI (Vuolo, Goffman, & Zelaznik, in review). Because of the overlap in symptoms, there has been some debate as to whether ASD and SLI are distinct developmental disorders (e.g., Bishop, 2010). We predicted that timing tasks, such as tapping and clapping, might be able to differentiate children with ASD from those with SLI.

Objectives: The goal of our study was to determine whether children with ASD perform more similarly to an individual with cerebellar dysfunction or SLI on timing tasks with one and two-effectors. If children with ASD show impaired single-effector timing, the results would support the hypothesis of cerebellar dysfunction in children with ASD. If children with ASD do not show impaired single-effector timing, but do show bimanual (multi-effector) coordination difficulties on timing, then the results would indicate that ASD is more similar to SLI.

Methods: Eleven children with ASD and 4 age-matched children with SLI (to date) participated in a tapping and a clapping task. Hand movements were recorded. Participants were trained to tap and clap to a 600 ms tone presented by a metronome, and to continue tapping and clapping at the same rate for 32 continuation intervals after the metronome disengaged. Six trials were completed for each task. The within-trial, within-participant variability (CV%) of the interval durations was calculated to provide a measure of timing precision. All children also completed the Movement Assessment Battery for Children – Second Edition to index general gross and fine motor skills.

Results: (Preliminary) The children with ASD (M = 13.29CV%, SD = 8.57) were more variable than their peers with SLI (M = 10.83CV%, SD = 3.96) on the single-effector, finger tapping task, but equally variable on the multi-effector clapping task (ASD, M = 15.30CV%, SD = 6.21; SLI, M = 15.00CV%, SD = 6.07). The children with ASD also performed more poorly on the standardized test of gross and fine motor skills (M = 4.73, SD = 2.49) than their peers with SLI (M = 8.57, SD = 2.22).

Conclusions: Unlike children with SLI, children with ASD exhibited a decrement in timing precision on the single-effector timing task. This finding lends support to the cerebellar sensitive period hypothesis of ASD put forth by Wang and colleagues (2014). It also highlights the role of timing tasks, and potentially fine and gross motor tasks, in differentiating children with ASD from those with SLI.

155 **146.155** Can't Tone It Down? Auditory Habituation in ASD

N. Top[1], *K. G. Stephenson*[1], *S. Luke*[1] *and M. South*[1,2], *(1)Brigham Young University, Provo, UT, (2)Psychology and Neuroscience, Brigham Young University, Provo, UT*

Background: Improved understanding of the mechanisms that underlie unique manifestations of anxiety in autism spectrum disorders (ASD) may provide targets for etiological research as well as for better treatment specificity. Recent studies using either psychophysiological measures or fMRI have shown atypical reversal learning and extinction in ASD during fear conditioning tasks. However, it is unclear if these abnormalities in ASD are due to a failure to learn new associations, a failure to extinguish previous associations, or an inability to habituate to novel stimuli.

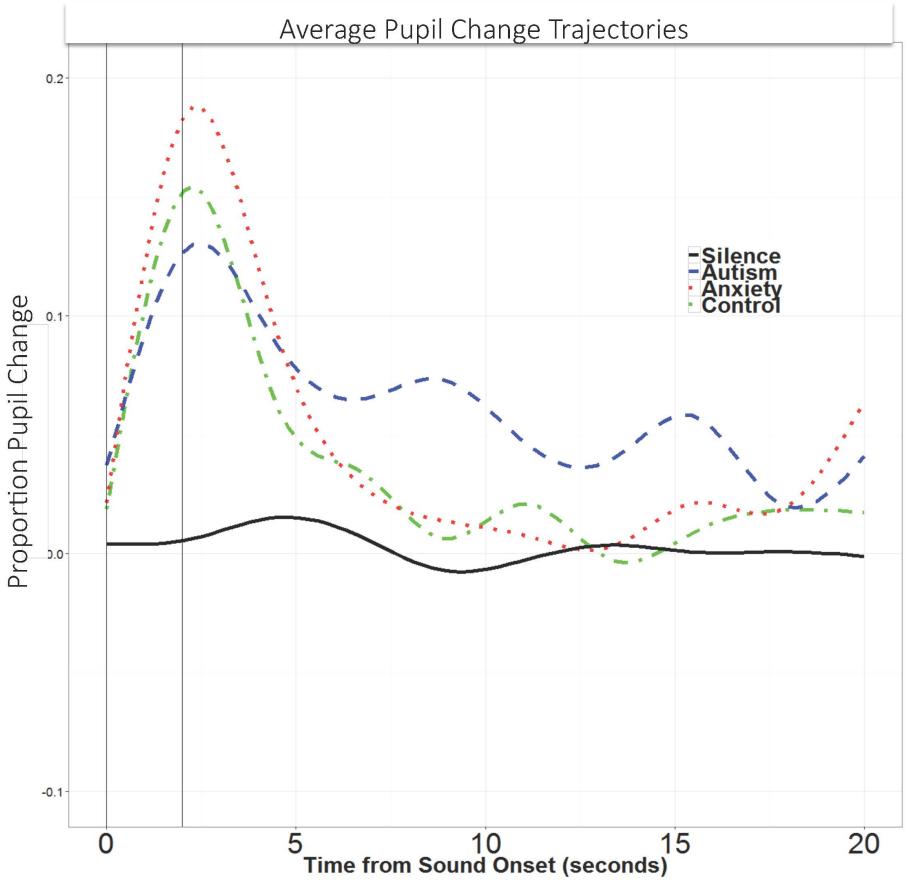
Objectives: We report findings from an auditory habituation study including adults diagnosed with ASD, compared to typical and to anxious adults. In conjunction with previous studies in our lab regarding fear conditioning and extinction, we hypothesized that pupil dilation—a sensitive index of autonomic nervous system activity--would reflect delayed habituation in ASD and may serve as a mechanism underlying anxiety in ASD.

Methods: Twenty-eight adults ages 18-29 diagnosed with ASD (ASD group) were compared to 1) age-matched adults with high levels of anxiety in treatment at a university counseling center (ANX group); and 2) healthy adults with no known psychopathology (HC group). The habituation task consisted of three blocks (silence, 60db sine wave tone, 80db sawtooth wave tone) with 10 trials per block in which the tone was played for an average of two seconds with a jittered, ~20 second inter-trial interval. Pupil dilation was measured using SR Research Eyelink 1000 Plus eye tracker. We used Hierarchical Linear Modeling (HLM) to track average percent change in pupil dilation trajectories across all three groups.

Results: HLM analyses reveal that the ANX group had significantly higher physiological reaction to the tones than the ASD and HC groups. Both the ANX and HC groups follow a similar habituation trajectory, showing a return to baseline around 6 to 10 seconds after sound offset. However, the ASD group did not return to baseline until approximately 15-20 seconds after tone onset (see attached figure). Trial-by-trail analysis showed delayed habituation to the tones in the ASD group, but not in the HC or ANX groups.

Conclusions: Sensitive pupillometry measures suggest that habituation to even simple sensory stimuli may be delayed in ASD. After multiple exposures the ASD group showed atypically higher arousal during the recovery periods, indicating that they were not able to “calm down” from initial shock of these mild noises. These delays support

previous finds of delayed fear extinction in ASD and suggests the possibility that this failure to habituate may be a prominent factor underlying anxiety as well as difficulties with change and transition. Exposure therapy and other treatment approaches for anxiety in ASD will likely take more time and would benefit from a focus on integrating internal and external stimuli.



156 **146.156** Continuous and Extreme Autistic Trait Ratings Are Associated with Avoidance of Alcoholic Beverages

S. Chaturvedi[1], *G. Wallace*[2] *and N. L. Zucker*[3], *(1)Speech and Hearing Sciences, The George Washington University, Washington, DC, (2)The George Washington University, Washington, DC, (3)Duke Center for Eating Disorders, Duke University, Durham, NC*

Background: Selective (i.e., 'picky') eating is common in autism spectrum disorder (ASD) with as many as 70% of individuals exhibiting this behavior. Prior reports suggest that although preference for particular foods and drinks is highly idiosyncratic, broader patterns emerge across children with ASD. For example, studies suggest that children with ASD have generally less varied diets, including eating fewer vegetables, salad, and fresh fruit, as well as less sweets and fizzy drinks (Emond et al., 2010; Pediatrics) than typically developing controls. The vast majority of studies to date have been conducted with children. While selective eating is persistent and extends into adulthood in ASD (Kuschner et al., 2015, Res Autism Spectr Disord) and it is more common than previously believed within the general population of adults, very little is known about specific food/drink preferences (including alcohol consumption) and their associations with ASD-like behaviors during this developmental window.
Objectives: Examine food/drink preferences as a function of continuous and extreme autistic trait ratings within a large sample of adults.
Methods: A large group of 1,992 adults (1,445 females) completed online surveys including questions about how often they avoided various food/drink classes (e.g., fruits/vegetables, juices, alcoholic beverages, salty and sweet crunchy bread products, salty and sweet soft bread products, meats, and dairy products) on a scale of 1 (never) to 5 (always) as well as self-ratings of autistic traits utilizing the original 50-item Autism-Spectrum Quotient (AQ).
Results: Correlational analyses revealed that as self-ratings of autistic traits (using the AQ total score) increased the likelihood of trying alcoholic beverages decreased (r=.14 , p<.01). Autistic social traits (from the Social Skills subscale) was the component of the AQ most strongly correlated with a general avoidance of alcoholic beverages (r=.18, p<.01). When submitted to regression analyses, autistic social traits predicted significant additional variance (F=58.80, p<.001; ΔR^2=.03) above and beyond the influence of food neophobia and aversions to smells, each of which contributed its own significant variance (ts>2.36, ps<.02), to the likelihood of trying alcoholic beverages.
Conclusions: This study provides further evidence linking ASD-like behavior with food/drink preferences, albeit among a relatively large population of adults. The food/drink that was most strongly related to subclinical ASD behavior was alcoholic beverages. This finding is perhaps unsurprising given prior research finding highly reduced rates of alcohol use and abuse among adolescents and adults with ASD (Fortuna et al., 2015, J Gen Intern Med; Mangerud et al., 2014, J Adolesc). Moreover, ASD-like social traits, in particular, were most strongly linked with avoidance of alcoholic beverages, and these influences were independent of generalized food neophobia and sensory aversions to smell, consistent with the notion of limited 'social drinking.'

157 **146.157** Correlates of Restricted and Repetitive Behaviours: The Role and Anxiety and Intolerance of Uncertainty. Insights Directly from Young People with ASD

J. Rodgers[1], *E. Honey*[2] *and C. Joyce*[3], *(1)Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)CNDS, Northumbria Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, (3)Newcastle University, Newcastle, United Kingdom*

Background: Restricted and Repetitive Behaviours (RRB) such as repetitive movements, routines, restricted interests, and resistance to change can interfere with the ability to learn new skills and take part in daily living. Despite their ubiquity in ASD, research into RRB is relatively neglected in comparison to other features of the disorder. In order to reduce the potential negative consequences of RRB, research is required which provides information about the motivators for and correlates of RRB to inform the development of effective and targeted interventions. Some research suggests a relationship between RRB and anxiety and intolerance of uncertainty (IU) in ASD. This research is based on parental report of these phenomena with no research investigating these relationships by gaining information directly from people with ASD.
Objectives:
This study aimed to further current understanding about the experience of RRB and how these behaviours may relate to uncertainty and anxiety in ASD by gaining information directly from young people with ASD and their parents.
Methods: Nineteen families participated. Young people with ASD were aged between 13 and 20 (mean age 16 years 8 months). Young people with ASD and their parents completed the Repetitive Behaviour Questionnaire 2 (RBQ2), Spence Child Anxiety Scale (SCAS) and the Intolerance of Uncertainty Scale (IUS-12). Ten of the young people also took part in a novel semi-structured interview. The goal of the interview was to explore motivations for engagement in and cessation of a self-selected example of an RRB.
Results:

Significant correlations were found between both parent reported (r = .670, p = .002) and young person self-reported (r = .570, p = .042) RBB and anxiety. Parent reported young person intolerance of uncertainty and RBB were also significantly correlated (r = .560, p = .013). Thematic analysis of the interview data identified five themes (Insight into RRB, experience of RRB, motivating factors anxiety and uncertainty).
Conclusions:
This study is the first to date to collect self-report information from young people with ASD about their RRB. This is important in two respects; firstly it provides evidence in support of existing findings that have previously only been evidenced through parent report and secondly it provides evidence that young people can self-report, providing support for such practices in ASD research. The results support and extend previous findings, demonstrating a significant positive relationship between parent reported RRB and anxiety. Further support is also provided for the centrality of the role of uncertainty to the relationship between anxiety and RRB in ASD. This study has a number of implications for clinical practice, suggesting that consideration should be given the role of anxiety and IU in understanding RRB. Young people's responses to the interview provide insight in to how clinicians can potentially engage young people in talking about their RRB.

158 **146.158** Directly Measured Physical Activity of 4 Year Old Children with Autism Spectrum Disorder

E. Bremer[1] *and M. Lloyd*[2]*, (1)Infant and Child Health Lab, Department of Family Medicine, McMaster University, Hamilton, ON, Canada, (2)Faculty of Health Sciences, University of Ontario Institute of Technology, Oshawa, ON, Canada*

Background: Engagement in physical activity (PA) is critical to maintain good health and can also provide important behavioural benefits to children with autism spectrum disorder (ASD) (Bremer, Crozier, & Lloyd, In Press). It is recommended that preschool aged children (3-4 years of age) engage in 180 minutes of PA each day (Tremblay et al., 2012), which equates to approximately 9,000 steps/day (Vale, Trost, Duncan, & Mota, 2015). To date, the PA of preschool aged children with ASD has not been evaluated.
Objectives: The objectives of this pilot study are 1) To explore the PA levels of 4 year old children with ASD; 2) To examine the correlations between PA, motor skills, and adaptive behaviour in this population; and 3) To examine the potential feasibility of measuring PA in preschool aged children with ASD via pedometers.
Methods: Fourteen children that were 4 years of age with ASD participated in this study as part of a larger intervention study. Participants were assessed using the following measures: Vineland Adaptive Behavior Scales-2 (VABS-2) and Peabody Developmental Motor Scales-2 (PDMS-2). Height and weight were directly measured and BMI was calculated. Demographic information was obtained from the participant's parents. Each participant was given a time-stamped pedometer to wear for 7 consecutive days to measure PA. Pedometer data was analyzed for validity using the following criteria: worn 3 days for at least 10 hours/day. Average steps/day was calculated for participants with valid data. Pearson correlations were used to explore the relationships between PA, motor skills, and adaptive behaviour. T-tests were used to explore baseline differences in behaviour, motor skills, BMI, and socioeconomic status between those participants with and without valid pedometer data.
Results: Participants (n=9) who wore their pedometer for at least 10 hours/day for 3 days took an average of 10,044 steps/day. Participants (n=3) who did not wear their pedometer for the necessary time but, had at least one valid day of data (i.e. wore it for at least 10 hours on 1 day) took an average of 8,195 steps/day. Average steps/day were positively correlated with the VABS-2 adaptive behaviour composite standard score (r=0.682, p=0.015) but, not with any of the PDMS-2 outcomes. The only difference between the participants with and without valid pedometer data was in BMI with those participants who wore their pedometer having a lower BMI than those who did not wear it [t (12) = 3.452, p = 0.005]. Anecdotally, parents reported sensory issues as the main factor preventing their child from wearing the pedometer.
Conclusions: On average, participants in this study were meeting the recommended PA guidelines for preschool-aged children. Future research should further examine the relationship between adaptive behaviour and physical activity, particularly as a mode of intervention. Further research with larger, representative samples of children with ASD is also needed to determine their PA levels and the reliability and validity of using pedometers in this population.

159 **146.159** Early Sensory Hyporesponsivity Predicts Later Deficits in Language Understanding in Infants at High Risk for Autism Spectrum Disorder

T. Woynaroski[1]*, C. R. Damiano*[2,3]*, C. J. Cascio*[4]*, W. L. Stone*[5]*, L. V. Ibanez*[5]*, S. M. Bowman*[6] *and A. Morgan*[6]*, (1)Vanderbilt University, Thompsons Stn, TN, (2)Carolina Institute for Developmental Disabilities, University of North Carolina School of Medicine, Chapel Hill, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC, (4)Vanderbilt University School of Medicine, Nashville, TN, (5)Department of Psychology, University of Washington, Seattle, WA, (6)Vanderbilt University, Nashville, TN*

Background:
Individuals with autism spectrum disorder (ASD) often show atypical responses to sensory stimuli, even as early as infancy. A pattern of hyporesponsivity (characterized by absent or reduced responding to sensory stimuli) in particular seems most prevalent in, and specific to, ASD. It has been proposed that reduced responsivity to sensory stimuli early in life may produce cascading effects on higher level abilities, such as language, in individuals with ASD. Past work has found that sensory hyporesponsivity covaries with *concurrent* language in *preschool* and *school-age* children with ASD. However, to date no study has evaluated whether hyporesponsivity in infancy predicts future language in younger children with ASD. A primary obstacle to this work is our inability to diagnose ASD in infancy. One way to overcome this challenge is to prospectively study infants who are known to be at high risk for ASD, such as infant siblings of children diagnosed with ASD (Sibs-ASD).
Objectives:
This pilot project, carried out at Vanderbilt University and the University of Washington, specifically sought to determine (a) whether Sibs-ASD differed from infants with a typically developing older sibling (Sibs-TD) in early sensory hyporesponsivity and (b) whether early hyporesponsivity predicted later language, at least in Sibs-ASD.
Methods:
Sensory hyporesponsivity of 14 Sibs-ASD, as well as 18 Sibs-TD was assessed at 18 months using the Sensory Experiences Questionnaire. Receptive and expressive language was assessed at 24 months using the Vineland Adaptive Behavior Scales. An independent samples t-test was used to evaluate mean differences in early hyporesponsivity between Sibs-ASD and Sibs-TD, and bivariate correlational analyses were used to examine predictive associations between early hyporesponsivity and later language abilities for Sibs-ASD and Sibs-TD.
Results:
We found several anticipated effects, including a trend towards higher hyporesponsivity—reduced responding to sensory stimuli— at 18 months in the Sibs-ASD group relative to the Sibs-TD group (d = .64). Hyporesponsivity at 18 months was strongly predictive of receptive language at 24 months in the Sibs-ASD group (r = -.82), but not the Sibs-TD group (r = -.26). Associations between early hyporesponsivity and later expressive language were non-significant. Further analyses for an expanded sample (anticipated total N = 50) will be presented at IMFAR.
Conclusions:
Results provide increased support for the proposal that early sensory differences may produce cascading effects on higher-level abilities, such as language, in children at high risk for ASD. Findings specifically suggest that sensory hyporesponsivity may be a valuable predictor of later deficits in receptive language in this population. Implications for practice and needs for future research will be discussed.

160 **146.160** Epilepsy and Repetitive Behaviors in ASD

G. D. Glinos[1]*, J. M. Lee*[2]*, E. R. Martin*[3]*, J. R. Gilbert*[2]*, M. A. Pericak-Vance*[2] *and* ***M. L. Cuccaro***[4]*, (1)John P. Hussman Institute for Human Genomics, Miami, FL, (2)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, (3)John P Hussman Institute for Human Genomics, University of Miami, Miami, FL, (4)University of Miami, Miami, FL*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder with a variable phenotype. Approximately 8-21% of individuals with ASD have epilepsy. Differentiating the complex ASD phenotype based on co-occurring symptom patterns may provide meaningful subgroups. Epilepsy and repetitive behaviors are present in ASD and may yield meaningful subgroups when examined in tandem. Understanding the ASD-epilepsy relationship has implications for identifying a genetic etiology of ASD and improving care.
Objectives: To determine whether repetitive behavior profiles among individuals with ASD are associated with frequency of epilepsy.
Methods: This is a cross-sectional study of symptom patterns of individuals with ASD from the Simons Simplex Collection (SSC). The SSC is a well-characterized collection of individuals with ASD from simplex families (i.e., one individual with ASD in the family). Data were collected at multiple clinics across the US using standard procedures. Our dataset consisted of 2683 participants with ASD from the SSC.
Participants were between 4-18 years of age at enrollment. The sample was predominantly male (86%) and white (79%). All procedures were approved by the respective local institutional review boards. The primary measures were derived from the Autism Diagnostic Interview-Revised (ADI-R), a semi-structured caregiver interview that assesses ASD symptoms, and medical history. Our analyses used 13 ADI-R items, which assess repetitive behaviors (RRBs) common to ASD (e.g., repetitive use of objects) and a measure of epilepsy from the ADI-R and medical history.
Results: We identified 145 (5.4%) individuals with epilepsy using previously published criteria. Across individual RRB items the frequency of epilepsy ranged from 5.1%-6.7%. For four RRB items, *compulsions*, *unusual sensory interests*, *hand and finger mannerisms*, and *unusual attachments*, the frequency of epilepsy was significantly higher among those with these RRB. Using a two-step clustering approach with previously identified RRB factors (Repetitive Sensory Motor Behavior, Insistence on Sameness) as inputs, we identified four high quality clusters of individuals. Among these clusters, the frequency of epilepsy ranged from 4.2% to 7.2%. While these differences were not statistically significant (p = 0.13), the group with the highest frequency of epilepsy was the most socially and behaviorally impaired.
Conclusions: The frequency of epilepsy is ASD does not differ significantly among groups of individuals with different RRB profiles. However, at the item level, epilepsy was more frequent among individuals with compulsions and hand and finger mannerisms. Further study is needed to develop subtypes among individuals with ASD for genetic

studies.

161 **146.161** Evaluating the Role of Social and Motor Engagement for Reducing Restrictive and Repetitive Behaviors in Autism

A. Lampi[1], *P. Fitzpatrick*[2], *V. Romero*[3], *J. Amaral*[3], *M. Richardson*[3] *and R. Schmidt*[4], *(1)Psychology, Assumption College, Worcester, MA, (2)Psychology Department, Assumption College, Worcester, MA, (3)University of Cincinnati, Cincinnati, OH, (4)College of the Holy Cross, Worcester, MA*

Background:
Restrictive and repetitive behaviors (RRBs) are some of the most common and most stigmatizing symptoms of ASD. Research has found that motor engagement can reduce RRB presentation without affecting academic ability (Celiberti, Bobo, Kelly, Harris, & Handleman, 1997; Rosenthal-Malek & Mitchell, 1997); while other research has found that social engagement also reduces RRB presentation (Enloe & Rapp, 2014; Lee, Odom, & Loftin, 2007). While both of these research areas have found that different forms of engagement reduce the levels of RRB presentation in children with autism, few if any studies have looked at the joint effect of social and motor engagement. Additionally, many of the previous studies had a small sample of participants.
Objectives:
This research intended to evaluate the impact of social and motor engagement on RRB presentation in children with autism. In particular, we were interested in whether diagnosis affected RRB presentation levels, if differences in presentation were based on RRB type, if type of engagement differentially influenced RRB presentation, and if RRB presentation was related to other measures of symptoms of autism.
Methods:
A sample of 91 children (46 ASD, 45 Control) was coded over four tasks that varied in the levels of both social and motor engagement. Frequency coding was conducted using video analysis software (Interact, Mangold Inc.) for four different types of RRBs: motor-based RRBs, nonverbal-oral RRBS, oral-motor RRBs, and vocal/verbal RRBs. We also correlated the frequency measures to clinical measures of social skill: the RBSR, CBCL-ADHD, ADOS, and SRS; as well as to measures of social cognition: theory of mind, initiating joint attention, and responding joint attention.
Results: A 2X2X2X4 ANOVA with independent variables of diagnosis, motor engagement, social engagement, and RRB type revealed a significant four way interaction between all independent variables ($F(3,267)=4.75, p<.001$, $h_p^2=.05$). This interaction meant that for the children diagnosed with autism, an environment with both high social and motor engagement had the greatest impact on reducing certain RRBs more than others, namely the motor and vocal/verbal based RRBs. We also found significant main effects for all independent variables, as well as significant two-way and three-way interactions between all combinations possible between variables. We found significant positive correlations between frequency of RRBs and clinical measures of social skill, and significant negative correlations between the dependent variable and measures of social cognition.
Conclusions:
These findings suggest that a combined effect of social and motor engagement has the greatest possibility to reduce the number of RRBs in children with autism. Observed frequencies were also related to clinical measures of social skill and measures of social cognition. These findings are important because they demonstrate a potential for future research to examine how to best utilize combined forms of engagement in ways that improve the social skills and education of children with autism, while simultaneously reducing the most stigmatizing behaviors of the disorder.

162 **146.162** Examining the Relationship Between Restricted and Repetitive Behavior Type and Internalizing and Externalizing Behaviors

E. Hanson[1], *D. Peterson*[2] *and* ***A. K. Walsh***[2], *(1)Children's Hospital Boston, Boston, MA, (2)Developmental Medicine Center, Boston Children's Hospital, Boston, MA*

Background: Restricted and repetitive behaviors (RRBs) are a core diagnostic feature of Autism Spectrum Disorders (ASD) and are often difficult to evaluate without a comprehensive tool (DSM-V; American Psychiatric Association, 2013). The Behavior and Sensory Interest Questionnaire (BSIQ) is a newly published continuous dimensional instrument designed to meet these needs (Hanson et. al., in press). The BSIQ comprehensively evaluates type, frequency, and intensity, age of onset and duration of RRBs. The BSIQ also separates the two types of RRBs, Repetitive Sensorimotor (RSM) behaviors and Insistence on Sameness (IS) behaviors. This present study looks to further understand RSM and IS behaviors in relation to internalizing (i.e., anxious, depressive, and over-controlled) and externalizing (i.e., aggressive, hyperactive, noncompliant, and under-controlled) behaviors using the Child Behavior Checklist (CBCL) (Farmer & Aman, 2011).
Objectives: N/A
Methods: 185 ASD affected participants (149 male) with both BSIQ and CBCLs were examined. Ages of participants ranged from (24-201 months) (mean=69.4, SD=40.2). BSIQs were evaluated with CBCL internalizing and externalizing behavior scores. Correlations between IS and RSM behaviors and internalizing and externalizing behaviors were examined using Pearson correlations in SPSS.
Results: Pearson correlations were run to compare CBCL Internalizing behaviors and externalizing behaviors to RSM and IS behaviors. Preliminary analyses demonstrated that of individuals exhibiting IS behaviors, there was a larger positive correlation between Internalizing behaviors (r=0.522, p=0.000) than externalizing behaviors (r=0.358, p=0.000). Similar to the IS results, those participants exhibiting RSM behaviors also found a larger positive correlation between Internalizing behaviors (r=0.462, p = 0.000) than externalizing behaviors (r=0.391, p =0.000).
Conclusions: As a result, both RSM and IS behaviors have a strong positive relationship to CBCL internalizing behaviors and moderate positive relationships to externalizing behaviors. Future research is needed to determine what specific internalizing behaviors may be more strongly correlated to RSM and IS behaviors.

163 **146.163** Examining the Relationship of Specific Repetitive and Restricted Behaviors on Adaptive Functioning of Children with ASD

K. Loftus Campe*, S. M. Attar, D. Peterson and E. Hanson, Developmental Medicine Center, Boston Children's Hospital, Boston, MA*

Background: Restricted and repetitive behaviors (RRBs) include a broad category of behaviors which are considered core characteristics required for a diagnosis of Autism Spectrum Disorder (ASD) according to the Diagnostic and Statistical Manual (DSM-V; American Psychiatric Association, 2013). RRBs can be subdivided into repetitive and sensory motor behaviors (RSM) and Insistence on Sameness behaviors (IS). In previous studies, researchers found significant negative correlations between IQ and RSM behaviors and positive correlations between IQ and IS behaviors (Richler et al. 2010). Also, parents have often reported that RRBs can be the most stressful aspect of ASD (Bishop, Richler, Cain & Lord, 2007). This study uses a newly standardized measure, the Behavior and Sensory Interest Questionnaire (BSIQ) to classify a wide range of RRBs. Previous studies using the BSIQ have found negative correlations between RSM behaviors and overall adaptive functioning. Yet, no study has detailed which specific RRBs provide the most interference within the various domains of adaptive functioning. This study attempts to identify specific RRBs that are highly correlated with domains of adaptive functioning to help specify behaviors to be targeted for intervention when aiming to improve socialization skills amongst the ASD population.
Objectives: Using a newly standardized measure, this study aims to delve deeper into the relationship between RRBs and adaptive behavior to identify specific RRBs that highly coorleate to domains of adaptive functioning.
Methods: A sample of 503 children with ASD (82% male) was drawn from the Simons Simplex Collection and the Boston Autism Consortium. Participant ages were between 24-216 months, (mean=92.3, SD=45.75). ASD diagnosis was verified with the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R).Parents were administered the BSIQ, designed to evaluate the number, type, and intensity of RRBs, by a trained clinician, as well as the Vineland Adaptive Behavior Scale (VABS), which measures adaptive skills in multiple subdomains. Preliminary analysis included Pearson Correlations and descriptive statistics.
Results: Analyses revealed significant negative correlations between RSM behaviors and all three Subdomains of the Socialization Domain on the VABS, Interpersonal Skills, Play and Leisure Time, and Coping Skills. Specifically, RSM behaviors such as Flapping (-.329, p≤0.001), Repetitive Throwing (-.352, p≤0.001), and Toe Walking (-.310, p≤0.001) displayed the strongest negative correlation. No significant trend was revealed of age on IS behaviors, reconfirming previous studies. All analyses were controlled for IQ, age and gender.
Conclusions: Expanding on previous research, we have analyzed the relationship between RRBs and the socialization skills of children with ASD to a more specific level. We found significant effects of RSM but not IS behaviors on socialization skills, including Interpersonal Skills, Play and Leisure Time, and Coping Skills. By providing an understating of which repetitive behaviors are most strongly correlated with areas of socialization, we can begin to understand the impact of RRB's on the functioning of children with ASD and apply this knowledge in adapting interventions for children with ASD. Future research should focus on if there are specific behaviors driving the RSM impact on adaptive skills.

164 **146.164** Examining the Time Course of Repetitive and Restricted Behaviors of Children with ASD throughout Childhood and Adolescence. Taxonomy for Parents and Providers

S. M. Attar*, K. Loftus Campe and E. Hanson, Developmental Medicine Center, Boston Children's Hospital, Boston, MA*

Background: Restricted and repetitive behaviors (RRBs) include a broad category of behaviors which are considered core characteristics required for a diagnosis of Autism Spectrum Disorder (ASD) according to the Diagnostic and Statistical Manual (DSM-V; American Psychiatric Association, 2013). Parents of children with ASD have often reported that RRBs can be the most stressful aspect of raising their child (Bishop, Richler, Cain & Lord, 2007). Earlier research on RRBs may be difficult to generalize, since those studies tended to focus on a limited number of RRBs, measured predominantly by tools designed for assessing ASD and not RRBs per se. While previous studies have subdivided RRBs into Repetitive and Sensory Motor behaviors (RSM) and Insistence on Sameness behaviors (IS), no study has provided a comprehensive taxonomy of the most commonly presenting RRBs by age group.

Objectives: This study uses a newly standardized measure, the Behavior and Sensory Interest Questionnaire (BSIQ) (Hanson et. al. 2015) to classify a wide range of RRBs. Furthermore, by aggregating data by age from a large sample size, a proposed timeline of RRBs emergence has been created.
Methods: A sample of 503 children with ASD (82% male) was drawn from the Simons Simplex Collection and the Boston Autism Consortium. Participant ages were between 24-216 months, (mean=92.3, SD=45.75). ASD diagnosis was verified with the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R). Parents were administered the BSIQ, designed to evaluate the number, type, and intensity of RRBs, by a trained clinician. Preliminary analysis of behavior frequency determined top presenting RRBs in seven different groups. Groups were determined by age of participant.
Results: Preliminary analysis reveals three primary patterns of prevalence of RRBs in children with ASD. Repetitive motor behaviors often remain consistent in their prevalence across ages, for example, more than 33% of children with ASD present with flapping throughout their development. Sensory seeking behaviors generally showed decline with age, such as seeking deep pressure, which presented between 48-55% for children under the age of nine, but drops as low as 30% for children above the age of nine. In contrast, Insistence on Sameness behaviors are not as prevalent (26-36%) in 2-7 year olds, and instead increase with age, up to 44% in children 9-12 years of age.
Conclusions: Research has shown the impact of RRBs on adaptive functioning, so it is important to document the prevalence across childhood development. Further analysis will reveal the significance of RRB patterns of emergence and frequency. This information will produce a comprehensive taxonomy that is useful for families, clinicians, and researchers in the diagnosis and treatment of children with ASD.

165 **146.165** Extent and Burden of Auditory Hypersensitivity Issues in Children with ASD

E. Rubenstein[1], *J. K. Law*[2], *A. R. Marvin*[3] *and P. H. Lipkin*[4], *(1)Department of Epidemiology, University of North Carolina, Chapel Hill, NC, (2)Interactive Autism Network, Baltimore, MD, (3)Painter Bldg 1st Fl, Kennedy Krieger Institute, Baltimore, MD, (4)Kennedy Krieger Institute, Baltimore, MD*

Background:
Sensitivity issues are strongly associated with the autism spectrum disorder (ASD) phenotype. Research suggests 30-90% of people with ASD either over or under react to sensory stimuli. Auditory hypersensitivity is reported to be the most common, affecting 30-50% of children with ASD, and is highly concerning due to the often-unpredictable nature of the stimulation, and the potential to lead to avoidant or challenging behaviors.
Objectives:

- To describe the extent and burden of auditory hypersensitivity issues (AHI) in a sample of children aged 3-17 with at least one AHI in the previous six months.
- To determine whether sound type, emotional response to sound, and physical response to sound load into factors that may help identify subgroups based on response to auditory stimuli.

Methods:
The Interactive Autism Network (IAN), a large, well-validated, US-based autism research registry, invited participating families of children with ASD aged 3-17 years to complete a survey about their child's current and past AHI, and how AHI affects their child behavior and impacts their family.
Results:
497 children had a completed survey; 400 children (80.5%) had AHI in the six months prior to completing the survey, while 97 did not and were excluded from analysis. The sample was a majority male (83.0%), white (90.3%) and mean age was 11.1 years (standard deviation: 3.5).
Most common frequency for AHI was 'a few times a week' (30.0%) and 'a few times a month' (21.2%). Common specific sounds were yelling (80.3% react at least sometimes), crying (67.6%), and vacuuming (80.3%). Responses to sound often caused at least a somewhat unsafe situation (41.4%), with 14.4% of children physically injuring themselves and 25.5% hurting others. After AHI, parents noted increased anxiety (89.4%), fear (70.9%), impulsivity (65.6%) and difficulty to control (71.5%). Increased behaviors after AHI included covering ears (86.3%), yelling (58.4%), outbursts (82.6%), and escape (57.2%). AHI often led to frequently (25.4%) or sometimes (38.7%) missing school, family, or community activities. Parents most often indicated that management of AHI was minimally (39.2%) to moderately (39.9%) difficult. Exploratory factors were calculated to determine potential subgroups based on sound types that cause issues, and emotional and physical responses to those sounds. Two-factor solutions were found to explain variance in emotional response (fear and aggression factors), physical response (hyperactive/injury and avoidance factors) and sound type (high pitch and low pitch factors).
Conclusions:
AHI occur frequently among children with ASD. These issues lead to safety concerns, increase in challenging behaviors, and loss of opportunities which impacts schooling and ability to experience public life. Preliminary factor analyses suggest that there are different responses types that may help us understand more about the nature of AHI. Better understanding the manifestation of AHI will help lead to effective therapies and prevent AHI which will reduce their negative impacts. Results of this study will inform parents and care providers about management of AHI in the community and its potential impact on child behavior and safety.

166 **146.166** Gait Analysis, Physical Activity and Motor Coordination in Children with Autism Spectrum Disorders and Developmental Coordination Disorder

D. Kindregan[1], *L. Gallagher*[2] *and J. Gormley*[1], *(1)Physiotherapy, Trinity College Dublin, Dublin 8, Ireland, (2)Psychiatry, Trinity College Dublin, Dublin, Ireland*

Background:
Children with Autism Spectrum Disorder (ASD) may demonstrate motor stereotypies such as pacing, jumping/hopping, skipping and spinning and it has been suggested that these may be considered restricted and repetitive behaviours. Studies examining gait in children with ASD suggest a tendency to augment walking stability with a wider base of support and decreased range of motion, which may imply a motor deficit. To date, no study has investigated gait in children with Developmental Coordination Disorder (DCD). Furthermore, children with ASD or DCD may be less physically active than typically developing peers, and no study has compared physical activity in the two groups or a group with a dual-diagnosis of both conditions.
Objectives:
To describe gait patterns, physical activity and motor coordination in children with ASD when compared to children with DCD and typically developing peers.
Methods:
Children with a diagnosis of ASD and/or DCD aged 6-14 years with no other conditions altering gait patterns were included. Height, weight, bodyfat and leg dimensions were measured. Gait analysis was carried out using the Codamotion system on a treadmill at preferred speed and a set speed of 3k/h. Actigraph GT3X tri-axial accelerometers measured physical activity. Motor coordination was assessed using the Movement Assessment Battery for Children, 2nd Edition (MovementABC-2). One-way ANOVA evaluated between-group differences.
Results: (Preliminary)
Thirty four children were recruited into four groups: ASD-only (n=8), DCD-only (n=10), Dual-diagnosis ASD&DCD (n=8), and typically developing (TD) controls (n=8). There were no between-group differences in age or height and no gender effects ($p>0.05$). A larger proportion of children with neurodevelopmental disorders were overweight/obese than controls (ASD: 50%; DCD: 30%; ASD&DCD: 50%; TD: 12.5%).
Children with ASD-only spent a significantly shorter period of time in single stance than the other groups ($p=0.0454$). Knee extension was reduced in the ASD-only, DCD-only and dual-diagnosis groups compared to controls, with a p-value approaching significance ($p=0.054$).
The percentages of time spent in sedentary activity, light activity and the combined moderate-to-vigorous physical activity (MVPA), the total time spent in MVPA, number of Freedson bouts (bouts of MVPA lasting at least ten minutes) and the total duration of these bouts did not show any between-group differences.
The control group scored significantly higher than the other groups in the three categories of the Movement ABC-2 (Manual Dexterity $p=0.000489$, Aiming & Catching $p=0.018992$, and Balance $p=0.034859$). Controls also ranked highest in total test score percentiles at 44.75, DCD group at 7.6, ASD group at 6.2125 and the dual-diagnosis group at 5.825 ($p=0.00001$).
Conclusions:
Preliminary findings suggest that children with ASD and/or DCD may have different physical attributes to typically developing peers, but it is unclear whether children with ASD have defining physical and movement characteristics which may be useful in diagnosis and treatment planning. Children with ASD seem to have poorer coordination than their typically developing peers, as has been noted in published research (Ghaziuddin & Butler, 1998; Fournier et al., 2010). Further research with larger sample size may have implications for clinical practice in areas such as physiotherapy or occupational therapy.

167 **146.167** Gait and Balance Assessment in Children with Genetic Neurodevelopmental Disorders with and without Autism Spectrum Disorders

S. Goldman[1], *S. Dunaway Young*[1], *C. Mueller*[2], *A. K. Boehme*[1], *G. Sherwood*[1], *A. Stahl*[1], *A. Zoeller*[2], *L. D. Abbruzzese*[3], *A. K. Rao*[1] *and J. Montes*[1], *(1)Columbia University Medical Center, New York, NY, (2)Columbia University, New York, NY, (3)Physical Therapy, Columbia University, New York, NY*

Background: Neurodevelopmental disorders are frequently associated with motor impairments including locomotion. The lack of objective measures combined with the challenges inherent in studying children with neurodevelopmental disorders, hinder valuable quantitative motor assessments. The cerebellum controls gait and balance and has shown the most consistent neuroanatomical alterations in Autism Spectrum Disorders (ASD). The basal ganglia has also been implicated in ASD and plays an important role in repetitive behaviors, control of movements, and is associated with aspects of social and emotions processing. Gait and balance are amenable to quantitative methods and may help to refine the motor phenotype in neurodevelopmental disorders. Furthermore, several genetically determined conditions such as 16p11.2 and 1q21.1 are known to be associated with ASD yet their motor phenotype has not been detailed. Motoric measures help characterize locomotion and permit comparisons amongst

neurodevelopmental conditions and as such can provide insight into neural pathway dysfunction.
Objectives: To determine the feasibility and sensitivity of quantitative gait assessments in children with neurodevelopmental disorders.
Methods: Thirty eight children (23 probands with 16p11.2 or 1q21.1 mutation and 15 unaffected siblings) mean age: 8.5 years (range 3.2–15.4), and 55.3 % male were enrolled. Among the probands, 23% carried a diagnosis of ASD and were all male. Gait assessments included: six-minute walk test (6MWT), 10 meter run/walk test (10MRW), timed-up-and-go test (TUG) and spatio-temporal measurements of preferred and fast-paced walking. The Pediatric Evaluation of Disability Inventory-Computer Adaptive Tests (PEDI-CAT), a caregiver-reported functional assessment was administered. Measures of balance were calculated using *Percent Time in Double Support* and *Base of Support*. Subsequently, the locomotion data from the 6 children diagnosed with ASD were compared with 6 age-matched non-ASD genetic probands and 6 non-ASD sibling controls.
Results: All but 2 of the youngest children completed the protocol. Probands had significantly lower scores than sibling controls on 6MWT (p=0.040), 10MRW (p=0.012), and TUG (p=0.005). Group differences were identified in *Base of Support* (p=0.003). Probands had significantly lower PEDI scores in all domains including the mobility scale (p<0.001). In the fast-paced condition, all participants increased velocity on average from 114.7 to 189.2 cm/sec by increasing both stride length and cadence. As for balance measures, the ASD group did not demonstrate the expected concurrent reduction in *Double Support* time during the fast-paced condition which was observed in the two age-matched non-ASD groups. In addition, only the ASD group presented with upper limb stereotypies.
Conclusions: Our motor assessment provides quantifiable results in children with 16p11.2 or 1q21.1 mutation as well as detailed characterization of locomotion performance. Differences in *Base of Support* highlight a balance impairment during locomotion activities in children with neurodevelopmental disorders with and without ASD. However, only the children with ASD had a blunted response to *Double Support* time in the fast-paced condition. This finding may contribute to their greater functional impairment. Our results confirm motor dysfunction including balance in children with known genetic neurodevelopmental disorders. The ability to characterize the motor phenotype in all children with ASD may help identify the neurological underpinnings of the disorder.

168 **146.168** Heightened Attention to Nonsocial Images Is Not Driven By Feature Salience in Children with Autism

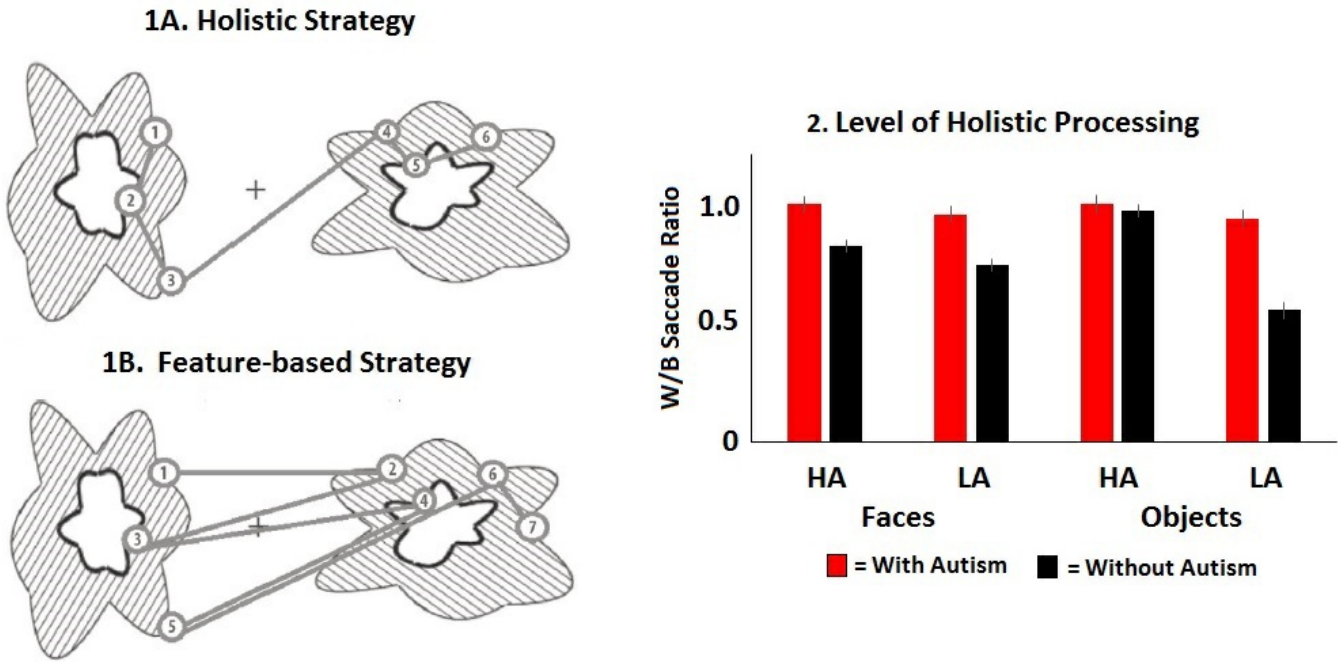
R. L. Shafer[1], *K. Unruh*[1], *J. P. Noel*[1] *and J. W. Bodfish*[2], *(1)Vanderbilt University, Nashville, TN, (2)Vanderbilt University School of Medicine, Nashville, TN*

Background: Circumscribed interests are one form of the diagnostically relevant restricted, repetitive behavior observed in autism spectrum disorders (ASD), and they are characterized by an intense, narrow interest in a given subject area or object type. It is not known how circumscribed interests in ASD may be influencing or influenced by the social deficits that are also characteristic of ASD. Eye-tracking studies have assessed attention to social and non-social stimuli in ASD and have shown that individuals with ASD show a preference for looking at non-social images (e.g., objects) over social images (e.g., faces); however, there is little understanding of what is driving attention to non-social stimuli relative to social stimuli in individuals with ASD.
Objectives: Our study aimed to determine if low-level features of the images could be driving the preferential looking to non-social stimuli (in particular, stimuli that are of high interest to people with ASD) over social stimuli in ASD.
Methods: We used gaze data from a paired-preference viewing task, whereby; typically developing children and children with ASD were presented with images of faces paired with either an image of an object of high interest to individuals with ASD (HAI) or an object of low interest to individuals with ASD (LAI). Gaze data (proportion of look time, average fixation duration, and first fixation duration) were analyzed in relation to the low-level visual features of the image (color, intensity, and orientation).
Results: Our results indicated that all low-level features of the images were predictive of look time to the HAI images for the typically developing children (Color: R = -.124, p = .019; Intensity: R = .234, p < .001; Orientation: R = .230, p <.001; Composite: R = .213, p < .001), but only the composite score for the children with ASD (R = .124, p = .020). There was very little relationship between the low-level features and look time for the LAI images and faces in both the typically developing children and the children with ASD. For typically developing individuals, low-level features were predictive of average fixation duration (Color: R = .180, p = .002; Intensity: R = .180, p = .002; Orientation: R = .130, p = .017; Composite: R = .233, p < .001) and first fixation duration (Color: R = .213, p < .001; Intensity: R = .216, p = .021; Orientation: R = .117, p = .028; Composite: R = .190, p = .001) only for faces that were paired with LAI images, but low-level features were not predictive of average fixation duration or first fixation duration in individuals with ASD.
Conclusions: Given that low-level visual features were minimally predictive of gaze patterns in individuals with ASD regardless of image type, our results suggest that preferential looking to non-social stimuli in ASD is likely due to more cognitively directed attention rather than stimulus-driven attention.

169 **146.169** Holistic Processing of Unfamiliar Faces and Novel Objects in Autism

R. A. Stevenson[1], *S. Ferber*[1], *L. K. Yeung*[1], *N. D. Hazlett*[2], *A. Philipp-Muller*[1], *K. R. Black*[1], *Z. Y. Wang*[1] *and M. D. Barense*[1], *(1)Department of Psychology, University of Toronto, Toronto, ON, Canada, (2)Occupational Therapy, University of Toronto, Toronto, ON, Canada*

Background:
Numerous studies have suggested that individuals with autism may have difficulties perceiving items (e.g. faces) as single, unified percepts (holistic processing), instead defaulting to perceiving the item's components as discrete parts (feature-based processing). There is some debate as to whether this perceptual difficulty in autism is specific to faces, which are typically processed holistically, or if this difficulty extends to visual processing in general.
Objectives:
1) Used a novel eye-tracking paradigm to assess the degree to which typically developing (TD) individuals holistically process unfamiliar faces and novel objects.
2) Investigate holistic processing difficulties in autism, and determine whether they are specific to faces or generalizeable to visual object stimuli.
Methods:
Twenty-eight individuals to date (data collection ongoing; ages 8-21 years) with and without autism have completed an eye-tracking paradigm in which participants were presented with pairs of stimuli from different viewpoints and responded as to whether the two stimuli were the same or different. Four types of stimulus-pairs were presented: low-ambiguity faces (50% morphs), high-ambiguity faces (80% morphs), low-ambiguity novel objects (highly distinct), and high-ambiguity novel objects (highly similar). 72 trials of each condition were presented, and pilot studies matched accuracies across stimulus types.
This eye-tracking paradigm was developed specifically to compare holistic and feature-based perceptual strategies. By comparing the number of *within-item* saccades (holistic strategy) to *between-item* saccades (feature-based strategy), one can assess the extent to which an individual relies on a particular visual processing strategy (see Figure 1). Thus, the ratio of within-item saccades to between-items saccades was calculated for each individual with each stimulus type (W/B-ratio), and used as an index of holistic processing. Higher ratios were indicative of greater use of holistic processing strategies.
Results:
W/B-ratio scores (Figure 2) were compared across stimulus types and diagnostic groups in a three-way ANOVA (diagnostic group x stimulus type x ambiguity level). A main effect of ambiguity was observed (F=9.28, p=0.005), as was a trend towards a main effect of diagnosis (F=2.70, p=0.11). No main effect of stimulus type was observed (F=0.10, p=0.75). Two-way interactions between stimulus type and ambiguity (F=7.95, p=0.01) as well as diagnosis and ambiguity (F=4.94, p=0.04) were observed, but no interaction between diagnosis and stimulus type (F=0.28, p=0.60). Finally, a significant three-way interaction between diagnosis, stimulus type, and ambiguity was observed (F=6.47, p=0.02).
Conclusions:
We confirmed that TD participants processed faces holistically, regardless of ambiguity level. In contrast, for novel objects, they applied a holistic processing strategy when the objects were high-ambiguity, but used feature-based processing when the objects were low-ambiguity. This faces versus objects difference was not observed in individuals with autism. While individuals with autism exhibited a numeric decrease in their holistic processing from high- to low-ambiguity stimuli, this change did not vary according to stimulus domain, suggesting that while TD individuals process faces differently than objects, individuals with ASD did not switch between processing styles based on ambiguity or stimulus type. Instead, their viewing patterns for all stimulus classes reflected an attempt at a holistic strategy.



170 **146.170** How Sensory Experiences Affect Adolescents with an Autistic Spectrum Condition within a Classroom at School

F. E. Howe *and S. D. Stagg, Psychology, Anglia Ruskin University, Cambridge, United Kingdom*

Background: Sensory processing difficulties have been consistently found amongst individuals with an autistic spectrum condition (ASC). These sensory abnormalities have a significant impact on an individual's ability to function in everyday life. Attending school is a normal part of a child's life but for a child with ASC this comes with multiple difficulties, including sensory problems. There is at present a limited amount of research conducted specifically on the effect of sensory difficulties whilst at school, and work on sensory processing in general tends to rely on observer reports. More research employing self-report and autobiographical accounts is needed in this area, in order to understand how sensory issues affect the schooling experience of children with ASC.
Objectives: The current research sought to establish how adolescents with ASC perceive sensory processing abnormalities to be affecting their learning experiences within the classroom.
Methods: The Adolescent/Adult Sensory Profile, a self-report measure, was used to establish objectively whether the participants had sensory issues. A qualitative questionnaire designed by the researcher was then used to investigate the participant's individual sensory experiences whilst in a classroom. The participants were 16 adolescents with a diagnosis of ASC with no co-morbid diagnosis of any learning disability. The participants were drawn from mainstream schools in the east of England.
Results: The participants in the current study showed processing difficulties in at least one of the sensory profile quadrants, and 86% scored outside the normal range on two or more of the quadrants. The participants were aware of their sensory issues, and all reported difficulties in the classroom within at least one sensory domain. Hearing was rated as being the sense that particularly affected the participants followed by touch, smell and vision. Content analysis revealed that the participants considered sensory sensitivity to affect their learning to some extent and that their sensory experiences within a classroom were largely negative. Despite similarities between the participants' sensory experiences, significant variations were found. This highlights the importance of considering adolescents with ASC as having individual experiences.
Conclusions: Sensory experiences vary between participants, highlighting how individual these can be for those with ASC and the need for schools to create sensory profiles specifically for each pupil. This could lead to more appropriate interventions that help children with ASC access the same level of education and schooling experience as neurotypical children.

171 **146.171** How Should We Measure Repetitive Behaviors in Infants and Toddlers with Autism Spectrum Disorder?

P. Towle[1] *and J. Cross*[2]*, (1)Westchester Insitute for Human Development, Valhalla, NY, (2)Developmental Pediatrics, Weill Cornell University School of Medicine, New York, NY*

Background:
There has been increased interest in restrictive and repetitive behaviors (RRBs) in individuals with autism spectrum disorder (ASD), since this symptom domain has been neglected compared to social-communication. This interest has recently applied to very young children with ASD, since the age of reliable diagnosis has been extended downward to 24 months and younger. It will be important to understand if infants and toddlers show the same forms of RRBs as older children, whether there are developmentally younger versions, or if there is discontinuity from RRBs shown in infancy to older children. These issues also have clinical implications, since reduced recognition of RRBs in infants and toddlers could potentially lead to fewer early diagnoses using the reconstructed DSM-5 criteria. Recently RRBS have been investigated in young children using the Repetitive Behavior Scale-Revised and the Repetitive Behavior Questionnaire. However, it is important to consider the implications of extending RRB descriptions and frameworks that were initially created for older individuals to infants and toddlers. Others have reported on early RRBs using the ADOS2 and ADOS-T, as well as other structured play tasks (Harrop et al., 2015); however, the RRB categories and exemplars have been predetermined, are potentially narrow, and do not allow for what children may show in other settings and at home. This study addressed these concerns by starting with a large set of behaviors observed and reported across settings for infants and toddlers diagnosed with ASD, matching them to categories that previous and current research has suggested, and creating a format to record those both observed by clinicians and reported by parents.
Objectives: To 1) Review currently available instruments and methods of measuring RRBs in young children with ASD. 2) Describe development of an instrument for measuring RRBs in infants and toddlers.
Methods: 1) Eight screening and assessment instruments for RRBs in very young children with ASD were reviewed for frameworks and consistencies in defining RRBs. 2) An exhaustive list of RRBs was developed by the first author to create the Infant-Toddler RRB Inventory (IRBBI). Item categories, based on previous research using factor analysis and other construct validity strategies include: Repetitive Behavior (Motor and Visual Stereotypies, Repetitive Play), Insistence on Sameness, Restricted Interests/Areas of Unusual Ability, and Sensory Behaviors. The exemplars were drawn from both existing instruments and extensive clinical experience with infants through preschoolers with ASD. The checklist was refined through review by highly experienced evaluators (n=5), piloting during diagnostic evaluations with 48 young children, and coding the checklist using 75 previous evaluation reports.
Results: The review of instruments showed more disagreement than agreement on what both the major categories of RRBs should be and what exemplars should operationalize them. The IRRBI was developed, piloted, and refined until it accommodated symptoms reported in clinical charts and during evaluations by experienced clinicians; the resulting categories, subcategories, and exemplars are presented.
Conclusions: There is currently little agreement on how and what to measure as RRBs in infants and toddlers. A new instrument developed from a combination of research frameworks and clinical experience/observation is described.

172 **146.172** Increased Force Variability in Autism Reflects Reduced Modulation of Motor Neuron Pool Beta Oscillations

M. Kwon[1]*, S. Mohanty*[2]*, K. Conroy*[2] *and M. W. Mosconi*[1,2]*, (1)Schiefelbusch Institute for Life Span Studies and Clinical Child Psychology Program, University of Kansas, Lawrence, KS, (2)UT Southwestern Medical Center, Dallas, TX*

Background: Sensorimotor impairments are common in individuals with autism spectrum disorder (ASD). We recently demonstrated that patients exhibit amplified force variability during precision gripping. The neurophysiological mechanisms associated with these impairments are not well understood. Recording of activity of the motor neuron pool represents a promising approach for understanding brain mechanisms as motor unit activity represents the final pathway of the voluntary command from the brain to the muscle. Here, we used surface electromyography (EMG) and specialized surface electrodes to record multiple motor units during a test of manual force control.
Objectives: To determine the neuromuscular mechanisms that contribute to impaired force control in ASD during isometric index finger abduction.

Methods: Seventeen individuals with ASD and 13 healthy controls matched on age, gender, IQ and handedness performed an isometric index finger abduction task at 20, 40 and 60% of their maximum force. Participants pressed with their index finger against a precision load cell while viewing visual feedback on a monitor in front of them. As they increased force against the load cell, a force cursor on the monitor increased in height. They were instructed to press against the load cell so that the force cursor reached the height of a target line for 27 seconds. To determine individuals' ability to modulate motor neuron pool activity, we used an EMG decomposition system To determine individuals' ability to modulate motor neuron pool activity, we used an EMG decomposition system to identify and record action potentials from multiple motor units. A specialized electrode was placed along the fibers of the first dorsal interosseous muscle to record neuromuscular activity. Participants performed 2 trials at each force level interleaved with 1 min rest blocks.
Results: Individuals with ASD exhibited greater force variability compared to healthy controls across force levels. Mean force was not different between groups at any force level. Mean discharge rate of the motor neuron pool decreased with increasing force levels. Individuals with ASD exhibited an increased mean discharge rate compared to healthy controls. Frequency analyzes showed that the majority of the modulation of motor neuron pool activity related to force control was in the beta range (10-35 Hz). Individuals with ASD showed reduced modulation of the motor neuron pool in the beta range compared to healthy controls.
Conclusions: Our findings show that amplified force variability in individuals with ASD reflects altered activation of the motor neuron pool. Increased firing rate of the motor neuron pool in ASD suggests that larger motor units recruited redundantly to produce force may impair force control in patients. We also found decreased motor neuron pool oscillations in the beta range (10-35 Hz) in ASD suggesting that neuromuscular activity associated with central commands involved in ensuring stable motor output are compromised in ASD. These results indicate that brain mechanisms involved in precisely stabilizing motor output are disrupted in ASD and may be promising targets for treatment and biomarker discovery research.

173 **146.173** Insistence on Sameness Behaviours Selectively Associate with Reported Childhood Pretend Play in Adults with ASD

***S. L. Barrett**, C. Jones and S. R. Leekam, School of Psychology, Cardiff University, Cardiff, United Kingdom*

Background: Research with children with ASD shows that restricted and repetitive behaviours (RRB) reliably group into two subtypes: repetitive sensory and motor (RSM) and insistence on sameness (IS) and that high levels of RRBs in general are associated with lack of play (Honey et al., 2007). The present study tests whether RSM and IS subtypes are found in adults with ASD, and whether these subtypes are associated with childhood pretend play.
Objectives: 1) Assess the RRB subgroups found in adults using the Adult Repetitive Behaviours Questionnaire–2 (RBQ-2A; Barrett et al., 2015), the first published self-report measure of RRBs for adults. Its component structure has not yet been assessed in adults with ASD.
2) Test whether there are any difference in RRBs between participants who played pretend as a child and those who did not play pretend.
Methods: The RBQ-2A was administered to UK participants (N = 787) in an online survey, along with open-ended questions about their childhood pretend play (quantified for the present analysis). Analyses were only conducted on complete datasets from participants who reported either a clinical diagnosis of ASD or no diagnosis of any kind (i.e. neurotypical [NT]). Participants in the final sample (N = 583) were aged 18-66 years (M = 36.51, SD= 11.67), 219 were male and 317 participants reported a clinical diagnosis of ASD. The RBQ-2A data were analysed using principal components analysis (PCA) with direct oblimin rotation to allow for correlation between components. The Autism-Spectrum Quotient (AQ; Baron-Cohen et al., 2001) was also completed.
Results: The final rotated PCA solution explained 45.36% of the total variance and resulted in the two predicted components, RSM and IS. Participants with ASD scored significantly higher in terms of total AQ score, mean total RBQ-2A score and mean RBQ-2A subscale scores. Fifty percent of the ASD group and 76% of the NT group reported playing pretend games as children. For both groups, participants who did not play pretend as a child scored higher on the imagination subscale of the AQ, supporting the role of pretend play as a predictor for imagination. In the ASD group, participants who did not play pretend as a child scored significantly higher on the IS subscale than those who did play pretend (p < .001), whereas no significant differences depending on pretend play were found for the NT group on either of the RBQ-2A subscales.
Conclusions: The component structure of the RBQ-2A was assessed for the first time in a sample that includes adults with ASD. As in previous research with children, we identified two reliable subscales comprising RSM and IS, with expected group differences across the total score and its subscales. The second objective was to test whether childhood pretend play has an effect on later RRBs and we found an ASD-specific effect for IS only. This is the first evidence that childhood pretend play may be associated with RRBs in adulthood. Further attention should be given to the importance of the relationship between imagination and RRBs in ASD.

Table 1: Pattern matrix for principal components analysis, and percentage of variance explained and internal consistency for each component

Rotated item loadings:	Component 1 Repetitive Sensory and Motor Behaviours	Component 2 Insistence on Sameness
1. Like to arrange items in rows or patterns?	**.406**	.268
2. Repetitively fiddle with items?	**.708**	.026
4. Rock backwards and forwards, or side to side, either when sitting or when standing?	**.748**	.119
5. Pace or move around repetitively	**.544**	.078
6. Make repetitive hand and/or finger movements?	**.737**	.057
7. Have a fascination with specific objects?	.357	**.430**
8. Like to look at objects from particular or unusual angles?	**.549**	.155
9. Have a special interest in the smell of people or objects?	**.543**	.009
10. Have a special interest in the feel of different surfaces?	**.661**	.022
11. Have any special objects you like to carry round?	**.435**	.293
12. Collect or hoard items of any sort?	.217	**.527**
13. Insist on things at home remaining the same?	.122	**.845**
14. Get upset about minor changes to objects?	.102	**.796**
15. Insist that aspects of daily routine must remain the same?	.044	**.806**
16. Insist on doing things in a certain way or re-doing things until they are "just right"?	.017	**.719**
17. Play the same music, game or video, or read the same book repeatedly?	.293	**.455**
18. Insist on wearing the same clothes or refuse to wear new clothes?	.251	**.478**
19. Insist on eating the same foods, or a very small range of foods, at every meal?	.080	**.567**
Percentage of variance explained:	37.02%	8.34%
Internal consistency (Cronbach's alpha):	.83	.88

174 **146.174** Insistence on Sameness in Parents and Their Children with ASD

***A. N. Esler**, S. T. Stronach and S. Jacob, University of Minnesota, Minneapolis, MN*

Background: Previous research has established the existence of the broader autism phenotype (BAP) (e.g., Piven et al., 1997), but work is emerging on its relationship with specific child ASD features. Insistence on sameness (IS) may be a heritable feature of ASD due to its relative independence from mediating variables, such as verbal IQ. It has been suggested that subtyping based on degree of IS to create more homogeneous groupings of individuals may increase the ability to detect genetic factors (Hus et al., 2007).
Objectives: Characterize IS in parents of children with ASD and examine its relationship with child IS. We hypothesized a positive association between parent and proband IS.
Methods: Participants were 2760 families who participated in the Simons Simplex Collection. Parent IS was measured using the Broader Autism Phenotype Questionnaire (BAPQ). A factor analysis was conducted to create an IS scale from BAPQ items. BAPQ-IS scores were divided into groups of the lowest and highest 25% and middle 50% (25-50-25). Proband IS was operationalized using subsets of items from the ADI-R and the RBS-R. Linear regression models were used to examine the relationship between parent IS and proband IS. Potential predictors were entered into a structured hierarchical regression model, in which Block 1 included proband verbal IQ, sex, and age (which are known to affect the expression of ASD and other psychological symptoms), and Block 2 included father and mother BAPQ-IS raw scores. Significant predictors were then entered into Forward Stepwise models to determine the relative contributions of these individual variables to proband IS.
Results: Our factor analysis generated a BAPQ-IS scale consisting of a subset of eight items from the original BAPQ-Rigid scale. Rigid items involving keeping things the same and disliking changes in routine were retained in our IS factor, and items involving disliking new or unfamiliar things were excluded. Our empirically derived BAPQ-IS factor differed only slightly from a previous BAPQ-IS scale generated through clinical consensus (Levin-Decanini et al., 2014); it contained the six items identified by Levin-Decanini et al. plus two additional items. Parent IS and proband IS were minimally related, although results reached statistical significance. Only proband RBS-R-IS scores had more than 2% of its variance explained by parental IS once significant proband variables were accounted for, and in all cases, parent IS explained the smallest amount of variance in each proband IS variable.
Conclusions: The relative lack of association between parent IS and proband IS was surprising given the literature documenting positive correlations between parental rigidity and BAP characteristics and proband ASD (Losh et al., 2008; Piven et al., 1997). Although sample size was large, it was a simplex family sample, which may have resulted in a weaker relationship between parent and child IS compared to previous studies of multiplex families (e.g., Piven et al., 1997). Scale and measurement differences (e.g. characterization of adult versus child IS symptoms) may contribute to these results. Further research is needed on the validity and reliability of measuring IS and BAP features over the course of development.

175 **146.175** Insistence on Sameness, Anxiety, and Social Motivation in Children with Autism Spectrum Disorder

R. S. Factor[1], *E. E. Condy*[2], *J. P. Farley*[3] *and A. Scarpa*[1,3], *(1)Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Virginia Tech Center for Autism Research, Blacksburg, VA*

Background: Restricted repetitive behaviors (RRBs) are a key feature of autism spectrum disorder (ASD; American Psychiatric Association, 2013). While the function of RRBs in ASD is currently unclear, RRBs have been identified as a possible anxiety reduction strategy (Joosten et al., 2009). Anxiety is prevalent in individuals with ASD (White et al., 2009), and anxiety triggers in ASD include social interaction and the disruption or change of routines (Ozsivadijan, Knott, & Magiati, 2012), which clearly intersect with the insistence on sameness (IS) domain of RRBs. RRBs can also affect socialization by decreasing the likelihood of positive peer interactions (Nadig, Lee, Singh, Bosshart, & Ozonoff, 2010) and interference with daily life (South, Ozonoff, & McMahon, 2005). Further, social skills training for children with ASD has been shown to increase social interactions and reduce RRBs (Loftin et al., 2008).
Objectives: The present study attempts to link low social motivation and anxiety to RRBs, specifically IS, by examining the mediating role of social motivation between anxiety and RRBs in children with ASD. Examining these relationships may provide guidance on intervention strategies for children with ASD.
Methods: Participants were part of an ongoing assessment database of individuals with and without ASD. At the time of analysis, the database had 81 participants. Unaffected controls ($n = 25$) were not included. After removing participants due to incomplete data, the sample used included 44 participants from 2 to 17 years ($M = 6.91$, $SD = 3.64$), were 80% male ($n = 35$), and race/ethnicities were reported as 84.1% White ($n = 37$), 6.8% Black ($n = 3$), 4.5% Asian ($n = 2$), and 4.5% Other ($n = 2$). At the assessment appointment, clinical interviews and behavioral assessments were completed and ASD diagnosis was determined by the assessment team and a licensed clinical psychologist, based on DSM-5 criteria.
Results: The Baron & Kenny (1986) approach was used as a preliminary evaluation of the proposed mediation model. Anxiety was positively associated with the proposed mediator, social motivation deficits ($\beta = 0.49$, $p < 0.01$), as well as the outcome variable, sameness behavior ($\beta = 0.46$, $p < 0.01$), such that higher anxiety was related to increased social motivation deficits and increased sameness behaviors. When both the mediator and the outcome variable were included, the total effect remained significant (*adjusted* $R^2 = 0.30$, $F(2,41) = 10.35$, $p < 0.01$). Furthermore, there was a significant direct effect ($\beta = 0.33$, $p = 0.03$), indicating partial mediation. To verify the indirect effect, a bootstrapping simulation using 1000 samples was performed. Results indicated social motivation partially mediated the relationship between anxiety and IS as evidenced by a significant indirect effect ($M = 0.13$, 95% CI [0.02, 0.27]).
Conclusions: These findings suggest a relationship between anxiety, RRBs, and social motivation. In particular, anxiety was positively related to IS, which was partially accounted for by deficits in social motivation. The results shed light on how these ASD features are linked and suggest that intervention for sameness behaviors should address both social motivation and anxiety.

176 **146.176** Integrating Behavioral and Electrophysiological Assessments of Sensory Reactivity in ASD

P. M. Siper[1], *J. L. George-Jones*[1], *S. M. Lurie*[1,2], *J. Zweifach*[1,2], *A. T. Wang*[1], *A. Kolevzon*[3], *J. D. Buxbaum*[1] *and T. Tavassoli*[1], *(1)Psychiatry, Seaver Autism Center at Mount Sinai, New York, NY, (2)Ferkauf Graduate School of Psychology, Yeshiva University, Bronx, NY, (3)Psychiatry, Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Sensory reactivity is now recognized as a symptom of autism spectrum disorder (ASD) in the Diagnostic and Statistical Manual of Mental Disorders (DSM-5). Previous literature indicates that sensory symptoms are present across the lifespan and affect individuals at all levels of functioning. In addition, greater sensory symptoms have been reported in more severely affected children. Obtaining quantifiable measures of sensory reactivity is particularly important for individuals who are unable to describe their own sensory experiences. While there is a clear need to objectively measure sensory reactivity, these symptoms have historically been described on the basis of caregiver report. The current study combines a direct observation and corresponding caregiver interview with an electrophysiological assessment in an effort to develop outcome measures that may be sensitive to change in response to treatment, while gaining insight on the underlying neurobiology of sensory symptoms in ASD.
Objectives: To examine whether observed and reported sensory reactivity is correlated with neural measures of sensory processing.
Methods: This study included minimally verbal children between the ages of 2 and 7 with a diagnosis of ASD. Diagnoses were established using DSM-5 criteria, the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), and the Autism Diagnostic Interview-Revised (ADI-R). All participants received the Seaver Sensory Assessment for Neurodevelopmental Disorders (SSAND), which consists of a standardized clinician-administered observation and corresponding caregiver interview that characterizes sensory reactivity symptoms based on DSM-5 criteria for ASD. The SSAND provides an overall total score (observed + reported), scores by sensory modality (visual, auditory, tactile), and scores by DSM-5 symptom domain (hyper-, hypo-reactivity, seeking). Visual evoked potentials (VEP) were collected using single-channel EEG recording over the occipital cortex. A contrast revering checkerboard pattern consisting of 32 x 32 checks (check size = 18.75 minarc) contrast reversed with a 1-Hz square-wave signal (100% contrast) was used to elicit transient VEPs.
Results: Results to date indicate a relationship between sensory reactivity symptoms and neural responses. Specifically, P100 amplitudes were negatively correlated with both SSAND total scores and SSAND visual domain scores. P100 reflects inhibitory (GABAergic) activity and therefore the smaller the inhibitory response, the greater were the number of behavioral sensory symptoms. Importantly, there were no correlations between P100 amplitude and auditory or tactile domain scores, confirming the specificity of this finding. Activity in several frequency bands was also correlated with overall SSAND scores and visual domain scores (observed and reported), indicating that greater sensory reactivity at the behavioral level was associated with weaker VEP signal power.
Conclusions: Our results suggest that there is a relationship between observed and reported visual reactivity symptoms and electrophysiological responses. Future directions include examining whether auditory evoked potentials are correlated with auditory domain scores on the SSAND. Ultimately, the goal is to develop outcome measures that combine information from behavioral and neural testing and to examine whether these measures are sensitive to change in the context of clinical trials.

177 **146.177** Interpersonal Sensory-Motor Synchronization in Adults with and without ASD during a Joint Improvisational Mirror Game

ABSTRACT WITHDRAWN

Background:
Recent research on Autism Spectrum Disorders (ASD) suggests that individuals with autism may have a basic deficit in synchronizing with others, and that this difficulty may lead to more complex social and communicative deficits (Marsh et al., 2013). The current project aims to conduct an in-depth investigation of interpersonal sensory-motor synchrony in ASD, using an innovative experimental paradigm - the Mirror Game (MG, Fig 1) – that allows high-resolution temporal and spatial motion tracking in an open-ended joint improvisation game (Noy et al., 2011).
Objectives : To investigate the ability of adults with ASD, as compared with typically developing (TD) adults, to synchronize their movements with another person.
Methods:
Participants: data from 25 participants with high-functioning ASD was compared with that of 25 TD adults.

MG procedure: two players face each other holding handles which can move along parallel tracks, and are told to “imitate each other, create synchronized and interesting motions, and enjoy playing together” (Fig 1a,b). All participants played against the same expert improviser. Participants were instructed to first lead the motion (Leader), then follow the experimenter’s motions (Follower), and then engage in Joint Improvisation (JI), with no designated leader; in 3-minute trials. The motion of the two handles is sampled at 50 HZ (Fig 1c,d).

Data analysis: Players’ synchronization was measured using the mean relative difference in velocity (*dV*) and the timing differences between zero-velocity events (*dT*). Periods of synchronized, co-confident (CC) motion (Fig 1d) were defined as periods of nonzero motion longer than 2sec with minimal jitter (i.e., in which the Fourier rms power in the 2-3 Hz band of the difference between the players’ velocities is less than 10% of their mean velocity (Noy et al., 2011)).

Results:

We found that individuals with autism *can* attain co-confident (CC) motion when playing the Mirror Game with an expert improviser. Interestingly, we found an interaction effect of diagnostic group (ASD, TD) by Round (Leader, Follower, Joint Improvisation), such that individuals with ASD had significantly reduced levels of CC compared to TD participants when following the experimenter ($t(33)=4.44$, $p<.01$), but not when leading or jointly improvising with them.

Conclusions:

These data provide the first evidence, to our knowledge, that individuals with autism can attain highly-synchronized, co-confident motion, when playing with another player in an open-ended joint improvisation game. Further data collection and analysis are currently underway to determine whether ASD participants differ from TD participants in their patterns of interpersonal synchronization, and whether these interpersonal motion patterns are associated both with background characteristics such as autism severity, IQ, motor coordination, and imitation ability and with more complex, everyday social and communication abilities.

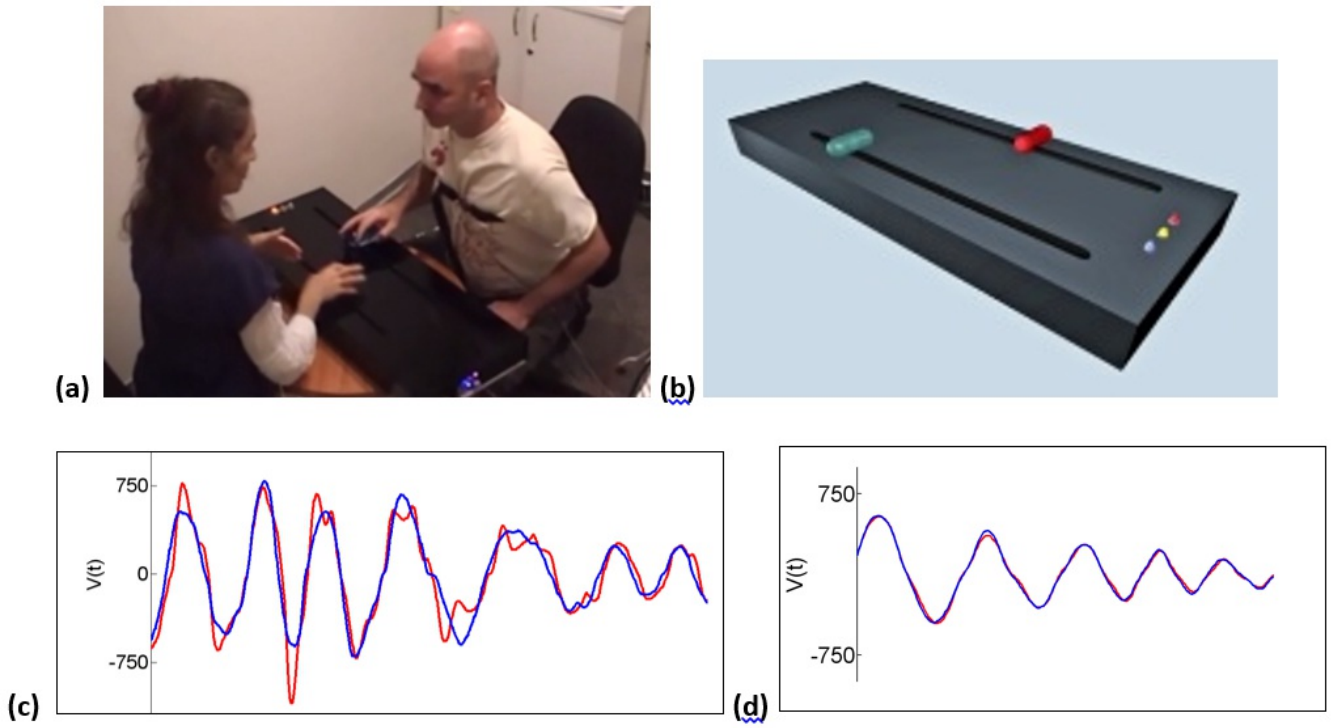


Figure 1: (a) Two players mirror each other, producing jointly synchronized motion, on **(b)** the mirror game measurement system. Players are instructed to: “imitate each other, create synchronized and interesting motions, and enjoy playing together.” **(c)** *Leader-follower pattern*: the follower (red) shows 2-3Hz oscillations around the leader’s (blue) smooth trajectory. **(d)** *Co-confident pattern*: two highly synchronized smooth motion tracks, with no jitter.

178 **146.178** Is There a Relationship Between Sleep Problems and Motor Impairment in Children with Autism Spectrum Disorder?

S. J. Thomas[1], *T. Hinkley*[2], *L. Barnett*[3], *T. May*[1,4], *N. Papadopoulos*[1], *J. McGinley*[5], *A. Timperio*[6], *H. Skouteris*[1], *J. A. McGillivray*[1], *J. Salmon*[6] *and N. J. Rinehart*[1], *(1)School of psychology, faculty of health, Deakin University, Burwood, Australia, (2)Centre for Exercise and Nutrition Research, Deakin University, Burwood, Australia, (3)Health and Social development, Deakin University, burwood, Australia, (4)Royal Children's Hospital, Parkville, Australia, (5)department of physiotherapy, University of Melbourne, Parkville, Australia, (6)Centre for Exercise and Nutrition, Deakin University, Burwood, Australia*

Background: Two of the main neurological problems children with Autism Spectrum Disorder (ASD) are faced with are; motor impairment, and sleep problems. Sleep problems have been reported to occur in up to 83% of children with ASD and have both behavioural and neurological underpinnings (Cortesi et al., 2010). Motor impairment has been reported to occur in up to 79% of children with ASD (Green et al., 2002). Both sleep problems and motor impairment have been linked to dysfunction in specific cortical and subcortical structures such as the fronto-straital circuits (Maski & Kothare, 2013). Previous studies have linked sleep deprivation to problems with motor movements in healthy adolescents and adults (Maski & Kothare, 2013). To date, no studies have investigated the possible association between sleep problems and impaired motor proficiency in children with ASD. It is plausible that impaired motor function will be associated with greater sleep problems as a result of disruption to similar underlying brain circuitry.

Objectives: The current study aimed to investigate the association between motor proficiency and behavioural sleep problems in children with ASD.

Methods: Participants aged 4-6 years (n=30, 80% male, 80% without Intellectual Disability) with a current ASD diagnosis were recruited from the larger Active Kids study, a study investigating physical activity, sleep and motor impairment in children with ASD. Level of motor proficiency was measured using the Movement Assessment Battery for Children (MABC-2) subscales (manual dexterity, ball skills and balance and coordination) and total score. Behavioural sleep problems were measured using the subscales and total scores Children’s Sleep Habits Questionnaire (CSHQ; sleep onset delay, sleep duration, bedtime resistance, sleep anxiety, night waking, parasomnias, sleep disordered breathing, daytime sleepiness). Correlations investigated associations between the subscales and total MABC-2 and with the subscales and total CSHQ.

Results: There were moderate negative correlations between sleep onset delay and poorer motor proficiency as measured by the MABC-total ($r = -.49$, $p = .008$), manual dexterity ($r = -.60$, $p=.001$), ball skills ($r = -.41$, $p=.03$, and balance and coordination ($r = -.40$, $p=.03$). Moderate negative correlations between sleep duration and motor proficiency as measured by the MABC total score ($r = -.41$, $p=.03$) and manual dexterity ($r = -.41$, $p=.03$) were also found. There were no further associations between the other subscales of the CSHQ and the subscales or total MABC-2.

Conclusions: The findings confirm the presence of a relationship between motor proficiency and sleep in children with ASD. Further research to investigate the overlap in brain circuitry between sleep problems and motor proficiency and directions of these relationships (i.e. to determine whether behavioural sleep problems influence children’s motor impairment or whether motor impairment predicts behavioural sleep problems) is required. Such research will set the scene for informing the development of assessments and novel interventions that seek to promote healthy outcomes in individuals with ASD such as improving sleep patterns and motor proficiency.

Table 1 Correlations between motor proficiency and sleep problems in children with ASD

	M-ABC Total Score	Manual dexterity	Ball skills	Balance and coordination
Sleep onset delay	-.49**	-.60**	-.41*	-.40*
Sleep duration	-.41*	-.41*	-.29	-.35
Sleep anxiety	-.20	-.20	-.14	-.09
Night waking	-.14	-.10	-.09	-.15
Parasominas	-.30	.07	.01	-.11
Sleep Disordered Breathing	.02	.18	-.02	-.13
Daytime sleepiness	-.23	-.31	-.05	-.24
Bedtime resistance	-.22	-.22	-.20	-.17
CSHQ Total	-.27	-.24	-.16	-.26

Note: ** correlation significant at the .01 level; * correlation significant at the .05 level; *M-ABC* Movement Assessment Battery for Children; *CSHQ* Child Sleep Habits Questionnaire.

179 **146.179** Key Individual Characteristics Related to Circumscribed Interests in Youths with ASD

C. E. Brown[1], *T. N. Takahashi*[2] *and S. M. Kanne*[3], *(1)University of Missouri Columbia, Columbia, MO, (2)University of Missouri Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (3)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Circumscribed interests (CI) are a specific type of repetitive behavior that commonly occurs in youths with autism spectrum disorder (ASD), involving intense focus on a narrow range of topics (e.g., collecting objects, memorizing facts). Youth invest considerable time in activities involving these interests, often at the expense of prosocial activities. Interfering with these interests can be an antecedent for disruptive behaviors (e.g., physical aggression), often leading parents to describe these interests as their child's most impairing symptom. Though studies have examined prevalence and delineated categories of CI, less research has examined phenotypic characteristics associated with types of CI.

Objectives: The current study aimed to examine key phenotypic characteristics (e.g., youth intelligence, ASD core symptoms) in relation to types of CI in a large, well-

characterized sample of youths with ASD. This study explores possible links between individual characteristics and CI as reported by parents.
Methods: The sample consisted of caregivers (n = 186) who completed the Autism Diagnostic Interview - Revised (ADI-R) as part of the Simons Simplex Collection. Caregiver responses on the "circumscribed interests" and "unusual preoccupations" items of the ADI-R were transcribed. Only participants who endorsed pervasive or disruptive interests on these items were included. Using qualitative methodology, transcriptions were coded by selecting dialogue that described CI (e.g., "obsessed with Pokémon cards") and placing responses into categories (e.g., Collecting). Categories were derived from examination of the responses and considering existing measures of youth interests (e.g., The Interest Scale, Cambridge University Obsession Questionnaire). Individual phenotypic data were then associated with the various categories to examine characteristics of individuals with the purported interest.
Results: Interests were grouped into 31 categories, which were consistent with those found in other studies (e.g., Bodfish, 2003; Klin et al., 2007).. Caregivers reported their child's interests falling into an average of 2.8 categories. The most frequent interests reported were Strong Attachment to Fictional Characters (12%) and Televisions/Movies (10%). The least frequent reported were Mechanical Systems (0.4%) and Religion/Occult (0.6%). Youth with mean IQs in the average or above average range endorsed interests such as Building/Construction, Factual Information, and Biology, whereas youth with mean IQs in the impaired range endorsed interests in Rocks/Geology. Those with a high degree of core ASD symptoms by parent report had interests ranging from Religion/Occult, to Fictional Universes, Collecting, and Weather/Natural Disasters. Those with a high degree of core ASD symptoms by clinician report had interests ranging from the Signs, to Mechanical Systems, Reading/Writing, and Music. Older youth endorsed interests in Japanese Culture, Rocks/Geology, and Factual Information, whereas younger youth endorsed interests in Words/Letters and Math/Counting.
Conclusions: Youth with ASD endorse a broad range of CI. Specific interests are endorsed more frequently than others and certain types of interests appear to be associated with level of intelligence and core ASD symptoms, though this may differ based on parent or clinician observation. Further understanding of the etiology and types of CI and how interests relate to phenotypic characteristics will contribute to better evaluating and reducing impairment for individual youth.

180 **146.180** Latent Constructs Underlying Sensory Subtypes: An Independent Components Analysis

B. Hand[1], *S. J. Dennis*[2], *E. J. Marco*[3] *and A. E. Lane*[4], *(1)The Ohio State University, Columbus, OH, (2)School of Psychology, University of Newcastle, Callaghan, Australia, (3)University of California in San Francisco, San Francisco, CA, (4)School of Health Sciences, University of Newcastle, Callaghan, Australia*

Background: Sensory features (SF) are atypical responses to sensory stimuli that influence the functioning of children with neurodevelopmental disorders (NDD) including Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactive Disorder (ADHD). Due to the heterogeneous nature of SF, there is a need to define clinically meaningful subtypes, which may differentially respond to intervention. Sensory features are highly relevant to the ASD population due to their recent inclusion in diagnostic criteria. Distinct sensory subtypes have been identified in children with ASD through parent responses on the Short Sensory Profile (SSP) (Lane et al., 2014). Clinical profiles led to the hypothesis that two sensory dimensions underlie SF: 1) sensory reactivity (the intensity of a response to a stimulus), and/or 2) multisensory integration (the ability to process multiple concurrent stimuli). The use of Lane et al.'s sensory subtypes facilitates systematic examination of behavior and symptom profiles associated with each subtype. It is necessary, however, to have a sound understanding of the theoretical basis underlying the subtypes before they can be adopted confidently in clinical settings. As a next step to validate this schema, we performed independent component analysis (ICA) to elucidate the latent constructs underlying sensory subtype classification.
Objectives: To determine the latent constructs that underpin sensory subtype classification.
Methods: Two datasets were analyzed in the present study. The first is a sample of 228 children with ASD aged 2-10. The second included 155 children aged 4-10 years with ADHD, Sensory Processing Disorder or ASD and typically developing controls.
Parents of study participants completed the SSP, which measures behaviors associated with responses to everyday, environmental sensory stimuli in children aged 3–10 years. Parents respond to each item using a 5-point ordinal scale, with higher scores indicating more typical performance.

Independent component analyses (ICA) were conducted via a multistep process using z-scores from the seven SSP domains and item-level data. First, our hypothesis of a two-component structure was tested on domain z-scores. Next, z-scores were analyzed using model-fitting software to determine if any model had superior model fit than the hypothesized solution. The optimal number of components was determined, balancing interpretability with model fit. Lastly, item-level data were analyzed via ICA to determine which specific items on the SSP contribute most to the underlying latent constructs.

Results: A three-component model best explained the data for both samples, each with major contributions from one of the following domains: 1) taste/smell sensitivity, 2) low energy/weak, and 3) underresponsive/seeks sensation and auditory filtering. Key items from those domains that heavily contributed to the corresponding latent components were identified.
Conclusions: We propose that components one and two represent specific *foci* of SF, vis a vis taste/smell sensitivity and low energy/weak. Component three represents the construct of *severity*. Indeed, the Lane et al.'s sensory subtypes can be mapped onto these components in a conceptually meaningful way. The present study asserts a novel conceptual framework of constructs (*focus* and *severity*) that underlie sensory subtypes to guide future research and clinical practice on SF in ASD.

181 **146.181** Less Efficiency in Execution and Observation, but Not Imitation, of Actions in High-Functioning Young Adults with an Autism Spectrum Disorder

M. Vanvuchelen[1], *K. Cuypers*[1,2], *L. Van Schuerbeeck*[1], *M. A. Braeken*[1], *V. Ross*[3], *E. M. Jongen*[4], *R. L. Meesen*[1] *and C. Beelen*[1,5], *(1)Faculty of Medicine and Life Sciences - Rehabilitation Research Center (REVAL), Hasselt University, Diepenbeek, Belgium, (2)Department of Biomedical Kinesiology - Motor Control Laboratory - Research Center for Movement Control and Neuroplasticity, Katholieke Universiteit Leuven, Leuven, Belgium, (3)Transportation Research Institute (IMOB)-School for Mobility Sciences, Hasselt University, Diepenbeek, Belgium, (4)Transportation Research Institute (IMOB)- School for Mobility Sciences, Hasselt University, Diepenbeek, Belgium, (5)Faculty of Psychology and Educational Sciences - Parenting and Special Education, Katholieke Universiteit Leuven, Leuven, Belgium*

Background: Autism spectrum disorders (ASDs) are often accompanied by problems in planning and execution of goal-directed actions. The concept of planning movements in order to attain comfort at completion, though sacrificing initial comfort, is known as end-state comfort (ESC) (Rosenbaum et al., 1990). Hence, the application of ESC points to efficient action planning. The bar-transport paradigm is a simple, but very effective measurement tool for providing valuable information on the application of ESC and the efficiency of a persons' motor planning skills (Rosenbaum et al. (1990). Several studies suggest that persons with ASD are impaired in the spontaneous application of ESC (Hughes, 1996; Conson, et al. 2013, Gonzalez et al., 2014), but not when they are allowed to imitate this application (Hamilton, Brindley & Frith, 2007; Jiménez, Lorda, & Méndez, 2014). To the best of our knowledge, there are no studies which have investigated the understanding and prediction of efficient goal-directed actions applying ESC.
Objectives: The present study investigated the efficiency of goal-directed actions in the domains of action execution, imitation and prediction in young adults with an ASD compared to typically developing peers.
Methods: A cross-sectional study was conducted containing 21 persons with ASD and 26 typically developing persons (TDP) between 17 and 29 years of age. In the first experiment, action efficiency was investigated by analyzing the spontaneously application and imitation of ESC in addition with speed and timing of actions. In the second experiment, the prediction of efficient actions was studied.
Results:
Experiment 1 showed that participants with ASD were less able to spontaneously perform efficient actions compared to TDP ($U = 98.5$; $Z = -2.14$; $p = .03$). Results of a mixed model analysis with group, trial and their interaction as fixed factors and individual participants as random factor showed that the timing ranging from stimulus onset to action start ($F1,35 = 2.2$; $p = .14$) and from action start to lifting the bar ($F1,35 = 3.2$; $p = .08$) did not differ between both groups. In contrast, participants with ASD were significantly slower than TDP in the executive part ($F1,35 = 5.2$; $p = .03$; $\beta 0$ ASD = .91; $\beta 0$ TDP =.91-.04; $\beta 1 = -.005$). This was no longer true when their actions were visually guided online in the imitation condition ($F1,34 = .03$; $p = .86$; $F1,34 = .5$; $p = .47$; and $F1,34 = 2.9$; $p = .10$, respectively). Furthermore, in this condition both groups did not differ in their application of ESC when imitating the actions ($U = 149.5$; $Z = -.35$; $p = .72$).
Experiment 2 showed that participants with ASD were less able to predict ESC when they observe efficient actions compared to TDP ($U = 177.5$; $Z = -2.06$; $p = .04$). In contrast, according to mixed model analysis both groups did not differ in their reaction times towards observed actions ($F1,45 = 1.5$; $p = .23$).
Conclusions: Persons with ASD were less able to spontaneously execute and predict efficient actions, although they were able to imitate them.

182 **146.182** Motor Ability and Oculomotor Function in Children with an Autism Spectrum Disorder

E. Sumner[1] *and E. L. Hill*[2], *(1)Department of Psychology, Goldsmiths, University of London, London, United Kingdom, (2)Goldsmiths, University of London, London, United Kingdom*

Background: Eye movements provide a window into cognitive processing. Deficits in oculomotor control (i.e. suppressing reflexive saccades) have been shown to relate to language ability in ASD. In addition to language problems, an increasing number of studies have highlighted motor difficulties in this population. Of note, research supports a link between motor skill and aspects of oculomotor control, such as smooth pursuit (e.g. the ability to track an object); as reported in a population of children with a core motor impairment. However, at present, very little is known about the relationship between motor and oculomotor function in ASD.
Objectives: The present study set out to measure motor ability and the integrity of the oculomotor system in ASD. The study aimed to determine if eye movements can differentiate between children with ASD and controls; and to investigate the relationship between motor skill and oculomotor function.
Methods: Twenty-two children with ASD, aged 7-10 years, were compared to 22 typically-developing children matched by age. ASD diagnosis was confirmed using the Autism Diagnostic Observation Schedule (ADOS-2), and Full Scale IQ (WISC-IV) and motor competency were assessed (using the Movement Assessment Battery for Children, MABC-2). Children completed four short tasks designed to assess oculomotor function: fixation, smooth pursuit, pro- and anti-saccades. Eye movements were

recorded using the Eyelink 1000 (SR-research).
Results: Preliminary analyses reveal that children with ASD demonstrated poorer fixation stability and made more drifts away from the visual target than their peers. Children with ASD were comparable to their peers on the slow speed measure of smooth pursuit, but demonstrated lower pursuit gain than the controls in a faster pursuit task. Reflexive eye movement (pro-saccades) were similar across the two groups. However, children with ASD had more difficulty with the anti-saccade task, making many errors. Individual case analyses revealed that those children with ASD that had poorer motor skills also performed worse on the measures of fixation and smooth pursuit.
Conclusions: The findings are the first demonstration of a link between motor and oculomotor difficulties in children with ASD. Further examination of oculomotor dysfunction in this population may help to identify neural mechanisms involved in this disorder. Moreover, the findings highlight the need to examine co-occurring difficulties, such as poor motor skill, when interpreting eye tracking data.

183 **146.183** Motor Differences in Children with Autism Engaged in Ipad Gameplay

*A. Anzulewicz[1], K. Sobota[2], M. Ferrara[3] and **J. T. Delafield-Butt**[3,4], (1)Psychology, Jagiellonian University, Krakow, Poland, (2)Harimata, Krakow, Poland, (3)University of Strathclyde, Glasgow, United Kingdom, (4)St. James Road, University of Strathclyde, Glasgow, United Kingdom*

Background:
One of the early markers of autism spectrum disorder (ASD) are abnormalities in the development of intentional movements. However, very few studies directly addressed the question of whether children suffering from ASD can be distinguished from typically developing ones solely on the basis of analysing how they make intentional movements. Individuals diagnosed with ASD should display abnormalities in prospective planning and execution of movements, thus we hypothesised that their movement patterns while using mobile device should be different from patterns found in typically developing individuals.
Objectives:
The aims of the study were the following: (1) To determine whether or not motor information could differentiate children with autism from children developing typically; (2) To determine the kinds of movements responsible for differentiating between children with autism and children developing typically.
Methods:
45 children aged 3 to 6 years old and clinically diagnosed with Childhood Autism (n=42) were included in the 'Autism' group of the study. Of these, 12 were female. 45 children age-matched and gender matched typically developing children were included in the 'Control' group. All the participants had normal or corrected-to-normal vision and no other sensory or motor deficits that could make engaging in tablet gameplay difficult. For the purpose of investigating movement patterns, iOS tablets (iPad minis) were used. The children were asked to use two educational applications: *(1)* 'Sharing' where the main gameplay was to divide a piece of food (e.g. an apple) and distribute it evenly among four children present on the screen. *(2) Creativity where* the game open and unstructured and involved colouring pictures of toys and animals. During gameplay, data from tablets' inertial sensors (tri-axial accelerometer, gyroscope and magnetometer) and data from its touch screen were collected. 262 features were selected and subsequently analysed using the Regularized Greedy Forest (RGF; Johnson, Zhang, 2014) machine learning algorithm with 10 repetitions of 10-fold cross-validation with pre-selected features.
Results:
The RGF algorithm with classified movement patterns as related to ASD with up to 83% sensitivity and 85% specificity based solely on motor features, suggesting that movements of children diagnosed with ASD can be distinguished from those displayed by typically developing ones. In the Sharing game, 4 out of 10 of the most salient (greatest difference between ASD and control group) features were those derived from the inertial sensors (accelerometer and gyroscope), while the other 6 features were measures of the finger swipe kinematic. In the Creativity game, 10/10 of the most salient features were derived from the inertial sensors.
Conclusions:
The analysis of movements could add significant value to the process of early diagnosis of ASD and could be used as a biobehavioural marker of the disorder. The results indicate that it is the increased force of impact onto the screen made during a touch, or maintained during a swipe, that is specific to children with ASD. Finger swipe kinematics are another distinctive feature of the disorder. Altogether, motor assessment made during iPad gameplay proves to be an accessible and enjoyable paradigm for autism research and assessment.

184 **146.184** Motor Kinematic Differences in Children with ASD: Ecological Gameplay with a Sensorised Toy

***M. Ferrara**[1], V. C. Zuccala[2], F. Cecchi[3], C. Laschi[3], J. T. Delafield-Butt[4] and G. Passetti[3], (1)University of Strathclyde, Glasgow, Scotland, United Kingdom, (2)University of Pisa, Pisa, Italy, (3)Scuola Superiore Sant'Anna, Pisa, Italy, (4)University of Strathclyde, Glasgow, United Kingdom*

Background:
Trevarthen and Delafield-Butt (2013) proposed that one of the early markers of ASD are abnormalities in the development of intentional movements. A growing body of literature demonstrates kinematic and action patterns differences in children and adults with ASD. However, these experiments typically require laboratory-based optical motion tracking systems. Here, we developed, sensorised wooden cubes for motor assessment of children's play and report on the kinematic and action pattern differences of the children with autism compared to children developing typically.
Objectives:
A description of ASD-specific action patterns and kinematics using sensorised toys.
Methods:
Participants. Children 3 to 5 years with ASD (n = 15) recruited from the Scottish Centre for Autism, Glasgow, UK. Children 3 to 5 years old developing typically recruited from nurseries in Glasgow, UK. Adults 20 to 25 years old without ASD recruited from Glasgow, UK. In children with ASD, pre-screening with Vineland-II, AQ-Child and Leiter-R Brief IQ was performed.
Procedure. The children were seated at a table and instructed to play two simple games that involved moving the cube from one position to another: a Serially Organized Action (SOA) game and a Single Repetitive Action (SRA) game. The first required complex motor sequencing and engagement with the experimenter, while the second consisted of a simple repetitive movement. An electronic board inside the cubes was equipped with tri-axial magnetometer, gyroscope and accelerometer wirelessly transferred the cube's motion data to a laptop. The signal (raw motion data) was extracted through a Matlab-based platform and analysed.
Data Analysis. Kinematic features of movement duration; maximum value of acceleration, velocity, and jerk during each movement; time to maximum value; % duration to maximum value; and the acceleration, velocity, and jerk action patterns profiles were calculated.
Results: The jerk profile of children with ASD showed increased maximum jerk, reduced time to maximum value and duration to maximum value, and lower variability than typically developing children. Further, movement duration was shorter compared to age-matched typically developing children, and maximum velocity was significantly higher in children with ASD compared to children developing typically.
Conclusions:
The increased jerk values and onset times in the ASD group are a particularly interesting finding that support new data appearing by other groups. It appeared, especially in the SRA game, that when moving the cube from one position to the next, the children with autism impacted on the surface of the table with greater velocity and typically included the resulting force immediately into to the next movement, giving it a greater jerk value in a shorter span of time that typically children. Typically developing children, on the other hand, paused for a moment (>100 ms) before commencing the next movement. The repetitive simplicity of the SOA game and its resulting jerk profile appears to report on a particular behavioural motor feature distinct to ASD, namely stopping an action and starting a new one, while also describing an underlying motor difference that may contribute to it.

185 **146.185** Multimethod Longitudinal Analysis of Repetitive Behavior Measures in Children with ASD

***C. Farmer**, L. Joseph, D. L. Mead and A. Thurm, Pediatrics and Developmental Neuroscience Branch, National Institute of Mental Health, Bethesda, MD*

Background: There are no systematic investigations of the consistency of results among the various methods used to measure restricted and repetitive behavior (RRB) in ASD, such as the Autism Diagnostic Interview, Revised (ADI-R), the Autism Diagnostic Observation Schedule (ADOS), and the Repetitive Behavior Scale, Revised (RBS-R) (Leekam, Prior, & Uljarevic, 2011). Further, there have been few longitudinal studies examining the unique predictive utility of these popular instruments (Honey, Rodgers, & McConachie, 2012).
Objectives: In the current study, we explore ADI-R, ADOS, and RBS-R scores in children with ASD, aged 2-7 years at the initial evaluation. Our first goal was to explore forms of measurement (observation, interview, questionnaire) using cross-sectional data. Our second goal was to characterize the relationships among initial ADI-R, ADOS, and RBS-R scores and follow-up scores on the same measures, 2 to 5 years later.
Methods: Participants were part of a natural history study of ASD (N=100; 81% male; mean age=4.5±1.6; mean nonverbal developmental quotient=58.9±18.6). Screening evaluation confirmed DSM-IV-TR Autistic Disorder, using the ADI-R, ADOS, and clinical judgment by expert clinicians. Data from screening and follow up were used in these analyses. Cross-sectional and longitudinal relationships between ADI-R (current algorithm), ADOS, and RBS-R scores in subjects with both timepoints (n=58) were first examined in a multimethod correlation matrix, and will be examined in a structural equation modeling framework to quantify the shared and unique measurement of RRB among methods (n=100) (Figure 1).
Results: The pattern of correlations suggested differential relationships between methods and across time (Table 1). Cross-sectionally, the ADOS was related to few other subscales, but many subscales of the RBS-R and ADI-R were moderately-to-strongly correlated. Longitudinally, the ADOS calibrated severity score and raw score were

unrelated to themselves and to the other scales. Generally, the correlations observed cross-sectionally between the RBS-R and ADI-R persisted longitudinally. Conclusions: The RBS-R, ADI-R, and ADOS appear to measure different aspects of RRB, both cross-sectionally and longitudinally. Our results may be partially explained by method variance, as the scales with parental input were most strongly related. The longitudinal bifactor decomposition that we will present will shed light on this possibility. The content of the scales must also be considered, given that the early ADOS modules assess mostly lower-order RRB. Finally, it is possible that the behaviors did actually change over time; however, the relative stability of the RBS-R and ADI-R suggest that this is not sufficient explanation. In summary, the method used to quantify RRB appears to strongly influence characterization of symptom severity and change.

Variables with the suffix 1 refer to Time 1, while those with the suffix 2 refer to Time 2. Squares represent observed variables; circles represent unobserved (latent) variables.

186 **146.186** Multisensory Contributions to Autism: Behavioral and Neural Evidence

M. T. Wallace[1], *R. A. Stevenson*[2] *and S. H. Baum*[3], *(1)Psychology, Psychiatry and Hearing & Speech Sciences, Vanderbilt University, Nashville, TN, (2)Department of Psychology, University of Toronto, Toronto, ON, Canada, (3)Vanderbilt Brain Institute, Vanderbilt, Nashville, TN*

Background:
In addition to deficits in social communication and the presence of restricted interests and repetitive behaviors, autism spectrum disorder (ASD) is characterized by changes in sensory function. These changes have been observed in a number of different sensory modalities, suggesting that it may be useful to think of these changes in a more multisensory framework. Indeed, the integration of information across the different sensory systems is essential for the construction of healthy perceptual and cognitive representations. Consequently, it is vitally important to understand the nature of the sensory and multisensory changes in ASD and their contributions to higher-order function.
Objectives: To characterize the nature of sensory and multisensory changes, and to examine associations with higher-order function, in children with ASD.
Methods:
A cohort of children with ASD ages 10-14 and a matched cohort of children who were typically developing (TD) were examined on a battery of tasks assessing various aspects of auditory, visual and audiovisual (i.e., multisensory) performance. The battery included tasks that are focused on general aspects of sensory and multisensory performance (i.e., speeded reaction times, sound-induced flash illusion, McGurk effect) as well as tasks that focus on temporal acuity within and across the sensory systems (i.e., temporal order judgments, simultaneity judgments). These measures of (multi)sensory function were compared with a battery of neuropsychological measures. In addition, neuroimaging (EEG and fMRI) was carried out on a subset of children in an effort to examine for differences in networks subserving sensory and multisensory function.
Results:
Children with ASD were found to differ from their TD peers on a number of measures within the sensory battery. The two most salient of these differences were in heightened trial-by-trial variability in their reaction times to sensory stimuli in children with ASD, as well as poorer audiovisual temporal acuity compared to children with TD. Measures of audiovisual temporal acuity were found to correlate with the magnitude of multisensory integration or “binding,” most notably for speech stimuli. Ongoing correlational analyses are focused on exploring the links between these changes in sensory function and changes on the neuropsychological tasks, and on differences in sensory networks and their relationship to networks supporting social communication.
Conclusions:
These results provide one of the first empirical characterizations of both sensory and multisensory function in a cohort of children with ASD, and demonstrate a pattern of sensory changes characterized by greater variability and poorer multisensory temporal function. Perhaps more important than the changes in sensory function is the putative formative role that these processing alterations are playing in the more established deficits seen in ASD (i.e., in the domain of social communication). Indeed, sensory and multisensory function forms the “building blocks” for perceptual and cognitive representations, and changes in (multi)sensory function appear to scaffold changes in these higher-order domains.

187 **146.187** Multisensory Temporal Integration Deficits in Sensory Processing Disorder

M. T. Wallace[1] *and S. H. Baum*[2], *(1)Psychology, Psychiatry and Hearing & Speech Sciences, Vanderbilt University, Nashville, TN, (2)Vanderbilt Brain Institute, Vanderbilt, Nashville, TN*

Background:
Sensory processing disorder (SPD) is a neurodevelopment disorder in which both the processing and integration of information across the various sensory modalities is affected. Despite a growing recognition of the prevalence and impact of SPD on activities of daily living, the neural bases for this disorder (or constellation of disorders) has remained elusive.
Objectives:
In the current study, we attempted to better characterize the nature of the sensory processing changes in a cohort of children with SPD (compared against an appropriate age-matched control group). The focus of the current work was on auditory, visual and combined audiovisual function, and with a preferential emphasis in better detailing the temporal acuity within which auditory and visual stimuli are integrated and perceptually “bound.”
Methods:
Children performed a battery of temporal order judgment (TOJ) and simultaneity judgment (SJ) tasks in which auditory, visual and combine audiovisual stimuli were presented with varied temporal structure.
Results:
On average, children with SPD were found to integrate audiovisual stimuli over longer temporal intervals when compared with control children, and perhaps more interestingly to show enormous individual variability in this series of measures. Ongoing neuroimaging work is attempting to better understand the neural circuits that underlie these differences, and ongoing psychophysical and neuropsychological assessments is attempting to better understand the contributions of altered (multi)sensory function to higher-order domains of dysfunction.
Conclusions:
These results suggest altered multisensory temporal acuity in children with SPD, and that these changes in multisensory temporal function may play an important contributing role in the constellation of sensory, behavioral, perceptual and cognitive symptoms seen in these children.

188 **146.188** Perceptual Inference in Autism Spectrum Disorders: Insights from Time-Order Effect in Tactile Discrimination

L. A. Sapey-Triomphe[1], *G. Sanchez*[2], *S. Sonié*[1], *C. Schmitz*[1] *and J. Mattout*[1], *(1)Lyon Neuroscience Research Center, Lyon, France, (2)Centre for Cognitive Neuroscience, Salzburg, Austria*

Background:
Perceptual decisions are known to be influenced by global context as much as by sensory evidence[1]. Computationally, this can be cast in Bayesian terms where behavior results from the optimal combination of acquired priors and incoming sensations, such that the more ambiguous the sensory input, the larger the influence of prior knowledge. In Autism Spectrum Disorders (ASD), it has been suggested that an imbalance in the way prior information and sensory evidence are trade could explain many of the symptoms.[2,3]
In a previous tactile study[4], we showed that people with ASD were able to build up priors in a stable learning context. However and against some current theories, we found that those priors would have a stronger effect in ASD than in neurotypical (NT) controls. We thus further hypothesized that people with ASD would have difficulties adapting their priors to a new context.
Objectives:
We used a very similar tactile task as before, so as to reveal the process of prior updating in ASD. We made use of the so-called time-order effect (TOE)[5], whereby the percept of the first stimulus appears to be strongly biased by contextual priors.
Methods:
We tested 20 NT adults and 17 adults with ASD (diagnosed according to the DSM V using their ADOS or/and ADI-R score) matched on age, gender and IQ. Non-painful electrical stimulations were delivered on their index finger. Participants were asked to compare the frequencies of two consecutive stimuli (F1, F2). In a first experimental phase, F1 was delivered at 30Hz. In the second phase, F1 varied from trial to trial, with a mean frequency of 26Hz. The first phase was used to induce a strong prior expectation of a fixed first stimulus at 30Hz, while the second phase, designed to elicit a TOE, was meant to trigger a process of prior updating. We recorded performances and used computational modelling to characterize perceptual inference in each group[6].
Results:
NT and ASD participants showed similar performances (75% and 73% correct discriminations on average, respectively). Both groups exhibited a TOE of similar amplitude. However, model comparison showed that contrary to NT, ASD subjects were slow in adapting their perceptual priors when changing the context. We also observed a trend in ASD participants such that the higher the Autistic Quotient, the slower the updating ($p = 0.052$). Importantly, this effect was not due to a difference in the precision of the encoding of sensory information.
Conclusions:
ASD people differ from NT in the way they update their perceptual expectations. They appear to be less flexible, which may point to a deficit in the way the relative weight of prior belief and sensory evidence is adjusted[7]. Further assessments should combine advanced computational models, informed task designs and neurophysiological measures in order to refine our understanding of ASD.

189 **146.189** Physical Activity in Children with Autism Spectrum Disorders and Developmental Coordination Disorder

D. Kindregan[1], *J. Gormley*[1] *and L. Gallagher*[2], *(1)Physiotherapy, Trinity College Dublin, Dublin 8, Ireland, (2)Psychiatry, Trinity College Dublin, Dublin, Ireland*

Background:
Children with ASD typically have difficulty with social communication and restricted repetitive behaviours, which may in turn impact physical activity (PA). PA is known to have benefits on overall health, promotes psychological well-being and improves mood while reducing perceived-anxiety. Studies which have examined PA in children with ASD or developmental coordination disorder (DCD) have found a reduced amount of time spent in moderate-to-vigorous PA (MVPA) than typically developing peers. Children with ASD are 40% more likely to be overweight or obese than typically developing peers and children with DCD are also more likely to be overweight. The American College of Sports Medicine guidelines for PA state that children should participate in at least 60 minutes of moderate to vigorous PA every day.
Objectives:
The objectives of this study were to evaluate PA and sedentary behaviour across four groups – ASD, DCD, dual-diagnosis (ASD&DCD) and typically developing controls (TD).
Methods:
A parent-reported online survey was circulated via social media. School-going children with a diagnosis of ASD-only, DCD-only, ASD and DCD, and typically developing controls were included. The survey assessed children's PA during a typical school week – modes of to school, structured PA during and after school, and sedentary time. Chi-squared tests evaluated data proportions for significant differences.
Results:
Of 884 parental responses to the survey, 737 met inclusion criteria and were allocated into study groups. The sample was 75% male, 25% female. The Survey Demographics figure shows sample characteristics. There was no correlation between gender and activity levels in the groups, and no difference in mode of transport to school or time spent in PE class.
Children with ASD and/or dyspraxia spent significantly less time in structured PA than controls – 62% of children with ASD spent two hours or less; 33% of controls ($p<0.05$). All groups demonstrated a high percentage of children participating in less than six hours of PA per week ($p=0.0003$). Children with ASD and/or DCD were less likely to participate in group sports than individual sports than controls ($p=0.003$).
There was a significant difference in the time spent in sedentary-type behaviours (screen time or reading) - 61% of children with ASD&DCD spent more than six hours per week in sedentary behaviour, similar to ASD group at 58% and DCD group at 52% but significantly more than the controls at 38% ($p=0.009$) and 20% of all children with ASD and/or dyspraxia spent 14 hours or more each week in sedentary-type behaviours. Age from 11+ years was positively correlated with time spent in these behaviours.
Conclusions:
Results suggest that children with ASD spent more time in an average week in sedentary behaviour and less time in structured PA, and were less active compared to TD controls. A large proportion of all groups spent less than six hours per week in PA, not meeting recommended daily guidelines of at least 60 minutes of MVPA and suggesting an increased risk of health issues related to overweight or obesity. Further study involving activity monitoring may allow objective measurement of MVPA.

190 **146.190** Postural Control Mechanisms Underlying Reduced Stability in Autism Spectrum Disorder (ASD)

Z. Wang[1,2,3], *R. Hallac*[4], *K. C. Conroy*[5,6], *S. P. White*[7], *A. A. Kane*[8], *A. L. Collinsworth*[8] *and M. W. Mosconi*[2,9], *(1)Psychiatry, UT Southwestern Medical Center, Dallas, TX, (2)Schiefelbusch Institute for Life Span Studies and Clinical Child Psychology Program, University of Kansas, Lawrence, KS, (3)Center for Autism and Developmental Disabilities, UT Southwestern Medical Center, Dallas, TX, (4)Analytical Imaging and Modeling Center, Children's Medical Center, Dallas, TX, (5)Center for Autism and Developmental Disabilities, Dallas, TX, (6)Psychiatry, University of Texas Southwestern Medical Center, Dallas, TX, (7)Center for Autism and Developmental Disabilities, University of Texas Southwestern, Dallas, TX, (8)Analytical Imaging and Modeling Center, Children's Medical Center, Dallas, TX, (9)Dole Human Development Center, University of Kansas, Lawrence, KS*

Background: Postural stability has been repeatedly shown to be disrupted in autism spectrum disorder (ASD). Prior studies have quantified the amount of sway during standing, but examining postural stability at the individual level requires analysis of sway relative to each individual's postural limitation boundary, or the maximum extent to which they are able to lean in each direction without losing their balance. In the present study, we examined postural sway relative to each individual's postural limitation boundary in individuals with ASD and healthy controls using a novel virtual time-to-contact (VTC) approach.
Objectives: To examine center of pressure (COP) variability, the shared information of the COP time series for anterior-posterior (COP_{AP}) and mediolateral (COP_{ML}) directions, and spatiotemporal VTC in individuals with ASD and healthy controls during static and dynamic standing postures.
Methods: Twenty-two children with ASD (12.72 ± 3.64 yrs) and 21 healthy controls matched on age, gender and IQ completed tests of static and dynamic stances. Prior to testing, participants were instructed to stand with their feet shoulder width apart on a force platform. Their foot position was traced on the platform so that their starting position at the beginning of each trial was consistent. Participants' postural limitation boundary was determined by having them lean their body in each of four different directions (anterior, posterior, left and right) as far as they could without losing balance, and then fitting an ellipse to the COP maxima for each direction. COP measurements were derived from the force platform.
During *static* stance trials, participants were instructed to stand as still as possible. During *dynamic* stance trials, participants were instructed to continuously sway their body either front-back or left-right at a comfortable speed and magnitude. Participants completed three 30-sec trials for each stance. Each participant's VTC was derived by comparing the spatiotemporal relation between their postural sway relative to their own postural limitation boundary during each trial. The amount of shared information of COP_{AP} and COP_{ML} also was quantified.
Results: Individuals with ASD showed increased COP standard deviation and trajectory length during all conditions. Individuals with ASD showed increased shared information suggesting less independence of COP_{AP} and COP_{ML} sway mechanisms, especially during dynamic stances. In static stance, individuals with ASD were able to compensate for their increased postural sway variability by reducing their temporal VTC duration. In contrast, they were not able to show the same type of compensation during dynamic stances.
Conclusions: Individuals with ASD showed increased postural sway variability relative to controls, but the quality of this deficit varied across different postural conditions. In static stance, ASD patients' ability to compensate for internal perturbations was relatively intact. During dynamic stances, individuals with ASD failed to acquire spatial VTC information for postural stability. Their ability to utilize temporal VTC adjustment to compensate for increased sway also was compromised during dynamic but not static stance. These findings indicate that ASD patients are impaired when attempting to use spatiotemporal information to correct their sway during naturalistic stances similar to those they use during everyday activities.

191 **146.191** Postural Control Relates to Accuracy of Eye Movement in Autism Spectrum Disorder and Developmental Coordination Disorder

H. L. Miller[1], *P. Caçola*[2], *G. Sherrod*[3], *R. Patterson*[4] *and N. L. Bugnariu*[5], *(1)Physical Therapy, University of North Texas Health Science Center, Fort Worth, TX, (2)Kinesiology, University of Texas at Arlington, Arlington, TX, (3)University of North Texas Health Science Center, Fort Worth, TX, (4)Family Medicine, University of North Texas Health Science Center, Fort Worth, TX, (5)Physical Therapy; School of Health Professions, University of North Texas Health Science Center, Fort Worth, TX*

Background:
Autism Spectrum Disorder (ASD) and Developmental Coordination Disorder (DCD) share similar motor features, including difficulty maintaining postural stability and coordinating body movement. However, the specific overlap in symptoms between these two disorders remains unclear. Further, while there are known differences in visual information processing in ASD, this research question remains unanswered in DCD. *Visuomotor integration* – the use of visual information to guide motor behavior – may have a different impact on postural stability in ASD vs. DCD depending upon the influence of visual information processing.
Objectives:
To identify differences in visuomotor integration between individuals with ASD and DCD during tasks requiring the use of eye movement and visual information processing to maintain postural control.
Methods:
We conducted a preliminary investigation of visuomotor integration in 5 participants with ASD and 5 age-matched individuals with DCD. Data were collected from mobile eye-tracking, motion-capture, virtual reality, and force plate systems. Participants completed 30 seconds of quiet standing with eyes open and eyes closed as a baseline. They then completed two tasks in the virtual environment (Safe Zones, Disc Match) that required integration of visual information with motor plans. Participants controlled an object in the virtual space by shifting their Center of Pressure (CoP) or leaning to move a marker placed on the C7 vertebrae and the sacrum, in order to match the position of a static or moving target.
Results:
Individuals with ASD differed from those with DCD in their movement profiles during the three tasks. During quiet standing, individuals with DCD exhibited greater postural sway during both eyes open and eyes closed conditions. During the Disc Match task, both individuals with ASD and DCD struggled to match their CoP to the oscillating trajectory of a target, and their accuracy varied by frequency of oscillation. During the Safe Zones task, individuals with DCD had greater medial-lateral displacement in their

C7 and sacral marker positions.
Conclusions:
While DCD and ASD share similar functional movement symptoms, quantitative analysis of motor skills reveals key differences between the two disorders when tasks require integration of visual and motor information. Motor markers such as CoP may serve to differentiate between these two developmental disorders in a way that would inform intervention approaches. Preliminary analysis of the corresponding eye-tracking data supports the hypothesis that atypical eye saccadic and pursuit eye movements may influence the degree of difficulty that individuals with ASD, but not DCD, have with maintaining postural stability during tasks that require integration of visual information to plan and execute full-body movement.

192 **146.192** Postural Stability and Its Limits in Autism Spectrum Disorder Relate to Visual Context

H. L. Miller[1], *L. Mattingly*[2] *and N. L. Bugnariu*[3], *(1)Physical Therapy, University of North Texas Health Science Center, Fort Worth, TX, (2)Physician Assistant Studies, University of North Texas Health Science Center, Fort Worth, TX, (3)Physical Therapy; School of Health Professions, University of North Texas Health Science Center, Fort Worth, TX*

Background:
Many studies of ASD report behavioral and neural differences in visual and motor systems. However, few studies of Autism Spectrum Disorder (ASD) quantitatively examine *visuomotor integration* – the use of visual information to guide motor behavior – and its influence on postural stability. Postural stability is a critical building block of motor development with downstream influence on a wide array of functional skills (e.g., ambulation, gesturing, self-care, driving, playing physical games).
Objectives:
To define the relationship between postural stability, eye movement, and visual context in ASD.
Methods:
We conducted a preliminary investigation of visuomotor integration in 3 adolescent participants with ASD and 3 age-matched typically-developing (TD) controls. Data were collected in a community setting using mobile eye-tracking and a portable force platform. Participants completed the Clinical Test of Sensory Integration in Balance (CTSIB), which requires quiet standing with eyes open, with eyes closed, and with eyes open while wearing a translucent dome over the head. The dome condition tests stability when visual and proprioceptive systems are stimulated, but context-based visual information is unavailable. Participants also completed 3 runs of a Limits of Stability task, which requires participants to shift Center of Pressure (CoP) to reach each of 9 target positions displayed on a screen.
Results:
The ASD group had higher sway and stability indices than the TD group across all 3 conditions of the CTSIB (eyes open, eyes closed, dome) (Fig. 1). The ASD group also had greater increases in sway and stability indices between conditions of the CTSIB as difficulty increased. Standard deviations were considerably larger in the ASD across all variables. The ASD group had lower control than the TD group for 5 of the 9 Limits of Stability target positions (2, 3, 4, 6, 7), but higher control than participants in the TD group for 4 positions (1, 5, 8, 9), two of which required only lateral movement (1, 5) and one of which was the center position (9). Overall, the ASD group had lower average control than the TD group across all targets, and took longer to complete the test. Time to complete is a proxy for movement accuracy, since the task advances when participants meet hit criteria for each target. Again, standard deviations were considerably larger in the ASD group for most variables.
Conclusions:
Results from postural stability data support our hypothesis that individuals with ASD would have greater postural instability than TD controls. When visual context was eliminated (CTSIB dome condition), individuals with ASD had markedly greater impairment in stability, suggesting that integration of context-based visual information into motor plans may have greater influence than visual or proprioceptive information alone. Further, when limits of stability were tested, individuals with ASD had greater difficulty maintaining postural control during a CoP shift, especially for more difficult target positions. Preliminary examination of eye movement data also suggests that atypical gaze patterns relate to impairments in postural stability, and postural stability is significantly impacted by the presence or absence of visual context (i.e., CTSIB condition) in ASD.

193 **146.193** Predictors of Parent Responsiveness to One-Year-Olds at-Risk for ASD

J. Kinard[1], *J. Sideris*[2], *L. R. Watson*[3], *G. T. Baranek*[4], *E. Crais*[3], *L. Wakeford*[5] *and L. Turner-Brown*[6], *(1)University of North Carolina at Chapel Hill, Cary, NC, (2)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)UNC Chapel Hill, Chapel Hill, NC, (5)University of North Carolina at Chapel Hill, Morrisville, NC, (6)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Parent responsiveness is critical to child development of cognition, social-communication, and self-regulation. When parents are “responsive,” they provide quick, meaningful responses to a child, based on the child’s focus of attention. Parents may respond differently, depending on the child’s initial characteristics. In children with and without risk for ASD, higher social-communication skills tend to elicit more parental responses. Research has also found associations between hyperresponsiveness in infants and lower maternal responsiveness. However, no research has examined how parent responsiveness is associated with sensory characteristics of children at-risk for ASD. It is essential to understand factors that influence parent-child relationships, specifically parent responsiveness, so that professionals and families can use this information to inform early interventions targeting parent-child relationships.
Objectives: For the current study, we examined the extent to which child social-communication and sensory response patterns (i.e., hyper- and hypo-responsiveness) predicted parent responsiveness to one-year-olds recently identified as at-risk for ASD.
Methods: The sample included 97 parent-infant pairs. Infants were at risk for an ASD diagnosis, based on parent responses to the First Year Inventory 2.0 at 12 months of age. Data were collected on the following child variables: nonverbal cognitive level (“Visual Reception” subscale on the Mullen Scales of Early Learning); social-communication (Communication and Symbolic Behavior Scales-Developmental Profile: Behavioral Sample [CSBS-DP-BS] and Caregiver Questionnaire [CSBS-DP-CQ]); and sensory response patterns (“hyporesponsiveness” and “hyperresponsiveness” scores on the Sensory Experiences Questionnaire [SEQ] and Sensory Processing Assessment for Young Children [SPA]). Parent responsiveness was measured via a 10-minute parent-child free-play video, and was later coded using an interval coding system. Parent responsiveness was calculated using a proportion: the numerator included 5-second intervals with a parent response and the denominator included the total 5-second intervals. We ran hierarchical regression models with parent responsiveness as the dependent variable and child behaviors as independent variables.
Results: Hyporesponsiveness consistently added power to predict variance in parent responsiveness across multiple models, whereas hyperresponsiveness did not consistently do so. The addition of either hyporesponsiveness measure increased the predictive power, regardless of which child communication measure was included in the baseline model. All models that included a combination of child communication (CSBS-DP-CQ or CSBS-DP-BS) and hyporesponsiveness (SPA or SEQ) significantly predicted: (a) 13 – 21% of the variance in single play responses (i.e., parents tended to play without talking when children demonstrated more hyporesponsiveness and lower communication skills); and (b) 8 – 12% of the variance in single follow-in responses (i.e., parents tended to talk without playing when children demonstrated less hyporesponsiveness and higher communication skills).
Conclusions: Among a community sample of infants at-risk for ASD, a combination of child communication and sensory hyporesponsiveness was the most robust predictor of parent responsiveness. Specifically, parents tended to use fewer verbal responses and more physical play responses when their child demonstrated less communication and more hyporesponsiveness. These findings highlight the importance of communication and sensory characteristics (particularly hyporesponsiveness) of children at-risk for ASD, as these characteristics may influence the nature of parent responsive behaviors, which have theoretical importance for early parent-mediated interventions.

194 **146.194** Psychophysical Correlates of Excitatory/Inhibitory Imbalance during Visual Motion Perception in Adults with ASD and Schizophrenia

B. D. Adkinson[1,2], *J. H. Foss-Feig*[3], *W. J. Park*[4], *E. J. Levy*[5], *N. Santamauro*[6], *C. Schleifer*[7], *K. B. Schauder*[8], *K. Deckert*[5], *V. Srihari*[6], *J. Krystal*[9], *D. Tadin*[4], *J. McPartland*[3] *and A. Anticevic*[6], *(1)Department of Psychiatry, Yale School of Medicine, New Haven, CT, (2)Marietta College, Marietta, OH, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Brain and Cognitive Sciences, University of Rochester, Rochester, NY, (5)Yale Child Study Center, New Haven, CT, (6)Yale University School of Medicine, New Haven, CT, (7)Yale University, New Haven, CT, (8)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (9)Yale University - Psychiatry, New Haven, CT*

Background: Recent evidence implicates neural excitatory (E) and inhibitory (I) imbalance as a mechanistic underpinning of autism spectrum disorder (ASD). E/I imbalance is also implicated in other disorders, such as schizophrenia (SZ), that are associated with social and cognitive deficits. While phenotypic similarities across diagnoses suggest common mechanistic origins, no studies have tested the existence of shared markers of E/I imbalance across ASD and SZ. Surround suppression and gain control are two well-established neural processes affecting perception of visual motion that rely on precise E/I balance. Previous studies examining visual motion processing in ASD and SZ have identified surround suppression and gain control abnormalities. However, none of these studies directly compared these processes across both populations.
Objectives: Evaluate E/I balance in the context of surround suppression and gain control affecting visual motion perception in young adults with ASD relative to SZ and healthy controls.
Methods: Participants were 10 young adults with ASD, 9 with SZ, and 14 healthy controls, matched for demographic variables. Recruitment is ongoing with expected final sample sizes of 20 per group. Participants completed three visual processing tasks that involved motion discrimination of gratings that varied by size at high (Task 1) and low (Task 2) contrast, as well as gratings with fixed, small size but varied contrast level (Task 3). Task order was counterbalanced across participants. Duration thresholds were computed for eight different sizes and contrasts. Suppression index (Tasks 1 and 2) and response gain control (Task 3) were computed by contrasting thresholds at the highest level of contrast/largest size to those at the lowest contrast level/smallest size for each task. Group differences were assessed using one-way ANOVAs.
Results: Results revealed few differences between groups in duration thresholds across contrast levels or sizes. Contrary to predictions, response gain control did not differ among ASD, SZ, or controls ($F=.070$, $p=.93$). Likewise, at high contrast, the suppression index did not differ by group ($F=.556$, $p=.58$). However, at low contrast, there were

group differences in suppression index (F=4.378, *p*=.023), wherein, relative to controls, SZ, but not ASD, was characterized by an unexpected increase in spatial suppression.
Conclusions: Contrary to predictions, differences in surround suppression for high contrast stimuli and gain control with increasing contrast during motion discrimination were not observed in ASD or SZ relative to controls. Moreover, an unexpected increase in suppression was observed at low contrast for SZ participants. These data suggest that, at least in the context of low-level visual motion processing, young adults with ASD and SZ may have intact E/I balance. Transdiagnostic correlations with measures of sensory, social, and cognitive functioning are ongoing to quantify if deficits in surround suppression and gain control are associated with symptoms that cross traditional diagnostic categories.

195 **146.195** Reduced Restricted and Repetitive Behaviors after Pivotal Response Treatment

***S. M. Abdullahi**, D. G. Sukhodolsky, C. A. Paisley, M. L. Braconnier and P. E. Ventola, Yale Child Study Center, Yale School of Medicine, New Haven, CT*

Background:
Children with ASD show a high frequency of Restricted and Repetitive Behaviors (RRBs), and these behaviors interfere with daily functioning (Harrop et al., 2014). However, RRBs have remained largely resistant to behavioral interventions and pharmacological treatments within the context of controlled trials (Harrop, 2015; Tanner, Hand, O'Toole, & Lane, 2015). Pivotal Response Treatment (PRT) is a naturalistic behavioral treatment that focuses on increasing a child's motivation and improving social function.
Objectives:
We investigated change in the severity of RRBs in children with ASD who participated in a 16-week trial of PRT.
Methods:
Participants included 15 children with ASD between the ages of 4 and 7 (Mean IQ = 98.7, SD = 19.7) who took part in a 16-week PRT trial. Treatment included 6 hours per week of individual work with the child as well as training the parents in implementing PRT at home. Inclusion criteria for the study were diagnosis of ASD and IQ > 70 as measured by the Differential Abilities Scales-2nd Edition. To assess RRBs, parents completed the Repetitive Behavioral Scales- Revised (RBS-R) and Aberrant Behaviors Checklist (ABC) before and after the 16 weeks of PRT.
Results: Overall, RRBs decreased significantly following 16 weeks of PRT (RBS-R Total Score: pre-PRT M= 28.36, SD= 19.70; post-PRT M= 16.27, SD= 12.60, $p<0.01$). Individual RBS-R subdomains for stereotyped behavior ($p < 0.01$), self-injury ($p < 0.02$), ritualistic behavior ($p < 0.05$), sameness ($p < 0.01$) and restricted behaviors ($p < 0.02$) decreased significantly as did the stereotypy subdomain of the ABC (pre-PRT M= 3.57, SD= 3.23; post-PRT M= 1.43, SD = 2.71, $p < 0.001$).
Conclusions:
Based on these preliminary results, RRBs significantly decreased following a 16-week trial of PRT. This improvement may be a result of greater communication competency and improved social engagement, potentially in combination with stronger emotion regulation. Further study can determine if these results hold in a broader sample and investigate the mechanisms of improvement.

196 **146.196** Relationship of Atypical Prosodic Features to Acoustic Startle Measures in Children with Autism Spectrum Disorders and Those with Typical Development

***H. Takahashi**[1], A. Kondo[2], T. Konishi[2], K. Nishikawa[2], T. Nakahachi[1], S. Komatsu[1], R. Mazuka[2] and Y. Kamio[1], (1)National Center of Neurology and Psychiatry, Japan, National Institute of Mental Health, Tokyo 187-8553, Japan, (2)RIKEN, BSI Lab. for Language Development, Wako-city, Saitama, Japan*

Background: People with autism spectrum disorders (ASD) has long been known to have atypical prosodic features in their speech. Yet their prosodic difference from typically developing (TD) people as well as its physiological background, has not been well-understood. Recently, using an intonational phonological framework, we found that ASD participants can produce lexically and syntactically intact prosody, on the other hand, ASD children produced many more various atypical prosodic and non-prosodic features in spontaneous speech than TD children, which appeared to be associated with the core symptoms of ASD in social, communicative interaction difficulty. As the ability to produce prosody is acquired during infancy, investigation of the physiological aspect of prosodic atypicality in ASD might increase understanding of the biological mechanisms underlying the development of ASD characterisitics.
Objectives: The objectives of this study is to investigate the relationship between intonational phonological framework of prosody and physiological indexes of acoustic startle response (ASR), which is a promising endophenotype of developmental and psychiatric disorders.
Methods: Participants were 11 children diagnosed with high functioning ASD, and 12 TD children. Spontaneous speech of participants was recorded while each child talked with an experimenter about common topics for 5-10 minutes. Three trained phoneticians listened to the speech, and marked the sections that were judged "atypical." The atypical sections were then annotated using the X-JToBI scheme, and, were classified into subtypes of prosody [utterance too long, too much emphasis (stress, pitch), sudden speech rate changes, pitch range too narrow, inappropriate boundary pitch movement (pitch contour, type), and, others]. As for acoustic startle measurements, mean ASR magnitudes to acoustic stimuli presented at 65 dB to 105 dB in increments of 10 dB were analyzed. Average peak startle latency (PSL) and startle modulations (habituation and prepulse inhibitiion) was also examined.
Results: Compared to TD control, children with ASD had more atypical prosodic section for prosody subtype of "utterance too long" and "too much emphasis". And, the total number of atypical prosodic sections was also significantly larger in ASD compared to TD. As for ASR measures, ASD children had greater ASR magnitude to small stimuli intensity of 75 and 85 dB, and, more prolonged PSL compared to TD children.
The total number of atypical prosodic sections and the number of atypical prosodic section for prosody subtype of "too much emphasis" and "others" significantly correlated to startle measures of PSL as well as ASR magnitude to large stimuli intensity of 95 and 105 dB.
Significant correlations to PSL were also found in the number of atypical prosodic section for prosody subtype of "utterance too long" and "sudden speech rate changes."
Conclusions: Our results suggest that various atypical prosody subtype of ASD in spontaneous speech is associated in part with the mechanism of ASR latency delay. Considering the fact that PSL in TD is usually 60-80 msec, atypical neural mechanism to acoustic stimuli around this latency window might contribute to the development of prosody production as well as the core symptoms of ASD in social, communicative interaction difficulty.

197 **146.197** Restricted Interests and Repetitive Behaviors Behavior As a Distinguishing Feature of Autism Spectrum Disorder (ASD) in Nonverbal Children

***A. R. Marvin**[1], J. K. Law[2], Y. Zhang[3], P. H. Lipkin[4], P. A. Law[5], E. M. Arthur[4], D. J. Marvin[6], A. A. Westreich[6] and J. N. Constantino[3], (1)Painter Bldg 1st Fl, Kennedy Krieger Institute, Baltimore, MD, (2)Interactive Autism Network, Baltimore, MD, (3)Washington University School of Medicine, Saint Louis, MO, (4)Kennedy Krieger Institute, Baltimore, MD, (5)Congo Protestant Unversity, Baltimore, MD, (6)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD*

Background:
Differentiating ASD from other developmental disorders can be particularly difficult among nonverbal patients (NV).
Objectives:
To explore diagnostic accuracy and autism symptom profiles of nonverbal children with ASD (ASD-NV) in a large autism registry.
Methods:
Fifty-five ASD-NV children ages 6-17 years were recruited from a large, voluntary ASD registry. Participants had a confirmatory score >=12 on the Social Communication Questionnaire (SCQ)-Lifetime. Nonverbal status was determined by a "no" response to the SCQ-Lifetime question: "Is she/he now able to talk using short phrases or sentences?" Participation was limited to one of four US geographic regions so participants could receive an in-person ASD assessment and cognitive testing. Parents completed online questionnaires -- Social Responsiveness Scale (SRS); Adaptive Behavior Assessment System-Second Edition (ABAS-II); Repetitive Behavior Scale, Revised (RBS-R) -- and produced evidence their child had received a community ASD diagnosis. Parents asked a teacher to complete an SRS on their child. Data were compared via ANOVA and post-hoc tests with ratings of 108 *verbal* ASD (ASD-V) children enrolled in a university-based ASD research program at one of the sites. ASD-V children were split into higher-functioning (ASD-V-HighSoc; n = 75) and lower-functioning (ASD-V-LowSoc; n = 33) based on Vineland-II Adaptive Behavior Scale Socialization Domain score of >=70 and <70, respectively.
Results:
All 55 ASD-NV children were judged by clinicians to meet criteria for ASD (CI_{95}: 0.935-1.00), and all met ASD cut-offs on both the ADI-R and the ADOS. All exhibited low adaptive functioning at the floor of the ABAS-II, and cognitive functioning was either untestable or at the floor of the selected test(s).
RBS-R: The RBS-R was scored according to the Lam/Aman five-factor solution and scores compared across the three groups controlling for age and sex. There were no statistically significant differences across the three groups for "Ritualistic/Sameness Behavior" and "Restricted Interests." There were no statistically significant differences across ASD-NV and ASD-V-LowSoc for "Self-Injurious Behavior" and "Compulsive Behavior"; however, both lower-functioning groups more prone to such behaviors than the ASD-V-HighSoc group [$F(4,156)=7.086$, $p<.000$ and $F(4,156)=4.392$, $p<.002$, respectively]. "Stereotypic Behavior" presented a unique pattern whereby there were statistically significant differences between each group [$F(4,156)=21.205$, $p<.000$], with increased presentation of stereotypies corresponding with lower functioning [ASD-NV=11.8(4.88) >ASD-V-LowSoc=7.3(5.12)>ASD-V-HighSoc=5.2(3.99)].
Composite indices of Restricted Interests and Repetitive Behavior (RRB): There were no statistically significant differences across groups for ADI-R Repetitive Behavior. SRS-Teacher Report RRB T-Scores (higher is more severe) were inversely related to level of functioning [$F(3, 132)=24.810$, $p<.000$; ASD-NV=90.1.8(12.25) >ASD-V-LowSoc=81.6(17.08)>ASD-V-HighSoc=71.4(12.79)]. SRS-Parent Report RRB T-Scores were comparable for ASD-NV and ASD-V-LowSoc, and both higher than ASD-V-HighSoc [$F(3, 157)=11.242$, $p<.000$; ASD-NV=84.2 (10.6) <>ASD-V-LowSoc=87.1 (10.47)>ASD-V-HighSoc=76.8 (11.29)].

See Table 1.

Conclusions:

ASD-NV children with community diagnoses of ASD met formal diagnostic criteria for ASD and share Restricted Interests/Repetitive Behavior characteristics with ASD-V children, with severity of such characteristics – both composite and at the factor-level – either comparable or greater than those of ASD-V children. Further research may be valuable in determining whether such Restricted Interests/Repetitive Behavior characteristics may be useful in distinguishing ASD-NV children from NV children with other development disorders.

198 **146.198** Restricted and Repetitive Behavior As Predictors of Diagnosis and Clinician Confidence in Toddlers at Risk of ASD

D. Hedley[1], *M. Uljarevic*[2] *and R. E. Nevill*[3], *(1)School of Psychology and Public Health, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia, (3)The Ohio State University, Columbus, OH*

Background: A wide range of restricted and repetitive patterns of behaviors (RRBs) has been consistently reported among the earliest infant predictors of a later Autism Spectrum Disorder (ASD) diagnosis (Ozonoff et al., 2008; Wolff et al., 2014). However, it has also been suggested that RRBs may develop later, and may not be a good predictor of differential diagnosis in young children (Young, 2007). Furthermore, the relationship between RRBs and clinical judgements regarding diagnosis of ASD in young children (i.e., < 3 years) has not been explored. Here we examined the role of RRBs in the confidence expressed by clinicians when making judgements of a child's diagnosis, and also in the final diagnostic status of the child following assessment. We were interested in whether or not observed and parent reported RRBs predicted clinicians' confidence in their diagnostic judgements, and also diagnostic status, independently of child characteristics (e.g., age, gender, SES, adaptive functioning), and in particular social communication.

Objectives: Our aim was to examine the relationship between RRBs, diagnosis of ASD, and clinicians' confidence in their judgments regarding diagnosis. Specifically, we examined both the ADOS-2 RRB score and the parent reported ASRS Unusual Behaviors and Behavioral Rigidity subscales on a) clinicians' confidence in their judgments of diagnosis, and b) final diagnostic status, controlling for demographic variables such as age, gender, socioeconomic status, and child characteristics such as developmental level and adaptive functioning.

Methods: Participants were 125 children aged under 14-39 months (M = 28.62, SD =5.41) who presented for screening at a Midwestern hospital child development center due to developmental concerns. Screening clinicians were asked whether or not they thought the child would receive a diagnosis of ASD. A Likert scale was used to generate a confidence score. Diagnostic status and assessment results were retrieved from medical record review.

Results: Correlational analysis were first used to explore the association between diagnosis (ASD, non-ASD), clinician confidence, and relevant variables. Diagnosis was significantly correlated with ADOS-2 RRBs, $r(89) = .70$, $p < .001$, but not ASRS Unusual Behaviors, $r(66) = .08$, $p > .05$, or Behavioral Rigidity, $r(66) = .14$, $p > .05$. Clinicians' confidence was significantly associated with ADOS-2 RRBs, $r(89) = .32$, $p = .002$, ASRS Unusual Behaviors, $r(66) = .34$, $p = .005$, and Behavioral Rigidity, $r(66) = .29$, $p = .017$. Regression analysis identified both ADOS-2 SA, $t = 2.55$, $p = .013$, $\beta = .335$, and RRBs, $t = 2.14$, $p = .036$, $\beta = .249$, as significant predictors of diagnosis, however only ADOS-2 RRBs independently predicted clinicians' confidence, $t = 3.35$, $p = .002$, $\beta = .492$.

Conclusions: Neither parent reported unusual behaviour nor behavioural rigidity was found to be associated with diagnosis of ASD and was not an independent predictor of clinicians' confidence in their diagnostic judgements. Of interest, however, the ADOS-2 RRB scale was identified as a predictor of both diagnosis and, moreover, was the only independent predictor of clinicians' confidence.

199 **146.199** Risk Factors for Self-Injurious Behavior Among Infants at-Risk for Autism Spectrum Disorder

A. Dimian[1], *J. J. Wolff*[2], *J. T. Elison*[1], *R. T. Schultz*[3], *L. Zwaigenbaum*[4], *J. Piven*[5] *and .. The IBIS Network*[5], *(1)University of Minnesota, Minneapolis, MN, (2)University of Minnesota, University of Minnesota, Minneapolis, MN, (3)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)University of Alberta, Edmonton, AB, Canada, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Lifetime prevalence of self-injurious behavior (SIB) is approximately 50% among individuals with autism spectrum disorder (ASD). Once entrenched, SIB can be difficult and costly to treat. Commonly identified risk factors for this behavior include a diagnosis of ASD, lower intellectual functioning, communication impairment, and presence of motor stereotypy (Baghdadli et al., 2003; Oliver & Richards, 2015). To date, there is little empirical research utilizing a prospective research design to identify risk factors for SIB during the first years of life.

Objectives: Our aims were two-fold: 1) investigate the relationship of early SIB to a diagnosis of ASD; and 2) identify early risk factors for SIB.

Methods: Participants were from a longitudinal study of infants at familial risk for ASD. The present sample included 237 high-risk infants who completed the following

assessments at ages 12 and 24 months: MSEL, Vineland-II, and Repetitive Behavior Scales-Revised (RBS-R). The RBS-R was used to characterize SIB and motor stereotypy. The study sample was 62.9% male. Mean ages at 12 and 24 month assessment dates were 12.54 (*SD* = 0.62) and 24.82 (*SD* =1.47), respectively. Logistic regression was used to evaluate potential 12 month predictors of SIB at age 2.

Results: SIB was reported for 32% of participants at age 24 months and was significantly higher among children also meeting diagnostic criteria for ASD (χ^2 = 4.30, p =.04). The risk of engaging in SIB at 24 months was 1.85 times higher among children who were later diagnosed with ASD compared to children with no diagnosis. The first logistic regression model included sex, total composite scores from the MSEL and Vineland-II, and SIB and stereotypy from the RBS-R at 12 months. The overall model significantly predicted 24 month SIB (χ^2 = 31.2, p < .001, R^2_{pseudo} = 0.22). Of individual predictors, Mullen composite score and presence of SIB at 12 months were significantly associated with SIB at age 24 months. A second model excluding Vineland composite and RBS-R stereotypy score was fit. The overall model was significant (χ^2 = 34.8, p < .001, R^2_{pseudo} = 0.19). For participants who exhibited SIB at 12 months, the odds of SIB at 24 months increased by 93%. Odds of SIB increased by 3% for each point decrease in MSEL composite score.

Conclusions: The purpose of this study was to evaluate behavioral characteristics predicting early SIB among children at high familial risk for ASD. SIB was more prevalent among those children receiving a diagnosis of ASD but was not exclusive to this subset of high-risk infants. Logistic regression results indicated that presence of SIB and lower intellectual functioning at age 12 months significantly predicted later SIB. In contrast with previous studies, motor stereotypy was not associated with SIB in our sample. This may indicate a developmental relationship between stereotypy and SIB which, early in life, qualitatively differs from that observed in older individuals. Identifying risk factors for the early development of SIB has the potential to inform prevention and early intervention programming.

200 **146.200** Sensory Dis-Integration: Theoretical Foundations for and Practical Barriers to Interdisciplinary Collaboration Among Neuroscientists and Clinical Practitioners Focused on Sensory Function in Autism Spectrum Disorder

C. J. Cascio[1], *T. Woynaroski*[2], *G. T. Baranek*[3] *and M. T. Wallace*[4], *(1)Vanderbilt University School of Medicine, Nashville, TN, (2)Vanderbilt University, Thompsons Stn, TN, (3)UNC Chapel Hill, Chapel Hill, NC, (4)Psychology, Psychiatry and Hearing & Speech Sciences, Vanderbilt University, Nashville, TN*

Background:

Heightened interest in sensory function in persons with autism spectrum disorder (ASD) presents an unprecedented opportunity for impactful, interdisciplinary work between neuroscientists and clinical practitioners for whom sensory processing is a focus. In spite of this promise, and a number of overlapping perspectives on sensory function in persons with ASD, neuroscientists and clinical practitioners are faced with significant practical barriers to transcending disciplinary silos. Barriers to interdisciplinary collaboration include divergent goals, values, and approaches that shape each discipline, as well as different lexical conventions. In this overview to the panel, some of the most salient differences between fields will be described, alongside shared perspectives that may serve as a common foundation upon which interdisciplinary work can build. These shared perspectives include 1) the assumption that differences in behavioral reactivity reflect differences in neural response to sensory stimuli, 2) the assumption that "higher-order" deficits in ASD, such as social-communication deficits, arise at least in part from differences in basic sensory processing, and 3) the assumption that sensory function may be malleable with treatment or environmental manipulation. These foundational concepts will be presented as testable hypotheses that form a potential framework for the conceptualization of sensory function in individuals with ASD (see Figure 1), which researchers from a range of disciplines may work collaboratively to test. The divergent goals, values, and approaches of each discipline will be described in order to facilitate improved cross-disciplinary dialogue. Although challenging, engaging in interdisciplinary work will capitalize on the complementary strengths of each field to unveil the links between neural and behavioral manifestations of sensory differences in persons with ASD. Ultimately, the experimental tractability and early developmental onset of sensory function will be powerful advantages in determining the role of sensory processing in the more developmentally complex socio-communicative and repetitive behaviors that characterize ASD. A better understanding of this putative role for foundational sensory function is critical to facilitate early identification and improved intervention for persons with ASD.

201 **146.201** Sensory Processing Disorders: Phenotypic Characterization Pre and Post Intensive Occupational Therapy Based Model (STAR Model)

L. J. Miller[1] *and S. A. Schoen*[2], *(1)Sensory Processing Disorder Foundation, Greenwood Village, CO, (2)Sensory Processing Disorder Foundation, Greenwood, CO*

Background:

Sensory processing challenges negatively effect an individual's functioning in daily life. However, debate continues to exist in the literature as to the effectiveness of many sensory-based interventions. The literature is rampant with descriptions of many protocolized approaches or equipment specific sensory strategies (such as brushing, sitting on a ball or wearing a weighted vest) that are misrepresented as individualized occupational therapy, which relies on a broader clinical reasoning approach. Problems exist in previous studies because the intervention is poorly defined, lacks a manualized approach, and reports no method for maintaining fidelity to the intervention.

Objectives:

The present study aims to determine whether there are sensory and behavioral changes, which can be reliably measured after the administration of a manualized OT intervention, the STAR Approach, which combines regulation and relationship-based OT with principles of sensory integration and mental health consultation (Miller, 2014: chapter 4).

Methods:

This study used a retrospective pretest and posttest design. All referrals to STAR Center between 2007 and 2013 were included if they met criteria for a Sensory Processing Disorder. Children with ASD, known brain injury or genetic conditions, and movement disorders were excluded. The final dataset included 179 children ranging from 2 to 13 years of age (mean = 6.1 years, SD = 2.3), 139 males. All children engaged in the STAR approach, which is a short term, intensive program with 50-minute sessions, scheduled 3-5 times a week for a total of 20-40 sessions. Each family participates in all direct treatment sessions with their child as well as 5-6 parent-only, education sessions. The model includes pre and post testing for all participants using standardized scales, parent report measures and individualized goals. Post testing is conducted within 2 weeks of completing the program.

Results:

In this study, we noted significant improvement over the course of the intervention on all sensory and motor measures as well as standardized behavioral measures. Specifically, using the MFUN and GOAL scales, we noted significant improvement on visual motor control, fine motor control, and gross motor control/coordination (effect sizes (ES) > 0.52). Using the SPD3, a standardized parent report measure of sensory related behaviors, we found a reduction in sensory craving, sensory-over and under-responsivity. Using the ABAS-II and BASC, two commonly used standardized parent report measures of function and behavior, we again saw significant changes in many composite scores including general adaptive function, social function, internalizing behaviors and externalizing behaviors with moderate to large effect sizes (r>0.41).

Conclusions:

This study provides preliminary support for the effectiveness of a novel treatment, the STAR Approach that combines short-term intensive occupational therapy using principles from DIR/Floortime ™, and sensory integration, with extensive parent education and training. Children improved on standardized measures of adaptive behavior, emotional functioning, sensory processing and motor skills, thus suggesting that these measures are sensitive to change. Prospective studies may benefit from using these outcome measures.

202 **146.202** Sensory Processing Relationships to Autism Spectrum Disorder Risk in Toddlers Diagnosed with ASD

S. D. Tomchek[1,2], *L. Little*[2], *W. Dunn*[2] *and E. Dean*[2], *(1)University of Louisville - Weisskopf Center, Louisville, KY, (2)University of Kansas Medical Center, Kansas City, KS*

Background: Early identification of ASD in young children creates opportunity for early intervention to improve outcomes. Sensory processing differences are common in toddlers with an ASD (Ben-Sasson et al., 2007) and been reported to predate diagnosis (Adrien et al., 1993; Baranek, 1999; Dahlgren & Gillberg, 1989; Lord, 1995). This, coupled with the addition of the new DSM-5 item related to hyper- or hypo-reactivity to sensory input or unusual interests in sensory aspects of the environment (APA, 2014) heightens the need to better understand sensory processing in toddlers with ASD and the relationship to early screening measures. Therefore, the purpose of this study was to examine the extent to which sensory processing patterns are related to autism spectrum disorder (ASD) risk status as measured by the MCHAT and STAT in very young children with a diagnosis.

Objectives: Understand the relationships between sensory processing patterns in toddlers and ASD risk as measured by ASD screenings

Methods: We analyzed developmental and sensory processing variables from the diagnostic evaluation process. Participants included children with a diagnosis of ASD (n=60), mean age 27.82 months (SD=4.98; range=17-35 mos). The sample currently includes 43 boys and 17 girls; sample size will increase to n=75 by time of presentation. Sensory pattern variables were compared to ASD screenings. We used the Toddler Sensory Profile-2 (Dunn, 2014), the Modified Checklist for Autism in Toddlers series (M-CHAT) (Robins et al., 2001; 2013), and the Screening Tool for Autism in Toddlers & Young Children (STAT) (Stone et al., 2000).

Results: Preliminary results suggest that sensitivity and registration scores were positively associated with MCHAT total risk score (p<.01 and p<.05, respectively). Although sensory processing scores were not significantly associated with STAT total risk score, analysis of STAT subscale risk scores showed that sensitivity and registration neared significance with directing attention (p=.077 and p=.081, respectively).

Conclusions: Research suggests that the ways in which toddlers process sensory information contributes to participation in daily routines and to their overall development.

Caregivers of children with ASD notice sensory processing differences early in development, particularly when children show aversion to sensory experiences (i.e., sensitivity) or seem to be unaware of sensory stimuli (i.e., registration). In this very young sample of children with ASD, sensitivity and registration were associated with early risk scores on ASD screening measures. It may be that particular behaviors associated with these patterns illuminate aspects of early development in ASD, providing potential avenues for both early identification and intervention approaches in this population.

203 **146.203** Sensory Response Patterns Are Associated with Attentional Deficits in Preschoolers with ASD

M. Sabatos-DeVito[1], *M. Murias*[2], *B. P. Rardin*[1], *S. T. Major*[1], *J. Newman*[1], *K. S. Davlantis*[1] *and G. Dawson*[1], *(1)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (2)Duke University, Durham, NC*

Background: Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) are common childhood neurodevelopmental disorders that often co-occur, and include both sensory processing and attention difficulties. Many individuals with ASD demonstrate aberrant sensory response patterns, including *hyporesponsiveness*, *hyperresponsiveness*, and *sensory seeking* (Baranek et al., 2006). Children with ADHD also demonstrate sensory deficits, particularly *hyperresponsivness*. Children at-risk for and diagnosed with ASD demonstrate attentional disengagement differences, and children with ADHD exhibit poor sustained attention. These findings suggest a link between sensory and attentional processes early in development; however, research regarding the nature of and relations between attention and sensory difficulties in ASD are limited.
Objectives: Aim one of this study explores the extent to which sensory response patterns are related to ADHD symptoms in preschoolers with ASD. Aim two investigates the degree to which sensory responsiveness and ADHD symptoms predict orienting and sustained attention during a naturalistic eye-tracking paradigm.
Methods: Participants included preschoolers with ASD (N=25, Mean Age=4.47 years, Range=2.27-5.98 years; Mean Nonverbal IQ=64.3 +/- 24.6). ASD diagnosis was based on the ADOS-2 and ADI-R. The Sensory Experiences Questionnaire (Baranek et al., 2006) yielded scores for hyporesponsiveness, hyperresponsiveness, and sensory seeking, and the Behavior Assessment System for Children (Reynolds & Kamphaus, 2004) provided inattention/hyperactivity scores. Measures of orienting (time to first look) and sustained attention (proportion of time looking) were derived from a naturalistic eye-tracking paradigm in which participants viewed an actress and four dynamic, nonsocial stimuli (Chawarska et al., 2012). Final results will include additional participants' data.
Results: All three sensory response patterns were significantly, positively correlated with attention problems, with hyporesponsiveness showing the strongest relation (r=0.55, p<0.01), followed by hyperresponsiveness and sensory seeking (r=0.49, p<0.05). Hyperresponsiveness was significantly, positively related to hyperactivity (r=0.44, p<0.05). Total sensory scores (collapsed across all patterns) were significantly, positively associated with both attention problems (r=0.71, p<0.01) and hyperactivity (r=0.46, p<0.05). Hyporesponsiveness and attention problems showed trends toward significance (t=1.99, p=0.06; t=1.77, p=0.09) as positive predictors of orienting to dynamic stimuli, accounting for 16.5% and 13.5% of the variance in time to first look, respectively. Sensory response patterns and attention deficits were not predictors of proportion of time looking at dynamic, nonsocial stimuli.
Conclusions: Sensory response patterns were associated with attentional deficits in preschoolers with ASD. All patterns related to difficulties maintaining attention and hyperresponsiveness related to hyperactivity. Additionally, hyporesponsiveness and attention problems showed trends toward predicting attentional orienting speed to dynamic, nonsocial stimuli. These findings shed light on early sensory symptoms' relations to the presence of attentional deficits in preschoolers with ASD, identify relations between sensory and attentional behaviors across measures, and can inform behavioral interventions targeting sensory responsiveness and attentional patterns in ASD.

204 **146.204** Sensory and Motor Difficulties Predict Severity of Autism Symptoms

P. Hannant[1], *S. A. Cassidy*[1], *F. Mann*[2] *and T. Tavassoli*[3], *(1)Coventry University, Coventry, United Kingdom, (2)University of Birmingham, Birmingham, United Kingdom, (3)Psychiatry, Seaver Autism Center at Mount Sinai, New York, NY*

Background: Recent research has linked motor coordination difficulties with atypical sensory processing, and demonstrated abnormalities in either sensory processing and motor coordination separately in Autism Spectrum Conditions (ASC). However, few studies have explored both sensory and motor difficulties together, and their impact on the severity of autism symptoms.
Objectives: 1) To explore whether children with ASC have significant motor and sensory difficulties compared to typically developing (TD) children; 2) To explore whether sensory and motor difficulties predict severity of ASC symptoms.
Methods: 36 children took part: 18 (13 male, 5 female) children with ASC (mean age = 9.93 years, SD = 2.71) and 18 (7 male, 11 female) TD children (mean age = 9.16 years, SD = 1.89), matched on age and non-verbal IQ. All children completed a battery of tasks to assess performance IQ (WASI), receptive language ability (BPVS-III), motor coordination (Movement ABC), visual motor integration (BEERY-VMI), sensory processing (Sensory Profile) and autistic traits (Social Communication Questionnaire; SCQ). Autism diagnosis was confirmed and severity measured using both the Autism Diagnostic Observation Schedule General (ADOS-II), and the Autism Diagnostic Interview Revised (ADI-R).
Results: Children with ASC scored significantly higher on parent reported autistic traits (SCQ) ($p < 0.001$, $d = 0.831$) than TD children, and significantly lower than TD children on receptive language ability (BPVS-III) ($p < 0.001$, $d = 0.565$), Movement ABC total ($p < 0.001$, $d = 0.616$), Sensory Profile total ($p < 0.001$, $d = 0.797$), and Modulation of Movement (a sensorimotor sub-component of the Sensory Profile) ($p < 0.001$, $d = 0.565$). After Bonferroni correction, there was no significant group difference in visual-motor integration (BEERY VMI) ($p = 0.009$, $d = 0.529$). Stepwise multiple regression analyses were conducted with autism severity as outcome measures (ADOS-II, ADI-R and SCQ), and the Sensory Profile, Movement ABC, and BPVS scores as predictors. In the ASC group the BPVS and Sensory Profile were retained as significant predictors of ADI-R Communication ($R^2 = .55$, $p < 0.05$); the BPVS was retained as a significant predictor of ADI-R total ($R^2 = .36$, $p < 0.01$); the Movement ABC was retained as a significant predictor of ADOS-II Communication ($R^2 = .46$, $p < 0.01$) and ADOS-II total ($R^2 = .42$, $p < 0.01$); and the BPVS and Sensory Profile total were retained as significant predictors of the SCQ ($R^2 = .79$, $p < 0.001$). Modulation of Movement significantly predicted autism symptom severity across all measures (ADOS, ADI-R and SCQ) (all $p < 0.05$).
Conclusions: Results show that children with ASC have significant difficulties in sensory processing, motor coordination, sensorimotor integration and receptive language compared to controls. Furthermore, after accounting for receptive language difficulties in the ASC group, the Sensory Profile significantly predicted parent reported autism symptom severity (ADI-R and SCQ), whereas the Movement ABC significantly predicted an in-person measure of autism severity (ADOS-II). Additionally, sensorimotor integration difficulties significantly predicted autism symptom severity across all diagnostic measures. These results suggest that sensory and motor difficulties together impact severity of autism symptoms.

205 **146.205** Sensory-Motor and Language Behaviors in Infants with High and Low ASD Risk in the First Year of Life

J. Heathcock[1], *A. Bean Ellawadi*[2], *B. Hand*[2] *and A. E. Lane*[3], *(1)Division of Physical Therapy, The Ohio State University, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)University of Newcastle, Callaghan, Australia*

Background: Early motor, sensory, and language signs of ASD are a priority for the field as they could provide: 1) earlier diagnosis criteria and 2) the development of targeted interventions. Currently, early signs of ASD including reliable language, social, cognitive, and motor differences have been identified from 12 to 24 months of age. More recent work has begun to identify differences between typical development and infants at high risk for ASD in the first year of life. These high-risk infants are identified in infancy as having an older sibling who has ASD. There are reports of upper extremity and language developmental variation in the first year of life in infants at-risk for ASD. For example poor midline behaviors and poor coordination of upper extremity movements with early babbling have been identified.
Objectives: We conducted a multi-disciplinary, behavioral study of infants with and without risk factors for autism to characterize gross motor, upper extremity movement and sensory response trajectories in the first year of life and their relationship to early signs of autism including language and gesture.
Methods: Thirty-nine infants participated in a longitudinal study at 2, 4, 6 and 12 months of age. Twenty-five infants were at high risk for ASD with a sibling or first cousin with ASD, and the remaining 14 infants were classified as typically developing with no ASD risk factors. Five infants went on to receive an ASD diagnosis at age 3–4 yr. Infants were part of larger study to develop earlier diagnostic tools for ASD.
Results: Infants' gross motor skills, spontaneous and upper extremity movements, sensory response (visual, auditory, tactile) and language behaviors were evaluated from standardized video recordings during a naturalistic play session at 2, 4, 6 and 12 months of age. Repeated measures statistical approaches (parametric or non-parametric) were used to analyze main effects of risk group and changes in trajectory. Differences in trajectory were observed in gross motor skills ($p < .05$), midline performance with the hands ($p < .05$), and response to sensory stimulation ($p < .1$). All groups of infants produced vocalizations and arm movements (rhythmic arm movements and gestures) at 6 & 12 months. At 12 months a higher proportion of children with ASD did not produce coordinated overlapping gestures with the upper extremities and vocalizations.
Conclusions: Identification of specific behaviors that are discriminative of ASD in the first year of life is of high impact because interventions that begin early in life can reduce the severity of cognitive and behavioral impairments ultimately lessening the expression of disability.

206 **146.206** Studying Restricted and Repetitive Behaviors : An Individual Items Versus a Clustered Approach of Analysis

V. Langlois[1], *A. Beauchamp Chatel*[2], *V. Larose*[3], *V. Courchesne*[4], *S. Mineau*[1], *L. Mottron, M.D.*[5] *and C. Jacques*[6], *(1)Centre d'excellence en Troubles envahissants du développement de, Montréal, QC, Canada, (2)Psychiatry, University of Montreal, Montreal, QC, Canada, (3)Université du Québec en Outaouais, Gatineau, QC, Canada, (4)University of Montreal, Montréal, QC, Canada, (5)Centre d'Excellence en Troubles Envahissants du Développement, Montréal, QC, Canada, (6)Universite du Quebec en Outaouais, Gatineau, QC, Canada*

Background: Restricted and repetitive behaviors (RRBs) are one of the two core domains required for an autism diagnosis (APA, 2013). Different classifications of RRBs have been used in young autistic children. Some observational studies have used a small number of clusters (Turner, 1999; Barber et al. 2012; MacDonald et al. 2007; Stonach & Wetherby; 2012), while others have used a more detailed approach (Goldman et al. 2008; Loh et al. 2007; Mottron, et al. 2007; Ozonoff et al. 2007). Using many items gives a more precise picture of RRBs, but could mean a loss of statistical power when multiple tests are conducted. Therefore, comparing different methods of clustering RRBs will help understand how these methods influence the results.
Objectives: This study aims to compare the RRBs profiles of autism spectrum disorder (ASD) and typically developing (TD) preschooler groups using the Montreal Stimulation Play Situation (MSPS) items analysed individually or in 3 clusters inspired by the ADOS-2 classification.
Methods: 53 autistic children (43.4 months ± 15.2; MSEL standard score 65.5 ± 20.0) and 46 TD children (48.1 months ± 11.5, p<0.05; MSEL standard score 110.8 ± 17.3, *p*<0.001) were exposed to the MSPS, which includes free and semi-free play sessions with objects of interest to ASD children. The frequency and duration of the 49 RRBs were coded twice by coders blind to the diagnosis using Noldus Observer. The mean duration and frequency of the 49 items were compared between the ASD and TD groups using non-parametric analysis. The 49 RRBs items of the MSPS scale were then pooled according to the clusters of the ADOS-2 algorithm (except those related to vocalization): 1) unusual sensory interests in play material/person; 2) hand, finger and other complex mannerisms; 3) unusually repetitive interests/stereotyped behaviors. Differences between the groups in the mean duration and frequency of these three clusters were determined using a Student's *t*-test.
Results: When analysed separately, three of the 49 items were significantly higher on both mean duration and frequency in the ASD group (p<0.01): *hand flapping*, *arm movements*, *close look to an object*. *Hand flapping* and *arm movements* are included in the *mannerisms* cluster, while *close look to an object* is included in the *unusual sensory interests* cluster. When pooled using 3 clusters from the ADOS-2 classification, only *mannerisms* was significantly higher on both frequency and duration for the ASD group.
Conclusions: When the RRBs were analysed separately, differences between the ASD and TD groups were found in one of the *unusual sensory interests*. However, this information was lost in the pooled analysis, where only the *mannerisms* cluster showed significant differences. This suggests that by using a small number of RRB clusters, the differences between TD and ASD children may be blurred by RRBs which are less specific to ASD children. Future studies should aim to determine the optimal number and the contents of clusters.

207 **146.207** The Content and Function of Interests in the Broad Autism Phenotype

K. E. Morrison[1], *L. Chambers*[2], *D. J. Faso*[3] *and N. J. Sasson*[2], *(1)The University of Texas at Dallas, Dallas, TX, (2)University of Texas at Dallas, Richardson, TX, (3)University of Texas at Dallas, Allen, TX*

Background: Many recent studies have demonstrated that the social features of ASD can be found in qualitatively similar but milder forms in members of the general population with the Broad Autism Phenotype (BAP). Less clear is whether individuals with the BAP are also characterized by non-social features of ASD, such as "circumscribed interests" (CI), defined by an intense preoccupation within a narrow range of topics.
Objectives: This study compared the content and function of interests between adults with and without the BAP. We predicted that individuals classified as having the BAP would report greater interest in hobbies related to common CIs found in ASD (e.g., video games) compared to those without the BAP, and that the hobbies they endorsed would be more limited in range (i.e., more circumscribed) but pursued with greater intensity (i.e., time per hobby).
Methods: Seventy-four undergraduates (59% female; Mean Age: 22.81) completed the Broad Autism Phenotype Questionnaire (BAPQ), an interest survey, and a computerized task in which images related to various interests were rated on valence (i.e., pleasure) and arousal (i.e., excitement). Both the survey and the ratings task consisted of content related to common CI previously reported for individuals with ASD, as well as control content (i.e., interests not disproportionately prevalent in ASD).
Results: Twenty-eight participants were classified as "BAP-positive" by exceeding the gender-specific self-report cutoff score on the BAPQ (Sasson et al., 2013). On the ratings task, a repeated-measures ANOVA with BAP-status and gender as the between-group variables, and image-type (ASD vs non-ASD interests) as the within-group variable, produced a significant group x object type interaction for both valence ($F(1,69)=18.41$, $p<.001$) and arousal ($F(1,69)=7.56$, $p=.007$). Post-hoc tests showed that these interactions were driven by BAP-positive individuals having lower valence ratings of images related to non-ASD interests ($t(71)=2.45$, $p=.015$), and higher arousal ratings of images related to ASD interests ($t(71)=2.17$, $p=.033$). On the survey, BAP-positive individuals endorsed fewer hobbies than BAP-negative individuals ($p=.049$), but the groups did not differ in the intensity in which hobbies were pursued. Compared to BAP-negative individuals, BAP-positive individuals reported significantly lower interest in exercising, playing sports, watching sports, running/biking, hunting/fishing, and studying religion, but significantly higher interest in programming, reading fiction, using phone apps/games, and a trend towards greater interest in computer games. Although many gender differences emerged on both the ratings task and the interest survey, they largely did not interact with BAP status.
Conclusions: Across multiple measures, adults classified as having the BAP differed in their interests from those classified as not having the BAP. Those with the BAP rated images related to interests common in ASD as more exciting, and those related to interests less common in ASD as less pleasurable. They also self-reported fewer interests overall, with lower interest in many outdoor activities and sports (both playing and watching) but greater interest in some solitary (e.g., reading) and technology-related areas (e.g., computers). These findings suggest that many of the differences in the content and function of interests previously reported in ASD may extend to the BAP.

208 **146.208** The Difference in Sensory Processing Between Children with and without ASD

T. Brahim, *N. Gaddour, S. Missaoui and L. Gaha, University of Monastir, Monastir, Tunisia*

Background: Autism spectrum disorder (ASD) is a very heterogeneous condition. Sensory processing abnormalities are common and can be detected very early. Several methods exist to assess these abnormalities; the most accessible ones rely on description of behavioral responses to different stimuli**.**
Objectives: to describe the differences in sensory processing between children with and without ASD.
Methods:
A case-control study was conducted from July 2014 to August 2015, at the Child and Adolescent Psychiatry Unit at the University Hospital of Monastir. We included all outpatients diagnosed with ASD seen during their routine follow-up. A control group was chosen randomly in 4 different kindergarten of the region of Monastir. Each group included 100 children, with a sex ratio M/F of 4.2 and a mean age of 3.2 years. ASD was diagnosed according to DSM-IV criteria by certified Child and Adolescent Psychiatrists and the Childhood Autism Rating Scale (CARS). We excluded children with neurological or genetic comorbidities. In the control group, we excluded children with abnormal m-CHAT or abnormal psycho-emotional development.
The Sensory Profile for Toddlers 2, translated to Arabic, was used to describe sensory abnormalities and was filled during clinical sessions with parents
Results:
All the children with ASD had abnormalities in at least one sensory domain (p<0.001). The most significant differences in T-scores between the two groups were noted in general score, oral and tactile sections (p<0.001 for the three section) then in auditory sections (p=0.013), and movement (p=0.026); all more problematic in ASD group. No difference was found for vision (p=0.724).
More than 62% of children with ASD had more sensitivity/sensor patterns (+1 to +2 SD) versus 7% in the typically developing group. More than 80% of the children with ASD had less seeking/seeker patterns (between -1 and -2SD) against only 35% of the typical developed children. Approximately 62% of children with ASD were more bystander versus 5% in the control group. There was no difference in the quadrant of avoiding/avoider.
We noted a correlation between the severity of ASD rated on the CARS and the presence of abnormalities on the sensory profile (p<0.001).
Conclusions: With the exception of visual processing, sensory domains were clearly different and impaired in ASD group. Underlying neuronal processing abnormalities need to be clarified.

209 **146.209** The End-State Comfort Effect in Children with Autism Spectrum Disorder and Typically Developing Children: The Importance of Functionally Relevant Motor Tasks

G. C. Bellinger[1], *R. A. Rodgers*[1], *S. J. Gannon*[1], *B. G. Travers*[2] *and A. H. Mason*[1], *(1)University of Wisconsin - Madison, Madison, WI, (2)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI*

Background: The end-state comfort effect occurs when one adopts an initially uncomfortable posture during a movement sequence in order to attain a comfortable posture at the completion of object manipulation, thus demonstrating motor planning (Rosenbaum et al., 1990). For example, one may grasp a key with an awkward underhand grip, so that a comfortable hand position is achieved after the key is rotated in the lock. Previous studies suggest that children and adolescents with Autism Spectrum Disorder (ASD) do not exhibit the end-state comfort effect (Hughes, 1996; Simermeyer & Ketcham, 2015), but it is unclear whether these motor impairments generalize from lab tasks to more functional types of motor behaviors.
Objectives: To determine if the end-state comfort effect is demonstrated in children with ASD compared to children with typical development (TD) in both the traditional paradigm and a more functional task.
Methods: Twenty-one participants with ASD and 16 age-matched TD participants (ages 6-17 years, $p=.76$) completed a traditional dowel task and a more functionally relevant task which required them to use a mallet to hammer a peg. In the dowel task, participants were instructed to grasp a horizontally positioned dowel and touch one end to a target positioned to the left or right. The ends of the dowel and the targets were different colors so that participants understood the directions (e.g., touch the blue end of the dowel to the red target). Each condition was repeated twice. In the mallet task, participants were instructed to use the mallet to tap a peg to the left of the stand holding the mallet. Initially, the head of the mallet was positioned to the participant's right or left side. Each condition was repeated four times and the tasks were counter-balanced. In both tasks, two researchers live coded whether the participant used an overhand or underhand grasp to complete the task. A two-way repeated-measures ANCOVA with group as the between-subjects factor, task as the within-subjects factor, and age as a covariate was used to test the percentage of trials completed in accordance with end-

state comfort.
Results: The two groups did not differ in the percentage of trials completed in accordance with the end-state comfort effect for either task. There was a significant effect of task, with the mallet task (*M*=88.5) having a higher percentage of comfortable end-state positions compared to the dowel task (*M*=65.1) (*p*=.001). This result suggests that both children with ASD and with typical development demonstrate a greater degree of motor planning when the task has functional relevance. There was a trend toward a higher percentage of comfortable end-state positions in the dowel task with increasing age (*r*=.30, *p*=.07).
Conclusions: Participants with ASD did not differ from their TD peers in the percentage of movement sequences performed in accordance with the end-state comfort effect. This is in contrast to previous work but suggests the ability to plan motor sequences. The results of this study emphasize the importance of using functional tasks when evaluating motor planning in children with and without autism.

210 **146.210** The Factor Structure of Restricted and Repetitive Behaviors in Young Children with and without Autism Spectrum Disorder

D. Dow *and A. M. Wetherby, Florida State University Autism Institute, Tallahassee, FL*

Background: Given the heterogeneity of restricted and repetitive behaviors (RRBs) and their relevance to DSM-5 diagnostic criteria for autism spectrum disorder (ASD), empirical evidence informing which RRB factors are prevalent in young children is critical in improving early detection. While it is clear that RRBs are present at a young age (Elison et al., 2014; Guthrie et al., 2013), RRB symptoms do not discriminate young children with ASD as effectively as social communication (SC) symptoms in early screening instruments (Berument et al., 1999; Rowberry et al., 2015), and clinicians do not endorse the presence of RRBs as frequently as SC symptoms (Stone et al., 1999). Children with developmental delays (DD) and typical development (TD) also frequently demonstrate RRBs (Evans et al., 1997; Bodfish et al., 2000), leading to further challenges in determining whether certain behaviors are symptomatic of ASD at an early age.
Objectives: (1) To determine the factor structure of RRBs in two through five year olds using the Repetitive Behavior Scale–Revised (RBS-R), and (2) to examine whether the factor structure of RRBs is consistent across children with ASD, DD, and TD.
Methods: There were 363 participants selected from a larger sample of children recruited for the FIRST WORDS® Project at Florida State University, a longitudinal, prospective study investigating early detection of ASD and other communication disorders. Children were included if an RBS-R had been completed between ages 2 and 5 (*mean*=34.81 months, *SD*=7.19). The RBS-R is an empirically derived clinical rating scale for measuring the presence and severity of a range of RRBs that are characteristic of ASD.
Outcome measures of developmental level (Mullen Scales of Early Learning), adaptive behavior (Vineland Adaptive Behavior Scales, Second Edition) and autism symptoms (Autism Diagnostic Observation Schedule) were obtained to determine a best estimate diagnosis. The sample included 190 children with ASD, 99 with DD, and 74 with TD. Confirmatory Factor Analysis (CFA) was used to evaluate previously supported three-, five-, and six-factor models using the RBS-R in toddlers (Mirenda et al., 2010). Because models were nested within each other, a difference test was computed to determine whether the most parsimonious model was preferable. Further analyses utilizing Measurement Invariance techniques will also be reported in order to examine diagnostic group differences in RRB factor structure.
Results: Results suggested that the three-factor model, consisting of stereotyped/restricted, compulsive/ritualistic/sameness, and self-injurious behaviors provided preferable fit (χ^2/df=1.36, CFI=.98; TLI=.98; RMSEA=.03). Similarly, the five- and six-factor models provided good fit, but were not as parsimonious (five-factor: χ^2/df=1.30, CFI=.98; TLI=.98; RMSEA=.03; six-factor: χ^2/df=1.31, CFI=.98; TLI=.98; RMSEA=.03).
Conclusions: The RBS-R allows for thorough assessment of a range of RRBs in toddlers and young children. Stereotyped and restricted behaviors emerge as a single factor, a second consists of compulsive, ritualistic, and sameness behaviors, and self-injurious behaviors fall independently on a third factor. Evidence-based support regarding the structure of RRBs in children across diagnostic groups is critically important in understanding early symptomology and improving early detection of ASD.

211 **146.211** The Flexibility Scale: A Parent-Report Inventory of Flexibility Skills in Children with Autism Spectrum Disorders without ID

J. F. Strang[1]*, L. Kenworthy*[2]*, L. G. Anthony*[3]*, B. E. Yerys*[4]*, K. Hardy*[5] *and G. Wallace*[6]*, (1)Children's National Medical Center, Silver Spring, MD, (2)Children's Research Institute, Children's National Medical Center, Rockville, MD, (3)Children's National Medical Center, Rockville, MD, (4)The Center for Autism Research, Philadelphia, PA, (5)Neuropsychology, Children's National Medical Center, Rockville, MD, (6)The George Washington University, Washington, DC*

Background: Restricted, repetitive behaviors and interests (RRBI) comprise one of two core symptom domains in autism spectrum disorders (ASD). Existing RRBI measures are limited in their utility to measure RRBI symptoms dimensionally. The Autism Diagnostic Interview is a widely used diagnostic evaluation of RRBI symptoms and has been inappropriately used as a quantitative measure. The Behavior Rating Inventory of Executive Function provides quatitative measurement of cognitive and behavioral flexibility, and has consistently indentified flexibility deficits in ASD, but its eight items do not measure possible subcomponents of cognitive/behavioral flexibility. A novel measure, the Flexibility Scale (FS) targets broad flexibility characteristics in ASD using a larger set of items with the goal of increasing power and specificity when describing the inflexibility phenotype in ASD without ID.
Objectives: Evaluate the factor structure of the FS in children with ASD.
Methods: The original 50-item FS was developed through an iterative process based on known RRBI/flexibility characteristics in ASD without ID. Parents of 227 children with ASD (age 7-14) completed the FS. Polychoric exploratory factor analysis (EFA) and assessments of internal consistency were conducted.
Results: Minimum Average Partial and Parrallel Analysis tests indicated best fit with a 5-factor model accounting for 45% of the variance. Items with factor correlations falling below .4 were eliminated. Ten international ASD/executive function experts evaluated significantly cross-loaded items for factor placement or removal, and generated descriptions of the factors based on item set and known ASD flexibility characteristics. The resulting 29-item questionnaire has 5 factors: Routine/Rituals, Transitions/Change, Special Interests, Social Flexibility, and Generativity.
Conclusions: These results suggest that RRBI/flexibility characteristics in ASD without ID are multi-dimensional. If confirmed, this factor structure has important implications for the phenotypes of RRBI in ASD without ID, including intervention development and measurement.

212 **146.212** The Impact of Movement Complexity on Movement Planning and Execution in Individuals with an Autism Spectrum Disorder

R. Zheng[1]*, S. R. Passmore*[2,3] *and* ***C. M. Glazebrook***[3,4]*, (1)University of Alberta, Edmonton, AB, Canada, (2)Faculty of Kinesiology & Recreation Management, University of Manitoba, Winnipeg, MB, Canada, (3)Health, Leisure, & Human Performance Research Institute, Winnipeg, MB, Canada, (4)Kinesiology & Recreation Management, University of Manitoba, Winnipeg, MB, Canada*

Background:
Basic fine motor skills provide a foundation for developing more complex communication skills and performing activities of daily living. Difficulties with some aspects of reaching movements are now reported consistently in the literature; however the details are not always consistent (Fournier et al., 2010). Reaction time (RT) results, a measure of movement planning, consistently indicate that individuals with ASD spend more time preparing to move (Glazebrook et al., 2006; Rinehart et al., 2006). That said, whether people with ASD also spend longer executing their movements, and if these movements are performed as consistently and accurately as age-matched peers, is unclear (Glazebrook et al., 2006, 2009; Rinehart et al., 2006; Papadopoulos et al., 2010). On closer examination of the tasks used for the above work we predicted that the inconsistent results for movement execution may be due to differences in movement complexity.
Objectives:
The present study sought to determine: 1) If differences in movement complexity account for the inconsistent reports of movement time and variability. 2) If longer RTs were associated with the cognitive aspects of movement planning, or the motor preparation needed to initiate a voluntary movement.
Methods:
We manipulated movement complexity by comparing sliding (1D and 2D) and aiming (3D) movements. We recruited 11 young adults with ASD and 13 typically developing (TD) age-matched peers to perform three types of reaching movements to targets in the sagittal plane: 1) sliding along a track on a piece of Plexiglas (1D, constrained); 2) sliding along a piece of Plexiglas (2D, constrained); and 3) aiming (3D, unconstrained). Movements were recorded using a 3D motion-analysis system (Optotrak 3D Investigator, NDI) and muscle activity was recorded using surface electromyography (CED 1902 dual system amplifier). RT was parsed into premotor and motor time to assess the relative contributions of cognitive and motor processes respectively. Movement time and the variability of the movement path were derived from the 3D motion analysis data. All dependent variables were submitted to a 2 Group (ASD, TD) by 3 Movement Type (1D, 2D, 3D) mixed analysis of variance.
Results:
No group differences for RT was found (Fs<0.6). A significant Group by Movement Type interaction for MT was consistent with predictions that there were no differences between groups for sliding movements, but the ASD group took longer to execute unconstrained movements. The TD group also exhibited significantly shorter premotor RTs for less constrained movements, whereas premotor RT did not change as a function of movement type for the ASD group. Finally, the ASD group's movements were more variable throughout the entire movement.
Conclusions:
We propose the lack of group difference for RT occurred because the task allowed participants to plan ahead since movement direction was consistent. Based on the group interaction for premotor RT, MT, and other kinematic variables, we suggest that unconstrained reaching movements are more difficult for people with ASD. The present findings will be discussed in the context of brain connectivity models and related preferences for sensorimotor integration.

213 **146.213** The Influence of Atypical Sensory Processing and Anxiety on ASD Symptomatology

K. R. Black[1], *R. A. Stevenson*[1], *B. L. Ncube*[2], *M. Segers*[2], *S. Z. Sun*[1], *J. M. Bebko*[2], *A. Philipp-Muller*[1], *M. Johnston*[3], *Z. Y. Wang*[1], *M. D. Barense*[1] *and S. Ferber*[1], *(1)Department of Psychology, University of Toronto, Toronto, ON, Canada, (2)York University, Toronto, ON, Canada, (3)University of Western Ontario, London, ON, Canada*

Background: Restricted interests and repetitive behaviors (RIRBs) are a defining feature of autism spectrum disorder (ASD). These symptoms can be divided into three distinct constructs: insistence on sameness (I/S), repetitive motor behaviors (RMB) and sensory processing abnormalities. High rates of co-morbid anxiety in ASD have been linked to both I/S and RMB, yet conflicting findings suggest that atypical sensory processing may also play a role in the relationship, particularly with I/S.
Objectives: This novel investigation had 2 goals:

1. Determine if the contribution of atypical sensory processing in ASD to I/S and anxiety varies depending on sensory phenotype (hyper- or hypo-sensitive, sensory avoiding or seeking) and specific type of anxiety.
2. Compare these relationships between individuals with ASD and typically-developing (TD) children.

Methods: Parents of 87 children (ASD, n=49, M_{age}=12.0 years, SD=3.1; TD, n=38, M_{age}=11.6 years, SD=3.1, data collection ongoing) completed questionnaires reporting on sensory processing (the Sensory Profile-2), I/S (the Repetitive Behavior Questionnaire-2), and anxiety (the Spence Children's Anxiety Scale). A two-step analysis was undertaken:

1. A correlational analysis was used to investigate the relationships between variables in both the ASD and TD group, then correlations were compared across groups to highlight between-group differences.
2. A hierarchical regression was run to examine the unique contributions of atypical sensory processing and anxiety to I/S in the ASD group.

Results:
Correlational analysis
The correlational analysis revealed significant differences between ASD and TD groups for anxiety subscales and I/S, and anxiety subscales and sensory sensitivity (Figure 1). Specifically, significantly different correlations were observed between I/S and separation anxiety (p=.03, z=2.15), I/S and panic (p=.01, z=2.47), I/S and general anxiety disorder (p=.05, z=1.91), I/S and total anxiety symptoms (p=.02, z=2.33), as well as between separation anxiety and sensory sensitivity (p=.05, z=1.93). Neither social anxiety, physical anxiety, nor obsessive compulsive disorder were significantly different for correlations with I/S or sensory sensitivity when compared between groups.
Hierarchical regression
In the hierarchical regression, we explored which variables significantly predicted the occurrence of I/S symptomatology (Table 1). I/S was significantly predicted by the sensory phenotype of *hypersensitivity* (β=.34, t=2.86, p=.007) and the subscale of *separation anxiety*(β=.252, t=2.41, p=.021). Notably, I/S decreased with age (r=-.39, p=.003).
Conclusions: Our correlative findings indicate that I/S is atypically related to three specific types of anxiety (separation, panic, and general anxiety) in individuals with ASD. The results from the hierarchical regression suggest that the expression of I/S in children with ASD varies based on a child's level of hypersensitivity to sensory stimulation, and distress due to separation anxiety. Furthermore, younger children may demonstrate more frequent I/S behaviors. Finally, despite the numerous differences between TD and ASD groups' relationships between sensory processing, RIRB, and anxiety, there was also a significant amount of overlap between groups, underscoring the importance of non-clinical control groups.

Figure 1

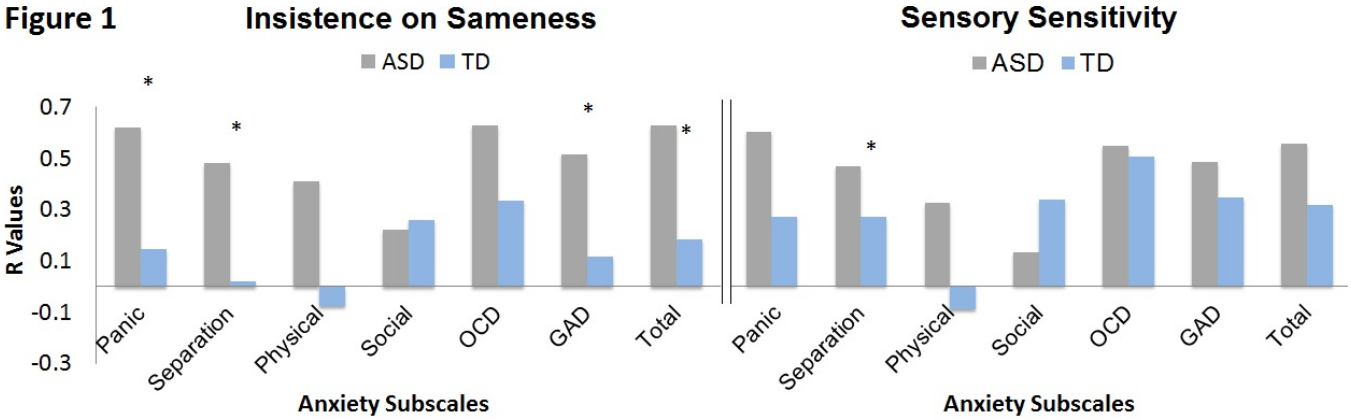

Table 1| Hierarchical multiple regression predicting I/S

Predictor	Partial correlation (*pr*)	*p*-Value
Step 1: *R* = 0.72, *F-change*(4,41) = 11.11, *p-change* < 0.001		
Gender	0.26	0.09
Age	-0.47	**0.002**
IQ	0.03	0.84
Step 2: *R* = 0.82, *F-change*(1,40) = 17.54, *p-change* < 0.001		
Gender	0.21	0.18
Age	-0.38	**0.01**
IQ	0.07	0.68
Sensory Sensitivity	0.55	**<0.001**
Step 3: *R* = 0.84, *F-change*(1,39) = 5.78, *p-change* = 0.021		
Gender	0.28	0.78
Age	-0.35	**0.02**
IQ	0.17	0.28
Sensory Sensitivity	0.42	**0.007**
Separation Anxiety	0.36	**0.02**

Significant results of added predictors are shown in **bold**.

146.214 The P-Gsq: A New Self-Report Sensory Questionnaire for Children

D. R. Simmons[1], *A. E. Robertson*[2] *and L. Brown*[1], *(1)School of Psychology, University of Glasgow, Glasgow, Scotland, (2)Psychology, University of Dundee, Dundee, Scotland*

Background: The Glasgow Sensory Questionnaire (GSQ; Robertson & Simmons, 2013) is a 42-item self-report questionnaire which measures the frequency and severity of sensory difficulties (both hyper- and hypo-responsiveness), giving a score ranging from 0 (no sensory difficulties) to 168 (Extremely severe and frequent difficulties in all sensory modalities). Research with this questionnaire has shown that there are strong correlations of sensory score with self-reported autistic traits (Robertson & Simmons, 2013; Horder et al, 2014) and (in a Japanese translation) significant differences in sensory scores between diagnosed ASD and control populations (Takayama et al, 2014). However, so far the GSQ has only been critically tested with adults. We have therefore developed a version of the questionnaire adapted for children: the Pictured-Glasgow Sensory Questionnaire (P-GSQ).
Objectives: To develop and validate a version of the GSQ adapted for children (8-15 years).
Methods: The questionnaire adaptation was achieved by (a) modifying the language slightly to make it understandable to a typical 8-year-old and (b) incorporating eye-catching illustrations to support the question text. After performing pilot experiments to verify that the text and pictures were adequately understood, the questionnaire was completed by 234 children (mean age 10.15 years, age range 8-15 years) during the course of a public workshop at a local "hands-on" science museum. The caregiver with the child was asked to complete the Children's version of the AQ (Auyeung et al, 2009) at the same time, so that the link between P-GSQ and autistic trait level could be evaluated.
Results: Overall results show only a modest, if significant, correlation between P-GSQ and AQ score (Pearson's $r(234) = 0.147$, $p < 0.05$, $R^2 = 0.022$). Subsequent analysis of sub-scales of the P-GSQ indicated that this correlation was largely driven by auditory and gustatory hyper-sensitivity and by the proprioceptive modality. Splitting the ages up into two groups showed that the correlation was only significant in the 8-11 age range and not in the 12-15-year-olds. Splitting the group by gender found that the correlation was only significant in females and not males. Cronbach's Alpha revealed a good degree of internal consistency (alpha = 0.835).
Conclusions: These results are curious given the well-documented and replicated significant correlations between GSQ sensory scores and autistic trait levels found in adults (16+). Pilot data collected with 12-15-year-olds and the adult GSQ in a similar way to these data also revealed no significant correlations. The general response seems to be a modest amount of sensory difficulty (somewhere between "often" and "sometimes") for most of the young people we tested. One explanation is that all young people have mild difficulties with sensory stimulation: the difference is how they *react* to it, and this "sensory reactivity" is what is picked up in the more-frequently used caregiver questionnaires. Alternatively, young people may lack the insight necessary to self-report on their own sensory difficulties and/or the difficulties that they experience may be qualitatively different from those that adults experience.

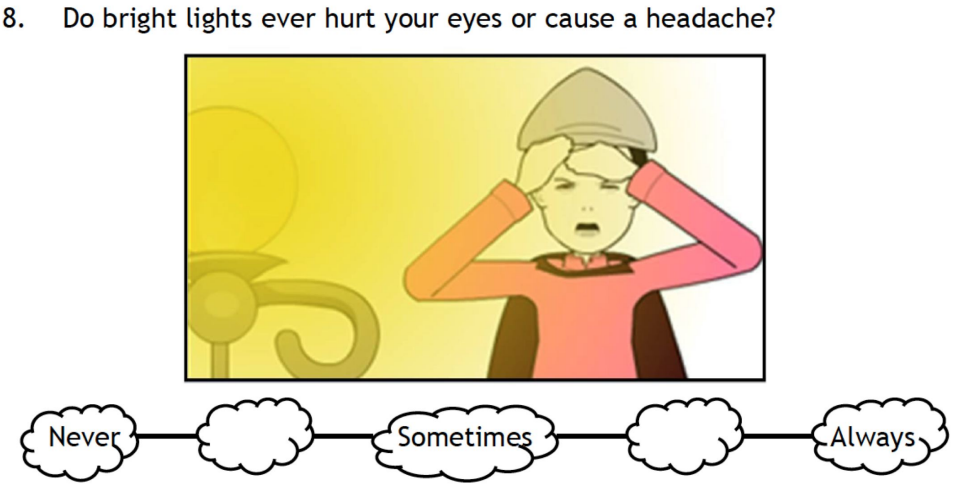

Figure: A sample question and associated illustration from the P-GSQ

215 **146.215** The Use of a Kinect-Based Technology to Enhance Sensory-Motor Skills in Children with Autism

M. Mademtzi[1], *K. Guldberg*[2] *and K. Wittemeyer*[3], *(1)University of Birmingham, Bimringham, United Kingdom, (2)University of Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland, (3)University of Birmingham, Birmingham, United Kingdom*

Background: Current estimates indicate that 80% of children diagnosed with autism present sensory processing problems. These problems refer to all sensory systems, including tactile, auditory, visual, gustatory, olfactory and also vestibular and proprioceptive. The last two systems along with input from the visual system, play a crucial role in many areas of development, mostly in sensory-motor development (Baranek, 2002). The most known interventions in this area include sensory integration therapy (Ayres, 1972; 1979), traditional occupational therapy and physical exercise. These interventions require trained personnel (e.g. occupational therapists) and specialized equipment. As a result, they cannot be delivered by classroom teachers. Another medium recently started used for dealing with the same matters is technology. Platforms like Nintendo Wii and Microsoft Kinect allow full body input and they enable physical and sensory stimuli.
Objectives: The objective of this study was to investigate whether a new, free and easily implemented kinect-based technology called *Pictogram Room* can contribute to the development of children's with autism sensory-motor skills as observed in three school settings (i.e. physical education, classroom and playground).
Methods: *Pictogram Room* uses augmented reality to help children with autism to develop a range of skills, creating a virtual space with highly customizable educational activities. Through the recognition of movement, it is possible to reproduce the image of the player himself/herself augmenting with a series of graphic and musical elements that guide the learning process. A matched control group design was followed with 5 children (all males, M_{age}=5.4 years) in the intervention and 5 children (4 males and 1 female, M_{age}=5.2 years) in the control group. The children completed a set of 20 sessions in total working on *Pictogram Room* (2 familiarization sessions and 18 sessions delivered twice a week for a period of 9 weeks) in a mainstream school with autism units in the UK. Pre and post intervention the children's teachers completed the Balance, Body Awareness and Planning (BBAP) checklist, developed by the researcher, to monitor potential changes in the targeted skills.
Results: Following intervention there was a significant difference between the two groups' sensory-motor skills in physical education (intervention group: M=104.4, SD=5.9; control group: M=93.2, SD=6.98; $t(4)=7.6$, $p=0.0016$; Cohen's $d=1.7$). In the classroom environment the difference between the two groups was close to being significant but with large effect size (intervention group: M=74.8, SD=6.94; control group: M=69, SD=6.75; $t(4)=2.4$, $p=0.0694$; Cohen's $d=0.8$). Finally, in playground, the difference in sensory-motor skills development between the two groups was not significant (intervention group: M=60.8, SD=5.63; control group: M=58.2, SD=4.55; $t(4)=1.35$, $p=0.2457$; Cohen's $d=0.5$).

Conclusions: This study suggests that teachers can use *Pictogram Room* as an effective way to support students' with autism sensory-motor skills. However, more research is needed, with larger samples, as well as using different methods with which greater generalization of skills can be achieved. It does not cut off the need for professional support like occupational therapy but it is a tool that teachers can easily use in the classroom and incorporate it with curriculum goals.

216 **146.216** The Validation of a New Measure for Assessing the Frequency and Impact of Sensory Sensitivities in Autism, the Sensory Processing Behaviour Questionnaire, and Its Association with Anxiety Symptoms

*L. E. Neil[1], **E. Pellicano**[1] and D. Green[2], (1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)Oxford Brookes University, London, United Kingdom of Great Britain and Northern Ireland*

Background:
Sensory sensitivities are included in the DSM-5 criteria for autism yet there are few well-validated measures to assess them. A newly developed scale, the Sensory Processing Behaviour Questionnaire (SPBQ: Green, 2013) has been uniquely designed to measure the frequency (e.g., 'How often have you noticed your child show an unusual response to bright lights in the last month?') and impact ('How much of a problem is it?') of 25 sensory behaviours in multiple domains. Evidence suggests that sensory sensitivities are closely associated with anxiety in autism. The DSM-5 specifies several different types of anxiety disorder yet the differential relationship sensory sensitivities may show with anxiety symptoms in different domains remains hitherto unexamined.
Objectives: The aims of this study were twofold: (1) to investigate the psychometric properties of the SPBQ, including internal consistency, factor structure and convergent validity, and (2) to determine the association between autistic children's scores on the SPBQ and subtypes of anxiety.
Methods:
Parents of 67 children with autism and 71 typically developing children, aged between 6 and 17 years were administered the Sensory Processing Behaviour Questionnaire (SPBQ), the Short Sensory Profile (SSP) and the Spence Children's Anxiety Scale (SCAS), which assesses anxiety symptoms in six domains in keeping with the DSM-IV. Groups were matched on age (p = .25) and IQ (p = .20).
Results:
As expected, children on the autism spectrum scored significantly higher on the SPBQ than typically developing children of similar age and ability, indicative of greater levels of sensory sensitivities, t(136) = 12.0, p <.001. Internal consistency, factor structure and convergent validity were assessed in the autistic sample only. The 50-item SPBQ showed excellent internal consistency (α = .97) as did the separate frequency (α = .93) and impact (α = .94) scales. Principal components analysis, with varimax rotation, suggested an 8-factor solution. Six of these factors broadly related to daily routines, posture and balance, sensation seeking, noise sensitivity, visual sensitivity and food sensitivities. The two remaining factors were less straightforward to interpret, but one featured difficulties dealing with cluttered environments and the other motor behaviours such as rocking and mouthing objects. The SPBQ scores showed good convergent validity with the most commonly used assessment of sensory symptoms in autism, the SSP (total: r = .79; frequency: r = .78; impact: r = .74). Consistent with previous work, the SPBQ showed a medium-to-strong correlation with children's anxiety scores on the SCAS (r = .58, p <.001). The SPBQ was most strongly associated with the generalised anxiety subscale (r = .60), and most weakly associated with the social anxiety subscale (r = .17).
Conclusions:
The SPBQ is a psychometrically valid tool to assess sensory sensitivities in children on the autism spectrum. Its assessment of the impact, as well as the frequency, of sensory sensitivities makes it particularly useful in a clinical context.

217 **146.217** Tip-Toe Behavior (TTB) Presentation Pattern and Achilles's Tendon Shortening: Are They Related in ASD Children?

***G. Valagussa**, V. Balatti, L. Trentin and E. Grossi, Autism Unit, Villa Santa Maria Institute Neuropsychiatric Rehabilitation Center, Tavernerio, Italy*

Background:
About twenty percent of individuals with ASD walk on their tiptoes. Persistent toe-walking in children with ASD may contribute to secondary motor deformities by producing a shortening of the Achilles's tendon (made up by the soleus muscle SM and gastrocnemius muscle GM). It is not clearly understood why some ASD subjects develop this tendon shortening while others do not. A possible contributing factor could be the amount of time children spend in TTB during the day, i.e. if TTB is present only in running (class 3) or in walking and running (class 2) or in standing, walking and running (class1), three mutually exclusive patterns we described in a previous study.
Objectives:
The aim of this cross-sectional study is to evaluate the relationship between the three TTB presentation patterns described above and the Achilles's tendon shortening.
Methods:
The study includes 69 consecutive children (57 males, 12 females, mean age = 14 years – 3.6 SD) diagnosed with ASD according to the DSM V criteria and under observation at our institute. The severity of ASD was established through ADOS (2nd version). A therapist assessed the presence of Tiptoe behavior (TTB) during standing, walking and running using direct observation and an interview of the main caregiver living with the children. Another therapist assessed both the soleus and gastrocnemius muscles length using a manual goniometer.
Results:
Overall 23/69 children presented TTB. Ten children exhibited it in standing, walking and running (class 1), 8 only during walking and running (class 2) and 5 children only during running (class 3).
There were no significant differences in the mean overall ADOS score of the TTB children according to TTB classes: 20.13 (5.48 SD) no TTB class; 23.90 (5.36 SD) class1, vs 21.13 (4.29 SD) class 2 and vs 23.60 (5.13 SD) class3.
The mean length of the **left GM** of non TTB children was 9.20° (5.18°SD) vs a value of -0.2°(10.16°SD) TTB class 1(p<0.01), vs 6° (2.73°SD) TTB class 2 (p NS) , vs 10.2° (9.92°SD) TTB class 3 (p NS). The mean length of the **right GM** of non TTB children was 9.02° (5.39°SD) vs a value of 1.7°(10.91°SD) TTB class 1(p<0.01), vs 8.75° (4.58°SD) TTB class 2 (p NS), vs 11.6° (4.39°SD) TTB class 3(p NS). The mean length of the **left SM** of non TTB children was 21.07° (7.67°SD) vs a value of 10° (9.65°SD) TTB class 1 (p< 0.05), vs 18.63° (9.90°SD) TTB class 2(p NS), vs 22.80° (6.30°SD) TTB class 3(p NS). The mean length of the **right SM** of non TTB children was 19.33° (6.87°SD) vs a value of 9.7°(8.84°SD) TTB class 1(p <0.05), vs 19.25° (8.26°SD) TTB class 2(p NS), vs 21.8° (6.61°SD) TTB class 3 (p NS).
Conclusions:
The data confirm the existence of a positive relationship between the presence and severity of TTB and the Achilles's tendon shortening, with a significant difference between the NonTTB group and Class 1 TTB group.

	NON TTB children (46 subjects)	TTB class 1 (10 subjects)	TTB class 2 (8 subjects)	TTB class 3 (5 subjects)
Left gastrocnemius	9.20° (5.18°SD)	-0.2°(10.16°SD)	6° (2.73°SD)	10.2° (9.92°SD)
Right gastrocnemius	9.02° (5.39°SD)	1.7°(10.91°SD)	8.75° (4.58°SD)	11.6° (4.39°SD)
Left soleus	21.07° (7.67°SD)	10°(9.65°SD)	18.63° (9.90°SD)	22.80° (6.30°SD)
Right soleus	19.33° (6.87°SD)	9.7°(8.84°SD)	19.25° (8.26°SD)	21.8° (6.61°SD)

218 **146.218** Typology of Temporal Patterns: Identifying Subgroups of Individuals with ASD

***M. S. Goodwin**[1] and H. McGee[2], (1)312 E Robinson Hall, 360 Huntington Ave., Northeastern University, Boston, MA, (2)University of Rhode Island, Kingston, RI*

Background: Technological advances in data acquisition and analytics have increased the feasibility and usefulness of employing idiographic methods in autism research. While there are many advantages to employing an idiographic approach, a major criticism has been lack of generalizability from single subject research to the larger population of interest. This is an especially important issue in Autism Spectrum Disorder (ASD) given the high heterogeneity observed in the population, and fact that important individual differences in data can be obscured by group-level averages.
Objectives: Develop a novel analytic method that combines time series analysis and dynamic cluster analysis (Typology of Temporal Patterns; TTP) to identify subgroups of individuals who share similar longitudinal trajectories, helping address the issue of generalizability in idiographic research in autism research.
Methods: Apply TTP to the assessment of cardiovascular arousal to environmental stressors in individuals with ASD. Data analyses were performed on heart rate (HR) data collected telemetrically from 43 severely affected (*M* IQ = 31) individuals with confirmed diagnoses of ASD (*M* = 14.55 yrs, *SD* = 4.24) during rest and several psychological and physical challenges established in previous studies by Goodwin and colleagues (Goodwin et al., 2004; 2006; Groden et al., 2005). Interrupted time series analysis was performed for each participant to examine individual-level HR patterns across rest and challenge conditions. High variability observed across interrupted time series results demonstrated the presence of subgroups of individuals with similar HR patterns. Accordingly, dynamic cluster analysis was conducted on HR time series data from the 43 participants.
Results: While HR response patterns were generally elevated for all participants (80bpm <), the first cluster analysis revealed a three-cluster solution (Low, Middle, and High) largely dominated by differences in HR level (i.e., mean). Importantly, if only the total sample level average was considered, results suggest that all participants are in the Middle group (denoted by the black line in Figure 1, top panel). A second cluster analysis, focused on shape and scatter of HR patterns, revealed two subgroups (Autonomic

Stabiles and Autonomic Labiles) that differed in their patterns of HR reactivity to stressors and HR recovery during rest conditions. Thus, TTP yielded a combined six-cluster solution defined by level and shape (Figure 1, bottom panel). Following these clustering results, a series of ANOVAs produced statistically significant differences between identified subgroups, even after controlling for age, sex, IQ, verbal ability, medication status, and motor movements.
Conclusions: Our findings provide support for the utility of TTP to evaluate idiographic data at both individual and subgroup levels, and suggest that cardiovascular reactivity is a useful biological marker for identifying meaningful individual differences in the heterogeneous population of ASD. Furthermore, this is the first report of clearly defined ASD subgroups relating to cardiac stability/lability. This variable may represent an important dimension for assessing ANS as an indicator of hypo- or hyper-reactivity to environmental conditions (i.e., not just level and variability, but shape) – a new feature in the DSM-5 symptom description of ASD.

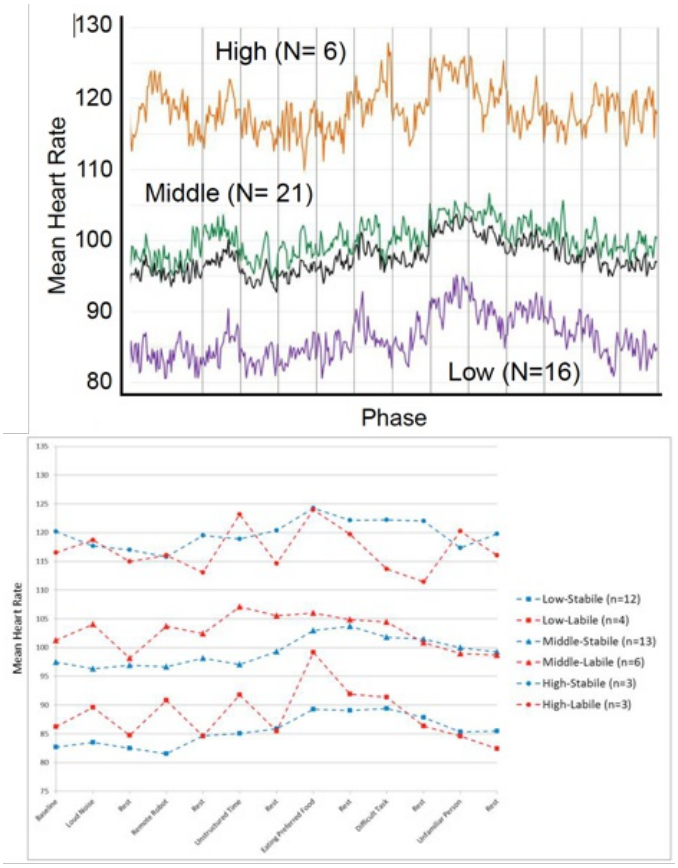

Figure 1. Top Panel: Three-cluster solution based on HR level (black line represents grand mean for total sample, and obscures Low and High Cluster). Bottom Panel: Six-cluster solution based on HR level, shape, and scatter.

219 **146.219** Unusual Sensory Behaviors in Infants at Risk for Autism

A. N. Bhat[1], *H. Van Etten*[2], *M. Kaur*[1], *S. Srinivasan*[1] *and K. R. Dobkins*[3], *(1)University of Delaware, Newark, DE, (2)UCSD Department of psychology, San Diego, CA, (3)Department of Psychology, University of California, San Diego, La Jolla, CA*

Background:
Autism Spectrum Disorder (ASD) is characterized by the presence of social communication deficits as well as restricted and repetitive behaviors (American Psychiatric Association, 2013). Comorbidities in ASD include unusual sensory behaviors (USBs) and this feature has now been incorporated into the DSM 5. To date, little is known about whether USBs can be observed early on in ASD.
Objectives:
In the current study, we employed the Infant/Toddler Sensory Profile (ITSP) parent questionnaire (Dunn, 2002) to track USBs in infants at a High-Risk for developing ASD because they have an older sibling with ASD. Although one previous study has used the ITSP in 12-month-olds (Mulligan & White, 2012), the current study is the first to look at multiple time points in order to gain a more comprehensive view.
Methods:
At two testing sites (University of Connecticut-Storrs and the University of California, San Diego), parents were asked to fill out the ITSP at several time points from 3 to 36 months. The final data sample included 32 High-Risk infants, and for comparison, 39 Low-Risk infants (i.e., infants from families with no history of ASD). The ITSP was used to determine USBs (i.e., outside the "typical" range) within each of the five sensory processing domains (low registration, sensation seeking, sensory sensitivity, sensation avoidance, and low threshold) and five sensation types (auditory, visual, vestibular, tactile, and oral). In our sample, for each domain, we asked whether – at any time point – a child's ITSP score was indicative of USBs, in which case, they were given a score of "1", or else, the child received a score of "0".
Results:
In terms of sensory processing domains, greater proportion of USBs were observed in High-Risk than Low-Risk infants, specifically in the domains of *low registration* (High-Risk=78.1%, Low-Risk=46.2%, x^2 = 41.2, p <.001), *sensation avoidance* (High-Risk=62.5%, Low-Risk=41%, x^2 = 20, p <.001), *and low threshold* (High-Risk= 62.5%, Low-Risk= 41%, x^2 = 20, p <.001). In contrast, *sensation seeking* and *sensory sensitivity* domains showed no group differences. In terms of the various sensation types, greater proportion of USBs were observed in the *auditory* (High-Risk= 68.8%, Low-Risk= 53.8%, x^2 = 9.1, p<.01), *visual* (High-Risk= 71.9%, Low-Risk= 51.3%, x^2 = 17.6, p <.001), *tactile* (High-Risk= 90.6%, Low-Risk= 64.1%, x^2 = 31.6, p<.001), and *vestibular* (High-Risk= 93.8%, Low-Risk= 43.6%, x^2= 101.5, p<.001) sensations. There were no significant differences in oral processing.
Conclusions:
Infants at a High-Risk for ASD showed elevated unusual sensory behaviors compared to Low-Risk infants within multiple sensory processing domains and sensation types. These results have implications for early interventions that target sensory processing abilities in ASD. To be clear, clinicians must screen for USBs in High-Risk infants and address them through appropriate sensori-motor and behavioral interventions.

220 **146.220** What Interests Young Autistic Children? Assessing Object Exploration and Repetitive Behaviors in a Stimulating Play Situation

C. Jacques[1], *V. Courchesne*[2], *A. A. S. Meilleur*[3], *S. Mineau*[4], *S. Ferguson*[5], *D. Cousineau*[6], *L. Mottron, M.D.*[7] *and M. Dawson*[4], *(1)Universite du Quebec en Outaouais, Gatineau, QC, Canada, (2)University of Montreal, Montréal, QC, Canada, (3)Centre d'excellence en Troubles envahissants du développement, Montreal, QC, Canada, (4)Centre d'excellence en Troubles envahissants du développement de, Montréal, QC, Canada, (5)Centre d'excellence en Troubles envahissants du développement, Montréal, QC, Canada, (6)Hôpital Ste-Justine, Montréal, QC, Canada, (7)Centre d'Excellence en Troubles Envahissants du Développement, Montréal, QC, Canada*

Background: Restricted and repetitive behaviors (RRBs) now play a more prominent role in autism diagnosis (APA, 2013), but remain understudied in young children. RRBs in autism range from repetitive movements to intense interests and are targeted in early interventions as barriers to progress (e.g., Rogers & DawsonG. 2010). However, studies in typical children suggest a positive relationship between intense interests and intelligence or expertise (DeLoache et al., 2007; Johnson et al. 2004; Krapp, 2002). Further, there are suggestions that autistics may learn well given access to materials related to their interests (DawsonM et al. 2008; Dunst et al. 2012). Thus one question about young autistic children is whether their repetitive behaviors limit or interfere with their object exploration. Another is whether they are interested only in simple sensory

objects, or are also attracted to more complex materials such as those related to literacy.
Objectives: To document object exploration and repetitive behaviors in young autistic and typical children, during periods of free and semi-free play in the Montreal Stimulating Play Situation (MSPS).
Methods: 53 autistic and 46 typical children were exposed to the MSPS. Autistic children were on average somewhat older (*M*=48.1 months, *SD*=11.5) than typical children (*M*=41.7 months, *SD*=16.0, *p*<0.05) but their mean MSEL composite standard scores (*M*=65.5, *SD*=20.0 vs *M*=110.3, *SD*=17.3, *p*<0.001) and language T-scores (expressive: *M*=25.9, *SD*=11.8 vs *M*=55.6, *SD*=12.7, *p*<0.001; and receptive: *M*=28.8, *SD*=12.8 vs *M*=53.3, *SD*=11.2, *p*<0.001) were dramatically lower. Using Noldus Observer, two naive raters coded 49 previously selected and defined repetitive behaviors in all children. They also coded the use of the 40 objects in the MSPS. 30% of the videos were double coded (K=0.47).
Results: Autistic children displayed a significantly greater overall number (*p*=0.02) and duration (*p*<0.001) of repetitive behaviors than typical children. Three specific repetitive behaviors were found in a greater proportion of autistic children, with higher frequency and greater duration: hand-flapping; arm movements; and the combination of close gaze, waving fingers, and lateral glances; all *p*s<0.05. In contrast, there were no significant differences between groups in duration (*p*=0.71) and frequency (*p*=0.24) of overall object exploration in the MSPS. For specific objects, exploration of mirror balls and books were observed in a greater proportion of autistic children, with higher frequency and longer duration (all *p*s< 0.05); whereas a greater proportion of typical children explored the roller caterpillar and remote-controlled car, with more frequent and longer explorations (all *p*s<0.05). With respect to literacy-related objects, proportion of autistic vs typical children who explored each was as follows: books 17% vs 6%; magnetic letters and numbers 59% vs 53%; picture dictionary 17% vs 17%; and regular dictionary 15% vs 6%.
Conclusions: Our results are preliminary but suggest that increased repetitive behaviors do not interfere with object exploration in young autistic children. In addition, these children showed equal or greater interest in literacy-related objects, in striking contrast to their low MSEL composite and language scores. These findings raise questions about popular assessments and interventions for young autistic children.

Oral Session - 6A
148 - Perinatal Risk Factors
1:45 PM - 2:35 PM - Hall B

1:45 **148.001** Neonatal Inflammation and Autism Risk in a Swedish Birth Cohort

R. M. Gardner[1], *B. Lee*[2,3,4], *H. Karlsson*[1] *and C. Dalman*[1], *(1)Karolinska Institutet, Stockholm, Sweden, (2)Drexel University, Philadelphia, PA, (3)Drexel University School of Public Health, Philadelphia, PA, (4)A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Mounting evidence from both animal and human studies indicates that early life immune function can influence neurodevelopmental outcomes relevant to autism. However, there are few biomarker-based studies of larger birth cohorts.
Objectives: We aimed to measure acute phase proteins in neonatal dried blood spots, as markers of neonatal inflammation, and determine associations with later risk of autism spectrum disorders (ASD).
Methods: We performed a case-control study of 851 ASD cases and 1,132 controls born 1996-2000 in Sweden, with case ascertainment as of December 2011. Blood spots were collected from a central biobank. Nine acute phase proteins were measured using a magnetic bead-based multiplex panel: α-2 microglobulin, C-reactive protein, haptoglobulin, serum amyloid P, procalcitonin, ferritin, tissue plasminogen activator, fibrinogen, and serum amyloid A. We examined logistic regression models of the inflammatory markers adjusted for total protein content, sex of child, maternal age, and birth year. Inflammatory markers were individually examined, as well as combined into an acute phase protein risk score based on ridge regression coefficients.
Results: All neonatal acute phase proteins were moderately to highly correlated, ranging from Spearman correlations of 0.31 (fibrinogen and C-reactive protein) to 0.80 (ferritin and α-2 microglobulin). Higher levels of 6 of the 9 acute phase proteins were individually associated at p < 0.05 with increased risk of ASD in a monotonic fashion. For example, the highest tertile of serum amyloid P had a 1.49 (95% CI: 1.17, 1.90) times higher odds of ASD, compared to the lowest tertile. Factors including maternal hospitalization with infection in the third trimester, low Apgar score, and higher gestational age appeared to be associated with higher levels of the acute phase proteins. A 1 standard deviation increase in the acute phase protein risk score was associated with a 21% increase in odds of ASD, OR: 1.21, 95% CI 1.10-1.33.
Conclusions: Because acute phase proteins are not thought to cross the placenta, the results suggest that the perinatal innate immune system may influence later risk of ASD. We discuss the results in the context of environmental obstetric influences of early life immune function.

1:57 **148.002** Prenatal Maternal Thyroid Antibody, Immune Context and Risk of Autism in a Finnish Prenatal Birth Cohort

K. Cheslack-Postava[1], *H. M. Surcel*[2], *S. Hinkka-Yli-Salomäki*[3], *Y. Bao*[1], *A. Sourander*[3] *and A. S. Brown*[1], *(1)Columbia College of Physicians and Surgeons, New York, NY, (2)National Institute for Health and Welfare, Oulu, Finland, (3)University of Turku, Turku, Finland*

Background: Prenatal maternal autoimmunity has been associated with an increased risk of autism in the offspring, for example through studies showing a higher incidence of autoimmune disease diagnoses in mothers of children with autism versus those of controls. This has not been tested using clinical biomarkers of autoimmune disorders. Additionally, the role of prenatal maternal autoimmunity in relation to autism risk has not been examined in the context of additional biomarkers of immune dysfunction or other potentially related factors.
Objectives: To assess: a) the association between maternal thyroid peroxidase (TPO) autoantibodies in prenatal serum samples and the subsequent diagnosis of childhood autism in the offspring; and b) additional immune related factors that may influence this association.
Methods: The Finnish Prenatal Study of Autism (FIPS-A) is a case-control study nested in a national birth cohort. Cases with childhood autism (ICD-10 F84.0) born from 1987-2005 were identified using national registries and matched with controls by birth date, sex, location of birth, and residence in Finland. Prenatal maternal serum samples from 967 pairs of cases and matched controls were analyzed for thyroid peroxidase antibodies (TPO-Ab), a marker of autoimmune thyroid disease, using a chemiluminescent microparticle immunoassay. Data were analyzed using conditional logistic regression. Stratified analyses were conducted by offspring sex, the presence or absence of intellectual disability in the case, and birth year. Heterogeneity of the association across strata was determined using tests of interaction. We will further test this association in the context of additional immune related factors such as biomarkers of inflammation and exposures/conditions potentially related to inflammation/immune dysfunction.
Results: TPO antibody positivity was associated with a significantly increased odds of autism (OR (95% CI) =1.78 (1.16-2.75)) after adjusting for potential confounders. Log transformed TPO antibody defined as a continuous variable was also positively associated with the odds of autism (OR (95% CI) =1.09 (1.01-1.17)). The association between TPO antibody positivity and autism was stronger for cases without intellectual disability (OR (95% CI) = 2.35 (1.33-4.14)) than for cases with intellectual disability (OR (95% CI) = 1.13 (0.57-2.27)), although the difference between groups was not statistically significant. A lack of association between thyroid hormone levels and autism suggested that altered hormone levels secondary to autoimmunity did not mediate the relationship. We will also present results of analyses assessing the joint role of TPO antibody and additional immune related factors.
Conclusions: These findings provide biomarker-based evidence for the association of prenatal maternal autoimmune thyroid disease with autism. The results suggest that the association may be related to underlying maternal autoimmunity or immune factors rather than thyroid dysfunction. We will also present results on the relationship of maternal inflammation to TPO autoantibodies and whether the association is mediated by inflammation.

2:09 **148.003** Hypertensive Disorders with Placental Insufficiency Associated with Increased Autism and Intellectual Disability Risk

P. Krakowiak[1], *D. J. Tancredi*[2], *G. Xing*[3] *and C. Walker*[4], *(1)2825 50th Street, UC Davis, Sacramento, CA, (2)Pediatrics, UC Davis School of Medicine, Sacramento, CA, (3)Center for Healthcare Policy and Research, University of California, Davis, Davis, CA, (4)MIND Institute, University of California, Davis, Sacramento, CA*

Background: Pregnancies complicated by hypertensive disorders have been linked to poor neurodevelopmental outcomes, such as autism and intellectual disability (ID). Hypertensive disorders can lead to inflammation, vascular damage, and restricted nutrient transfer at the placental level; these physiologic changes may result in aberrant neurodevelopment. Although we have previously investigated preeclampsia and placental insufficiency (PI) in relation to neurodevelopmental outcomes, we were unable to examine the finer categories of hypertensive disorders, including chronic hypertension only and hypertension with superimposed preeclampsia.
Objectives: To determine whether the risk for autism or ID relative to the general population (GP) differed across specific categories of hypertensive disorders and whether the presence of PI changed these associations.
Methods: We used a large population-based cohort of California births from 1991 to 2008 with linked information on autism and ID diagnoses from the California Department of Developmental Services (DDS). Hypertensive disorders were identified by ICD-9-CM codes and grouped into chronic hypertension (HTN), preeclampsia (PE), and HTN with superimposed PE (HTN+PE), and evidence of PI included intrauterine growth restriction, oligohydramnios and/or small-for-gestational-age birthweight. We conducted log-binomial regression models with mutually exclusive categories of hypertensive disorders plus or minus PI as predictors of interest and neurodevelopmental disorders autism and ID as outcomes relative to GP. All models were adjusted for birth year, maternal age, race, delivery payer, and parity to estimate risk ratios (RR) and 95% confidence intervals (CI).
Results: Women with any type of hypertensive disorder had approximately a 20% increased risk for having a child with autism relative to GP. Although PI alone was only modestly associated with autism, the risk for autism increased in relation to these hypertensive disorders in the presence PI: 19% to 32% for HTN and 23% to 35% for PE. HTN+PE was associated with a 39% increased risk for ASD; however, HTN+PE in the presence of PI was not associated with ASD. Associations between hypertensive

disorders and ID were more pronounced. Women with HTN+PE had a nearly 2-fold increased risk for having a child with ID; whereas women with PE or HTN only each had a 1.4-fold increased risk for ID. In contrast to autism, PI alone was associated with a nearly 3-fold increased risk for ID. Similar to autism, the presence PI with any hypertensive disorder elevated the risk for ID: 40% to 214% for HTN+PE; 40% to 214 for HTN, and 31% to 186% for PE.
Conclusions: Risks for autism and especially for ID were increased in fetuses whose mothers had any form of hypertensive disorder during pregnancy, particularly when PI was present. Suboptimal placentation limits oxygen and nutrient transfer creating oxidative stress, growth restriction and progressive hypoxemia. Although the exact causal mechanisms linking hypertensive disorders and adverse neurodevelopmental outcomes are unknown, improved prepregnancy health may help to reduce the likelihood of developing these conditions.

2:21 **148.004** Diabetes and Hypertension in Pregnancy in Association with Autism Spectrum Disorder in the Child

C. Cordero[1], *G. C. Windham*[2], *M. D. Fallin*[3], *L. A. Croen*[4], *W. Thompson*[5], *L. A. Schieve*[5] *and J. L. Daniels*[6], *(1)The University of North Carolina-Chapel Hill, Carrboro, NC, (2)California Department of Public Health, Richmond, CA, (3)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, (6)University of North Carolina, Chapel Hill, NC*

Background: Previous studies have shown complications of pregnancy, labor, and the neonatal period to be associated with autism spectrum disorder (ASD). However, because specific conditions are relatively rare, multiple conditions of pregnancy have often been examined in aggregate and with inconsistent results. More common complications in pregnancy should be investigated independently.
Objectives: To examine the association between 1) maternal diabetes and 2) maternal hypertension active during pregnancy and the development of ASD in the child.
Methods: Our analysis uses the Study to Explore Early Development (SEED), a multi-site, case-control study. Children born from 2003-2006 were enrolled in SEED at 2 to 5 years of age. Developmental assessment in the clinic was used to classify children into three groups based on presence of ASD (n=702), non-ASD developmental delay (DD; n= 893), or non-ASD controls drawn from the general population (POP; n=982). Mothers who had an active diagnosis of diabetes or a hypertensive disorder during pregnancy were identified from prenatal medical records, maternal interviews, and questionnaires. We examined the associations between diabetes, hypertension, and case status (ASD and DD groups to POP) using adjusted multivariable logistic regression models. We examined the impact of diabetes and hypertension independently, as well as adjusted for the co-occurrence of each condition. Odds ratios were further adjusted (aOR) for maternal age, race/ethnicity, education, smoking during pregnancy, and pre-pregnancy body mass index. Models of hypertension were additionally adjusted for parity and plurality.
Results: From a sample of 2,577, we identified 244 mothers (9.5%) with diabetes and 433 mothers (16.8%) with hypertension in pregnancy. The crude OR=1.32 (95% confidence interval (CI) 0.94, 1.86) for diabetes was attenuated after adjusting for covariates, aOR=0.99 (95% CI 0.68, 1.45). No differences in association were seen between mothers with gestational diabetes (n=199) and preexisting diabetes (n=45). For hypertension, the crude OR=1.71 (95%CI 1.32, 2.23) was attenuated slightly with covariate adjustment, but remained elevated, aOR=1.37 (95% CI 1.02, 1.84). A stronger association was observed for mothers with a preexisting diagnosis of hypertension (n=134) that persisted into pregnancy and ASD relative to mothers without a diagnosis of hypertension (adjusted OR=1.61 [95% CI 1.00, 2.58]. Associations were slightly stronger when comparing DD vs. POP, diabetes aOR=1.22 (95% CI 0.87, 1.71) and hypertension aOR=1.49 (95% CI 1.13, 1.96).
Conclusions: Our results did not show an association between diabetes during pregnancy and ASD in the child. An association was found with hypertension during pregnancy. A stronger association was observed with preexisting hypertension, which may highlight the importance of the early prenatal period in the development of ASD. In general, most associations between mother's conditions and child outcomes were slightly stronger when examining children with a non-ASD developmental delay. Further analysis will be conducted to examine these differences and explore additional factors related to the etiology of ASD.

2:40 **149.001** Air Pollution, Developmental Delays and Autism Spectrum Disorder in the Early Markers of Autism (EMA) Study

B. Park[1], *L. A. Croen*[2], *M. Kharrazi*[3], *M. Pearl*[3], *G. C. Windham*[3], *O. Zerbo*[2] *and* ***H. E. Volk***[4], *(1)Drexel University, Philadelphia, PA, (2)Division of Research, Kaiser Permanente, Oakland, CA, (3)California Department of Public Health, Richmond, CA, (4)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore,*

MD

Background: Many epidemiologic studies have suggested that air pollutants may play a role in impaired neurodevelopment and more specifically in the etiology of ASD However, it is unclear whether the air pollution effects are ASD-specific or extend to individuals with developmental delays (DD). Studies examining exposures during the gestational period are also needed to better understand the role of air pollution in autism risk.
Objectives: To examine the relationship between prenatal and first year of life air pollution exposure and ASD or DD risk in the Early Markers for Autism (EMA) study.
Methods: This study includes 420 children with ASD, 169 with DD, and 428 general population (GP) controls from a population-based case-control study of pregnant women in San Diego, Orange, and Imperial counties created through the linkage of California birth records, Department of Developmental Services (DDS) records, and the California Prenatal and Newborn Screening Program records. All diagnoses were derived from DDS records and verified by expert medical record review. The maternal residence on the birth certificate and addresses reported during prenatal screening visits were used to estimate exposure for each trimester of pregnancy and first year of life. Regional air pollutant measures (NO_2, PM_{10}, $PM_{2.5}$, Ozone) were based on the Environmental Protection Agency's Air Quality System data and near roadway air pollution (NRAP) estimates from the CALINE-4 traffic dispersion model. Logistic regression models were used to determine the association between estimated air pollutant levels and ASD or DD risk, compared to GP controls. We further examined if this relationship differed among children with ASD and comorbid intellectual disability (ID) (n=184), as compared to GP controls. Models were adjusted for maternal education, method of prenatal payment, and county of birth.
Results: Comparison of the highest and lowest quartiles of the air pollution distribution showed non-statistically significant increased ASD risk for prenatal and first year of life exposure to $PM_{2.5}$, PM_{10}, and NO_2. Analyses with continuous measures of air pollutants during pregnancy or the first year of life showed no significant associations with ASD risk after adjusting for confounders, in particular county of residence at birth. Examination of the subset of children with ASD+ID indicated an increased risk per 2 standard deviation (2 SD) increase in ozone exposure in the first year of life [aOR=1.52 (1.04-2.23) per 6.7 ppb] relative to GP controls. Increasing PM_{10} exposure during the first trimester was significantly associated with DD risk [aOR=2.09 (1.10-4.04 per 16.8 ug/m^3 (per 2SD increase))], after adjusting for all confounders.
Conclusions: Air pollutant exposure may have broad neurodevelopmental effects, which manifest differently across ASD, DD, and ID phenotypes. In contrast to previous studies we did not observe a statistically significant association of air pollutants with ASD risk overall. Differences in case ascertainment, ASD severity, and pollutant exposure range may have affected our results and should be considered in further examinations of geographically-defined exposures for ASD.

2:52 **149.002** PBDE Exposures during Pregnancy and Risk of Autism Spectrum Disorders at 3 Years: Results from the Prospective MARBLES Study

I. Hertz-Picciotto[1], *C. Philippat*[2], *D. J. Tancredi*[3], *D. Bennett*[4], *Y. Lin*[5] *and B. Puschner*[5], *(1)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Pediatrics, UC Davis School of Medicine, Sacramento, CA, (4)Public Health Sciences, University of California, Davis, Davis, CA, (5)University of California, Davis, Davis, CA*

Background: Polybrominated diphenyl ethers (PBDE) are flame retardants that were used in consumer products such as electronic devices, construction materials, foam furniture, car seats, and home textiles to reduce their flammability. Both federal and state bans on PBDE mixtures (penta and octa-BDE formulations) were enacted in the early to mid 2000s in response to both evidence that levels in humans were rising and results from toxicologic studies showing adverse neurodevelopmental outcomes in experimental animals. Nevertheless, exposure to PBDE is still widespread in the general population as a result of long half-lives of these compounds and bioaccumulation up the food chain. PBDE can interact with pathways involved in normal brain development, such as thyroid hormone homeostasis and cell signaling.
Objectives: To study the associations between exposure to four prevalent PBDEs during pregnancy and the risk of having a child with Autism Spectrum Disorders (ASD) or other developmental concerns (ODC), which include speech and language delay, hyperactivity, and broader autism phenotype.
Methods: Mothers participating in the ongoing MARBLES (*Markers of Autism Risk in Babies – Learning Early Signs*) Study have previously delivered a child who received an ASD diagnosis, and are either pregnant or planning a pregnancy. Interviews, self-administered questionnaires, and blood specimens are collected at multiple time points from enrollment through the child's 3rd birthday. The child is assessed on various instruments by expert clinicians during study visits at the participant's home (6 and 12 months) and the UC Davis MIND Institute (24 and 36 months). At 36 months these include the Mullen Scales of Early Learning, Vineland Adaptive Behavior Scales, SRS, ADOS, and ADI-R, which are used to assign final diagnoses: ASD (n = 26), ODC (n = 29) or typically developed (TD, n = 77), based on a consensus clinical best estimate from two independent clinicians and, for ASD only, results of the ADOS and ADI-R. We measured four PBDEs using gas chromatography/ mass spectrometry/mass spectrometry, along with lipids in repeated blood samples collected during pregnancy (1 to 3 samples per woman). Adjusted ORs from multiple logistic regression models are reported for a 2 fold increase in PBDE concentrations (ng/g lipids), along with 90% confidence intervals.
Results: PBDEs were detected in 82% to 99% of maternal pregnancy plasma samples. After adjustment for maternal age, body mass index, maternal education and year of birth, PBDE153 trended to be associated with increased risk of ASD (OR = 1.35, 90%CI: 1.00; 1.81). This association was strengthened when we restricted analysis to boys (OR = 1.53, 90%CI: 1.07; 2.18). The number of girls with ASD was too few for separate analysis (n=3). No other PBDE was associated with the risk of ASD (p-values > 0.26) or ODC (p-values > 0.35), compared to TD.
Conclusions: These results from the MARBLES Study indicate PBDE153 is associated with increased risk of ASD, especially among boys. This is, to our knowledge, the first report of an association between clinically confirmed ASD diagnoses, and PBDEs measured prospectively during critical periods during gestation.

3:04 **149.003** Neonatal Thyroid Hormone Levels in Association with Autism Spectrum Disorder

K. Lyall[1], *M. Anderson*[2], *M. Kharrazi*[3] *and G. C. Windham*[3], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Impact Assessment, Inc., La Jolla, CA, (3)California Department of Public Health, Richmond, CA*

Background:
Thyroid hormones (TH) are critical in early neurodevelopment, but whether neonatal TH levels influence risk of autism spectrum disorder (ASD) is not well-researched.
Objectives:
The goal of this study was to examine whether neonatal levels of thyroxine (T4) and thyroid-stimulating hormone (TSH) are related to risk of ASD, using existing data from California state-wide programs.
Methods:
Program data from California neonatal screening in 1996 and 2002 were linked with live birth certificates and Department of Developmental Services records in order to examine TH levels in association with ASD (defined as ever receiving services for ASD by 2014). T4 and TSH levels were measured in newborn bloodspots as part of routine screening. Mean levels of T4 (measured in 1996) and raw and log-transformed TSH (measured in 2002) were compared between ASD cases and the general population of births from the same years. Binomial regression, using categories of T4 and TSH percentiles separately by year, was used to obtain crude and adjusted risk ratios (RR), adjusting for maternal age, race, education, parity, and child gestational age and gender as well as hours until specimen draw. In addition, a number of stratified analyses were conducted to examine potential effect modification.
Results:
447,059 singleton births from 1996 and 446,424 from 2002 were used in these analyses, including 4,818 ASD cases. ASD cases had significantly lower mean levels of T4 than those of comparison births. Individuals in the lowest 5th percentile of T4 levels (<9.3ug/dl) had modestly increased risk of ASD, an association that was no longer significant in primary adjusted analyses (RR 1.13, 95% 0.93-1.37). This association appeared stronger in certain subgroup analyses, including those with advanced maternal age (≥35 years; RR 1.43, 95% CI 0.96, 2.12), those with Cesarean deliveries (RR= 1.35, 95% CI 0.94, 1.94), and in particular, those with blood drawn ≥24 hours after birth (RR=1.46, 95% CI 1.11, 1.91), after which TH levels become more stable. No significant associations were found with TSH levels and ASD in primary crude or adjusted analyses, though a significant reduction in risk was seen for those in the highest percentile (≥95thpercentile, corresponding to ≥1.05 log-transformed concentration) of TSH for those with Cesarean deliveries (RR=0.56, 95% CI 0.32, 0.96). No other subgroups demonstrated significant associations with TSH levels and ASD.
Conclusions:
Results from this large, population-based study did not suggest strong associations between neonatal TH and ASD, but individuals with the lowest T4 levels may have modest increases in risk of ASD.

3:16 **149.004** Maternal Plasma Folate, Vitamin B12 Levels and Multivitamin Supplement during Pregnancy and Risk of Autism Spectrum Disorders in the Boston Birth Cohort

R. Raghavan[1], *A. Riley*[2], *D. M. Caruso*[3], *X. Hong*[4], *G. Wang*[2], *B. Ajao*[5], *J. Zhang*[6], *Y. Ji*[2], *M. Li*[7], *H. He*[2], *Z. Chen*[2], *M. C. Wang*[2], *C. Pearson*[8], *L. K. Hironaka*[8], *L. Sices*[8], *M. D. Fallin*[9] *and X. Wang*[10], *(1)Center on Early Life Origins of Disease, Population, Family and Reproductive Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Center on the Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD, (4)Johns Hopkins University School of Public Health, Baltimore, MD, (5)Population, Family and Reproductive Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)Johns Hopkins School of Public Health, Baltimore, MD, (8)The Boston University Medical Center, Boston, MA, (9)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (10)Center on Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD*

Background: The role of preconception/prenatal nutrition in the development of Autism Spectrum Disorder (ASD) is under-studied. Folate deficiency is a well-recognized risk factor for neural tubal defects. For this reason, universal cereal grain fortification of folic acid, synthetic form of folate, has been implemented in the U.S. since 1998 and

pregnant women are advised to take multivitamin supplements. While some studies have suggested that mothers' periconceptional multivitamin use, dietary folic acid intake and/or folic acid supplementation are associated with a decreased risk of ASD in their children, others have suggested the opposite effect. Most previous studies were based on maternal self-report of vitamin intake. Only a few have simultaneously examined the relationships using self-report and biomarker data and inconsistencies have been reported. Uncertainty remains whether excess folate and other B-vitamin exposure during critical gestational periods can adversely affect neurodevelopment.
Objectives: To understand the relationship between maternal multivitamin supplementation during pregnancy and maternal plasma biomarkers of folate and vitamin B12 measured 24-72 hours after delivery and risk of later ASD in children.
Methods: Data are from the Boston Birth Cohort, an ongoing longitudinal prospective birth cohort study that recruited low-income urban, primarily minority mother-offspring pairs (n=1,391) at the Boston Medical Center and followed them from birth through childhood between 1998-2013. Using electronic medical records, children ever diagnosed with autism, Asperger syndrome and/or pervasive developmental disorder not otherwise specified were categorized as having ASD (n=107); those without ASD, ADHD, intellectual and developmental disabilities constituted 'typical' group (n=1284). Cox proportional hazard regression was used to account for differential follow-up time and pertinent covariates were adjusted.
Results: Maternal multivitamin supplement of 3-5 times/week was associated with significantly lower risk of ASD in offspring across all trimesters (adjusted hazard ratio (HR): 0.33, 0.38 and 0.43 for 1st, 2nd and 3rd trimesters respectively) (Table 1). However, when maternal plasma folate and vitamin B12 levels were analyzed as exposure variables, high levels of maternal vitamin B12 (>600 pmol/L) were associated with significantly increased risk of ASD (HR: 3.01; 95% CI: 1.64 – 5.52; p value: 0.001). High maternal folate levels (>59 nmol/L) were also associated with increased risk of ASD (HR: 2.27; 95% CI: 1.26 – 4.09; p value: 0.007). The risk was greatest for those children whose mothers had both high plasma folate (>59 nmol/L) and vitamin B12 (>600 pmol/L) (HR: 17.59; p value: <0.001) (Table 2).
Conclusions: In this urban low-income minority birth cohort, we observed an elevated risk of ASD associated with high maternal plasma folate levels (>59 nmol/L), which far exceeds the excess cutoff suggested by the WHO (>45.3 nmol/L). Excess maternal vitamin B12 (>600 pmol/L) was also shown to be associated with greater ASD risk in offspring. The risk of ASD was highest if mothers had both excess in folate and B12 levels. Our findings warrant additional investigation and highlight the need to identify optimum prenatal folate and vitamin B12 levels that maximize health benefits, at the same time minimize the risk of excess and its associated adverse consequences such as ASD.

Oral Session - 7A
150 - White Matter Development in ASD
1:45 PM - 2:35 PM - Room 307

1:45 **150.001** White Matter Development in Infancy Predicts Repetitive Behavior and Sensory Features

J. J. Wolff[1], *M. R. Swanson*[2], *J. T. Elison*[1], *H. C. Hazlett*[3], *J. R. Pruett*[4], *R. T. Schultz*[5], *M. D. Shen*[2], *C. Vachet*[6], *L. Zwaigenbaum*[7], *J. Piven*[2] *and .. The IBIS Network*[2], *(1)University of Minnesota, Minneapolis, MN, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Washington University School of Medicine, Saint Louis, MO, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of Utah, Salt Lake City, UT, (7)University of Alberta, Edmonton, AB, Canada*

Background: Restricted and repetitive behaviors are early emerging (Wolff et al., 2014) and possibly prognostic features (Lord et al., 2006) of autism spectrum disorder (ASD). Recent changes to diagnostic criteria include for the first time unusual responses to sensory stimuli as part of the restricted and repetitive behavior domain despite a lean body of literature supporting this conceptual grouping. To date, little is known about the neurobiology underlying the development of these features of ASD early in life, with the vast majority of published work focused on older children, adults, or adult non-human animal models (see Langen et al, 2011, for a review).
Objectives: To investigate the development of specific white matter pathways in relation to emerging repetitive behaviors and sensory features in infants who developed ASD.
Methods: Diffusion tensor imaging data were collected longitudinally from high-risk infant siblings at ages 6, 12, and 24 months during natural sleep as part of an ongoing study. The present sample includes 44 infant siblings meeting clinical best-estimate criteria for ASD at age 2 years. Cognitive and behavioral data, including the Repetitive Behavior Scales, Revised (Bodfish et al., 2001) and the Sensory Experiences Questionnaire, v2.1 (Baranek et al., 2009) were collected at age 2. Five white matter fiber pathways of interest (see **Figure 1**) were selected on the basis of previous empirical or conceptual work (e.g. Kern 2002; Langen et al 2014; Pierce et al. 2001; Wolff et al. 2015). Pathways were deterministically segmented in common atlas space (see Verde et al. 2014) and microstructure characterized by fractional anisotropy (FA), a measure reflecting magnitude of diffusion based on tensor shape. The relationships between FA development and repetitive behavior/sensory features were examined using generalized estimating equations controlling for sex and age.
Results: Repetitive behaviors and sensory features were strongly correlated ($r = .74$, $p < .001$) and this relationship held when controlling for social symptom severity and IQ. Development of the genu from 6 to 24 months of age significantly predicted repetitive behaviors and sensory features. The mid- and superior- cerebellar peduncles also significantly predicted both repetitive behavior and sensory features. Development of striatal pathways (ATR, CST) was not significantly associated with these behaviors (see full results in **Table 1**). To determine the specificity of our findings, we next examined whether development of targeted pathways predicted social symptom severity as indexed by the ADOS. This analysis yielded no significant results ($p \geq 0.20$).
Conclusions: Our findings suggest that 1) restricted and repetitive behaviors and sensory features co-occur in toddlers with ASD; and 2) share a common relationship with underlying neural circuitry. We specifically identified that these core features of autism are predicted by the structural development of callosal and cerebellar white matter pathways over the first two years of life, suggesting a possible shared mechanism unique to infancy. These brain-behavior relationships were strikingly specific given the absence of any association between targeted pathways and social symptom severity.

1:57 **150.002** Structural Abnormalities in Corpus Callosum Fibers during Early Autism Development

N. Fingher[1], *I. Dinstein*[2], *M. Ben-Shachar*[3], *S. Haar*[1], *A. M. Dale*[4], *L. T. Eyler*[5], *K. Pierce*[6] *and E. Courchesne*[6], *(1)Cognitive and Brain Sciences, Ben Gurion University, Beer Sheva, Israel, (2)Psychology, Ben Gurion University, Beer Sheva, Israel, (3)Linguistics, Bar Ilan University, Ramat Gan, Israel, (4)Radiology, University of California San Diego, La Jolla, CA, (5)Psychiatry, University of California San Diego, San Diego, CA, (6)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA*

Background: It has been hypothesized that abnormalities in the development of the corpus callosum (CC) may be a common characteristic of many individuals with autism. This hypothesis, however, has rarely been tested during early stages of autism development, in infants and toddlers. Furthermore, previous diffusion tensor imaging (DTI) studies have subdivided the CC roughly into two or three segments without determining the cortical projections of the fibers in each segment. A more detailed examination of

CC development, which takes into account the projection of CC fibers into specific cortical areas, is critical for determining which inter-hemispheric connections develop abnormally in autism and for revealing the nature and timing of abnormalities in each fiber group.
Objectives: To determine the nature and developmental timing of potential abnormalities in specific inter-hemispheric CC tracts of 1-4 year old toddlers with autism.
Methods: We examined DTI scans from 68 toddlers with autism and 29 toddlers with typical development. All toddlers were 1-4 years old during the MRI scan and underwent thorough behavioral assessments including ADOS, ADI, Mullen, and Vineland tests. The DTI protocol was a single-shot, echo-planar diffusion-weighted sequence that was applied along 51 diffusion directions in fifty 2.5mm thick axial slices (±10, depending on head size) with in-plane resolution of 1.875 x 1.875 mm and b-value of 1000 sec/mm^2. Toddlers who were under the age of 2.5 years old returned for a second visit to establish a final diagnosis and assess potential changes in symptom severity. DTI analyses were performed using the Automated Fiber Quantification toolbox, which utilizes a deterministic tractography algorithm to identify seven CC fiber tracts according to their cortical projections in the native space of each subject. The different diffusion properties were then compared across groups in each of the tracts.
Results: Younger (<2.5 years old), but not older (> 2.5 years old) toddlers with autism exhibited abnormally high fractional anisotropy and low mean, radial, and axial diffusivity values in the CC tracts connecting occipital, temporal, mid-frontal, and anterior-frontal areas (t-test, $p<0.05$ in all cases, FDR corrected). Furthermore, *early* diffusion measures in the temporal CC tract of the young toddlers were correlated with outcome measures of autism severity at *later* ages.
Conclusions: We suggest that abnormally low diffusivity values, which indicate that water diffusion is more restricted in the CC of young toddlers with autism, may be due to an overabundance of small caliber axons as predicted by the early overgrowth and excess neuron theories of autism. These findings reveal critical details regarding the nature, timing, and location of CC abnormalities in early autism development and add to accumulating evidence which suggests that poor inter-hemispheric connectivity in the first years of life is a hallmark of the disorder.

2:09 **150.003** Longitudinal Development of White Matter in Autism Spectrum Disorder

D. C. Dean[1], *B. G. Travers*[2], *N. Adluru*[1], *D. Tromp*[1], *D. Destiche*[1], *A. Freeman*[1], *B. A. Zielinski*[3], *M. D. Prigge*[4], *J. S. Anderson*[5], *E. D. Bigler*[6], *N. Lange*[7], *A. L. Alexander*[1] *and J. E. Lainhart*[1], *(1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI, (3)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (4)Pediatrics, University of Utah, Salt Lake City, UT, (5)University of Utah, Salt Lake City, UT, (6)Psychology/Neuroscience Center, Brigham Young University, Provo, UT, (7)McLean Hospital, Cambridge, MA*

Background: Increasing evidence has suggested autism spectrum disorder (ASD) to be a disorder of impaired brain connectivity, and in particular, microstructural alterations of underlying white matter (see Travers et al. 2012 for review). In particular, diffusion tensor imaging (DTI) has been influential to the study of white matter alterations in ASD, while recent evidence has implicated aberrant development of specific white matter regions in association with ASD. These region of interest studies impart great insight into the neurobiological changes of white matter in ASD, however, it is unclear the magnitude and extent of such alterations across the whole brain. To assess this, we can examine and longitudinally model developmental change at the voxel-level. Understanding these specific white matter network “signatures” at the group and individual levels may help us better determine meaningful subgroups within the autism spectrum.
Objectives: We examined and characterized the developmental changes of DTI parameters across the brain in a large, longitudinal sample of ASD and and typically developing (TD) individuals. We specifically compared the developmental trajectories of FA, MD, RD, and AD between TD and ASD individuals.
Methods: *MRI Acquisition*: Participants for this study consisted of 100 males with ASD and 57 age-matched males with typical development (TD) between 3 and 39 years of age. A total of 434 (287 ASD, 147 TD) longitudinal DTI datasets were acquired. Images were corrected for distortion and head motion and maps of fractional anisotropy (FA), mean diffusivity (MD), and radial diffusivity (RD) were calculated. Images were subsequently aligned to a population-specific template using DTI-TK. *Analysis:* Developmental changes of diffusion parameters (i.e. FA, MD, RD) of the brain were modeled using a semi-parametric approach with penalized smoothing splines. This modeling was performed at the voxel-scale, creating statistical maps of developmental changes across the brain. Results were subsequently corrected for multiple comparisons using the false discovery rate.
Results: Across white matter, the group with ASD had significantly different developmental trajectories ($p<0.05$, FDR corrected) than the group with typical development (Fig 1). In particular, trajectory differences of FA were observed in genu of the corpus callosum, bilateral posterior limb of the internal capsule, cortical spinal tract, superior longitudinal fasciculus and inferior fronto-occipital fasciculus (Fig. 1A). While overlapping MD trajectory differences were found in the internal capsules, widespread and distinct MD trajectory differences were also observed (Fig 1B).
Conclusions: Longitudinal studies have traditionally focused on examining developmental differences within predefined brain regions. However, this has the potential of masking subtle changes within a particular brain region. By utilizing a voxel-wise mixed-effect modeling approach, our findings reveal the developmental trajectory of white matter to differ between ASD and TD across much of the brain. While these findings agree with the literature of white matter microstructure alterations in ASD, they also raise questions about the behavioral processes involved with these alterations as well as the specific neurobiological mechanisms underlying these changes.

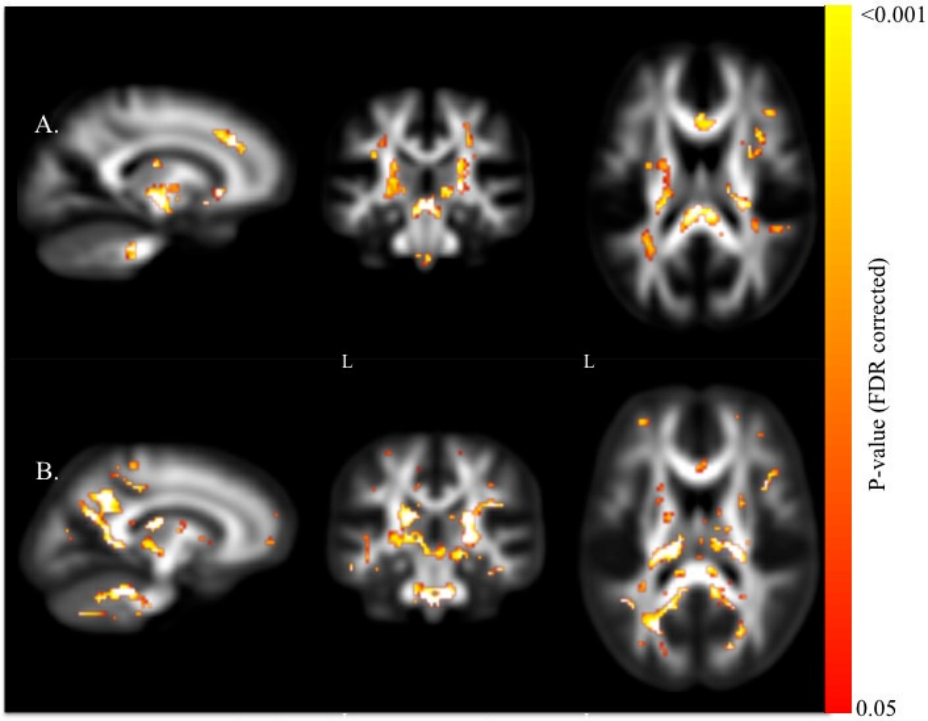

Figure: Representative views of significant ($p<0.05$, FDR corrected) age x group interactions, demonstrating altered areas of altered developmental trajectory between ASD and TD individuals. **A**. Trajectory differences of FA were observed across the internal capsules, genu and splenium of the corpus callosum. **B**. Trajectory differences of MD were also observed to be different in the internal capsules between ASD and TD groups, while also having widespread differences in the thalamic radiations, cerebellum, and optic radiations.

2:21 **150.004** White Matter Microstructure in Youth with a History of Autism Spectrum Disorder Who Have Achieved an Optimal Outcome

B. Castelluccio[1], *M. Stevens*[2,3], *I. M. Eigsti*[1], *R. T. Schultz*[4], *L. Naigles*[1], *E. A. Kelley*[5] *and D. A. Fein*[6], *(1)University of Connecticut, Storrs, CT, (2)Olin Neuropsychiatry Research Center, Hartford, CT, (3)Psychiatry, Yale University School of Medicine, New Haven, CT, (4)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Queen's University, Kingston, ON, Canada, (6)Psychology, University of Connecticut, Storrs, CT*

Background: A minority of persons with an autism spectrum disorder (ASD) lose the symptoms, a phenomenon referred to as an "optimal outcome" (OO). Ongoing research is revealing clinical differences between OO and ASD youth, but the neural basis of the phenomenon is currently unknown. One functional MRI investigation of language comprehension in a sample that overlaps with the current study found evidence of compensatory functional activation and residual ASD-like activation patterns, but no evidence of normalization toward the activation patterns of typically developing (TD) comparison participants. This suggests an equifinality model, in which multiple neurodevelopmental pathways yield similar behavioral outcomes. There has not yet been an attempt to uncover neurostructural differences that facilitate or characterize OO. Given the prominence of white matter atypicalities in ASD and the emergence of a disconnection model of ASD (e.g. Belmonte et al., 2004, *J. Neuroscience*), the current study investigated white matter microstructure in OO.

Objectives: This study evaluated white matter tract microstructure in OO youth to determine whether it differed from those with ASD and TD.

Methods: Three age- and IQ-matched groups comprised 14 typically developing, 22 high functioning ASD (HFA), and 11 youths with a well-established early childhood history of an ASD who no longer met diagnostic criteria (OO). Participants underwent magnetic resonance diffusion tensor imaging (DTI). Data were subjected to strict screening for head motion, leading to exclusion if more than 10% of motion estimates for any image was greater than one voxel length. One OO and two HFA participants were excluded on this basis. A tract-based spatial statistics analysis was implemented using Functional MRI of the Brain Software Library (FSL) tools. Whole-brain three-group ANOVAs were conducted to compare fractional anisotropy (FA), radial diffusivity (RD), and axial diffusivity (AD). Post-hoc pairwise comparisons were evaluated on tracts with positive findings.

Results: FA differences did not survive correction for multiple comparisons. Uncorrected findings showed differences in multiple cortical association tracts. The TD group had the highest FA, followed by the HFA group. The OO group had the lowest FA of the three groups in multiple tracts. These FA differences were driven by RD differences, which appropriately showed the opposite pattern. The OO group had the greatest RD, followed by HFA and TD. There were no group differences in AD.

Conclusions: The presence of white matter microstructural differences in OO raises the possibility that these characteristics contribute to achievement of OO. Lower FA and greater RD in OO youth may represent plasticity mechanisms that facilitated movement off the spectrum. Provided they can be replicated, these findings can guide future research seeking to understand the relationship of white matter structure to OO. The findings converge with prior functional MRI work to support a model in which movement off the spectrum involves compensation rather than normalization.

Table 1. Group differences in white matter microstructure.

Tracts with Group Differences in FA by ANOVA	Post-hoc Comparisons
R hippocampal cingulum	TD, HFA > OO
L inferior longitudinal fasciculus	TD > HFA > OO
R inferior longitudinal fasciculus	TD, HFA > OO
L superior longitudinal fasciculus	TD, HFA > OO
R superior longitudinal fasciculus	TD > HFA > OO
L cingulum	TD > HFA > OO
R cingulum	TD, HFA > OO
L forceps major	TD > HFA > OO

Tracts with Group Differences in RD by ANOVA	Post-hoc Comparisons
L corticospinal tract	OO > HFA, TD
R corticospinal tract	OO > HFA, TD
L anterior thalamic radiations	OO > HFA, TD
R anterior thalamic radiations	OO > HFA, TD
L inferior longitudinal fasciculus	OO > HFA > TD
R inferior longitudinal fasciculus	OO > HFA, TD
L inferior fronto-occipital fasciculus	OO > HFA > TD
R inferior fronto-occipital fasciculus	OO > HFA, TD
L superior longitudinal fasciculus	OO > HFA, TD
R superior longitudinal fasciculus	OO > HFA, TD
R uncinate fasciculus	OO > HFA, TD
R forceps minor	OO > HFA, TD
Corpus callosum body	OO > HFA, TD

Note: Results did not survive correction for multiple comparisons. Results shown are $p<.05$ (uncorrected). FA= fractional anisotropy; RD= radial diffusivity; L=left; R=right. TD= typically developing; HFA = high functioning autism; OO= optimal outcome.

151 - Brain Connectivity and neural networks in ASD

2:40 PM - 3:30 PM - Room 307

2:40 **151.001** Dysfunctional Brain Communities in Autism

A. Venkataraman[1], *D. Yang*[2], *K. Pelphrey*[2] *and J. S. Duncan*[1,3], *(1)Diagnostic Radiology, Yale University, New Haven, CT, (2)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (3)Biomedical & Electrical Engineering, Yale University, New Haven, CT*

Background: Univariate analyses of fMRI activation patterns have allowed us to localize group-wise functional differences. However, there is increasing evidence that autism reflects distributed impairments across multiple brain systems. These findings underscore the importance of network-based methodologies for fMRI data. In accordance, community detection is the process of identifying highly interconnected subgraphs within a larger network. These regions often share common properties and are crucial to understanding complex neurodevelopmental processes, such as those induced by autism.

Objectives: We develop a novel probabilistic framework to extract both hyper- and hypo-synchronous functional communities from task fMRI data. Our approach differs from prior literature in three ways. First, we propose a unified Bayesian model that describes the relationship between population templates and individual subject observations. Second, we perform community detection in the space of group-level functional *differences*, which allows us to identify both heighted and reduced synchrony. Finally, we use a clustering framework to simultaneously detect multiple abnormal communities of varying type.

Methods: Our model assumes that the altered whole-brain functional synchrony associated with autism can be explained by K non-overlapping communities. Each community is associated with a binary label that indicates either a hyper- or hypo-synchronous subgraph. We use multinomial variables to represent the latent functional synchrony within each population. Empirically, we find that three states (low, medium and high) best capture the dynamic range and variability in our fMRI dataset. The fMRI metrics are modeled as noisy Gaussian observations of the underlying latent structure. We apply our model to an fMRI study of social perception in autism. The dataset consists of 72 high-functioning autistic children and 43 age-matched ($p > 0.124$) and IQ-matched ($p > 0.122$) neurotypical controls. The experimental paradigm features coherent and scrambled point-light animations. The coherent biological motion depicts a point-light figure performing movements relevant to early childhood experiences, and the scrambled animations combine random trajectories from the coherent displays.

Results: Our model identifies a hyper-synchronous community that concentrates in the left superior temporal sulcus, the visual cortex and the somatosensory cortex. Concurrently, we detect a hypo-synchronous community that localizes to the bilateral ventral prefrontal cortex, insula, posterior cingulate, caudate and amygdala. The corresponding network diagram reveals increased synchrony between temporal and occipital nodes and reduced synchrony between the frontal and parietal nodes. Consistent with neurocognitive findings, these results suggest hyper-functionality in a visual perception network; individuals with autism tend to outperform their neurotypical peers in such tasks. In contrast, the hypo-synchronous circuits include regions that are well known for their role in social cognition and the high-level interpretation of social stimuli. A comparison with the Neurosynth meta-analytic database (www.neurosynth.org) also exposes a clear functional distinction between the two communities.

Conclusions: Our novel Bayesian framework for fMRI community detection in autism retrieves key networks associated with autism. Unlike prior methods, we explicitly model multivariate *differences* in the global functional organization of the brain. Subsequent decoding via Neurosynth confirms the clinical validity of our results within the neuroimaging literature.

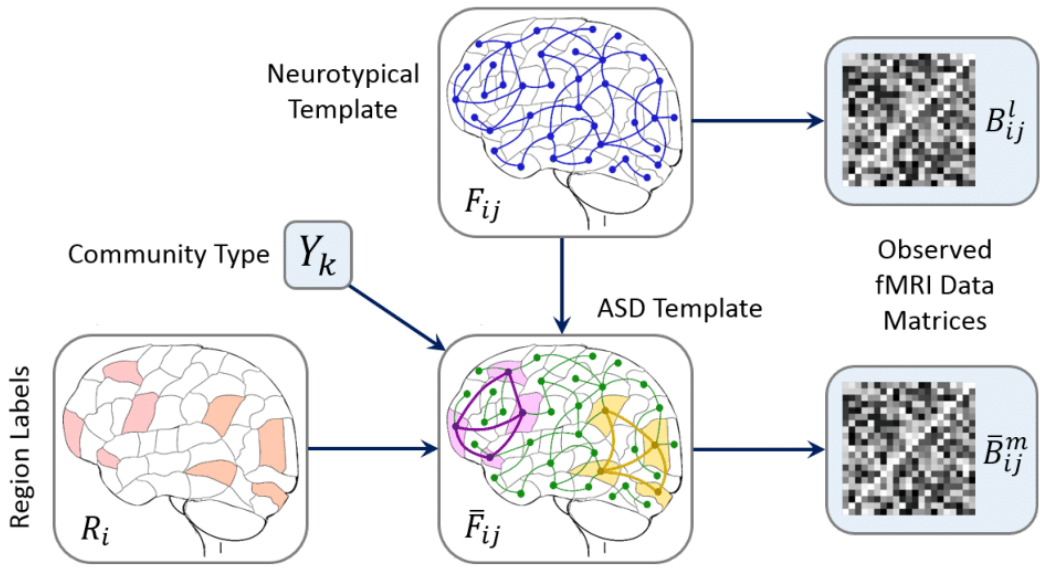

Figure 1: Hierarchical model of community structure for $K = 2$. The label R_i indicates whether region i is healthy (white) or whether it belongs to one of the two abnormal communities (red). The binary variable Y_k denotes either a hyper-synchronous or hypo-synchronous subgraph k. The neurotypical template $\{F_{ij}\}$ provides a baseline functional architecture for the brain, whereas the clinical template $\{\bar{F}_{ij}\}$ describes the latent organization of ASD. The green connections $\langle i, j \rangle$ are unchanged from baseline; the purple and yellow lines signify heightened and reduced synchrony, respectively. Each template generates a set of subject observations $\{B^l_{ij}\}$ and $\{\bar{B}^m_{ij}\}$ for the group.

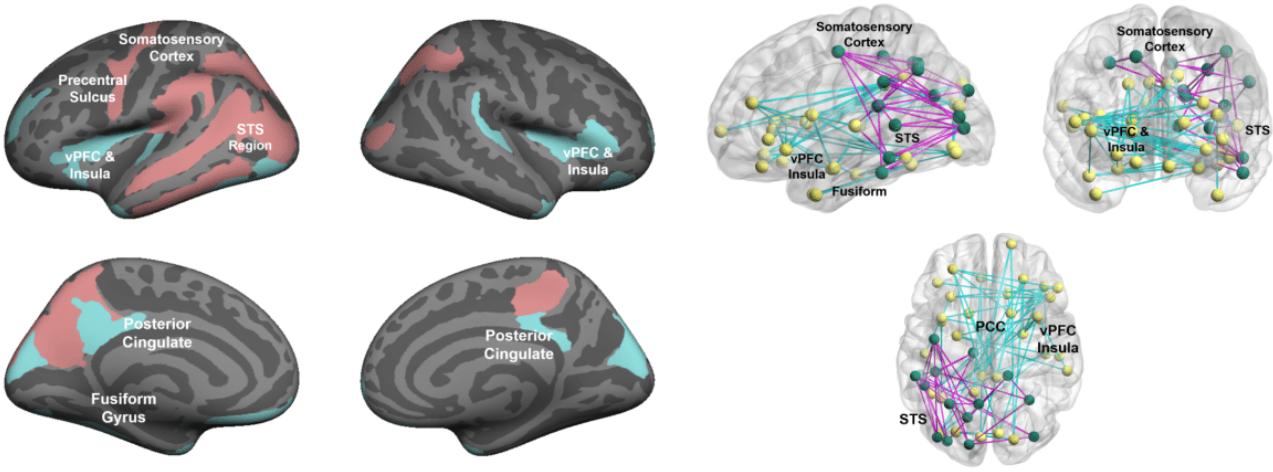

Figure 2: Abnormal functional communities inferred by our Bayesian model for $K = 2$. **Left:** Region membership in each community. Red indicates hyper-synchrony, and blue areas delineate hypo-synchronous activity. **Right:** Estimated network of abnormal functional synchrony. Nodes correspond to regions within each community. Blue lines signify reduced functional synchrony in ASD across the paradigm; magenta lines denote increased functional synchrony in ASD.

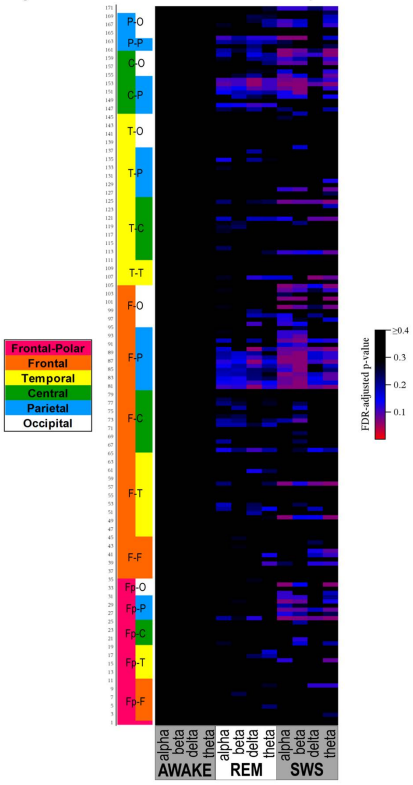
2:52 **151.002** Differences in EEG Coherence Between ASD and Typical Development Are State-Dependent

A. W. Buckley[1], *C. Farmer*[1], *R. Scott*[2], *A. Tyler*[2], *J. M. Mahoney*[2], *S. Burroughs*[2], *G. Holmes*[2], *S. E. Swedo*[1] *and A. Thurm*[1], *(1)Pediatrics and Developmental Neuroscience Branch, National Institute of Mental Health, Bethesda, MD, (2)University of Vermont College of Medicine, Burlington, VT*

Background: The role of sleep in the proper maturation of the developing brain is an area of current intense interest, with the contribution of state-specific processes to synaptic refinement just beginning to be understood. There is increasing evidence of altered brain connectivity in autism, however, the vast majority of ASD coherence studies are not performed during sleep, and taken as a whole, show very mixed results.
Objectives: The aim of the present study was to compare connectivity in children aged 2 to 6 years with ASD (n=87) to that of typically developing controls (TYP; n=29).
Methods: Digital EEGs were recorded during the fully awake, drowsy, and sleep states using the 10–20 System of Electrode placement (Figure 2). Ten minute segments of awake, slow wave sleep, and rapid eye movement sleep were selected for analysis. Analysis was performed masked to participant diagnosis using Neuroguide software. Coherence values were subjected to Fisher-transformation for statistical analysis. Differences in mean coherence and phase lag between groups were assessed using the general linear model, controlling for age.
Results: Significantly increased coherence was observed in ASD relative to TYP, concentrated in the frontal-parietal pairs (Figure 1). Significantly decreased phase lag, particularly in long-distance pairs, was also observed in ASD relative to TYP (Figure 2). Strikingly, these differences were found exclusively during sleep, most commonly during slow wave sleep. No differences in coherence or phase lag were observed during the awake state.

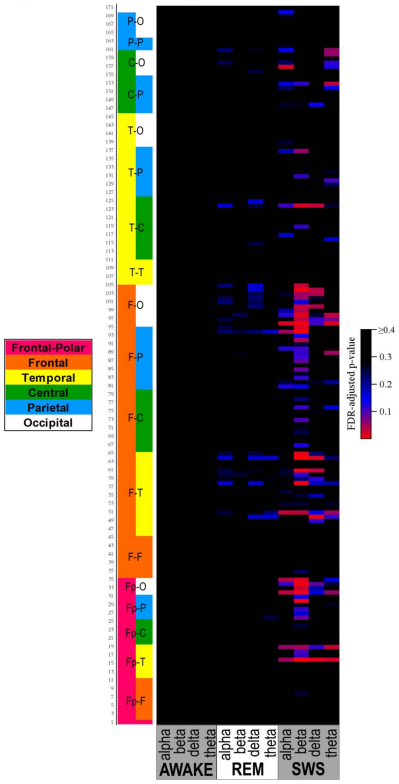
Conclusions: Evaluation of brain connectivity during sleep is extremely important, as the sleep EEG reflects the maturation of the brain and allows for examination of dynamic neural networks in the absence of external stimuli. Future attempts to classify developmental disorders by using differences in connectivity must take into account brain state.

Figure 1. Increased EEG coherence in ASD compared to TYP is concentrated in SWS



Note: Row axis refers to the lead pair; abbreviations are explained in the left legend. Pairs are numbered but specific pair names are omitted due to space constraints. All differences reflect increased coherence in ASD. REM=rapid eye movement, SWS=slow wave sleep.

Figure 2. Decreased phase lag in ASD compared to TYP is concentrated in SWS



Note: Row axis refers to the lead pair; abbreviations are explained in the left legend. Pairs are numbered but specific pair names are omitted due to space constraints. All differences reflect decreased phase lag in ASD. REM=rapid eye movement, SWS=slow wave sleep.

3:04 **151.003** Functional Connectivity Scanning in Minimally-Verbal Children with ASD

M. South[1], *T. P. Gabrielsen*[1], *B. Hansen*[2], *R. Kellems*[2], *E. Anderberg*[1], *K. G. Stephenson*[1], *L. Peacock*[1], *A. Ward*[1], *C. J. Kipp*[1], *M. D. Prigge*[3], *R. A. Lundwall*[1], *B. A. Zielinski*[4], *P. T. Fletcher*[5] *and J. S. Anderson*[5], *(1)Brigham Young University, Provo, UT, (2)Department of Counseling Psychology and Special Education, Brigham Young University, Provo, UT, (3)Pediatrics, University of Utah, Salt Lake City, UT, (4)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (5)University of Utah, Salt Lake City, UT*

Background: Functional connectivity analysis is a powerful tool for examining neural phenotypes in ASD. However, there are multiple challenges to successful scanning of less verbal individuals and there is very little published research regarding functional scanning in this population. Recent advances in fMRI protocols and data analysis techniques, combined with specially-developed behavioral protocols, have allowed us to obtain adequate functional connectivity data for about ¾ of children and adolescents we have scanned.
Objectives: To obtain valid functional connectivity data from minimally verbal children diagnosed with ASD.
Methods: After initial phone screening regarding suitability for scanning, we recruited 12 children ages 8-16 who qualified based on current functional language level for either Module 1 or 2 on the ADOS-2. There were three key elements to successful imaging and interpretation. 1) A rich behavioral management program that included a) iPad-based video modeling practiced at home and in the imaging facility; b) as much time as needed in a mock partial scanner using a 3D printed head coil; c) as much time as needed over several sessions in the actual MRI scan room; d) true noise-cancelling headphones to reduce background sensitivities; e) parent and research assistant in the scan room to provide reassurance at all times; f) a short (8 minute) movie created especially for maintaining interest and calm for vulnerable samples. 2) implementation of multiband sequences that allow for rapid collection of high resolution functional data, counteracting unwanted physiological artifacts and allowing for discarding of epochs contaminated by movement and other artifacts. This allowed us to scan for as long as possible (a maximum of 2 x 8 minute sessions) while keeping and interpolating data from shorter periods of successful data acquisition. 3) Analytic techniques including standard ICA methods and a novel Bayesian fcMRI analysis method for estimating individual functional networks using a hierarchical Markov random field tool.
Results: Preliminary results indicated successful data acquisition from more than 75% of participants. Data indicates markedly elevated internetwork synchrony relative to controls, similar to that seen in a previously-reported low-functioning Down Syndrome cohort. Increased short-range connectivity seems to be specifically abnormal for the low-functioning cohort versus previous higher-functioning autism samples and is negatively correlated with IQ. We hypothesize that ongoing analyses will show that connectivity between fusiform face area and language areas (Broca Area, Wernicke Area, lateral premotor cortex) with default mode network hubs will respectively predict social and language prognosis, respectively.
Conclusions: Methods for successful scanning of lower-functioning, minimally-verbal individuals have the potential to substantially increase our understanding of the whole spectrum of autism, including both structural and functional scanning and the capacity to identify cross-sectional and longitudinal functional connectivity MRI biomarkers for language function, restrictive and repetitive behaviors, and social impairment. We will continue to share ongoing improvements to behavioral protocols and imaging/analysis methods in pursuit of this important goal.

3:16 **151.004** Cerebellar Connectivity and Glutamatergic Metabolite Concentration in ASD As Assessed By fcMRI/MRS

J. P. Hegarty II[1], *D. Weber*[2] *and D. Q. Beversdorf*[3], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)University of Missouri, Columbia, MO, (3)University of Missouri, Columbia, Columbia, MO*

Background: Cerebellar pathology is observed in ASD. Atypical cortico-cerebellar functional connectivity has also recently been reported in ASD. Furthermore, several lines of evidence have suggested atypical excitatory-to-inhibitory (E/I) balance in ASD, with an imbalance between glutamate and GABA, observed in brain regions including the cerebellum.
Objectives: We examined the relationship between E/I balance using magnetic resonance spectroscopy (MRS) and functional integrity of cerebrocerebellar connections in ASD for language-associated cerebellar regions and their cortical projections.
Methods: Twelve adults with ASD and 12 gender, age, and IQ -matched controls participated. Social communication was assessed with the Social Responsiveness Scale (SRS), maladaptive behaviors with the Aberrant Behavior Checklist (ABC), and language competence with the Test of Language Competence (TLC). MRI was performed at 3T and BOLD sequences were collected at rest. Functional connectivity (FC) analyses were performed with conservative motion correction. Single voxel spectroscopy spin-echo sequences were used to detect glutamate, and J-coupling edited sequences were used to detect GABA. Voxels were localized in each participant in the right postereolateral cerebellar hemisphere junction of crus I&II (RCere) and the left dorsolateral prefrontal cortex (LDLPFC). Metabolite levels were quantified with LCModel.
Results: ASD participants were impaired on the SRS, ABC, and TLC. Within the ASD group, LDLPFC-RCere connectivity was associated with listening comprehension (r=0.588, p=0.027). Furthermore, RCere-LFLPFC FC was significantly associated with RCere E/I, regardless of diagnosis.
Conclusions: Significant variability exists in the literature regarding FC and MRS of glutamate and GABA in ASD. Our data suggests connectivity and pharmacopathology may be interrelated in ASD. Furthermore, this may relate to behavior, as FC to the portion of the cerebellum most involved with language was related to language comprehension performance. Future studies will need to explore whether these might serve as markers for or predictors of response to pharmacological agents targeting E/I balance in ASD.

Oral Session - 8A
152 - Early Detection and Access to Care
1:45 PM - 2:35 PM - Room 308

1:45 **152.001** Increasing Access to Autism Diagnostic Care: A Quality Improvement Model

***H. L. Johnson**, P. Manning-Courtney and B. Cunningham, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Timely access to autism spectrum disorder (ASD) diagnostic services is a well known problem. Demand for diagnostic services is expected to increase as reported prevalence rates continue to increase and awareness efforts continue.
Objectives: Demonstrate access to ASD diagnostic evaluations can be improved using Quality Improvement methodology and employment of access principles.
Methods: Cincinnati Children's Hospital Medical Center (CCHMC) is a member of the Autism Speaks-Autism Treatment Network. CCHMC participated in yearlong consultation from access consultants, Mark Murray and Associates, to improve access to ASD diagnostic services. After mapping the diagnostic process, and identifying constraints, access principles were employed to identify opportunities for interventions and systems change. CCHMC specifically employed strategies to increase clinician supply without adding additional clinical providers (FTE), and manage and reduce patients on waitlists. Access principles employed included supply demand management, backlog reduction and reducing system complexity. Specifically, CCHMC reduced visit lengths for some providers, implemented standardized clinic blocks and utilized incentives to temporarily increase clinician supply to address backlog reduction. CCHMC also developed a new, more efficient clinical model for the diagnosis of children under age 3 years at risk for ASD, which decreased redundancy in clinical assessments that were occurring at different times.
Results: Time to first ASD diagnostic visit was improved at CCHMC from 122 days to 52 days in patients referred under the age of 6 years and from 404 days to 78 days for patients referred over 6 years of age. These gains have been sustained through ongoing collection and analysis of demand and supply data. Time from first diagnostic appointment to final diagnosis was reduced from 119 days to 21 days using a same day diagnostic model for children under age 3 referred for risk of ASD.
Conclusions: Despite increasing demand for ASD diagnostic services, improvement in access to ASD diagnostic services can be obtained through implementation of Quality Improvement Methodology and access principles.

1:57 **152.002** Mobilizing Community Systems to Tackle Challenges of Early Detection of ASD in Underserved Populations

***R. R. Grinker**[1], A. Delehanty[2], A. M. Wetherby[3], A. Evans[4], J. Brown[5], J. L. Stapel-Wax[6], C. Ahmann[1], T. N. Day[7], S. Mazzatenta[8], R. Turchi[9], E. Kaiser[10], K. L. Traub[11], D. L. Robins[11], H. Flynn[12], A. Klin[13], C. J. Newschaffer[14] and C. Lord[15], (1)George Washington University, Washington, DC, (2)Communication Science & Disorders, Florida State University, Tallahassee, FL, (3)Florida State University Autism Institute, Tallahassee, FL, (4)National Black Church Initiative, Washington, DC, (5)College of Medicine, Florida State University, Tallahassee, FL, (6)Emory University School of Medicine, Atl, GA, (7)Psychology, Florida State University, Tallahassee, FL, (8)Autism Institute, College of Medicine, Florida State University, Tallahassee, FL, (9)Drexel University, Philadelphia, PA, (10)Infant Toddler Community Outreach, Marcus Autism Center, Atlanta, GA, (11)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (12)Florida State University, Tallahassee, FL, (13)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (14)A.J. Drexel Autism Institute, Philadelphia, PA, (15)Weill Cornell Medical College, White Plains, NY*

Background: There is a pressing need to improve the capacity of communities to detect ASD early to change developmental trajectories and improve outcomes. Although delays in social communication usually appear by 18-24 months, most children are not diagnosed until 4-5 years of age. Underserved families are identified even later and are underrepresented in intervention research. This new collaborative of 4 universities in partnership with the National Black Church Initiative (NBCI) has infused community-based participatory research and implementation science within a services research study to build consensus with stakeholders in the planning stages to lay the foundation for sustained utilization. The long-term project aim is to study effectiveness of mobilizing community systems using a web-based professional development platform with links to family resources and tools to increase family engagement and expedite receipt of screening, diagnosis, and early intervention services.
Objectives: To describe qualitative research findings from focus groups with families and providers designed 1) to identify challenges and barriers to early detection and access to early intervention (EI) for children under 24 months, and 2) to develop strategies to promote EI in underserved populations.
Methods: Focus groups with community stakeholders, including parents (n = 105) and professionals (n = 45), were conducted in Southwest Florida, Atlanta, Philadelphia, and NYC. Separate groups were held for primary care physicians, parents/grandparents from NBCI, and parents of children at-risk for developmental delay. Topics included: 1) barriers to early screening in primary care settings; 2) strategies to engage families and professionals and improve participation in the screening/referral process; and 3) information sharing about EI with families at the time of screening, diagnosis, and referral. Focus groups were audio-recorded and transcribed.
Driven by an iterative, grounded theory approach, researchers analyzed transcripts with an inductive, open-coding technique to identify emergent thematic dimensions, recurrent patterns and analytical categories. Focused coding of the remaining transcripts, using Dedoose software, identified major themes and frequency counts linked to core theoretical concepts. The use of multiple sites and the mapping of diverse stakeholder viewpoints within the same community (physicians, grandparents, and parents) onto themes allowed for increased dimensions of variation in this purposive sample, and for saturation of themes. Research team members completed five inter-rater reliability tests in Dedoose, resulting in very good agreement (average pooled Cohen's kappa=93.6). Further measures of inter-rater reliability included consensus coding, data review, and discussion and resolution of discrepancies.
Results: Sixteen major themes emerged from 1,709 excerpts, and illustrative quotes were drawn from diverse topics surrounding culture, early developmental milestones and red flags, family-physician trust, previous experience with individuals with autism/other disabilities, stigma, materials, resources, support, and practical and psychological/motivational barriers to accessing screening, assessment and intervention (Figure 1).
Conclusions: Topics for further exploration include the role of family power structures and processes impacting engagement in community screening, diagnosis and early intervention services; trusted materials and resources used in information gathering about ASD and developmental milestones; where families turn when traditional support systems fail; and family feelings, perspectives, and resistance to classifying a child who is continuously growing.

2:09 **52.003** Use of Smartphone Technology and Machine Learning to Improve Access to Care

Vaughan[1], (1)Cognoa, Inc., Palo Alto, CA, (2)Biomedical Engineering, University of Southern California, Los Angeles, CA

Background: The use of cell phones and other patient-centered technology is making an impact on the way people access and engage in their healthcare. Increased use of mobile platforms for healthcare delivery can also be effective in providing improved access for low income and minority populations who face greater healthcare disparities. This is particularly relevant to early screening of young children who may wait as long as 18 months to receive an early diagnosis despite the early warning signs of a developmental delay. Cognoa's evidence-based mobile tools leverage the use of big data and machine learning to give parents and providers an estimate of a child's risk of a developmental delay based on information that parents collect from the privacy of their homes. Providing clinicians with a child's results using a web-based user interface can help parents and providers flag concerning behaviors sooner and can help high-volume clinics with screening and triage.
Objectives: To determine whether Cognoa's mobile evidence-based risk assessment could be integrated into a high volume developmental clinic and evaluate parent and clinician satisfaction with the Cognoa interface and video-based platform.
Methods: In preparation for a multi-site clinical study, the Center surveyed over 400 families on their wait list to determine smartphone or tablet use. Of those that owned a smartphone/tablet, 356 were invited to complete the Cognoa flow prior to their clinic visit. Completion rates for Cognoa were compared to the standard clinic completion rate and qualitative ratings of parent and clinician satisfaction were obtained.
Results: Ninety-six percent (96%) of respondents surveyed owned a smartphone or tablet. Fifty-five percent (55%) had android phones, 35% iOS, and the remainder used a different kind of smartphone. The average completion rate was 50%, which was similar to the Center's average completion rate (p>.05). The majority of respondents (72%) were identified as having elevated risk of a developmental delay on the Cognoa questionnaire. Seventy-eight percent (78%) of those who received elevated risk on the questionnaire completed the video evaluation. Ninety-four percent (94%) of parents surveyed indicated that they were very happy with the experience and personalized results. Clinicians and staff found the clinician dashboard easy to use and a select number of high risk children were fast tracked by Center staff upon review of the video assessment. Sensitivity of the tool in this small pilot was .85.
Conclusions: Results demonstrate that the use of smartphone-based screening can be easily integrated in a clinic population. The use of mobile technology to engage parents is extremely promising and highlights the potential to develop high quality, rapid approaches to improve early detection and reach a more diverse population.

2:21 **152.004** The Effects of Autism Insurance Mandates on Treated Prevalence and Service Use

D. S. Mandell[1], *A. Epstein*[2], *M. Xie*[3], *S. 2. Marcus*[3], *K. Shea*[3], *K. T. Mullan*[3], *Z. Cidav*[4] *and C. Barry*[5], *(1)University of Pennsylvania School of Medicine, Philadelphia, PA, (2)Medicine, University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Center for Mental Health Policy and Services Research, University of Pennsylvania, Philadelphia, PA, (5)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: In the US, 42 states have passed autism insurance mandates that require commercial insurance plans to pay for autism-related services. These mandates have not been rigorously evaluated. The few studies of the mandates have not assessed their effects directly on the number of children diagnosed with autism or the services they received as a result of the mandates.
Objectives: To assess the effects of the autism insurance mandates on the treated prevalence of autism and use of and spending on behavioral therapies among children with autism.
Methods: We used data from the Health Care Cost Institute from 2008–2012. HCCI data includes health care claims from three large insurance companies in 50 states and the District of Columbia. A difference-in-differences design with state and year fixed effects was used to identify the independent effects of the mandates, separate from other state characteristics. Outcomes among four groups of children were compared: 1) children in states with an active mandate who had insurance subject to the mandate; 2) children in states with an active mandate whose insurance was not subject to the mandate; 3) children in states without a mandate whose insurance would have been subject to the mandate if one were active; and 4) children in states without a mandate whose insurance would not have been subject to the mandate if one were active. Additional analyses estimated the impact of mandates on treated prevalence in the first, second, and third or later years after implementation. Regression models also adjusted for patient age, sex, insurance plan type, and calendar month and standard errors were adjusted to account for clustering at the state level. A second set of analyses using a similar analytic approach will examine the effects of the mandates on service use among children diagnosed with autism.
Results: Analyses of the effects of the mandate on service use and spending are ongoing. Mandates were implemented in 29 states by the end of the study period. Mandate enactment increased the treated prevalence of autism overall by 12.2% (95% confidence interval [CI]: 6.1%, 18.63%) from a base of 2.4 per 1,000. Treated prevalence increased by an average of 9.9% (95% CI: 4.7%, 15.2%) in the first year after enactment, by 16.6% (95% CI: 7.1%, 26.0%) in the second year, and by 17.2% (95% CI: 8.6%, 25.8%) in the third or later year.
Conclusions: This study represents the most rigorous analysis to date of a widespread state-level insurance mandate policy in the US. We found that autism mandates have had a statistically significant but small effect on treated prevalence, which remains far below what would be expected based on community prevalence studies. Mandates may be a necessary but not sufficient policy for helping children obtain services reimbursed through private insurance. Analyses that will be completed prior to the conference will examine whether the mandates had an effect on use of behavioral health care, functional therapies, and other types of relevant care and total and out-of-pocket spending on these services paid for through private insurance.

Oral Session - 8B
153 - School and Community Deployed Randomized Trials
2:40 PM - 3:30 PM - Room 308

2:40 **153.001** Efficacy of the ASAP Intervention for Preschoolers with Autism Spectrum Disorder

B. Boyd[1], *L. R. Watson*[1], *M. Alessandri*[2], *G. T. Baranek*[3], *E. Crais*[1], *A. L. Donaldson*[4], *L. D. Johnson*[5], *A. Gutierrez*[2] *and S. S. Reszka*[6], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Miami, Coral Gables, FL, (3)UNC Chapel Hill, Chapel Hill, NC, (4)Speech & Hearing Sciences, Portland State University, Portland, OR, (5)Educational Psychology, University of Minnesota, Minneapolis, MN, (6)UNC-Chapel Hill, Chapel Hill, NC*

Background: Behavioral interventions aimed at improving the social-communication and/or play skills of children with ASD have led to positive short- and longer-term outcomes. Yet, many of these interventions were implemented in clinic-based settings or by research staff. This presents a need to develop and examine the efficacy of interventions implemented by real-world practitioners in natural settings. The Advancing Social-communication And Play (ASAP) intervention targets these skill areas, with classroom educational teams implementing the intervention in public school-based, preschool classrooms.
Objectives: The objectives of this multi-site, four-year study were to examine the effects of the ASAP intervention for the (a) primary outcomes of social-communication and play, and (b) secondary outcomes of engagement and challenging behavior.
Methods: A cluster randomized trial design was used to assign classrooms to ASAP (n=40) or a “business-as-usual” (BAU) control (n=38) group. Eligible preschool-aged children within a classroom were consented prior to informing educational teams of their group assignment. For children in the ASAP group (n=85), their educational team had to consist of at least one teacher, teaching assistant, and related service provider. To support ASAP implementation, the team received intervention materials, didactic training and ongoing coaching throughout one school year. Children in the BAU control group (n=76) continued to receive their typical classroom instruction. Blinded observational coding was used to assess the primary outcomes of social-communication and play as well as the secondary outcome of engagement. Teacher report on the Caregiver-Teacher Rating Form (CTRF) was used to measure challenging behavior. Primary outcome measures were collected at three time points, while secondary outcome measures were collected at two time points.
Results: Random intercept mixed models or hierarchical linear models (HLM) were used to assess primary and secondary outcomes. The primary outcome models were three-level HLM with observations nested within child and child within classroom. The secondary outcomes, with two time points, were run as pretest controlled ANCOVA. These were two-level models with child nested in classroom. Based on preliminary findings, no significant group differences were found for the primary social-communication or play outcomes. However, significant differences in favor of the ASAP group were found for both engagement and challenging behavior. There were statistically significant differences and moderate to large treatment effects found for: unengaged (d=.71), some engagement (d=.50), and overall engagement (d=.59). By post-test, the ASAP group spent more time in the some engagement state, less time unengaged, and blind observers rated them higher for overall engagement compared to the BAU group (Table 1). Further, children in the ASAP group received significantly lower scores on the CTRF measure for externalizing behavior and total challenging behavior (Table 2).
Conclusions: When delivered in authentic settings by real-world practitioners, ASAP led to improvements in children’s ability to appropriately engage in classroom activities and decreased their level of challenging behavior. Although no group differences have been found for social-communication or play, from a theoretical standpoint it may be that changes in engagement (or challenging behavior) must be achieved first in order to lead to downstream changes in these core deficit areas.

2:52 **153.002** Community-Partered Practice: Delivery of a Social Communication Intervention By Paraprofessionals with Toddlers with ASD

S. Y. Shire[1], *Y. C. Chang*[2], *S. Bracaglia*[3], *M. Kodjoe*[3], *W. I. Shih*[4] *and C. Kasari*[1], *(1)University of California Los Angeles, Los Angeles, CA, (2)California State University, Cerritos, CA, (3)New York Center for Child Development, New York, NY, (4)UCLA, Monrovia, CA*

Background: Disparities in bridging the research to practice gap may be greatest in low resourced settings that support child development programs for disadvantaged and developmentally delayed children. The present project aimed to bring an evidence-based early intervention module into a community program in order to improve child social and communication outcomes. Within a community partnered participatory framework, we focused on supporting the delivery of the intervention by non-specialists within the existing structure of the child development program. A randomized controlled intervention trial was conducted in which paraprofessionals from the community were taught to deliver the intervention. Outcomes included paraprofessional implementation and maintenance of strategies as well as child social communication and language outcomes.

Objectives: First, to explore the implementation of non-specialist delivery of a modular naturalistic developmental behavioural intervention- Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2008; 2014; 2015). Second, to examine if children receiving 30 minutes of JASPER intervention a day on top of center-based applied behaviour analytic (ABA) programming would show greater gains in joint attention gestures, language, play, and engagement over those receiving the ABA programming only.

Methods: 147 children age 2-3 years (mean age=31.5 months) were randomized to immediate treatment (IT) or wait list control (WL) for 11 weeks plus 1 month follow up.

137 children had received an autism spectrum disorder (ASD) diagnosis while 10 received other diagnoses. Forty-nine paraprofessionals (teaching assistants), 12 group supervisors and two research coordinators also participated. All but one paraprofessional and four children were members of an ethnic minority group.
Intervention. Paraprofessionals were provided with two weeks of in-vivo training with the research team to learn the social communication intervention: JASPER. Significant effects on joint engagement, joint attention gestures, play skills, and language outcomes have been demonstrated in multiple JASPER RCTs conducted in laboratory and community settings by specialists or parents (Kasari et al, 2008; 2010; 2014; 2015). This is the first study of implementation by non-specialists with ASD toddlers in center-based care. JASPER was delivered 30 minutes a day for children in IT for 11 weeks, while children in WL continued with 30 minutes of music and movement social group time.
Measures. Ten minute paraprofessional-child interactions at entry, exit, and follow up were coded for children's engagement and social communication and paraprofessionals' JASPER implementation. Independent assessors also administered assessments of play, joint attention, and language.
Results: Paraprofessionals in IT demonstrated significant gains in JASPER implementation scores over WL (f(1,91)= 239.94, p<.01) while children in IT made significant gains over WL in child-initiated joint engagement (f(1,70)= 46.13, p<.01), initiations of joint attention language (f(1,70)= 9.72, p<.01) and nonverbal skills (f(1,70)= 13.98, p<.01). Further gains in initiations of joint attention gestures transferred to independent assessments completed by assessors unfamiliar to the children (f(1,98)= 4.45, p=.038). All treatment gains were maintained at follow up.
Conclusions: Paraprofessionals' high strategy implementation scores, maintenance of strategies and positive child outcomes over control indicate that non-specialists can feasibly deliver and maintain previously determined evidence-based and specialized intervention for children with ASD.

3:04 **153.003** Evidence for Maintenance of Emotion Recognition Gains Using the Transporters Animated Series: Results of a Randomized Controlled Trial

***T. Gev**, R. Rosenan and O. Golan, Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel*

Background: Emotion and mental state recognition (ER) difficulties are a core characteristic of ASD. Previous attempts to teach ER to individuals with ASD have often resulted in poor generalization and maintenance of acquired skills. The Transporters (TT) is an animated series that uses faced mechanical vehicles and social stories to expose children with ASD to facial expressions and emotions. A user guide offers parents additional activities aimed to enhance generalization. Previous evaluations of TT have demonstrated positive effects on children's emotional vocabulary and ER, compared to treatment as usual (Golan et al., 2010), and to an animated control series (Young & Posselt, 2012). However, the maintenance of acquired ER skills and the unique effect of the series, vis-a-vis parental support (PS) were not examined.

Objectives: (1) To evaluate TT vs. an animated control series in a RCT with preschoolers with high functioning ASD. (2) To examine the maintenance of acquired ER skills 3 months post intervention. (3) To examine the unique effects of TT and of PS on children's gains.

Methods: 77 Participants with high functioning ASD, aged 4-7 were randomly assigned into four intervention groups using a 2x2 design (TT/control series X with/without PS). Participants' emotional vocabulary and ER skills at 3 levels of generalization were tested, following Golan et al. (2010) before and after the intervention, with a follow-up 3 months after its completion. Each child in the intervention groups received an animation series (TT/Control), and watched it for 10 minutes per day for 8 weeks. Parents in the with PS conditions were asked to use activities from the parental guide on a daily basis, for at least 20 minutes per day. Parent and child fidelity were monitored on a weekly basis by the research team. A fifth group of 25 typically developing (TD) children, matched on mental age and gender was tested three times with no intervention.
Results: A Series (TT/control) by PS (with/without) by Generalization level (3 levels) by Time (pre/post/follow-up) MANOVA was conducted. The analysis yielded a significant time by series effect for the ER tasks, over and above level. Post-hoc analysis revealed the TT groups, that did not differ from the control series groups on ER pre-intervention, improved significantly post intervention, and maintained their gains at follow up. Furthermore, TT groups' ER did not differ from that of TD controls post intervention and at follow-up. No effect was found for parental support. Only time effects were found for the vocabulary task. Verbal ability and autism severity were generally related to ER, but not to intervention gains. No age effects were found, supporting the designated age range for the series.

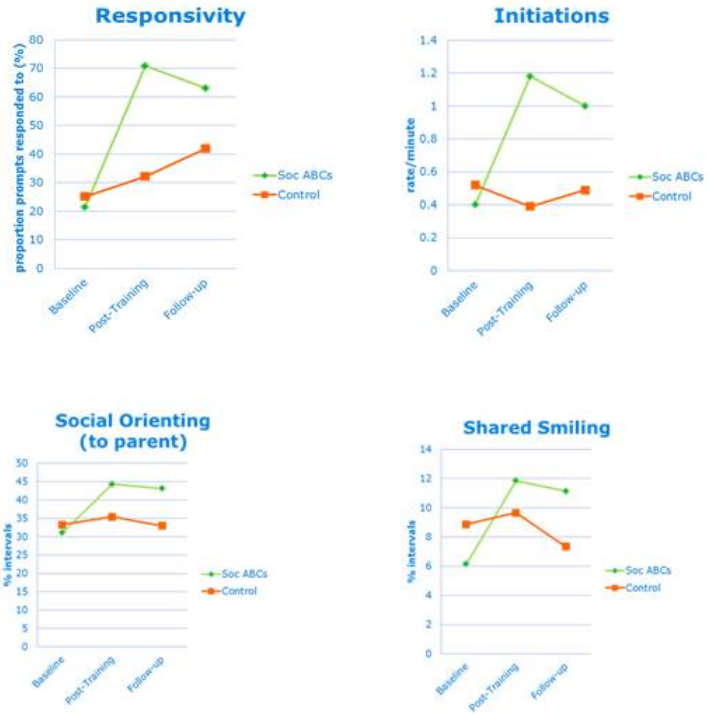
Conclusions: The results support The Transporters series as a an effective ER intervention for young children with ASD, with maintenance of acquired skills at 3 month follow-up. Improvement following series' use narrowed down users' developmental gap on ER skills. The lack of a PS effect on ER, suggests PS may have better effects on more generalized socio-emotional skills.

3:16 **153.004** Randomized Control Trial of the Social ABCs Parent-Mediated Intervention for Toddlers with Confirmed or Suspected ASD

***S. E. Bryson**[1], J. A. Brian[2], I. M. Smith[3] and L. Zwaigenbaum[4], (1)Dalhousie University, Halifax, NS, Canada, (2)Bloorview Research Institute, Toronto, ON, Canada, (3)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (4)University of Alberta, Edmonton, AB, Canada*

Background: The *Social ABC's* is a parent-mediated intervention based on empirically supported Pivotal Response Treatment (PRT; Koegel & Koegel, 2006). The main targets are early (vocal/verbal) communication and positive emotion sharing between child and parent among infants/toddlers who have suspected or diagnosed ASD. Bolstered by promising pilot findings (NAME REMOVED, in press), we have now completed an RCT.
Objectives: To compare groups (treatment vs. control) on post-training and follow-up gains in: (1) child communication, (2) parent-child positive affect sharing (shared smiling), and (3) child engagement (looking at parent's face).
Methods: 62 parent-toddler dyads were randomized into the *Social ABCs*(treatment) group or received treatment as usual (controls) across 2 Canadian research sites (Toronto, Halifax). Parents of toddlers aged 16 to 30 months received 8 weeks in-home, live coaching plus 4 weeks refresher and consultation, followed by 12-week parent implementation, and follow-up assessment (week 24). Video-coding occurred for 3 key time-points: Baseline (BL), Post-training (PT; week 12), and Follow-up (F-up; week 24). Positive Emotion Sharing, Social Orienting, and several indices of communication were coded at all 3 time-points. Repeated measures ANCOVAs were used to evaluate change across time-points and groups.
Results: This abstract presents findings from **interim analyses** (n=31-59), but full analyses will be completed in time for IMFAR. All group X time interactions favour the treatment group, including significant gains (BL vs. F-up) for Auditory Comprehension (receptive language) raw scores on the Preschool Language Scale-4, p =.023. Significant group X time interactions were obtained for several video-coded variables (see Figure 1), with medium-to-large effect sizes (ES): Responsivity (p < .001, ES = .71), Initiations (p < .001, ES = .32), Shared Smiling (p = .020) and a trend for child Social Orienting (p < .053). Parent fidelity of implementation was achieved, also with a group X time interaction in the expected direction (p < .001, ES = .73).
Conclusions: Significant gains, favouring the treatment group, were observed in children's communication on (proximal) video-coded measures, and a standardized measure of language comprehension, as well as increased shared smiling and child social orienting to their parent. Parents attained fidelity in use of the intervention techniques after 12 weeks of parent training. The parent-training model allows for the integration of intervention into daily activities, thus enabling very early intensive intervention. Next steps involve community translation of this portable, feasible, and cost-effective intervention (underway).

Figure 1a-d. Video-coded data for (a) child vocal/verbal responsivity to parent cues, (b) child-initiated language, (c) social orienting to parent, and (d) shared smiling with parent.



Oral Session - 9A
154 - Preparing Youth with ASD for Adolescence and Beyond
1:45 PM - 2:35 PM - Room 309

1:45 **154.001** Parents' Decisions to Disclose Their Child's Autism Spectrum Diagnosis to Their Child

C. Moody[1], *L. Berkovits*[1], *J. Blacher*[2] *and B. L. Baker*[3], *(1)University of California Los Angeles, Los Angeles, CA, (2)University of California - Riverside, Riverside, CA, (3)UCLA, Los Angeles, CA*

Background:
Although research exists on parents' experience in receiving an autism spectrum disorder (ASD) diagnosis for their child (Brogan & Knussen, 2003), there is a dearth of research on parents' experiences in relaying that diagnosis to their child. In one interview study, researchers identified diagnosis disclosure as an important theme present in the perceptions of high-functioning college students with ASD, who indicated that their families were aware of the ASD diagnosis before it was shared with them (Huws & Jones, 2008). What factors prompt families to share an ASD diagnosis at a specific time and how do parents explain the diagnosis to their children? Given the highly personal and vulnerable nature of this information, parents would likely benefit from more research on how and when to disclose, and what strategies may be most effective.
Objectives:
The aim of this study is to gather descriptive data about when, how, and why parents shared the ASD diagnosis with their now adolescent (age 15) son or daughter. A secondary objective will be to connect these factors to youth outcomes.
Methods:
Subjects included families of children with ASD (n=43) who were interviewed when the children were 15 years old. Parents were interviewed about various aspects of their son's or daughter's life including whether and when they have shared the diagnosis, how they described ASD, and why they chose that particular time. Interview responses were transcribed and coded for themes. Parents also completed questionnaires, including the CBCL and SCARED, on the youth's current functioning.
Results:
Results indicated that the majority of parents disclosed their child's diagnosis by the time the youth was age 15. The mean youth age at disclosure was 8.58 years old (*SD*=3.39; range: 1-13 years), supporting the presence of a discrepancy for many families between parent knowledge and child knowledge of the diagnosis. Parents reported a wide range of reasons why they chose a given time to share the diagnosis with their child. Most commonly, parents led the discussion; however, several children initiated the discussion with their parents. In parents' self report of how they described the diagnosis, parents included significantly more negative comments (e.g., explaining deficits) than positive comments (e.g., strengths), t=4.233, p<.001.
Preliminary analyses regarding youth outcomes indicated that children told in middle childhood (ages 8-10) showed higher levels of internalizing problems at age 15 than children told in early childhood (age < 7) or early adolescence (ages 11-13) by parent report on the SCARED, F=3.602, p=.038, and CBCL Internalizing, F=2.912, p=.068.
Conclusions:
The prevalence of ASD has dramatically increased over the past 20 years (CDC, 2014). As these children grow, more research needs to be targeted at when and how families should disclose this diagnosis to their children. These qualitative analyses indicated that parents vary with respect to how, when, and why diagnosis disclosure occurs. It is possible that there may be a developmental window that is optimal for a discussion of diagnosis with a child with ASD, but the current analyses are limited due to their cross-sectional nature.

1:57 **154.002** The Sword in the Soul: Meanings of Autism Spectrum Conditions Among Diagnosed Adolescents

E. Fein*, Psychology, Duquesne University, Pittsburgh, PA*

Background: As the rate of autism diagnosis continues to increase, a growing number of youth are coming of age diagnosed with autism spectrum conditions. Little is known about how the diagnosis affects the developing identities of these youth as they grow into adulthood (Petalas et al, 2013). Meanwhile, the kinds of meanings that the diagnoses hold for individuals affected have become increasingly diverse and contentious (Ortega, 2009; Bumiller, 2008; Bascom, 2012). Ethnographic research can reveal how the meanings of autism spectrum conditions are negotiated in particular contexts of daily life, and show some consequences of those meaning-making practices for those affected by autism (Solomon and Bagatell, 2010; Grinker and Cho, 2013).
Objectives: This study investigated how adolescents diagnosed with Asperger's Syndrome and related autism spectrum conditions define what autism is, and how it should be treated. In particular, the study foregrounded two popular models of autism in contentious conflict: the model of autism as a disease separate from the affected person, and the model of autism as a fundamental and often valued element of the affected person's neurogenetic identity (Sinclair, 1999; Solomon, 2008). How do youth coming of age

with an autism spectrum diagnosis reconcile these seemingly incompatible understandings of autism and the self?
Methods: The research consisted of two years of ethnographic fieldwork at sites where the meanings of autism spectrum conditions were being negotiated and put into practice in consequential ways: a public and a private school, a psychiatric clinic, and a community center/summer camp, all serving adolescents with Asperger's Syndrome and related ASC's. I also conducted 130 semi-structured interviews with people diagnosed with ASC's, their family members, and the professionals working with them.
Results: Youth on the spectrum who participated in this study tended to see autism as (as one participant put it) "a double-edged sword". It gives them cherished strengths, unique perceptual experiences, and terrifying vulnerabilities. It isolates them socially while also bringing them into fellowship and a sense of community with affected others. It helps make them who they are, but also profoundly disrupts their sense of self. In this presentation, I will describe how these youth often look outside of medicalized models of autism-as-disease and autism-as-identity to make sense of this experience, drawing instead on a folk mythology of embodied difference from roleplaying games, Japanese animation films, and other fantastical popular media. In their games, their art, and other informal creative practices, they playfully depict themselves as hybrid creatures: mutant antiheroes who are half human and half demon, pierced by shards of evil swords, or possessed by powerful ancestors. In doing so, they reconcile the valued and troubling elements of their experience.
Conclusions: Through a shared mythology that transcends the limitations of medical models, youth on the spectrum are better able to articulate the complexities and ambiguities of their condition. Attention to the subjective experience of autism in cultural context can help illuminate such unexpected and productive practices.

2:09 **154.003** How Adolescents with Autism and Their Parents Perceived the Chilled Program: A Treatment Acceptability Framework for Autism Researchers

T. C. Kidd[1], *R. Rooney*[2] *and T. G. Mazzucchelli*[3], *(1)Curtin University, Perth, WA, Australia, (2)Curtin University, Perth, Australia, (3)School of Psychology and Speech Pathology, Curtin University, Perth, Australia*

Background: To prevent researchers in the field of autism from making erroneous assumptions about the effectiveness of interventions, the subjective experience of individuals with autism, and their families, participating in randomised controlled trial interventions, warrants attention in autism cognitive and behavioural research. Currently, limited emerging evidence of participant adherence to and acceptance of cognitive behavioural therapy intervention exists, however a more comprehensive evaluation model of assessing social validity in autism research is warranted.
Objectives: To assess the social validity of an anxiety reduction program for adolescents with high functioning autism, and to devise a framework for clinicians and researchers to measure participant satisfaction and acceptability of psychosocial interventions.
Methods: A randomised controlled trial was employed to assess the social validity of a group, family-based, cognitive behavioural therapy intervention (CBT) for adolescents with high functioning autism spectrum disorder (HFASD), and co-occurring anxiety disorder/s (AD). Forty-four adolescent-parent dyads participated in the 12-session program, an adaptation of the 'Cool Kids' ASD anxiety program (Chalfant, Lyneham, Carrol, & Rapee, 2010). Both quantitative and qualitative methodology determined the social validity of treatment.
Results: The results will be presented in four parts a) adolescent quantitative feedback which consists of the overall ratings of the intervention, b) adolescent qualitative feedback which is comprised of responses to five open-ended questions, c) Parent quantitative feedback consisting of overall feedback about the program and any changes in their adolescent since completing the intervention, and d) qualitative feedback from parents comprising of three responses to open-ended questions.
Conclusions: High program adherence and acceptability of the Chilled program were found by both adolescents and their participating parent/s. A feasible model for effectively assessing the relevance and acceptability of behavioural interventions in autism research and practice will be presented.

2:21 **154.004** Life after High School: Trends in Post-Secondary Education and Employment for Individuals with ASD Across Virginia

S. Carr *and S. M. Prohn, Virginia Commonwealth University, Richmond, VA*

Background:
The U.S. Bureau of Labor Statistics reported that 68% of 2014 high school graduates enrolled in colleges or universities. By contrast, only 48% of students with ASD in Virginia enrolled in 2 or 4-year institutions of higher education. Generally, research has reported poor post-school outcomes for individuals with ASD (Henniger & Taylor, 2013). While the Interagency Autism Coordinating Committee (IACC) has identified a need for research on transition for students with ASD, relatively little is known about students with ASD who enroll in college.
Objectives:
To examine the Virginia Department of Education Indicator 14 Data (post-secondary outcomes) for students with ASD enrolled in public school across the state while paying close attention to racial and geographic disparities.
Methods:
This study utilized the current Virginia Department of Education Database from 2014. This secondary data analysis looked specifically at post-secondary outcomes for youth with Autism Spectrum Disorder across the Commonwealth.
Results:
By examining Virginia Department of Education's postsecondary transition data, and specifically the 511 students with ASD who left high school in the 2012-13 school year, it is clear that African American students and those from rural Virginia were less likely to attend college than white students or those from urbanized areas. Additionally, high school students with ASD who received alternative degrees were also less likely to attend college than students with regular or advanced degrees, results that are consistent with previous literature (Chiang, Cheung, Hickson, Xiang, & Tsai, 2012). Disparities in college enrollment among students with ASD also contribute to disparities in quality of life, present and future, with those enrolled in college reporting significantly higher life satisfaction.
Conclusions:
The achievement of students with ASD who receive special services lags far behind their non-disabled counterparts. Only 40% students with ASD in Virginia leave high school with a standard diploma. To reduce college enrollment gaps between those with and without ASD as well as within the ASD diagnoses, Virginia must further develop postsecondary education models that increase college accessibility for those with multitudinous support needs including geographical location.

Oral Session - 9B
155 - Quality of Life, Internalizing Symptoms, & Employment
2:40 PM - 3:30 PM - Room 309

2:40 **155.001** Characterizing Objective Quality of Life and Normative Outcomes in Adults with Autism Spectrum Disorder: A Latent Class Exploratory Analysis

L. Bishop-Fitzpatrick[1], *J. Hong*[1], *L. E. Smith*[2], *R. A. Makuch*[1], *J. S. Greenberg*[2] *and M. R. Mailick*[1], *(1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)University of Wisconsin-Madison, Madison, WI*

Background: There is little consensus about how best to assess normative outcomes and objective quality of life (QoL) in adults with autism spectrum disorder (ASD). Past outcome research has found that very few adults with ASD achieve the conventional markers of adulthood – becoming employed and self-supporting, living independently, developing a network of friends, contributing to the community. Some have called for a reconceptualization of QoL for adults with ASD, but little empirical research has been conducted that can inform such a reconceptualization or identify strategies for improving the QoL of adults with ASD.
Objectives: The current study aims to construct a unified definition and conceptualization of normative outcomes and objective QoL for adults with ASD by: (1) characterizing the heterogeneity of normative outcomes and objective QoL; and (2) identifying predictors of positive normative outcomes and good objective QoL.
Methods: 180 adults with ASD between the ages of 23.72 and 60.47 (*M*=34.06, *SD*=7.99) were drawn from a longitudinal study (Adolescents and Adults with Autism). Three indicators of normative outcomes (employment, independent living, social engagement) and four indicators of objective QoL (physical health, quality of neighborhood, family contact, mental health issues) were assessed using a dichotomous scale and entered into an exploratory latent class analysis in order to determine groups of adults with ASD who were similar in their normative outcome and objective QoL profiles. A multinomial logistic regression then tested the association between intellectual disability (ID) status, age, daily living skills (Waisman Activities of Daily Living), autism symptomatology (Autism Diagnostic Interview-Revised), and executive functioning (Behavior Rating Inventory of Executive Function).
Results: Exploratory latent class analysis findings identified three discrete groups – Greater Dependence, Good Health, and Greater Independence – of adults with ASD in terms of normative outcomes and objective QoL. The Greater Independence group experienced the most favorable normative outcomes, while the Greater Dependence group experienced the worst. The Good Health and Greater Independence groups experienced the most favorable objective QoL while the Greater Dependence group experienced the worst. In addition, findings indicate that better daily living skills (Good Health vs. Greater Dependence: *exb(B)=1.110, p<.001*; Greater Independence vs. Greater Dependence: *exp(B)=1.175, p<.001*) and better executive function (Good Health vs. Greater Dependence: *exp(B)=.966, p<.05*; Good Health vs. Greater Independence: *exp(B)=.964, p<.10*) are associated with membership to outcome groups with better normative outcomes, when controlling for ID status, age, and autism symptomatology.
Conclusions: This research proposed a broad conceptualization of normative outcomes and objective QoL that takes into account many facets of life, is long-term in nature, and is variable over time. Our findings indicate that normative outcomes and objective QoL for adults with ASD may be quite nuanced; having good normative adult outcomes may not necessarily lead to good QoL, and vice versa. Notably, there appears to be a relatively strong association between better daily living skills and membership to a

group with improved normative outcomes and objective QoL. These findings have important implications for future research and for interventions designed to improve outcomes and QoL in adults with ASD.

2:52 **155.002** High Early Parental Expectations Predict Improved Independent Living and Quality of Life for Adults with Autism Spectrum Disorder

E. T. Schroeder[1], *P. S. Powell*[2], *E. M. Lamarche*[3], *M. R. Klinger*[4] *and L. G. Klinger*[5], *(1)UNC TEACCH Autism Program, Carrboro, NC, (2)University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)UNC TEACCH Autism Program, Chapel Hill, NC, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC*

Background:
Previous studies examining the effect of parental expectations of children with autism spectrum disorder (ASD) have shown that expectations predict outcome, at least in the short –term (Chiang et al., 2012; Taylor et al., 2011). However, these studies provide conflicting findings on whether expectations serve as predictors across domains (educational, vocational, etc.), and no study to date has studied the relationship between parental expectations and long-term outcomes. The current study examined the relationship between early parental expectations of independence (living, education, and relationships) and long-term outcomes in these same children 20 to 40 years later.
Objectives:
The present study examined how early parental expectations relate to long-term outcomes in adults with ASD. It was predicted that higher parental expectations in childhood would relate to better outcomes in middle adulthood, regardless of childhood functioning.
Methods:
As part of a longitudinal follow-up study of families seen by the University of North Carolina TEACCH Autism Program between 1965 and 1999, 52 archival records of childhood parental estimates of current adaptive functioning and future adult outcome were obtained. Future estimates of adult outcome included expectations regarding living situation (e.g., group home, home, or independent), education level (e.g., special education, high school, college), and relationships (e.g., never date, date but not marry, married, married with children). These predictions were combined to produce an overall estimate of parental expectations. We compared these expectations to measures of adaptive behavior (Waisman Activities of Daily Living) and quality of life in the same children 20 to 40 years later.
Results:
A hierarchical linear regression with a stepwise progression was conducted using adult W-ADL as the dependent variable. The number of years between childhood and follow-up study (M = 29 years; range: 20-41 years) and parental estimates of childhood adaptive functioning (as a proxy for developmental level) were entered first into the model with adult outcome expectations as the last predictor to examine the impact of parental expectations of adult outcome after controlling for these other variables. Parental outcome expectations during childhood significantly predicted adult adaptive behavior (R^2_{change}=.07, p=.04). The same analysis was performed on quality of life with parental outcome expectations during childhood significantly predicting adult quality of life (R^2_{change}=.10, p=.01).
Conclusions:
Taken together, these findings suggest that higher parental expectations during childhood lead to higher levels of adaptive behavior and quality of life in adulthood. This was evident after controlling for parental perception of childhood adaptive behavior as a proxy for current developmental level and the length of time between childhood and adulthood evaluation. Given generally poorer outcomes for individuals with ASD, one might expect higher parental expectations to result in lower ratings of quality of life given the disparity between the expected and the actual outcomes. However, the current findings suggest that parental expectations are not only related to quality of life, but may be important for improving the level of independence in adulthood. These results suggest that parents should be encouraged to hold high expectations for their young children with ASD.

3:04 **155.003** Health Care Service Utilization in an Integrated Healthcare Delivery System Among Adults with Autism Spectrum Disorders

L. A. Croen*, O. Zerbo and Y. Qian, Division of Research, Kaiser Permanente, Oakland, CA*

Background: Adults with autism spectrum disorder (ASD) have a significantly higher burden of most major medical and psychiatric conditions compared to adults without ASD. The reasons for this are not known, but may be related to less adequate utilization of preventive healthcare services or poorer control of chronic conditions. Currently, very little is known about healthcare service utilization among this growing population.
Objectives: To compare healthcare utilization patterns of adults with ASD and adults without ASD among a large and diverse population of adults receiving healthcare services in an integrated healthcare delivery system.
Methods: The study population was drawn from the adult membership (≥ 18 years) of Kaiser Permanente in Northern California (KP) who were enrolled in the health plan for at least 9 months each year from 2008-2012. ASD cases (N=1,507) were adults with at least two ASD diagnosis (ICD-9-CM 299.0-299.8) recorded in the electronic medical record by December 2012. A control group of adults without any ASD diagnoses (N= 15,070) was sampled at a 10:1 ratio and frequency matched to cases on total length of KP membership, sex, and age. Health care utilization data were obtained from the KP inpatient and outpatient databases for the year 2012. Utilization occurring at KP facilities and authorized non-KP facilities was defined in terms of the percentage of patients with outpatient clinic visits, hospitalizations, emergency department visits, and specialty care visits in the study year. Proportions of each healthcare service utilization category were compared between cases and controls after adjusting for several covariates using multivariable logistic regression models. Covariates included age, sex, race/ethnicity, total length of membership, and eight categories of medical and psychiatric comorbidities (immune conditions, cardiovascular diseases, metabolic disorders, neurologic diseases, gastrointestinal disorders, sleep disorders, nutritional conditions, and psychiatric conditions).
Results: Compared to controls, adults with ASD had significantly higher utilization of outpatient visits for primary care (74% vs.59.1%), mental health (43.3% vs. 5.4%) and neurology (5.6% vs. 1.5%). Utilization of hospice/home healthcare (1.3% vs. 0.3%), skilled nursing services (0.6% vs. 0.1%) and speech therapy (0.8% vs. 0.1%) were uncommon but all significantly higher among adults with ASD compared to adults without ASD. The higher rate of utilization in these categories was evident among both men and women. Among men only, utilization of inpatient hospitalizations (4.8% vs. 1.9%) and laboratory services (55.5% vs. 38.9%) was significantly higher among ASD cases than controls, and utilization of physical or occupational therapy services was significantly lower (2.8% vs. 4.2%). Among women, utilization of gynecology services was significantly lower among ASD cases compared to controls (35.1% vs. 49.1%). Finally, for most healthcare service utilization categories, case-control differences were most pronounced for adults over 50 years of age.
Conclusions: With the exception of gynecologic service utilization among women, adults with ASD have higher utilization of most healthcare services compared to controls, even after controlling for medical and psychiatric comorbidities. More research is needed to determine reasons for these utilization differences and to develop strategies to improve delivery of health care to adults with ASD.

3:16 **155.004** Virtual Reality Job Interview Training and 6-Month Vocational Outcomes for Young Adults with Autism Spectrum Disorder

M. J. Smith*, Department of Psychiatry and Behavioral Sciences, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Young adults with high-functioning autism spectrum disorder (ASD) have low employment rates and job interviewing presents a critical barrier to employment for them.
Objectives: To evaluate the acceptability, efficacy, and vocational outcomes for young adults with ASD who completed a virtual reality job interview training (VR-JIT) program compared to a treatment-as-usual (TAU) control group.
Methods: We conducted a randomized controlled trial with 16 participants randomly assigned to the VR-JIT treatment group and 10 participants randomized to a treatment-as-usual (TAU) group. The primary outcome measures were: 1) blindly rated video-recorded job interview role-plays (with professional actors) that assessed interview skill level as pre-test and post-test measures and 2) self-reported interviewing self-confidence. Acceptability measures included session attendance, total minutes spent using the intervention, and a self-report regarding VR-JIT's ease-of-use and perceived helpfulness at improving interview skills. Vocational outcomes at 6-month follow-up were determined by surveying: 1) if the study participants completed interviews for a competitive position (employed or volunteer), 2) accepted a competitive position, and 3)the number of weeks participants sought a competitive position. We used descriptive statistics to report the acceptability data for VR-JIT. We used repeated measures analysis of variance to assess if the VR-JIT group demonstrated improved interviewing skills between the pre-test and post-test interview role-plays. We used logistic regression to evaluate if training with VR-JIT was associated with a greater odds of attaining a competitive position (job or volunteer).
Results: Participants attended 90% of the lab-based training sessions, and more than 90% of participants reported that VR-JIT was easy-to-use, enjoyable, and prepared them for real-life interviews. VR-JIT participants had greater improvement during live standardized job interview role-play performances than the control group ($p<0.05$) and had greater improvement in interviewing self-confidence at the trend level ($p=0.06$). Eighty-eight percent of participants (23 of 26) completed the 6-month follow-up survey. Logistic regression indicated that the VR-JIT group, compared to the TAU group, had greater odds of attaining a competitive position (OR 7.82, $p<0.05$). Exploratory correlations revealed that, among VR-JIT participants, improvement in role-play performance between pre-test and post-test was correlated with completing more interviews at 6-month follow-up ($r= 0.55$, $p<.05$).
Conclusions: Vocational training in the community is a critical issue within the ASD community and this study provides initial evidence that VR-JIT may be a helpful intervention for young adults with ASD searching for a job or competitive volunteer work. Future directions include evaluating the community-based effectiveness of VR-JIT as well as modifying for VR-JIT for adolescents with ASD who are preparing to pursue employment.

Oral Session - 10A
156 - Exploring Cognitive Processes to Inform ASD Characteristics
1:45 PM - 2:35 PM - Room 310

1:45 **156.001** Exploring What's Missing: What Do Target Absent Trials Reveal about Autism Search Superiority?

B. Keehn[1,2] *and B. Joseph*[3]*, (1)Psychological Sciences, Purdue University, West Lafeyette, IN, (2)Speech, Language, and Hearing Sciences, Purdue University, West Lafeyette, IN, (3)Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA*

Background: Individuals with autism spectrum disorder (ASD) excel at visual search, performing better than their typically developing (TD) peers across the lifespan. This disparity in performance generally becomes greater as target-distractor similarity increases and when the target is absent.
Objectives: First, to assess the roles of enhanced stimulus discrimination and peripheral selection in superior visual search among individuals with ASD, and, second, to examine the search mechanisms underlying the well-documented superiority of individuals with ASD to discern target absence.
Methods: We administered a paradigm in which distractors varied on difficulty of discrimination and selection to 22 school-age children and adolescents with ASD and an age- and non-verbal IQ-matched comparison group of 30 TD children. The stimulus array had a fixed set size of 24 items. The target was a circle and the distractors were "C" shaped figures. Peripheral selection was varied by increasing the line-width of distractors; discrimination between target and distractors varied by increasing the size of the gap in the distractor Cs (Figure 1a). The experiment was divided into four 40-trial blocks.
Results: Groups did not differ in error rate. Children with ASD were faster at visual search than their TD peers, $F(1,50) = 3.5$, $p = .068$. However, there were no significant interactions between group and discrimination, selection, or a three-way interaction between group, discrimination, and selection (all p>.05). Rather, consistent with the large majority of ASD visual search, group differences were mainly the effect of faster ASD performance on target absent trials, $F(1,50) = 6.7$, $p = .013$. Next, we conducted a series of analyses to examine the search characteristics that confer a unique advantage in absent trials to individuals with ASD. Faster RT to target absent trials was not due to speed-accuracy trade-off, response bias, quitting threshold, or post-error slowing (all p>.05). Instead, we found faster RT to targets appearing on the left side of the array for our TD group. However, this left-side bias was not present in individuals with ASD (Figure 1b-d). Consistent with our RT results, TD individuals, but not individuals with ASD, showed a leftward bias in saccadic endpoint (Figure 1e). Lastly, ASD symptom severity was positively associated with ASD search superiority (Figure 1f).
Conclusions: Consistent with previous reports, we found accelerated search in ASD, which was driven primarily by faster responses to target absent trials. Behavioral and eye-tracking results suggest that absent advantage may be due to reduced leftward search bias in ASD. Because target proximity is an important factor in determining subsequent target fixation and search termination, non-biased saccades are likely to make targets more accessible, facilitating search in ASD. These findings together with fewer fixations and reduced saccadic error in target present trials lends support to the hypothesis that enhanced perceptual load may contribute to superior search in ASD. Additionally, indices of target absent search and reduced search bias were related ASD symptom severity, indicating that mechanisms underlying absent search advantage may have explanatory significance with regard to the development of ASD social and communicative impairments.

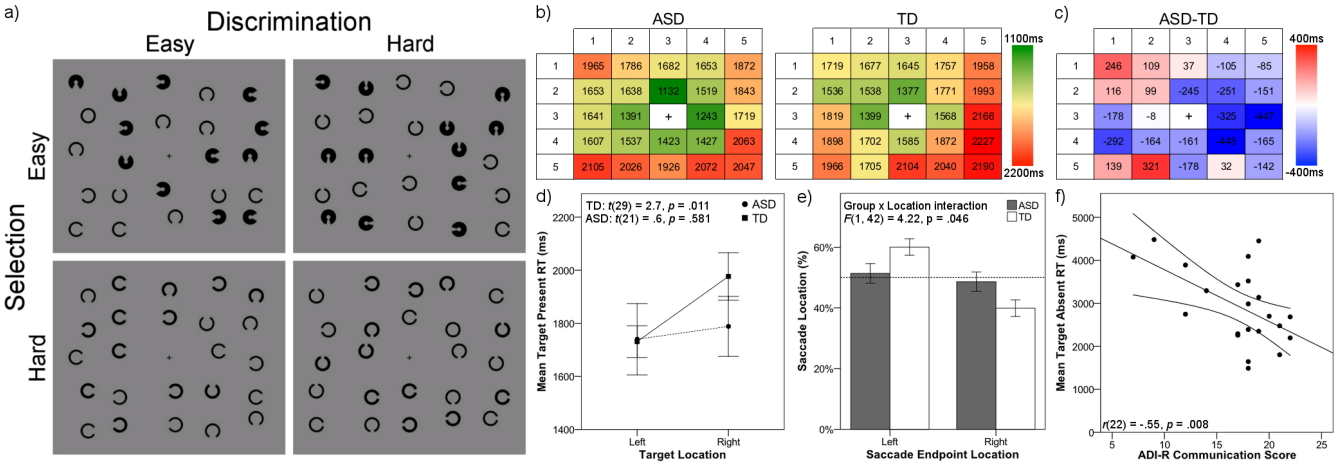


Figure 1. Illustration of search array for each trial type. Manipulation of gap size (discrimination) and distractor width (selection) were used to create four conditions: discrimination easy, selection easy (upper left), discrimination easy, selection hard (lower left), discrimination hard, selection easy (upper right), and discrimination hard, selection hard (lower right). The target (circle) is present for DESE and DHSH conditions, target absent for DHSE and DESH conditions (a). Heat maps representing RT for ASD and TD group (b). The difference between ASD and TD (ASD-TD) for RT at each possible target location (c). Cool colors (blues) represent target locations with faster RT for the ASD group; Warm colors (reds) represent target locations with faster RT for the TD group. Average RT for ASD and TD groups for targets appearing in left and right locations (d). Endpoint of initial saccades for ASD and TD groups on the left or right side of the search array (e). Scatter plot of absent RT and ADI-R Communication score (f). Error bars represent ± 1 SEM.

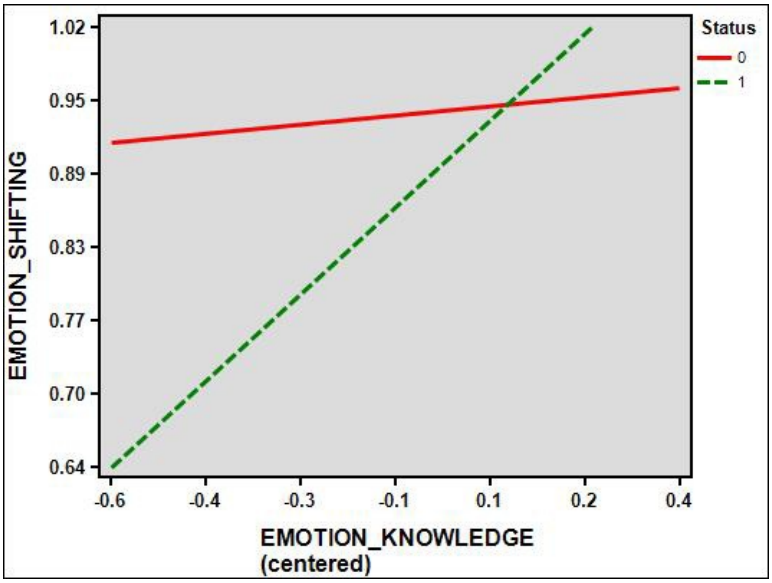
1:57 **156.002** Emotion Shifting, Emotion Knowledge and Inhibitory Control in Children with ASD

B. Wilson*, E. F. Geib, A. F. Lee and E. Bisi, Clinical Psychology, Seattle Pacific University, Seattle, WA*

Background:
Children's ability to shift attention between different emotional events predicts positive outcomes such as prosocial behavior, emotion regulation and academic competence in children with typical development (TD; Wilson, 2003; Wilson, Derryberry, & Kroeker, 2006). Children with autism spectrum disorders (ASD) tend to have difficulty with two skills thought to underlie emotion shifting skills, the ability to recognize emotions in others and shifting attention between different events (Swettenham et al., 1998; Wilson, 2003). Most prior research on attention shifting research has failed to include emotional stimuli.
Objectives:
We investigated whether the relation between children's status (ASD vs TD) and their emotion shifting skills would be moderated by their inhibitory control and emotion knowledge skills.
Methods:
Participants were ninety-six who were from 3 years to 6 years 11 months old. Fifty-four children were TD (61% male) and 42 children had ASD (83% male). Children's emotion shifting was assessed with the Children's Attention Shifting Task, a computerized task that requires children to move their attention between different emotion faces (CAST; Wilson, 2003; Wilson et al., 2006); emotion knowledge was measured with the Facial Expressions subscale of the Assessment of Children's Skills Emotions task (ACES); and inhibitory control with the Boy/Girl task (Diamond et al., 2002). Data were collected during a home visit and a laboratory session.
Results:
A multiple additive moderation analysis was conducted using PROCESS (Hayes, 2015) to examine the conditional effects of developmental status on emotion shifting based on inhibitory control and emotion knowledge. After controlling for children's age and verbal skills, children's developmental status, inhibitory control (IC) and emotion knowledge (EK) each explained unique variance in their emotion shifting skill. The main effect of developmental status on emotion shifting was significant (t = -4.52, p < .001). Although the contribution of IC as a moderator was nonsignificant, EK significantly moderated the relation between developmental status and emotion shifting while holding the moderating effects of inhibitory control constant (t = 3.57, p < .001). In other words, the relation between status and emotion shifting was moderated by children EK whereas their IC skills had an additive effect on children's emotion shifting skills. As can be seen in Figure 1, the emotion shifting skills of children with ASD were higher when their EK skills were higher, whereas emotion shifting skills in children with TD was not related to their EK skills.
Conclusions:
We found that emotion knowledge was more strongly associated with the emotion shifting skills for children with ASD than for children with TD. Our findings suggest that interventions that improve the emotion knowledge skills of young children with ASD may also facilitate their ability to shift attention effectively between different emotional events.



2:09 **156.003** Auditory Perceptual Capacity Is Superior in Autism

A. Remington[1] *and J. Fairnie*[2]*, (1)Centre for Research in Autism & Education, UCL IOE, London, United Kingdom, (2)UCL, London, United Kingdom*

Background:
Autism Spectrum Disorder (ASD) has an intriguing profile of both deficits and abilities. Individuals show enhanced pitch discrimination (e.g. Bonnel et al 2003), higher rates of absolute ('perfect') pitch compared to general population (Miller, 1999) and often find seemingly innocuous sounds distressing. In 2013, altered sensory processing was added to the diagnostic criteria for the condition (APA, 2013). It is essential to find ways to reduce auditory distraction and the negative impact that auditory stimuli have on individuals with ASD.
Objectives:
This study used two behavioural experiments to examine whether an increased capacity for processing sounds in ASD could be underlying both the negative and positive aspects of this behaviour.
Methods:
16 autistic adults and 16 neurotypical adults took part in the study. In Experiment 1, an inattentional-deafness paradigm was used. Participants listened to a scene containing characters preparing for a party and were asked to concentrate on a conversation between two women in order to answer subsequent questions. Halfway through, an additional male character walked through the scene, continually repeating ''I'm a gorilla''. After the scene, participants were asked whether they heard anything unusual. Experiment 2 examined the limits of auditory capacity in ASD by measuring detection of a critical stimulus (CS) under various levels of perceptual load. In this task, increased capacity would manifest as more task-relevant processing and enhanced task performance. Participants were asked to detect a target sound (dog/lion) among varying numbers of non-target sounds (other animals). Binaural sound recordings were used to position auditory components on an imaginary semi-circle in front of the head. A car noise (the CS) was also present on 50% of the trials, in positions that lay on an imaginary semi-circle of greater eccentricity than the animal sounds. Participants were asked to indicate which target was present (e.g. lion or dog) and whether the CS was present or absent on that trial.
Results:
In Experiment 1, 50% of autistic participants detected the 'gorilla', whereas only 12.5% of neurotypical controls did ($p = 0.022$). This suggests that autistic individuals process more irrelevant information from the auditory scene; evidence of increased perceptual capacity.
In Experiment 2, controls showed a significant reduction in detection sensitivity to the CS as the auditory load of the central task increased. In the ASD group, detection rates of the CS were significantly higher overall, and as auditory load of the central task increased rates did not drop to the same extent as for neurotypical controls .
Conclusions:
The experiments demonstrate that autistic people were better at detecting additional unexpected and expected sounds, suggesting that they have increased auditory perceptual capacity relative to non-autistic controls.
This offers an explanation for the auditory superiorities seen in autism (e.g. heightened pitch-detection). Somewhat counter-intuitively, this same 'skill' could result in the sensory overload that is often reported – which subsequently can interfere with social communication. These findings have important practical implications and could be used to develop intervention programs to minimise the distress that is often seen in response to auditory stimuli.

2:21 **156.004** Recognition Memory in Adults with Autism Spectrum Disorder – the Pupil Old/New Effect

M. Ring[1]*, D. M. Bowler*[2] *and S. B. Gaigg*[3]*, (1)City University London, London, England, United Kingdom, (2)Psychology, City University London, London, United Kingdom, (3)City University London, London, United Kingdom of Great Britain and Northern Ireland*

Background:
Memory in individuals with Autism Spectrum Disorder (ASD) has characteristic areas of strength and difficulty. ASD individuals show greater difficulty on less supported tests like free recall but are similar to typically developing (TD) individuals on more supported procedures such as recognition. Most of this research is however done with adults with average intelligence and language abilities. Research into less verbal or younger individuals is uncommon, partly because of methodological challenges. However, in typical as well as clinical populations, gaze measures are becoming popular as indices of memory function and are a good option to overcome these challenges. One such measure - pupil size - has shown robust effects and breakthroughs in terms of understanding the underlying neurochemistry of memory.
Objectives:
The aim was to establish whether pupil dilation indices would be sensitive to recognition memory processes in ASD adults. We used a wide range of materials to make the findings as generalizable as possible. We aimed to discover more about the utility of the current paradigm with less verbal ASD populations as well as its potential usefulness in the search for a biomarker for ASD.
Methods:
Data were available for 27 ASD and 30 TD adults aged between 22-64 years and IQs between 75-136. Participants were asked to study sets of 10 words, pictures, non-words and abstract shapes. Materials were black and white images matched for luminance presented one by one in the centre of a computer screen. After the study phase, participants' memory was tested with a 'Yes-No' recognition memory procedure. Pupil size data were measured with a Tobii TX300 remote eye-tracking screen. We calculated a pupil size ratio (pupil size for test item divided by baseline) to control for natural pupil size fluctuation and differences in pupil size between participants at baseline.
Results:
Both groups remembered visual materials (pictures and abstract shapes) better than verbal materials (words and non-words) and showed superior memory for meaningful over meaningless materials. We compared participants on a pupil size ratio for old (studied) and new (unstudied) materials and found larger pupil sizes for old materials ($M = 1.04$, $SD = 0.03$) compared to new materials ($M = 1.01$, $SD = 0.03$) for the TD group ($p < .0001$, Cohen's $d = 0.89$). This pupil old/ new effect was absent for the ASD group ($M_{old} = 1.03$, $SD_{old} = 0.04$; $M_{new} = 1.03$, $SD_{new} = 0.08$; $p = .80$, Cohen's $d = 0.04$).
Conclusions:
The current data suggest different underlying recognition memory mechanisms in ASD. Large effect sizes, consistency in findings as well as the dependent measure's independence from either language or conscious awareness suggest that the pupil size old/new effect might be a good measure to investigate memory in ASD further, especially in less verbally able individuals. In addition the current results give some indication for possible differences in underlying neurochemistry in ASD and therefore make changes in pupil size in ASD a candidate biomarker in autism research.

Oral Session - 10B

157 - Cognitive and Perceptual Influences on Learning and Daily Functioning

2:40 PM - 3:30 PM - Room 310

2:40 **157.001** The Role of Executive Function on Adaptive Behavior Skills

J. L. Mussey[1], *K. M. Dudley*[2] *and L. R. Guy*[1], *(1)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (2)TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background:
Adaptive behavior abilities are the real-world everyday skills needed for independent living and social functioning, and are often impaired in individuals with ASD, even in those without co-occurring intellectual disability (ID). Impaired adaptive behavior skills have been shown to predict adult outcome over and above intellectual level, highlighting the critical importance for intervention in this area (Klinger et al., 2015 IMFAR panel presentation). In order to better understand the cognitive factors that impact adaptive functioning, research by Pugliese et al. (2014) has documented weaknesses in executive function (EF) skills, particularly initiation, working memory, organization of materials, and mental flexibility were associated with more impaired adaptive functioning.
Objectives:
The aim of the current study is to support and expand the previous work showing a relationship between EF and adaptive behavior in four ways: 1) using a different adaptive behavior measure, the Adaptive Behavior Assessment System (domains = Conceptual, Social, Practical) as most previous research has used the Vineland Adaptive Behavior Scales (domains = Communication, Daily Living, Socialization); 2) extending the age range across the lifespan to include both children and older adults; 3) including a measure of comorbid psychopathology; and 4) including a clinical non-ASD comparison group.
Methods:
This IRB-approved study is a record review of diagnostic evaluations of a clinically-referred population ages 5-66 years seen at a university-affiliated, community-based outpatient clinic. The ADOS-2 and experienced clinical judgment were used to determine ASD diagnosis, and the SRS-2 was used to describe ASD symptom severity. A standardized age-appropriate IQ measure was also administered. EF skills were assessed by parent/teacher/informant report on the BRIEF. The Achenbach scales for children and adults were used to assess co-occurring psychopathology.
Results:
Data collection and analyses are ongoing with a total anticipated n = 80-100. Current n = 46; children ages 5-18 (n=25) and adults ages 19-66 (n=21) with Full Scale IQ ranging from 57-138 (8% diagnosed with ID). 60% met ASD criteria while 40% received other diagnoses instead (e.g., anxiety, depression or ADHD). Preliminary analyses show a significant correlation between adaptive behavior composite and overall EF (r = -.71, p = .001) for those with ASD. In contrast, in the clinical non-ASD group, this relationship was not significant despite also having low adaptive and EF scores (p's > .29). Hierarchical regressions will be run to examine the contributions of age, IQ, EF, and comorbid psychopathology to adaptive behavior. Analyses for individual subgroups will be performed including stratifications across age.
Conclusions:
Preliminary data show relationship between EF and adaptive behavior skills is particularly important in ASD as compared to other developmental and psychiatric disorders. A better understanding of the cognitive and emotional processes that contribute to adaptive behavior can inform interventions that will likely lead to a better outcome for individuals with ASD. Intervention techniques targeting EF skills look promising. One such strategy is Structured TEACCHing, an evidence-based intervention framework that provides supports for deficits in several aspects of EF skills.

2:52 **157.002** Educational Implications of Auditory Processing Deficits in Students with High-Functioning Autism Spectrum Disorders

L. E. Swain-Lerro[1,2], *N. S. McIntyre*[2], *M. C. Zajic*[2], *P. C. Mundy*[3], *J. B. McCauley*[4], *H. K. Schiltz*[5] *and T. Oswald*[4], *(1)School of Education, UC Davis, Davis, CA, (2)University of California at Davis MIND Institute, Davis, CA, (3)Education and Psychiatry, University of California at Davis, Sacramento, CA, (4)University of California at Davis MIND Institute, Sacramento, CA, (5)Human Development, University of California at Davis, Davis, CA*

Background: Reading comprehension and math problem solving difficulties are areas of weakness that impact the academic success of students with higher functioning Autism Spectrum Disorder (HFASD). These academic difficulties are also common to students who suffer from Auditory processing disorders. Imaging studies have reported auditory abnormalities in individuals with autism. Few if any, studies, however, have investigated if auditory abnormities are related to educational difficulties in students with HFASD.
Objectives: This issue was addressed by: 1) Examining if 9- to 17-year-old HFASD students display more evidence auditory processing deficits than clinical and typical control samples, 2) Examining if auditory processing was associated with deficits in reading comprehension in the samples of students.
Methods: A sample of 138 students in four groups HFASD, ADHD, HFASD+ADHD symptoms, and typical development participated in this study. (Table 1). ASD symptoms were confirmed with the ADOS (cutoff score > 7) and ADHD symptoms were confirmed with the Conners-3 parent report (cutoff score >70). Audiological processing was assessed with the SCAN-3:C Tests for Auditory Processing Disorders for Children and reading comprehension was assessed as a latent variable assessed with both the Gray Oral Reading Tests-5 (GORT) and the Qualitative Reading Inventory-4 (QRI).
Results: A repeated measures MANCOVA with IQ as a covariate for the SCAN subtests [Auditory Figure Ground, Filtered Words, Competing Words Directed Ears, Competing Sentences, Competing Words, and Time Compressed Sentences] revealed a significant Diagnostic Group effect, Wilks Lambda= .66, F (21,365) = 2.66, p < 001, eta squared = .13. Pairwise comparisons revealed impairments of the HFASD+ADHD group from the TD and ADHD group on five of the six SCAN measures (see Figure 1). The ASD sample differed from the TD group on four measures but only differed from the ADHD and TD group on Time Compressed Sentences. The HFASD+ADHD group displayed the most consistent pattern of correlations of Reading Comprehension with the SCAN: Auditory Figure Ground r(45) = .43 p < .01, Auditory Reasoning, r(45) = .34 p < .02, Pseudo Word Decoding, r(44) = .33 p < .03, Competing Words Directed Ear r(43) = .40 p < .01, Auditory Reasoning r(43) = .37 p < .02, and Recalling Sentences, r(38) = .42 p < .01. ADOS Total Score was also correlated with SCAN Scores in the HFASD and HFASD+ADHD samples, r(44) = -.30 & -.36, p < .05, respectively.
Conclusions: This study provides evidence that Auditory Processing deficits may be common in HFASD students, related to ADOS symptoms, and contributes to the academic difficulties experienced by these children in elementary and secondary school. The HFASD+ADHD children displayed the greatest impact of Auditory Processing disturbances. Further research is needed to disentangle the degree to which auditory or attention impairments contribute to the poor SCAN responses in this subgroup of children with HFASD.

Table 1

Demographic Mean Data (with Standard Deviations in Parentheses)

	Diagnostic Group			
Variable	HFASD (N=22)	ADHD (N=33)	HFASD+ADHD (N=44)	TD (N=39)
Age	11.19 (2.08)	11.87 (2.36)	11.46 (2.04)	11.46 (2.31)
FIQ [a]	101.25 (13.65)	100.28 (15.74)	99.55 (13.69)	114.85 (13.51)
SCQ Total [a, c, e,f]	19.60 (8.43)	6.53 (5.96)	21.70 (6.32)	2.38 (2.18)

3:04 **157.003** Metacognitive Support for Mathematics Learning in Children with Autism Spectrum Disorder (ASD)

K. L. Maras[1], *M. Brosnan*[2] *and T. Gamble*[2], *(1)Claverton Down, University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom*

Background:
Metacognition is awareness of one's own cognition, sometimes termed 'learning how to learn'. One of the best predictors of mathematical achievement is metacognition, predicting outcomes better than IQ (Iacalano et al., 2014). There are different aspects of metacognition that underpin learning, such as monitoring when or where mistakes are made (metacognitive monitoring) and adjusting learning strategies accordingly (metacognitive regulation). Metacognitive tuition enhances mathematics learning among individuals within *and* below the 'normal' range of mathematical ability (Maxwell et al., 2014).
On average, mathematics ability is substantially lower among people with Autism Spectrum Disorder (ASD) than would be expected on the basis of IQ (Mayes & Calhoun, 2003; 2006). Previous research has shown that those with ASD are likely to make two distinct metacognitive monitoring errors when learning mathematical skills. Firstly, they are more likely than children without ASD to think that they have an answer correct when in fact they have answered it wrongly. Secondly, when informed that they have made an error, those with ASD are more likely to report that they meant to make the error (Brosnan et al., 2015; see also Williams & Happé., 2010). This indicates that learners with ASD need specific support for metacognitive monitoring (error awareness, judgments, intentions) in order to effectively adapt their learning strategies (metacognitive regulation).
Objectives:
The aim of the current research was to test computer-based metacognitive support for learners with ASD.

Methods:
Participants: 40 participants with ASD (mean age 13.3 years) and age- and ability-matched typical comparisons.
We developed a “maths challenge” computer program whereby, to maximise points won, participants needed to monitor their performance and adapt their strategy accordingly. The program comprised 7 levels of difficulty and each question answered correctly was worth points commensurate to that level. After each question, participants were asked metacognitive monitoring questions concerning whether they thought they had got the answer correct and whether they had meant to get the answer correct. Participants answered 4 blocks of 3 questions, beginning at level 4. After each block, participants were given the choice of whether to stay at the same level, move up a level to harder questions (worth more points if answered correctly), or move down a level (worth fewer points but easier) for the next bock until they had answered 12 questions in total. In the metacognitive support condition, continuous feedback was provided concerning the accuracy of each answer, and reinforcing the goal. This was absent in the ‘no support’ condition.
Results:
Participants with ASD demonstrated diminished metacognitive monitoring and they made more post-test intention errors (i.e., incorrectly attributing errors as intended). However, when provided with feedback about their performance and goal reminders, learners with ASD won more points by the end of the program than when no metacognitive support was provided (p <.05, d =3.36).
Conclusions:
Children with ASD employed more effective learning strategies when provided with the metacognitive support condition of the Maths Challenge program. Findings highlight the potential for metacognitive support to improve mathematics learning in classrooms.

3:16 **157.004** Vestibular Stimulation Improves Skill Learning in Minimally Verbal Children with ASD: A Comparative Study with ADHD and Typical Controls

G. Katz Nave[1], *Y. Adini*[2], *O. E. Hetzroni*[3] *and Y. S. Bonneh*[4], *(1)Special Education, University of Haifa, Haifa, Israel, (2)Vision Research Inst., Kiron, Israel, (3)University of Haifa, Haifa, Israel, (4)Bar-Ilan University, Ramat Gan, Israel*

Background: ASD and ADHD children share many symptomatic characteristics, such as deficits in sensory processing, attention and learning. All these may jeopardize motor skill learning, especially in the severe minimally-verbal individuals with ASD, who often fail to learn basic perceptual and motor skills for unknown reason. In the current study, we sought to characterize the skill learning deficit in ASD in comparison with ADHD and explore ways for improvement. Previous findings suggest beneficial effects of vestibular stimulation on sensory processing, attention and learning in the typical & ADHD populations, but the data regarding ASD are limited. Preliminary results from this study were reported in IMFAR last year, while the current report extends and consolidates the previous findings.
Objectives: To investigate the evolution in time of skill (sequence) learning and the modulatory effect of vestibular stimulation, in 3 groups of children ages 6-13, comparing minimally-verbal ASD with ADHD and typical development (TD) children.
Methods: All children (N=45) were trained on a touch version of the cognitive related visual-motor SRT task, with 10 short (<300 trials, few minutes) weekly practice sessions. In the task, a fixed sequence of 12 spatial locations, cyclically repeated 8 times in each block of trials, was introduced via visual cues on a touch tablet. The responses were made by rapidly touching the cued location with a finger, thus, unbeknown to the children, the cues introduced a sequence of lateral movements to be learned. The measures for learning were the median and the mean of the series response-time (RT). Each group was divided into two sub-groups, one of which received a vestibular stimulation prior to each training block.
Results: All groups showed gradual median RT improvement (Figure A) with significant speed gains across the training period. The ASD children (n=18) were overall slower (by ~200 ms), with initial intermittent pauses that required prompting to resume. Importantly, the ASD sub-group who received vestibular stimulation (n=10) had significantly larger median speed gains and fewer long pauses in comparison to ASD controls. Vestibular stimulation had no effect on TD and had a small reversed effect on the ADHD group.
Conclusions: These results suggest that vestibular stimulation has a positive effect on learning in minimally-verbal children with ASD, which may have important therapeutic implications. Furthermore, contrary to some previous findings, minimally-verbal children with ASD can acquire and consolidate procedural skills with few short training sessions, spread over weeks, and with a similar time course as non-ASD controls. We suggest cortical arousal as a possible mediating variable, explaining the vestibular effect. For the ADHD group, the lack of positive vestibular effect could be attributed to the short and non-demanding practice sessions we used. For the ASD group, increased arousal may overcome their known deficits in disengagement and reorienting of attention and enhance sequence learning.

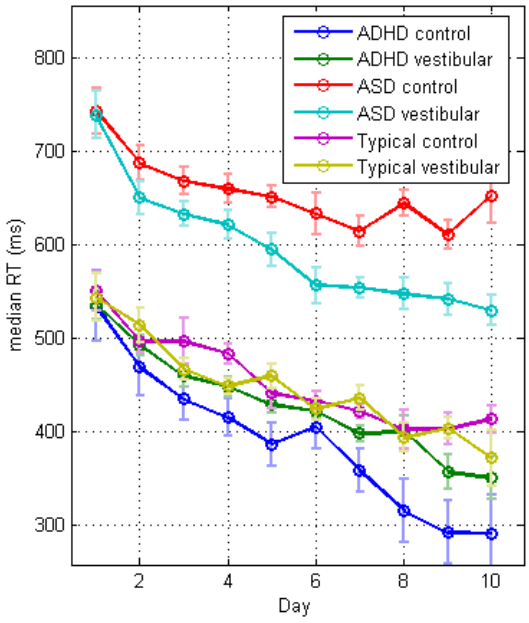

Figure A - The time-course of sequence learning (touch-SRT) in 6 groups of children. Median reaction times (RT) normalized and averaged across observers are plotted as a function of the training day. Error bars denote 1 SE of the average.

Panel Session
158 - Dissecting Comorbidity in ASD: Focus on Inattention, Hyperactivity and Impulsivity
3:30 PM - 5:30 PM - Room 307

Panel Chair: Adriana Di Martino, *Child Study Center, NYU Langone Medical Center, New York, NY*

Overwhelming evidence indicates that inattention, hyperactivity and impulsivity (I/HI), core characteristics of attention-deficit/hyperactivity disorder (ADHD), are among the most frequent psychiatric comorbidities in Autism Spectrum Disorder (ASD). Such comorbidity further compromises functioning and poses challenges for treatment. Yet, little is known regarding the mechanisms underlying the co-occurrence of ASD and I/HI symptoms. For example, it remains unclear if I/HI symptoms in ASD stem from distinct mechanism(s) from those in ADHD and whether assessment and treatment protocols should be identical. Research aiming to attain such knowledge can help advance neuroscientific models of ASD heterogeneity. Further, this work represents a critical step towards identifying individuals at greater risk of I/HI comorbidity, those more likely to respond to currently available treatments, and informing treatment development. This panel integrates state-of-the-art clinical and brain imaging research aimed to provide a nuanced understanding of the overlap of I/HI and ASD. In presenting empirical findings, we will highlight the processes of identifying clinically meaningful markers able to ‘stratify’ children with ASD and I/HI. The working

framework that we will present can inform a range of other efforts addressing sources of heterogeneity in ASD related to psychiatric comorbidities.

3:30 **158.001** Social-Communication and Repetitive Behaviors in Children with ADHD

S. L. Bishop[1], *A. Havdahl*[2], *R. Grzadzinski*[3] *and C. Lord*[2], *(1)Department of Psychiatry, University of California San Francisco, San Francisco, CA, (2)Weill Cornell Medical College, White Plains, NY, (3)Center for Autism and the Developing Brain, New York, NY*

Background: ADHD-like difficulties are present in a significant number of children with ASD. Similarly, children with ADHD have high rates of social difficulties and some authors suggest that, for at least a sub-group of these children, ASD symptoms may be at the root of their social problems. Despite previous restrictions on diagnosing ADHD and ASD together in DSM-IV, recent studies suggest that as many as 50-60% of children with ASD have been given a community diagnosis of ADHD (Blumberg et al., 2015). Recognizing that many children with ASD do indeed have ADHD symptoms that are not fully accounted for by the ASD diagnosis, DSM-5 now allows formal diagnosis of both disorders together. However, many questions remain about the boundaries and overlaps of these two disorders that have major implications for clinicians and researchers.
Objectives: This presentation will discuss symptom overlap between ASD and ADHD, with a particular focus on ASD symptoms that appear to best differentiate the two groups.
Methods: In addition to a discussion of recent literature debating issues of common symptom dimensions in ASD and ADHD vs. actual diagnostic overlap vs. different manifestations of one overarching disorder, new data will be presented from two samples of school-age children (N=50 per sample, FIQ≥80) with ADHD and matched comparisons with ASD. Participants completed ASD symptom measures, including the Autism Diagnostic Interview-Revised, Autism Diagnostic Observation Schedule, and Social Responsiveness Scale, as well as measures of IQ and behavior problems. One group of children with ADHD was comprised of clinical referrals to ASD specialty clinics who ultimately received ADHD diagnoses; the other was a group of children with previous diagnoses of ADHD who were recruited for a research study.
Results: Children with ADHD received elevated scores across standardized ASD symptom measures, with a significant minority meeting cut-offs on one or more of the instruments. Not surprisingly, children of parents seen at ASD specialty clinics (who were mostly self-referred) received much higher scores on parent-report measures of ASD symptoms than children with previous diagnoses of ADHD recruited. However, the two groups of children with ADHD were similar in terms of clinician-observed social-communication impairments and restricted and repetitive behaviors. Moreover, according to parents and clinicians, both clinically-referred and research-recruited children with ADHD exhibited particular impairments in higher level social behaviors (e.g., conversation, quality of overtures and responses), while impairments in basic social communication skills (e.g., eye contact, facial expressions) and social motivation were less frequently impaired in these children. Scores on the different ASD symptom measures showed different relationships with age, IQ, language, and behavior problems that sometimes varied between the two diagnostic groups.
Conclusions: These results raise several important points related to differential and comorbid diagnosis of ASD and ADHD in clinic settings. For researchers, information about how children with ADHD (without ASD) perform on ASD symptom measures must be carefully considered in studies designed to understand shared mechanisms in ASD and ADHD. Coordinated, multidisciplinary efforts to develop behavioral and biological measures of dimensions relevant to both disorders should be prioritized.

4:00 **158.002** Imaging the Connectome in Autism and ADHD: What' s Distinct and What's Shared?

A. Di Martino*, NYU Child Study Center, New York, NY*

Background: Although Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) were conceptualized as distinct disorders, their symptoms co-occur more often than expected by the prevalence of each alone. On one hand, this is consistent with recent models highlighting the dimensional nature of psychopathological domains across diagnostic categories. On the other hand, whether these co- occurring conditions stem from similar underlying biological mechanisms remains unknown. Recent advances suggest pediatric imaging is well positioned to address this question. In particular, several lines of evidence support the notion that both ASD and ADHD are neurodevelopmental connectopathies, i.e., disorders that stem from anomalies in the connections between brain regions, rather than from localized anomalies. Unfortunately, however, with a few exceptions, most brain imaging studies have examined individuals with ADHD and ASD separately.
Objectives: To present our empirical work examining the extent to which abnormalities in the functional architecture of the connectome is shared between ASD and ADHD.
Methods: Findings from resting-state fMRI studies of over 150 children with ASD, ADHD and typically developing controls (aged 7-13 years) stratified by symptom domains will be presented and integrated with the current literature.
Results: Results from a full-brain exploration of the functional connectome using network centrality identified several loci of dysconnections; some appeared specific to ADHD or ASD, others were shared between these conditions. When we accounted for ADHD comorbidity in children with ASD, we identified ADHD-related network abnormalities beyond categorical diagnoses. Specifically, children with ADHD and those with ASD and comorbid ADHD showed increased degree centrality in cognitive and motor striatal regions relative to either ASD without ADHD comorbidity or TDC. Notably, the degree of abnormal connectivity was significantly related to dimensional measures of ADHD symptom severity. This initial study was not designed to also assess autistic traits in both children with ASD and ADHD. Accordingly, we examined functional connectivity between two 'social brain' nodes in an extended sample of children with ADHD and ASD. We found that reduced connectivity between the right fusiform face area and rostral anterior cingulate was reduced in children with ADHD presenting autistic traits similarly to those with ASD, regardless of ADHD comorbidity.
Conclusions: This initial work illustrates the utility of eschewing extreme comparisons (i.e., only focusing on ASD vs. TDC) as it allows identifying potential biomarkers specific to and shared across psychiatric conditions. When this is combined with stratifying participants as a function of the degree of psychopathology, additional shared dysfunctions are identified. This suggests that hybrid models of psychopathology (categorical AND dimensional) should be considered for brain imaging analyses as well as for identification and treatment.

4:30 **158.003** Dimensional Analysis of Executive Dysfunction Comorbidity in ASD and ADHD

C. J. Vaidya[1], *X. You*[2], *M. Norr*[3], *E. Murphy*[3], *W. D. Gaillard*[2] *and L. Kenworthy*[4], *(1)Department of Psychology, Georgetown University, Washington, DC, (2)Children's Research Institute, Childrens National Medical Center, Washington, DC, (3)Department of Psychology, Georgetown University, Washington D.C., DC, (4)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: One challenge to understanding the neural basis of executive dysfunction comorbidity between Attention Deficit Hyperactivity Disorder (ADHD) and Autism Spectrum Disorder (ASD) is that executive function (EF) is multidimensional and extent of impairment highly heterogeneous within each disorder. Further, EF abilities vary greatly among typically developing children as well. Thus, which EF dimensions are most relevant to comorbidity is elusive.
Objectives: We first applied a novel data-driven graph theory method, community detection, to identify relevant EF dimensions across ADHD, ASD, and control children, and then examined their neural basis using task-based functional magnetic resonance imaging (fMRI). Our fMRI tasks were designed with the premise that controlling attention in an adaptive and flexible manner subserves EF.
Methods: We included 114 7-14 year-old children matched for age and IQ (35 ASD, 20 ADHD, 59 controls) and collected parent-report of 10 measures, Inattention and Hyperactivity/Impulsivity from ADHD Rating scale and 8 subscales selected from the BRIEF (Inhibit, Shift, Emotion Control, Initiate, Working Memory, Plan/Organize, Organization of materials, Monitor). Community detection was applied using a weight-conserving modularity algorithm not dependent on threshold, yielding 3 communities: #1 defined by worse planning and organizing but relatively better cognitive flexibility and hyperactivity/impulsivity (21 ASD, 6 ADHD, 29 Controls); #2 defined by worse cognitive flexibility but relatively better planning/organizing and hyperactivity/impulsivity (12 ASD, 4 ADHD, 16 controls); and # 3 defined by worse hyperactivity/impulsivity but relatively better planning organizing and cognitive flexibility (2 ASD, 10 ADHD, 14 Controls). Imaging was performed at 3T during 2 runs of a shape-classification task with right-hand response, in which distracters were flashed in the periphery. Runs differed in task-context, the first being stimulus-driven as distractors were irrelevant to the task, and the second requiring top-down control as a distractor was designated as target requiring left-hand response. Activation difference between the first to second run reflected attentional modulation by task-context, termed adaptive flexibility. Images were slice-time and motion-corrected, normalized to EPI template and resliced to 3mm, smoothed with 8mm FWHM and using stringent motion-criteria retained 88 subjects (51 controls, 26 ASD and 16 ADHD). We identified regions reflecting adaptive flexibility by Run x Distractor interaction in whole-brain ANOVA in SPM 8 ($p < .05$ Monte Carlo corrected; $p<.001$, $k=28$ voxels). For each cluster ROI, hierarchical linear regression tested whether clusters accounted for more variance than DSM-based groups.
Results:
Significant Run x Distractor interaction was observed in visual attention regions, bilateral middle frontal gyrus, bilateral insula and putamen, bilateral SPL-TPJ and postcentral gyrus, dorsal ACC, SMA, precuneus, right MTG and left visual cortex and community-based grouping accounted for more variance in right TPJ ($p=.04$) and right MFG ($p=.029$) than DSM groups, with greatest flexibility-related activation for community #1, scoring best on measures of attention and flexibility and worse on planning/organizing.
Conclusions:
Our results suggest that executive dysfunction variability across ASD, ADHD and control children is better conceptualized by three distinct functional profiles associated with variability in frontal-parietal cortical engagement during flexible attentional control

5:00 **158.004** ASD and Inattention: Multimodal Imaging Implicates the Salience Network

B. E. Yerys[1], *M. G. Mosner*[2], *L. Antezana*[3], *L. Kenworthy*[4], *B. Tunc*[5], *T. Satterthwaite*[5], *R. Verma*[6], *W. D. Gaillard*[7], *C. J. Vaidya*[8], *C. Davatzikos*[5] *and R. T. Schultz*[9], *(1)The Center for Autism Research, Philadelphia, PA, (2)University of North Carolina at Chapel Hill, Carrboro, NC, (3)Virginia Tech, Blacksburg, VA, (4)Children's Research Institute, Children's National Medical Center, Rockville, MD, (5)University of Pennsylvania, Philadelphia, PA, (6)Center for Biomedical Image Computing and Analytics, University of Pennsylvania, Philadelphia, PA, (7)Children's Research Institute, Childrens National Medical Center, Washington, DC, (8)Department of Psychology, Georgetown University, Washington, DC, (9)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Attention impairments are common in youth with autism spectrum disorder (ASD), and these impairments are associated with a number of negative outcomes. While stimulants are effective in reducing attention impairments, fewer children with ASD responded positively to stimulants (~50%) compared to children with attention deficit/hyperactivity disorder (70-90%). This suggests that in a sizable portion of children with ASD inattention may have a different underlying neural basis. There is limited data on the neural basis of inattention in the context of ASD across multiple imaging modalities, such as functional MRI (fMRI), resting state MRI (rsMRI), and diffusion tensor imaging (DTI).
Objectives: To characterize the neural basis of inattention symptoms in children with ASD using a modified flanker fMRI task, rsMRI, and DTI.
Methods: A total of 146 youth with ASD and 113 typically developing controls were enrolled across all three modalities. The flanker fMRI task (ASD n=36; TDC n=24) had three conditions: Neutral, Incongruent, and Congruent. Each trial started with a middle arrow surrounded by flanking stimuli. Participants responded to the direction of a middle arrow and ignored flanking diamonds (Neutral), flanking arrows pointing in the opposite (Incongruent), or the same direction (Congruent) as the target. We utilized a novel multivariate pattern analysis with the Interference Suppression contrast (Incongruent vs. Neutral) to identify unique brain signatures in the ASD group relative to the TDC group. For resting state data (ASD n=83; TDC n=83) and DTI data (ASD n=140; TDC n=109) we examined within and cross-network connectivity for regions distinguishing ASD subgroups in the fMRI analysis.
Results: The multivariate analysis found two distinct clusters within the ASD group. Cluster 1 was characterized by a prominent difference in the dorsal anterior cingulate that falls within the salience network, as well as middle cingulate, primary motor, left dorso- and ventrolateral prefrontal cortex, left orbitofrontal cortex, bilateral thalamus, bilateral hippocampus, and bilateral cerebellum. Cluster 2 was characterized by differences in the left inferior frontal and inferior parietal cortices associated with language, and the precuneus. Cluster 1 showed medium-to-large effects for more severe attention impairments and a larger interference suppression effect (RT) on the Flanker task. Resting state analyses demonstrated that the ASD group had lower within-network functional connectivity in the salience network, and this correlated with Inattention symptoms ($r=-.29$, $p<.05$). This correlation increased to $r=-.50$, $p<.05$ when probing the subset in Cluster 1. Finally, the DTI data revealed significantly reduced tracks between the salience and dorsal attention networks in youth with ASD and 6+ Inattention symptoms compared to the TDC group and youth with ASD and <6 Inattention symptoms.
Conclusions: Deviations in the salience network's function, and functional and structural connectivity associates with greater inattention symptoms in youth with ASD. Interestingly the salience network is not a primary target of stimulant medication. Thus this initial work provides insight into the neural basis of inattention for children with ASD. Moreover, we hypothesize the salience network may play a greater role for those who do not respond to stimulants.

Panel Session
159 - Translational Approaches to Abnormal Communication in ASD
3:30 PM - 5:30 PM - Hall B

Panel Chair: Laura Morett, *University of Pittsburgh, Pittsburgh, PA*

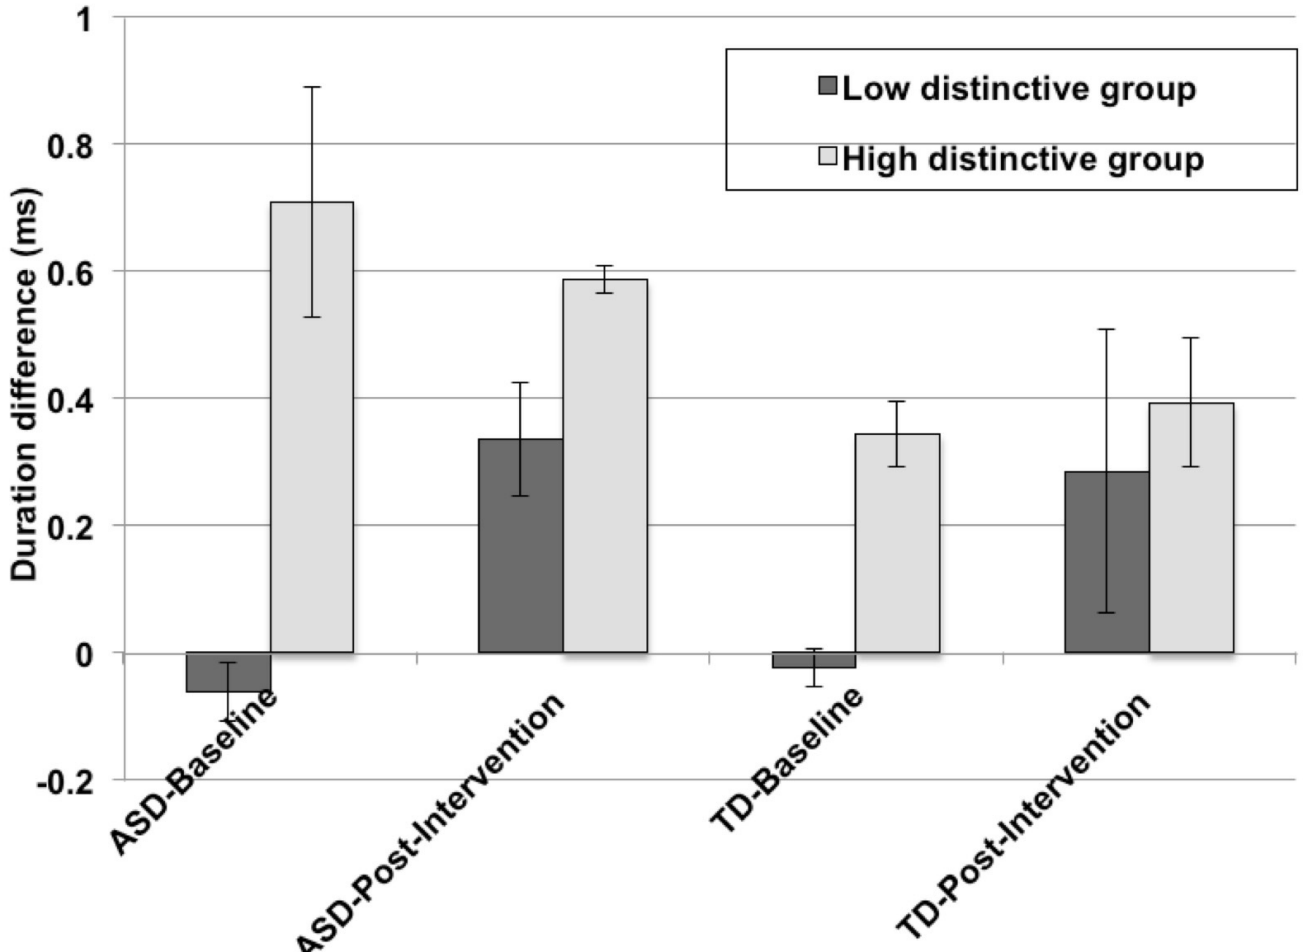
Discussant: Joshua Diehl, *LOGAN Community Resources, Inc., South Bend, IN*

According to the DSM-5, social communication impairments are one of two core diagnostic criteria for autism spectrum disorder (ASD), resulting in reduced ability to function independently. The goal of this panel is to show how basic research findings on communication deficits in ASD can improve the assessment and treatment of these impairments. This panel will present research on several aspects of abnormal communication in ASD, with particular attention to implications for diagnosis and treatment. One strand of research will focus on the use of vivo brain imaging techniques to reveal biomarkers of abnormal auditory processing, emotional language comprehension, and temporal gesture-speech integration. The ability of these biomarkers to improve impairment detection, individual stratification, and assessment of treatment efficacy will be discussed. Another strand of research will demonstrate the efficacy of a brief, low-cost intervention providing explicit instruction in prosodic phrasing. The implications of this intervention for theories of impaired communication in ASD will be discussed. A discussant who conducts research on communication in ASD and advises an organization providing evidence-based treatments for communication deficits in ASD will enrich discussion of the translational significance of the research presented in this panel, ensuring its informativeness for scientists, practitioners, and stakeholders alike.

3:30 **159.001** A Brief, Low-Cost Intervention for Prosodic Phrasing in High-Functioning ASD: Translating Science into Treatment

I. M. Eigsti[1] *and J. Mayo*[2]*, (1)University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Atypical prosody is frequently reported in autism spectrum disorder (ASD), and deficits have significant negative consequences for social and occupational functioning. They are also persistent: Even individuals who attain average expressive and receptive language skills (per standardized assessment) often have atypical prosody. Though novel methods have been developed (e.g., iPad applications), there is limited empirical evidence for these or other interventions for expressive prosody in ASD; this evidence points to the efficacy of explicit training on the nature and use of supra-linguistic cues, including prosody.
Objectives: We examined spontaneous ("baseline") production of prosodic cues, and compared these to productions following a brief intervention involving *explicit discussions* of prosody and opportunities for structured imitation and practice.
Methods: Participants included adolescents with ASD and typical development (TD; n=15 per group). Groups did not differ in age, IQ (>80), or gender, p's > .50. Participants were told to instruct a "partner" (a research assistant) to perform actions using small toys (Snedeker & Yuan, 2008). Eight critical trials had syntactically ambiguous phrasing; to provide a clear instruction, subjects had to rely on prosodic cues (*pause lengthening, clause duration*). We asked whether subjects were aware of the syntactic ambiguity, and what strategies they employed for disambiguation. Subjects then participated in a five-minute intervention, consisting of visual slides with a voiceover, that gave direct instruction to clarify the presence of the ambiguity, provided explicit instruction about prosodic phrasing, and prompted subjects to imitate prosodic phrasing. Finally, subjects completed "post-intervention" trials containing the same syntactic ambiguity (with trial-unique stimuli). Trials were recorded and analyzed using Praat. In addition, naïve college student raters listened to recordings and chose a syntactic match for each.
Results: Interestingly, there were *no* mean group differences in acoustic variables, at baseline; naïve raters were at chance in interpreting the ambiguity. Following the intervention, *all* participants increased pause length and clause duration, and raters were significantly *better* than chance at interpreting the ambiguity. While there were no mean group differences, there was a subset of participants, in the ASD only, who were unaware of the ambiguity. Following the intervention, naïve raters were above chance in interpreting productions of the "unaware" group. Also, a subset of subjects across groups ("low distinctiveness") was initially ineffective at producing prosodic cues; this subset was indistinguishable from the "high distinctive" group following intervention (Figure 1).
Conclusions: Results suggested intact groupwise performance for expressive syntactic prosody, consistent with reports that atypical prosody is not universal in ASD (Shriberg et al., 2001). Acoustic analyses indicated no group differences at baseline or after intervention. However, a subset of participants with ASD was initially unable to use prosodic cues effectively; they made *significant gains* in prosodic phrasing following intervention. Participants in *both* ASD and TD groups demonstrated more effective expressive prosodic phrasing following a brief, targeted intervention. Future research must examine generalizability of these findings to lower-functioning individuals and to other syntactic phrases, and efficacy of long-term retention. These promising results suggest that a low-cost, brief intervention may yield clinically-meaningful effects.



3:55 **159.002** MEG Measures of Auditory Processing in ASD: Prognostic Biomarkers

T. P. Roberts[1,2], *R. G. Port*[2], *L. Blaskey*[1] *and J. C. Edgar*[1], *(1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)Neuroscience Graduate Group, Biomedical Graduate Studies, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Biomarkers for ASD have been discussed in terms of their potential *diagnostic* utility and as a biologically-based rationale for population *stratification* with potential implications for patient management. Among a broad spectrum of approaches, candidate measures proposed as such biomarkers derive from imaging and, promisingly, electrophysiologic techniques (such as EEG and MEG). The latter have attractive features in terms of high temporal resolution, sensitivity for neuronal electrical activity and, importantly, mechanistic interpretation including anomalies of central conduction velocity and local circuitry functionality. This study extends prior studies of auditory processing using MEG and specifically focuses on *latency* and *spectrotemporal* indices (gamma-band oscillatory activity) as prognostic biomarkers in a *longitudinal*design over up to 5 years.
Objectives: To determine whether MEG measures of auditory processing, specifically the "M100" component latency and the evoked gamma-band power mature over a 2-5 year observation period, whether they are associated with behavioral measures, and whether baseline measures predict unique variance at follow-up.
Methods:
36 children (27 ASD, 9 TD, mean age 8yrs) underwent MEG examination (including auditory evoked responses) and clinical behavioral assessment (including ADOS, SRS, CELF-4 and IQ). 2-5yers later they repeated the combination assessment. Briefly, MEG assessments included characterization of the auditory evoked M100 response latency elicited by sinusoidal tone stimuli presented binaurally at 45dB SL while subjects underwent whole head MEG using a 275-channel device. Clinical/behavioral assessments were used to confirm ASD diagnosis as well as score dimensionally axes of autism spectrum (using the social responsiveness scale, SRS), language impairment (CELF-4) and general cognitive ability (WISC-IV). Linear mixed modeling was used to assess the association between MEG and behavioral measures. Hierarchical regression was used to assess the predictive value of baseline MEG in determining follow-up behavioral scores *above and beyond* that predicted by baseline scores and age alone.
Results: Consistent with previous reports, a main effect of Diagnosis on M100 latency (TD=119±7.9ms; ASD=139±5.0 ms; p <0.05) and gamma-band activity (TD=61.5±6.4% change from baseline; ASD=38.4±4.7%; p<0.01) was seen. Maturational shortening of M100 latency and increase in gamma-band activity was also observed over the 2-5year follow-up.
M100 latency showed a significant association with SRS, with longer latencies associated with higher scores (r=0.53, p<0.001). No association was observed between M100 latency and scores of language or general cognitive ability. Baseline M100 latencies did, however, predict additional variance in follow-up language (CELF-4) (p<0.05) and cognitive (WISC-IV) measures in a model that included baseline values of the behavioral measures.
Conclusions: MEG measures of auditory processing, including temporal and spectrotemporal (gamma-band) indices offer *prognostic* insight and behavioral correlation, in addition to their previously-suggested roles in diagnosis and stratification. The multiple biomarker roles served by such measures of neuronal function in ASD, coupled with suggested biological underpinnings and evidence of translatability to preclinical models, enhance the potential value of these measures in evaluating and characterizing the development of brain activity and behavioral sequelae in children with ASD.

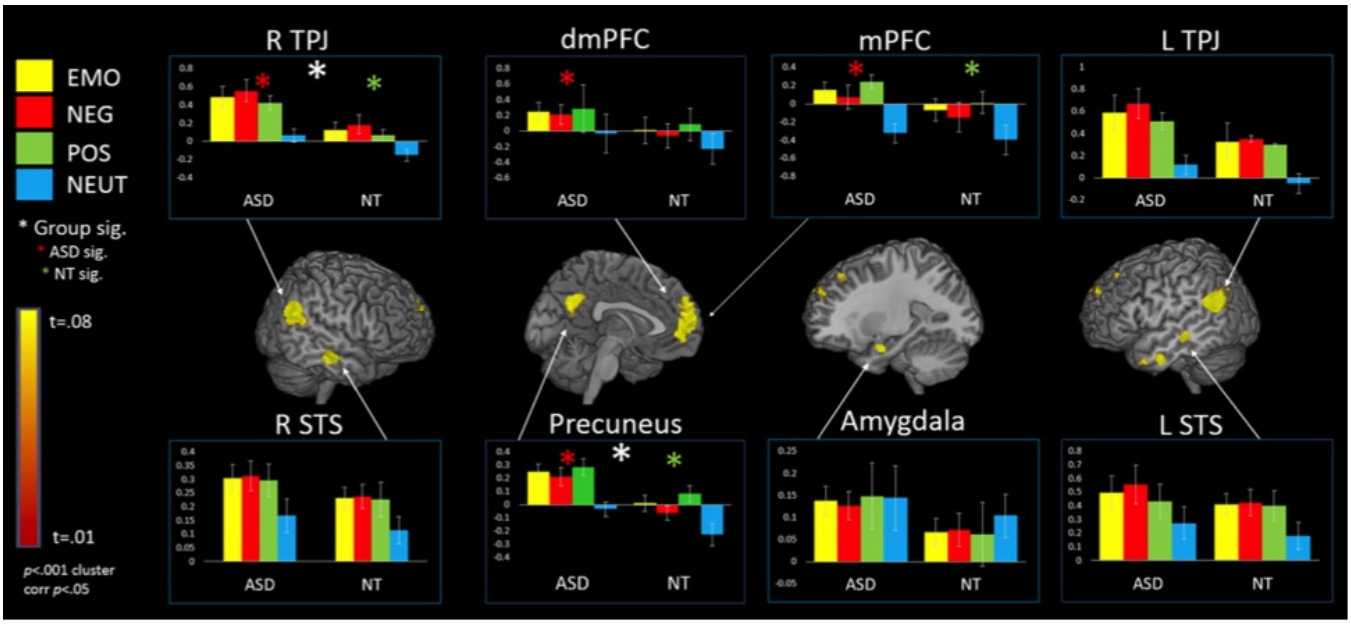
4:20 **159.003** Emotional Language Processing in Individuals with and without Autism

L. A. Sand[1], *E. Redcay*[2], *T. Zeffiro*[3] *and D. J. Bolger*[1], *(1)Human Development & Quantitative Methodology, University of Maryland, College Park, MD, (2)Department of Psychology, University of Maryland, College Park, MD, (3)Neurometrika, Potomac, MD*

Background: A fundamental aspect of successful social interactions is the ability to accurately infer others' intent through verbal communication, often including information related to the speaker's feelings. Autism (ASD) is characterized by atypical language and social-emotional processing, including aberrant neural responses to socially-relevant stimuli like faces, eyes, and prosody. While findings are mixed regarding the nature of emotional language processing in autism, existing evidence suggests that comprehension skills are generally stronger than expressive abilities.
Objectives: We investigated whether the process of making emotional inferences from spoken language in autism is associated with atypical neural activity in the brain regions subserving emotion processing, including anterior cingulate cortex (aCC), medial- and ventromedial prefrontal cortex (mPFC, vmPFC), and amygdala. A secondary question involved whether autistic individuals engage compensatory activity in areas typically involved in inferential language processing, including aSTS, pCC, dorsal medial prefrontal cortex (dmPFC), inferior frontal gyrus (IFG), or the superior temporal gyrus (STG) bilaterally.
Methods: Functional MRI data was collected from 15 ASD individuals and 16 controls (NT; 15-30yrs) on an emotional inference task (EIT). Activity changes were estimated during two epochs: hearing positive, negative, and neutral scenarios, and during responses to a related T/F question. Accuracy and response time were recorded. We used an accelerated multiband (MB) echo planar imaging (EPI) protocol that provides both high temporal and spatial resolution, thus enabling more accurate measurement of functional responses.
Results: For both groups, behavioral and neural results show that participants' reactions varied depending on sentence valence and congruency, but with differential effects. Behaviorally, both groups showed overall faster and more accurate responses to emotional relative to neutral scenarios, as well as for congruent compared to incongruent judgments. However, in comparison to the typicals, the ASD group showed greater difficulty evidenced as slower and less accurate responses for incongruent judgements,

especially in the negative (RT: ASD 1.57sec, NT 1.23sec; accuracy: ASD 87.9%, NT 95.3%) and neutral (RT: ASD 1.66sec, NT 1.45sec; accuracy: ASD 86.3%, NT 93.2%) valence conditions. Brain responses of the ASD group also differed from controls. Our main findings reveal similar activity patterns between groups, but with significant between-group effects including increased activity in individuals with ASD in right TPJ and precuneus for emotional but not neutral scenarios. Brain-behavior correlations showed that greater recruitment of rSTS was related to better social abilities as measured by the “Empathy Quotient” (EQ) and “Reading the Mind in the Eyes” (MinE) in controls, but this effect was not seen in ASD. In the autism group, improved social skills from EQ, MinE and the Autism Quotient (AQ) predicted greater amygdala and mPFC activity.

Conclusions: Our results suggest that autistic individuals are able to correctly identify others’ feelings from language that lacks overt prosodic elements or emotionally-charged words. Furthermore, like neurotypical individuals, their neural activity patterns are enhanced to positive compared to neutral valence conditions. However, in contrast to typicals, the autism group showed overall greater task-related brain activity, possibly suggesting that the task is more effortful for them.



4:45 **159.004** Biomarkers of Abnormal Temporal Gesture-Speech Integration in ASD

L. Morett[1], *B. A. Coffman*[1], *Y. Li*[2,3], *B. Luna*[1] *and A. S. Ghuman*[1], *(1)University of Pittsburgh, Pittsburgh, PA, (2)Center for the Neural Basis of Cognition, Carnegie Mellon University, Pittsburgh, PA, (3)Department of Neurological Surgery, University of Pittsburgh, Pittsburgh, PA*

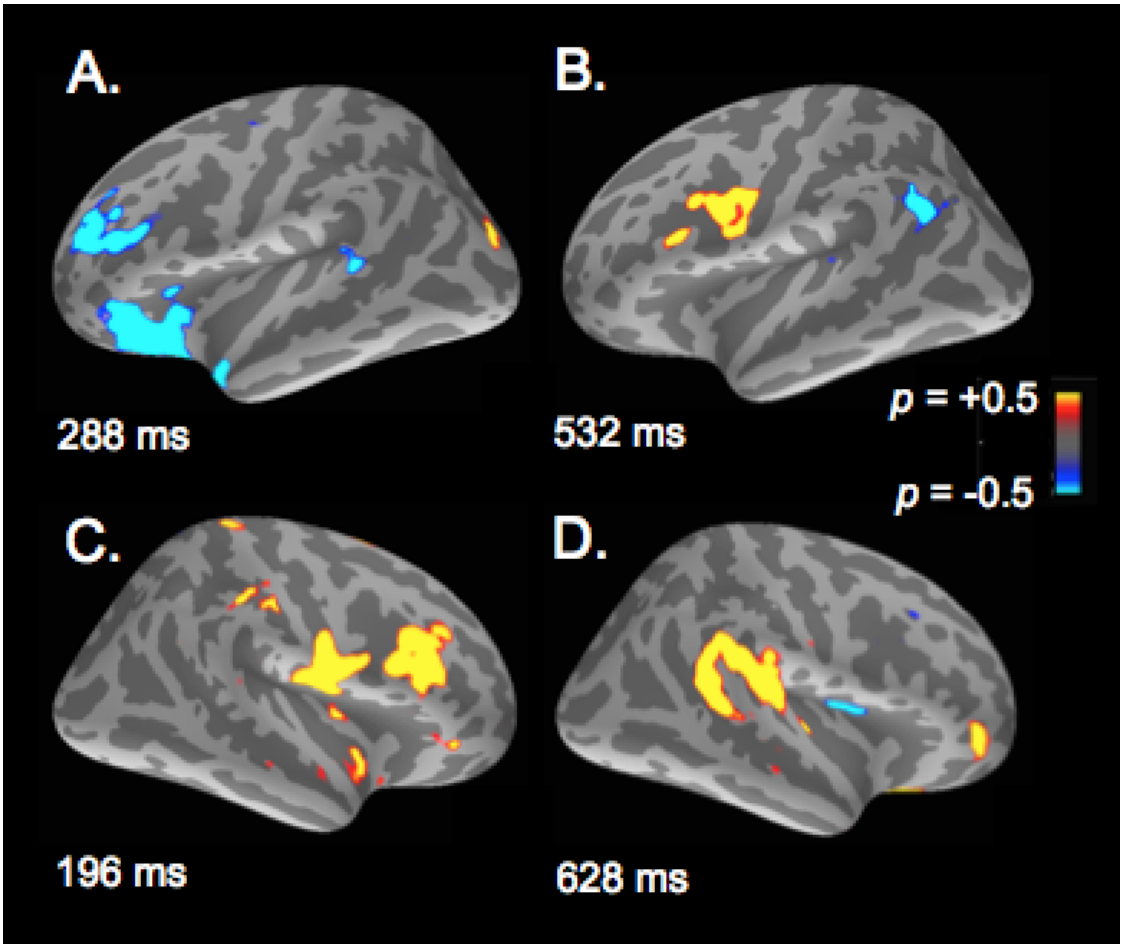
Background: Ineffective communication via speech and gesture (meaningful hand movements) is a primary diagnostic characteristic of Autism Spectrum Disorder (ASD). Typically developing (TD) individuals are highly sensitive to temporal asynchrony of gesture and speech. However, individuals with ASD show decreased sensitivity to temporal asynchrony of visual and verbal stimuli. Currently, it is unclear how this decreased sensitivity to temporal asynchrony affects gesture-speech integration in ASD, and whether it is reflected in the neural signal.

Objectives: The objectives of this research were (1) to examine temporal gesture-speech synchrony in ASD and (2) to determine whether neural activity reflects sensitivity to temporal gesture-speech asynchrony. It was predicted that gestures and speech produced by individuals with ASD would show greater temporal asynchrony than those of TD peers. Additionally, it was hypothesized that posterior superior temporal sulcus (pSTS) and inferior frontal gyrus (IFG), two brain regions critical to language and multimodal processing, would demonstrate sensitivity to temporal gesture-speech asynchrony.

Methods: Participants in study 1 included 18 high-functioning ASD and 23 TD individuals matched in age, gender, and verbal IQ (all *p*s < .05). In this study, participants viewed a brief cartoon video and retold its events to an experimenter while being tacitly video recorded. Gestures and speech were later transcribed and coded by two raters unaware of the experimental design and predictions (ICC=.79 for speech onset; .89 for gesture onset). To control for group differences in speech production, rate of gestures was normalized for speech production. Participants in study 2 included 15 TD individuals. In this study, participants viewed clips excerpted from a longer video of a speech, such that a beat (simple rhythmic) gesture always occurred at 1.5 s. Accompanying audio clips were presented either simultaneously with or 500 ms preceding video clips. Neural data was collected continuously using magnetoecepholagraphy (MEG), a neurophysiological method with high spatiotemporal accuracy, and was temporally synched to gesture onset for analysis.

Results: In study 1, individuals with ASD produced more temporally asynchronous gestures than TD individuals (p=.05). In study 2, less activity was observed in pSTC and IFG in left hemisphere during concurrent speech and gesture processing than during processing of speech preceding gesture by 500 ms ($p < .05$, corrected; see Fig. 1). In contrast, more activity was observed in these regions in right hemisphere during concurrent gesture-speech processing than during the processing of speech preceding gesture ($p < .05$, corrected).

Conclusions: The results of study 1 demonstrate greater temporal asynchrony in gesture-speech production in ASD than in TD, suggesting that insensitivity to temporal asynchrony in ASD is reflected in gesture-speech production. The results of study 2 show that activity in pSTC and IFG reflects sensitivity to temporal gesture-speech asynchrony. Furthermore, they indicate that laterality of activation in these regions reflects the directionality of this sensitivity. These results form the basis of future research that will use the methods employed in study 2 to examine the neural bases of temporal gesture-speech integration in ASD, which will reveal biomarkers of abnormal receptive communication in this disorder.



Panel Session
160 - The Well-Being and Potential Service Needs of Siblings of Youth with Autism Spectrum Disorder
3:30 PM - 5:30 PM - Room 308

Panel Chair: Megan Tudor, *Yale Child Study Center, Yale School of Medicine, New Haven, CT*

Discussant: Denis Sukhodolsky, *Yale Child Study Center, Yale School of Medicine, New Haven, CT*

As the number of youth with an autism spectrum disorder (ASD) diagnoses rises (Kim et al., 2011), the number of youth growing up with a brother or sister with ASD also multiplies. Research attempting to characterize these youth and identify distinctive patterns of their well-being and adjustment has yielded mixed and sometimes contradictory findings (e.g., Orsmond & Seltzer, 2007). This literature often examines the presence of a child with ASD in the family as a sole predictive factor of sibling outcomes, while ignoring other potentially relevant variables (e.g., Hodapp, Glidden, & Kaiser, 2005). This panel will aim to broaden the lens of sibling outcome research by exploring novel predictive factors, such as sibling relationships and maternal psychological functioning, which may inform sibling outcome pathways across families, rather than identify a singular sibling profile. Findings draw from parent and sibling-report in various contexts (e.g., across the lifespan, pre- and post- intervention groups). Ultimately, this panel will provide a framework for this "new wave" of sibling research that allows for a more multifaceted approach to studying both risk and resilience for siblings, as well as providing effective services for the subset of these youth that may be in need of clinical supports.

3:30 **160.001** Psychosocial Outcomes Among Adult Siblings of Individuals with ASD and Other Developmental Disorders: Support for Potential Risk/Protective Factors and Points of Intervention

T. S. Tomeny[1], *L. K. Baker*[1], *S. W. Eldred*[1], *J. A. Rankin*[1] *and T. D. Barry*[2], *(1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)Psychology, Washington State University, Pullman, WA*

Background: Typically-developing (TD) adult siblings are often tasked with caring for their siblings with ASD or other developmental disability, both during childhood and in adulthood (e.g., Heller & Kramer, 2009). Given genetic (e.g., broader autism phenotype) and environmental (e.g., increased burden) risk factors, conventional thinking suggests that TD adult siblings may be at increased risk for negative outcomes. However, research on TD child siblings has found wide variability in childhood psychosocial constructs (e.g., Meadan et al., 2010; Orsmond & Seltzer, 2007). These discrepancies suggest that negative outcomes only occur under certain conditions; however, little research has examined TD siblings during adulthood.
Objectives: This presentation aims to provide descriptive information about psychosocial outcomes among a sample of adult siblings of individuals with ASD and/or intellectual disabilities (IDs). Possible risk and protective factors and points of intervention will be discussed. Finally, examination of differences according to sibling disability type and indirect effects of diagnostic group inclusion through sibling relationship attitudes on psychosocial outcomes will be presented.
Methods: 105 TD siblings (*M*age = 33.04, *SD* = 14.13) completed a demographic form, the Depression Anxiety and Stress Scale (DASS; measure of distress in siblings), the Parentification Inventory (PI, measure of childhood parentification), the Interpersonal Support Evaluation List (ISEL, measure of social support), the Lifespan Sibling Relationship Scale (LSRS; measure of sibling relationship attitudes) and the Satisfaction with Life Scale (SLS; measure of life satisfaction).
Results: Descriptive statistics and correlations among the variables of interest will be presented to provide context. For specific mediation analyses, covariates were determined *a priori* and entered into the models where necessary. A series of multiple regression analyses revealed that sibling relationship attitudes predicted several outcomes in TD siblings across both groups: level of assistance provided, $\Delta F(5, 76) = 7.65$, $p = .01$, $\Delta R^2 = .07$; life satisfaction, $\Delta F(3, 78) = 6.39$, $p = .01$, $\Delta R^2 = .07$, depression $\Delta F(3, 77) = 9.33$, $p = .003$, $\Delta R^2 = .09$, and stress, $\Delta F(3, 78) = 4.78$, $p = .03$, $\Delta R^2 = .05$. TD siblings in the ASD group reported significantly fewer positive sibling relationship attitudes compared to siblings in the ID group. Using bootstrapping analytical methods via Hayes's PROCESS macro (Hayes, 2013), indirect effects of group membership on assistance [point estimate = -.93 (95% CI [-2.26, -.22])], depression [point estimate = 2.00 (95% CI [.52, 4.53])], and stress [point estimate = 1.52 (95% CI [.25, 3.61])] in TD siblings through sibling relationship attitudes were identified (Figure 1).
Conclusions: Overall, TD siblings' report of outcomes varied, with some differences related to the type of disability (ASD or ID) experienced by the affected sibling. Over and above demographic correlates, sibling relationship attitudes appear to be an important predictor of psychosocial outcomes among TD adult siblings. Moreover, the identified indirect effects suggest that sibling relationship attitudes may be a particularly salient point of intervention for improving sibling functioning, particularly among siblings of individuals with ASD. Clinical implications of other identified risk- and protective-factors (e.g., low or high social support) will also be discussed.

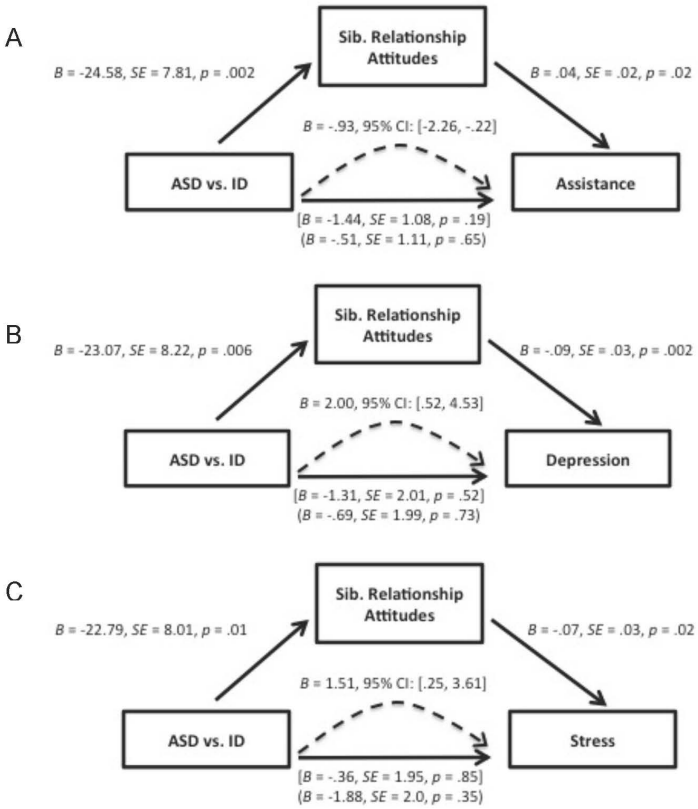


Figure 1. Mediated outcomes on TD sibling assistance provided (panel A), depression (panel B), and stress (panel C) showing indirect effects of group membership through sibling relationship attitudes. *Note:* Propensity scores were entered as a control variable for all three panels. For panel A, birth order, race (dichotomized: 1 = white, 0 = nonwhite), geographic distance, and sibling age difference (absolute value) were additional covariates. For panel B, TD sibling marital status (dichotomized: 1 = living with significant other, 0 = living alone) and TD sibling income were additional covariates. For panel C, birth order and TD sibling income were additional covariates. Unstandardized regression covariates are reported. Statistics in brackets show the total effect of the predictor on the outcome; statistics in parentheses show the direct effect of the predictor on the outcome, after controlling for the indirect effect of the mediator. Each indirect effect (depicted above each curved, dashed arrow) was significant based on an asymmetric 95% confidence interval with 5000 resamples with replacement (Hayes, 2013).

3:55 **160.002** Enhancing the Sibling Relationship: Outcomes of a Support Group for Brothers and Sisters of Children with Autism

M. Coffman[1], *A. Muskett*[1], *R. S. Factor*[1], *L. Delk*[1], *A. Trubanova*[2], *N. Kelso*[1], *A. Scarpa*[3], *J. A. Richey*[1] *and J. M. Wolf*[4], *(1)Virginia Tech, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (4)Yale Child Study Center, New Haven, CT*

Background:
Sibling relationships are typically the longest-lasting relationships in an individual's life. Siblings of children with autism spectrum disorder (ASD) often take on increased responsibility in the home and become the primary caregiver of their affected sibling in approximately 73% of cases (Gidden, 2007). These stressors may have negative impacts on the unaffected siblings (UAS), such as feelings of guilt or shame. Support groups specifically for this population remain limited (Tudor and Lerner, 2015).
Objectives:
In the current study, we present data from three 10-week support groups for UAS of children with ASD. We hypothesize that as a result of participating in the support group, UAS will a) develop a more positive relationship with their sibling with ASD, b) show a decrease in internalizing problems (e.g., depression and anxiety), and c) gain increased understanding of ASD.
Methods:

Sixteen children (ages 5-12) who have a brother or sister with ASD participated in one of four 10-week support groups based off of the SibShop model (Meyer, 1994). One group is currently in progress, and will be completed in December, 2015. As such, current data only include the three completed groups. Curriculum was developed to provide psychoeducation, problem-solving skills, and coping strategies. Parents and participants completed several questionnaires pre- and post, regarding the relationship between the UAS and the sibling with ASD the: Sibling Relationship Questionnaire, and Satisfaction with the Sibling Relationship Questionnaire. Parents reported on the UAS's internalizing symptoms on the Behavioral Assessment System for Children – 2. Participants completed a semi-structured interview to assess their understanding of ASD: The Understanding of Autism Interview.

Results:

Analysis of data from participants (N=12) indicate that UAS reported increased satisfaction with their relationship with their sibling with ASD (Cohen's *d*=2.4), but decreased pro-sibling behavior by their sibling with ASD (*d*=1.09). Parents noticed an increase in pro-sibling behavior from the UAS (*d*=0.5) and child with ASD (*d*=1.6). Parents reported that UAS showed increased adaptability (e.g., better ability to change plans; *d* =1.05). Additionally, pre-group interviews indicated that 25% of the participants thought that ASD could be 'caught,' although none of the children believed this after the conclusion of the group. Effect sizes, rather than *p* values are presented due to the low sample size, and as yet insignificant results.

Conclusions:

Participants noted improved satisfaction with their sibling and the relationship. This, coupled with the improved understanding of ASD, indicates that the support group provides adequate psychoeducation to help improve the sibling relationship. Parents observed an increase in UAS ability to change routines, as well as increased pro-sibling behavior from the sibling with ASD. Additionally, these results indicate that parents also noticed this improved relationship, including more positive interactions from both the UAS and their child with ASD.

Interestingly, UAS reported decreased pro-sibling behavior from their sibling with ASD. It could be possible that participant's increased understanding of autism led to reappraisal of their siblings' behavior, resulting in increased ability to take changes in stride, as well as improved perception of the sibling relationship.

4:20 **160.003** Quality of Sibling Relationships When One Child Has ASD: Parent-Child Agreement and Contributions of the Affected Vs. Unaffected Child

***J. M. Wolf**, Yale Child Study Center, New Haven, CT*

Background: Research suggests that the quality of the sibling relationship is impacted, both positively and negatively, when one sibling has autism spectrum disorder (ASD). While there is general agreement between parents and unaffected siblings regarding the quality of the sibling relationship, there is some evidence that unaffected siblings view the relationship more positively than do their parents (Rivers and Stoneman, 2003; Diener et al., 2015). However, the specific domains in which parents and siblings may differ have not previously been investigated. Furthermore, little research has examined the behaviors of affected vs. unaffected siblings that may differentially impact the sibling relationship.

Objectives: 1) To evaluate agreement between parents and unaffected siblings regarding the quality of the sibling relationship when one sibling has ASD. 2) To examine differences in the behaviors of affected vs. unaffected siblings within the context of the sibling relationship.

Methods: The Sibling Relationship Questionnaire (SRQ; Slomkowski et al., 2001) was administered to parents (N=32) and siblings (N=22) of children with ASD to evaluate the quality of the sibling relationship. The SRQ asks about the unaffected child's behaviors toward the affected child, as well as the affected child's behaviors toward the unaffected child, in both positive and negative domains.

Results: Responses of parents and unaffected siblings on the SRQ were positively correlated, suggesting general agreement in their ratings of sibling relationship quality. Likewise, there were few significant differences between parent and child ratings. The only exception was with regard to hitting behavior, in which children reported more hitting directed at them by their sibling with ASD than parents reported (p=.004). Both parents and children rated the unaffected child as demonstrating more positive behaviors within the sibling relationship than the affected child (parents: p=.002; children: p=.08). Specific positive behaviors exhibited by unaffected siblings tended to fall in the domains of providing help and support to the sibling with ASD. While overall negative behaviors did not differ between affected and unaffected siblings, unaffected siblings reported a trend toward being hit by their sibling with ASD more frequently than they themselves hit their sibling (p=.09).

Conclusions: Unaffected siblings exhibit more positive behaviors within the sibling relationship than do their siblings with ASD, largely in domains pertaining to help and support. This is consistent with prior literature suggesting that unaffected siblings often take on a caretaker role toward their sibling with ASD (Benderix & Sivberg, 2007; Angell et al., 2012; Diener et al 2015). Parents and siblings of children with ASD generally agree about the quality of the sibling relationship; however, there may be critical areas (e.g. aggression) in which siblings are perceiving challenges of which parents are not aware. Prior literature has suggested that aggression is a significant stressor for unaffected siblings (Ross & Cuskell, 2006), often causing siblings to feel unsafe (Benderix & Sivberg, 2007). This is an important target area of intervention, particularly if parents are unaware of the extent to which aggression is being directed at the unaffected sibling.

4:45 **160.004** Getting to Know Siblings of Youth with Autism Spectrum Disorder: Family Predictors and Clinical Outcomes

***M. Tudor**[1] and M. D. Lerner[2], (1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Stony Brook University, Stony Brook, NY*

Background: Current research findings remain unclear as to whether or not siblings of youth with ASD present with consistent emotional, behavioral, or social "adjustment" difficulties (e.g., Cuskelly, 1999). Many studies have attempted to examine what risks may be associated with this unique sibling experience, but no consistent clinical profile is supported, perhaps due to a narrow view of having a sibling with ASD as a risk factor for these youth (e.g., Orsmond & Seltzer, 2006; Stoneman, 2005). This current status of the literature is especially relevant in light of the growing number of therapy and support programs directed at siblings (Tudor & Lerner, 2015). Thus, there is an apparent need for a clearer understanding of of sibling functioning, as well as potential predictive factors thereof (McHale, Updegraff, & Feinberg, 2015).

Objectives: The goal of the current study was to examine family factors that may predict outcomes for siblings of youth with ASD. A theoretically-based model of these factors was proposed drawing from both TD and ASD literatures (e.g., Goodman & Gotlib, 1999; Feinberg et al., 2012).

Methods: A total of 239 mothers of youth aged 6-17, including one youth with ASD (*M*=11.14 years; simplex families) and at least one other youth (*M*=11.74 years), completed a questionnaire battery. Measures reflected familial factors: ASD severity and problem behavior of affected sibling, maternal depression and stress, differential attention towards siblings, family social support, and sibling relationship quality. Mothers also reported on demographic characteristics, such as number of children in family, presence of second parent, and SES, as potential model covariates. An initial theoretical model was proposed. A final model was obtained using confirmatory path analysis and progressive model fitting.

Results: Overall, only 6%-23% of siblings were identified within the clinical range of emotional, behavioral, or social functioning (see Table 1). The final model (see Figure 1) demonstrated that maternal depression positively predicted clinical outcomes while maternal stress predicted less clinical elevations. More positive sibling relationships were associated with poorer emotional, behavioral, and social functioning. Contrary to expectation, ASD symptom severity and ASD problem behavior were not direct predictors of TD sibling outcomes but, rather, predictors of other areas of familial functioning that ultimately predicted TD sibling outcomes.

Conclusions: The current sample represents the largest study of sibling emotional, social, and behavioral functioning to date, and suggests that the majority of siblings are demonstrating emotional, behavioral, and social functioning similar to the general population of youth. Particular family factors may be of especial importance in understanding why some youth may be in need of support or intervention – family factors that have been largely ignored in sibling research to date. The current model is presented as a base for the development of future research and evidence-based programs for supporting the apparent resilience and strengths of siblings while also identifying and serving those who may be at risk.

Panel Session

161 - From Animal Neurocognitive Trials to Humans: How Do We Find the Most Appropriate Outcome Measures and Trial Designs for Tuberous Sclerosis Complex and Other Genetic Disorders?

3:30 PM - 5:30 PM - Room 309

Panel Chair: Petrus de Vries, *Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Discussant: Elizabeth Berry-Kravis, *Pediatrics; Biochemistry; Neurological Sciences, Rush University Medical Center, Chicago, IL*

Tuberous Sclerosis Complex (TSC) has become a powerful model to study a range of TSC-associated neuropsychiatric disorders (TAND), including autism spectrum disorder (ASD) and specific neuropsychological deficits. Given the success of mTOR inhibitors to treat SEGA (subependymal giant cell astrocytomas) and renal angiomyolipomas, there has been growing interest in molecularly-targeted treatments of TAND. However, translation from animal trials to humans has not been straightforward in other genetic disorders such as Fragile X and Neurofibromatosis Type 1, in spite of strong pre-clinical findings. In this panel we will discuss translation from pre-clinical to clinical trials to consider possible challenges in this effort. Our first presentation will be a recent pre-clinical study of neurocognition and social behavior in the Tsc2+/- (Eker) rat. Next, we will explore current clinical trials of

neurocognition and ASD in TSC and consider what we have learnt along the way. In the third presentation we will examine executive deficits in normally-intelligent adults with TSC to reflect on neuropsychological profiles and the impact of different analysis approaches. In our final talk, we will present a study of resting state EEG as potential biomarker for TSC-associated and non-syndromal ASD.

3:30 **161.001** mTOR Inhibitor Reverses Autistic-like Behaviour in Tsc2+/- Rats with Developmental Epilepsy

*M. Schneider[1], P. J. de Vries[2], K. Schönig[1], V. Rößner[3] and **R. Waltereit**[3], (1)Central Institute of Mental Health, Mannheim, Germany, (2)Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Child & Adolescent Psychiatry, University Hospital Carl Gustav Carus, Dresden, Germany*

Background: Developmental epilepsy is a major risk factor for autism spectrum disorder (ASD) and complicates clinical manifestations and management of ASD significantly. Tuberous Sclerosis Complex (TSC), caused by TSC1 or TSC2 mutations, is one of the medical conditions most commonly associated with ASD and has become an important model to examine molecular pathways associated with ASD. Previous research showed reversal of autism-like social deficits in Tsc1+/- and Tsc2+/- mouse models by mammalian Target of Rapamycin (mTOR) inhibitors. However, at least 70% of individuals with TSC also have epilepsy, known to complicate the severity and treatment-responsiveness of the behavioural phenotype. Tsc2+/- (Eker)-rats express autism-like social deficits similar to Tsc2+/- mice, with additive social deficits from status epilepticus during development.
Objectives: Here we hypothesised that the mTOR inhibitor everolimus would exert beneficial effects on social interaction and cognition in Tsc2+/- (Eker)-rats with previously induced developmental epilepsy.
Methods: The experimental group that modelled TSC pathology carried the Tsc2+/- (Eker)-mutation and was challenged with pharmacologically induced status epilepticus at postnatal days (P) 7 and P14 (n=12). The control group consisted of wild-type carriers from the Eker rat line and did not receive developmental epilepsy (n=10). At the age of four months, all animals were investigated in the pre-treatment behavioural analysis (T1). They were then treated for one week every other day with 1 mg/kg everolimus per bodyweight by intraperitoneal injection. Finally, they were retested in the post-treatment behavioural analysis (T2).
Results: Everolimus successfully treated the social interaction and social cognitive deficits in Tsc2+/- (Eker)-rats with status epilepticus induced during development. The drug was well tolerated and did not affect body weight. Non-social activity behaviour was not changed by everolimus. The mTOR-inhibitor specifically rescued the autistic-like phenotype of impaired social exploration behaviours. It also reversed the deficits in social recognition memory.
Conclusions: Our findings suggest that mTOR-inhibitors may be a potential treatment of autistic-like behaviours not only associated with a TSC mutation but also of social deficits associated with epilepsy in TSC. Results suggest that mTOR inhibitors may therefore be a potential treatment also of social deficits associated with other seizure-related disorders.

3:55 **161.002** Clinical Investigations in TSC

***M. Sahin**[1], M. Bebin[2], J. Y. Wu[3], H. Northrup[4], A. W. Byars[5], A. Sadhwani[6], K. Kapur[7], P. J. de Vries[8] and D. Krueger[5], (1)Department of Neurology, Boston Children's Hospital, Boston, MA, (2)University of Alabama, Birmingham, AL, (3)UCLA, Los Angeles, CA, (4)University of Texas, Houston, TX, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Boston Children's Hospital, Boston, MA, (7)Neurology, Boston Children's Hospital, Boston, MA, (8)Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background: Rare genetic diseases that affect behavior and cognition provide a unique opportunity to study the mechanisms of neurodevelopmental disorders through the examination of animal models, which can lead to development of hypotheses and treatments testable in human beings. Tuberous sclerosis complex (TSC) is an autosomal dominant disease that presents with autism, epilepsy, and intellectual disability. TSC can be diagnosed very early in life before autism symptoms arise. This provides a unique opportunity to study the pathogenesis underlying autistic symptoms in TSC and identifying signaling pathways that may be targeted for novel treatments.
Objectives: A series of knockout mouse models have been used to examine the role of Tsc1 and Tsc2 genes in neuronal development and function. These studies all indicate the mTORC1 inhibitors are effective in improving the neurological deficits in the animal models, including epilepsy and autism-like behaviors. Now, the challenge is to translate these funding to TSC patients.
Methods: As an initial step, we launched a Phase II clinical trial testing the efficacy of an mTOR inhibitor on improving neurocognition in children with TSC (NCT01289912). Children with TSC between the ages of 6 and 21 years were recruited to this study.
Results: One of the key issues that remain unanswered in the translation from preclinical to clinical trials is the selection of primary outcome measures. For this trial, the primary endpoint is neurocognition; secondary endpoints are autism, epilepsy and sleep disturbances. Inclusion criteria included an IQ cut off of 60 and higher so the subjects could complete the neurocognitive battery. 47 subjects were randomized; 32 patients were enrolled in the treatment group and 15 patients in the placebo groups. The two groups were comparable in terms of demographics and past medical history. Testing was performed at 0, 3 and 6 months. Analysis of the results is ongoing.
Conclusions: Single gene disorders with high penetrance of autism such as TSC provide powerful model systems to study the roles of individual molecules and associated signaling pathways in the genesis of autism, epilepsy, cognitive impairment and neuropsychiatric symptoms. Future trials need to incorporate translational biomarkers that can be employed in both animal models and patients. These diseases are leading to disease-modifying human therapies that may eventually translate to wider therapeutic strategies for autism.

4:20 **161.003** Executive Function Deficits in Adults with Tuberous Sclerosis Complex: Implications for Clinical Practice and Clinical Trials

***L. Leclezio**[1], D. L. McCartney[2] and P. J. de Vries[3], (1)Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Cancer Research UK Clinical Trials Unit, University of Birmingham, UK, Birmingham, United Kingdom, (3)Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background: Tuberous Sclerosis Complex (TSC) is a genetic disorder with multi-system involvement. The lifetime prevalence rates of TSC-associated neuropsychiatric disorders (TAND) are in the region of 90% and lead to significant burden of disease. TAND includes a range of neuropsychological manifestations, including executive deficits. There are, however, few studies that have investigated executive skills in the disorder, either by group-wise comparisons or by examining the profile of executive deficits. There has also been interest in clinical trials with neurocognition as primary outcome in TSC and other genetic disorders, but given the novelty of the field, much is still unknown in terms of selection and analysis of neurocognitive outcomes, such as of executive functions.
Objectives: The aim of this study was to examine four components of executive skills in normally-intelligent adults with or without TSC and to analyze findings in two different ways – a group-wise analysis, and an individual profile analysis. We hypothesized that the TSC group would perform significantly worse than a non-TSC control group, and that a specific set of executive deficits to target in trials may be identified.
Methods: The sample consisted of 21 adults with TSC and a gender-, age- and performance IQ-matched control sample of 18 non-TSC adults. Four subtests of the Cambridge Neuropsychological Test Automated Battery (CANTAB) were used to assess simple spatial working memory (SSP task), self-ordered spatial working memory (SWM task), planning (SoC task), and attentional set-shifting (IDED task). Data were analysed for group difference. In addition, the individual profiles of the TSC group were examined to identify the rates and pattern of clinical executive deficits (performance <5th Percentile).
Results: Results showed significant group-wise differences on the Spatial Span (SSP) task and the Between Error Score of Spatial Working Memory (SWM), but not on the other tasks. Individual profile analysis revealed different results. None of the TSC participants were impaired on the spatial span (SSP) task, ten percent (10%) were impaired on the self-ordered spatial working memory (SWM) task, 20% on the planning (SoC) task, and 30% on the extra-dimensional aspects of the set-shifting (IDED) task. Overall 52% of TSC individuals scored in the impaired range on one or more of the executive function tasks.
Conclusions: We confirmed that a significant proportion of adults with TSC presented with clinically significant deficits on various executive functions, but without a pattern that suggested a 'target' executive deficit. Interestingly, group-wise comparisons gave a different impression of executive weaknesses in TSC. The study highlighted the importance not only of performing group-wise comparisons but also of investigating profiles of clinical deficits in those with TSC and other genetic disorders. Findings suggest that the variability of neuropsychological profiles, and the differences between 'group-based' and individual profile analysis should be considered in determining clinical trial design and analysis methods of molecularly-targeted trials with neurocognition as primary outcome in TSC and other genetic disorders.

4:45 **161.004** Recurrence Quantification Analysis of Resting State EEG As Risk Biomarker for Non-Syndromal and Syndromal ASD

***T. M. Heunis**[1], C. Aldrich[2], M. Nieuwoudt[1,3], S. S. Jeste[4], M. Sahin[5], J. M. Peters[6] and P. J. de Vries[7], (1)Mechanical and Mechatronic Engineering, Stellenbosch University, Stellenbosch, South Africa, (2)Mining Engineering and Metallurgical Engineering, Western Australian School of Mines, Curtin University, Perth, Australia, (3)South African DST/NRF Centre for Epidemiological Modelling and Analysis (SACEMA), Stellenbosch University, Stellenbosch, South Africa, (4)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (5)Department of Neurology, Boston Children's Hospital, Boston, MA, (6)Division of Epilepsy and Clinical Neurophysiology, Department of Neurology, Boston Children's Hospital, Boston, MA, (7)Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background: There has been growing interest in electroencephalography (EEG) as an investigational tool for biomarker development in autism spectrum disorder and other neurodevelopmental disorders. However, one of the key challenges lies in the identification of appropriate multivariate, next-generation analytical methodologies that can characterise the complex, nonlinear dynamics of neural networks in the brain. Recurrence quantification analysis (RQA) may be a potential next-generation approach for the identification of individuals 'at risk' of ASD. A proof of principle study, comprising 7 ASD and 5 typically developing (TD) subjects (8-17 years), showed that linear discriminant analysis (LDA) of RQA features could classify subjects as ASD or TD with 83.3% accuracy, 85.7% sensitivity and 80.0% specificity. The sample size was, however, small, and

did not consider age, gender and intellectual ability as potential confounders. Furthermore, a robust biomarker for ASD should be able to differentiate ASD not only from TD, but also from other neurodevelopmental aberrations, as seen in genetic syndromes, for example.
Objectives: Here we present further exploration of this method in a larger dataset comprising non-syndromal ASD, Tuberous Sclerosis Complex (TSC) with ASD (syndromal ASD), TSC without a concurrent diagnosis of ASD, and TD subjects.
Methods: Raw resting state EEG (rsEEG) data were filtered and preprocessed, artefact contaminated segments were manually rejected and semi-automated ocular artefact correction was performed using independent component analysis. Data were extracted in continuous 5 second segments. RQA features were extracted from recurrence plots of multivariate embedded rsEEG data. LDA, multilayer perceptron (MLP) neural network and support vector machine (SVM) classifiers were used to classify the RQA feature vector. A leave-one-subject-out approach was utilised to simulate the diagnosis of an unseen subject. Biomarker performance was evaluated in three samples, each matched for age, gender and intellectual ability, where possible. Multiple segments per subject were evaluated to determine test-retest reliability. Study 1 analysed 666 segments from 7 ASD (mean age 3.96 years) and 7 TD (mean age 3.93 years) subjects. Study 2 analysed 1202 segments from 5 TSC+ASD (mean age 5.92 years) and 5 TSC-ASD (mean age 5.99 years) subjects. Study 3 analysed 832 segments from 6 ASD (mean age 3.90 years) and 6 TSC+ASD (mean age 3.89 years) subjects.
Results: In study 1, 92.9% accuracy, 100% sensitivity, and 85.7% specificity was achieved using an SVM classifier. Study 2 showed 90% accuracy, 80% sensitivity, and 100% specificity, using a MLP classifier. In study 3 both the SVM and MLP classifiers achieved 100% accuracy, sensitivity and specificity.
Conclusions: Results suggested that RQA may be a reliable approach to classify individuals with syndromal and non-syndromal ASD. Age, gender and intellectual ability were identified as potential confounders for classification performance in poorly matched samples. With comparison of the non-syndromal and TSC+ASD sample population, epilepsy and medication use were also identified as possible confounding factors. Rigorous investigation of each of these factors in a well matched and larger sample population will be required with further biomarker development. Consistent test-retest reliability will also need to be established.

Panel Session
162 - Biomarker Development in the Era of Rdoc: Common and Distinct Mechanisms of Function and Dysfunction in ASD and Schizophrenia
3:30 PM - 5:30 PM - Room 310

Panel Chair: James McPartland, *Yale School of Medicine, New Haven, CT*

Discussant: James McPartland, *Child Study Center, Yale School of Medicine, New Haven, CT*

Autism spectrum disorder (ASD) and schizophrenia spectrum disorders (SZS) are both characterized by atypical social behavior and cognition. Common genetic pathways and neural processes are implicated in both disorders, but few studies have directly compared clinical populations with ASD and SZS. For this reasons, shared and distinct characteristics are poorly understood. This panel presents four studies applying complementary methods at multiple levels of analysis, spanning brain structure to neurophysiology to psychophysiological assessment of behavior to clinical observation and self-report. These novel approaches are applied to converge upon functional processes related to core features of both disorders: social-communication, gaze perception, neural connectivity, and sensory processing. At the level of clinical symptomatology, results concord with behaviorally defined diagnostic categories. In contrast, measures of specific neural mechanisms and functional processes indicate significant overlap in ASD and SZS, aligning with performance at both clinical and subclinical levels rather than diagnostic taxon. Discovery of shared neural bases of phenomenologically distinct disorders holds promise for understanding specific strengths and vulnerabilities and offers straightforward clinical implications. Panel discussion focuses on relevance to a dimensional characterization of neurodevelopmental disorders and its implications for biomarker development in ASD.

3:30 **162.001** Common and Distinct Neuroanatomical Abnormalities in Adult ASD and Schizophrenia

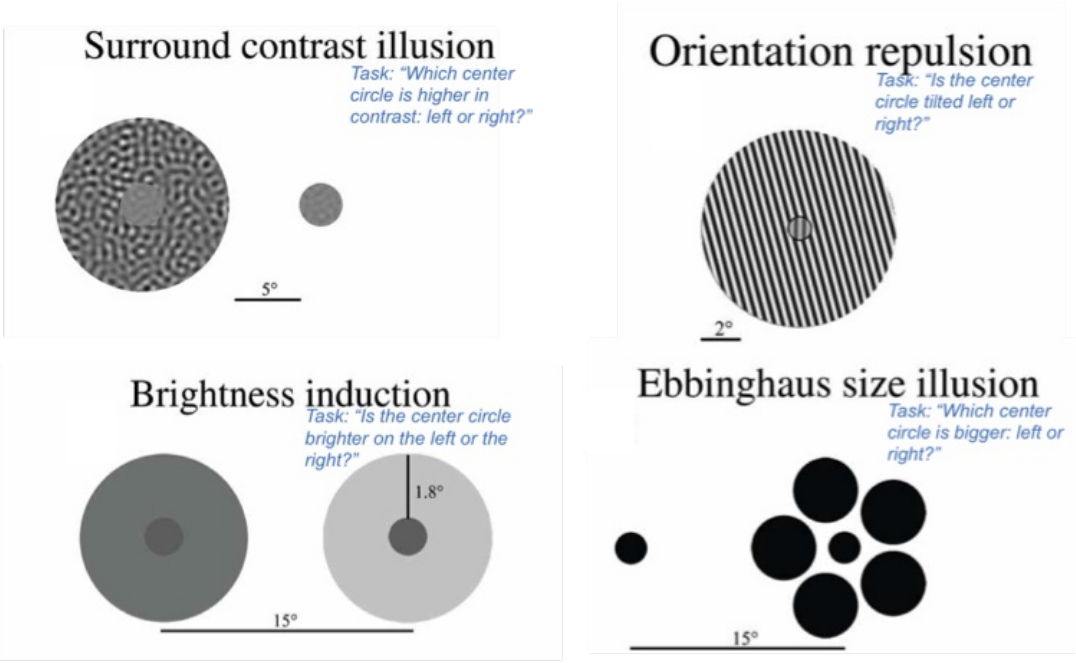
S. M. Eack[1] *and N. J. Minshew*[2]*, (1)School of Social Work, University of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Autism spectrum disorder (ASD) and schizophrenia are characterized by significant impairments in social and non-social information processing, which may reflect similar underlying brain abnormalities, yet few studies have directly examined convergence in the neuroanatomical basis of these conditions.
Objectives: The purpose of this study was to use high-resolution structural magnetic resonance imaging to identify and compare regional gray matter morphological abnormalities between adults ASD and schizophrenia relative to healthy volunteers.
Methods: A cross-sectional, cross-diagnostic case-control structural neuroimaging study was conducted with 14 verbal adults with ASD, 42 stabilized adult schizophrenia outpatients, and 20 healthy adult volunteers. Regional measurements of gray matter volume were collected using high-resolution structural magnetic resonance imaging using a 3T Siemens Trio whole-body scanner and head coil. Broad fronto-temporal regions of interest were defined using Wake Forest University Pickatlas including relevant areas of the prefrontal cortex, medial-temporal lobe, and superior and middle temporal gyri based on previous studies of ASD and schizophrenia. All data were preprocessed and analyzed using Statistical Parametric Mapping, version 12.
Results: Adults with ASD demonstrated significant and broadly increased gray matter in the bilateral middle temporal gyrus (all $k > 100$, all $p < .001$) and insular cortex (all $k > 158$, all $p < .001$) relative to healthy volunteers. In addition, a significant cluster of increased gray matter in the left medial prefrontal cortex was also present in adults with ASD ($k = 162$, $p < .001$) compared to healthy individuals. Individuals with schizophrenia demonstrated similarly increased gray matter volume in the left middle temporal gyrus ($k = 66$, $p = .001$), although this finding was less pronounced than in ASD. In contrast to adults with ASD, patients with schizophrenia also showed significantly reduced amygdala volume bilaterally (all $k > 20$, all $p < .003$). When comparing ASD and schizophrenia directly, individuals with ASD had significantly greater gray matter volume in a bilateral medial-temporal cluster encompassing the amygdala and parahippocampal gyrus (all $k > 130$, all $p < .001$). Increased right putamen volume was also observed in ASD relative to patients with schizophrenia ($k = 49$, $p = .001$).
Conclusions: Autism and schizophrenia are associated with neuroanatomical abnormalities in medial-temporal regions that are only partially overlapping along the middle temporal gyrus implicated in social information processing. Overall, ASD was characterized by widespread increases in cortical gray matter not observed in schizophrenia, which was primarily associated with reduced amygdalar volume. These findings support models of distinct neurodevelopmental processes converging on shared social disability in people with ASD and schizophrenia.

3:55 **162.002** Dissociating Visual Correlates of Context Modulation in ASD and Schizophrenia

J. H. Foss-Feig[1]*, B. D. Adkinson*[2]*, W. J. Park*[3]*, E. J. Levy*[4]*, N. Santamauro*[5]*, C. Schleifer*[6]*, K. Deckert*[4]*, V. Srihari*[5]*, J. Krystal*[7]*, D. Tadin*[3]*, J. McPartland*[1] *and A. Anticevic*[5]*, (1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)Department of Psychiatry, Yale School of Medicine, New Haven, CT, (3)Brain and Cognitive Sciences, University of Rochester, Rochester, NY, (4)Yale Child Study Center, New Haven, CT, (5)Yale University School of Medicine, New Haven, CT, (6)Yale University, New Haven, CT, (7)Yale University - Psychiatry, New Haven, CT*

Background: Theoretical and empirical accounts implicate altered contextual modulation as an underlying brain dysfunction in both ASD and schizophrenia spectrum disorders (SZS). Both disorders are also characterized by altered sensory processing, including differences in visual perception. In ASD, much attention has been paid to global-local interactions and perceptual biases, and in schizophrenia inability to filter information from the surround has been attributed to neural disinhibition associated with an excitatory/inhibitory imbalance. Contextual modulation reflects the way in which a visual feature is perceived dependent on the surrounding spatial context. There is some evidence that contextual modulation is impacted in both ASD and SZS; however, it has never been tested concurrently in both clinical populations.
Objectives: Examine behavioral correlates of visual context processing in young adults with ASD, in comparison to both adults with SZS and healthy controls.
Methods: Preliminary analyses included 9 adults with ASD, 9 with early-course SZS, and 14 controls, matched on relevant demographic variables. Recruitment is ongoing with an anticipated final sample size of 20 per group. Participants completed a visual contextual modulation battery (**Fig.1)**. Following prior studies examining center-surround interactions (Yang et al., 2013), we used staircase procedures to measure psychophysical thresholds during forced choice comparisons of stimuli assessing surround modulations in: a) contrast, b) luminance, c) orientation, d) size. For each participant, the point of subjective equality (PSE) was computed for each task, quantifying the influence of the surrounding context. Group differences were assessed using one- and two-way ANOVAs.
Results: Across tasks, results revealed significant main effects of context (ps<0.001), indicating significant influence of the surrounding context (i.e., contextual modulation occurs) for all groups. In the orientation task, relative to controls, surround suppression was reduced in ASD but decreased in SZS (F=2.117, p=.13). In the Ebbinghaus (size) illusion, contextual effects on size perception were increased in ASD but decreased in SZS relative to controls (F=2.924, p=.07). When comparing contrast, surround suppression was lower in both ASD and SZS relative to controls, though the interaction did not approach significance (F=1.254, p=.30). Finally, in the luminance task, neither individuals with ASD nor SZS showed differential surround suppression relative to controls (F=0.473, p=.63). Work is ongoing to relate patterns of context modulation to specific clinical features transdiagnostically.
Conclusions: Results revealed that patterns of contextual modulation differentiate ASD from SZS under specific conditions, whereas the two disorders are comparable in other contextual conditions. Specifics patterns of dissociation versus overlap may provide clues to underlying neural processes affected by context processing and neural excitation and inhibition within and across disorders. Future work directly measuring brain response during visual context processing will be crucial for teasing apart the extent to which this mechanisms characterizes ASD and related disorders where sensory, perceptual, and social deficits are key.



4:20 **162.003** Neural Correlates of Emotion Processing during Simulated Social Interactions in Adults with Autism Spectrum Disorder and Schizophrenia

K. Deckert[1], *J. H. Foss-Feig*[2], *A. Naples*[2], *E. J. Levy*[1], *K. K. Stavropoulos*[2], *M. Rolison*[2], *L. Mohamed*[1], *C. Schleifer*[3], *N. Santamauro*[4], *A. Anticevic*[4], *V. Srihari*[4] *and J. McPartland*[2], *(1)Yale Child Study Center, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT, (3)Yale University, New Haven, CT, (4)Yale University School of Medicine, New Haven, CT*

Background: Both autism spectrum disorder (ASD) and schizophrenia (SCZ) are characterized by social deficits, including in emotional recognition, eye contact, and theory of mind. Previous research utilizing electrophysiology and measuring event-related potentials (ERPs) shows atypical structural encoding of faces, as indexed by N170 amplitude and latency, in both adults with ASD and SCZ.
Objectives: Using gaze contingent ERP in response to happy and fearful faces that responded to participant gaze, the current study examined emotional processing and ERP components (N170, P300) in adults with ASD, SCZ, and typical development (TD). We examined diagnosis-specific findings as well as transdiagnostic associations between neural processes and behavioral correlates of emotion recognition abilities. These results address divergence between disorders but also highlight common biological processes underlying disorders characterized by social communicative deficits.
Methods: 42 adults (TD=16, ASD=12, SZ=14) completed EEG, along with self-report questionnaires and direct assessment clinical measures. Groups were matched on IQ, age, and sex. Emotion recognition was assessed using the Reading the Mind in the Eyes Task (RMET). EEG was recorded with high density 128 channel Geodesic Sensor Nets with concurrent eye tracking, in response to neutral faces that dynamically changed to express either happy or fearful emotional expressions upon participant gaze towards the eyes. ERP was time-locked to emotion onset. N170 amplitude and latency were analyzed over bilateral occipitotemporal electrodes; P300 was analyzed over midline parietal sites. A repeated measures ANOVA was conducted to analyze amplitude and latencies of ERP components (within-subject factors: Hemisphere, Emotion; between-subjects factor: Diagnosis). Bivariate correlations with RMET scores were also conducted.
Results: Adults with SCZ showed longer N170 latency compared to controls, $F(2,39) = 2.67$, $p = .081$. Irrespective of diagnostic group, right hemisphere N170 amplitude ($r = -.324$, $p = .038$) and latency ($r = -.410$, $p = .007$) were correlated with emotion recognition ability, with faster and more robust N170 responses in individuals with better emotional identification. In the left hemisphere, N170 response to happy versus fearful faces showed greater amplitude in ASD relative to SCZ and controls, $F(2,39) = 5.49$, $p = .008$. Left hemisphere N170 latency did not differ by group, but happy faces elicited a faster N170 response across groups, $F(2,39) = 5.04$, $p = .031$. P300 amplitude was enhanced to fearful versus happy faces in ASD and TD, but not in SCZ, $F(2,39) = 4.95$, $p = .012$. SCZ was characterized by attenuated P300 amplitude across emotions, $F(2,39) = 2.73$, $p = .077$.
Conclusions: Our results show that individuals with ASD and schizophrenia have altered neural responses to emotional face stimuli. A nuanced pattern of results indicates both common and distinct mechanisms in these disorders; moreover, delayed and attenuated neural response to faces is associated with reduced emotion recognition abilities across clinical and non-clinical populations alike. These findings have important implications in determining the neurobiological underpinnings of emotion recognition and social functioning deficits in ASD and other disorders affecting social cognition and for the utility of diagnostic taxonomies based on behavioral symptoms versus dimensional measurement of specific functional processes.

4:45 **162.004** Comparing Social Skills Between Adults with ASD and Schizophrenia

N. J. Sasson[1], *K. E. Morrison*[2] *and A. Pinkham*[3], *(1)University of Texas at Dallas, Richardson, TX, (2)The University of Texas at Dallas, Dallas, TX, (3)School of Behavioral and Brain Sciences, The University of Texas at Dallas, Richardson, TX*

Background: Although Autism Spectrum Disorder (ASD) and Schizophrenia (SCZ) are both characterized by social dysfunction, their non-shared features and different developmental trajectories suggest that the pathways and mechanisms underlying this impairment may differ. Systematically-matched comparisons of the two groups can help identify disorder-specific features that are missed when simply comparing each clinical group to typically-developing (TD) controls.
Objectives: While an increasing number of studies have compared ASD and SCZ on social cognitive abilities and their neural correlates (for a review, see Sasson et al., 2011), no work has yet compared the two on social behavior. This project sought to examine how social skills are similar and different between ASD and SCZ relative to TD adults.
Methods: 164 individuals (54 ASD; 54 SCZ; 56 TD) participated. The groups were matched on gender (all 87% male), and comparable on age (group means between 25.69-28.68 years), ethnicity (80-89% Caucasian), educational attainment (group means between 13.45-13.89 years), and IQ (group means between: 103.32-106.02). Participants completed the Social Skills Performance Assessment (SSPA; Patterson et al., 2001), a structured three minute role-play involving a social interaction scenario (meeting a new neighbor). Eleven social skills were coded on a one-to-nine scale (Pinkham & Penn, 2006): verbal clarity, verbal fluency, meshing, involvement, asks questions, gaze, appropriate affect, flat affect, appropriate content, social anxiety, and overall social skill. Additionally, three codes were added for their relevance to ASD: repetitive verbal content, repetitive nonverbal content, and verbosity. Two coders, blind to the diagnostic category of the participants, were trained to adequate reliability (ICC>.7 for all codes).
Results: As measured by the PANSS (Kay et al., 1987), the SCZ group had greater positive, negative, and general symptoms relative to the ASD group (*p*s <.001). Only negative symptoms correlated with overall social skill (r=-.56, p<.001), and thus were co-varied in analyses. Both clinical groups were rated lower on each of the 14 social skills relative to the TD group (all *p*s<.05), with the exception of SCZ not differing from controls on two ASD-specific items (repetitive verbal and nonverbal content), ASD not differing on verbal clarity, and both groups not differing from controls on meshing. When directly compared, the SCZ group was rated as higher on overall social skill than the ASD group (p=.001). The SCZ group also asked more questions (p=.004), were rated as more involved (p=.008), demonstrated less repetitive nonverbal (p=.002) and verbal (p=.050) content, and trended towards more appropriate affect (p=.064) and content, and less anxiety (p=.077). IQ correlated with overall social skill in SCZ (r=.35, p=.011) but not in ASD (r=.15, p=.271).
Conclusions: Both ASD and SCZ are characterized by significant social skill impairments relative to controls. When directly comparing the clinical groups, ASD demonstrated poorer social skills, both overall and within several specific areas (reciprocity, appropriate content and affect, and repetitive behaviors). These results underscore the significant social impairment experienced by intellectually-capable adults with ASD. Future work will examine how these patterns of social skills relate to social cognition and other areas of social functioning.

Poster Session

163 - Adult Outcomes: Medical, Cognitive, Behavioral

5:30 PM - 7:00 PM - Hall A

1 **163.001** A Mixed Methods Study of Employment Perspectives of Youth and Young Adults on the Autism Spectrum

*L. A. Crabtree[1] and **B. B. Demchick**[2], (1)Towson University, Lutherville, MD, (2)Occupational Therapy & Occupational Science, Towson University, Towson, MD*

Background: Participation in employment experiences in the community is a rite of passage to adulthood. A majority of transition-aged individuals with autism have identified goals to obtain gainful employment, although fewer than 20% are able to obtain employment after exiting the educational system (Wehman et al., 2014). Furthermore, those who are employed are typically under-employed, and they face higher rates of poverty, obliging many to be financially dependent on their families (Lindstrom, Kahn, & Lindsey, 2013). However, barriers to employment participation have not been fully explored, and it is unclear how perceptions of individuals with autism may contribute to poor employment outcomes.
Objectives: The purpose of this pilot study was to explain perspectives of youth and young adults with autism regarding employment participation in order to support improved methods of employment preparation. Specifically, two research questions were identified.

1. What are the perspectives of youth and young adults with autism regarding employment?
2. How do perspectives help and hinder success in preparation for, transition to, and participation in the workplace?

Methods: An explanatory sequential mixed methods design was used to identify patterns of perceptions, followed up with qualitative data collection to explain identified patterns. Researchers used a recently piloted and revised instrument based on items from the *Career Maturity Inventory*(Crites and Savikas, 2011) to survey 29 individuals with autism aged 16-28, followed by interviews with 8 young adults with autism. Descriptive statistical analysis was used to identify patterns of perceptions regarding employment, comparing those with and without employment experiences. Qualitative coding and thematic development, with constant comparative methods were used to analyze transcribed interviews.
Results: Survey results indicated that nine youth with employment experience (EE) identified positive perceptions of employment, but 56% of those in this group identified difficulties in the workplace. Twenty without employment experience (WE) indicated perceptions of worry about employment and lack of knowledge about employment constructs, although they indicated a desire to pursue employment opportunities. Themes from qualitative analysis of interviews with individuals from both groups (EE and WE) identified motivating factors of money and participation, as well as challenges of sustainability, social interactions, and transportation. Through comparative analysis of both data sets, two consistent patterns that restricted the employment opportunities for transitioning youth with autism were identified. 1) Lack of knowledge and 2) limited experiences. Youth in this study had limited knowledge of the constructs of employment, including knowledge of what entailed full-time employment. At the same time, they described very limited employment experiences.
Conclusions: With significant increases in both the number of youth with autism entering adulthood and the rising cost of vocational services, it is important to ensure that program supports lead to positive outcomes for both individuals with autism and for society at large (Burgess & Cimera, 2014). Preliminary results of this pilot study identify two key aspects of programming to support better employment outcomes. Specifically, by providing explicit knowledge and practical experiences related to meaningful employment opportunities for youth with autism, vocational programs can become more effective.

2 **163.002** A Statewide Needs Assessment Survey for Adults with Autism Spectrum Disorder

***L. O'Regan**[1], S. Srinivasan[2], S. Trost[1], A. Ekbladh[3], B. Freedman[4,5] and A. N. Bhat[2], (1)Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE, (3)Center for Disability Studies, University of Delaware, Newark, DE, (4)University of Delaware Center for Disabilities Studies, Newark, DE, (5)Center for Disabilities Studies, University of Delaware, Newark, DE*

Background:
Autism Spectrum Disorder (ASD) is a lifelong multisystem neurological disorder that affects social communication, perceptuo-motor, cognitive, and behavioral skills of individuals across the lifespan (Roux et al., 2015). In spite of the growing number of children with autism entering adulthood every year, surprisingly, there is a dramatic decline in access to services for these youth and adults. Around 40% of youth with autism do not receive any medical services, mental health counseling, or speech therapy once they reach early adulthood (Shattuck et al., 2011).
Objectives:
In 2011, the Center for Disabilities Studies (CDS) at the University of Delaware conducted a statewide comprehensive needs assessment survey for adults with ASD. This survey was designed to obtain information about critical areas related to the health and life status of individuals with ASD in order to develop a strategic plan to improve adult services for ASD.
Methods:
91 caregivers of adults with ASD as well as 18 high-functioning adult self-advocates with ASD between 20 and 50 years of age filled out a caregiver survey in online or paper form. The survey covered several aspects of the lives of individuals with ASD including their primary diagnosis, additional comorbidities, health service needs, educational status, employment status, living conditions, and participation in the community.
Results:
90% of the low-functioning group had a primary diagnosis of ASD whereas 67% of the high-functioning group had a primary diagnosis of Asperger Disorder. More than 60% of individuals in both groups had additional comorbidities, most commonly developmental delay, learning disability, anxiety, intellectual delay, depression, and attention deficit hyperactivity disorder. In the low-functioning group, over 75% of individuals lived with parents or in group homes, only around 50% of individuals had managed to obtain some high school education, and around 50% of individuals were unemployed. This group was independent in basic activities of daily living (ADLs) such as feeding, dressing, and toileting but required help in instrumental ADLs such as cooking meals, managing money, and getting around in the community. In the high-functioning group, around 50% of individuals continued to stay with parents, around 75% of individuals had some high school or college education, and only around 25% had a part time or full time job. In addition, this group had poor participation in community-based activities. Both groups identified the need for several different health care services including socials skills training, behavioral interventions, vocational training, mental health counseling, neurological services, and medication management.
Conclusions:
Results of the survey confirmed the lifelong nature of impairments in individuals with ASD. Adults with ASD continued to demonstrate multisystem impairments that interfered with their ability to independently engage in activities of daily living, pursue meaningful employment opportunities, and participate in activities within the community. Our findings highlight the need for continued services into adulthood for youth and older adults with ASD.

3 **163.003** ASD and Juvenile Justice Training for Judges, Magistrates and Probation Officers

***T. Hughes**, Counseling, Psychology and Special Education, Duquesne University, Pittsburgh, PA*

Background:
Due to the unique social and communication challenges, individuals with ASD can also be at risk of committing socially inappropriate actions that reach the level of illegal, offending behaviors. For example, the social deficits associated with autism may impact psychosexual development to a degree where inappropriate pursuits, interests or touching may result in an act that is unlawful. Further, communication deficits may also impact expressed anger to a degree where violent and aggressive behaviors rather than more appropriate verbal exchanges result. Relatedly, emotion dysregulation, executive function deficits as well as co-occurring psychiatric symptoms may also be related to the probability of individuals with ASD committing illegal acts (Newman & Ghaziuddin, 2008). Indeed, researchers have found, the number of individuals with ASD who are classified as offenders in the criminal system is more than expected (Haskins & Silva, 2006). One state facility, open to housing offenders with complex comorbid diagnosis, found among 37 adolescents adjudicated delinquent for sexual offenses, 22 (or 60%) met the diagnostic criteria for an ASD (Sutton, et.al., 2013).

While the acts themselves may be unlawful, the intent driving the act may not be similar to antisocial attitudes commonly found in offender populations. That is, social deficits (associated with a developmental delay) rather than social maladjustment (associated with psychopathy characteristics such as callous and unemotional traits where behavior is controlled) may distinguish these groups. Indeed, “counterfeit deviance” as described by Hingsburger, Griffiths and Quinsey in 1991 highlights how “behaviors that are the result of a pervasive lack of social skills, a core naïveté, or a lack of accurate knowledge are not deviant behaviors per se.” Thus, a primary aim of this presentation is to inform relevant juvenile justice personnel about the treatment needs for juveniles with ASD who are adjudicated.
Objectives: This presentation shows a training program for judges, magistrates, and probation officers that is designed to meet the community safety priorities of those offices while advocating for appropriate deterrent programing. A video case of probation officer working with an adolescent with ASD highlights the challenges unknown to many professionals.
Methods: Pre-post training data for 49 probation officers with one to thirty-five years of experience show statistically significant increase in their knowledge across all groups a) probation officers with autism experience, b) probation officers without autism experience, c) probation officers with previous autism training and d) probation officers without previous autism training.
Results: Discussion about how to approach training for various juvenile justice personnel is provided. Coordinating professional development across all relevant parties from police contact, through probation and the adjudication process in the context is considered.

Conclusions: Meeting the needs of individuals with ASD who are in contact with the juvenile justice system requires training for key decision makers. Trainings must identify relevant leverage points useful for selecting intervention protocols tailored to meet the needs of individuals with autism.

4 **163.004** ASD and Sexuality Education

***R. L. Loftin**, Autism Assessment, Research & Treatment Services Center, Chicago, IL*

Background:
There is an urgent need to teach people with ASD about sexuality. Individuals with ASD are at increased risk of sexual victimization (Selever, Roth & Gillis, 2013). People with ASD may also be at increased risk of problematic sexual behaviors that can include undesired touching, public masturbation and other illegal activity (Hellemans et al., 2007). Legal cases involving people with ASD often have a sexual component. In this clinician's practice alone, legal allegations have included viewing pornography in public locations, possession of child pornography, pedophilia, and inappropriate touching/ sexual advances toward other adults. Inappropriate sexual behaviors can limit employment and inclusion opportunities (Sullivan & Caterino, 2008), as well as opportunities for relationships. Many illegal or otherwise inappropriate sexual situations experienced by people with ASD could have been prevented with adequate sex education. One of the biggest challenges in developing appropriate sexuality education for people with ASD has been bridging the gap between people who know about sexuality education and people who know about ASD (Mesibov, 2012). The proposed presentation assessed use of a manual for sexuality education that was developed by ASD specialists and a consultant from Planned Parenthood.
Objectives:
This presentation will outline the research investigation of a sexuality education curriculum and practical implications for practice.
Methods:
Ten young men with ASD completed a 14-week sexuality education courses in a community-based center. A published curriculum in sexuality education for people with ASD served as the manual (Davies & Dubie, 2012). Planned Parenthood's standards, adapted from the federal standards for sexuality education, were used as a framework for reorganizing the Davies & Dubie manual. Supplementary lessons were created for additional areas of need that were not fully addressed.

All participants participated in pre and post-testing that included measures of social validity, knowledge questionnaires and vignettes of social situations. Additionally, feedback from participants, course leaders and parents was collected to assess acceptability of the intervention.

Results:
The final post-tests are occurring in October, and data will be analyzed in November and December. Participants are expected to demonstrate learning. Attendance in groups was good, and the acceptability of the intervention is expected to be high among attendees. Because it can be very difficult to motivate people with ASD to participate in activities outside of the home, the extent to which the young people are willing to learn about these topics will be very informative. The feasibility aspect will provide important information about whether the proposed intervention is relevant and sustainable in the community. If it is found to be feasible, it should be exportable.
Conclusions:
There is a tremendous need for interventions for young adults with ASD and, in particular, for appropriate, comprehensive sexuality instruction. Sexuality education in adolescence is particularly important because they are forming a sense of gender, identity and values (Goldman, 2011). Further, sexuality education can help future adults with ASD to be safer, more independent, and to have more opportunities for integration (Gerhardt & Lainer, 2010).

5 **163.005** Adapting the Social Skills Performance Assessment (SSPA) for Assessing Social Skills for Adults with ASD in Vocational Training Settings

*M. J. Baker-Ericzen[1,2], **M. M. Jenkins**[1], M. Fitch[3] and M. Kinnear[2], (1)Child and Adolescent Services Research Center, Rady Children's Hospital San Diego, San Diego, CA, (2)Rady Children's Hospital San Diego, San Diego, CA, (3)Child & Adolescent Services Research Center, Rady Children's Hospital, San Diego, San Diego, CA*

Background:
Difficulties with social communication are a main characteristic of individuals with autism spectrum disorders (ASD) that continues into adulthood. Consequently a need to treat and adequately assess social performance is of utmost importance. Currently most social skill assessments for adults with ASD are questionnaires or interviews, both being subject to over or under-estimation biases (Norton et al, 2010). Adults also often lack available informants to complete responses on their social abilities for accurate assessment. Behavioral observations, by means of role plays, have been found to be appropriate for adults with ASD (Verhoeven et al 2013). However, few observational measures have been studied for this population. The Social Skills Performance Assessment (SSPA), developed and tested for schizophrenia, may also be useful for ASD research and clinical assessment.
Objectives:
This study used a community-based participatory research (CBPR) approach to 1) qualitatively investigate the suitability and adapt the Social Skills Performance Assessment (SSPA) for ASD research within vocational settings and 2) pilot test the adapted SSPA.
Methods:
The CBPR group was made up of researchers, educators, public agency administrators (Department of Rehabilitation and Development Disabilities), community providers, family members and individuals with ASD. Study involved qualitative data collection on role-play scenes, administration and scoring suitability. Quantitative study included pilot testing the adapted measure with 9 participants to date (15-20 additional participants by April), aged 18-28 years old, participating in a vocational training program. The majority of participants were male (78%), white race/ethnicity (78%) and all graduated with a high school diploma.
Results:
Qualitative study: The group determined it was suitable but required adaptation. Two new scenes (chatting with a coworker and asking a boss for time off) were created to be relevant for vocational settings. Administration changes of increased standardization was recommended and 6 additional codes (eye contact, intonation and pattern of speech, body language, facial expression, reading social cues, & perspective-taking) were developed to score to capture common social skill targets in ASDs.
Quantitative study: Analyses consisted of calculating means for each scene (1,2,3 & 4) and comparing the 2 new scenes (3 & 4) to the original scenes (1 & 2) within group and comparing the means of the original scenes across groups with published studies of ASD and normal populations. Effect sizes were calculated to measure group differences (Refer to Tables). Administrators and raters were trained to criterion. Reliability was calculated. Scores ranged from 1-5 with lower numbers indicating more social impairment. Adults with ASD in this community sample performed the worse. They also had significantly lower fluency and overall conversation scores with the new "chatting with coworker" scene compared to other scenes. Participants and administrators reported ease in administration and scoring on new scenes and codes.
Conclusions:
The SSPA measure, an observational social performance measure commonly used in schizophrenia studies, shows promise for ASD research as well. The adaptations suggested by a research-community collaborative for use with adults with ASD in vocational settings appear to assess social performance and provide a potential for accurate measurement of social ability.

Table 1. Social Skills Performance Assessment Measure Sample Comparisons

SSPA	ASD			Non-ASD
	Current sample mean n=9	Published sample mean n=24	Effect size *Cohen's d*	Normal sample mean n=20
SSPA Total Score	65.89 (10.5)	72.13 (5.71)	- .77	78.40 (4.24)
SSPA Scene 1 Total	30.78 (3.8)	34.38 (2.76)	- 1.1	37.30 (2.25)

reading social cues	3.67 (1.12)	3.78 (1.20)	3.44 (1.30)	3.67 (1.18)
perspective-taking	3.44 (1.33)	3.44 (1.13)	3.78 (.97)	3.22 (1.09)

6 **163.006** Adults with ASD in Community Mental Health Settings: Evidence for the Services Cliff

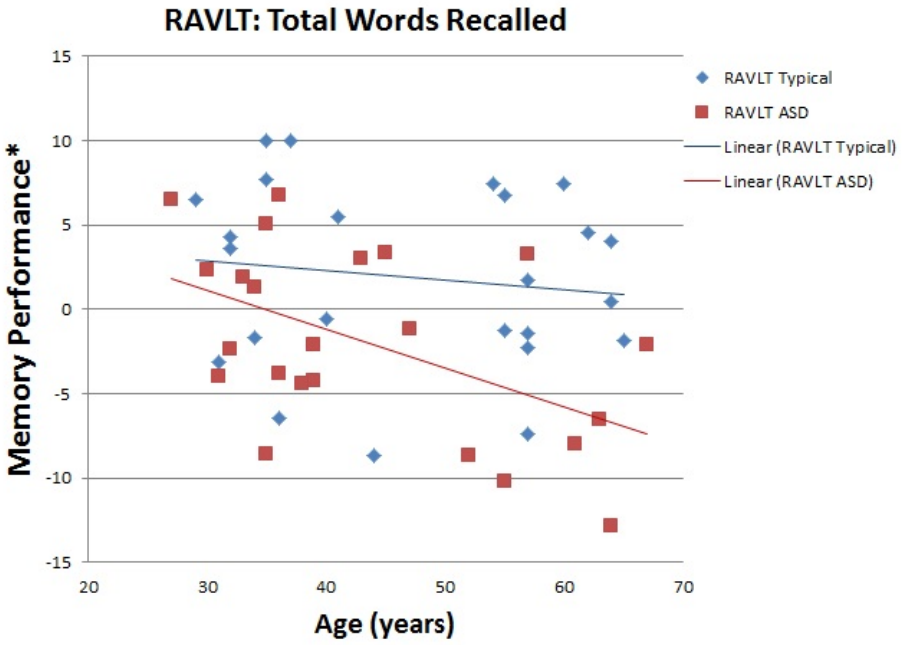
B. B. Maddox[1], *E. S. Brodkin*[2], *M. E. Calkins*[2], *J. Miller*[1], *K. T. Mullan*[2], *K. Shea*[2] *and D. S. Mandell*[3], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania School of Medicine, Philadelphia, PA*

Background: Most adults with autism spectrum disorder (ASD) struggle with mental health problems and require considerable support throughout the lifespan. Given this high rate of psychiatric comorbidity, adults with ASD may be overrepresented in mental health settings. Community mental health (CMH) centers serve a large number of adults with a variety of mental health problems, along with many school-age youth with ASD and co-occurring psychiatric disorders; however, the number of adults with ASD receiving CMH services in the United States is currently unknown. Evidence suggests that ASD often is missed or misdiagnosed among adults receiving psychiatric care, so a thorough investigation is needed to accurately determine the prevalence of adults with ASD in the CMH system.
Objectives: This study aims to estimate the prevalence of adults with ASD in outpatient CMH settings.
Methods: As part of the screening phase, staff from three CMH centers completed the Social Responsiveness Scale, Adult version (SRS-A) and the Autism Spectrum Disorders in Adults Screening Questionnaire (ASDASQ) for their adult clients. Our research team then conducted chart reviews to extract information found to discriminate adults with ASD from adults with other psychiatric disorders in prior studies (e.g., developmental history, substance use). A subset of these clients, stratified to heavily recruit participants with SRS-A scores > 60, completed in-person evaluations. The in-person assessment included Module 4 of the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), a brief clinical interview about ASD related characteristics not assessed by the ADOS-2, and the Overview and Psychosis modules of the Structured Clinical Interview for DSM-IV-TR Axis I Disorders (SCID). The clinical evaluation team was blind to results from the SRS and ASDASQ. Clinical case conferences were conducted for all participants to make a final determination of ASD.
Results: To date, screening packets have been collected for 1134 clients, and 321 charts have been reviewed. We have currently completed in-person evaluations with 58 participants (39 males; mean age = 48.6 years old). An additional 35 evaluations are expected by May 2016. Of the 58 participants, 2 males met diagnostic criteria for ASD (3.45%).
Conclusions: Despite weighting our sample with high SRS-A scores, we have found a remarkably low number of adults with ASD in general outpatient CMH settings. Although CMH centers play an important role in treating school-age youth with ASD and co-occurring psychiatric disorders, our preliminary findings suggest that there are not many individuals with ASD (previously diagnosed or not) in general outpatient care. Our results support the growing public health concern that there may be significant unmet mental health needs experienced by adults with ASD. The extent of this problem will only increase as more and more children with ASD transition to adulthood. Clinical and policy implications will be discussed, including (1) possible reasons why general outpatient CMH service use decreases when adolescents with ASD become adults, and (2) the importance of identifying where adults with ASD can access appropriate mental health care.

7 **163.007** Age-Related Changes in Processing Speed and Free Recall in Middle-Age and Older Adults with ASD

P. S. Powell[1], *N. Peyravian*[2], *A. T. Meyer*[3], *L. G. Klinger*[4] *and M. R. Klinger*[5], *(1)University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)Psychology, University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)University of North Carolina, Carrboro, NC, (4)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:
Little is known about age-related changes in cognitive functioning in middle-age and older adults with ASD. However, two previous studies of cognitive aging in ASD show smaller or absent age-related changes on standardized measures of explicit memory suggesting that older adults with ASD may be buffered against some of the deleterious effects of aging (Geurts & Vissers, 2012; Lever & Geurts, 2015).
Objectives:
The primary objective of this study was to further examine age-related effects on cognition across two measures of cognitive function, processing speed and free recall, which have consistently revealed patterns of age-related decline in studies of normal aging.
Methods:
Twenty-three adults with ASD and 24 adults with typical development were recruited for this study (age range: 27 to 67); data collection is ongoing. Participants were provided with a measure of processing speed (e.g., Trail Making Test; TMT) and a measure of explicit memory (e.g., Ray Auditory Verbal Learning Test; RAVLT). The TMT administration was taken directly from the Delis-Kaplan Executive Function System (D-KEFS). In the number-letter switching subtest, participants connect the circles in ascending order by switching from a number to a letter (e.g. 1-A-2-B-3-C-4-D). Each subtest is timed. The RAVLT involves three trials of immediate free recall after listening to a list of 15 unrelated words.
Results:
Results from the TMT number-letter switching subtest were examined using a hierarchical linear regression. Full scale IQ (FSIQ) was entered first followed by diagnosis as a categorical predictor, then age, and finally an age by diagnosis interaction term. This analysis found diagnosis and age significantly predicted performance on the TMT (R^2_{change}=.13, p=.003; R^2_{change}=.11, p=.003, respectively). There was no age by diagnosis interaction indicating similar rates of decline across diagnoses.
The same regression analysis was performed on the RAVLT with total number of items recalled as the dependent variable. This analysis revealed diagnosis and age to be significant predictors of performance (R^2_{change}=.11, p=.01; R^2_{change}=.07, p=.05, respectively), and a non-significant age by diagnosis interaction
Conclusions:
The present findings demonstrate both diagnostic differences and age-related declines in processing speed and explicit memory in adults with ASD. Current findings demonstrated a similar rate of decline with age for adults with ASD as adults with typical development. However, evidence of poorer overall performance in adults with ASD coupled with age-related decline suggest that older adults with ASD may reach a level of performance that is markedly lower leading to impaired functioning at younger ages than those with typical development. Thus, increased caregiving needs associated with cognitive decline in typical adults may be needed sooner for adults with ASD.



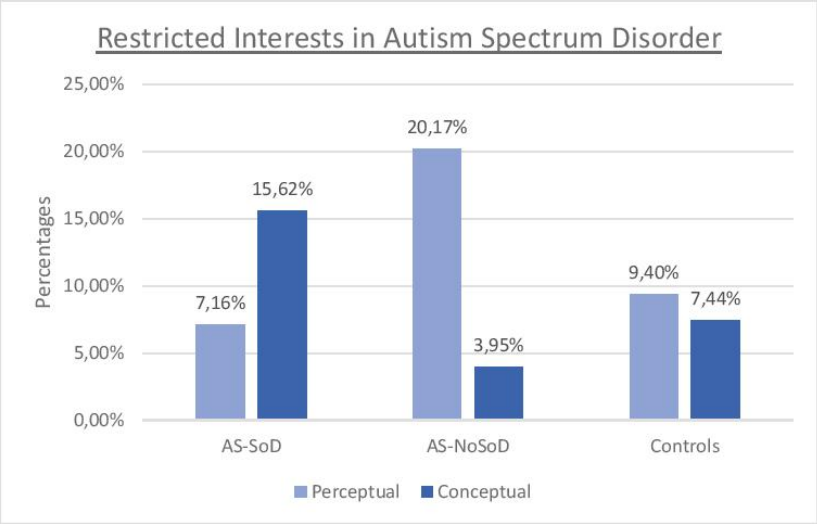
*Unstandardized Residual of Memory Performance with effect of IQ regressed out

8 **163.008** An Analysis of Restricted Interests in Autism Spectrum Disorder with Versus without Speech Onset Delay: The Importance of Perceptually Versus Thematically Organized Interests

L. Chiodo[1], *S. Majerus*[2], *S. Eusèbe*[2] *and L. Mottron, M.D.*[3], *(1)Université de Liège, 4000 Villers-St-Simeon, Belgium, (2)Université de Liège, Liège, Belgium, (3)Centre d'Excellence en Troubles Envahissants du Développement, Montréal, QC, Canada*

Background:
Recent findings (Bonnel et al, 2010; Barbeau et al, 2013) indicate that autistic people with/without speech delay can be differentiated on the basis of the perceptual vs. non-perceptual nature of their ability peaks. Neuroimaging findings support this hypothesis, by showing that autistic people with or without speech onset delay can be contrasted by the perceptual versus linguistic nature of the cortical areas displaying overactivation during the presentation of visual and auditory material (Samson et al, 2013, 2015).
Objectives:
In the light of these findings, the present study aims at exploring the nature of restricted interests in these two autistic populations, by examining whether autistic people with/without speech delay can be differentiated on the basis of the perceptual versus thematic nature of their interests.
Methods:
30 adult participants with autism spectrum disorder (based on ADI / DSM-4R criteria) participated in this study, and were allocated to AS-SOD (speech onset delay; N=15) or AS-NoSOD (no speech onset delay; N=15) subgroups, while being matched for IQ (> 70; Raven's SPM, 1981) and age. 13 typically developing controls, also matched for age and IQ, were recruited on the basis of presenting specific interests while being free of symptoms of autism spectrum disorder. Information about restricted interests was obtained by having participants answer to 19 questions based on the Yale survey of special interests (Klin & Volkmar, 1996) and the semi-structured interview by Mercier et al. (2000). Data were qualitatively analyzed with NVivo 10 textual analysis software in order to segment and categorize the content of the verbal reports provided by the participants.
Results:
A repeated measures ANOVA revealed that the proportion of thematically organized interests (interests with a rich semantic organization) was significantly higher in AS-NoSOD participants relative to both AS-SOD participants and controls (Figure 1). Conversely, the proportion of perceptually organized interests (interests based on accumulation of factual information such as historical dates, car license plates) was significantly higher in AS-SOD participants relative to both AS-NoSOD participants and controls.
Conclusions:
Restricted interests in AS-SOD are characterized by perceptually organized structures while these interests present a rich conceptual organization in AS-NoSOD individuals. These differences in the nature of restricted interests may provide important clues with respect to the mechanisms of information processing characterizing autism with speech delay as opposed to autism without speech delay. Our findings may also have implications for the definition of optimal and differentiated educational learning tracks in these two subgroups of autism spectrum disorders.

Figure 1



9 **163.009** Associations Between Compulsive Internet Use and the Autism Spectrum

C. Shane-Simpson[1], *P. J. Brooks*[2], *R. Obeid*[3], *E. G. Denton*[4] *and K. Gillespie-Lynch*[5], *(1)The Graduate Center & College of Staten Island, New York, NY, (2)College of Staten Island, Staten Island, NY, (3)CUNY Graduate Center, New York, NY, (4)Psychology, The College of Staten Island, Staten Island, NY, (5)CUNY Graduate Center, Brooklyn, NY*

Background: Research suggests that people in the general population with heightened autistic traits (Finkenauer et al., 2012; Romano et al, 2013; 2014) and people with ASD (MacMullin et al., 2015) are at increased risk for compulsive Internet Use (CIU). Researchers have interpreted associations between autistic traits and CIU as evidence for the *social compensation hypothesis* wherein individuals with social challenges use the Internet to compensate for social difficulties. However, ASD is defined not only by

social difficulties, but also by restricted interests and repetitive behaviors (RIRB; APA, 2013). Prior work has not evaluated whether observed associations between autistic traits and CIU are attributable to social symptoms or RIRB or examined if CIU is elevated among college students with ASD in particular.
Objectives: Study One examined whether CIU was associated with (1) social difficulties or RIRB, and (2) different functional uses of Facebook. Study Two evaluated if (1) associations between autistic-like traits and CIU replicated among college students with ASD, and (2) whether students with ASD reported greater CIU than matched peers without ASD.
Methods: In Study One, 597 undergraduates (316 women, 281 men) took an online survey measuring CIU (Meerkerk et al., 2009), autistic-like social symptoms and RIRB (SRS-2; Constantino & Gruber, 2012), self-esteem (Rosenberg, 1965), and Facebook connection strategies (Ellison et al., 2011). Study Two measured CIU and autistic traits among college students with (*n*=33) and without (*n*=33) ASD matched on age, gender, ethnicity, and self-esteem.
Results: Study One: Heightened CIU was associated with greater social symptoms ($r_s(532)=.415$, $p<.001$), greater RIRB ($r_s(532)=.455$, $p<.001$), and lower self-esteem ($r_s(545)=-.330$, $p<.001$), replicating previously documented associations between autistic-like traits and CIU. When entered into a binary logistic regression model predicting high vs. low CIU, only RIRB was associated with high CIU ($R^2=.196$, $X^2(4)=76.86$, $p<.001$). When Facebook connection strategies were entered into a binary logistic regression predicting high vs. low CIU, only information-seeking (but not initiating or maintaining contact) was associated with high CIU ($R^2=.062$, $X^2(3)=23.74$, $p<.001$). Study Two: Among participants with ASD, associations between CIU and social symptoms ($r_s(31)=.347$, $p=.048$), and between CIU and RIRB ($r_s(31)=.377$, $p=.031$) were observed. Although students with ASD exhibited heightened social symptoms and RIRB relative to students without ASD ($ps<.05$), students with and without ASD did not differ in CIU ($p=.102$).
Conclusions: Findings suggest that non-social traits (RIRB) and functions of Internet use (i.e., information seeking on Facebook) contribute more strongly to CIU than autistic-like social challenges and social uses of Facebook (initiating and maintaining contact). Although people with heightened RIRB may be susceptible to CIU due to opportunities to explore focused interests online, only some interests can most effectively be explored through the Internet. Indeed, participants with ASD in Study Two exhibited heightened RIRB, but not elevated CIU. Findings suggest that concern about CIU among individuals with ASD should be tempered by attention to developmental level and the nature of people's interests.

10 **163.010** Autism and Sleep: Understanding Insomnia in Adults with Autism Spectrum Disorder

M. M. Jenkins *and M. J. Baker-Ericzen, Child and Adolescent Services Research Center, Rady Children's Hospital San Diego, San Diego, CA*

Background: Little research has examined insomnia in adults with autism spectrum disorder (ASD). Insomnia symptoms include difficulty falling or staying asleep, early morning awakenings, sleep dissatisfaction, and distressed or impaired daytime functioning from sleep disturbance (American Psychiatric Association, 2013). Insomnia is associated with significantly lower quality of life (LeBlanc et al., 2007), greater risk for accidents (Léger et al., 2002), and high rates of psychiatric comorbidities (Morin & Jarrin, 2013). Children with ASD are prone to insomnia (Sivertsen et al., 2012; Souders et al., 2009), particularly difficulties with sleep initiation and sleep continuity (Richdale, 1999). Adults with ASD also likely experience insomnia (Tani et al., 2003); however, this line of research is still in its infancy.
Objectives: The present study examines the prevalence of insomnia in young adults with ASD using the Insomnia Severity Index (ISI). A secondary goal is to explore perpetuating factors of insomnia.
Methods: Nineteen adult participants, ages 18-29, with an ASD diagnosis, have been enrolled in a community-based intervention targeting social, cognitive and vocational domains. At least 15-25 additional participants will enroll by April 2016. Participants and their parents/caregivers complete a comprehensive assessment including sleep functioning. Participants complete the ISI (Morin et al., 2011), a widely used measure of insomnia with well-established reliability and validity. The ISI assesses severity of insomnia as well as satisfaction with sleep pattern, effect of sleep on daytime and social functioning, and concern about current sleep. A score of ≥10 indicates insomnia (86% sensitivity; 88% specificity) with 4 severity categories: 0-9 (none); 10-14 (mild); 15-21 (moderate); and, 22-28 (severe). Parents/caregivers complete the ISI reporting on participant sleep.
Results: Preliminary findings reveal participant (n=19) ratings on the ISI ranged from 0 (none) to 19 (moderate insomnia). Parent/caregiver (n=19) ratings ranged from 0 (none) to 27 (severe insomnia). Table 1 indicates how many participants exceeded the clinical cutoff for insomnia and the severity of their insomnia. Table 2 characterizes the type of insomnia (i.e., early, middle, late) and the related severity. Participant and parent report on the ISI demonstrated a small to medium positive association, $r=.42$, $p=.07$. Qualitative data indicate participants most commonly stay in bed and use electronics inside their bedroom when they cannot sleep. To compensate for poor sleep, participants most commonly sleep late and take naps.
Conclusions: We are aware of no previous studies using the ISI in adults with ASD. By participant report, >20% are above threshold for insomnia. By parent/caregiver report, >50% are above threshold. More research is needed to better understand how to best assess insomnia in ASD populations including how to maximize informant report. It is also important to further explore perpetuating factors of insomnia in this population (i.e., factors maintaining or exacerbating insomnia), as these are treatment targets for CBT for Insomnia, the frontline treatment. Improving the detection of insomnia in adults with ASD is an important yet largely unexplored area that could have a meaningful impact on research and clinical practice.

Table 1. Examining ISI scores over the clinical cutoff and severity of insomnia.

Informant	*Above Threshold Insomnia*	*Mild*	*Moderate*	*Severe*
Participant	21%	5%	16%	0%
Parent	53%	16%	26%	11%

Table 2. Characterizing type of insomnia and severity of sleep difficulty.

	Mild 30-45 minutes	*Moderate 45-90 minutes*	*Severe 90 -120 minutes*	*Very Severe >120 minutes*
Participant				
Difficulty Falling Asleep	26%	11%	11%	11%
Difficulty Staying Asleep	16%	11%	0%	0%
Problems Waking Too Early	26%	0%	0%	0%
Parent/Caregiver				
Difficulty Falling Asleep	17%	6%	22%	11%
Difficulty Staying Asleep	11%	22%	6%	6%
Problems Waking Too Early	33%	0%	6%	6%

11 **163.011** Autonomic Symptoms Endorsed By Adults with Autism Spectrum Disorders

B. K. Woodruff[1]*, J. Adams*[2]*, M. Temkit*[3] *and B. Goodman*[1]*, (1)Neurology, Mayo Clinic Arizona, Scottsdale, AZ, (2)Arizona State University, Tempe, AZ, (3)Research Biostatistics, Mayo Clinic Arizona, Scottsdale, AZ*

Background: Autonomic features such as abnormal skin conductance and pupillary responses have been reported in individuals with autism spectrum disorders (ASDs), but to our knowledge no systematic approach to identifying autonomic symptomatology has been conducted in adults with ASDs.
Objectives: To quantify autonomic symptoms endorsed by a sample of adults with ASDs on the Compass 31, a survey instrument that captures multiple autonomic symptoms.
Methods: The Compass 31, a quantitative measure of autonomic symptomatology was administered anonymously to 48 adults with ASDs. Subjects were recruited at local

autism community meetings or were mailed the instrument after expressing interest in participation. The latter subjects were identified from a database maintained by the Arizona State University Autism/Asperger's Research Program.
Results: Weighted Compass 31 total and subscale scores [mean (SD), (range)] were as follows: Total score (Maximum = 100) - 23.5 (16.1), (2.8-60.7); Orthostatic intolerance subscale (Maximum = 40) - 9.5 (9.8), (0.0-28.0); Vasomotor subscale (Maximum = 5) - 0.6 (1.2), (0.0-4.2); Secretomotor subscale (Maximum = 15) - 3.7 (3.2), (0.0-10.7); Gastrointestinal subscale (Maximum = 25) - 6.2 (3.8), (0.0-18.7); Bladder subscale (Maximum = 10) - 1.2 (1.5), (0.0-6.7); Pupillomotor subscale (Maximum = 5) - 1.8 (1.3), (0.0-5.0). The most commonly endorsed subscales (weighted subscale score > 0) in this sample were Gastrointestinal (97.9%) and Pupillomotor (83.3%).
Conclusions: Autonomic symptomatology was not uncommon in this sample of adults with ASDs, with gastrointestinal and pupillomotor symptoms commonly endorsed. Such symptomatology may represent autonomic dysfunction amenable to therapeutic intervention, which will need to be confirmed in future studies including clinical autonomic testing. Amelioration of such symptomatology may help to improve quality of life for a subset of individuals with ASDs.
Supported by: Mayo Clinic Intramural Career Development Award

12 **163.012** Basic Auditory Processing Difficulty in the Youth with Autistic Feature

H. Song[1], *M. K. Kwon*[2] *and M. Park*[3], *(1)Graduate school for the professional therapeutic technology, Seoul Woman's univeristy, Seoul, South Korea, (2)Autism Center of Excellence, University of California, San Diego, La Jolla, CA, (3)Graduate school for the professional therapeutic technology, Seoul Woman's University, Seoul, South Korea*

Background: The population with ASD is hypersensitive to simple stimuli. This atypical perceptual processing is observed in both visual (Bertone, 2005) and auditory modalities (Lepisto, 2008). One explanation for this hypersensitivity is internal noise in neurons. According to this hypothesis, the complexity of stimuli influences the ability to perceive/discriminate basic perceptual properties. However, it is difficult to assess the 'internal noise' at the behavioral level. In addition, it is still unclear how this internal noise is related to ASD people's social skills.
Objectives: The present study was designed 1)to assess 'internal noise' in young adults with Autistic feature using the modified auditory Go-NoGo task (Song & Kwon, 2015), and 2)to examine whether basic auditory processing predicts the severity of Autistic feature, even after controlling for IQ and visual processing.
Methods: Participants were 102 undergraduate students (Mean Age =21.43; 40 males and 62 females). IQ(M = 12.49 for Block design, M=11.94 for Vocabulary), EQ (Baron-Cohen & Wheelright, 2004; Her & Lee, 2011), and AQ (Baron & Cohen, 2001) were assessed. Based on their performance on the AQ test, we divided the subjects into two groups: high AQ group (the top 30% (AQ>22)) and low AQ group (the bottom 30% (AQ <14)). None of gender, age and IQ differed across the two groups. The visual processing was assessed by using Bertone et al's (2005) Orientation Identification Task, and the auditory processing was assessed by using the modified auditory Go-No Go task (Song & Kwon, 2015). The modified auditory Go-No Go task required the ability to inhibit their dominant response (e.g. pressing an arrow key) when a softer sound was presented right after the first sound was presented. Their performance level was evaluated by assessing individual thresholds to reach 70% accuracy. A low threshold meant a high sensitivity. A half of the trials contained simple tones and the other half contained complex tones.
Results: We conducted hierarchical multiple regression analyses to analyze the relationships among IQ, the visual processing and the auditory processing. There were interesting group differences between the high AQ group and the low AQ group. In the high AQ group, their IQ score was positively associated with the visual processing ($r=.545$, $p<.05$) and their performance on the Go-NoGo test in both pure tone and complex tone conditions predicted their EQ (social function) scores respectively ($t=-.2.235$, $p<.05$ for pure tone; $t=-2.103$, $p<.05$ for complex tone), even after controlling for IQ and the visual processing. In contrast, none of significant relationships for the same tests was observed from the low AQ group.
Conclusions: Basic auditory processing is a significant predictor of the social function in the youth with ASD feature, even after controlling for IQ and visual processing. In addition, the Go-Nogo task was proved to indirectly represent the internal noise-related function. ASD people's difficulty in inhibiting a response to a softer volume could be a valuable variable in developing a method for the early detection and intervention.

13 **163.013** Changes in Social Activities for Youth with Autism Spectrum Disorders during the Transition to Adulthood

ABSTRACT WITHDRAWN

Background: Although low rates of social participation are common among youth with autism spectrum disorders (ASD), it is not known how leaving high school impacts their social/recreational activities, or whether changes in social activities have mental health implications.
Objectives: This study uses a longitudinal design to examine changes in social/recreational participation for youth with ASD from before to after high school exit. We also examined whether changes in activities were related to internalizing symptoms.
Methods: Participants were 33 youth with ASD and their families. Data were collected two times: when youth were in their last year of high school, and 6-12 months after high school exit. Youth averaged 18.8 years of age at the start of the study (range = 17-22). Most (84.8%) were male and the majority was white non-Hispanic (90.9%). Just over 30% had an intellectual disability. Parent respondents included 29 mothers and 4 fathers, who were generally well-resourced (although 25% had incomes < $40,000).
At both time points, parents reported how often their son/daughter participated in 10 activities (from 0 = less than yearly/never to 4 = several times a week). Activities were grouped into three areas: unstructured social activities (social time with relatives, friends/neighbors, or with people from school/work); structured social activities (religious services, church social events, formal/informal recreational activities, playing sports with others); and other activities (working on hobbies, travel, exercise). Average participation and a count of the number of activities were calculated for each area. Internalizing symptoms were measured both times using Achenbach's Adult Behavior Checklist.
Results: The most common activity was participating in a formal or informal recreational activity (e.g., bowling, movies) and the least common was playing sports with others. Most youth spent some unstructured social time with classmates, co-workers, friends, or neighbors, but few did this regularly. For example, when in high school, 55% of youth spent some time with people from school/work outside of school/work hours, but only 15% did this once a week or more.
Youth in their last year of high school, on average, participated in 7.7 activities; this average decreased to 7.0 activities after exit, $t(32)=2.8$, $p<.01$. There were no differences in the amount of unstructured social activities or "other," primarily non-social activities, $ts(32)=.06$ and .24, respective, p=ns. There was a significant decline in structured social activities after high school – both in average amount of participation and in number of activities, $ts(32)=3.10$ and 2.97, respectively, $ps<.01$. The extent of decline in structured social activities was marginally related to internalizing problems when youth were out of high school, Spearman $rho=-.33$, $p=.07$. Youth who had a greater drop in structured social activities were more likely to have borderline or clinical-level internalizing symptoms.
Conclusions: In addition to difficulties obtaining vocational/educational activities, our findings suggest that many youth with ASD lose some structured social activities after high school. This loss of activities might be related to internalizing problems. Further analyses will continue to examine the relations between changes in social and recreational activities during the transition to adulthood and mental health.

14 **163.014** College Experiences for Students with Autism Spectrum Disorder (ASD): Identity, Disclosure, and Accommodations

B. E. Cox[1], *A. Anderson*[2], *J. Edelstein*[2] *and A. Wolz*[2], *(1)P.O. Box 3064452, Florida State University, Tallahassee, FL, (2)Florida State University, Tallahassee, FL*

Background:
College students with autism face daunting social, emotional, independent-living, self-advocacy, and communication challenges both inside and outside of the classroom (Adreon & Durocher, 2007; Gobbo & Shmulsky, 2013). However, critical holes in the empirical literature make it difficult to develop low cost, high yield, evidence-based interventions to improve student grades, persistence, graduation, and subsequent employment.
Objectives:
The current study begins to fill these knowledge gaps by (1) defining salient issues affecting college success for individuals with autism and (2) describing institutional initiatives with potential to promote college success for students with autism. The study's primary research question is: How do students with autism make sense of their experiences in higher education and respond to barriers potentially limiting postsecondary success?
Methods:
Data for the study are drawn from interviews, following the guidelines outlined by Fetterman (1998), with nine students with a formal diagnosis of ASD. Interviews centered upon student inputs, experiences, and outcomes in higher education (Astin, 1991). For example, participants were asked to describe their initial fears about going to college and their decisions about whether to disclose their diagnosis.
Analyses proceeded using a constant comparative approach (Straus & Corbin, 1998) with researchers coding data independently but meeting periodically to ensure convergence during two distinct rounds of coding. First, two of this paper's authors used Astin's (1991) framework as an *a-priori*descriptive coding structure. The second round of coding was led by a third researcher. To confirm appropriate interpretation, two of the participating students reviewed and approved this paper.
Results:
As expected, all of the interviewed students cited postsecondary enrollment as a major life event. Once in college, students took a pragmatic approach to disclosing their autism diagnosis, only revealing diagnoses if needed to acquire formal accommodations from the postsecondary institution or when asked directly by peers. One student explained, "I don't know when or how to say it so I was always wait for it to come up" while another said "that never really came up."
Student comments also revealed an internal tension regarding the manner in which autism fit into their own sense of identity. Decisions to disclose their diagnosis to peers or the institution or to seek formal accommodations, therefore, were the outward manifestations of the internal identity development process for each student. For example, one student boasted "So I'm very proud of the fact that I'm able to fake out as many people as I do, honestly" but, moments later, concluded "I mean I know that's not really a healthy way to relate to one with autism or Asperger's."
Conclusions:

The voices of college students with ASD have generally been drowned out by the overwhelming emphasis (in the general public and scholarly literature) on young children and early interventions. This study amplifies their voices and empowers individuals with ASD to self-advocate as they consider opportunities for continued educational advancement. Now professionals working in postsecondary education must listen to these voices and act on behalf of the growing number of college students with autism.

15 **163.015** College Students' Knowledge and Attitudes Towards Students on the Autism Spectrum: A Five Year Follow-up

***D. White**, A. Hillier, A. Frye and E. Makrez, Psychology, University of Massachusetts Lowell, Lowell, MA*

Background: Autism spectrum disorder (ASD) is characterized by social and communicative deficits, as well as patterns of rigid and repetitive behavior. However, with the appropriate supports in place, many individuals with ASD are capable of academic success, including success at the university level. In recent years, the importance of acceptance from peers and integration into the university has been increasingly recognized as contributing factors to success for university students with ASD.
Objectives: This study aimed to evaluate university students' knowledge and attitudes towards students on the autism spectrum, to identify underlying factors which contribute to such attitudes, and to examine whether attitudes changed over a five year period.
Methods: Participants were undergraduate students at a mid-sized university in the northeast. Data was collected for the first cohort in 2008 and included 111 participants. The second cohort was collected five years later in 2013 and included 103 participants. Participants in each cohort completed a questionnaire which asked about their knowledge of traits associated with ASD, whether they knew someone with ASD, and their attitudes towards students with ASD.
Results: As predicted the second cohort endorsed significantly more correct traits associated with ASD than those in the first cohort. They also demonstrated significantly more positive attitudes. In looking at the relationship between knowledge (measured by number of identified correct traits) and attitudes, no significant correlation was found. To investigate further the relationship between cohort, attitudes and knowledge, we examined associations between attitudes and nine subscales of traits including correct and incorrect traits. Positive traits were positively correlated with positive attitudes, and negative traits were negatively correlated with positive attitudes. In addition, students who identified a high number of incorrect traits were likely to have less positive attitudes toward their peers with ASD, regardless of the number of correct traits that were identified.
Conclusions:
While our findings indicate that student attitudes and knowledge improved over the course of five years, many students who were knowledgeable about ASD still reported negative attitudes toward participating in university and classroom based activities with students with ASD. These findings have implications for increasing knowledge and understanding of autism spectrum disorders on college campuses, and ultimately academic success and graduation rates for this population.

16 **163.016** Correlates of Academic Success in College Students with an Autism Spectrum Disorder: Do the Traditional Measures Apply?

***S. W. Eldred**[1], S. M. Ryan[2], L. K. Baker[1] and J. A. Rankin[1], (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)The University of Alabama, Tuscaloosa, AL*

Background:
Colleges use both the American College Testing college readiness assessment (ACT) and high school GPA as measures of students' previous educational achievements in order to help determine potential for success in college (ACT, 1997). Studies have found positive linear relationships between both ACT scores and college GPA, as well as previous GPA and college GPA, indicating that these are valid predictors of college success in neurotypical populations (Coyle, 2015; ACT, 2002). While cognitive ability is not traditionally used to predict success in college students, it is strongly correlated with ACT scores and may serve as an additional factor to help predict success in college (Coyle, 2015). The relationship between these factors and academic success in college have not been studied in college students with ASD.
Objectives:
The current study examines the relationship between students' GPA at the end of their first semester, and factors typically associated with success in college, (i.e., ACT scores, previous GPA, FSIQ).
Methods:
This study included 10 students enrolled in an ASD specific support program for degree-seeking undergraduate students with ASD at a major public university. Enrolled students meet 3 times per week with a mentor, participate in study hall, and attend group meetings. Three cohorts of students entering the University in 2012, 2013, and 2014 were included in the current analysis. Of these students, 7 entered as freshmen and 3 entered as transfer students. As part of their applications, each student provided past cognitive assessments, their high school GPA, and their ACT scores.
Results:
Correlations between ACT scores, previous GPA, FSIQ, and cumulative spring GPA were examined. These correlations revealed that, similar to studies with typically developing students, there was a strong positive correlation between ACT scores and IQ scores, ($r = .77$, $p = .01$). However, unlike neurotypical students, neither ACT scores nor IQ scores were significantly related to first-year GPA, ($r = .49$, $p = .15$; $r = -.05$, $p = .85$). Additionally, neither ACT scores, nor IQ scores were significantly related to previous GPA, ($r = .42$, $p = .20$; $r = .23$, $p = .40$). There was a significant positive correlation between high school GPA and first-year GPA ($r = .54$, $p = .04$). It should be noted that the limited sample size result in limited power to detect small to moderate effects. Six to seven additional students will be added from the most recent cohort prior to the IMFAR meeting in May.
Conclusions:
Overall, these results indicate that factors that are used as predictors of college success for typically developing students might not be as significant in students with ASD. For the current sample of college students with ASD, ACT and IQ scores did not significantly correlate with first-year GPA, suggesting a weaker association between these factors compared to typically developing students. The strongest relationship was found between previous GPA and first-year

17 **163.017** Correlates of Self-Reported Quality of Life in Verbally-Able Young Adults with Autism Spectrum Disorder

***K. M. Frost**[1], L. A. Pepa[2], K. Gotham[3] and C. Lord[4], (1)Center For Autism and the Developing Brain, White Plains, NY, (2)Rutgers University, Smithtown, NY, (3)Vanderbilt University, Nashville, TN, (4)Weill Cornell Medical College, White Plains, NY*

Background:
Although adults with autism spectrum disorder (ASD) demonstrate a range of abilities, many remain dependent on their families or other support services in adulthood (Howlin, Goode, Hutton, & Rutter, 2004; Taylor & Seltzer, 2011). Studies of ASD in adulthood often focus on symptom profiles and independence. Additionally, it is important to consider an individual's perceived quality of life. Quality of life is an aggregate of various factors, such as interpersonal relations, material and emotional well-being, social inclusion, and rights (Schalock, 2004). While previous research has examined this construct for caregivers, few studies to date have focused on quality of life for individuals with ASD (Renty & Roeyers, 2006; Kamio, Inada & Koyama, 2012).
Objectives:
This study aims to characterize factors related to self-reported quality of life in a transition-age sample of verbally-able young adults with ASD.
Methods:
Participants were drawn from a well-characterized sample of individuals who were suspected of having autism at age two, and have been followed into young adulthood (Lord, Risi, DiLavore, Schulman, Thurm & Pickles, 2006; Anderson, Liang, & Lord, 2014). The following data is derived from questionnaires and in-person assessments collected at approximately age 18. In addition to standardized measures of autism symptoms (Autism Diagnostic Observation Schedule; ADOS), cognitive ability, and adaptive functioning (Vineland Adaptive Behavior Scales; VABS), participants completed self-report measures, including the Quality of Life Questionnaire (QoLQ; Schalock & Keith, 1993), the Social Interests and Habits Questionnaire (SIH; Gotham, Bishop, Brunwasser, & Lord, 2014), and the Social Support Questionnaire (SSQ; Sarason, Sarason, Shearin, & Pierce, 1987). Parents completed the Family Support Scale (FSS; Dunst, Jenkins, & Trivette, 1984), as well as a questionnaire about the participant's service use. Participants were included in the present study if they were verbally fluent, and able to complete self-report questionnaires on their quality of life (n=23).
Results:
Scores on the QoLQ were significantly positively correlated to verbal IQ (r=0.55) and all domains of the VABS (r=0.45 to 0.63), and negatively related the ADOS Calibrated Severity Scores (CSS) in restricted and repetitive behaviors (RRB) (r=-0.60). Additionally, youth quality of life was positively related to amount of social activity on the SIH (r=0.65) and satisfaction with social support on the SSQ (r=0.70), and negatively related to service use (r=-0.43). No significant relationship was found between FSS and QoLQ (r=-0.07). When controlling for effects of verbal IQ, QoLQ scores remained significantly related to ADOS RRB severity scores and VABS communication scores, in addition to social activity (SIH) and satisfaction with social support (SSQ).
Conclusions:
Results suggest that a combination of factors, including fewer repetitive behaviors, higher verbal intelligence, stronger adaptive skills, and increased social activity are associated with greater self-reported quality of life in young adults with ASD. These findings underscore the importance of access to social activity and support as individuals enter adulthood. It also suggests that self-reported quality of life is an important outcome measure in this population, and one that may reflect an integration of autism symptom level, social and adaptive functioning.

Table. Correlates of the Quality of Life Questionnaire.

		ADOS Calibrated Severity Score				Vineland Standard Scores

18 **163.018** Depression and Anxiety in the Aging ASD Cohort: Relationships with Cognition and Social Networks

B. B. Braden[1], *C. J. Smith*[2], *T. Glaspy*[1], *A. M. Thompson*[1], *B. R. Deatherage*[1], *E. Wood*[1], *D. Vatsa*[1] *and L. Baxter*[1], *(1)Barrow Neurological Institute, Phoenix, AZ, (2)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: The population of adults with autism spectrum disorder (ASD) is rapidly growing, yet there are few studies investigating the effects of aging. ASD individuals have high comorbidity with other psychiatric disorders, especially depression and anxiety. In typically developing (TD) individuals, psychiatric symptoms increase with age which is hypothesized to be related to decreased social support. Many ASD individuals struggle with decreased social support at even younger ages. It is critical to understand mood symptom changes with age, since these factors negatively affect cognition, which can further impair functioning of ASD individuals.
Objectives: To evaluate the relationship between age and mood measures in ASD, we utilized self-report measures of depression, anxiety, and social networks and related findings to cognitive scores. We hypothesized that psychiatric symptoms are exacerbated in older cohorts of ASD, and that symptoms are related to level of social support and predict cognition.
Methods: Data were obtained for 16 high-functioning middle-age (40-65 years) ASD, 11 young-adult ASD (18-25 years), and age-matched TD (16 middle-age; 9 young-adult) male participants. Self-report measures were Beck Depression Inventory-II (BDI-II), State-Trait Anxiety Inventory (STAI), and Social Network Index. Mood measures were correlated with cognitive measures of executive functioning, memory, and visual detail processing.
Results: Participants did not significantly differ in IQ (p=0.18). For all mood and social network measures, there were main effects for diagnosis, such that ASD participants reported higher levels of depression and anxiety and lower levels of social networks, as compared to TD (all p<0.01). Based on clinical cutoffs, 88% of the middle-age ASD group reported significant levels of anxiety and 44% reported significant depression, as compared to 45% in the young-adult ASD group for both anxiety and depression. Social network measures did not significantly correlate with mood measures in either middle-age or young-adult ASD participants. In young-adult ASD participants, mood measures significantly predicted performance on several cognitive measures, most pronounced for memory. However, mood measures did not correlate with cognitive performance in the middle-age ASD group. IQ levels did not account for a significant amount of the variance in any dependent measure and effects did not change when values were added as covariates.
Conclusions: Findings suggest older adults with ASD experience greater levels of depression and anxiety and less social support than their TD counterparts. Further, rates of clinically significant anxiety in this sample of older adults with ASD are higher than ever reported in younger samples, including the young-adults in the present study. Interestingly, mood symptoms did not correlate with measures of social support or cognition in middle-age ASD participants. This dissociation between mood and cognition suggests cognitive deficits in older adults with ASD may be mediated by other effects of aging. Further, increased rates of psychiatric symptoms may not be a result of lack of social support in older adults with ASD. Understanding age-related changes and accurately detecting symptoms through measures uniquely designed for the ASD population is essential to providing appropriate care plans and effective treatment interventions for mental health in ASD.

19 **163.019** Determining Sex Differences in the Social Cognition of Adults with High-Functioning Autism Spectrum Disorder Using Advanced Mindreading Tasks

M. Kuroda[1,2] *and Y. Kawakubo*[3], *(1)Graduate School of Education, The University of Tokyo, Tokyo, Japan, (2)Child Mental Health-care Center, Fukushima University, Fukushima-shi, Japan, (3)University of Tokyo, Bunkyo-ku, Japan*

Background: At even three years of age, girls can understand another individual's emotions and thoughts better than boys of the same age; that is, girls exhibit more advanced social cognition than boys in childhood (Baron-Cohen, 2003). Additionally, individuals with autism spectrum disorder (ASD) display inherent deficits in mindreading abilities. The results of the study, using the Cambridge Mindreading Face-Voice Battery, revealed that females recognized emotions from facial expressions better than males did, regardless of the diagnosis of Asperger syndrome (AS) (Golan et al, 2006). However, few studies have examined the role of sex differences in social cognition.
Objectives: We aimed to examine sex differences in the social cognition of adults with high functioning ASD using advanced mindreading tasks, as well as the relationship between mindreading abilities, the symptoms of ASD, and IQ.
Methods: The 60 participants consisted of 41 male adults with ASD (mean age = 30.9±8.3 yrs, mean Full IQ (FIQ) =108.5±13.3, mean Verbal IQ(VIQ)=113.3±13.8) and 19 female adults with ASD (mean age =31.7±8.0 yrs, mean FIQ =105.7±11.0, mean VIQ=109.4±9.7). There was no significant difference in age, FIQ and VIQ scores between these two groups. The participants performed advanced mindreading tasks "The Motion Picture Mind-Reading Test"(Wakabayashi & Katsumata,2011) consisting of the evaluation of 41 video clips that were designed to assess mindreading ability. A word or a phrase that expressed a mental state was shown along with each video clip. The participants were asked to judge whether each word or phrase was appropriate for the paired scene. Autism Diagnostic Observation Schedule testing was also conducted with all participants to evaluate ASD symptoms.
Differences between the groups regarding accuracy rates for the advanced mindreading tasks were evaluated using an independent t-test. Additionally, we examined the correlation between the accuracy rates for the advanced mindreading tests and verbal IQ (VIQ), performance IQ (PIQ), FIQ, and ADOS scores.
Results: There was no significant difference in the accuracy rate for the advanced mindreading tasks between males (67.3±16.1) and females (69.7±2.7). The accuracy rate of advanced mindreading tasks and the ADOS social score showed a significant positive correlation in females (r=.648, p<.01), but not in males (r=.211, p=.185). Conversely, the correlation between the accuracy rate of advanced mindreading tasks and VIQ was significant for males (r=.323, p<.05) but not for females (r=.277, p=.251).
Conclusions: These results suggest that male adults with ASD perform the mindreading tasks by using their intelligence, specifically that measured by VIQ. This result was the same as that in Happé's study (1995) but that study did not consider sex differences. Our results also suggest that females with high functioning ASD may process the mindreading tasks through social cognition (ADOS social area). In the real world, males with high functioning ASD compensate for mindreading deficiencies by use of that portion of intelligence measured by the VIQ, whereas females perform the mindreading tasks through social cognition. The female's strategy for mindreading may be the same as in individuals with typical development.

20 **163.020** Do College Students with ASD Face Specific Challenges Navigating Job Interviews Relative to Students with Other Disabilities and Students without Disabilities?

D. Bublitz[1], *K. Fitzgerald*[1], *M. Alarcon*[2], *J. D'Onofrio*[3] *and K. Gillespie-Lynch*[1], *(1)City University of New York, College of Staten Island, Staten Island, NY, (2)City University of New York, Brooklyn College, Brooklyn, NY, (3)Center for Student Accessibility, City University of New York, College of Staten Island, Staten Island, NY*

Background:
Employment challenges faced by individuals with disabilities may be exacerbated for those with ASD (Newman et al., 2011). Difficulty navigating employment interviews may contribute to disparities between the abilities of individuals with ASD and employment outcomes (Hendricks & Wehman, 2009). Interventions have improved the interview skills of adults with ASD (Morgan et al., 2014; Smith et al., 2015). However, these interventions have not used comparison groups to identify challenges specific to people with ASD and have not focused on college students. Although increasing numbers of students with ASD are entering college, evidence-based supports to help college students with ASD remain scarce (Barnhill, 2014). Research is needed to identify both specific challenges that college students with ASD face during job interviews and challenges they share with other students, to develop interventions consistent with the principles of Universal Design.
Objectives:

1. Compare the interview skills of college students with ASD, students with other disabilities and students without disabilities.
2. Examine associations between interview performance and autistic symptoms, anxiety, self-esteem, and prior interview experience.

Methods:
Sixteen college students with ASD, fifteen students with other disabilities, and fourteen students without disabilities engaged in mock employment interviews and completed assessments including the SRS-2, STAI, and Rosenberg's SES. Verbal responses were coded using non-mutually exclusive codes by two coders who achieved research reliability. Responses were timed in milliseconds. Non-parametric analyses were employed.

Results:
Students with ASD reported higher autism symptoms than students with other disabilities (p = .023) or no disabilities (p = .003) and more state anxiety than students with other disabilities (p = .04). Group differences in self esteem and prior interview experience were not observed (ps > .12).
When asked what they look for in a workplace, students with ASD were less likely to mention desiring social interaction than either comparison group (ps < .008).
Most students with ASD (63%) and students with other disabilities (67%) fully disclosed disability status. However, students with ASD (13%) and those with other disabilities (7%) rarely framed disclosure by emphasizing positive aspects of their disabilities. Students with disabilities who reported higher self-esteem (irrespective of ASD classification) disclosed their disability prior to being asked (p = .039).
Students with ASD exhibited longer and more variable durations of responses than those without disabilities (ps = .020). Higher autistic symptoms were associated with longer duration of responses (p = .014).
Conclusions:
Responses to many questions in the mock interview did not differ between students with ASD and their peers. Therefore, college students with ASD may benefit from interview skills interventions that include diverse peers and are based on the principles of Universal Design.
Students with disabilities were ineffective in educating the interviewer about strengths associated with their disability. Interventions should include guidance concerning disclosure of disability status during job interviews.
Students with ASD exhibited challenges modulating the length of their responses and rarely expressed interest in social interaction in the workplace. Therefore, interventions should help students with ASD express their viewpoints succinctly while conveying social interest during the interview and/or seeking jobs requiring less interaction with others.

21 **163.021** Does Baseline Physiological Arousal Influence Inhibitory Control in Adults with Autism Spectrum Disorder?

M. Kuiper[1], *L. Verhoeven*[2] *and H. M. Geurts*[3], *(1)Research, Development & Innovation (RD&I); Brain & Cognition, Dr. Leo Kannerhuis; University of Amsterdam, Doorwerth, Netherlands, (2)Dr. Leo Kannerhuis, Doorwerth, Netherlands, (3)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam; Dr. Leo Kannerhuis, Amsterdam, Netherlands*

Background:
Cardiac autonomic functioning (a.k.a. physiological arousal) is increasingly acknowledge to be related to problems that people with autism spectrum disorder (ASD) encounter in daily life. Baseline physiological arousal has been suggested to modulate inhibitory control in typically developing (TD) individuals: when confronted with a stressor, low baseline arousal would lead to more prepotent response inhibition difficulties than high baseline arousal. Recent meta-analysis showed that people with ASD have prepotent response inhibition difficulties (effect size: 0.55). However, a significant amount of heterogeneity between the studies was observed, suggesting there are unknown factors that influence inhibitory control in people with ASD. Baseline physiological arousal could be one of these factors.
Objectives:
We aim to examine the influence of baseline physiological arousal on prepotent response inhibition.
Methods:
Inhibitory control was measured with an emotional stop signal task (ESST) including neutral and negative pictures with stop signal reaction time (SSRT) as outcome measure. Participants were 32 male adults with ASD and 30 TD adults (age 18-45). Physiological arousal, at baseline and during the ESST, was indicated by heart rate variability (HRV). Data collection is expected to end in November 2015, with both groups containing 40 participants. Final results can be presented in May 2016.
Results:
Preliminary group comparisons revealed that the ASD group had significantly lower baseline HRV than the TD group. Both groups had similar SSRTs on the ESST. Using a median split on baseline HRV, both the ASD and TD group consisted of a significantly different low and high baseline HRV subgroup. The low ASD subgroup had significantly lower baseline HRV compared to the other three subgroups. The high ASD and high TD subgroup had similar baseline HRV. Mixed ANOVA analysis showed no interaction effect of baseline HRV on ESST, but indicated that all groups performed worse on the negative condition. Exploratory group comparisons revealed that the low ASD subgroup had significantly higher SSRTs compared to the high ASD subgroup.
Conclusions:
These preliminary findings suggest that adults with ASD are more aroused at baseline compared to TD adults but have similar prepotent response inhibition abilities. Both groups showed more prepotent response inhibition difficulties when confronted with a stressor. So far, results suggest no influence of baseline HRV on prepotent response inhibition. Exploratory analysis suggest a low baseline HRV subgroup within the ASD population that seem to have more prepotent response inhibition difficulties than adults with ASD with higher baseline HRV.

22 **163.022** Early Adult Outcomes of High-Functioning Children with Autism Spectrum Disorder (ASD) in Hong Kong

P. W. Leung *and R. Poon, Psychology, The Chinese University of Hong Kong, Hong Kong, China*

Background:
Autism spectrum disorder (ASD) is a neurodevelopmental disorder since childhood. Given the unavailability of a medical cure, it incurs considerable impairments to the psychosocial/educational/occupational development of the afflicted children. It is thus imperative to assess their adult outcomes for both academic and practical reasons.
Objectives:
This cross-sectional study in Hong Kong examines outcomes of high-functioning ASD children at their early adulthood (aged 18-28) in terms of persistence of ASD diagnosis/symptoms, psychosocial adjustment, and educational/occupational attainment. IQs assessed during childhood were investigated as predictors of adult outcomes.
Methods:
Sixty-four ASD adults were recruited from clinics and ASD groups in Hong Kong. They were Chinese with normal intelligence. All, except five, were males, aged between 18 to 28 years. A series of tests and interviews were administrated to them and/or their parents by clinicians in two half-day sessions.
Results:
Sixty-seven percent of the participants at early adulthood still retained an ASD diagnosis (by 3Di, a standardized diagnostic interview revalidated locally in Hong Kong, Kelly et al., *JADD*, 2015). For the remaining 33%, only one-third of them (or only 11% of the whole group) was completely symptom-free. The psychosocial adjustment of 58% of the ASD adults was rated “fair/poor”, in contrast to 42% “near normal/good”, on the basis of five areas, namely, work, friendship, independence, stereotyped/repetitive behaviors, and use of language. When compared to population age-peers, the ASD adults were also found to be under-achieved both in terms of educational/occupational attainment. IQs assessed at childhood, particularly Verbal IQ, were found to be good predictors of the adult outcomes, including persistence of ASD diagnosis/symptoms, psychosocial adjustment, and educational/occupational attainment, besides current IQs. Performance IQ remained essentially unchanged from childhood to adulthood, while Verbal IQ had made some significant improvement. The outcome variables were themselves all interrelated. Those ASD children starting with lower IQs at childhood would continue at early adulthood having lower IQs, persistence of ASD diagnosis/symptoms, poorer adjustment, and lower educational/occupational attainment or vice versa.
Conclusions:
Even amongst ASD individuals with normal intelligence, IQs remained potent predictors of their early adult outcomes. Our present outcome data indicated substantial developmental impairments/disadvantages with strong persistence of ASD diagnosis/symptoms. However, when compared to many previous studies, the early adult outcomes of our ASD individuals in Hong Kong were in fact at the favorable end. This could partly be explained by including only ASD adults with normal intelligence in our study. Or, this could also be partly due to facilitative environmental factors in Hong Kong such as an expanding economy with a labor market close to full employment, as well as to recent world-wide technological advances, including the mass availability of computers and web-based social networking platforms. Nonetheless, the overall chronicity and impairing nature of ASD identified here highlighted the needs for a wide range of services tailored to the adult problems of ASD in areas of education, vocational training, work, or independent living, besides those persistent autistic symptoms/traits.

23 **163.023** Effects of Internalizing Problems on Daily Living Skills Among High-Functioning Adults with Autism Spectrum Disorders in Japan

M. Tsujii[1], *Y. Murayama*[2] *and K. Suzuki*[3], *(1)Chukyo University, Toyota, Aichi, Japan, (2)Hamamatsu University School of Medicine, Nagoya-shi, Aichi, Japan, (3)Department of Psychiatry, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: Adaptive functioning encompasses behaviors deemed critical to living independently, including daily living skills. Such adaptive behavior is often impaired to some degree in individuals with Autism Spectrum Disorders (ASDs) (Sparrow et al., 2005), with deficits appearing to be particularly pronounced in individuals with high-functioning ASDs in Japan. In addition to issues with adaptive behavior, though, individuals with ASDs are also likely to have mental health problems. Studies have shown that rates of depressive and anxiety disorders are higher in those with high-functioning ASDs. These internalizing problems may exacerbate deficits in daily living skills and most adaptive behaviors. And, few studies have investigated the relationship between daily living skills and severity of internalizing problems in adults with high-functioning ASDs.
Objectives: In our cross-sectional study, we examined the effects of internalizing problems on daily living skills in adults with high-functioning ASDs.
Methods:
Participants were 116 adults (90 men and 26 women) who had been diagnosed with a high-functioning ASD. Mean age was 28.10±6.54 years, with a range from 20 to 52 years.
Measures: *Daily Living Skills* Participants' daily living skills were evaluated using Daily Living Skill domain, the Vineland Adaptive Behavior Scale-II Japanese version (VABS-J; Tsujii et al., 2014; Sparrow et al., 2005).
Internalizing Problems Due to impairment of self-monitoring in individuals with ASD, levels of internalizing problems were assessed using both self- and other-rated methods. For self-rating severity of internalizing symptoms, the Kessler Psychological Distress Scale (K10; Kessler et al., 2002) Japanese version (Furukawa et al., 2002) was used. For other-rating severity of internalizing problems, parents of participants answered questions regarding Internalizing Problems in Maladaptive Behavior Index, VABS-J.

Results:
With regard to scores of Daily Living Skills domain, we performed a hierarchical regression analysis with gender and age as independent variables in the first step, main effects of scores on the self- and the other-rated scales in the second step, and the two way interaction of K10×Internalizing Problems in VABS-J in the final step. Finding from this analysis indicated the interaction was significant (β =-.292, p<.05). Simple slope analysis showed that, for adults with high K10 scores, other-rated severity of internalizing problems was negatively associated with daily living skills (t=-2.19, p<.05), whereas among those with low K10 scores, no association was noted between other-rated severity of internalizing problems and daily living skills (t=0.49, *n.s.)*. Further, with regard to Community subdomain scores, a significant effect of interaction was noted between K10 score and the other-rated score (β =-.360, p<.05). For adults with high K10 scores, other-rated severity of internalizing problems was negatively associated with Community scores (t=-2.42, p<.05), whereas among those with low K10 scores, no association was noted between other-rated severity of internalizing problems and Community scores (t=1.19, *n.s.)*.
Conclusions:
Results in the current study suggest that severity of internalizing problems negatively affects daily living skills in adults with ASD in Japan. Pharmacotherapy or psychological treatment (i.e. cognitive behavior therapy) may therefore improve degree of adaptive behavior in individuals with ASD.

24 **163.024** Emotional Suppression Moderates the Relationship Between Autistic Traits and Physiological and Cognitive Responses to Acute Social Stress in a Healthy Adult Sample

ABSTRACT WITHDRAWN

Background:
In the past decade, Autism has undergone a reconceptualization from a dichotomous, all-or-nothing clinical diagnosis to a dimensional classification including milder variants of the disorder, giving rise to interdisciplinary research on the broader autism phenotype (BAP). BAP examines subthreshold symptoms of ASD with the assumption that traits associated with the autistic spectrum are widely distributed and can be measured using self-administered instruments among adults with normal intelligence. Recently, we have demonstrated that the core features of AT, specifically social-communication deficits and restricted and repetitive behaviors, are associated with maladaptive emotion regulation strategies. Furthermore, it has been established that AT are related with dysfunctional stress coping; importantly, individuals with high levels of AT are more likely to have co-occurring stress-based disorders such as anxiety. To date, no studies have examined whether AT are associated with physiological responses to acute social stress and whether this link is moderated by emotion regulation.
Objectives:
The aim of this study is twofold: 1) To explore whether AT are associated with higher levels of the stress hormone cortisol, higher heart rate, and lower levels of cognitive performance in response to acute social stress in lab. 2) To determine whether the link between AT and physiological responses to acute stress are moderated by emotional suppression. We hypothesized that individuals with high AT will have higher physiological responses to stress, and this association will be more pronounced with individuals high in emotional suppression (ES).
Methods:
Data was acquired from a community sample of 39 male adults between 19 and 54 years old (M=27.79, SD=8.24). Participants were exposed to a standardized psychosocial laboratory stressor, the Trier Social Stress Test (5-minute simulated job interview, followed by 5-minute mental arithmetic task). Heart rate was continuously tracked throughout the TSST and salivary cortisol was collected at eight 10-minute intervals, during baseline, adaptation, stress, and recovery phases. Number of mistakes on the mental arithmetic task was recorded as an indicator of cognitive performance. AT was measured using Autism Spectrum Quotient and ES was measured by the Emotion Regulation Questionnaire.
Results:
AT was positively associated with cortisol and heart rate and negatively with the number of mistakes (rs > 0.37, ps < 0.03). Furthermore, emotional suppression significantly moderated the relationship between AT and salivary cortisol (β=1.72, t(35)=2.74, p<0.01) and the number of mistakes (β=1.44, t(35)=2.19, p=0.04). Simple slope analysis revealed that individuals high in AT and ES produced the highest levels of cortisol and made the most cognitive errors.
Conclusions:
The results of the current investigation extend the literature on AT by focusing on its physiological correlates for the first time. They also contribute to the growing volume of evidence that AT is associated with dysfunctional emotion regulation. Since dysfunctional emotion regulation and higher cortisol levels are linked to negative health outcomes, targeting maladaptive emotion regulation strategies of individuals high in AT through therapeutic interventions may be a way to preempt such outcomes.

25 **163.025** Employment for Adults with Autism Spectrum Disorders: A Retrospective Review of a Customized Employment Approach

***S. Carr**, Research, Rehabilitation and Training Center, Virginia Commonwealth University, Richmond, VA; Virginia Commonwealth University, Virginia Commonwealth University, Richmond, VA*

Background: Over the past few decades, there has been an increase in prevalence of children with autism spectrum disorders (ASD), and those children are now becoming young adults in need of competitive integrated employment (CIE). Customized employment (CE) is one pathway to employment that has been successful for other individuals with developmental disabilities (DD), though research has been very limited on the effectiveness with individuals with ASD.
Objectives: The purpose of this study was to explore the effect of supported employment and systematic fading of employment specialist support for individuals with ASD over a 5 year period in a variety of employment settings.
Methods: This is a retrospective review of 64 individuals with ASD who came to our program from 2009 to 2014 for supported employment services as referred by the state vocational rehabilitation services agency. Employment specialists engaged in situational assessment, discovery, job development, customized job descriptions, on-site training and support, positive behavioral supports, and job retention techniques. The employment specialists were responsible for tracking their actual time spent working directly with or for the jobseeker with Autism Spectrum Disorders (ASD).
Results: All vocational rehabilitation clients with ASD served during this time successfully secured CIE, and maintained their employment with ongoing supports, with intensity of support time decreasing over time. The majority (63/64, 98.4%) of individuals successfully secured CIE through the use of supported employment, in 72 unique employment positions. Of the majority of the individuals who secured employment, 77% (50) individuals indicated that they had never worked before and additional 18% (12) reported having short intermittent histories of employment.
Conclusions: Individuals with ASD present a broad array of individual support needs to obtain and maintain competitive employment. Some of the specific areas where the employment specialists concentrated their instructional and training activities included discovery and career development, career search, job interview preparation, disability disclosure, transportation planning and training, customizing jobs, job tasks, and workplace environments, instructional support, designing compensatory strategies, and coworker education. Despite this lack of employment experience, in all cases the jobseeker directed the job search and ultimately the job selection.

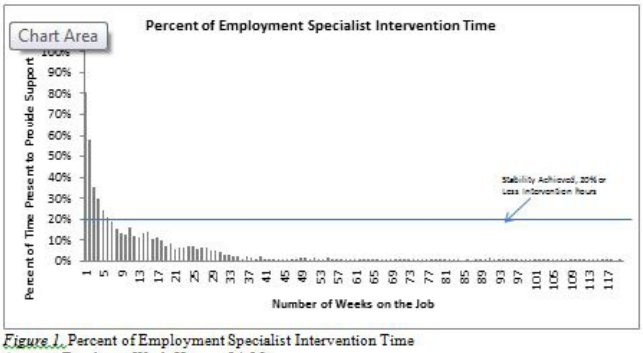

Figure 1. Percent of Employment Specialist Intervention Time
Average Employee Work Hours: 24:25

26 **163.026** Environmental Factors Impacting Work Satisfaction and Performance in Adults with Autism Spectrum Disorders

***B. A. Pfeiffer**, Rehabilitation Sciences, Temple University, Philadelphia, PA*

Background: The numbers of individuals with Autism Spectrum Disorders (ASD) transitioning into post-secondary roles such as employment has substantially increased in

parallel with escalating prevalence rates (CDC, 2014). Unfortunately, 90% of individuals with ASD over the age of 22 cannot find and maintain meaningful employment (Gal, Ben Meir, & Katz, 2013) and there are limited mechanisms to support needed transitional interventions. Many interventions focus on specific deficits in the person, such as communication and socialization difficulties, and its effects on work performance. There are fewer studies attempting to understand the environmental factors influencing the work experience from the perspective of the adult with ASD.
Objectives: The primary objective of this study was to explore the relationship between environment factors and work satisfaction/performance from the perspective of adults with ASD in order to better understand important outcomes and necessary components of interventions in the workplace.
Methods: A mixed methods design was used which involved collecting quantitative data through self-report questionnaires and qualitative data through recorded interviews with participants. Participants were individuals over the age of 21 years, diagnosed with ASD who worked at least 10 hours a week. All potential participants completed a demographics questionnaire and the Ritvo Autism Asperger Diagnostic Scale-Revised (RAADS-R). Participants needed to score 65 or higher on the RAADS-R for inclusion in the study. Individuals completed the Job Satisfaction Survey (JSS), Work Environment Scale (WES), and the Adolescent/Adult Sensory Profile (ASP) (n=50). Sixteen participants completed extensive qualitative interviews. Quantitative data was analyzed using t-tests and correlation coefficients to examine the relationships between work satisfaction and factors in the environment. Qualitative interviews were transcribed, crosschecked, and analyzed by multiple researchers using a constant comparison method until data saturation. Additionally, a reflective comparative analysis was completed between the quantitative and qualitative results.
Results: Quantitative results identified significant differences between participants that were satisfied and not satisfied with their work in how they perceived specific environmental factors including supervisor support (t = 34.26, p = .001) autonomy (t = 38.68, p = .02), task orientation (t = 33.3, p = .05), and physical comfort (t = 39.2, . p = .04). Additionally, adults who reported higher levels of sensory avoiding and/or sensory sensitivity reported significantly lower job satisfaction on the JSS. Qualitative results consistently identified that attitudinal, social and sensory environmental factors impacted on work satisfaction/performance for participants in the study. Specific themes were identified across data sources including the positive or negative impact of supervisory attitude and social demands on satisfaction/performance. The sensory environmental was identified as a barrier if adaptations were not incorporated into the work environment.
Conclusions: Results of the study identified the need for interventions targeting attitudinal, social, and sensory environmental factors to support individuals with ASD in the workplace. Future research is necessary to determine the effectiveness of these types of interventions.

27 **163.027** Exploring the Association Between Autistic Traits and Executive Function Among Typically Developing Adults

***N. Albein-Urios**, S. Kaur Girn, A. Beirne, C. Davies, M. Kirkovski and P. Enticott, Deakin University, Melbourne, VIC, Australia*

Background: The investigation of autistic traits in the “typically developing” population has shown that people with sub-threshold behavioural autistic traits perform poorer on some cognitive tasks. However, little is known about how these traits relate to executive functioning and self-regulation in an everyday environment.
Objectives: The present study examined whether young adults with higher autistic traits experience increased behavioral and cognitive difficulties associated with poorer executive function.
Methods: 57 young adults (18-25 years old) were administered the Autism Spectrum Quotient (AQ), and designated as high autistic traits (n=22) or low autistic traits (n=35). The Behavior Rating Inventory of Executive Function (BRIEF-A) was used to evaluate executive function. The BRIEF-A self-report was compared with the BRIEF-A informant-report to evaluate the construct of self-awareness. Cognitive flexibility skills were also measured using the Trail Making Test (TMT), Gender-Emotion Switch Task, and the Intra-dimensional/extra-dimensional (IDED) task.
Results: Individuals with higher autistic traits reported having more difficulties than the low autistic traits group in the BRIEF-A self-report in three scales: Shift (p<0.01), Emotional Control (p<0.01) and Behavioural Regulation Index (BRI; p<0.05). Four scales were found to be significant only in the high autistic traits group in the BRIEF-A informant-report: Inhibit (p<0.05), Emotional Control (p<0.01), Self-monitor (p<0.05) and BRI (p<0.01). Significant differences were found in the emotional control scale within the group of high autist traits when comparing the BRIEF-A self-report with the BRIEF-A informant-report (p<0.05). No significant differences were found in cognitive flexibility tasks between the two groups.
Conclusions: Individuals with higher autistic traits reported having more executive functioning difficulties, suggesting that difficulties with executive function might extend beyond those meeting clinical criteria for autism spectrum disorder. Parents and close friends of individuals with higher traits in autism also reported poorer executive function of their children/friends. Individuals with high autistic traits were found to have lower self-awareness associated with difficulties on the emotional control domain. These findings call for further research on the relationship between autistic trait and executive abilities, particularly with respect to underlying mechanisms that might mediate this association.

28 **163.028** Exploring the Prevalence and Predictors of Depression in Young Adults with Autism Spectrum Disorders

***V. Hallett**[1], T. Charman[2], J. Briskman[3], R. Kent[2], S. Lukito[3], F. Khalid[2] and E. Simonoff[2], (1)South London and the Maudsley NHS Foundation Trust, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Child & Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Although co-occurring psychiatric disorders are recognised to affect up to 70% of individuals with ASD, there have been few large-scale epidemiological investigations of adult comorbidity. With regard to symptoms of depression in ASD, previous studies have revealed widely varying prevalence estimates (from 0.9%-77%), and no studies to date have explored the longitudinal predictors of these difficulties.
Objectives: The current study aimed to explore the prevalence and predictors of depressive symptoms within a longitudinal, epidemiologically-derived cohort.
Methods: A subsample of 96 young adults (aged 21-24 years) from the population-derived Special Needs and Autism Project (SNAP) were assessed for depression using a standardised clinical interview (the Young Adult Psychiatric Assessment: YAPA) and the Beck Depression Inventory (BDI-II). Parent-report measures of young adult depression were also available for 104 families. Analyses assessed the prevalence of depression in the full sample and in those with IQ above and below 70. Predictors of depression were assessed cross-sectionally and longitudinally (at age 1, 16 and 23 years), including IQ, ASD severity, internalising symptoms, stressful life events and demographic / family characteristics. Associations between quality of life and depressive symptoms were also explored.
Results: 18.9% of young adults with ASD reached criteria for ‘any depressive disorder’, with significantly higher rates in those with IQ above compared to below 70. The prevalence of depression at age 23 years was significantly higher than the rates observed earlier in the study, at age 12 (1.4%) and age 16 (5.5%). Depression at age 23 was predicted significantly by self-reported ASD severity (OR: 1.06 CI 1.00-1.12; p<0.05) at the same age and the number of significant life-events experienced (OR: 1.54 CI 1.14-2.07; p<0.01). Young adult depression was also predicted, longitudinally, by the individual’s level of adaptive functioning at age 12 (OR: 1.07 CI 0.99-1.15, p=0.05). No family characteristics or demographic factors emerged as significant predictors of depression. Additional associations were observed between symptoms of depression, anxiety across development and reduced quality of life at age 23 years.
Conclusions: Rates of depression were higher in young adults with ASD compared to the general population, with an emergence of symptoms in late adolescence and early adulthood. Certain individuals, including those with higher IQ, higher perceived ASD severity and a history of emotional difficulties may be more susceptible to depressive symptoms. Co-occurring depressive symptoms constitute key targets for prevention and treatment in young adults with ASD.

29 **163.029** Factors Influencing Healthcare Satisfaction in Adults with Autism Spectrum Disorder

***A. H. Gerber**[1], C. McCormick[1,2], T. P. Levine[2], E. M. Morrow[1,3], T. F. Anders[1] and S. J. Sheinkopf[1,4], (1)Rhode Island Consortium for Autism Research and Treatment (RI-CART), Bradley Hospital, East Providence, RI, (2)Brown Center for the Study of Children at Risk, Women & Infants Hospital The Warren Alpert Medical School of Brown University, Providence, RI, (3)Department of Molecular Biology, Cell Biology and Biochemistry and Institute for Brain Science, Brown University, Providence, RI, (4)Brown Center for the Study of Children at Risk, Women & Infants Hospital, Providence, RI*

Background: Adults with autism spectrum disorder (ASD) have medical needs that require higher healthcare service utilization than typically developing adults (Croen et al., 2015). Prior research also has indicated that adults with ASD are less satisfied with their healthcare than typically developing adults. (Nicolaidis et al., 2013).
Objectives: The current study examined healthcare satisfaction and factors contributing to satisfaction in adults with ASD.
Methods: The sample consisted of 92 adults with ASD, ranging in age from 18 to 64 years (M=31.1 years, SD=12.6). Participants were divided into young adults (< 26 years of age; 46%), and adults (≥ 26 years of age). This cut point was selected because in the US a number of significant health care transitions take place by age 26. 76 participants completed an Autism Diagnostic Observation Schedule, second edition (ADOS-2). All participants, recruited from community service agencies and clinicians, entered the study with a diagnosis of ASD and/or met criteria for ASD on the ADOS-2. 62 participants had a parent or guardian available to complete a Vineland-II questionnaire. Participants or their caregiver completed a survey about their experiences with their primary care physician, dentist, vision care practitioner, and mental health clinician. Each practitioner was rated on a 1-5 scale (1=extremely dissatisfied, 5=extremely satisfied). A total healthcare satisfaction score was computed by averaging the four satisfaction subscales. All participants completed this questionnaire.
Results: In contrast to previous reports, study participants were highly satisfied with their healthcare (M=4.39, SD=0.88). The mean adaptive skills score of study participants (M=52.3, SD=19.7) was two standard deviations below average, indicating significant impairment. The majority of participants in the study were living in their family home (68%). 97% of the sample had public and/or private health insurance. While 60% were their own guardians, only 30% completed the satisfaction questionnaire on their own, and only 29% were involved in their own healthcare decisions. A series of correlation analyses revealed age to be the only significant predictor of satisfaction, $r(90) = .24$, $p < .05$. Specifically, participants below 26 ($M = 4.62$) were more satisfied with their healthcare than participants 26 and older ($M = 4.19$). Further analysis demonstrated that participants under 26 were significantly more likely to live at home, $\chi^2 (1) = 31.24$, $p < .001$, have private health insurance, $\chi^2 (1) = 18.03$, $p < .001$, have someone else complete the questionnaire, $\chi^2 (1) = 11.34$, $p < .01$, and have others make their healthcare decisions, $\chi^2 (1) = 10.62$, $p < .01$, than participants 26 and above. Additionally,

participants below 26 (M = 67.76, SE = 3.64) had significantly greater communication skills than participants 26 and older (M = 47.21, SE = 4.78), $t(57.72) = 2.59$, $p < .05$. *Conclusions:* Healthcare satisfaction, in a significantly impaired adult ASD population, can be high in a community that emphasizes family care, adequate health insurance and supportive services. Future studies need to define the context as well as correlated factors associated with satisfaction.

30 **163.030** Feasibility of a Systematic Outcomes Assessment Protocol for Adults with ASD Participating in Community-Based Programs

A. C. Jozkowski[1], *K. P. Wilson*[2], *G. Chasson*[3], *K. Hoer*[1], *A. Focazio*[1], *B. Finklestein*[1] *and A. Grant*[1], *(1)Occupational Therapy & Occupational Science, Towson University, Towson, MD, (2)Department of Audiology, Speech-Language Pathology, and Deaf Studies, Towson University, Towson, MD, (3)Department of Psychology, Towson University, Towson, MD*

Background: There is a lack of research regarding the services beneficial to transition-aged youth and young adults with Autism Spectrum Disorder (ASD) as they transition out of the school system and enter a more autonomous life stage. This population is at an increased risk for an array of lifestyle challenges and health problems. Fortunately, a variety of adaptive skills including self-advocacy and problem-solving are believed to contribute to improved quality of life and more positive outcomes. However, uncertainty on how to promote these skills remains. In 2007 a community-based center was established at a regional university in an effort to facilitate meaningful social experiences that support the development of the adaptive skills of self-advocacy, self-expression, self-regulation, problem solving, and teamwork among transition-aged

youth and young adults with ASD. However to date, program effectiveness has not been comprehensively assessed.
Objectives: The aim of the current pilot study is to determine the feasibility of a protocol developed to standardize the method for assessing the effectiveness of programs offered at a community-based center. This center aims to enhance the adaptive skills of transition-aged youth and young adults on the Autism spectrum. The data collected will be used to refine the assessment process we intend to use during a larger program evaluation/outcome study planned for Spring 2016.
Methods: During the Fall 2015 pilot study, quantitative and qualitative data have been collected at a single time point from ten program participants and/or their legal guardians. Demographic and social impairment data were collected using the *IAN Adult on the Autism Spectrum* measure, the *Social Responsiveness Scale, 2nd Edition,* and the *Hospital Anxiety and Depression Scale* or the *Anxiety, Depression, and Mood Scale.* The dependent variables of self-advocacy, self-expression, self-regulation, problem solving, and teamwork were assessed with the *American Institutes for Research Self-Determination Scale*, the *Adaptive Behavior Assessment System-II,* the *Emotion Regulation Questionnaire* or the *Emotion Regulation Checklist*, the *Behavior Rating Inventory of Executive Function*, and the *Youth Outcomes Battery-Teamwork Scale.* Following quantitative data collection, participants were invited to participate in a semi-structured interview to provide qualitative feedback that will be useful for recommending tool modifications/adaptations in preparation for the forthcoming repeated-measures outcomes study.
Results: The research team is presently completing data collection and analysis, and will have conclusive results to report by January 2016. Because both quantitative and qualitative data is being collected and the questionnaires being used have proven to be reliable and valid in this population, we hypothesize that the pilot study will yield rich data regarding the effectiveness of the proposed assessment procedure.
Conclusions: Through this study, the research team aims to support the establishment of a systematic and rigorous method for assessing the effectiveness of a community-based program in developing adaptive living skills among transition-aged youth with ASD. We seek to do so in order to refine future programs that will better serve this population. The data collected during this pilot study will lay the foundation for future research that has more global implications for individuals with ASD and their families in the community.

31 **163.031** Gender Differences in Adult Outcomes for Individuals Diagnosed with ASD in Childhood

W. T. Brooks[1], *L. G. Klinger*[1], *E. M. Lamarche*[2], *J. L. Mussey*[3] *and M. R. Klinger*[4], *(1)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Research in autism spectrum disorders (ASD) has historically focused on males, as they are diagnosed 4-to-5 times more often with the condition than females. However, interest in females with ASD has been on the rise, with recent studies suggesting gender differences in the presentation of symptoms and associated behavioral features. Research suggests that parents of girls with disabilities may provide their daughters with fewer opportunities to practice activities that encourage independent daily living skills, which may affect adult outcomes (Hogansen et al., 2008); however, few studies have examined how childhood daily living skills and other characteristics impact life outcomes of women with ASD.
Objectives: The aim of this study was to examine gender differences in a variety of measures associated with well-being (e.g., employment status, daily living skills, quality of life) in adults with ASD, including how their childhood characteristics affected adult outcomes.
Methods: This project is part of a larger study examining adult outcomes of children diagnosed with ASD during childhood between 1970 and 1999. Measures of ASD symptoms (CARS; Schopler et al., 1986), adaptive behavior skills (Vineland ABS; Sparrow & Cichetti, 1984), and IQ were assessed during childhood, and caregivers completed surveys assessing a variety of outcomes in their adult children, including independent daily living skills, quality of life (QoL), current ASD symptom severity, and employment status. Participants included caregivers of 189 adults with ASD including 38 women and 151 men. Women and men with autism did not differ on age, ethnicity, parent education level, or communication ability.
Results: In childhood, there were no gender differences in IQ scores or ASD symptom severity; however, girls with ASD scored lower on childhood Vineland standard scores than boys ($t(186)=-2.99$, $p=.004$). In adulthood, women with ASD scored lower on the Waisman Activities of Daily Living Scale (Maenner et al., 2013) ($t(187)=-2.9$, $p=.004$) and on the QoL-Questionnaire (Shalock & Keith, 1993) ($t(186)=-2.1$, $p=.04$) than men. Women (41.9%) were less likely to have been employed in the past two years ($\chi^2=6.13$, $p=.05$) than men (56.6%), and they exhibited higher scores on current ASD symptom severity (SRS-2; Constantino & Gruber, 2012) ($t(182)=-2.8$, $p=.006$). When adult outcomes were examined while controlling for childhood Vineland scores, gender was no longer significantly related to the outcome measures, with childhood Vineland mediating all of the effects of gender on adult outcomes.
Conclusions: Despite exhibiting similar childhood ASD symptom severity and intellectual functioning to males, females with ASD exhibited lower childhood adaptive behavior skills. Poorer outcomes for females in adulthood were accounted for by differences in childhood adaptive functioning skills, suggesting that early gender differences in adaptive behavior may be at the heart of why women with ASD show more significant difficulties in adulthood than men. It is unclear if these outcomes reflect fundamental gender differences in early adaptive skills or if they are due to gender differences in childhood experiences, parental expectations, and learning opportunities. Future research in this area is needed to examine whether early intervention targeting adaptive skills may improve outcomes for females with ASD.

32 **163.032** Gender Variance in Men and Women with Autism

M. C. Lai[1,2,3], *A. N. Ruigrok*[4], *A. S. Baron*[5], *M. V. Lombardo*[1,6], *B. Chakrabarti*[4,7], *S. H. Ameis*[3], *P. Szatmari*[3], *K. J. Zucker*[8] *and S. Baron-Cohen*[1,9], *(1)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (2)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (3)Centre for Addiction and Mental Health, The Hospital for Sick Children, and Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (4)Department of Psychiatry, Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (5)Department of Psychology, University of British Columbia, Vancouver, BC, Canada, (6)Department of Psychology and Center for Applied Neuroscience, University of Cyprus, Nikosia, Cyprus, (7)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (8)Centre for Addiction and Mental Health, Toronto, ON, Canada, (9)Cambridgeshire and Peterborough NHS Foundation Trust, Cambridge, United Kingdom*

Background: Autism reflects one form of human variation of neurotypical norms. Binary gender is prevalent in neurotypical individuals, but one study (Bejerot & Eriksson, 2014) has shown increased gender variance in women with autism and decreased stereotypical masculine (but not feminine) gender role characteristics in both men and women with autism, using self-report measures. Increased rates of autism diagnosis or level of autistic traits in children, teenagers and adults with gender dysphoria have also been reported. The phenotypic and underlying developmental relationships between autism and gender variance have yet to be clarified.
Objectives: To investigate variations in gender identity and gender role characteristics in men and women with autism using both self-report and implicit measures.
Methods: A total of 167 adults participated, including 34 biological males and 48 females with autism, and 46 neurotypical (control) males and 39 females. Self-reported gender variance was measured using the Gender Identity/Gender Dysphoria Questionnaire for Adolescents and Adults (GIDYQ-AA), and Lippa's gender-stereotyped occupational (10-item) and hobby (18-item) preference questionnaires. Implicit association between self and gender (tested using self-related versus gendered terms) were measured using an Implicit Association Test (IAT). Group differences were tested using nonparametric (when involving GIDYQ-AA) and parametric methods.
Results: Men with autism self-reported more variant gender identity (against natal sex) than control men (Mann-Whitney $U=261.5$, $p<0.001$), as did women with autism compared with control women ($U=493$, $p<0.001$); no sex differences were noted within either the control or autism group. Across diagnosis, men consistently showed stronger preferences for gender-stereotyped masculine hobbies/occupations than women (hobbies: $F(1,158)=60.2$, $p<0.001$; occupations: $F(1,158)=32.4$, $p<0.001$). After sex-stratification, women with autism reported significantly stronger preferences for gender-stereotyped masculine hobbies/occupations than control women (hobbies: $T(82)=5.0$, $p<0.001$; occupations: $T(82)=4.3$, $p<0.001$). These effects were in the same direction but less strong (occupations: $T(72)=2.6$, $p=0.01$) or non-significant (hobbies: $T(72)=0.4$, $p=0.72$) in men with autism compared with control men. IAT showed a strong implicit association between self and gendered terms of one's natal sex in both sexes, irrespective of diagnosis. After sex-stratification, there was no difference in gender-identity IAT effects (the association strength between self and male-gender) between men with and without autism ($T(76)=0.2$, $p=0.82$), whereas women with autism, on average, showed weaker gender-identity IAT effects (between self and female-gender) than did control women ($T(83)=2.5$, $p=0.01$). Correlations between IAT effect and self-report variant gender identity (GIDYQ-AA) were significant in women with autism (Spearman's $rho=0.28$, $p=0.03$) but minimal in other groups.
Conclusions: We found increased rates of men and women with autism self-reporting variant gender identity that did not fit the neurotypical gender-binary norm, compared with control men and women. Women with autism compared with control women, particularly, further reported stronger preference for gender-stereotyped masculine hobbies/occupations, weaker implicit association between self and female-gender, and stronger implicit-explicit correlation in gender identity. These effects were not evident in men with autism compared with control men. Gender variance is more prominent in adults, especially women, with autism. This may reflect phenotypic overlap between the autistic and gender spectra, and common biological underpinnings and/or gender socialization experiences during development.

33 **163.033** How Do You Feel about Driving? Development of the Scale for Apprehensive Driving to Measure Driving-Related Attitudes in Novice Drivers

V. Ross[1], *D. J. Cox*[2], *R. E. Reeve*[3], *T. Brown*[4], *M. Moncrief*[2], *R. A. Schmitt*[5] *and G. Gaffney*[4], *(1)Hasselt University, Diepenbeek, Limburg, Belgium, (2)University of Virginia, Charlottesville, VA, (3)University of Virginia, Earlysville, VA, (4)University of Iowa, Iowa City, IA, (5)National Advanced Driving Simulator, University of Iowa, Iowa City, IA*

Background: Impairments related to autism spectrum disorders (ASDs) can pose limits on daily living skills. One example relates to driving, which allows autonomy and permits maintenance of social- and work-related contacts. Research regarding ASD and driving has been steadily increasing in the past years. Most studies however focus on difficulties they might experience with the execution of the driving task. Meanwhile, research suggest that there are additional barriers related to driving. For instance, a previous study investigating viewpoints of individuals with ASD reported anxiety as an important barrier (Chee et al., 2014). Although several driving anxiety measures exist, none specifically focus on novice drivers. Furthermore, driving apprehension might not only be present during the drive itself but also in phases preceding driving (e.g.,

getting ready to drive). Finally, it is possible that novice drivers are reluctant to report their feelings, making parents important sources of information as they usually play a large role in the process of learning how to drive.
Objectives: The aim of the present study was to develop a parent questionnaire measuring their child's attitudes towards driving, allowing to compare whether novice drivers with ASD are more apprehensive towards driving than a control group.
Methods: The 18-item (1-4 answering category) Scale for Apprehensive Driving (SAD), to be filled in by parents, was developed to measure positive and negative attitudes towards driving during three phases: 'thinking about driving', 'preparing to drive', and 'while driving'. Considering that emotions can be expressed cognitively, behaviorally and physically, questions were developed to tap each dimension. The questionnaire was completed by a group of parents of novice drivers (age range= 15-24), who earned their learners permit, without (n= 98) and with ASD (n= 66). Reliability analyses were executed per group, after which a 2x2 ANOVA (Valence: total positive, total negative; Group: control, ASD) was conducted to determine whether the ASD group reported more negative attitudes compared to the control group.
Results: Correlations between positive and negative items showed the expected direction for both the control (r= -.39, p= .00) and the ASD (r= -.65, p= .00) group. Furthermore, the Cronbach's alpha coefficient was also high for both the control (α= .85) and the ASD (α= .90) group. A significant interaction effect of Valence*Group (F= 92.58, p= .00, η^2p= .20) indicated a difference in the reported attitudes between the control and ASD group. Further analyses, indicated that the control group reported more positive attitudes (F= 203.16, p= .00, η^2p= .68, μPos= 18.67, μNeg= 7.00), while the ASD group reported more negative attitudes (F=3.71, p= .00, η^2p= .058, μPos= 10.73, μNeg=13.30).
Conclusions: The results showed that the ASD group was less positive towards driving when compared to a control group. As driving apprehension could pose an important barrier for driving independently, future research should take this factor into account.

34 **163.034** Identifying and Addressing the Concerns of College Students with Autism

J. Edelstein[1], *B. E. Cox*[2], *A. Wolz*[1] *and A. Anderson*[1], *(1)Florida State University, Tallahassee, FL, (2)P.O. Box 3064452, Florida State University, Tallahassee, FL*

Background:
With roughly 16,000 ASD students entering postsecondary institutions each year (Wei et. al, 2015) colleges and universities must understand the needs of this population and provide support to best enable success. While transitioning into college, students with ASD are likely to experience considerable stress and anxiety as they face social, academic, and personal challenges they have not encountered before. Yet there is remarkably little research regarding the experiences of ASD individuals in higher education.
Objectives:
The objectives of this study are threefold:

1. Identify concerns which are unique to those with ASD, as well as those which are heightened (i.e. exacerbated in those with ASD relative to non-ASD peers).
2. Analyze the effects of identified concerns.
3. Explore methods of alleviating the concerns of these students in an impactful manner.

Methods:
Student testimonials related to postsecondary education were gathered from the website WrongPlanet.net, an online resource for individuals with ASD that provides support through articles, forums, and discussions. Data were collected from discussions within the "School and College Life" forum. The statements were then coded using Astin's (1991) Inputs-Experiences-Outputs model. The second round of coding followed specific themes that were established by the first round of coding. Students' concerns were identified by the use of words expressing feelings (i.e., fear, afraid, concern).
Results:
Students expressed fourteen unique concerns which the researchers clustered into two types: ASD-specific concerns (e.g. bullying, loss of prior supports) and ASD-heightened concerns (e.g. change in routine, hurting others). Within each type, student concerns were further categorized as either social concerns (e.g. "I haven't succeeded in getting anyone's phone number or becoming close ") or transitional concerns (e.g. "I feel trapped with having so much responsibility so fast.")
Students commonly noted low levels of self-confidence and mental health issues (e.g. "So, how can I even begin to tell my parents in a week that I have failed… It is difficult for me not to constantly think of suicide because of this situation"). Few students indicated resolutions to their issues. Those who did resolve their concerns noted the importance of socialization (e.g. "Spend as much time developing social skills and… The school WILL NOT try to help you do this") and access to information as routes for overcoming their concerns successfully.
Conclusions:
Students with ASD often do not feel supported by their colleges and universities, suggesting they may not have the same perception of higher education as their neurotypical peers. However, by addressing the specific concerns expressed by these students, higher education professionals can help these individuals assimilate into postsecondary environments and maximize their academic and developmental potential.

35 **163.035** Implicit Vs Explicit Attitudes Towards Individuals with Autism

J. Zeman[1], *C. Dickter*[2], *J. Burk*[2] *and J. A. Kittel*[1], *(1)College of William and Mary, Williamsburg, VA, (2)College of William & Mary, Williamsburg, VA*

Background: Given the strengths and challenges associated with ASD, it is not surprising that some studies demonstrate that individuals with ASD are perceived negatively, whereas other research suggests positive perceptions (Swaim & Morgan, 2001). Most research has relied on self-report which is effective at evaluating explicit attitudes but is susceptible to social desirability biases. To better characterize the attitudes towards members of social groups, it is important to study both self-report and implicit measures because each method predicts different types of behavior. Due to the difficulties that may pose disproportionately greater challenges for students with ASD as they enter higher education (e.g., increased opportunity for social interactions, changes in daily routines; Lai et al., 2014), we focused on college students.
Objectives: The goal of this study was to address gaps in the literature by assessing college students' implicit and explicit attitudes towards people with ASD. We evaluated: (a) implicit and explicit attitudes toward individuals with ASD, (b) the relation between the two variables, and (c) whether attitudes would vary depending on the degree to which students self-reported autistic behaviors.
Methods: Participants were 178 college students (65 male; *M* = 19.15 years, 50.0% White). A modified version of the Implicit Attitudes Test (IAT, Nosek et al., 2002) was developed to assess attitudes towards autistic and neurotypical individuals. The Societal Attitudes towards Autism Scale (SATA, Flood et al., 2013) was administered that assessed explicit Societal Attitudes, Knowledge, and Personal Distance. The Autism Quotient questionnaire (AQ; Baron-Cohen et al., 2001) measured self-reported autistic traits with five subscales.
Results: There was an overall implicit bias against individuals with autism (*d* = -0.83, *SD* = 0.41), *t*(177) = -27.09, *p* < .001, suggesting that participants had more positive implicit associations with neurotypical compared to autistic individuals. For explicit attitudes, the means for the Knowledge subscale (*M* = 15.16, *SD* = 2.20) and Personal Distance subscale (*M* = 17.25, *SD* = 2.70) were similar to other college samples (Flood et al., 2012). Regarding the relations between implicit and explicit attitudes, there were significant positive correlations between the IAT and the Knowledge subscale, marginally positive significant relations with the Total SATA score and the Personal Distance subscale, and no significant association with the Social Attitudes Scale (see Table 1). The IAT was significantly positively correlated with the total AQ score, the AQ Social Skills subscale, and the AQ Communications subscale. Students scoring in the top third of the total AQ demonstrated less implicit bias than those in the bottom third. This pattern was replicated for the Social Skills and Attention Switching subscales (see Table 2). Thus, students reporting more autistic behaviors held less implicit bias towards those with autism.
Conclusions: We created the first IAT to measure students' implicit associations with neurotypical and neurodiverse individuals. Our sample appeared to be somewhat knowledgeable and hold relatively positive explicit attitudes towards individuals with ASD compared to the sample norms, but generally held an implicit bias against individuals with autism, except by those reporting autistic traits themselves.

Table 1

Correlations between IAT d scores and the Autism Quotient subscales, the Societal Attitudes towards Autism subscales

	IAT d score
AQ total	.18**
AQ Social Skill	.24***
AQ Attention Switching	.17*
AQ Attention to Detail	-.05
AQ Communication	.13+
AQ Imagination	.01
SATA Total	.13+
SATA Societal Attitudes	.08
AQ Knowledge	.16*
AQ Personal Distance	.13+

Note. AQ = the Autism Quotient (Baron-Cohen et al., 2001). SATA = the Societal Attitudes towards Autism Scale (Flood et al., 2013). $+p < .10$,* $p < .05$., **$p < .01$, *** $p < .001$

Table 2

Mean IAT differences and standard deviations in parentheses between participants in the bottom and top thirds of the Autism Quotient and its subscales

	Bottom Third	*Top Third*	*t-value*
Total AQ score	-.95 (.35)	-.78 (.43)	-2.43*
Social Skills	-.95 (.35)	-.72 (.43)	-4.04***
Communication	-.89 (.37)	-.80 (.45)	0.15

36 **163.036** In Their Own Words: The Experiences of Young Adults with High-Functioning Autism/Asperger's Syndrome Attending College or University

R. Nirmal, *Psychology, BC Children's Hospital, Vancouver, BC, Canada*

Background: According to the Centre for Disease Control and Prevention (2014), the prevalence of ASD in children has increased to 1 in 68, with more children being identified without significant cognitive impairment (i.e., high-functioning autism [HFA]). With the increasing prevalence of HFA, more students with HFA are beginning to transition to college or university, as they are generally capable of meeting the academic demands of postsecondary education (e.g., VanBergeeijk, Klin, & Volkmar, 2008). Unfortunately, studies have demonstrated poor postsecondary educational outcomes for students with HFA (e.g., Shattuck et al., 2012). Despite having the neurocognitive and academic ability to attend college or university, there are many students with HFA who do not enroll in postsecondary education or drop out soon after entry (Shattuck et al., 2012). There is a critical need to better understand the experiences of students with HFA currently attending college or university to help foster better postsecondary outcomes for this population (Gelbar, Smith, & Reichow, 2014).
Objectives: Understanding the experiences of students with HFA through their own voice can provide valuable insight into their successes and challenges in postsecondary education (Gelbar et al., 2014). Too often, the voices of students with disabilities are overlooked, minimized, or misunderstood (Scuitto, Richwine, Mentrikoski, & Niedzwiecki, 2012). To that end, the objective of this study was to understand the meaning of the lived experiences of attending college or university for students with HFA, the phenomenon in question, and to discover common aspects of their experiences.
Methods: Postsecondary students (n = 12; 9 males, 3 females) with either HFA or Asperger's disorder were recruited from 4 postsecondary institutions. Interpretive Phenomenological Analysis was the method of inquiry, which examines the meaning of personal and social experiences of individuals in a detailed way (Smith, Flowers, & Larkin, 2009). Each participant engaged in two semi-structured, in-depth interviews with the researcher. Data analysis was an iterative and interpretive process, including a case-by-case thematic analysis. Validity strategies were used to ensure scientific rigour and credibility of the research findings (Creswell, 2009).
Results: Eight broad themes and corresponding subthemes emerged from the data analysis depicting the phenomenon of attending college or university for students with HFA. The broad themes are 1) *Managing Academic Expectations*; 2) *Experiencing Support*; 3) *Managing Autism Spectrum Disorder and Related Symptoms*; 4) *Reference to or Influence of Past Experiences*; 5) *Having a Sense of Appreciation*; 6) *Understanding Autism Spectrum Disorder by Others and Self*; 7) *Managing the Transition*; and 8) *Entering a New Social World*.

Conclusions: The results of this study contribute greatly to our understanding of the lived experiences of students with HFA in college or university, including the successes and challenges experienced. The results also highlight how the needs of individuals with HFA persist into adulthood. It is hoped that the findings will help to inform the provision of services and supports for college or university students with HFA in order to foster both the transition to and success in postsecondary education.

37 **163.037** Life-Skills Coaching Reduces Anxiety Around Goals and Improves Functional Skills Among Adults on the Autism Spectrum

A. Hillier[1], *N. Poto*[2], *A. Frye*[1] *and M. Santangelo*[1], *(1)Psychology, University of Massachusetts Lowell, Lowell, MA, (2)Autism/Aspergers Network (AANE), Watertown, MA*

Background: The lack of services for adults on the autism spectrum is of considerable and growing concern. Given the complicated profile of ASD, individualized approaches can be particularly effective. Specifically, one-on-one mentoring is an intervention model which holds promise for this population.
Objectives: This study examined the life goals adults with ASD had set for themselves such as employment related goals, independent living, social skills etc., and evaluated the efficacy of a life skills coaching / mentoring program in reducing anxiety and increasing confidence surrounding these goals, as well as improving functional skills.
Methods: Participants were 322 young adults on the autism spectrum enrolled in a life skills coaching program run by a non-profit organization (Asperger/Autism Network (AANE) in Massachusetts). Participants' goals were coded by two independent raters in to one of eight categories: employment, social skills, academic, executive functioning, independent living, health/fitness/wellbeing, self-insight, and self-advocacy. To examine change in anxiety and confidence towards goals across time, we selected data from a subset of participants who had completed measures for at least three consecutive time points (measures were taken every 8 weeks). We also examined whether coaching led to an increase in functional skills over time in five different areas: social / communication skills, executive functioning / daily living skills, self-awareness, employment, and college.
Results: Our results showed the majority of participants had employment related goals, followed by independent living, executive functioning and social skills related goals. Participants demonstrated significant increases in goal related confidence over time, and significant decreases in anxiety. Regarding functional skills, participants rated themselves as significantly improving over time in all five areas measured.
Conclusions: Adults on the autism spectrum set themselves a broad range of life goals. Increased confidence and decreased anxiety around these goals can be fostered in a relatively short period of time using a one-on-one coaching model. These results support the efficacy of life-skills coaching / mentoring programs for adults with autism spectrum disorders for whom individualized intervention approaches might be key to successful outcomes in adulthood.

38 **163.038** Longitudinal Age-Related Impairments in Processing Speed, Anxiety, and Adaptive Functioning from Childhood to Adulthood in Individuals with Autism

J. E. Lainhart[1], ***K. L. Kane***[2], *M. D. Prigge*[3], *D. P. Samsin*[1], *B. G. Travers*[4], *A. Freeman*[1], *N. Lange*[5], *E. D. Bigler*[6] *and A. L. Alexander*[1], *(1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)ISLA, Waisman Center, UW-Madison, Madison, WI, (3)Pediatrics, University of Utah, Salt Lake City, UT, (4)Occupational Therapy Program in Kinesiology, University of Wisconsin Madison, Madison, WI, (5)McLean Hospital, Cambridge, MA, (6)Psychology/Neuroscience Center, Brigham Young University, Provo, UT*

Background: Despite special education services and other standard interventions (e.g., speech, language, and social skills therapy) received during childhood, the majority of indivduals with autism remain significantly impaired in everyday functioning into adulthood.
Objectives: To compare the trajectories of longitudinal age-related changes from childhood to adulthood in severity of core features of autism, IQ, processing speed, expressive and receptive language, anxiety, and adaptive functioning in individuals with autism compared to typically developing individuals.
Methods: Data were collected from 98 males with autism (age range 4-36 years at first assessment, nonverbal IQ ≥ 70) and 61 typically developing males (age range 4-39 years at assessment). Each participant was assessed 1-3 times, on average every 2.5 years (total of 350 datasets per instrument). At each point, IQ and processing speed (Wechsler Scales), language (EVT, PPVT, CELF-3, CTOPP Non-Word Repetition), quantitative composite of core features of autism (Social Responsiveness Scale), anxiety (SCARED), and everday adaptive functioning (Vineland Adaptive Behavior Scales) were assessed. Mixed effects models were used to describe longitudinal trajectories in the autism group in comparison to the typically developing control group (TDC).
Results: The autism group demonstrated age-related improvements in verbal and performance IQ, as well as expressive and receptive language. Autistic symptoms improved during childhood and adolescence; yet, began to worsen again in the early 20's. In contrast to these longitudinal trajectories showing improvement during childhood and adolescence, adaptive functioning was significantly impaired in the autism group and the degree of impairment remained fixed across development relative to that of the TDC group (age x group interaction, ns). Similarly, processing speed was lower and level of anxiety was higher in the autism group and the degree of severity, relative to the TDC group, remained fixed across development.
Conclusions: The results of this study provide insight as to why everyday functioning remains significantly impaired in the majority of indivduals with autism despite overall improvements in autistic symptoms, cognitive functioning, and language. Specifically, findings suggest that both processing speed and anxiety, which are not usually targeted directly by standard interventions in childhood, may contribute to sustained impairment in adaptive functioning from childhood into adulthood in autism. Future study will test these relationships longitudinally at the level of affected individuals.

39 **163.039** Medical Care Utilization and Costs Among Transition-Age Young Adult Medicare Beneficiaries with Autism Spectrum Disorder

T. W. Benevides[1], *H. J. Carretta*[2] *and K. Graves*[3], *(1)Thomas Jefferson University, Philadelphia, PA, (2)Florida State University College of Medicine, Tallahassee, FL, (3)College of Medicine, Florida State University, Tallahassee, FL*

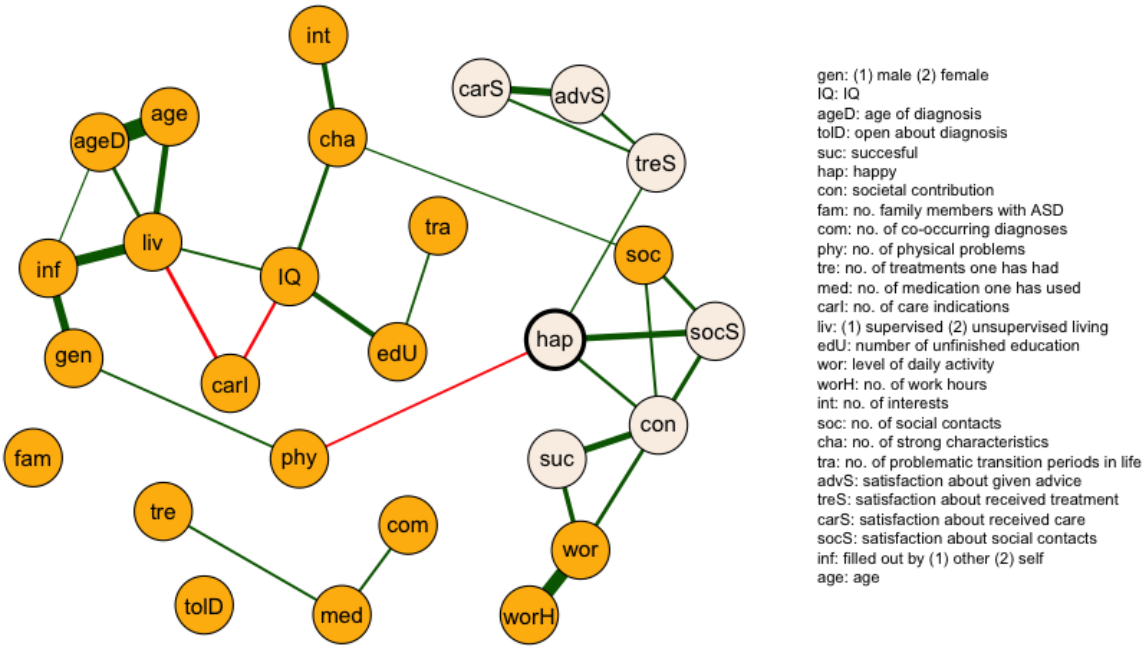
Background: Autism spectrum disorder (ASD) is a lifelong condition which globally impacts functioning (APA, 2013). Emerging research suggests increases in restrictive medical care for adolescents with ASD (e.g. Cidav et al., 2013) corresponding studies finding higher rates of psychiatric illness among adults with ASD compared to non-ASD adults (e.g. Croen et al., 2015). Additionally, comorbid intellectual disability (ID) contributes to greater healthcare needs. It is imperative to identify healthcare needs of young adults with ASD.
Objectives: We aimed to 1) describe utilization and cost of services (hospital-based services, ambulatory services, therapy services) among young adults in Medicare fee-for-service claims data (years 2008-2010), and 2) examine differences in utilization and costs between young adults with ASD without intellectual disability (ASD-ID) and with ID (ASD+ID).
Methods: We used CMS national Limited Data Files to identify persons with ASD and ID aged 18-25 years in the 5% physician visit (Carrier) claims files for 2008, 2009 and 2010. Individuals were included if they had a minimum of 1 claim of ASD (299.xx) in at least 1 file type; individuals with ID alone were identified as having a minimum of 1 claim of either 317.xx, 318.xx or 319.xx in 1 or more file types. Those with ASD+ID were identified as having a minimum of one claim with both an ASD and ID diagnosis code types in any claim file. Carrier claims records were linked to the other five claims types: inpatient hospitalization, home health, hospice, outpatient facility, and skilled nursing facility to create a dataset of identified claims based on diagnosis type. Weighted frequency counts of overall utilization and for each service type (hospitalizations, ambulatory services, therapy service), and bivariate comparisons were used to identify differences in utilization and costs between individuals with ASD+ID, ASD-ID, and ID only (no ASD). A total of 1,537 unique individuals with ASD+ID were available for analysis in 2008, 1,911 in 2009 and 2,090 in 2010. For individuals with ASD-ID, 2,073 unique individuals were available for analysis in 2008, 2,838 in 2009, and 3,603 in 2010.
Results: The number of unique individuals with an ASD-related claim increased in Medicare files 2008-2010, consistent with observed prevalence increases. Total payment costs almost doubled (44.87%) for all individuals with ASD with a Medicare claim from 2008 compared with 2010 claim year. We found that overall utilization and costs were higher among those with ASD+ ID compared with ASD-ID. Young adults with ASD+ID had significantly greater overall utilization (mean number of annual claims= 8.48) compared to those with ASD-ID (mean number of annual claims= 6.06). Average claim payment was higher among those with ASD+ID ($717.38) compared with those with ASD-ID ($547.99). Additional findings on specific healthcare services will be presented, as well as comparisons with an ID-only comparison group.
Conclusions: Similar to pediatric literature, individuals with ASD+ID utilize more healthcare and therefore costs are higher among this population. Across the three claim years, adjusted utilization and costs increased for both groups. Implications for care providers, policymakers, and researchers will be discussed.

40 **163.040** Multicausal Systems Ask for Multicausal Approaches: A Network Perspective on Subjective Well-Being in Individuals with ASD

M. K. Deserno[1], *D. Borsboom*[2], *S. Begeer*[3] *and H. M. Geurts*[1], *(1)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam; Dr. Leo Kannerhuis, Amsterdam, Netherlands, (2)Department of Psychology, University of Amsterdam, Amsterdam, Netherlands, (3)VU University Amsterdam, Amsterdam, Netherlands*

Background: Recent literature has highlighted the need to accommodate the multifactorial nature of antecedents of subjective well-being in Autism Spectrum Disorder (ASD) populations, as it is unlikely that there could be a single element of ASD that predicts well-being in all cases. Despite a large body of research identifying specific predictors of positive outcome, the predictive utility of such measures still differs in unanticipated ways and the *mechanisms* by which these factors may influence outcome for individuals with ASD remain poorly understood. These results suggest that we need further understanding of the multivariate framework in which variations in the combination of risk and protective factors contribute to individual differences in later outcome. Above all, given the vast heterogeneity within the ASD population, an important limitation of ASD research is that outcome measures are statistically modeled as separate dependent variables.
Objectives: The current study aims to lift this limitation, by providing the first assessment of a network structure risk and success factors relevant to subjective well-being in individuals with ASD.
Methods: We used network analyses to explicate the multivariate association pattern of potential risk and success factors taken from 27 life domains in 2341 individuals with ASD (aged 2 to 90). We assessed the centrality of specific life domains as well as their importance for well-being. Centrality is a metric that indicates the overall connectivity of

a variable in the network.
Results: We identified *social satisfaction* and *societal contribution* to be the strongest direct paths to subjective well-being (i.e., *happiness*), while *treatment satisfaction* also shows strong enhancing relations with feeling happy. *Physical complaints* were an important inhibiting factor for feeling happy. Factors most important in determining the network's structure include *IQ*, *living situation*, *level of daily activity*, and *happiness*. On the other hand, we found that *number of family members with ASD* and *openness about one's diagnosis* are least important of all factors, implying that they do not play a role in the multivariate pattern of risk and success factors for subjective well-being.
Conclusions: This study is the first to represent and analyze the multivariate network structure of factors involved in well-being in ASD. These results provide a potential roadmap for interventions and research directed at improving the well-being of individuals with ASD.



41 **163.041** Narratives of College Life from the Perspectives of Students with ASD and ADHD

Y. Bolourian[1], *S. M. Zeedyk*[2] *and J. Blacher*[1], *(1)University of California - Riverside, Riverside, CA, (2)Child and Adolescent Services Research Center, University of California, San Diego, San Diego, CA*

Background:
Youth with autism spectrum disorder (ASD) present with an array of deficits in social interactions, as well as with manifestations of problem behaviors. Despite the significant challenges that these diagnostic features can create for an individual's personal and academic development, many youth with high-functioning ASD are testing their independence by entering college. Additionally, there has been an increase in the number of high school students with attention deficit hyperactivity disorder (ADHD) pursuing higher education. Given the high comorbidity between ASD and ADHD, these youth are hypothesized to have similar, yet unique, experiences.
Objectives:
The purpose of this study is to investigate the narratives of students with ASD and ADHD on college life and to identify the commonalities and dissimilarities among these accounts.
Methods:
Undergraduate and graduate students with ASD (*N*=12 and ADHD (*N*=18) participated in semi-structured interviews, consisting of both open- and closed-ended questions. Audiotapes of these interviews were transcribed and qualitatively analyzed to identify themes that characterize the experiences of college students with disabilities.
Results:
Through the iterative coding process, seven main themes in the ASD sample were revealed: (1) *disclosure of diagnosis* (e.g., most students felt that disclosing their diagnosis was a privacy issue and waited to receive accommodations through the university disability services center, "until it becomes an issue"); (2) *self-awareness* (e.g., one student spoke of his experiences as a student on the spectrum by comparing himself to his typically developing peers. He revealed, "I think I really truly understood how different I was when I started college, and I saw the big gap between me and my peers"); (3) *comorbid conditions* (e.g., all students expressed that college was anxiety-inducing, mainly impacting their autism symptoms; for instance, finding and switching lab partners caused one student who ended up switching majors great angst); (4) *peer interactions* (e.g., many students described themselves as having few or no friends. One individual reported having only one friend in college with whom he speaks to occasionally on Skype); (5) *housing arrangements* (e.g., majority of students reported living at home, which can be "stressful and lonely"); *(6) academic expectations* (e.g., one student described college as a "zero sum game where [students with disabilities] can't ever catch up"); and (5) *anticipation of the future* (e.g., several participating students identified concerns regarding post-graduation, either in graduate school or on the job market. One student worried primarily about her social skills. During her preemptive job search she commented, "If you weren't very good at social skills, you wouldn't get a job"). Analyses of themes from the sample of students with ADHD are ongoing.
Conclusions:
In view of these self-reported challenges, youth with ASD and ADHD seem to be at risk for poor academic and social functioning in college settings. The number of college students with ASD and ADHD is expected to continue rising, and thus, it is imperative that we seek to gain a better understanding of the shared and distinct experiences of students with ASD and ADHD.

42 **163.042** National Autism Indicators Report 2016: Vocational Rehabilitation Services and Outcomes

A. Roux[1], *J. Rast*[2], *P. Shattuck*[3] *and K. A. Anderson*[4], *(1)3020 Market St., Ste 560, A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Approximately four in every 10 young adults with autism never work for pay outside the home between high school and their early 20s. Of these, 28% never receive services to assist them in attaining these outcomes. The U.S. Vocational Rehabilitation (VR) system is the largest provider of employment services for individuals with disabilities. Recent revisions to federal legislation aim to increase participation in integrated workplaces with sustainable wages for people with developmental disabilities who receive support services. Yet, we understand little about the role and effectiveness of VR services for those with autism.
Objectives: We characterize VR service users with autism, the services they receive, services outcomes, and how their experiences compare with other disability groups.
Methods: Data came from the federal Rehabilitation Services Administration (RSA) database which contains records for cases closed by state VR agencies. We

analyzed data for 10,534 clients with autism who received services and had a case that closed in FY2013. We compared outcomes of the autism group to those with intellectual disability (ID) and mental illness (MI) including anxiety, depression and other mood disorders.
Results: VR service users with autism were primarily male (83%), White (85%), and non-Hispanic (95%) with a mean age of 21.6 years. The majority (75%) had an IEP during high school, and 10% had a job at the time of application to VR. Average duration of services was 743 days - roughly comparable to those with ID and MI. The most frequent service types for those with autism were assessment (64%), VR counseling (60%) and job placement (47%). Over half (56%) of individuals with autism exited VR with employment - a rate slightly higher than those with ID (50%) and MI (46%). One-third of those with autism were in supportive employment (37%) and almost all had competitive employment (97%) - earning at least minimum wage in an integrated workplace and not paid less than a non-disabled person in the same position. Individuals with autism who were employed earned an average of $220 weekly, averaging 23 hours of work per week. Individuals with MI averaged higher pay ($336/week) and hours (30/week). Common occupations for those with autism were office and administrative support (22%), food preparation (17%), grounds cleaning/maintenance (12%). Fewer with ID worked in office and administrative support (12%), and more worked in food preparation (22%) and grounds cleaning/maintenance (23%). The array of job types the MI group experienced was much more varied.
Conclusions: Over half of individuals with autism who received VR services attained employment - a rate slightly higher than those with ID or MI. Approximately one-third were in supportive employment and nearly all had an outcome of competitive employment. They typically remained in the program for 2 years with services focusing on assessment, VR counseling, job placement and supports. Foundational information about VR services, experiences, and outcomes for those with autism may help inform transition planning and improve outcomes for those who receive VR services.

43 **163.043** Parent-Child Sexuality Communication for Adolescent Girls with ASD

L. Graham Holmes[1], *M. B. Himle*[2], *D. S. Strassberg*[2] *and A. Gillespie*[2], *(1)University of Utah, Salt Lake City, UT, (2)Department of Psychology, University of Utah, Salt Lake City, UT*

Background:
Adult sexual relationships are associated with physical and mental health benefits and risks. Despite the recent focus on transition issues and adult outcomes, and the interest most individuals with ASD have in sexual relationships, research on supporting health relationships remains limited. Furthermore, research on sexuality and ASD has primarily focused on males. This study addresses the need for research with females. Parents of youth with ASD have reported uncertainty about what to expect and how to support healthy sexual development. Most parents of males with ASD report covering basic topics (e.g., sexual abuse prevention, privacy, hygiene), but not other important topics such as sexual decision-making, contraception, and romantic relationships. If parents delay or omit covering such topics, youth may learn from less credible sources and have lower sexual knowledge, a known risk for victimization.
Objectives:
There is ample reason to believe that biological and cultural differences cause parents to engage in PCSC differently with male and female children. In this follow-up study, we determine whether previous research with males generalizes to females regarding the relationships between parent and child characteristics (e.g., ASD symptom severity, intellectual functioning), parental romantic expectations, parental sexuality concerns, and parent-child sexuality communication (PCSC).
Methods:
We surveyed 93 parents of 12 – 17 year-old females with ASD. Of these, 62 youth had average or above IQ and 31 had below average IQ. Data from parents of girls with below average IQ is not presented here due to small N; data collection is ongoing.
Simple and multiple regression was used to replicate results from previous research. Parents completed the Social Responsiveness Scale, 2nd edition (SRS-2), the Parent Sex Education Inventory indicating number of sexuality topics covered (range = 0 – 38), the Parent Romantic Expectations Inventory (range = 5 – 30, higher numbers indicate greater expectations) and the Parent Sexuality-Related Concerns Inventory (range = 25 – 125, higher numbers indicate more serious concerns).
Results:
Descriptive data will be presented on gender differences in specific topics and other variables. Results for parents of adolescent females were very similar to those for parents of males (see tables). Parental romantic expectations appear more important than concerns in parent engagement in PCSC, and mediate the relationship between SRS-2 and PSEI for the complete sample but not the subsample. Parents' feeling of preparedness to manage sexual development and ratings of self-efficacy for engaging in PCSC are the best predictors of number of topics covered.
Conclusions:
Healthcare providers and other personnel can encourage parents to discuss a variety of topics in order to increase sexual knowledge and decrease risks. Providers might also engage in discussion with parents and individuals with ASD about their romantic/sexual expectations and concerns, and provide resources to parents to help increase their feeling of self-efficacy and preparedness. Researchers should (a) consider cognitive functioning as an important factor in sex and relationships research and (b) continue to replicate studies with female samples to ensure efficacy of recommendations.

Combined Sample (N = 93)	*F test*	*B (SE)*	R^2
SRS-2 predicting PSEI**	$F(1, 92) = .559$, $p = .457$	$B = -.078$ (.098)	$R^2 = .006$
SRS-2 predicting Romantic Expectations**	$F(1, 91) = 10.001$, $p = .002$	$B = -.315$ (.062)	$R^2 = .099$
SRS-2 predicting Sexuality Concerns**	$F(1, 91) = 15.243$, $p = .000$	$B = .379$ (.134)	$R^2 = .143$
Romantic Expectations predicting PSEI**	$F(1, 91) = 40.413$, $p = .000$	$B = .555$ (.133)	$R^2 = .308$
Sexuality Concerns predicting PSEI**	$F(1, 91) = .093$, $p = .761$	$B = .032$ (.071)	$R^2 = .001$
Preparedness & Self-Efficacy predicting PSEI**	$F(2, 91) = 24.981$, $p = .000$	$B = .116(.966); .507$ (.922)	$R^2 = .354$
ASD+Average or Above IQ (N = 61)			
SRS-2 predicting PSEI**	$F(1, 60) = 1.018$, $p = .317$	$B = .129$ (.102)	$R^2 = .017$
SRS-2 predicting Romantic Expectations**	$F(1, 59) = 2.724$, $p = .104$	$B = -.210$ (.059)	$R^2 = .044$
SRS-2 predicting Sexuality Concerns**	$F(1, 60) = 23.878$, $p = .000$	$B = .534$ (.135)	$R^2 = .285$
Romantic Expectations predicting PSEI**	$F(1, 59) = 4.034$, $p = .049$	$B = .253$ (.218)	$R^2 = .064$
Sexuality Concerns predicting PSEI**	$F(1, 60) = .004$, $p = .949$	$B = -.008$ (.084)	$R^2 = .000$
Preparedness & Self-Efficacy predicting PSEI**	$F(2,59) = 6.949$, $p = .002$	$B = .314$ (1.379); .147 (1.4)	$R^2 = .191$

**** Indicates replication of findings with parents of male adolescents with ASD**

44 **163.044** Pay Attention during the Important Part: Adults with ASD Increase Their Gaze to Faces When Watching Richer Social Scenes

A. Pallathra[1], *L. Perez*[1], *A. Lee*[1], *R. T. Schultz*[2], *E. S. Brodkin*[1] *and J. Parish-Morris*[3], *(1)University of Pennsylvania, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Reduced attention to social information is a defining characteristic of autism spectrum disorder (ASD; (APA, 2013)), and can be directly measured using eye tracking technology (Klin et al., 2002). Despite overall reductions in attention to social information, however, some older individuals with ASD appear to utilize compensatory mechanisms to "hack the social code", particularly when cognitive reasoning skills are intact (Frith, 2004). In this study, we test whether adults with ASD show evidence of

contextually modulated attention to social information (faces) using an established paradigm that distinguishes children with ASD from typically developing counterparts (Chevallier et al., 2015). We hypothesized that adults with ASD would look relatively more at people's faces in the context of nonverbal communication (two children playing together) than in the absence of communication (two children playing in parallel).

Objectives: Assess contextual modulation of visual attention to social stimuli in adults with ASD.

Methods: Twenty-eight adult participants with ASD (4 female; see Table) watched a ~6-minute video comprised of 22 sequential 15.5-second scenes of children playing together (Joint condition) or separately (Parallel condition). A Tobii X120 infrared eye tracker measured participants' gaze direction and duration. Areas of interest (AOI) were drawn around faces (social stimuli) and background objects (nonsocial stimuli). To control for individual differences in overall attention, we calculated the proportion of looking time toward each AOI relative to total looking time at the full screen. Preliminary analyses revealed no significant correlations between gaze variables and age or IQ, so we did not include these as covariates.

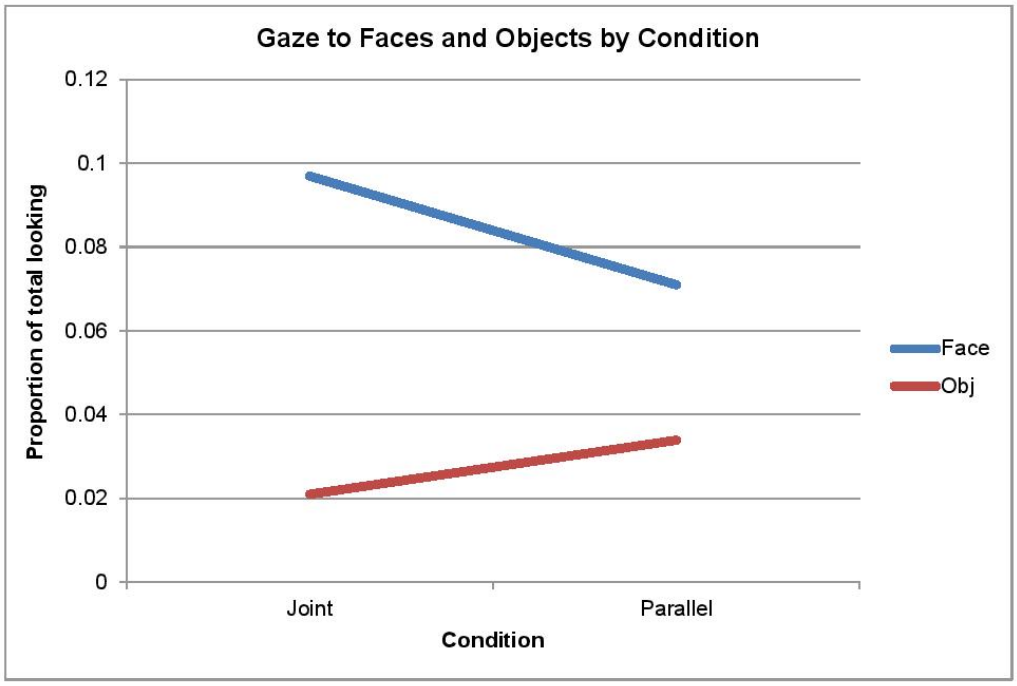
Results: A 2x2 repeated measures ANOVA revealed a significant interaction between condition (Joint, Parallel) and gaze duration to each stimulus type (Face, Background Objects), $F(1,27)=53.59$, $p<.001$, $\eta_p^2=.67$ (see Figure). Planned paired t-tests showed that participants looked more to faces in the Joint condition than the Parallel condition. To assess the nature of this effect, we calculated a Social Prioritization metric for each condition. Social Prioritization was defined as the total duration of looking at faces minus the total duration of looking at background objects. A paired samples t-test comparing average Social Prioritization in the Joint vs. Parallel condition showed that participants looked twice as long at faces relative to objects in the context of joint play between actors (mean=.08) than in the context of parallel play (mean=.04).

Conclusions: Contextual modulation of visual attention to social stimuli is an important skill that may be relatively preserved in adults with ASD. Despite clinically significant social impairments, participants looked more at children's faces in the context of interactive play than parallel play. This suggests that typical patterns of attention distribution may exist in older individuals with ASD, with the ability to tune into social context by modulating their gaze to capture communicative information from the face when it is present. Planned future analyses will explore whether this effect is also found in typically developing adults (data collection underway), will compare the magnitude of the modulation by diagnosis, and will assess whether contextual modulation can serve as a metric of treatment response.

Table. Participant demographic and phenotypic data. One participant is missing ADOS severity scores, 6 participants are missing IQ.

	Mean	SD	Min	Max
Age	25.96	7.34	20	48
SCQ	16.6	7.0	3	28
SRS-II	65.9	10.1	51	88
SRS-Self Report	63.8	8.6	47	80
WASI				
Verbal	110	21.8	71	160
Perceptual	100	26.4	57	160
FSIQ-4	106	21.7	72	140
ADOS severity	7.04	2.19	2	10

Figure. Significant interaction between condition (Joint vs. Parallel) and gaze to faces versus background objects (BG).



45 **163.045** Perception of Life As Stressful, Not Biological Response to Stress, Predicts Greater Social Disability in Adults with Autism Spectrum Disorder

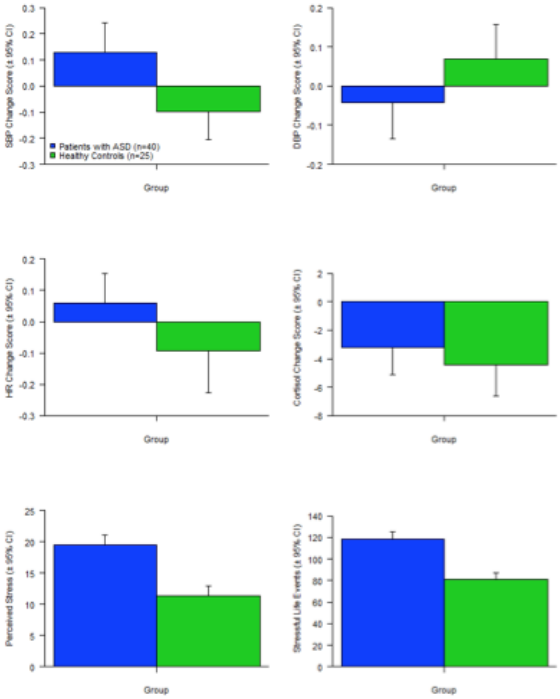
L. Bishop-Fitzpatrick[1], *C. A. Mazefsky*[2], *N. J. Minshew*[2] *and S. M. Eack*[3], *(1)Waisman Center, University of Wisconsin - Madison, Madison, WI, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)School of Social Work, University of Pittsburgh, Pittsburgh, PA*

Background: Poor social functioning is a central feature of autism spectrum disorder (ASD) and has far-reaching effects on multiple domains of life. Yet, we know little about modifiable factors that predict social functioning in this population. Preliminary work suggests that there may be differences in the underlying mechanisms that drive stress management in individuals with ASD and that these differences may be associated with adult outcomes.
Objectives: This study aimed to (1) identify differences in stress response among adults with ASD and healthy volunteers; and (2) examine the relationship between stress response and social functioning adults with ASD. We hypothesized that adults with ASD would experience greater biological stress, perceived stress, and stressful life events than healthy volunteers and that there would be a significant relationship between stress and social functioning in adults with ASD.
Methods: Cross-sectional data were collected from 40 adults with ASD and 25 healthy volunteers. Participants with ASD were ages 18-44 (M=24.2), had intelligence quotient (IQ) scores from 80-132 (M=106.3), and 90.0% male. Healthy volunteers were ages 18-32 (M=25.1), had IQ scores from 82-138 (M=110.6), and 84.0% male. Repeated measures of systolic blood pressure (SBP), diastolic blood pressure (DBP), and heart rate (HR) were taken during a social stress challenge task, while salivary cortisol was collected before and after the task. Measures also assessed perceived stress (Perceived Stress Scale), stressful life events (Stress Survey Schedule), social disability (Social Adjustment Scale-II), daily living skills (Waisman Activities of Daily Living), and social impairment (Social Responsiveness Scale). Analyses examined group differences between adults with ASD and healthy volunteers on biological stress response variables (SBP, DBP, and HR growth coefficients and salivary cortisol change scores) and

self-reported stress variables (perceived stress and stressful life events). The relationship between biological stress response and psychosocial stress variables and social functioning variables (global functioning, social impairment, social disability, and daily living skills) was analyzed using hierarchical multiple regression procedures.
Results: Results indicated that adults with ASD experienced significantly more perceived stress, *F(1, 63)=23.13, p<.001*, and stressful life events, *F(1, 63)=25.90, p<.001*, and greater SBP reactivity, *F(1,63)=4.95, p<.05* but did not differ from healthy volunteers in terms of DBP reactivity, HR reactivity, or cortisol reactivity. Results of regression analyses indicated that perceived stress, *β=0.07, t(35)=3.16, p<.05*, and stressful life events, *β=0.02, t(35)=3.20, p<.05*, significantly predicted social disability, when controlling for age, IQ, and treatment exposure. However, none of the biological stress response variables significantly predicted any social functioning variables, and perceived stress and stressful life events did not predict social impairment or daily living skills.
Conclusions: These results suggest that, while adults with ASD experience both greater systolic blood pressure reactivity and greater perceived stress and stressful life events than healthy volunteers, the perception of life as stressful is associated with social disability in this population while measured biological response to stress is not. Future research should examine both the directionality of the association between perceived stress and social functioning and interventions designed to help adults with ASD experience and respond to stress differently.

Figure 1

Group Differences on Stress Measures



46 **163.046** Prevalence and Predictors of Anxiety Disorders in Adolescent and Adult Males with Autism Spectrum Disorder and Fragile X Syndrome

J. Ezell[1], *S. McGrath*[1], *S. O'Connor*[1], *L. Abbeduto*[2] *and J. Roberts*[3], *(1)University of South Carolina, Columbia, SC, (2)MIND Institute, UC Davis, Sacramento, CA, (3)Psychology, University of South Carolina, Columbia, SC*

Background: Fragile X syndrome (FXS) is a monogenetic disorder characterized by abnormal social behavior and intellectual disability. FXS is also the most frequent inherited cause of autism spectrum disorder (ASD), which makes it an ideal model for studying ASD. Additionally, high rates of anxiety symptomatology have been reported in FXS (~90%) and ASD (~40%). Despite the high association of anxiety, few studies have examined predictive indicators of anxiety in FXS to those in ASD, or the trajectory of symptoms over time.
Objectives: Since nearly 70% of males with FXS meet criteria for ASD with considerable overlap with ASD and anxiety features, disentangling the trajectory of these features in FXS is critical to direct targeted treatments and can contribute to the latent heterogeneity in ASD. The purpose of this study is to advance our understanding of the nature of anxiety disorders in adolescent males with FXS compared to those with ASD by examining the prevalence and predictors of anxiety disorders using multiple measures over time.
Methods: Participants included males with FXS (n=30) or ASD (n=7) from 16 to 24 years of age from an ongoing longitudinal study (with 10 more ASD by IMFAR). Screening indices of anxiety preceded diagnostic determination a year later. Screening measures included the ADAMS and the CBCL anxiety subscales. The Children's Interview for Psychiatric Symptoms-Parent Version (P-ChIPS), a semi-structured interview with mothers, measured diagnosis of anxiety disorders including Specific and Social Phobias and Generalized Anxiety Disorder (GAD). The ADOS-2 documented autism severity and the Leiter-R measured nonverbal IQ.
Results: In preliminary analyses, no group differences were evident for chronological age or autism severity (p >.05). The FXS group did have a lower nonverbal IQ ($t(18)$=-4.43), p<.01); but, it was unrelated to anxiety diagnostic categorization for both groups. Findings indicate that 63% of the FXS adolescents met criteria for at least one anxiety disorder compared with 29% in ASD. Across the FXS and ASD groups respectively, 31% versus 14% met for Specific Phobia, 17% versus 14% met for Social Phobia and 33% versus 14% met for GAD. Anxiety problems from the CBCL were significantly greater in males with ASD than those with FXS ($t(8)$=-2.56), p<.05). In logistic regression models, group (B=2.13-2.25, p<0.05) predicted presence of an anxiety disorder while taking previous anxiety problems into effect as captured by the CBCL or ADAMS.
Conclusions: This study is somewhat consistent with previous work indicating high prevalence of anxiety disorders in FXS and ASD; however, our data indicate generally lower rates for both the presence and specific anxiety diagnoses across both groups. Our primary finding is greater anxiety behaviors in FXS than idiopathic ASD across general (any anxiety) and specific categories (Specific Phobia, GAD). We also report that early symptoms of anxiety on screening measures predicted the presence of an anxiety disorder a year later in ASD. This study is the first to document a tentative difference between anxiety symptoms and later diagnoses in ASD and FXS adolescent males, allowing for more targeted assessment and treatment of anxiety in these populations.

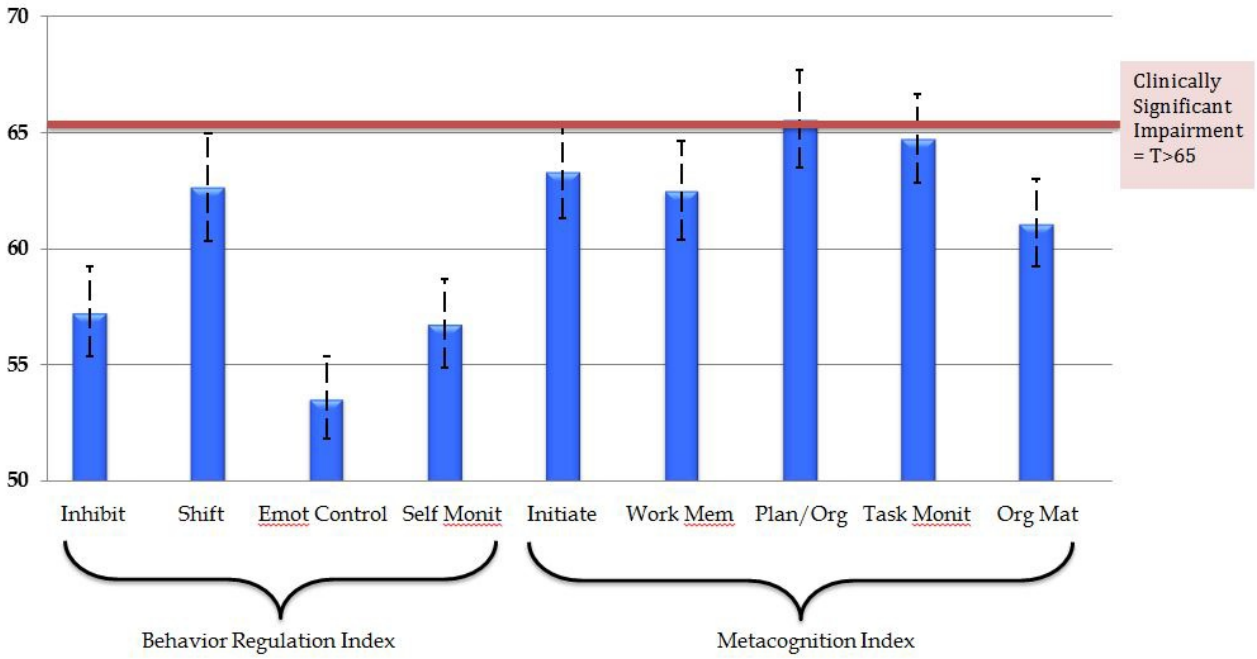
47 **163.047** Real-World Executive Functions in Adults with Autism Spectrum Disorder: Profiles of Impairment and Associations with Adaptive Functioning and Co-Morbid Anxiety and Depression

L. Kenworthy[1], *C. E. Pugliese*[2], *H. S. Popal*[3], *E. I. White*[3], *J. F. Strang*[4], *A. Martin*[3] *and G. Wallace*[5], *(1)Children's Research Institute, Children's National Medical Center, Rockville, MD, (2)Children's National Medical Center, Rockville, MD, (3)NIMH, Bethesda, MD, (4)Children's National Medical Center, Silver Spring, MD, (5)The George Washington University, Washington, DC*

Background:
Although executive functioning (EF) difficulties are well documented among children and adolescents with autism spectrum disorder (ASD), little is known about real-world measures of EF among adults with ASD. In spite of recent estimates indicating that nearly 70% of individuals with ASD do not have an intellectual disability, adult outcome in ASD remains poor. Two key components of outcome are psychiatric co-morbidities and adaptive behavior, both of which are related to EF in children and adolescents with ASD.
Objectives:
To examine real-world EF profiles as reported on the informant version of the Behavior Rating Inventory of Executive Function-Adult; and to investigate the links between real-world EF problems and both adaptive functioning and internalizing psychopathology (i.e., anxiety and depression symptoms).
Methods:
We examined parent-reported EF problems among 35 adults with ASD without intellectual disability (31 males; 18-40 years [M=21.55, SD=4.12]; Full Scale IQ 88-133 [M=112.47, SD=11.21]). We defined the profile of specific EF domain deficits in adults with ASD and investigated how EF was related to adaptive functioning and co-morbid

anxiety and depression symptomatology through regression analyses. Research reliable autism diagnosis using ADI and ADOS was confirmed by expert clinical opinion. Parent report was gathered on measures of: EF (Behavior Rating Inventory of Executive Functioning-Adult version [BRIEF-A]), adaptive behavior (Adaptive Behavior Assessment System-Second Edition) and internalizing psychopathology (Adult Behavior CheckList).
Results:
One-sample t-tests indicated that adults with ASD were impaired on all nine domains measured by the BRIEF-A relative to the normative mean (p's<.05). A repeated measures ANOVA demonstrated a variable EF profile in ASD (F=10.20, p<.001) with the most prominent deficits occurring in flexibility (i.e. the BRIEF-A Shift scale) and metacognition (i.e. the BRIEF-A Metacognition Index and the Plan/Organize scale). Hierarchical multiple regressions revealed that even after accounting for the influences of age, IQ, and ADHD symptoms, flexibility problems were associated with anxiety-related symptoms (F=8.56, p=.002; ΔR^2 =.38), while metacognition, and specifically problems on the Plan/Organize scale were associated with depression symptoms (F=4.62, p=.02, ΔR^2 =.17). Although neither age nor IQ scores were significant predictors of adaptive behavior, metacognition scores were. Adding ADHD problems to the regression model as a nuisance variable resulted in metacognition problems no longer significantly predicting adaptive functioning impairments however.
Conclusions:
Real-world EF problems persist into adulthood, with a profile of impairment that emphasizes problems with flexibility and metacognition, consistent with previous reports in children and adolescents. The relationship between EF problems and adaptive behavior may be mediated by ADHD symptomatology in this adult sample. Even after accounting for ADHD symptoms, EF problems are strongly associated with co-morbid anxiety and depression symptoms, making EF an important treatment target among adults with ASD.

Figure 1. Profile of informant ratings of real-world executive functioning among 35 adults with autism spectrum disorder by subscale of the Behavior Rating Inventory of Executive Function-Adult (T-scores; *M*=50, *SD*=10).



48 **163.048** Results of an Autism Screening Study Among Adults Receiving Community Mental Health Services

D. S. Mandell[1], *J. Miller*[2], *E. S. Brodkin*[3], *M. E. Calkins*[3], *K. Shea*[3], *K. T. Mullan*[3], *B. B. Maddox*[2], *S. 2. Marcus*[3] *and T. M. Moore*[4], *(1)University of Pennsylvania School of Medicine, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: Adults with ASD may be misdiagnosed, or their psychiatric comorbidities may be recognized without recognizing the ASD. Studies report that 10% of psychiatrically hospitalized adults in US and 6% in the UK have undiagnosed ASD. Studies from the UK, Sweden and Taiwan find 0.6 - 4% of adult patients with ASD in outpatient settings. The prevalence of ASD in adult US outpatient psychiatric settings is unknown. Accurately diagnosing ASD is challenging for community clinicians. ASD diagnostic tools are lengthy, most are validated only in children, and they require considerable training to administer correctly. Therefore they are not feasible for use with adults in community mental health settings.
Objectives: 1) Estimate the prevalence of undiagnosed ASD in community outpatient settings; 2) compare clinical characteristics, treatment and assigned diagnoses of adults with ASD with those of adults with other psychiatric disorders; and 3) develop and test a brief tool for community mental health practice to screen for ASD in adults.
Methods: Staff from three community mental health centers completed the Social Responsiveness Scale, Adult Version (SRS-A) and the Autism Spectrum Disorders in Adults Screening Questionnaire for their adult clients. Our research team conducted chart reviews to extract information found to discriminate adults with ASD from adults with other psychiatric disorders in prior studies. A subset of these clients, enriched for those with SRS-A scores >60, completed in-person evaluations. This evaluation included Module 4 of the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), a brief clinical interview about ASD-related characteristics not assessed by the ADOS-2, and the Overview and Psychosis modules of the Structured Clinical Interview for DSM-IV-TR Axis I Disorders (SCID). Clinical case conferences were conducted for all participants to make a final determination of ASD. Item response theory was used to reduce the number of items on the SRS. Logistic regression and recursive partitioning were used to identify the most parsimonious set of elements needed to accurately screen for and diagnose ASD.
Results: 1134 adults were screened, 813 of whom were not receiving developmental services, and therefore counted towards our denominator. To date, 296 charts were reviewed and >58 clinical interviews were conducted (35 more expected, enriched for autism). Seventeen individuals were already diagnosed with ASD and an additional 21 had a mention of ASD in their charts. Two met research criteria for ASD, although 22 had scores on the ADOS indicative of ASD. 18 items on the SRS, selected through item response theory, had a .95 correlation with the SRS total score. Analyses examining the combined accuracy of the SRS plus additional items pulled from charts will be completed by the time of submission.
Conclusions: Study results suggest that the prevalence of ASD among adults receiving outpatient psychiatric care is approximately .5%, although challenges in interviewing more severely impaired participants suggest that this is a lower-bound estimate. Traditional screening tools can be substantially shortened with no reduction of accuracy in this population, especially when combined with other data elements easily extracted from clinical charts.

49 **163.049** Seeking Safe Spaces: Autistic Students Finding Places to be Themselves on College Campuses

A. Wolz[1], *B. E. Cox*[2], *A. Anderson*[1] *and J. Edelstein*[1], *(1)Florida State University, Tallahassee, FL, (2)P.O. Box 3064452, Florida State University, Tallahassee, FL*

Background:
The traditional college setting is being challenged as students on the autism spectrum enter postsecondary education. This presents trials for students with ASD, as “failure

by universities to provide social supports would substantially impair the student's ability" to reach the goals of developing social skills and forming relationships (VanBergeijk, Klin,& Volkmar, 2008). One method of providing resources is the provision of formal and informal 'safe spaces' on campus to accommodate students with ASD, where they can self-regulate and feel prepared to accomplish the aforementioned objectives. Such spaces help students overcome potential barriers to academic and social engagement, thereby facilitating students' growth and success.
Objectives:
The purpose of this paper is to examine the need for safe spaces on college campuses as sustainable resources for students with ASD, from the perspectives of students with ASD who have postsecondary education experience. Safe spaces offer a place free from an otherwise overwhelming environment.
Methods:
Data were collected from a virtual platform for individuals with ASD, wrongplanet.net. Discussion threads were collected from the "School and College Life" board. Using Astin's Inputs-Environments-Outputs (IEO) framework, four researchers coded data in three separate rounds, with inter-coder reliability established by joint coding during the first round. Both procedural and thematic memos were taken throughout the coding process.
Results:
Students with ASD reported the college environment can be overwhelming and potentially hostile. These students expressed experiencing anxiety about certain college experiences, difficulties with social interactions, and feeling overwhelmed by new environments. Said one student, "I ended up having a serious meltdown due to over stimulation. It took me two months to recover."
Safe spaces in the college environment provide a place for these students to escape stressors. Despite the disruptive nature of the college settings, students with ASD reported safe spaces helped them to alleviate anxiety and propel success. One student found alternatives to spaces where he felt overwhelmed, saying "Sometimes I was so overwhelmed with nerves/fear that I would avoid going to the cafeteria for dinner and just eat something like popcorn in my room." Another student had strategies of active avoidance. "You need to secure some solitary hangout spots in and around campus. A hidden nook of the library, a café off-campus that's open late, etc.. Make it so you don't need to come back until your roomie(s) are asleep."
Conclusions:
College students with ASD need places into which they can retreat when feeling overloaded. Safe spaces provide the opportunity to process information in a secure setting. Safe spaces should enable separation from social environments, provide security, and vary to meet individual students' needs. These spaces may be pre-existing physical spaces, but may also include virtual systems. Moreover, institutional policies can enable temporal safe spaces by providing students adequate time to process all the necessary information before making a decision.
It is essential that the growing population of postsecondary students with ASD view institutional environments as conducive to their well-being. The creation of safe spaces is one promising means of doing so.

50 **163.050** Skilled Jobs for People with ASC Successful Dual Vocational Training and Job Placement in Germany

***M. Dalferth**, OTH Regensburg, University of Applied Sciences, Regensburg, Germany*

Background: Improvement of framework conditions and creating instruments for successful training qualifications and job placement

Objectives: Continuous evaluation of adolescents with autism spectrum in twelve vocational training centres; outcomes of vocational training and job placement; experiences with support measures, job coaching and mentoring.
Methods: Mail questionnaires (centres), Structured interviews with experts (staff), graduates (with autism) and entrepreneurs (companies)
Results: Special training programmes in twelve dual vocational training centres have led to a jump in numbers of participants with ASC from 348 (2010) to 649 (2013). 228 have successfully finished their training (2.5 – 3.5 years) and left the centres. 131 have provided information about their kind of employment: 40.5% have found work on the labour market, most of them in their trained jobs. 12.2 % have started further training or studies. 4.6 % work in a sheltered workshop. 2.3 % are not available for the labour market. 40.4 % are still looking for a job. Graduates supported by job coaches were more successful to find a demanding job on the labour market
Conclusions: People with ASC (especially with Asperger's Syndrome and High Functioning Autism) are able to successfully undergo vocational training and work in different kinds of qualified jobs where they can unfold their potentials and do skilled work for the companies. Nevertheless there is a discrepancy between successful graduation and job placement. Therefore, some prerequisites should be taken into account for the second step:
Graduates with autism should be especially trained for job interviews or accompanied by a coach. But most of them are living with their families. They need support to find an individual accommodation, to manage everyday life skills, and to establish social contacts. An ongoing social skill training helps them to develop flexibility and social competence. Job coaching tailored to their special needs highly increases the chances to get and maintain a job.
Companies need useful information about people with ASC and their capabilities, about how to adequately communicate with them and deal with their special characteristics. They benefit from external job coaches and colleagues who volunteer as mentors.

51 **163.051** Student-Professor Relationships and Needs Among University Students with ASD or ADHD: Student and Professor Perspectives

***S. M. Zeedyk**[1], Y. Bolourian[2] and J. Blacher[2], (1)Psychiatry, University of California, San Diego, San Diego, CA, (2)University of California - Riverside, Riverside, CA*

Background:
Increasingly, young adults with ASD are attending 4-year universities (Shattuck et al., 2012). At the postsecondary level, most supports offered during the K-12 years are no longer available (VanBergeijk et al., 2008), and accommodations at many campuses present challenges for students with ASD. Therefore, it is imperative to consider the role of university professors. Further, there is a high level of comorbid ADHD symptoms among individuals with ASD (van der Meer et al., 2012). Thus, students with ASD may share similar experiences in college as their peers with ADHD.
Objectives:
The present study aimed to evaluate the needs of college students with ASD or ADHD, including the similarities and differences identified between the groups. Additionally, we sought to identify the knowledge (or lack thereof) that faculty members possessed about working with these students.
Methods:
Participants included 18 professors, 13 students with ASD, and 18 students with ADHD, all from 4-year universities. Students and professors participated in individual semi-structured interviews, which were transcribed and analyzed through an iterative coding process to identify common themes.
Results:
Preliminary analyses of the interviews with professors and students with ASD revealed six main themes: (1) *Autism is an invisible disability* (e.g., One professor discussing a colleague's attitude disclosed, "He didn't think he needed to provide accommodations to students who appeared *normal*."); (2) *Available services* (e.g., academic accommodations were described as "a perfunctory/one size fits all" approach); (3) *Things professors need to know* (e.g., One student indicated that he switched majors because he was required to change lab partners almost daily; he explained that the new major was "more consistent," and he didn't have to constantly meet new people.); (4) *Interactions between students and professors* (e.g., One professor described a student who did not understand college classroom etiquette, "It took a little bit of management because one of the characteristics of his specific position on the spectrum is he's not shy at all about talking. So it was a matter of helping him learn when not to talk… It was a great learning experience for me as a teacher." Themes unique to the faculty interviews included, (5) *Interest in autism* (i.e., professors' personal and professional interests in ASD); and (6) *Education/training in autism* (e.g., One professor explained, "I would like to know what needs – what special needs they have? What can I expect in terms of their behavior or their frustration or their anxiety.") Analyses of the interviews with students with ADHD are ongoing. Comparison of the overlap and discrepancies between the two student groups will be identified.
Conclusions:
University professors have limited knowledge about working with students with ASD or ADHD. Unfortunately, available services are primarily geared toward students with learning disabilities. Changes in the administration of campus disability services and better faculty training may be useful in aiding these students to be more successful in college. Understanding the challenges faced by these students through in-depth accounts is valuable in uncovering the areas of need in assisting them at the postsecondary level.

52 **163.052** Support Systems for Students with Autism Spectrum Disorder during Their Transition to Higher Education: A Qualitative Analysis of Online Discussions

***A. Anderson**[1], B. E. Cox[2], A. Wolz[1] and J. Edelstein[1], (1)Florida State University, Tallahassee, FL, (2)P.O. Box 3064452, Florida State University, Tallahassee, FL*

Background:
Individuals with high functioning autism spectrum disorder (ASD), formerly diagnosed as Asperger syndrome, are graduating from high school and entering institutions of higher education (IHE) in greater numbers than ever before. Transitioning from high school to college can be challenging for all students, and can be particularly difficult for students with ASD, who often face adversity during periods of transition. Although a growing number of colleges and universities have begun developing programs to support these students, more efforts are necessary to better understand how to best serve this population. Further, much of the relevant literature relies on secondhand reporting from parents, faculty, and administration rather than the student with ASD him or herself.
Objectives:
This study is an exploration into how college students with high functioning autism spectrum disorder describe their support systems during the transition to higher education.

In particular, this study explores how these students describe their experiences within an online environment among their peers.
Methods:
The study used unobtrusive qualitative methods to collect and analyze online forum discussion posts from college students with autism spectrum disorder. Data was collected from the Wrong Planet "School and College Life" forum, which is a publicly viewable discussion forum. Source forum replies were coded into qualitative data analysis software NVivo in the first round of analysis as guided by (Astin's) I-E-O framework. Following this, a second round of coding occurred in which specific themes were established, from which this study draws data.
Results:
Support services do not work in isolation. Many students described multiple support systems (e.g. Housing, Counseling, and Advising) working in conjunction with one another during their successful transition to higher education. One student noted that "There are many support programs as well that can assist with the executive functioning issues, extra tutoring, and all the other things that come up like handling relationships, advocating, budgeting (a huge one), etc.". Students find their support systems through both formal and informal means. Many use services provided by their Office of Disability Services (ODS), but many students lack the awareness or documentation needed to obtain services. One student describes how he found his group of "interesting people" in a student association: "I prefer to meet people in a group that is interest-focused and where there is enough room to accommodate to slow processing speed and sensory processing differences."
Conclusions:
Institutions of higher education offer a variety of support services for students with ASD. Though services offered through ODS typically require documentation of a formal diagnosis, others are available without diagnosis or disclosure. Because some students do not have a formal diagnosis and many others choose not to disclose, colleges and universities must train faculty and staff throughout the institution to provide the support these students deserve.

53 **163.053** Supported Employment, Comprehensive Cognitive Enhancement and Social Skills (SUCCESS) Program for Adults with ASD: Who, What, Where, When and How Plus Outcomes

M. J. Baker-Ericzen[1], *M. Fitch*[2], *M. Kinnear*[3] *and M. M. Jenkins*[1], *(1)Child and Adolescent Services Research Center, Rady Children's Hospital San Diego, San Diego, CA, (2)Child & Adolescent Services Research Center, Rady Children's Hospital, San Diego, San Diego, CA, (3)Rady Children's Hospital San Diego, San Diego, CA*

Background:
The increasing population of adults with ASD is considered a pressing, challenging public health issue (Bailey, 2012). Longitudinal studies of intellectually able adults with autism have shown consistent and persistent deficits across cognitive, social, and vocational domains, indicating a significant need for effective treatments for these functional disabilities (Howlin, 2000). The cognitive and social skill deficits that are core features of ASD have been identified as major challenges to employment success for these adults (Hillier et al, 2007).
Objectives:
This study developed a novel, integrated community-based intervention, **Su**pported employment, **C**omprehensive **C**ognitive **E**nhancement & **S**ocial **S**kills (SUCCESS) treatment that augments existing community supported employment practice with a newly developed a manualized "soft skills" curriculum. A pilot study was conducted to obtain estimates of effects of outcomes which include cognitive skills and social skills for young adults with ASD.
Methods:
A total of 18 young adults participated in an open trial pilot study of the SUCCESS program to date with another 15-25 estimated to have participated by April 2016. SUCCESS was delivered weekly for 90minutes via active group participation during a simulated work meeting within a larger vocational training program in community services. The program involves 24 sessions over 5 months with first half of the curriculum teaching executive functioning skills as attention, learning, memory, prospective memory, cognitive flexibility, problem solving, goal oriented thinking and contextual awareness. The second half teaching social communication skills including social conversation (giving and receiving compliments, feedback and help), social relationships, initiations and social networking (including do's & don'ts of social media). Pre and post assessments include a full battery of assessments with the Behavior Rating Inventory of Executive Function- Adult Version (BRIEF-A) and Social Responsiveness Scale-2 (SRS-2) adult form presented. Participants and caregiver informants completed each measure. The majority of participants were male (84%), white race/ethnicity (84%) and all graduated with a high school diploma. Some were involved with various social services: 42% disability services, 26% department of rehabilitation, 11% social security income.
Results:
Analyses consisted of calculating effect sizes using Cohen's d to measure the magnitude of the effect of the SUCCESS intervention pre and post training program on executive functioning (8 clinical subscales; 2 indexes and 1 Total score: Global Executive Composite) and social skills (6 subscales and 1 Total score) by informants (self and caregiver). Preliminary findings reveal small to large negative effects per participant and caregiver report on the BRIEF. This may be a reflection of increased awareness of issues. Small to large positive effects were found on the SRS-2 subscales per parent report and minimal effects for participants (Refer to Tables).
Conclusions: This study demonstrates that it is feasible to develop the "soft skills", a cluster of cognitive abilities and social graces that make someone a good employee and compatible to work with, within a community supported employment environment for adults with ASD. Specifically, the SUCCESS program has potential to improve social skills and it can be offered within vocational preparedness programs. Additional measures should be analyzed to examine effectiveness.

Table 1. Social Skill Outcomes

Social Responsiveness Scale-2	Participant			Parent		
T Scores	pre-mean	post-mean	effect size	pre mean	post-mean	effect size
Social awareness	57.00	56.71	0.04	67.29	60.29	0.97

54 **163.054** The ADOS-2 in Adult Community Mental Health Settings

J. Miller[1], *E. S. Brodkin*[2], *M. E. Calkins*[2], *B. B. Maddox*[1], *K. T. Mullan*[2], *K. Shea*[2] *and D. S. Mandell*[3], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania School of Medicine, Philadelphia, PA*

Background:
For adults with possible ASD, the ADOS-2 is likely to be the instrument of choice to gather observations about social communication and restricted interests and behaviors. While insufficient on its own for a diagnosis, it might be the most standardized and objective information available about ASD related characteristics, especially when early developmental history is unavailable. Because evidence suggests many adults with ASD have unmet psychiatric care needs, it is thus particularly critical to know how to identify adults with ASD and ensure they are receiving needed services. To that end, it is critical to know how the ADOS-2 performs in different care settings, include CMH

centers.
Objectives: To examine the utility of the ADOS-2 to distinguish individuals with ASD from individuals with other diagnoses receiving CMH services.
Methods: Consumers of services at three large CMH centers in Philadelphia (n = 1134) were screened for social communication impairments with the Social Responsiveness Scale, Adult version (SRS-A) and the Autism Spectrum Disorders in Adults Screening Questionnaire (ASDASQ). Of these, a sample stratified to heavily recruit participants with SRS-A scores >60 was recruited to participate in a clinical evaluation that included an ADOS-2, brief clinical interview about ASD related characteristics not assessed by the ADOS-2, social history questions from the KIDDIE-SADS-Present and Lifetime Version (K-SADS-PL), and the Overview and Psychosis modules of the Structured Clinical Interview for DSM-IV-TR Axis I Disorders (SCID). The clinical evaluation team remained blind to results from the SRS-A and ASDASQ. The ADOS-2 was always administered first, and scored independently of subsequent information gathered. After the full evaluation, clinical case conferences were conducted for all participants to make a final determination of ASD.
Results: To date, 58 in-person evaluations have been conducted. An additional 35 evaluations are expected by May 2016. Results from clinical case conferences suggested that 2 of the 58 had an ASD (3.45%); 43 had some form of psychosis (74.14%). However, 22 participants obtained ADOS-2 scores above the cutoffs suggestive of ASD; 2 were the individuals with ASD, 16 were individuals with psychosis, and the remaining 4 had existing mood disorder diagnoses and suspected personality disorders. From clinical observation, it was often the negative symptoms of psychosis that resulted in elevated ADOS-2 scores.
Conclusions: Social communication impairments are not specific to ASD, and of course the ADOS-2 is not intended to be used as the sole source of data in a diagnostic evaluation. However, our data suggest that ADOS-2 scores may yield a very high rate of false positives in adults with complex mental health issues. Across these CMH settings, 20/56 (35.7%) of our sample obtained elevated ADOS-2 scores, although clinical case conference judgment determined the client did not have ASD. The high rate of false positives on the ADOS-2 among adults with complex psychiatric issues suggests the ADOS-2 may not be a helpful tool for discriminating ASD in this population, or at least must be considered in the context of other developmental and clinical information.

55 **163.055** The Economic Cost of Adults with Autism Spectrum Disorder on Households

*J. Shannon, **A. Arrieta**, B. C. Amick and T. Page, Health Policy and Management, Florida International University, Miami, FL*

Background: In 2010, 1 in 68 children had been diagnosed with an Autism Spectrum Disorder (ASD), an increase of 120 percent in prevalence since 2000. As larger cohorts age and transition to adulthood, ASD will impose a greater economic burden on households. Few studies in the field have assessed the cost of ASD in adults, and even fewer have focused on the cost from a household perspective.
Objectives: The objective of this study was to produce preliminary estimates of the direct and indirect cost of ASD in adults from a household perspective.
Methods: We developed a survey instrument to gather data from households on the economic cost of caring for adults with ASD. We recruited 31 households in the South Florida area to participate in the study, and asked the household primary caregiver to complete the survey. The survey instrument was designed to match the Medical Expenditures Panel Survey (MEPS) database. Each adult with ASD from our study was matched to one or more adults without ASD from MEPS using the nearest neighbor matching method. The direct medical cost of ASD, defined as the additional cost of caring for adults with ASD compared to similar adults without ASD, was estimated with a generalized linear model to account for skewness in the MEPS cost data. Other direct costs (accommodations and other non-medical services) as well as indirect costs (productivity loss of the primary caregiver and the adult with ASD) were obtained from the survey.
Results: The average total economic cost of ASD in adults for households in our study was estimated at $42,684 annually (in 2015 dollars). Income loss from the primary caregiver ($11,665) and adult with ASD ($25,308) accounted for the majority of the cost. Direct medical costs for outpatient, emergency room, hospital stays, and dentist services were $554 annually. Direct non-medical costs for accommodation, paid helper, special needs school, speech therapy, occupational therapy, and vocational rehabilitation for the adult with ASD were $8,485 annually. Adults with ASD had 4.4 more outpatient visits and 1.0 more hospital visit per year than adults without ASD.
Conclusions: This is, to our knowledge, the first study to estimate the cost of ASD in adults in the U.S. We estimated the cost of ASD in adults for an average household in South Florida at $42,684. This translates to a total economic cost to households in Florida of $663 million per year and $21 billion nationwide.

56 **163.056** The Effect of Diaphragmatic Breathing on Stress Caused By a Socially Stressful Paradigm on Young Adult Males with Autism Spectrum Disorder

***T. Kozikowski**[1], R. M. Mizrahi[2], A. Herndon[1], S. Neumann[3], K. Hartmann[1] and M. Urbano[1], (1)Eastern Virginia Medical School, Norfolk, VA, (2)Psychological and Brain Sciences, University of Massachusetts, Amherst, MA, (3)Psychiatry, Eastern Virginia Medical School, Norfolk, VA*

Background:
One of the hallmarks of Autism Spectrum Disorder (ASD) is difficulty with social interactions and forming appropriate social relationships. ASD is often comorbid with social anxiety and those with ASD report higher levels of stress in social situations. Therefore, one predominate theory is that the social deficit seen in individuals with ASD is due to an increased anxiety associated with social interactions. Anxiety in those diagnosed with ASD is of considerable concern because frequent elevated levels of cortisol associated with stress and anxiety can negatively affect brain development and general health.
Diaphragmatic breathing (DB) techniques have consistently been shown to improve self-reported anxiety and associated autonomic cardiac responses. Furthermore, research has shown that these techniques have successfully lowered the stress response in other populations diagnosed with mental health disorders
Objectives:
The goal of this study was to investigate whether DB techniques would be useful in decreasing stress in young adult males with ASD following a socially stressful paradigm.
Methods:
Participants for this study were 26 males (M_{age} = 21.1) including participants with an ASD diagnosis (n_{ASD} = 16) and participants without an ASD diagnosis ($n_{non\text{-}ASD}$ = 10). Heart rate variability (HRV) for all participants was measured during baseline, a socially stressful activity, and recovery periods as a biomarker of autonomic nervous system response linked with emotional stress. The baseline period consisted of participants sitting quietly. The activity period consisted of participants taking part in The Talking, Feeling, and Doing Game® with two confederates. In order to induce a socially stressful paradigm, confederates were instructed prior to the session not to provide the participant any social feedback while playing the game. During the recovery period, participants were randomly selected into one of two conditions (DB or control conditions). Participants in the DB condition were coached through a DB exercise paced at 6-10 breaths per minute. Participants in the control condition were instructed to sit quietly. The associated stress response was evaluated through statistical analyses of the HRV parameters measured at the three data points.
Results:
Period (baseline, activity, recovery) x condition (DB, control) repeated measures ANOVAs were conducted analyzing high frequency: low frequency (HF:LF) HRV for the ASD and non-ASD groups separately. There was a significant main effect of condition ($F(1,14) = 6.84$, $p<.02$) on HRV for the ASD group.
Independent samples t-tests for the ASD participants indicated that HF:LF HRV did not differ between the DB and control conditions during baseline or activity periods (all $p>.43$). However, the DB group had a significantly lower HF:LF HRV (M_{DB} = -0.04, SD_{DB} = 0.02) than the control group ($M_{control}$ = 0.92, $SD_{control}$ = 0.39; $t(16) = -0.74$, $p<.001$) during the recovery period.
Conclusions:
Results reveal that DB successfully decreased stress as measured by HRV in a socially stressful paradigm in young adult males with ASD compared to controls (non-DB). These results indicate that DB may be a beneficial technique to decrease stress related to social anxiety for those with ASD.

57 **163.057** The Effects of Employment on Mental Health and Executive Functions in Adults with Autism Spectrum Disorder (ASD)

***L. Dockery**[1] and E. L. Hill[2], (1)Lewisham Way, New Cross, Goldsmiths, University of London, London, United Kingdom, (2)Goldsmiths, University of London, London, United Kingdom*

Background: Little is known about life for adults with Autism Spectrum Disorder (Howlin, 2013). This is worrying because research suggests adults with ASD experience poorer mental health than those without ASD (Joshi et al., 2013) with depression commonly reported (Moss et al., 2015). Some research also indicates executive functions (higher-order cognitive processes including planning, flexibility and inhibition) are also associated with difficulty in ASD (Hill, 2004). Few adults with ASD are in employment despite many being able and willing to work. However, employment can be seen as one route to independence and social inclusion. The effects of employment on mental health in adults with ASD are unknown. However, one study has suggested improved executive functioning performance following participation in a supported employment scheme in adults with ASD (Garcia-Villamisar & Hughes, 2007).
Objectives: This study will focus on mental health and executive functioning with the hypothesis that mental health and executive functioning will improve after a period of employment in adults with ASD.
Methods: 20 adults (age 18+) with ASD and 20 individuals without ASD (matched on IQ, age and gender) will take part. Those with intellectual disability, DCD, ADHD or dyslexia are excluded. Participants will be assessed at two time points: pre-employment and post-employment. Each session will involve a series of mental health questionnaires and executive functioning tasks. All participants will be unemployed at the pre-employment stage and employed, or have just completed a period of employment, at the post-employment stage.
Results: To date, eleven adults with ASD have taken part. Most participants are males (91%) aged 20-36 (M = 25.6, SD = 4.3). Pre-employment, participants reported mild symptoms of depression (M = 6.2, SD = 5.4), few or no symptoms of anxiety (M = 4.0, SD = 3.5), slightly below average levels of life satisfaction (M = 17.3, SD = 8.3) and slightly lower than average levels of well-being (M = 43.6, SD = 8.3). Initial data from the present study suggest an improvement in well-being ($t(6) = -2.19$, $p = .036$), verbal fluency ($t(6) = -2.14$, $p = .039$), cognitive flexibility($t(6) = 2.49$, $p = .024$) and response inhibition ($t(6) = 3.57$, $p = .006$) after a period of employment.

Conclusions: Whilst this is extremely tentative, as data collection and analysis are ongoing, the preliminary findings support the hypothesis that an improvement in mental health and executive functioning is observed in adults with ASD after a period of employment. This supports clinical guidelines recommending individual supported employment as a psychosocial intervention for adults with ASD (NICE, 2012) and links to funding opportunities for specialist adult ASD employment services. Few of these services exist and an improvement in well-being and some aspects of cognition means many adults with ASD would benefit from specialist supported employment services. Finally, the present study supports recent statutory guidance in the United Kingdom recommending employment be included in needs assessments for adults with ASD.

58 **163.058** The Impact of Postsecondary Education on Employment for Young Adults with Autism Spectrum Disorders

B. Freedman[1]*, S. Pi*[2] *and J. C. Lee*[1]*, (1)Center for Disabilities Studies, University of Delaware, Newark, DE, (2)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI*

Background: There has been a recent increase in the number of young adults with autism spectrum disorders (ASD) who are seeking postsecondary education (Gardiner & Iarocci, 2013). Specialized supports appear to foster greater academic success for young adults with ASD (Gelbar et al., 2014). However, little is known about whether participation in college promotes improved employment outcomes, which may deter support teams from encouraging postsecondary education. Limited previous research suggests that postsecondary education is a strong predictor of employment for young adults with ASD (Migliore et al., 2012) although the contribution of functional limitations has not yet been explored. Additionally, little is known about the types of occupations young adults who have postsecondary education successfully attain and whether these are different than positions held by those who do not have postsecondary education.
Objectives:

1. Examine the impact of participation in postsecondary education on employment status for young adults with ASD.
2. Explore the association between participation in postsecondary education and types of occupation among young adults with ASD.

Methods: The study population was individuals ages 14-24 with ASD who received services from the Vocational Rehabilitation (VR) agency in a Midwestern state and whose cases were closed during FY 2011-2013 (n=1,001). Rehabilitation Services Administration Case Service Report (RSA-911) dataset was used as the primary data source, and functional limitation data was extracted from the agency's case management system. Four logistic regression models were sequentially performed with "employment status at closure" as the outcome. Model 1 included only participation in postsecondary education. Individual characteristics, VR services, and functional limitations were sequentially entered in subsequent models. Chi-squared tests were performed to explore the association of participation in postsecondary education with different types of occupations for youth with ASD.
Results: Young adults with ASD who participated in postsecondary education were more likely to achieve employment compared to those who did not participate in postsecondary education (Adjusted Odds Ratio [AOR]=2.08; 95% CI = 1.5, 2.9), after controlling for individual characteristics, VR services received, and types of functional limitation. Functional limitation in self-care (AOR=0.6; 95% CI = 0.4, 0.9) or work-tolerance (AOR=0.7; 95% CI = 0.5, 0.9) was found as risks for not achieving employment. Chi-squared tests indicated a significant association between participation in postsecondary education and employment in sales; office and administrative support; and transportation and material moving. A higher proportion of those without postsecondary education obtained jobs in building and grounds cleaning and maintenance; and installation, maintenance, and repair.
Conclusions: Participation in postsecondary education is an effective vehicle for achieving employment for young adults with ASD, particularly when combined with specific VR services. A greater focus on self-care and work-tolerance during postsecondary education may improve the likelihood of employment. Participation in postsecondary education may lead to employment in a variety of fields beyond those, like grounds cleaning, which are traditionally associated with people with ASD. This study only focused on one particular geographic area and therefore requires replication in other states/regions.

59 **163.059** The Relationship Between ASD Symptoms and Adjustment to College

S. M. Ryan[1]*, L. K. Baker*[2]*, S. W. Eldred*[2] *and J. A. Rankin*[3]*, (1)The University of Alabama, Tuscaloosa, AL, (2)Psychology, The University of Alabama, Tuscaloosa, AL, (3)Stony Book University, Stony Brook, NY*

Background:
Estimates suggest that 46% of individuals with an ASD diagnosis have average or better cognitive functioning (CDC, 2014). According to the National Longitudinal Transition Study-2 (NLTS-2), 32% of students with an ASD diagnosis attend college (Wei, et al., 2012) with fewer than 20% of those enrolling in a 4-year university completing a degree (Shattuck, et al., 2012). In order to increase successful completion of college degrees it is important to examine how ASD symptoms effect students' adjustment to college. Trevisan et al., (2015) found that Broader Autism Phenotype symptoms in neurotypical students significantly predicted adjustment to college as measured by the Student Adaptation to College Questionnaire; however, this study did not examine symptoms in individuals with an ASD diagnosis.
Objectives:
The purpose of the current study is to examine the relationship between ASD symptoms as measured by the SRS-2 and adjustment to college as measured by the Student Adaptation to College Questionnaire and the students' GPA at the end of the first academic year.
Methods:
The current study included 10 degree-seeking college students who were admitted to an ASD Specific support program at a major public university. The sample included students across 3 cohorts (9 males/1 female; 7 freshmen/3 transfer students). Students were paired with a therapist-mentor who met with them 3 times per week to address academic organization, self-advocacy, social skill development, career building skills, and coping with anxiety and/or depression. Students were administered a battery of measures at summer orientation prior to beginning college and then each subsequent semester. The current study examined the correlation among ASD symptoms as reported by parents on the Social Responsiveness scale, Second Edition (SRS-2), the Student Adaptation to College Questionnaire completed at the end of the first academic year, and the cumulative GPA at the end of the first academic year.
Results:
Three subscales of the SRS-2 were significantly correlated with overall adjustment to college as measured by the SACQ. Specifically, there was a significant negative correlation between the SRS-2 Communication scale and the SACQ (r=-.660, p=.038), the SRS-2 Social Motivation and the SACQ (r=-827, p=.003), and SRS-2 Restricted Interests and Repetitive Behaviors and the SACQ (r=-.689, p=.028). High levels of symptoms were associated with poorer adjustment to college. It should be noted that all but one student in the sample had self-reported adjustment scores in the average range. GPA at the end of the first academic year did not correlate with any subscales of the SRS-2. Six additional data points from the 4th cohort will be added prior to presentation of this study in May 2016.
Conclusions:
Students with an ASD face unique challenges related to their ASD symptoms which can affect adjustment to the college setting and possibly retention in college as studies suggest that adjustment to college is one predictor of retention in college (Gerdes, et al 1994). Future studies with a larger sample size will be needed to confirm these findings and to further examine more specific aspects of college adjustment (i.e., academic, social, emotional).

60 **163.060** The Relationship Between Habitual Emotion Regulation, Anxiety, and Depression in Adolescents and Young Adults on the Autism Spectrum

R. Y. Cai[1,2]*, M. Uljarevic*[1,3] *and A. L. Richdale*[1,2]*, (1)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (2)Olga Tennison Autism Research Centre, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia*

Background: Anxiety and depression are among the most common and disabling comorbid psychiatric conditions in individuals on the autism spectrum. However, factors that may account for high rates of anxiety and depression in autism are currently not well understood. Although some studies suggest that age, gender and severity of autism traits might influence the presence of these internalising problems, it has been argued that non-autism specific traits, which vary across individuals, might be more important; one such trait is emotion regulation. Emotion regulation strategies such as suppression have been found to be associated with poorer mental health in the general population. It has been proposed that emotion regulation impairments are a risk factor for anxiety in autism as individuals on the spectrum tend to use suppression strategies more than typically developing individuals. Thus, while it might be expected that greater use of suppression strategies is associated with anxiety and depression in individuals on the autism spectrum, relationships between emotion regulation strategies and anxiety and depression have not been formally tested.
Objectives: To investigate whether or not the use of habitual emotion regulation strategies, specifically reappraisal and suppression, are related to anxiety and depression symptoms in individuals on the spectrum over and above age, gender and autism traits.
Methods: This study forms part of the Australian Autism CRC longitudinal study of school leavers; recruitment is ongoing. Participants aged 15 to 25 years were recruited Australia-wide via various channels. As part of the longitudinal study, participants completed the Emotion Regulation Questionnaire (ERQ), the Adult Autism Spectrum Quotient (AQ), the DSM-5 Cross-cutting Dimensional Anxiety Scale (Cross-D), and the Patient Health Questionnaire-9 (PHQ-9), which measures depression. To date, 37 individuals on the spectrum (25 males and 12 females; M_{age}= 18.59 years, SD_{age}= 2.37) have completed the questionnaires. Preliminary data are presented here; for our presentation, data will be re-analysed with the inclusion of all new participants.
Results: Pearson's correlation analyses were conducted to assess the relationships between age, gender, AQ, Cross-D, and PHQ-9 total scores, and suppression and reappraisal scores from the ERQ. PHQ-9 and Cross-D scores were significantly correlated with both reappraisal and AQ scores, but not with age, gender, or suppression score. Partial correlation was then used to explore the relationship between reappraisal, and anxiety and depression scores, while controlling for scores on AQ. There were significant moderate, negative correlations between reappraisal and anxiety, r = -.42, p = .02, and between reappraisal and depression, r = -.45, p = .01.

Conclusions: This is the first study to assess the relationships between emotion regulation strategies and anxiety and depression in individuals on the spectrum. Although it has been shown that individuals on the autism spectrum use suppression more frequently, the findings suggest reduced use of cognitive reappraisal is associated with increased levels of anxiety and depression symptoms over and above the influence of age, gender and autism traits. These findings have potential clinical implications and future work should replicate these results with a larger sample.

61 **163.061** The Transition to the Adult Health Care System Among Adolescents with Autism Spectrum Disorder

R. A. Nathenson[1] *and B. Zablotsky*[2]*, (1)University of Pennslyvania, Philadelphia, PA, (2)National Center for Health Statistics, Hyattsville, MD*

Background: The transition from the pediatric to the adult healthcare system is a noted challenge for all individuals, but particularly for those adolescents with special health needs (Stewart, 2009). A population of adolescents who may experience additional difficulties are those with autism spectrum disorders (ASD) because they are commonly diagnosed with co-occurring developmental, psychiatric, neurological, and other medical conditions (Levy et al., 2010) that may persist into adulthood and require frequent and intensive service and treatments (Liptak, Stuart, & Auinger, 2006).
These difficulties may be further compounded by the fact that many adolescents with ASD receive everyday services in the school setting (Kang-Yi et al., 2015) and may find themselves exiting both the educational system and the pediatric healthcare system simultaneously. The current study examines the use of medical services in a national population of privately insured adolescents/young adults (aged 16-22) diagnosed with ASD.
Objectives: 1) Calculate the percentage of adolescents/young adults with ASD receiving home, office/outpatient hospital, inpatient hospital and emergency department services annually by age; 2) Calculate the annual average number of services received at each place of service.
Methods: Data come from the Optum database, a clinically rich database that includes the health care claims of all individuals insured by Optum's parent company from May 2000 to June 2013. The sample includes individuals diagnosed with ASD (n=16,029).
Estimates were calculated using Stata 13.0 SE. Cross-sectional multivariate linear regressions were used to determine if an association exists between age and service usage after controlling for child characteristics, household characteristics, and insurance plan structure.
Results: Fewer individuals with ASD received services in an office/outpatient hospital department ($p<.01$) or inpatient hospital department ($p<.01$) as they aged, which was accompanied by a reduction in the annual number of visits each year. There was not a reduction seen in the percentage of individuals with ASD receiving services in either the home or emergency department as they aged.
Females with ASD were more likely to use services in all locations than males, with two-and-a-half visits more per year than males in the outpatient/office setting and two more visits a year in the home. Black children were less likely to use inpatient, emergency room, and office/outpatient services than white children with two fewer visits per year on average in the office/outpatient setting and one fewer visit to the emergency department. Children living in households with lower net worth had fewer annual office/outpatient setting visits than children living in households with higher net worth.
Conclusions: As adolescents with ASD age out of the pediatric health care system, there is a notable decline in both the percentage of adolescents that receive services and the number of annual services received across multiple settings. This decline, which potentially co-occurs with a "service cliff" upon graduating from high school (Roux et al., 2015), could lead to unmet service needs.

62 **163.062** Underlying Mechanisms of Deficient Social Problem-Solving Abilities in Adults with High-Functioning Autism: Exploring the Roles of Alexithymia, Emotion Dysregulation, and Executive Dysfunction

S. L. Jackson[1]*, B. Dritschel*[2] *and F. R. Volkmar*[3]*, (1)School of Psychology & Neuroscience, University of St Andrews, St. Andrews, United Kingdom, (2)School of Psychology & Neuroscience, University of St Andrews, St Andrews, United Kingdom, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background:
Adults with HFASD are reported to be a particularly susceptible population to episodes of depression. A recent study found deficits in social problem-solving (SPS) to account for a significant proportion of the association between ASD-related social impairments and depressive symptomology. This finding would suggest that psychosocial interventions designed to develop SPS skills may prove a valuable resource for treatment of depressed mood in adults with HFASD. A number of areas of impairment associated with ASD may play important underlying roles in the SPS deficits found in this population. Knowledge of these roles could provide instrumental insight for interventions designed to develop this area of social functioning.
Objectives:
The current study aims to better understand the underlying mechanisms resulting in SPS deficits for adults with HFASD by exploring the specific impacts of alexithymia, emotion dysregulation, and executive dysfunction on the different components of the SPS process.
Methods:
The study sample consists of 54 HFASD adults (39 female, 15 male) with an age range of 19-65 (M=32.61, SD=10.50). Participants were assessed on SPS ability (SPSI-R), alexithymia (TAS-20), emotion dysregulation (DERS), and executive dysfunction (BRIEF). Age, gender, educational attainment, ASD-related social deficits (SRS-2), and depressive/anxious symptomology (DASS) were assessed as potential confounds.
Results:
Both SRS-2 and the DASS-Depression scale were found to be potential confounds, and were thus controlled for in all analyses. Hierarchical regression analyses were performed with the SPS process components as the DV, DASS-Dep. and SRS-2 scores entered as IVs during the first step (enter-method), and TAS-20, DERS, and BRIEF entered as IVs during the second step of the analyses (stepwise-method). Results suggest difficulties with emotion dysregulation to be a significant predictor of increased utilizations of a Negative Problem Orientation ($\beta=0.34$); increases in alexithymic traits to be a significant predictor of increased use of Avoidance ($\beta=0.38$) and Impulsive/Careless ($\beta=0.48$) SPS styles, decreased use of a Ration Problem-Solving process in general ($\beta=-0.46$), and greater difficulties with the Generation of Alternative Solutions ($\beta=-0.38$) and Decision Making ($\beta=-0.34$) aspects of that process; and greater levels of executive dysfunction to be a significant predictor of increased use of an Impulsive/Careless Style ($\beta=0.33$), and greater difficulties with the Problem Development and Formulation ($\beta=-0.47$), Decision Making ($\beta=-0.35$), and Solution Implementation and Verification ($\beta=-0.37$) aspects of a rational problem-solving process. The inclusion of these variables to the models resulted in significant improvements in the predictive strength of all models ($\Delta R^2=0.07-0.36$, $p<0.05$).
Conclusions:
This study provides insight into the underlying mechanisms resulting in difficulties with different aspects of the SPS process for adults with HFASD. Problem-Solving Therapy (PST) has a history of proven utility in the treatment of depression for other populations, and a recent pilot study showed that PST can be effectively used with adults with HFASD. The current study can help improve the efficacy of future attempts to use PST for this population as it provides a more detailed understanding of why difficulties in certain aspects of SPS may be present, and thus, more insight into how to better design the intervention to work on these areas of need.

63 **163.063** Untended Wounds: The Unexplored Problem of Non-Suicidal Self-Injury in Adults with ASD

B. B. Maddox[1]*, A. Trubanova*[2] *and S. W. White*[2]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Non-suicidal self-injury (NSSI) involves deliberate injury to body tissue that is inflicted without suicidal intent and for purposes that are not socially sanctioned. Recent studies have examined the characteristics and predictors of NSSI in community and clinical samples, but there is no published research on NSSI in individuals with autism spectrum disorder (ASD). This is somewhat surprising given that many of the most salient predictors of NSSI, including depression and emotion dysregulation, have been widely reported among people with ASD. Given the focus on self-injury as a form of restricted, repetitive behavior in individuals with ASD, NSSI in the context of ASD may be overlooked by both researchers and clinicians.
Objectives: The purpose of this study was to examine NSSI methods, frequency, severity, functions, and initial motivations in adults with ASD. Our secondary aim was to compare NSSI characteristics across adults with ASD and history of NSSI and adults without ASD but with history of NSSI. In addition, we explored the degree to which depression symptoms and emotion regulation difficulties are associated with NSSI in adults with ASD.
Methods: This study involved a two-group, cross-sectional survey, with one survey for adults in the community with ASD ($n = 42$) and one survey for university students without ASD ($n = 1252$). The anonymous online survey included the Non-Suicidal Self-Injury Assessment Tool (NSSI-AT), the Severity Measure for Depression-Adult, and the Difficulties in Emotion Regulation Scale (DERS).
Results: In the ASD sample, 21 participants (50%) reported engaging in NSSI behavior. A gender-matched subsample of participants who endorsed NSSI was drawn from our university-based survey ($n = 21$) in order to compare individuals with and without ASD on NSSI characteristics. Of the 18 women with ASD, 13 (72.2%) reported NSSI, compared to only 8 of the 24 men with ASD (33.3%), $\chi^2(1) = 6.22$, $p = .013$. There were no statistically significant differences between the ASD and non-ASD groups on any of the NSSI-AT items. Within the ASD group, point-biserial correlations revealed that a history of NSSI was not significantly related to current depression ($r = -.013$, $p = .936$) or emotion dysregulation ($r = .054$, $p = .734$). Within the subset of individuals with ASD who endorsed a history of NSSI, more difficulty with emotion regulation was significantly related to Sensation Seeking functions of NSSI ($r = .512$, $p = .018$).
Conclusions: This descriptive study is one of the first investigations of NSSI in adults with ASD. Our preliminary findings suggest that NSSI is (1) phenomenologically distinct from core ASD symptoms and similar to NSSI as it is conceptualized in the non-ASD literature, (2) a common problem among adults with ASD, and (3) overlooked in the extant research, and likely overshadowed or misconstrued (e.g., as SIB, or core ASD symptoms) in clinical practice.

64 **163.064** Well-Being on the Autism Spectrum: Relationships Between Identity, Stigma, Self-Esteem, and Quality of Life

***T. A. M. McDonald**, University of Wisconsin- Madison, Atlanta, GA*

Background: Adults on the autism spectrum experience stigma, and stereotype threat research on other populations suggests stigma exerts direct and indirect detrimental impacts on wellbeing. Since there are multiple studies reporting undesirable objective and subjective quality of life (QoL) outcomes for adults on the autism spectrum, such as higher unemployment and poorer psychological health, possibly, experiences of stigma have a detrimental impact on wellbeing for adults on the autism spectrum. Moreover, this impact may be mediated by other factors, such as variation in identification with the autism spectrum and stereotype threat intersectionality.
Objectives: This study examined how perceptions of stigma, self-esteem, and QoL, both subjective and objective, interrelate and, also, relate to postsecondary outcomes for adults on the autism spectrum. This study, also, examined whether, and how, variation in identity, as measured by the Autism Spectrum Identity Scale (ASIS), gender, and identification with different diagnostic categories, relates to factors of subjective wellbeing.
Methods: Over 1000 adults who had a diagnosis of, or identified with, an autism spectrum disorder participated in a national online survey containing the Autism Spectrum Identity Scale (ASIS; McDonald, 2015a) along with other measures of well-being such as stigma, self-esteem, and objective and subjective QoL. The survey also gathered demographic data, including gender, diagnoses, diagnoses identification preference, age, and postsecondary student and employment statuses.
Results: Greater stigma consistently related to poorer outcomes and higher self-esteem related to better outcomes in well-being and postsecondary outcomes of education and employment. Without exception, higher scores in Changeability related to better outcomes across all of the other factors. The Positive Difference factor demonstrated a similar pattern; it related to all of the other measures except self-care. Both women and those who identified with autism reported higher stigma and poorer QoL, but no differences in self-esteem, than men or those who identified with Asperger's Syndrome, respectively.
Conclusions: These relationships may indicate stereotype threat acts as a mechanism to reduce performance and well-being for adults on the autism spectrum. Although, the DSM-5 has recently collapsed these two diagnoses into a single category, many adults in this study were diagnosed within the DSM – IV criteria. One rationale for the DSM-5 change was the inability to reliably distinguish differences between these two groups (Hazen, McDougle, & Volkmar, 2013). Based on that decision, it is surprising to find the consistent differences between these two groups in attitudes of autism identity, stigma, and subjective and objective QoL in this study. Since adults on the autism spectrum have lower rates of employment and education attainment than the mainstream population, the intersection of being a woman on the autism spectrum is particularly concerning. On a more optimistic note, higher self-concepts of Positive Difference and Changeability may represent important identity strategies to cope with stigma and preserve self-esteem. Possibly, attitudes which characterize the autism spectrum as a Positive Difference and as Changeable provides some resilience against experiences of frustrations, failures, and discrimination. Future research should examine causal relationships between these factors.

164 - Communication and Language
5:30 PM - 7:00 PM - Hall A

65 **164.065** Acoustic Predictors of Trained and Naive Rater Impressions of Speech Qualities in ASD

***I. M. Eigsti**, J. Mayo and E. Schoen Simmons, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Clinicians and teachers frequently report an intuition that they are able to diagnose autism spectrum disorder (ASD), after hearing a brief speech sample from an affected individual. Such differences in speech qualities have the potential to significantly disrupt social and work success. Few studies have been able to detect what specific qualities in speech differ in ASD; likely this reflects the broader challenge of speech invariance – that a single acoustic cue segment carries information about multiple phonemic segments (Liberman et al 1967).
Objectives: Our aim was to combine human perception with acoustic analyses of a single set of speech productions, to reveal which acoustic cues seem to guide listener perceptions of atypicality.
Methods: Participants included 15 adolescents with high-functioning ASD and 15 with typical development (TD). Groups did not differ in age, full-scale IQ (scores>80), or gender, *p*'s>.50; standardized language (CELF) scores were all in the typical range, but with a trend for higher scores in the TD group. We elicited a set of eight spoken sentences, all with similar sentence structures and vocabulary items, by giving participants a card with the printed sentence, asking them to learn it by heart, and then to speak it aloud using their normal voice. Stimuli were recorded for subsequent analyses using Praat. Acoustic analyses to date included measures of minimum, maximum, and median pitch; pitch range, excusion, and standard deviation (SD); and mean pitch divided by SD.
In addition, the speech samples were presented to 15 undergraduates and 10 clinicians with ASD expertise, all of whom were naïve to study hypotheses. Raters were asked to determine whether a given sample sounded "atypical or unusual" (in the undergraduate group) or "ASD-like" (in the clinician group), versus "typical," on a 1-3 scale (with "2" anchored as "somewhat unusual").
Results: Both groups of raters gave significantly higher "atypicality" scores to the ASD group (p's<.01, with CELF score as a covariate). Grouping the slightly (2) or very (3) atypical ratings into a single category, sensitivity for naïve raters was .80, specificity of .73; for expert clinicians, sensitivity was .86, specificity of .86. Interestingly, again holding CELF scores constant, there were *no* mean group differences in acoustic variables. Thus, both naïve and expert raters were highly accurate in sorting the groups on the basis of speech samples, although acoustic analyses failed to distinguish between groups. In a regression analysis of the acoustic variables that predicted atypicality ratings, the best predictors were not IQ, age, nor symptom severity, but rather, slow speech rate and high median pitch.
Conclusions: Both trained and naive listeners appear to be able to detect ASD based only on speech. The trained clinicians showed significant sensitivity and specificity, misclassifying 4/30 participants (2 per group). Naïve undergraduates were slightly less accurate, misclassifying 7/30. Speech rate and median pitch appeared to drive these perceptions. Future work should compare findings from children with other speech and language delays or developmental concerns. These findings suggest that speech rate and fundamental frequency may provide useful targets for acoustic analysis and for intervention.

66 **164.066** Analyzing Discourse Patterns of Young Adults with ASD

*C. O. Alm[1], E. T. Prud'hommeaux[2] and **B. Meyers**[1], (1)Rochester Institute of Technology, Rochester, NY, (2)OHSU, Beaverton, OR*

Background: Most previous work in analyzing speech transcripts from individuals with Autism Spectrum Disorder (ASD) has focused primarily on quantitative syntactic and lexical metrics and qualitative measures of pragmatics, which are usually applied in the restricted context of a narrative retelling or picture description task. Less research has been devoted to systematically examining higher-level discourse structures in less constrained conversational interactions, particularly among young adults on the spectrum.
Objectives: The objectives of this research are: (1) to confirm previous findings about low-level lexical and syntactic characteristics of language in high-functioning young adults with ASD; and (2) to detect differences in the high-level discourse patterns of college-aged males with and without ASD.
Methods: All participants in the study were male university students. Typically-developing (TD) participants were recruited to match the ASD participants according to age, college major, and GPA. Transcripts were produced for 6 male subjects (ASD n=3, TD n=3) from recordings of three tasks designed to elicit conversation with a TD confederate in (1) a usability task for a web application, (2) a collaborative game, and (3) an interactive math and computing tutoring task. Standard measures of syntactic complexity, vocabulary diversity, and disfluency frequency were automatically extracted from the transcripts. In addition, an existing discourse-based annotation scheme was used to manually code the discourse units ("dialog acts") in the transcripts in order to characterize the way that individuals with ASD acknowledge their interlocutors, seek actions, and ask for information.
Results: As previously reported in the literature, few between-group differences were found in the lower-level syntactic, pragmatic, and lexical features. Several differences in discourse features, however, were observed. In the cooperative game task, individuals with ASD were less likely to acknowledge (oh alright) their interlocutor's comments and were far more likely to suggest (I'd say start out by moving past and jumping over...) -- and considerably less likely to request (ok push the block on to the ramp) -- that their interlocutors perform an action than their TD counterparts. When compared to their TD counterparts across all tasks, individuals with ASD were considerably more likely to (1) answer questions with "no", (2) apologize for something they had said or done, (3) request clarification, and (4) thank their interlocutor.
Conclusions: Many of the lower-level features typically used to characterize language in children with ASD seem to lose their discriminative power when applied to young adults, underscoring the need for the development of more complex and nuanced methods of language analysis. The study suggests that discourse analysis, particularly when applied to conversations produced in a collaborative and relatively unconstrained context, can provided insight into the linguistic differences that persist into adulthood. As results for lower-level features align with previous literature, future work will focus primarily on discourse-based comparisons between groups.

67 **164.067** Are There Phonological Consequences of Auditory Processing Differences in Autism Spectrum Disorder? Evidence from Phonological Categorization Tasks

***B. Castelluccio**[1], A. Canfield[2], J. Green[2], A. Hogstrom[2], E. Kapnoula[3], B. McMurray[4], J. Edwards[5] and I. M. Eigsti[1], (1)Psychology, University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Psychological and Brain Sciences, University of Iowa, Iowa City, IA, (4)Psychology, University of Iowa, Iowa City, IA, (5)Communication Sciences and Disorders, University of Wisconsin, Madison, WI*

Background: Speech comprehension requires rapid and accurate phonological categorization of temporal and spectral features of the acoustic signal. One well-studied example of phonological categorization is the contrast between voiced and voiceless stop consonants (e.g. /b/ vs. /p/) using *voice onset time* (VOT), the length of time

between stop release and onset of vocal fold vibration. While VOT is continuous, perception of these consonants seems to be categorical. Stop consonants produced along a range of VOTs are perceived as /b/, but with a VOT increase of just a few milliseconds, listeners perceive that sound as /p/. However, underneath this seemingly discrete behavior, the underlying cognitive representations for most listeners are highly gradient and continuous, which can be measured in tasks that accommodate a gradient response format. There appear to be reliable individual differences in the degree of gradiency or categoricalness; one study showed individual differences relate to the degree to which typically developing (TD) listeners integrate multiple cues, such as the primary temporal cue (VOT) and a secondary spectral cue (fundamental frequency [f0]). Although individuals with autism spectrum disorder (ASD) have largely been thought to possess intact phonological abilities, phonological impairments have been reported. Studies of low-level auditory processing, likely relevant for phonological development, have reported *impaired* temporal processing in ASD and *heightened* spectral processing. Additionally, individuals with ASD show more veridical perception, with less influence of top-down information, across perceptual domains.
Objectives: The current study examines whether auditory processing differences in ASD result in differences in phonological categorization or in cue weighting of temporal and spectral cues to the voicing contrast. We hypothesized that heightened spectral processing might be associated with greater use of f0.
Methods: Participants with and without ASD completed a classic two-alternative forced choice (2AFC) task and a visual analog scale (VAS) task. Adolescents with ASD (*n*=12) and TD (*n*=12) categorized bilabial (/b/, /p/) and alveolar (/d/, /t/) stop consonants with VOTs of 1- 45 ms and f0 of 90 or 125 Hz as either bull/pull or den/ten.
Results: Analyses indicated no group differences in boundary placement or categorization, and no group differences in use of f0 as a cue on the 2AFC task (Figure 1a). Additionally, there were no group differences in how continuously the voicing contrast was perceived using a VAS task (Figures 1b-d). Both groups showed high fidelity to VOT in the VAS task.
Conclusions: These data suggest that, in the absence of informative top-down lexical information, individuals with ASD surprisingly show no disadvantage in perceiving temporal information relevant for phonological categorization. Also surprising is the lack of difference in use of a spectral cue (f0) in individuals with ASD. While previous research has found that individuals with ASD show poor auditory discrimination of temporal differences and heightened spectral processing, these auditory processing differences appear not to affect phonological processing, at least in adolescence.

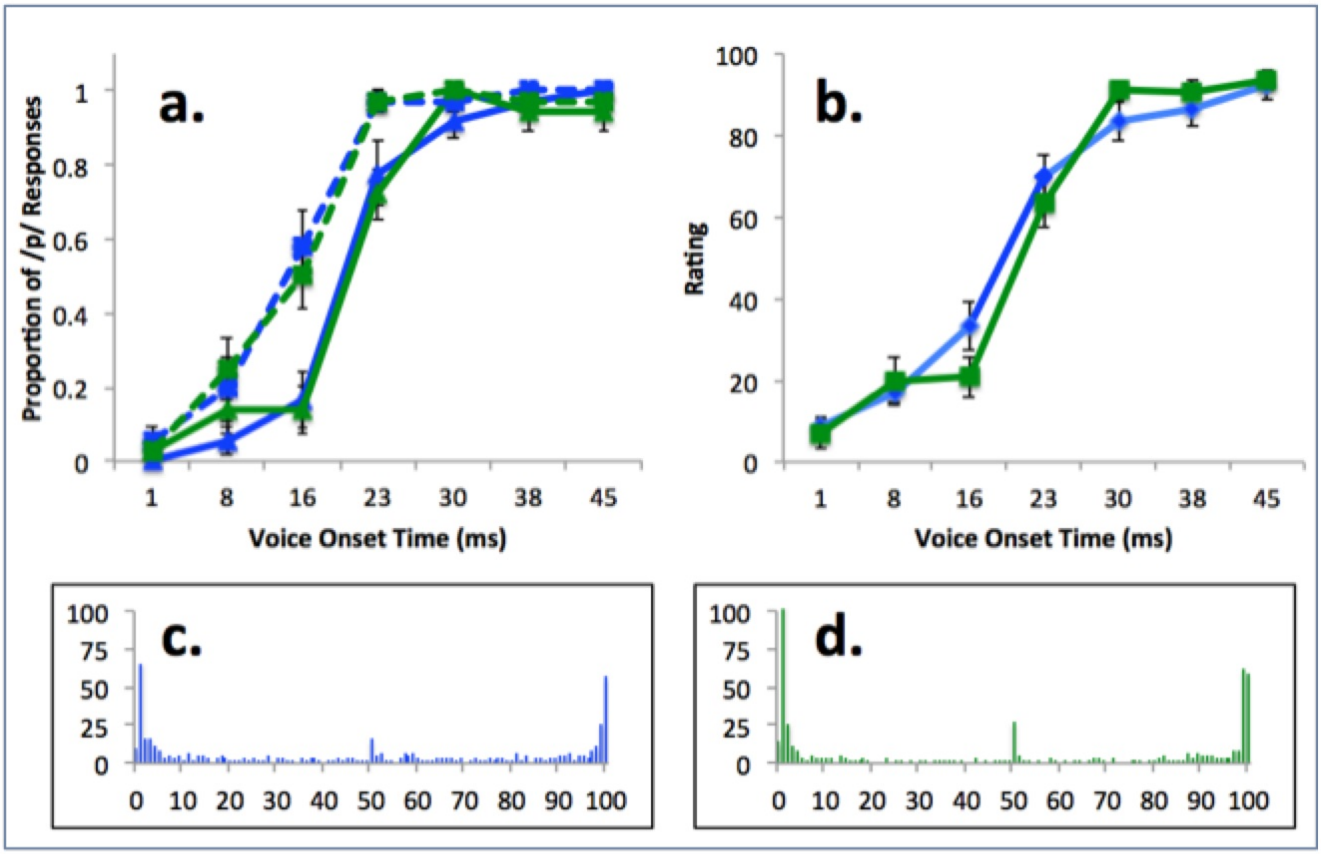

Figure 1. (a) Proportion of /p/ responses in the 2AFC task; blue = TD, green = ASD. Solid lines indicate a fundamental frequency of 90 Hz, and dashed lines indicate a fundamental frequency of 125 Hz. (b) Ratings on the VAS task, with more /p/-like judgments toward 100. Histograms of VAS ratings for the TD (c) and ASD (d) groups, showing the similar distributions of judgments.

68 **164.068** Assessing the Relationship Between Verbal Ability and Problem Behavior Among Children with Autism Spectrum Disorder

K. A. Smith[1,2], *A. Stedman*[1] *and M. Siegel*[3], *(1)Maine Medical Center Research Institute, Portland, ME, (2)Tufts University School of Medicine, Boston, MA, (3)Maine Medical Center Research Institute - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME*

Background:
The verbal ability of children with Autism Spectrum Disorder (ASD) is an important criterion for clinicians in selecting treatment strategies for problem behaviors. Available research literature has, to date, offered conflicting evidence on the relationship of verbal ability and problem behaviors in children with ASD, with varying results by age and ASD severity. There is also preliminary evidence that self-injury and aggression/tantrums, which are typically lumped together in treatment trial measurement, may have differential responses.
Objectives:
To analyze the relationship between verbal ability and the type, severity and frequency of problem behaviors, and to explore for potential variation of this relationship within models using the Aberrant Behavior Checklist – Irritability subscale (ABC-I) Self-Injurious Behavior (SIB) and Tantrum Behavior (TB) subdomains.
Methods:
Seventy-eight children and adolescents with ASD admitted to a specialized inpatient psychiatry unit were prospectively enrolled and a consistent parent was administered the ABC-I at admission, discharge, and 2-month follow-up. The subject's verbal ability was coded as non-verbal, limited verbal, or fluent verbal by a speech-language pathologist based upon caregiver information and extensive direct observation. Type and frequency of problem behaviors (i.e., aggression, self-injury, and tantrums) were recorded every 15 minutes by direct care staff. Model testing was conducted using multi-level models repeated measure analyses to examine differences in problem behaviors by verbal ability groups. Covariates included in the model were age, sex, intellectual disability, length of stay, number of behaviors of clinical concern, and number of medications.
Results:
A majority of the subjects were Caucasian (91%) males (81%) averaging 12.4 years old (*SD*=3.42, range=6-20) with fluent verbal ability (55.1%), limited verbal ability (26.9%) or non-verbal (17.9%) status. Forty-five percent of subjects had Intellectual Disability (ID) and the average length of inpatient stay was 52.27 days (*SD*=29.41, range=8-174). A significantly lower proportion of subjects with fluent verbal ability had intellectual disability (p=0.049), had a shorter length of stay (p=0.002), presented with fewer behavioral problems (p=0.027) and engaged in fewer self-injurious behaviors (SIB) (p=0.001) and pica (ingesting non-food objects) (p=0.001) than non-verbal and

limited verbal groups. Parents reported a significant decrease in their child's overall problem behavior between admission, discharge and 2-month follow-up, (see Table 1 for complete model results), though this difference did not significantly vary between verbal ability groups, (see Figure 1). Examination of the ABC-I SIB subdomain indicated a significant effect for both time (admission and discharge only) and by verbal ability group with fluent verbal patients having significantly less SIB compared to non-verbal patients (p<0.001). The ABC-I TB subdomain indicated a significant effect for time only (all three time points), p<0.001.
Conclusions:
Findings suggest that children in a specialized inpatient psychiatry unit reported a significant reduction in their child's overall problem behavior on the ABC-I from admission to 2-months post-discharge, regardless of the child's verbal ability. There appears to be important differences, however, in the response of self-injurious behavior based on verbal ability, which are not seen in the aggression/tantrum behaviors. Change in the SIB subdomain of the ABC-I is significantly affected by verbal ability.

69 **164.069** Association of Atypical Communication Characteristics with Psychiatric, Social, and Academic Functioning in Clinic-Referred Children with and without Autism Spectrum Disorder

***E. Kang**, M. D. Lerner and K. D. Gadow, Stony Brook University, Stony Brook, NY*

Background:
Children with autism spectrum disorder (ASD) experience a variety of atypical communication characteristics (ACC), such as echolalia, odd pitch, and pragmatic difficulties, which play a significant role in life adjustment. Although it is well established that ACC are associated with emotional and behavioral problems in non-ASD clinic-referred youth (Baker & Cantwell, 1987), little is known about their relation in children with ASD, despite common psychiatric comorbidities in children with ASD (Gadow et al., 2005). Of equal or greater interest is the relation between ACC and psychiatric symptoms across ASD and non-ASD populations, and how most common ACC in ASD influence functional outcomes.
Objectives:
This study explored the association of ACC with psychiatric symptoms in clinic-referred children with and without ASD, and of specific ACC with social and academic functioning in those with ASD.
Methods:
Clinic-referred children (6-18 years) with (N=283) and without (N=724) ASD were assessed with a well-validated parent-report questionnaire of psychiatric symptoms, ACC, and social (peer relations) and school functioning (i.e., special education, inclusion classroom).
Results:
Rates of ACC are summarized in Table 1. Bonferroni-corrected chi-square tests revealed higher rates of specific types of ACC in ASD versus non-ASD groups (p<.001). When analyses were confined to the youth with ACC, those with ASD evidenced higher rates of nonverbal behavior, speech delay, repeating words, echolalia, odd tone of voice, and pragmatic difficulties (p ≤.005). ROC results revealed an AUC=0.69 (p<.001) for pragmatic difficulties, followed by speech delay, repeating words, echolalia, perseveration, and odd voice (all AUC≥.559, p≤.026).
Two-way ANOVAs revealed interactions between group (ASD, non-ASD) and global ACC (present, not present) in predicting ADHD (p≤.007) and ASD (p≤.019) symptoms, with increasing severity with higher ACC in the ASD group. Controlling for age, gender, and IQ yielded same pattern of results.
We conducted moderation analyses of specific ACC shown in our ROC analyses to distinguish ASD from non-ASD groups in predicting ADHD and ASD symptoms. There were significant (all p<.05) interactions between ASD status and repeating words in predicting ADHD inattention and all ASD symptom domains; perseverative speech in predicting ADHD hyperactive-impulsive and ASD repetitive symptoms; speech delay in predicting ASD communication; echolalia in predicting all ASD domains; and odd voice predicting ASD communication and repetitive behavior. Post-hoc analyses revealed such associations *only* in the ASD sample (all B≥1.21, p≤.03 vs. all p>.07 in non-ASD).
In the ASD sample, we examined associations of specific ACC with functional outcomes: speech delay with intellectual disability (r=.22, p=.001), being in inclusion classroom (r=.31, p<.001), dominating play (r=.28, p<.001), having a best friend (r=-.15, p=.019) and wanting friend (r=-14, p=.039). Repeating words was associated with inclusion classroom (r=.18, p=.006). Echolalia was associated with intellectual disability (r=.24, p<.001), being in inclusion classroom (r=.22, p=.001), having any friend (r=-.18, p=.009) and wanting friend (r=-14, p=.044). Odd voice was associated with difficulty relating to peers (r=.16, p=.02).
Conclusions:
ACC are associated with more severe psychiatric symptoms and social and academic difficulties, and relations differ from non-ASD referrals. Results have implications for both clinical management and nosology.

70 **164.070** Attempt of Training Basic-Set of Communication with Small Humanoid Robot for Autism Spectrum Disorder

T. Onishi[1], *Y. Yoshikawa*[2], *H. Kumazaki*[3], *Y. Matsumoto*[4] *and H. Ishiguro*[2], *(1)Center for Special Needs Education, Nara University of Teacher Education, Nara, Japan, (2)Osaka University / JST ERATO, Osaka, Japan, (3)University of Fukui Research Center for Child Development, Yoshida-gun, Japan, (4)National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan*

Background:

One of the most important distinction on children with Autism Spectrum Disorder(ASD) is communication disability. Many of them lack eye-contact and joint attention, besides they don't pay attention and don't show interest to conversation partners. Their difficulty is responsible for a surfeit of information. They don't know where and what to watch during conversation.

A small humanoid robot, CommU, is expected to be recognized as a friendly and less-obtrusive interlocutor of the subjects due to its cute and moderately humanlike embodiment. It can produce verbal and nonverbal signals to engage in conversation with subjects by the tele-operation method based on the predefined scripts. CommU has a possibility of resolving this problem; it has a very simple appearance, shows less emotion, deals with others always in same way, and it has an obvious novelty.

We hypothesized that after practice of conversation with robot children's basic attitude toward person would be improved.

Objectives:

The objective is to ascertain the prediction that having interaction with a small humanoid robot would improve their basic-set of communication.
Methods:
10 boys with high functioning ASD, aged between 4 and 10 (mean age=6.13, IQ≧70) were randomly assigned to two groups. Three conditions were set; Room A=Human A, Room B=Human B, and Room C= Robot(CommU). Group 1 visited three rooms in order of 'HumanA - Robot - HumanA', and the order of Group 2 was 'HumanA - HumanB - HumanA'. In each room children had to talk with human or robot according to programed scenarios including communication tasks. All sessions were recorded by 3 videos which were located in different corner of the room.
Results:
First, four target behaviors were evaluated; Smile, Nodding/ Showing interest, Eye-contact, and Synchronizing with partner by listening music. Second, records of gaze following task were analyzed. About these results, Group 1 and Group 2 were compared for the purpose of excluding an effect of habituation.
There was no change in Group 2(HumanA - HumanB - HumanA) , on the other hand, in Group 1 'Nodding' and 'Synchronizing' increased at the third session [Nodding: $T(10)=-2.27$, $p<.05$; Synchronizing: $T(10)=-2.23$, $p<.05$)]. Gaze following was increased at the second session of Group 1 [$T(10)=3.07$, $p<.05$] though Group 2 didn't show any change.
Conclusions:
This study shows that conversation practice with robot has potential to improve the basic-set of communication of ASD. There are some factors listed; first, the novelty of robot raised their arousal level. Second, some listening skills formed because children had to adjust themselves to robot. Moreover, 70% of subjects responded that the conversation with robot was more fun and more strained. From these results, it is expected that they can face on the training with apposite feeling and arousal level.

71 **164.071** Auditory Responding to Joint Attention Skills and Language in Toddlers with Autism, Other Developmental Difficulties, and Typical Development

S. E. Vogt, *R. Bakeman, K. Suma and L. B. Adamson, Psychology, Georgia State University, Atlanta, GA*

Background: Joint attention skills, especially responding to bids for joint attention (RJA), are pivotal to language development. RJA skills are often compromised by autism spectrum disorder (ASD) even if a child with ASD begins to acquire language. RJA is usually assessed using multimodal bids for joint attention (RJA-M). Here we also assess responses to *auditory* bids for joint attention (RJA-A)—bids that rely solely on saying the child's name and labeling the target. Contrasting responses to multimodal and auditory bids can help clarify further the early relationship between joint attention skills and language.
Objectives: Our aim is to document how toddlers with ASD, other developmental difficulties (DD), and typical development (TD) respond to auditory and multimodal joint attention bids and to determine if preverbal children can respond to these bids.
Methods: 53 toddlers (mean age=22.5 months) participated: 18 with ASD, 24 with DD, and 11 TD. Joint attention skills were assessed using the Joint Attention Scales-Auditory (JAS-A) that includes 3 RJA-M trials adapted from the Early Social Communication Scales (Mundy et al., 2003) and 3 new RJA-A trials. In each trial, the examiner bids for joint attention twice to one of 6 target (pictures or toys with names that most 12-month olds understand according to the MacArthur Communication Development Inventory [MCDI; Fenson et al., 1993] norms). In RJA-M trials, the examiner says the child's name and then shifts gaze and points at the target; In RJA-A trials, she says his name and labels the target (e.g., "There's a ball!"). A pass indicated that the child responded by seeking the target. Children were categorized as preverbal if their parent reported 10 or fewer words on the MCDI.
Results: The percentage of children passing at least 2 of the 3 trials for RJA-M was 100%, 75%, and 22% and for RJA-A trials was 45%, 21%, and 17% in the TD, DD, and ASD groups, respectively (see Figures). Thus children in the TD and DD groups did significantly better on multimodal than auditory trials, with little difference for children with ASD. No TD children were preverbal. For children with DD, the odds of failing all multimodal trials was 8.50 times greater when children were preverbal and 12.0 times greater for auditory trials. For children with ASD, there was essentially no effect; corresponding odds ratios were 1.11 and 0.60, respectively.
Conclusions: Our results replicate previous studies that document an RJA deficit to multimodal bids in ASD. They also demonstrate that paring down bids so that they are solely auditory heightens their difficulty, even for TD two-year-olds who readily follow multimodal bids. Children with DD who are preverbal were less likely to follow multimodal and, even more so, auditory bids, suggesting that language delays may be affecting RJA. But the link between RJA and emerging language was less clear in ASD: regardless of language status, toddlers in the ASD group performed relatively poorly, suggesting that a core JA difficulty, not a language difficulty, might be paramount. Implications for intervention are discussed.

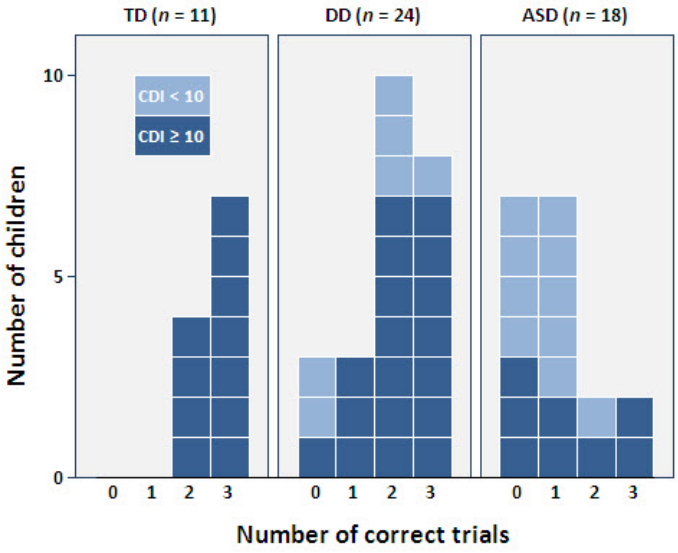

Figure 1. Number of children responding to 0, 1, 2, and 3 multimodal RJA trials for each diagnostic group.

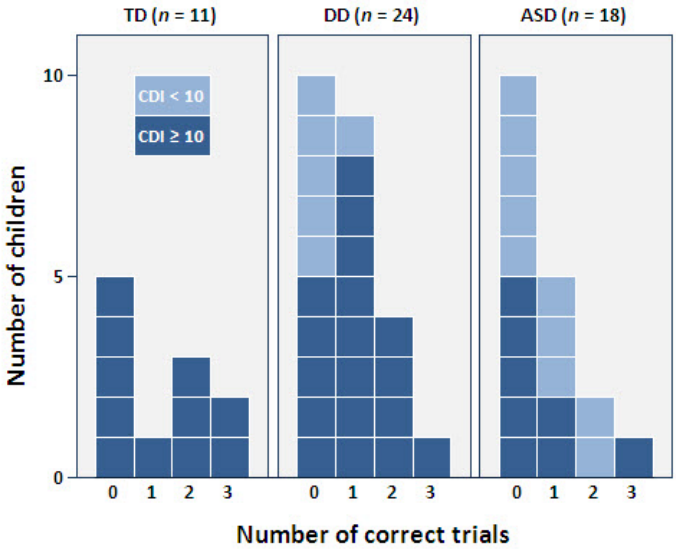

Figure 2. Number of children responding to 0, 1, 2, and 3 auditory RJA trials for each diagnostic group.

72 **164.072** Autism Severity and Language Improvements Using a Social Engagement Intervention for Toddlers with ASD

A. Barrett[1], *T. Vernon*[1], *A. Navab*[2], *J. Ko*[3], *J. Bradshaw*[4], *E. J. Horowitz*[1], *T. German*[1] *and R. L. Koegel*[1], *(1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Los Angeles, CA, (3)Koegel Autism Center, University of California Santa Barbara, Santa Barbara, CA, (4)Marcus Autism Center, Emory University, Atlanta, GA*

Background: Early language learning is strongly dependent upon the frequency and consistency of social interaction and engagement (Kuhl, 2015). Young children with autism demonstrate significant vulnerabilities in early engagement skills, such as social orienting and joint attention behaviors, which are found to be significant predictors of later language ability (Dawson et al., 2004). It is logical that early autism interventions that prioritize social interaction and engagement over the use of repetitive learning paradigms will result in superior improvements in core areas of development, including language acquisition. Research suggests that early interventions that integrate social elements into reinforcement paradigms can dramatically improve collateral levels of interpersonal engagement (Vernon, 2014; Vernon et al., 2012; Koegel et al, 2009). This study will report on the status of ongoing research efforts to optimize social engagement between adult and child as a means to bolster receptive and expressive language communication skills in children with autism.
Objectives: The study's objective was to evaluate the effectiveness of this 6-month social engagement intervention as an effective means for targeting social engagement and language skills.
Methods: Participants were 10 toddlers (ages 18-48 months) with ASD who had completed an ongoing randomized controlled trial. Participants were age-matched and randomly assigned to treatment or waitlist conditions. The active treatment group received early intervention using a modified Pivotal Response Treatment paradigm in which language efforts were reinforced using engaging social activities derived from each child's pre-existing (but non-social) interests. Comprehensive developmental assessment batteries were completed to thoroughly characterize participants and assess treatment effects. The measures of interest used for this preliminary investigation included the Autism Diagnostic Observation Schedule-2 and Mullen Scales of Early Learning. A multivariate analysis of variance test was conducted to assess for differences in autism symptom severity and language abilities between groups at post time-points.
Results: The treatment group demonstrated significant decrease in autism symptom severity (ADOS Social Affect and Restricted Repetitive Behaviors Score: pre = 16.2, post= 10.6) compared to the waitlist control group (pre=15.4, post=15.2; p=.036). Additionally, participants in the treatment condition demonstrated significant improvements on standardized language assessments in comparison to waitlist controls. Significant improvements in receptive language skills were evidenced in the treatment group (Mullen Receptive Language t-score: pre=35.4, post=52.0) that were not replicated in the waitlist group (pre=28.4, post=28.4; p=0.030), The treatment condition also demonstrated a trend toward improvement in expressive language (Mullen Expressive Language t-score pre=32.6, post=39.2) that was not observed in the waitlist condition (pre=28.8, post-test=28.8), although this finding was not significant given the preliminary nature of the data and small n.
Conclusions: Study results suggest that toddlers receiving an embedded social-reinforcement intervention demonstrate significant improvements in receptive and possibly expressive language skills not observed in wait-list controls. It also suggests that overall autism symptom severity can improve dramatically after six months of engaging intervention that combines their pre-existing interests with social elements. These preliminary findings suggest that efforts to target social engagement in a larger cohort of children with autism may have similar transformative effects to early single subject design empirical findings.

73 **164.073** Can Children with ASD Learn Language through Overhearing?

R. Luyster[1] *and S. Arunachalam*[2]*, (1)Communication Sciences and Disorders, Emerson College, Boston, MA, (2)Dept. of Speech, Language & Hearing Sciences, Boston University, Boston, MA*

Background: Much of the literature on language learning in children has focused on 'child-directed speech' – language directly addressed to a child. However, cross-cultural research has indicated that children do not REQUIRE child-directed speech in order to learn new words (Ochs & Schieffelin, 1984), and laboratory-based research has confirmed that young children learn new words via overheard speech (Akhtar et al., 2001). This is a valuable observation, because it highlights the extent to which children are very skillful at 'mining' their environment for useful language input, making good use of information that may not be provided explicitly for their benefit.
Children with autism spectrum disorder (ASD) often have language delays, but some children with ASD do not (Kjelgaard & Tager-Flusberg, 2001). We hypothesize that the ability to learn language through overhearing may help to explain why some children develop language faster than others: a child with ASD who is capable of learning via overheard speech has access to much larger set of useful language input than a child with ASD who is not capable of learning via overheard speech. Given previous findings associating *quantity* of adult language input with language and communication development for both typically developing children (Hart & Risley, 1995) and those with ASD (Warren et al., 2009; Bang & Nadig, 2015), these invididual differences may help to explain the variability in language ability for children with ASD.
Objectives: This pilot study serves as a first step in exploring the role of overhearing in language learning for children with ASD; the immediate objective was to address whether overheard language is 'accessible' for children with ASD.
Methods: This pilot study included two preschoolers with ASD (aged 4;3 and 4;6); diagnosis was confirmed using the Module 2 of the ADOS-2 (both children were speaking in phrases). Each child completed a within-subject quasi-experimental design (from Akhtar et al., 2001), comprised of two word-learning training conditions and subsequent test trials. In the 'addressed' training condition, children were directly addressed by an experimenter, who introduced a novel label for a new toy. In the 'overheard' training condition, the experimenter instead addressed a second experimenter, offering a second new label for a different toy (while the child with ASD was seated across the room). After the training conditions were complete, the child's comprehension of each novel label was tested. The primary question was whether the children were able to learn the new word in the 'overheard' training condition.
Results: Both children were successful at learning new words in the 'addressed' condition, as well as in the 'overheard' condition.
Conclusions: These preliminary results suggest that some children with ASD are capable of monitoring the conversations of others in order to learn new words. The extent to which children are able to do this could be a variable of interest in explaining heterogeneity of language development. In the upcoming months, we will enroll additional participants (estimated N=36) and include additional measures of social communication and language to better understand the correlates of this language-learning capability.

74 **164.074** Changes in Parenting Stress As a Predictor of Treatment Outcome

D. Swain[1]*, G. W. Gengoux*[2]*, M. B. Minjarez*[3]*, A. Y. Hardan*[4] *and A. Scarpa*[5]*, (1)Virginia Tech, Blacksburg, VA, (2)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (3)Seattle Children's Hospital, Seattle, WA, (4)Stanford University, Stanford, CA, (5)Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Social communication impairment is a hallmark characteristic of ASD that may manifest in delayed acquisition and use of functional language. These communication difficulties not only impact the individual (e.g. inability to express needs) but also caregivers. More specifically, parents of children with ASD have reported elevated levels of stress, in comparison to parents of typically developing children as well as parents of children with developmental disabilities. In addition, parent involvement in child directed therapies have become nearly commonplace, which results in increased amounts of time and resources on their child (e.g. therapy involvement, appointments, problem behaviors), leaving little time for them to focus on their own emotional and psychological needs. Several treatment studies have begun to target parent well-being and stress separately; however, it is important to note that multiple studies targeting specific parent characteristics correspond with increased levels of dropout rates. Pivotal Response Treatment (PRT) is an empirically based, naturalistic therapeutic approach that teaches parents how to elicit language for minimally verbal children with ASD. Previous studies by our group have demonstrated significant parent gains in treatment implementation as well as child gains in functional language skills through a group format. However, while improvement was noted, parenting stress remained at elevated levels during post treatment assessment. An important first step to understanding the relationship between parent stress and child outcomes is examining the change in parent stress over the course of treatment and its effects on treatment outcome (e.g. spontaneous child language).
Objectives: This study evaluated the predictive nature of parent stress in relation to the parent-child relationship on the amount of spontaneous words produced during a Structured Laboratory Observation (SLO). Parents participated in a randomized controlled trial who were randomly assigned to either PRT group or parent psychoeducation control group.
Methods: 27 parents of children with ASD between the ages of 2.3 and 6.5 (M= 4.2, SD = 1.2) participated in a 12-week group PRT parent training to target child language. Parents completed the Parenting Stress Index, Short Form at baseline and week 12 of the training. Children's frequency of spontaneous language was scored during SLO, which took place under standard conditions. Parents were instructed to elicit child language during a 10-minute period of time.
Results: A percent change score in parent stress related to dysfunctional parent-child relationship was computed for all parents who completed the PSI-SF at baseline and week 12. While controlling for age and gender, the change score in parent stress remained as a significant predictor of SLO spontaneous language for children at week 12 ($B = -2.793$, $p = .033$) and uniquely accounted for 19.2% of the variance in child spontaneous language at week 12.
Conclusions: Grounding parent-focused strategies squarely within a child intervention may increase levels of retention while still addressing important parental difficulties such as stress. Overall, the need for a treatment to concomitantly target parent and child difficulties appears to be imperative.

75 **164.075** Comparing Structural and Pragmatic Language Abilities in Subgroups of ASD Children with and without Comorbid Intellectual Disability

A. Whitten[1] *and J. W. Bodfish*[2]*, (1)Vanderbilt University, Nashville, TN, (2)Vanderbilt University School of Medicine, Nashville, TN*

Background: Currently, the general consensus is that structural features of language (e.g., syntax, phonology) are intact while the social use of language, referred to as pragmatic language, is universally impaired in ASD. However, most of the research on language impairment in autism has been restricted to high-functioning individuals with autism. Consequently, it is not known whether a comorbid intellectual disability further affects language impairment in low-functioning individuals, and thus may require more extensive interventions. Furthermore, studies that directly compare structural and pragmatic language are necessary to advance knowledge of the language phenotype within all of ASD.
Objectives: We aimed to compare both structural and pragmatic aspects of language across three groups: low functioning children with ASD (LFA), high functioning children with ASD (HFA), and an age-matched typically developing group (TD).
Methods: Using the Children's Communication Checklist-2 (CCC-2), we compared mean scores between LFA (n=15, Nonverbal IQ < 80, mean age = 12 years, range = 5 – 17 years), HFA (n=57, Nonverbal IQ > 80, mean age = 10 years, range = 6 – 17 years), and TD (n=52, mean age = 11 years, range = 6 – 17 years). We used one-way ANOVAs with planned post-hoc tests across 4 subscales measuring structural language (Speech, Syntax, Semantic, Coherence) and 4 subscales measuring pragmatic language (Initiation, Scripted Language, Context, Nonverbal Communication).
Results: There was a significant main effect of group for all four structural language subscales ($F(2, 21)$ = Speech: 18.75, Syntax: 49.49, Semantic: 93.34, Coherence:101.80, all $p < .001$). Post hoc Tukey tests revealed the same pattern for all four structural subscales ($p < .001$), such that there were no significant differences between LFA and HFA, while both LFA and HFA groups scored significantly lower than TD. This same pattern was replicated across all four pragmatic subscales, with a main effect of group ($F(2, 66)$ = Initation: 61.32, Scripted Language: 64.58, $F(2, 121)$ = Context: 175.04, Nonverbal Communication: 170.12, all $p < .001$). Again, post hoc Tukey tests showed no significant differences between LFA and HFA, with both LFA and HFA scoring significantly lower than TD. Pearson correlations between IQ and structural and pragmatic CCC-2 subscales found no significant associations, with one exception. The pragmatic subscale 'Context' was significantly associated with IQ within the LFA group only ($r = 0.60$, $p < .05$).
Conclusions: We found evidence that the language deficits do not differ between LFA and HFA groups. Furthermore, our results refute the idea that structural features of language are spared in ASD, as both LFA and HFA groups tended to score well below the TD group on all structural language subscales. Our results suggest that future studies on language impairment in ASD should no longer exclude low functioning individuals, and examine both structural and pragmatic aspects of language; such research will be vital to improving language interventions in ASD, especially for children with ASD whose language deficits do not respond to intervention.

76 **164.076** Comparison of Two Speech Therapies for Minimally Verbal Children with Autism

K. V. Chenausky[1,2] *and G. Schlaug*[3]*, (1)Neurology, Beth Israel-Deaconess Medical Center, Boston, MA, (2)Brain and Psychological Sciences, Boston University, Boston, MA, (3)Beth Israel Deaconess Medical Center, Boston, MA*

Background: Up to 25% of children with autism remain minimally verbal past the age of 5. Inadequate communication skills are related to challenging behaviors such as aggression, self-injury, and property destruction (Dominick et al., 2007; Matson et al., 2009). Thus, it is vital for children with minimally verbal ASD (MV ASD) to acquire at least some spoken language.
Objectives: We report on a comparison of two interventions to teach minimally-verbal children with autism their first words. One, Auditory-Motor Mapping Training (AMMT), aims to promote speech production directly by training the association between sounds and articulatory actions using intonation and bimanual motor activities. The other, Speech Repetition Therapy (SRT), is a traditional therapeutic approach involving neither musical intonation nor bimanual motor activity.
Methods: Minimally verbal children with autism between the ages of 5 and 9 years of age were treated with either AMMT (n=23) or SRT (n=7). Inclusion criteria included a

diagnosis of autism and the ability to imitate at least 2 speech sounds. Exclusion criteria included other known neurological conditions and use of more than 20 words or word approximations functionally. Therapy consisted of 1-hour sessions, five days per week for 25 sessions. Probe assessments were conducted periodically during baseline, therapy, and post-therapy follow-up sessions to assess children's speech production on a set of 15 trained two-syllable words and a set of 15 untrained two-syllable words.
Results: Two-way mixed-measures ANOVAs showed that number of consonants correct, vowels correct, CV syllables correct, and CV syllables approximately correct all improved significantly with therapy (all $p < .01$). Trained words showed significantly more consonants correct, CVs correct, and CVs approximately correct than untrained words (all $p < .005$). Both types of therapy resulted in statistically similar magnitudes of improvement; however, children receiving AMMT showed steeper improvement trajectories.
Conclusions: Both AMMT and SRT resulted in significant improvement in speech production and in children's ability to produce or approximate the pronunciation of two-syllable words. Because these children had no or minimal vocal output prior to treatment, the acquisition of speech sounds and word approximations through therapy represents a critical step in expressive language development in children with autism. Participant factors associated with therapeutic success will be discussed, as will changes in speech production ability associated with therapeutic progress.

77 **164.077** Family Experiences in Bilingual Children with Autism Spectrum Disorder (ASD)

K. Jalalian[1], *K. Oshiro*[2], *M. Lorch*[3], *S. J. J. Webb*[4], *N. Navot*[4], *S. Ghods*[5], *S. Corrigan*[6] *and K. Toth*[6], *(1)Seattle Children's Research Institute, Auburn, WA, (2)University of Washington Autism Center, Seattle, WA, (3)Birkbeck, University of London, London, United Kingdom, (4)University of Washington, Seattle, WA, (5)Seattle Children's Research Institute, Issaquah, WA, (6)Seattle Children's Research Institute, Seattle, WA*

Background: Many parents of children with autism spectrum disorders (ASD) have been discouraged by clinicians and medical practitioners from exposing their child to more than one language (Wharton et al., 2000; Kremer-Sadlik, 2005; Jegatheesan, 2011; Yu, 2013). Four studies have explored the relationship between multiple language exposure and language development in children with ASD (Hambly & Fombonne, 2012; Ohashi et al, 2012; Peterson et al., 2012; Valicenti-McDermott et al., 2012). All rejected the claim that multiple language exposure has an adverse effect on language and social development for children with ASD. Whereas bilingual children with ASD are more likely to vocalize and utilize proto-imperative gestures than monolingual counterparts (Valicenti-McDermott et. al, 2012), and have larger total production vocabularies (Peterson et al., 2012), with similar patterns to typically developing bilingual children (Pearson et al., 1993). Furthermore, non-native English parents elicit greater responsiveness from their children when communicating in their native language then in English (Wharton et al., 2000). To date, there is a lack of data regarding the effect of advice on language choices to bilingual parents of children with ASD.
Objectives: We investigated the relationship between language environments and the impact of family dynamics on language choices based on the advice given by health and educational professionals in diagnosed bilingual children with ASD.
Methods: Preschool aged children with ASD (N=13) averaging from 24-60 months from bilingual families were selected for this study. The study included a standardized observational testing for social interaction, communication and autism severity (ADOS), nonverbal (visual) reasoning (Mullen Scales of Early Learning) and expressive and receptive language (Preschool Language Scale IV). Measures were repeated at three time points in English. Parents answered 25-questions for the Family Experience Bilingual Questionnaire regarding their child's ASD diagnosis, language choices and ability in both languages, and advise regarding bilingualism four years after their initial entry to the study.
Results: Bilingual parents with children with ASD expressed three common concerns: language and social development and behavioral issues. Their children had different levels of exposure in both languages, beginning their first year of 71% English and 28% non-English and current exposure as 78% English vs. 20% non-English. Parents reported anxiety over their language choices, leading to consultation with professionals and peers. This consultation process was often uninformative: 66% of parents received no recommendation, while 17% of the families were encouraged, and 17% discouraged about bilingualism. Overall, parents who raised their child bilingually reported positive experiences, while parents who raised their child monolingually reported negative experiences specifically, family relationships and dynamics.
Conclusions: While evidence suggests that bilingual children with ASD have similar language development in comparison to monolingual children with ASD, parents reported a lack of advice from professionals on language choices. Specifically parents that raised their child bilingually reported more positive experiences than their monolingual counterparts because of the maintenance of communication and cultural exchange with extended family members. Supporting families in maintaining more than one language, even if English is the dominant language, is critical in supporting social skills and family relationships.

78 **164.078** Differences in Caregiver Behaviors of Infants at Risk for Developing Autism and Typically Developing Infants during an Object Sharing Paradigm

S. Srinivasan[1], *T. Nguyen*[2], *M. Hoffman*[2], *A. Dinar*[2], *M. Pugliese*[2], *M. Kaur*[1] *and A. N. Bhat*[1], *(1)University of Delaware, Newark, DE, (2)Physical Therapy, University of Delaware, Newark, DE*

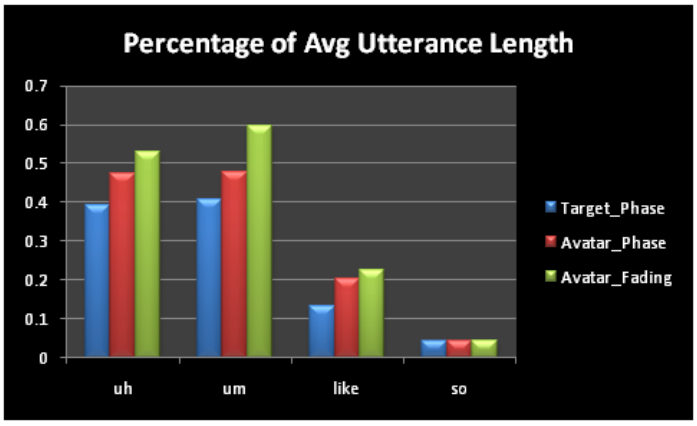
Background:
Towards the end of first year, infants begin to share object play with their caregivers through pointing, showing, and giving (Bakeman & Adamson, 1984). Advancements in infants' perceptuo-motor skills and onset of walking lead to a surge in object sharing skills. Advances in infants' motor and social development may influence the way caregivers interact with their infants, which in turn may further influence infant behaviors. Our previous work shows that infants at risk for developing Autism Spectrum Disorder (ASD) (i.e. infant siblings of children with ASD or AR infants) demonstrated poor object sharing skills compared to typically developing (TD) infants over the first 15 months of life.
Objectives:
In the current study, we explored differences in caregiver behaviors between TD and AR infants during an "object sharing" paradigm. We were specifically interested in the differences in caregiver proximity/social distance, verbalizations, and gestural use as they communicated with their infant.
Methods:
16 AR infants and 16 TD infants were observed during an object sharing task at 9, 12, and 15 months with developmental follow-up and autism screening at 18 and 24 months. Infants were provided a set of standard toys to play with in the presence of their caregivers and played spontaneously or with caregiver reinforcement. We coded for the caregivers' social distance, gestures, and verbalizations. Specifically, we coded all instances of caregiver initiated proximity-seeking behaviors. In terms of caregiver gestures, we coded for rates of object-directed, attention directing, reinforcing, requesting, and grabbing behaviors. Lastly, in terms of caregiver verbalizations, we coded for rates of directives, prohibitions, reinforcements, and attention-seeking phrases used.
Results:
Caregivers of AR infants engaged in greater rates of proximity-initiating behaviors (0.84 ± 0.76) compared to caregivers of TD infants (0.22 ± 0.21, $p = 0.008$) at 15 months. In terms of gestural use, caregivers of AR infants demonstrated greater rates of grabbing objects compared to TD caregivers ($p = 0.03$) at 15 months. In terms of verbalizations, caregivers of AR infants (12 months: 0.66 ± 0.24, 15 months: 0.72 ± 0.24) used greater directives, attention-seeking phrases, and prohibitions at 12 and 15 months compared to caregivers of TD infants (12 months: 0.50 ± 0.14, 15 months: 0.46 ± 0.13, $p$values < 0.03).
Conclusions:
There were significant differences in the way caregivers of AR infants interacted with their infants compared to caregivers of TD infants. These differences in caregiver behaviors stem from the different social cues offered by AR infants and may differentially contribute to the future motor and social development of AR infants. Future studies should test this hypothesis by examining the effects of reduced versus excessive caregiver scaffolding on future outcomes of infants at risk for developing ASD.

79 **164.079** Discourse Marker Usage in School-Aged Children with ASD and ADHD in a Virtual, Public Speaking Task

N. S. Alpers-Leon[1], *L. Naigles*[2], *N. S. McIntyre*[3] *and P. C. Mundy*[4], *(1)University of Connecticut, Vernon, CT, (2)University of Connecticut, Storrs, CT, (3)University of California at Davis MIND Institute, Davis, CA, (4)Education and Psychiatry, University of California at Davis, Sacramento, CA*

Background: There has been little previous research regarding usage of discourse markers (DM's), small words which not only 'glue' conversational utterances together (e.g.,'so', 'like', 'uh', 'um'; Shiffrin, 1988) but also signal to an interlocutor that a conversational turn is not finished (Kam & Edwards, 2008.) DM's may also signal a disfluency (Arnold et al., 2007) that can affect the way a listener will interpret what is to come next in the conversation and perhaps the way they judge the speaker. Previous research found that children with ASD produce 'uh' but not 'um' (Canfield et al., in press) suggesting that 'um' may be more social in nature as children with ASD experience social impairment.
Objectives: This study examined children's language during a virtual reality public speaking task, designed for use with school-aged children with HFA. Language use was assessed across conditions that varied in social and non-social context, as well as higher versus lower attention demands.
Methods: 98 children aged 8-16 are currently participating in a longitudinal study of attention, social, and academic development in children with HFA. Data are presented on 21 HFA, 22 TD, 24 ADHD, and 31 comorbid children Age- (Ms = 11.60, 12.45, 11.93, 12.12 respectively) and Verbal IQ- (Ms= 96, 111, 97,and 96 respectively) matched participants. Children viewed a virtual classroom through a head-mounted display and were asked to answer questions about their interests and daily activities while addressing 9 targets. There were three 3-minute conditions: In the Non-Social Attention condition children talked to 9 "lollipop" shaped forms positioned to their left and right in the classroom; in the Social Attention Condition children talked to 9 avatar "peers" to the left and right, and in the High-Demand Social Attention Condition they talked to 9 avatars that faded if children did not fixate on them every 15 seconds. Children's speech was audiotaped, transcribed, and analyzed for seven measures of language use (Mean-Length-of-Uttreance (MLU), noun types and tokens, verb types and tokens, discourse marker types and tokens).
Results: ANOVAS revealed no significant group effect for each DM individually; however usage of particular DM's varied across phases. 'Um' $F(3, 94)=6.021$ $p = .003$ and

'like' $F(3, 94)= 3.653$, $p = .028$ usage varied across phase. There was no significant difference between 'um' and 'uh' usage across phase, but there was a group effect for the usage of 'um' vs. 'uh,' $F(3, 94)=3.448$ $p = .020$.
Conclusions: All children in this study, including those with HFA are producing the DM 'um' contrary to previous findings. The usage of 'um' increases across the phases, which could be the result of a non-threatening social situation of talking to avatars or the result of cognitive load due to higher attention demands. 'Like' appears to be used in a similar fashion as 'um' or 'uh,' increasing in usage across phases, whereas the usage of 'so' remains constant across all phases and perhaps signals a causal event or conclusion.



80 **164.080** Discrimination of Non-Native Speech Pitch and Autistic Traits in Non-Clinical Population

L. S. Iao[1], *A. Wippich*[1], *G. Y. H. Lam*[2] *and C. K. S. To*[3], *(1)Division of Psychology, Nottingham Trent University, Nottingham, United Kingdom, (2)School Psychology Program, Department of Educational and Psychological Studies, University of South Florida, Tampa, FL, (3)University of Hong Kong, Hong Kong, Hong Kong*

Background: Children with Autism Spectrum Disorders (ASD) shows enhanced discrimination of speech pitch. However, this enhancement seems no longer exist in adulthood due to a developmental increase in pitch discrimination abilities, which is associated with receptive vocabulary in native language, in individuals without ASD (Mayer, Hannent, & Heaton, 2014). If this is the case, it is possible that their increased discrimination of speech pitch is tied to native speech only and may not be carried over to non-native speech. Given that autistic traits are evident in individuals without ASD, those with higher levels of autistic traits may be more able to discriminate non-native speech pitch.
Objectives: This study investigated the discrimination abilities of non-native speech pitch and its relationships with autistic traits in typically developed adults without ASD.
Methods: One hundred English-speaking university students (52 females; mean age = 21.65 years, SD = 3.55 years, range = 18 – 35 years) participated in the study. All participants took a pitch discrimination task, in which they determined whether there were pitch differences between pairs of monosyllabic Cantonese words presented at either 0, 1, 2 or 3 semitone difference, and filled in the Autism Spectrum Quotient questionnaire (AQ; Baron-Cohen, Wheelwright, Skinner, Martin, & Clubley, 2001).
Results: Participants' performance in discriminating non-native speech pitch was significantly above chance level and was comparable to previous findings using native speech pitch (Mayer et al., 2014). Correct judgement of 'same' pitch was near ceiling and correct discrimination of 'different' pitches significantly improved with increases in semitone intervals. There was no correlation between pitch discrimination and overall autistic traits but pitch discrimination was negatively correlated with the social skill subscale in the AQ even after musical training was controlled.
Conclusions: Contrary to our prediction, adults without ASD performed well in discriminating non-native speech pitch. Moreover, those who were less sociable were less able to discriminate non-native speech pitch. This finding suggests a link between autistic-like social traits and speech processing in general population.

81 **164.081** Disfluencies Distinguish the Speech of Children with Autism Spectrum Disorder

M. Santulli[1], *J. Parish-Morris*[2], *E. F. Ferguson*[2], *L. Bateman*[2], *R. T. Schultz*[3] *and J. G. Donaher*[4], *(1)Temple University, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Childhood Communication and the Department of Speech-Language Pathology, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Communication skills vary substantially in children with autism spectrum disorder (ASD), but receptive, expressive and pragmatic language deficits are frequently reported (Tager-Flusberg, Paul, & Lord, 2005). A growing body of research suggests that individuals with ASD, especially those with high functioning autism and Asperger's Syndrome, are more prone to produce a variety of disfluencies while speaking (Shriberg et al., 2001). However, research has yet to determine whether certain disfluency patterns are unique markers of ASD or whether they define a subgroup of individuals with ASD who are struggling with coexisting cognitive-linguistic, motor and/or pragmatic impairments.
Objectives: Compare and categorize disfluency rates in the speech of children with ASD and typical development during a semi-structured interview, and assess correlations with clinical and parent ratings of social impairment.
Methods: Research-reliable PhD-level clinicians administered the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2012) to 30 children with ASD and 14 typically developing controls that were matched on age, IQ, and sex ratio (Table 1). The conversation and reporting section of the ADOS was extracted and all utterances, were transcribed verbatim. Two reliable raters blind to diagnostic status coded disfluent behaviors, which were classified as stuttering-like disfluencies (SLD), repetitions (REP) or atypical disfluencies (AD; see Table 2). Interjections, revisions, and abandoned phrases (ABD) were analyzed independently. We used Welch's t-tests to compare group means for total disfluency level (TDL), frequency per type of disfluency, and proportion of disfluencies. Clinicians assigned each child a calibrated severity score based on behavior during the ADOS, and parents completed the Social Responsiveness Scale (SRS; Constantino, 2005).
Results: Participants in the ASD and TDC groups produced an equal number of total words with no significant differences in TDL (ASD=.09, TDC=.08, p=ns). However, the ASD group produced higher rates of SLD (t=-1.99, p=.05) as compared to the TDC group. No significant differences were found in rates or counts of AD, REP, ABD, interjections, or revisions, although the percentage of children that produced abandoned phrases in the ASD group (63%) was marginally higher than the TDC group (36%, Chi-square=2.94, p=.09). In the ASD group, TDL correlated positively with ADOS severity scores (*Pearson*=.39, p=.03), as did REP (*Pearson*=.44, p=.02). In the TDC group, higher SLD rates were associated with more social impairment as measured by the SRS (*Pearson*=-.56, p=.04).
Conclusions: Higher rates of certain disfluency types may contribute to the perception of impaired pragmatic language in ASD. Consistent with previous studies, the ASD group in the current study produced higher rates of SLDs than the TDC group, and disfluency rates correlated with clinical ratings of autism severity. Interestingly, 30% of participants in the ASD group produced prolongations (initial, mid-word, and/or final) versus 0% in the typical group. This latter, atypical finding warrants further exploration and may indicate enhanced diagnostic specificity when compared to other disfluency types. Transcription and coding of an extended sample is currently underway, and will be complete by May 2016.

Table 1. Groups did not differ on age, IQ, verbal IQ, or nonverbal IQ. SRS t-scores and ADOS severity scores were significantly higher in the ASD group than the TDC group, all *ps*<.001.

Dx	ASD Mean (SD)	TDC M (SD)
N	30	14
Age	10.67 (2.01)	11.10 (1.61)
Sex ratio M:F	19:11	8:6
Overall IQ[1]	105 (14.06)	108 (12.13)
Verbal IQ	107 (15.32)	111 (12.66)
Nonverbal IQ	108 (15.00)	104 (14.23)
SRS (t-score)[2]	82.23 (16.76)	40.57 (5.21)
ADOS severity	6.43 (2.92)	1.43 (.94)

[1] Overall IQ is the Global Composite Ability from the Differential Abilities Scales - II
[2] Four participants in the ASD group did not have scores on the Social Responsiveness Scale.

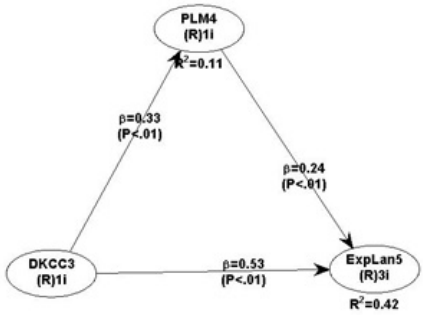
Table 2. Disfluencies were classified as stuttering-like disfluencies (SLD), repetitions (REP) or atypical disfluencies (AD). Interjections, revisions, and abandoned phrases (ABD) were analyzed independently.

SLD	AD	REP
Part-word repetitions	Mid-word prolongations	Multi-syllable word repetitions
Initial position prolongations	Final-word prolongations	Phrase repetitions
Blocks	Final- part-word repetitions	Single-syllable whole-word repetitions produced without tension

82 **164.082** Empirical Support for a Transactional Model of Spoken Language Acquisition in Preschoolers with Autism Spectrum Disorder

T. Woynaroski[1], *P. J. Yoder*[2] *and L. R. Watson*[3], *(1)Vanderbilt University, Thompsons Stn, TN, (2)Vanderbilt University, Nashville, TN, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:
There is a pressing need to explain individual differences in “useful speech” of young children with autism spectrum disorder (ASD) because learning to use spoken language to communicate early in life has been repeatedly linked with long-term outcomes in this population. Transactional theory suggests that models considering both parent and child factors, and the dynamic way in which such factors interact, will best account for individual differences in spoken language acquisition. One instantiation of transactional theory specifically suggests that early child vocalizations that are more “speech-like” or “complex” elicit parent linguistic responses, which in turn scaffold spoken language learning. We have previously confirmed this model in a group of young children with developmental disabilities not due to autism (Woynaroski, Yoder, Fey, & Warren, 2014).
Objectives:
The present study tests whether the transactional model of spoken language acquisition additionally applies to preschoolers with ASD.
Methods:
We drew on extant data from a recent longitudinal investigation of useful speech development involving 87 preschoolers with ASD (Yoder, Watson, & Lambert, 2015). An index of the complexity of children’s vocalizations (i.e., consonant inventory in communicative vocalizations) was measured at Time 1 from the Communication and Symbolic Behavior Scales-Developmental Profile (CSBS-DP). Children’s spoken language outcomes were measured 8 months later at Time 3 using an aggregate of scores from the CSBS-DP word scale, the Macarthur-Bates Communicative Development Inventories: Words and Gestures expressive vocabulary checklist, and the number of different words produced in a semi-structured communication sample with an examiner. Midpoint parental linguistic mapping was measured at Time 2 (4 months after Time 1) in a 10 minute parent-child interaction. Mediation analysis with stochastic regression handling of any missing data points was used to test the statistical significance of the indirect effect of early child vocal complexity on later spoken language outcomes through mid-point parental linguistic mapping (Hayes, 2009).
Results:
As expected, children’s early vocal complexity predicted their later spoken language outcomes ($r = .61$; $p < .001$). Additionally, early child vocal complexity was positively associated with mid-point parent linguistic mapping ($r = .33$; $p < .001$), and mid-point parent linguistic mapping predicted later spoken language outcomes, controlling for early child vocal complexity ($r = .24$; $p < .01$). The indirect effect of early child vocal complexity on later spoken language outcomes through mid-point parent linguistic mapping was statistically significant. Thus, mid-point parent linguistic mapping mediated the relation between early vocal complexity and later spoken language in our sample.
Conclusions:
These findings lend empirical support to the transactional theory of spoken language development in preschoolers with ASD. We confirmed that one child factor (early vocal complexity) and one parent factor (linguistic mapping) contribute in a dynamic manner to impact spoken language outcomes in children with ASD. This result suggests that we might best support spoken language acquisition in this population by targeting both the complexity of children’s vocalizations and parents’ responses to such prelinguistic child productions. Implications for theory, research, and practice will be discussed.



83 **164.083** Evaluating the Utility of Narratives in Assessing Language Abilities of Bilingual Children with Autism Spectrum Disorders

S. B. Vanegas *and K. Acharya, University of Illinois at Chicago, Chicago, IL*

Background:
To date, there is sparse research on how children with ASD raised in bilingual environments develop language. The few studies that have explored this issue have primarily focused on young children (i.e., 1.5 – 5 years of age), with most results showing no significant delay or deviance in the early stages of language development (Ohashi et al., 2012; Valicenti et al., 2012). An additional concern is the use of standardized instruments in measuring language development in children, as these may underestimate the abilities of children from diverse backgrounds. Narratives have been identified as useful tools in the assessment of bilingual typically developing children (Bedore et al., 2010); however, to date there is no published research evaluating its utility in the assessment of children with ASD from diverse language backgrounds.
Objectives:
The current study aims to clarify how narratives can be used to measure language abilities of children from diverse language backgrounds.
Methods:
Monolingual (English) and bilingual (English/Spanish) children with Autism Spectrum Disorders who were between 8 and 14 years of age were recruited to participate. Children were eligible to participate if they were verbal and had a nonverbal IQ of 70 or higher. Data collected thus far includes six monolingual and nine bilingual children. All children completed a standardized language assessment and two narratives in English (*Frog, Where Are You?, Frog on his Own)*. Bilingual children also completed a standardized language assessment and two narratives in Spanish (*Frog Goes to Dinner; One Frog Too Many*). Parents of all children also completed a Language Background Questionnaire and the Social Communication Questionnaire.
Results:
Preliminary analyses on the age of early language milestones found no differences between bilingual and monolingual children on the age of babbling and single words; however, differences emerged in the development of short phrases and sentences with bilingual children reaching these milestones later than monolingual children (*p*'s < .05). A MANOVA was then conducted on the English-language narratives controlling for age. These findings showed that bilingual and monolingual children with ASD did not differ on the mean length of words per utterance (MLUw) or number of utterances containing grammatical errors (all *p*'s > .05). The only difference that emerged between groups was on the Type/Token ratio, with monolingual children exhibiting a greater lexical variety than bilingual children with ASD ($p = .032$).
Conclusions:
The preliminary results indicate that although bilingual children with ASD had lower scores on a standardized language test than monolingual children with ASD, narratives may provide a more complete profile of language abilities in bilingual children with ASD. These results are relevant as diverse families often receive recommendations to maintain English-only households (Bird et al., 2012) and these recommendations often result in feelings of loss, decreased communication in the home, and isolation from their community (Garcia et al., 2012). These findings contribute to the growing literature on the development of two languages in children with ASD and provides a support for the utilization of narratives in the language assessments of children with ASD.

Table 1

Demographic and language characteristics of Bilingual and Monolingual children with ASD

	Bilingual (n = 9)	Monolingual (n = 6)	Sign.
Age (Years)	10.6 (1.95)	12.5 (1.38)	$p = .057$
Gender (M:F)	8:1	5:1	ns
Nonverbal Reasoning	98.9 (14.47)	97.0 (9.78)	ns
Age of First ASD Diagnosis	5.5 (3.02)	4.7 (2.17)	ns
Social Communication Questionnaire	23.6 (6.04)	19.5 (8.46)	ns
Core Language (English)	79.9 (14.32)	105.7 (21.79)	$p = .026$

84 **164.084** Examination of Script-Based and Non-Script Based Narrative Retellings in Children with Autism Spectrum Disorder

E. Hilvert[1]*, D. Davidson*[2] *and P. B. Gámez*[1]*, (1)Psychology, Loyola University Chicago, Chicago, IL, (2)Loyola University Chicago, Chicago, IL*

Background: Narrative production is often challenging for children with Autism Spectrum Disorders (ASD), particularly in terms of creating coherent and cohesive stories (see Stirling et al., 2014). However, differences between the narratives of children with and without ASD may be minimized when the cognitive and linguistic demands are reduced (e.g.,Losh & Capps, 2003; Novogrodsky et al., 2013). Research on neurotypical (NT) children indicates that incorporating a script-framework into a story can improve narrative coherence and cohesion because having prior event knowledge can help children predict what will happen in a story (Davidson, 2006; Shapiro & Hudson, 1991). It is not known, however, how event knowledge might improve narratives in children with ASD.

Objectives: The current study was designed to 1) gain a comprehensive understanding of the pervasiveness of narrative difficulties in children with ASD by examining whether providing more structure, in the form of a script-framework, would allow children with ASD to produce more well-formed narratives, and 2) examine how Theory of Mind (ToM) ability may predict narrative production in children with ASD, regardless of script or non-script framework.

Methods: This study compared the narrative abilities of 19 children with ASD and 26 NT children (*M*= 10;0, *SD*= 1.6), on two story-retelling tasks: a script-based and a non-script based story. Children were matched on age, nonverbal-reasoning, and receptive language (Table 1). Narratives were coded for a number of microstructure and macrostructure variables. Script-based stories were examined for the types of events included (script, non-script) to gain an understanding of children's script knowledge. ToM was assessed using a battery of measures (e.g., Birthday Puppy Task, Strange Stories Test).

Results: Lexical diversity and productivity were relative strengths for children with ASD. Unexpectedly, the narration of both stories was equally difficult for children with ASD for the majority of narrative variables assessed, including grammatical complexity, appropriate use of references, adverbials, and connectivity, structure, content, which resulted in narratives that were less cohesive and coherent than the NT group (Table 2). All children told *non-script based* stories that were more semantically complex. Closer examination of the script-based story revealed that children with ASD were including the same number of script details as the NT children, but were less likely to include the non-script details that were essential to the plot of the story. ToM ability predicted narrative coherence and cohesion for both story types, but only for the children with ASD.

Conclusions: These findings provide evidence that impairments in narrative microstructure and macrostructure may be pervasive across narrative type for children with ASD, even when using a retelling task. Although children with ASD did not use the script-framework to produce more well-formed script-based narratives, the apparent difficulties with the script-based story appear to reflect more general narrative impairments, instead of abnormalities in their representation of script knowledge. These findings confirm the importance of considering socio-cognitive (ToM) impairments when studying the narrative abilities of children with ASD.

Table 1. ***Comparison of Matching Variables and Participant Characteristics***

	Diagnostic Group	
	ASD (N=19)	***NT (N=26)***
Age	10;03 (1.5)	9;09 (1.7)
Males/Females	17:2	18:8
SRS-2 T-Score'''	66.6 (5.5)	50.25 (5.9)
CARS-2 Raw Score	33.7 (3.9)	---
CARS-2 T-Score	50.2 (5.5)	---
WASI-2 FSIQ	95.1 (14.7)	102.0 (11.7)
Nonverbal Reasoning	47.8	50.1
PPVT-4 Standard Score	100.4 (24.7)	105.1 (17.5)
ToM Total Score (out of 25)'''	10.9 (7.7)	17.7 (3.7)

Note. SRS-2: Social Responsiveness Scale-2. CARS-2: Childhood Autism Rating Scale-2. WASI-2: Wechsler Abbreviated Scale of Intelligence-2. WASI-2 FSIQ refers to the full-scale IQ score obtained from the Wechsler Abbreviated Scale of Intelligence. The score on Nonverbal Reasoning indicates the mean scaled score on the matrix-reasoning subtest of the WASI-2. PPVT: Peabody Picture Vocabulary Test, Fourth Test. The ToM total score was a combined score from children's scores on the unexpected contents task, Birthday Puppy, and Strange Stories Test. * p < .05. ** p < .01. *** p < .001.

Table 2. ***Mean Score on Microskills and Macroskills by Story Type and Diagnostic Group***

	Diagnostic Group	
	ASD	NT
Productivity		
Non-script based	130.4 (91.9)	150.7 (58.3)
Script-based	140.8 (91.8)	161.2 (60.5)
Lexical Diversity		
Non-script based	67.7 (37.9)	73.5 (23.4)
Script-based	66.9 (35.2)	74.2 (21.9)
Grammatical Complexity		
Non-script based	6.6 (3.8)	10.0 (2.5)
Script-based	7.2 (4.2)	11.0 (3.5)
Vocabulary (out of 3)		
Non-script based	1.73 (.99)	2.04 (.76)
Script-based	1.47 (1.2)	2.27 (.68)
References (out of 3)		
Non-script based	1.58 (1.1)	2.62 (.55)
Script-based	1.42 (1.3)	2.62 (.70)
Connectors (out of 3)		
Non-script based	1.11 (.94)	2.13 (.88)
Script-based	1.21 (1.3)	1.44 (.80)
Adverbials (out of 3)		
Non-script based	1.16 (1.0)	2.19 (1.1)
Script-based	1.05 (1.0)	1.85 (.83)
Narrative Structure (out of 3)		
Non-script based	1.62 (1.1)	2.56 (.72)
Script-based	1.58 (1.2)	2.42 (.70)
Narrative Content (out of 3)		
Non-script based	1.26 (1.2)	2.42 (.70)
Script-based	1.23 (1.0)	2.03 (.53)

Note. Productivity was measured by total number of words, lexical diversity was assessed by total number of different words, and grammatical complexity was measured by mean length of utterance (MLU). All other mircoskills and macroskills were rated on a 4-point scale (0-3) using the coding rubric from Peter and the Cat Narrative Assessment (Leitao & Allan, 2003), the non-script based narrative used in the current study.

85 **164.085** Eye Movement during Reading and Answering Inferential Questions in High-Functioning Autism: Strategies and Cognitive Components

M. Micai[1], *H. Joseph*[2], *M. Vulchanova*[3] *and D. Saldana*[1], *(1)Department of Developmental and Educational Psychology, University of Seville, Seville, Spain, (2)Department of Psychology, Oxford Brookes University, Oxford, United Kingdom, (3)Department of Language and Literature, NTNU, Trondheim, Norway*

Background:
Reading comprehension problems in Autism Spectrum Disorder (ASD) are well documented in the literature, however, it is still unclear which processes contribute to this deficit (Brown, Oram-Cardy & Johnson, 2013). The ability to make inferences has been shown to be essential for discourse (Snyder & Caccamise, 2010) and reading comprehension (Cain, Oakhill, Barnes & Bryant, 2001). The results in literature regarding inference generation across ASD individuals are not entirely consistent. Studies have shown individuals with ASD interpret expressions literally (Loukusa, et al., 2007) and have difficulty drawing inferences (Arciuli et al. 2013; Huemer and Mann 2010; Ricketts et al. 2013). However, others have reported that inference generation was intact in ASD when primed for implicit inferences (Saldaña & Frith, 2007). Hence, the reading strategies underlying inference generation in ASD remain unclear.
Objectives:
First, the present research aimed to investigate whether ASD were as accurate as typically developing (TD) individuals in answering inferential questions. Second, eye movement strategies of ASD and TD during the reading of texts that required answering text-based or inferential questions were explored. Finally, it aimed to explore cognitive components related to gaze behavior during inference generation in ASD.
Methods:
Twenty-two high-functioning children and adolescents with ASD and twenty-two TD participants, matched for chronological age, intelligence scores, language skills, and reading ability, read five stories, each divided into six paragraphs. Following each paragraph participants answered an inferential or text-based question. Global and target word (word defined *a priori* as fundamental to question responding) eye movement data was recorded continuously during text reading. Cognitive abilities were measured using the Wechsler Intelligence Scale for Children or Wechsler Adult Intelligence Scale, and the Spanish Peabody Picture Vocabulary Test.
Results:
Results showed that ASD were as accurate as TD in responding to inferential and text-based questions. Analyses of eye movement data revealed longer reading time in the inferential condition only for ASD with respect to the target word. No group differences were found with respect to global paragraph reading and responding time or eye movement around distractor words. With regard to cognition, in the ASD group only, results revealed a positive relationship between vocabulary size and inferential accuracy and a negative relationship between perceptual reasoning and re-reading time of the target word in the inferential condition. Finally, analyses of correct answers revealed that ASD spontaneously fixated on the question prior to the text more often in inferential condition and that a positive relationship existed between the frequency of the question-before-text strategy and score of total intelligence, perceptual reasoning, and working memory.

Conclusions:
Despite similar accuracy scores and global paragraph reading, ASD exhibited delayed processing of the target words in the inference condition. In addition, higher cognitive functions appeared to be related to inferencing ability, target word eye movement behavior, and self-initiated question reading strategy.

86 **164.086** Contextual and Visual Cues in the Interpretation of Idioms in High Functioning Autism

S. Chahboun[1], *V. Vulchanov*[1], *B. Sullivan*[2], *D. Saldana*[3], *H. Eshuis*[1] *and M. Vulchanova*[1], *(1)Department of Language and Literature, NTNU, Trondheim, Norway, (2)Tobii Company, Stockholm, Sweden, (3)University of Seville, Seville, Spain*

Background:
The difficulties experienced by autistic individuals with regard to communication and language are widely known and well documented. Individuals with High functioning autism (ASD) are distinguished by relative preservation of linguistic and cognitive skills. However, problems with pragmatic language skills have been consistently reported across the autistic spectrum, even when structural language is intact. Many studies establish failure to understand metaphors, idioms and other forms of figurative language (Gold & Faust, 2010; Vulchanova, Talcott, Vulchanov & Stankova, 2012).
Objectives:
Our main goal was to investigate how ASD individuals process idioms as a type of figurative language, and, specifically, how they integrate information from multiple sources (e.g. visual modality and language) in this process. In this study, we were interested in the extent to which visual context, e.g., an image corresponding to either the literal meaning or the idiomatic meaning of the expression can facilitate responses to such expressions.
Methods:
Four categories of figurative expressions were included: biological idioms, cultural idioms, instructive idioms (proverbs) and novel metaphors. Participants with high-functioning autism and their typically developing peers (matched in intelligence and language level) had to complete a sentence-picture matching task for idioms and their target meaning represented in images. The expressions were presented visually on a computer screen or auditorily via loudspeakers. We measured the participants' performance based on their accuracy, reaction times, mouse tracking data and eye tracking data.
Results:
We hypothesized that since individuals with ASD have a tendency for literal interpretation, they would have difficulties in appreciating the non-literal or extended nature of idioms and figurative language in general. Analyses of accuracy (ACC) and reaction times (RTs) showed clearly that the ASD participants were less accurate. In addition, the modality in which the stimuli were presented turned out to be an important variable in task performance. The auditory modality seems to assist the control group for better understanding. We also found differences in performance depending on the category of the expression. Participants with ASD had more difficulties understanding cultural and instructive idioms. In contrast, controls were faster and more accurate in all categories and showed no differences between the two modalities. Furthermore, ASD participants presented longer RTs and errors in the instructive idioms in comparison with the other categories in both modalities. Eye-tracking and mouse-tracking data were interpreted to support these findings.
Conclusions:
This research highlights the way in which the processing figurative language differs from typically developing individuals and individuals in the autistic spectrum. In addition, this study can contribute to better understanding of the causes of pragmatic language problems in autism, and more broadly the well-attested comprehension and communication problems in that population.

87 **164.087** Family Matters: Children and Adolescents with ASD Talk More about Family Than Friends

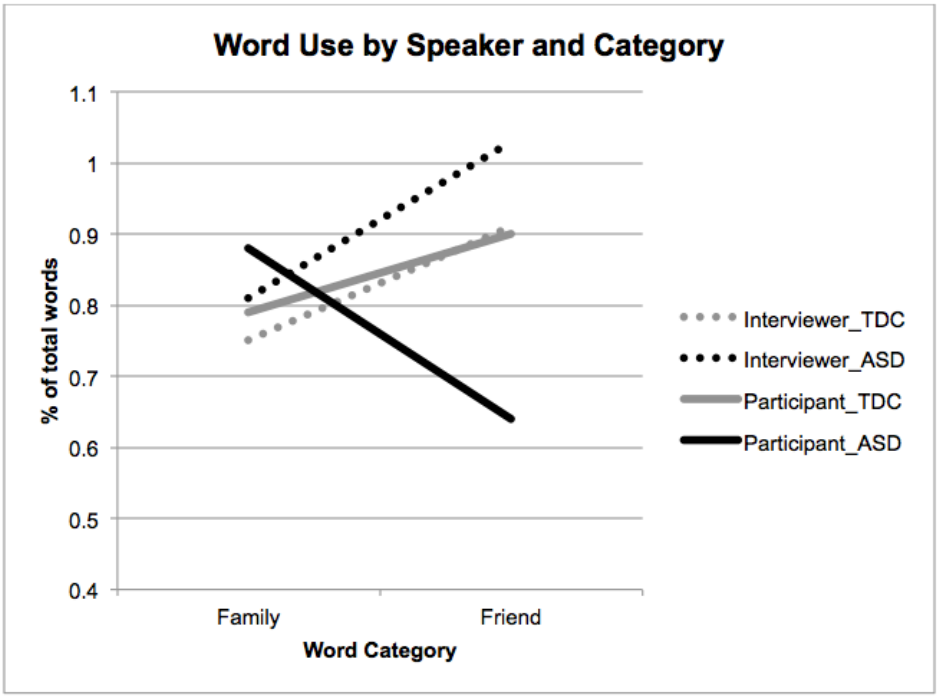
L. Bateman[1], *E. F. Ferguson*[1], *K. J. Payton*[1], *R. T. Schultz*[2] *and J. Parish-Morris*[1], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: As children grow older, their focus naturally broadens to include peers as well as family (Berndt, 1992). Autism Spectrum Disorder (ASD) is characterized by varying degrees of social impairment, and individuals often have smaller social networks and friend groups than age-matched children without ASD (Kasari et al., 2011). Measuring the frequency of friend words (e.g., friend, acquaintance, buddy) versus family words (e.g., mom, dad, cousin) produced in natural language is one way to assess the relative prominence of friends versus family in a child's life.
Objectives: Measure how often children with ASD, typically developing controls (TDC) and interviewers use "friend" and "family" words during the conversation and reporting section of the Autism Diagnostic Observation Schedule (ADOS), and correlate rates of "friend" and "family" word usage with social functioning (ADOS calibrated severity scores and scores on the Social Responsiveness Scale).
Methods: Research reliable PhD-level clinicians administered the ADOS to 65 participants (ASD: 48, TDC: 17). Participants were matched on full-scale IQ and sex ratio, with a slightly younger ASD group (Table 1). Trained annotators transcribed the words produced by clinicians and participants during the conversation and reporting section of the ADOS (~20 minutes). We processed each transcript using the Linguistic Inquiry and Word Count software (Tausczik & Pennebaker, 2010), then extracted the ratio of words categorized as "friend" words and "family" words for each speaker, relative to the total number of words produced. There were no significant correlations between age and word use between- or within-groups, so age was not included as a covariate in our primary analyses. Due to significant correlations between interviewer and participant word use (.3-.4), we controlled for interlocutor language in our omnibus tests.
Results: We conducted an ANCOVA for each speaker type, with word category (friend, family) as a repeated measure and diagnosis as a between-group factor. There was a trending interaction between participant word category use and diagnosis, $F(1,61)=2.77$, $p=.10$, and no significant effects of interviewer language. Paired t-tests showed that participants in the ASD group produced a significantly higher percentage of family words than friend words, $p=.01$, while TDCs used family and friend words at equal rates (Figure 1). Interviewers in both groups used significantly more friend than family words, $ps<.01$. After partialing out interviewer language, we found a significant positive correlation between the rate of "family" words used by all participants and their SRS t-scores, and a significant negative correlation between ADOS calibrated severity scores and "friend" words.
Conclusions: Natural language processing holds great promise as research tool. It has the potential to provide highly granular, quantitative data that varies dimensionally in the majority of individuals with ASD. In this study, we explored one metric of social functioning that emerged in the language produced by in children with ASD and non-ASD peers. The difference between "friend" and "family" words held even after controlling for interlocutor language, suggesting that participants with ASD may engage in less linguistic accommodation than peers. Future research with a larger cohort will explore age effects in older adolescents.

Table 1. Demographics and cognitive/social profiles by group. The ASD group was younger than the TDC group, t=2.04, p=.05, but groups did not differ on sex ratio or IQ. IQ is the General Conceptual Ability score from the DAS-II (Elliott, 2007). Three participants in the TDC group were missing ADOS severity scores and four participants in the ASD group were missing SRS t-scores.

	ASD (N=48)	TDC (N=17)	Difference
Sex (M, F)	33, 15	8, 9	Chi-square=2.54, p=.11
Age in years - Mean (SD)	10.10 (2.01)	11.29 (2.20)	t=2.04, p=.05
IQ - Mean (SD)	103 (12.54)	105 (14.04)	t=.30, p=.77
SRS t-score - Mean (SD)	82.57 (17.55)	39.82 (5.05)	t=-9.84, p<.001
ADOS severity - Mean (SD)	6.35 (2.66)	1.43 (.94)	t=-6.77, p<.001

Figure 1. Estimated Marginal Means for each speaker by word category, after controlling for the other speaker's word use in each category. Although there appears to be a main effect of diagnosis on the amount of family/friend words produced by interviewers, this effect does not reach statistical significance (independent samples t-tests revealed no statistically significant main effects of group in either category by interviewer or participant, all ps>.15).



88 **164.088** Fathers' and Mothers' Responsiveness and Broad Autism Phenotype Characteristics and the Language Skills of Children with ASD

M. Flippin[1] *and L. R. Watson*[2]*, (1)Communicative Disorders, University of Rhode Island, Kingston, RI, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Given that parent verbal responsiveness is strong predictor of later language outcomes for children with autism spectrum disorder (ASD), increasing parent responsiveness is a popular target of communication intervention for young children with ASD. However results of interventions to improve communication skills via increasing parent responsiveness have been mixed. Some communication interventions have been unsuccessful in improving either parent responsiveness or child communication skills, others have shown effects in increasing both parent responsiveness and child communication outcomes, whereas other interventions have been shown to improve parent responsiveness but not child communication skills. One proposed explanation for differences in treatment effect for parent-implemented social communication interventions is pre-treatment child characteristics (e.g., baseline cognitive, joint attention, imitation, communication skills). A less explored explanation for differences in treatment effect of parent-implemented social communication intervention may be parental pre-treatment characteristics. Compared to both parents of children who are typically developing and parents of children with other developmental disorders, parents of children with ASD are more likely to present with milder variants of the characteristics associated with ASD, known as the broad autism phenotype (BAP). Parents who demonstrate BAP characteristics with resulting difficulties in social and communication skills, may need more tailored supports to effectively deliver parent-implemented social communication interventions.
Objectives: This observational study examined the interactions of 16 young children with ASD and their mothers and fathers in order to investigate concurrent associations between parental verbal responsiveness and three characteristics of the parental broad autism phenotype (i.e., aloofness, rigidity, pragmatic language deficits), and child language skills.
Methods: Child language skills were assessed by the Preschool Language Scale- 4 (Zimmerman, Steiner & Pond, 2002). Parental BAP characteristics were measured with Broad Autism Phenotypes Questionnaire BAPQ (Hurley, Losh, Parlier, Reznick & Piven, 2006). Parent verbal responsiveness was coded from video recordings of naturalistic parent-child play sessions using interval-based coding.
Results: Fathers' BAPQ scores were not related to child language skills. Concurrent negative associations were found between child language skills and mothers' scores on two subscales of the BAPQ, (i.e., Aloof and Rigid). After accounting for maternal verbal responsiveness, mothers' scores on the Aloof subscale were no longer negatively associated with child language scores; negative associations between child language skills and mothers' scores on the Rigid subscale remained significant after controlling for maternal verbal responsiveness.
Conclusions: In this study, negative concurrent associations were found between child language skills and maternal scores on two BAPQ subscales (i.e., Aloof and Rigid). However, after controlling for maternal verbal responsiveness associations between aloof characteristics and child language skills were no longer significant, whereas negative concurrent correlations between Rigid Subscale scores and child language remained significant. These data warrant the investigation of pre-treatment parental characteristics in future observational research and research of parent-implemented social communication intervention for children with ASD.

89 **164.089** Gesture Development from 9 to 24 Months in Infants with Fragile X Syndrome, Infant Siblings of Children with Autism and Typically Developing Infants

L. Ragué[1]*, K. E. Caravella*[2]*, J. Klusek*[2] *and J. Roberts*[1]*, (1)Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC*

Background: Individuals with autism experience deficits in the realm of social communication. One important and early emerging aspect of social communication is gesture

use, an area shown to predict important later communication outcomes (Rowe, Özçalışkan, & Goldin-Meadow, 2008). Two populations at risk of developing autism and social communication deficits are individuals with fragile X syndrome (FXS; Kover & Abbeduto, 2010) and children who have an older sibling diagnosed with autism (ASIB; Yirmiya et al., 2006). Characterizing gesture development is an important first step in identifying the best approach to intervention in these populations.
Objectives: Identify developmental trajectories of gesture use in infants with fragile X syndrome and infants with an older sibling with autism contrasted to typically developing infants.
Methods: The sample includes 80 males recruited through two longitudinal studies conducted at UNC-Chapel Hill and at the University of South Carolina. Participants included 31 infants with FXS, 25 ASIBs and 24 TD infants. The Visual Reception domain of the Mullen Scales of Early Learning (MSEL) was used as a measure of nonverbal ability, and the Early Gesture score on the MacArthur-Bates Communication Development Inventory (CDI) was used as a measure of gesture use. The MSEL and the CDI were collected at 9, 12 and 24 months of age.
Results: A growth model was run with time centered at 24 months to determine whether rates of gesture development differed between groups, controlling for nonverbal ability. Analyses indicated that at 24 months, infants with FXS have developed, on average, about 4 less gestures than TD infants (β=-4.29, p=0.00), while ASIB infants have developed about 3 less gestures than TD infants (β=-2.94, p=0.01). All three groups increased in the number of gestures used over time (β=0.46, p=0.00). The rate of increase did not differ between the TD and FXS groups (β=0.15, p=0.07) or between the TD and ASIB groups (β=-0.12, p=0.12).
Conclusions: FXS and ASIB infants both demonstrate fewer gestures used by 24 months than TD infants. The rates of gesture development in these two high-risk groups do not differ from the rate of gesture development in TD infants. Therefore, while FXS and ASIB infants are delayed, they are still gaining gestures at a similar rate as TD infants in their first two years of life. These findings suggest that targeting gesture use before 24 months for these high-risk groups may improve their chances of demonstrating gesture use consistent with typical development at later time points.

90 **164.090** Idioms As a Measure of Pragmatic Language Abilities in Adolescents with Autism Spectrum Disorders

A. Canfield *and I. M. Eigsti, University of Connecticut, Storrs, CT*

Background:
Individuals with autism spectrum disorders (ASD) have well-documented deficits in pragmatic language, such as narrative production and use of idiosyncratic language; however, few studies have examined comprehension of idiomatic expressions in ASD. (e.g., *spilled the beans*). While clinicians and parents of children with ASD often cite idiomatic expressions as an area of weakness, studies of idiom comprehension have found that, in the absence of significant structural language deficits, children with ASD tend to perform similarly to their peers with typical development (TD) peers in defining idioms.
Objectives:
Our objective was to study the comprehension of idioms in ASD as a means of understanding the pragmatic language deficits associated with the disorder. We compared idiom definitions produced by adolescents with TD and ASD using standardized testing, quantitative methods (i.e., coding) and through the use of quality ratings from naïve readers.
Methods:
Participants were adolescents with ASD (diagnoses confirmed by ADOS, n = 13) with a history of language delay but functioning in the average cognitive range and TD (n = 12). Groups did not differ on chronological age, gender, and full scale IQ. Participants completed the "Figurative Language" subtest of the Test of Language Competence (TLC), where they were asked to interpret an idiom used in context (i.e., "Situation: A boy talking about his girlfriend. Expression: She is easily crushed."). Participants also read several common American idioms in isolation (*turn a corner*, *swim against the tide,* etc.) and were asked to define their meaning. Their responses were transcribed and coded for: 1) accuracy, 2) focus on literal definition, and 3) whether an example was included. The transcribed definitions were rated by 10-12 college students, naïve to diagnosis and study hypotheses, for *goodness* and *accuracy*.
Results:
The ASD group scored lower than the TD group on the TLC Figurative Language subtest (i.e., idioms used in context; $F(1, 23) = 6.44$, $p < 0.02$, $h^2 = 0.22$). Scores on the experimental idiom task did not differ (p's > 0.22) on any of the coding measures (i.e., how accurate or literal the definition was, whether an example was used in the definition), indicating that the groups were similarly able to define idioms when presented in isolation, rather than in context. Furthermore, naïve readers were unable to detect differences between the ASD and TD definitions (p's > 0.38), a notable result given that naïve readers have been shown to detect differences between ASD and TD in narrative quality.
Conclusions:
For idioms presented and defined in isolation, adolescents with ASD and TD produced similar idiom definitions, according to quantitative coding and quality ratings from untrained raters. However, when asked to interpret the meaning of idioms in the context of a social situation, adolescents with ASD performed significantly worse than their peers. This indicates that deficits in idiom comprehension likely reflect social deficits rather than language or word knowledge deficits. Interventions that teach idiomatic expressions should emphasize the use of idioms in context, rather than in isolation, to most effectively impact pragmatic language use.

92 **164.092** Joint Attention and Language in Children with ASD and Typical Development

E. F. Geib[1]*, K. J. Hamilton*[1,2] *and B. Wilson*[1]*, (1)Clinical Psychology, Seattle Pacific University, Seattle, WA, (2)Seattle Pacific University, Seattle, WA*

Background:
Children with autism spectrum disorders (ASD) exhibit language impairments when compared to their typically developing (TD) peers (APA, 2013; Tager-Flusberg, 2000). Children with ASD tend to develop language along an atypical pattern often acquiring expressive language before receptive language (Charman, 2003). Preliminary research suggests that joint attention serves as protective factor against language impairments in children with ASD (Bates, 1979; Charman, 2003; Mundy, Sigman, & Kasari, 1990). Mundy and Gomes (1998) found that the initiation of joint attention uniquely related to expressive language while responsivity to joint attention related to receptive language. In children with ASD, joint attention significantly correlated with expressive and receptive language (Charman, 2003). Murray et al. (2008) found that responsivity to joint attention uniquely related to receptive language. The language children gain in moments of joint attention may represent an important factor for social and cognitive development for children with ASD.
Objectives:
The purpose of our study was to examine language ability profiles in relation to children's joint attention skills during a parent-child reading task. We hypothesized children with ASD who engaged in increased moments of joint attention would display receptive language abilities similar to their TD peers.
Methods:
Our analysis included 85 children ages 3:1 to 6:11 and their parents. Forty-five children were diagnosed with ASD and forty were typically developing. Subjects were recruited from local preschools, elementary schools, and autism treatment clinics. Language ability was assessed by the Differential Ability Scale-II (Elliot, 2007) and joint attention was assessed through a coded parent child reading task (Vo, 2011).
Results:
A mediation analysis was conducted using PROCESS (Hayes, 2013) to examine the indirect effects of developmental status on receptive language ability through joint attention. Developmental status significantly correlated with receptive language, r = -.328, p = .002, but not expressive language, r = -.155, p = .156. Developmental status negatively related to joint attention, $t(85)$= -3.852, p < .001) and significantly predicted receptive language ability while controlling for developmental status ($t(85)$= 3.004 p = .004). The direct effect of status on receptive language ability while controlling for joint attention, $t(85)$= -1.877, p = .064) represented a trend toward significance. The Sobel test (z_{ab} =-2.32, p = .02) supports joint attention as a mediator between developmental status and receptive language ability; however, a bootstrap confidence interval (95%) using 1,000 bootstrap samples (-12.87, 0.38) included zero. Therefore, these results may not support that the full mediation, but nonetheless provide data for further implications of the relation between joint attention and language development in children with ASD.
Conclusions:
The acquisition of joint attention skills is a significant predictor of language development in children with ASD. Our results support past findings regarding the complexity of language ability in children (Tager-Flusberg, 2000). In terms of language profiles, joint attention is uniquely related to receptive language. More specifically, these results support the role of joint attention to support receptive language development in children with ASD.

93 **164.093** Language Abilities at the Age of 36 Months in Children at Risk for Autism Spectrum Disorder

E. Bruyneel*, P. Warreyn, E. Demurie, M. Dereu, S. Van der Paelt and H. Roeyers, Ghent University, Ghent, Belgium*

Background:
Research shows that language problems are highly prevalent in children with autism spectrum disorder (ASD). The profile of language problems, however, is variable across children and changes with age. Almost all children with ASD show significant difficulties in pragmatics. On the contrary, only some children with ASD show difficulties regarding vocabulary and grammatical language skills. Language ability is a critical element in the overall development and quality of life of individuals with ASD. Furthermore, the quality of early language and speech development is highly predictive of adult outcome. Younger siblings of children with ASD have a higher risk of developing the disorder themselves, a mild expression of the disorder and/or other developmental problems such as delayed language development or atypical general development. It is therefore important to investigate possible language problems and their locus in high-risk siblings.
Objectives:

The aim of the current study was to systematically investigate language at 36 months in children at high and low risk for ASD by looking into different linguistic levels of language.
Methods:
Younger siblings of children with ASD (high-risk siblings, n = 58) and typically developing children (low-risk siblings, n = 65) are followed as part of a larger longitudinal study. Preliminary analyses were conducted with a subsample of 17 high-risk siblings and 16 low-risk siblings. At 36 months expressive and receptive language abilities were assessed using the Dutch version of the Reynell Developmental Language Scales (RTOS). Scores for the different linguistic levels were acquired by combining item scores on the RTOS. Regarding receptive language, scores were obtained for three linguistic levels: lexicon, syntax and semantics. Concerning expressive language, scores for six linguistic levels were calculated: lexicon, morphology, syntax, semantics, pragmatics and grammar (morphology and syntax).
Results:
High-risk siblings showed similar age equivalents when compared to low-risk siblings on receptive, expressive and total language as measured by the RTOS. Nonetheless, differences were found at linguistic level. High-risk siblings scored significantly lower on lexicon ($U = 58.5$, $p = .004$) and syntax ($U = 81.5$, $p = .049$) in receptive language and on lexicon ($U = 74.0$, $p = .043$) in expressive language.
Conclusions:
At the age of 36 months language abilities of high-risk siblings were in general similar to language abilities of low-risk siblings. Despite similar general language scores, high-risk siblings did show significantly lower scores with regard to lexicon (receptive and expressive) and syntax (receptive). It seems to be important to look at the language abilities of high-risk siblings in detail as difficulties might be missed otherwise. In contrast to what was expected from the literature no significantly lower scores were found for pragmatics and semantics. Results of an extended sample of low-risk and high-risk siblings as well as the diagnostic outcome of the latter group will be presented at the conference.

94 **164.094** Linking Language: Characterizing Developmental Traits in Preschoolers with ASD

K. Berry[1], *J. Panganiban*[2], *W. I. Shih*[3] *and C. Kasari*[4], *(1)UCLA, Los Angeles, CA, (2)University of California Los Angeles, Arcadia, CA, (3)UCLA, Monrovia, CA, (4)University of California Los Angeles, Los Angeles, CA*

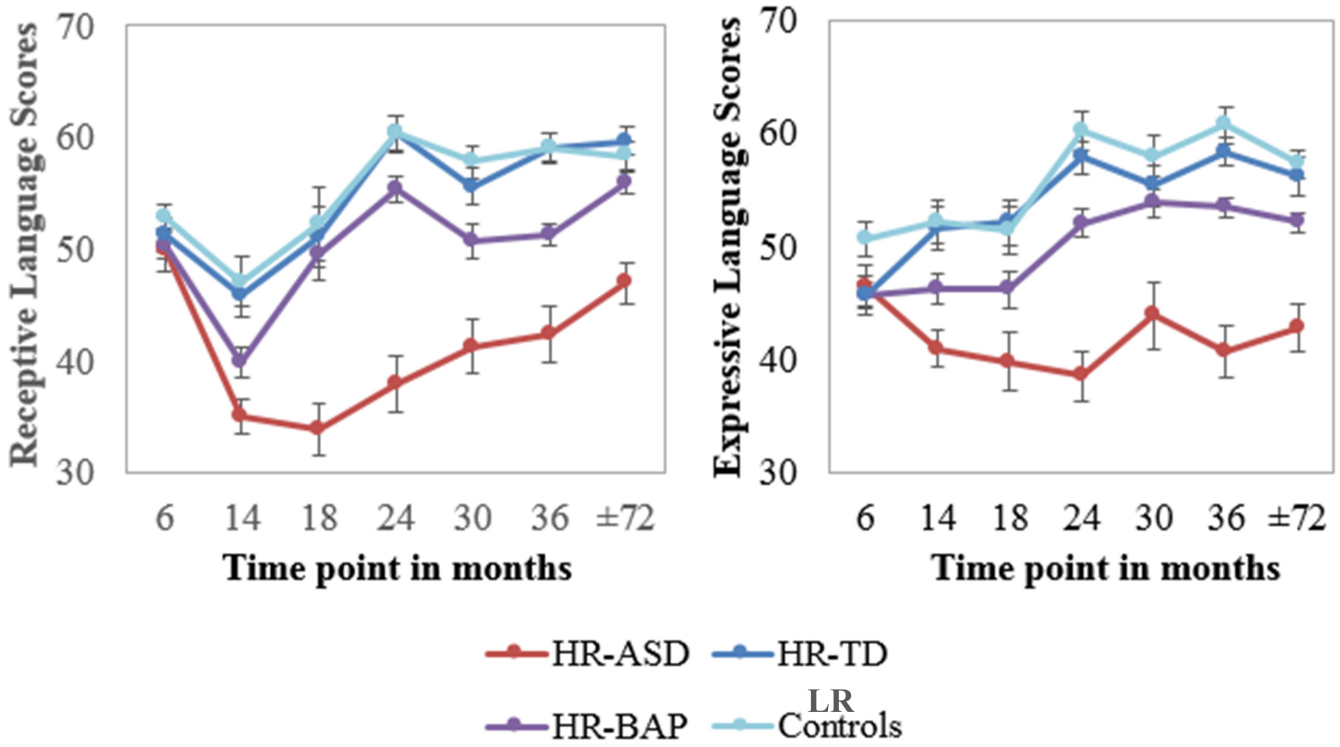
Background: Children with autism spectrum disorders (ASD) are characterized by marked impairment in communication. It is estimated that as much as 30% of children with ASD remain minimally verbal, even after receiving intervention.
Objectives: The goal of this study is to examine developmental characteristics of verbal and minimally verbal children with ASD between the ages of 2 and 5.
Methods: Eighty- five children between 24 and 63 months old (M= 46 mos.) diagnosed with ASD were included in this study. All participants completed a battery of experimental and developmental assessments such as the Mullen Scales of Early Learning to measure cognitive functioning, the Early Social Communication Scale which measures social communication and the Structured Play Assessment which is coded for spontaneous play acts. Participants were identified as minimally verbal based on their language produced during the ADOS (less than 5 words spoken). The groups were compared to examine developmental characteristics associated with expressive language group designation.

Results: Of the 85 children included in the sample 33 (39%) were identified as minimally verbal. Results indicate that the minimally verbal group is significantly lower in their overall DQ (p<.001), initiations of requests (p= .001), chronological age (p= .001), symbolic play types (p= .006) and frequency of symbolic play acts (p= .012). Surprisingly, initiations of joint attention gestures (IJA), excluding joint attention language, in the verbal group (M = 5.88) and minimally verbal group (M = 4.57) did not differ significantly.
Conclusions: These findings highlight several important factors in studying young, minimally verbal children with ASD. As expected, minimally verbal children with ASD scored lower on cognitive measures and were younger in age. Because younger children would be expected to be minimally verbal, these children should likely be considered preverbal. Longitudinal follow up data are critical to determine if younger preverbal children acquire spoken language or if there are particular characteristics that place them at high risk for remaining minimally verbal. Finally, contrary to expectations, minimally verbal children with ASD exhibited comparable levels of IJA gestures compared with their verbal counterparts. Considering the important role of social communication skills, such as IJA, in language acquisition, these data require further investigation.

95 **164.095** Longitudinal Predictors of Receptive and Expressive Language Outcomes at 6 Years in Younger Siblings of Children with ASD

R. Landa[1] *and K. J. Greenslade*[2], *(1)The Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD*

Background: During the second and third years of life, younger siblings of children with ASD have a higher risk of developmental difficulties, including reduced receptive and expressive language abilities.
Objectives: To explore receptive and expressive language functioning in younger siblings of children with ASD, at school-age, and to identify early predictors of these outcomes.
Methods: Receptive and expressive language performance in 157 younger siblings of children with ASD (high risk, HR) and 33 low risk (LR) controls were assessed at least once between 4 and 12 years of age, using the *Test of Language Development* (*TOLD*), and at least once between 6 and 36 months (6,14,18,24,30, and/or 36 months), with the *Autism Diagnostic Observation Schedule* (*ADOS*; Lord et al., 2002, 2012) and *Mullen Scales of Early Learning* (*MSEL*; Mullen, 1995). Based on the 36-month assessments, siblings were subgrouped into ASD (HR-ASD, n=39), broad autism phenotype (BAP) (HR-BAP, n=73), and typically developing (HR-TD, n=45). The three HR groups and LR group were compared at each time point between 6 and 36 months, and the time point closest to 72 months (±72months). Analyses also examined predictive relationships with the *ADOS* and *MSEL*.
Results: Analyses of variance (ANOVAs) with the 3 HR groups and LR group revealed no significant differences at 6 months. ANOVAs at each subsequent time point revealed significant between-group differences (all p's<.001). LR and HR-TD groups did not differ significantly on receptive or expressive language scores at any time point. In contrast, after 14 months, the HR-ASD group consistently demonstrated significantly lower receptive and expressive language than the HR-TD group (p's≤.002). The HR-BAP group also demonstrated significantly lower receptive language at 14,24,30,36, and ±72 months (p's ≤.04) and expressive language at 14,18,24,36, and ±72 months (p's≤.04) in comparison with the HR-TD group. To examine early predictors, multiple linear regression models were generated for receptive and expressive language outcomes at ±72 months, using *ADOS* Communication+Social scores and *MSEL* Expressive Language scores at 24 months as predictors. The predictors accounted for a significant amount of variance in receptive and expressive language scores at ±72 months, p<.001. Both predictors had a unique effect on receptive language (positive for *MSEL*, p<.001; negative for *ADOS*, p=.03) and on expressive outcomes (positive for *MSEL*, p<.001; negative for *ADOS*, p<.01).
Conclusions: Younger siblings of children with ASD as a group are susceptible to reduced receptive and expressive language functioning compared to LR children. However, this susceptibility manifests differently based on 36-month diagnostic status: children meeting ASD or BAP criteria have the highest susceptibility to later lower language functioning. *ADOS* Communication+Social scores and *MSEL* Expressive Language scores at 24 months appear to be predictive of later language outcomes.



96 **164.096** Longitudinal, Cross-Modal Associations Appear to Differ in Typically Developing Toddlers As Compared to Children with ASD

K. Bottema-Beutel[1], *T. Woynaroski*[2] *and P. J. Yoder*[3], *(1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Vanderbilt University, Thompsons Stn, TN, (3)Vanderbilt University, Nashville, TN*

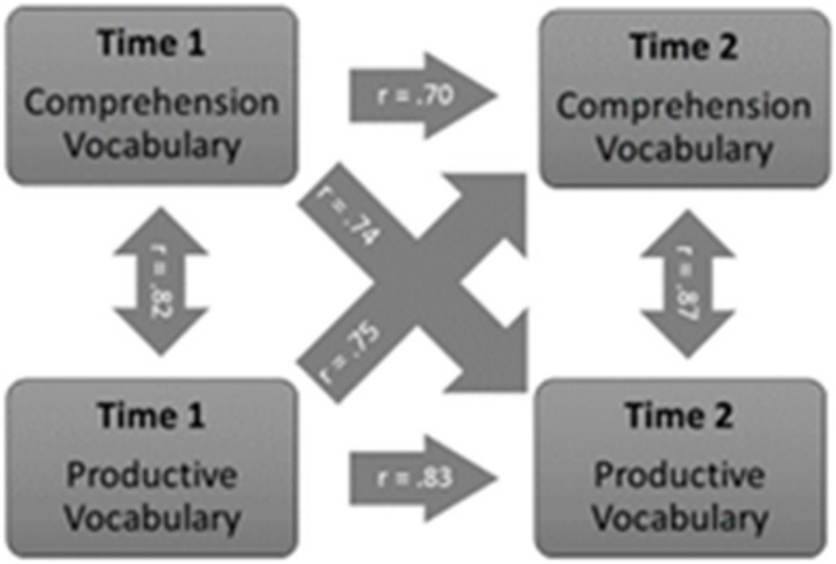
Background:
Recent research has found evidence that expressive language "drives" later receptive language in young, minimally verbal children with autism spectrum disorder (ASD) (Woynaroski et al., 2015). This result was interpreted as "atypical" because receptive language is presumed to drive expressive language in typically developing (TD) children. This assumption regarding what constitutes "typical" language development, however, rests largely on findings from descriptive research. For example, TD children have been observed to understand words before they are able to produce words and, at any given point in time, to have a larger receptive vocabulary than expressive vocabulary (e.g., Benedict, 1979). However, cross-modal longitudinal associations between expressive and receptive language in TD children have not been explicitly tested. Doing so would help researchers understand how the developmental trajectory found in ASD differs from typically developing children.
Objectives: To compare the cross-modal, longitudinal associations between expressive and receptive vocabulary in mental-age-matched TD toddlers and in young children with ASD who participated in Woynaroski et al. (2015).
Methods:
Participants included 62 TD toddlers with an average mental age equivalent of 14.4 months as assessed by the Mullen Scales of Early Learning. Parent-reported vocabulary was assessed at two time points, eight months apart, via the MacArthur Bates Communicative Development Inventories (MCDI) vocabulary checklist. Receptive and expressive vocabulary sizes were operationalized as the raw number of words that parents reported their children "understood" and "said", respectively. Missing data was handled using multiple imputation. . In making the cross-lagged comparison, this statistic takes into account concurrent associations across modalities and longitudinal associations within each language modality. We descriptively contrast our current results to Woynaroski et al.'s (2015) report on an ASD sample (n= 87), whose mental age equivalent was similar to the existing sample. Data collection and analysis procedures in the present study were identical to those employed by Woynaroski and colleagues.
Results: Cross-lagged, cross modal associations were high for both early receptive language to later expressive language (r = .74), *and* early expressive language to later receptive language (r = .75) for our TD sample. The difference in cross-lagged, cross-modal correlation magnitudes was not statistically significant (ZPF = -0.17, p= 0.87; See Figure 1). Table 1 juxtaposes results with the previously reported ASD sample.
Conclusions: This study provides added support for Woynaroski et al.'s interpretation of an "expression driven" profile observed for children with ASD as "atypical." Surprisingly, we did not find evidence that receptive language drives expressive language for TD children, as has previously been theorized. Unlike children with ASD, TD children experience a bi-directional effect of reception and expression. Further research is needed to tease apart divergent developmental trajectories in these two groups.

Table 1

Zero-order Correlations (Pearson's r), Test Statistic, and p Value for the Cross-lagged Panel Comparisons of the Associations between Early to Late Comprehension and Production Vocabulary for Typically Developing Children

Association		TD Sample Panel	ASD Sample Panel (Woynaroski et al., 2015)
Early Comprehension and Later Production		**.74*** **	**.42*** **
Early Comprehension and Early Production		.82***	.58***
Early Comprehension and Later Comprehension		.70***	.83***
Early Production and Later Production		.83***	.80***
Later Comprehension and Later Production		.87***	.53***
Early Production and Later Comprehension		**.75*** **	**.57*** **
	ZPF	-.17	-1.94
	p	.87	.05

Note. Scores are raw MCDI scores presenting size of comprehension and production vocabulary. Bolded coefficients are for associations of primary interest. ZPF is the test statistic for the difference between the nonindependence-adjusted partial correlations. For zero-order correlations, * p < .05, ** p < .01, *** p < .001.



Note. Coefficients are zero-order correlations.

Figure 1. Typically developing children do not show the atypical cross-modal profile that we have previously seen in a mental-age matched sample of children with autism spectrum disorder.

97 **164.097** The Relationship Between Joint Attention and Language in Autism Spectrum Disorder and Typical Development: A Systematic Review and Meta-Regression Analysis

***K. Bottema-Beutel**, Lynch School of Education, Boston College, Chestnut Hill, MA*

Background: Research has shown that joint attention plays a crucial role in the development of expressive and receptive language. However, joint attention is a complex construct, and the relative correlations of all different types on development have not been sorted out. In children with autism spectrum disorder (ASD), parsing the impacts of of joint attention is especially important, as joint attention delays negatively impact language development. This study used a structured literature search and meta-regression procedures to synthesize Pearson's *r* effect sizes measuring correlations between joint attention and language in typically developing (TD) children and children with ASD.
Objectives: To determine: 1) summary associations between joint attention and receptive and expressive language, for TD and ASD children, 2) whether diagnostic group moderates effect sizes, 3) whether joint attention type moderates effect sizes, and 4) which moderators maintain significance when significant moderators from simple meta-regressions were entered together.
Methods: Studies were located using database searches, hand searches, and electronic requests for data from approximately 200 experts in the field. The search resulted in 71 reports or datasets and 605 Pearson's *r* effect sizes, representing 1,859 participants with ASD and 1,835 TD participants (see Table 1 for sample and study characteristics). Robust variance estimation was used to account for clustering of effect sizes within studies. Meta-regression was used to answer research questions

regarding potential moderators of effect sizes. Joint attention types were categorized into initiating joint attention, responding to joint attention (RJA), coordinated attention, supported joint engagement, and coordinated joint engagement.
Results: Summary effect sizes collapsed across joint attention types varied by diagnostic group and language outcome (receptive language, $r = .27$ and $r = 43$ for TD children and children with ASD respectively; expressive language, $r = .22$ and $r = .45$ for TD children and children with ASD respectively). Meta-regression analyses indicated that effect sizes were significantly higher for the ASD group as compared to the TD group, and for RJA as compared to non-RJA joint attention types for both expressive and receptive language. Approximate mental age trended toward significance for expressive language, even after controlling for diagnosis and RJA (see Table 2 for full results of regressions).
Conclusions: Joint attention may be more tightly tied to language in children with ASD as compared to TD children because TD children exhibit joint attention at sufficient thresholds so that language development is a 'sure thing' and untethered to variations and joint attention. Conversely, children with ASD who exhibit deficits in joint attention develop language contingent upon their joint attention abilities. Because RJA was more strongly related to language than other types of joint attention, future research should consider carefully the operationalization and measurement of joint attention constructs. The results of this meta-analysis support intervention approaches that facilitate joint attention as a means to improve language outcomes in children with ASD.

Table 1

Means and standard deviations for continuous variables by diagnostic group and language variable

	ASD		TD	
	Expressive	Receptive	Expressive	Receptive
% male	81.16 (16.20)	80.52 (19.28)	47.75 (10.23)	52.03 (6.27)

98 **164.098** Mobile Technology Usage By the Other Numbers: User Analytics for Assessing and Justifying Implementation of Mobile Applications

M. G. Zentner, *Information Technology, Purdue University, West Lafayette, IN*

Background:
Internet based businesses routinely collect data regarding customer behavior in order to exploit such behavior to expand their business. However, such companies also use these data to understand their effectiveness in serving their customers. The translation of research efforts in autism technology demands these same types of user analytics as rationale for those who would invest in and seek to promote the commercial enterprises that are essential for the translation of such research into practice. Translation necessitates the confluence of at least 4 key elements: societal recognition of a problem, a common understanding of the economics involved in addressing the problem, proof that delivery of a solution to the problem is accepted in the marketplace, and protectable intellectual property that allows an enterprise to recover the costs of translating the research into practice in the market.
Objectives:
The objectives of our activity are to address the double bottom line problem: how to translate research into practice in a manner that is economically feasible and

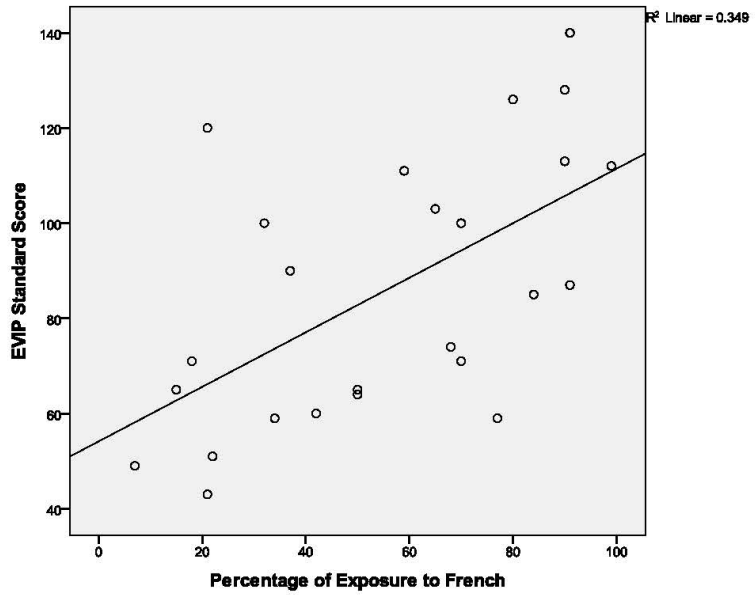
simultaneously provides societal benefit. The former activity is addressed by assessing the societal value of delivering more effective mobile technology solutions to the population affected by autism, while the latter focuses on measuring the degree to which this activity has the potential for impact.
Methods:
Autism tools created for today's popular tablet architectures (e.g. iOS, Android) can be fitted with common usage analytics collection tools (e.g. Google Analytics) as a first order usage information collection mechanism. We illustrate this scenario using an application for augmentative and alternative communication (AAC) training in minimally-verbal autism: The SPEAKall!® tablet application was instrumented with the Google analytics package to begin measurement of the communication activities performed by the population using SPEAKall!. This instrumentation allows the collection of usage patterns from a large population of AAC users, which is distinct from the assessment of individual effectiveness in and immediately after therapy delivery sessions. While collecting such usage patterns does not suffice as evidence for the effectiveness of a therapeutic approach, it does demonstrate the market acceptance and employment of an approach in practice, and is a completely objective measure of mobile technology usage intensity.
Results:
We present results of a population of users with autism using the SPEAKall! application instrumented with usage analytics. Specifically, we examine the difference in usage behaviors between those who receive free applications versus those who pay for the application. We also review the intensity of usage across the user population by studying the length of messages produced with the AAC solution. Further, we examine vocabulary growth by studying the degree to which users create new symbol vocabulary for use in their AAC applications. Finally, we also present a study of session length that provides a view into the frequency and timespan of user interaction with the AAC tool.
Conclusions:
Analytic collection tools can be used to track detailed usage of nearly all application features and provide a population based view of how mobile applications are used in intervention.

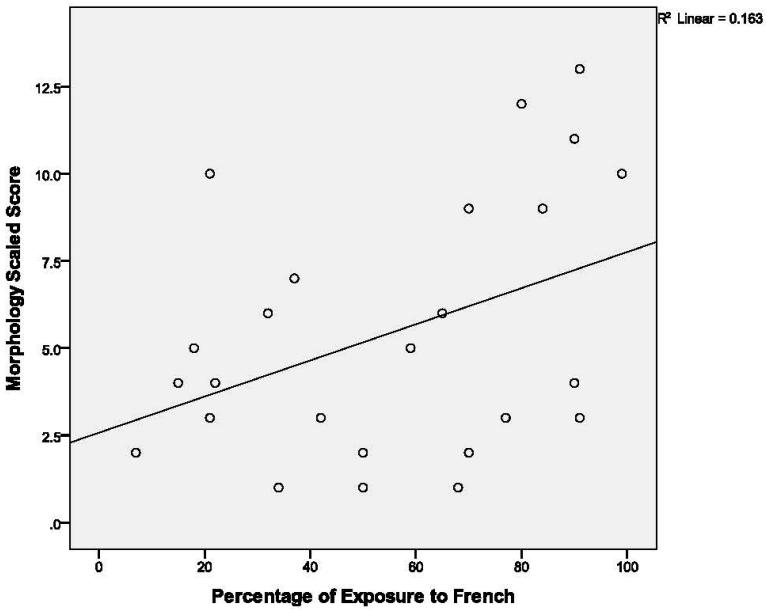
99 **164.099** Multilingual Language Environments and ASD: Relationships Between Amount of Language Exposure and Language Proficiency

A. M. Gonzalez Barrero *and A. Nadig, McGill University, Montreal, QC, Canada*

Background: It is commonly thought that children with communication disorders should only be exposed to one language, though research does not indicate additional language delays from bilingual exposure (e.g. Ohashi et al., 2012). To gauge the impact of bilingual environments on language development in Autism Spectrum Disorders (ASD), it is critical to understand the relationship between amount of language exposure and language proficiency**.** A recent study found that expressive vocabulary (by parent report) in the second language was highly correlated with the amount of recent exposure to that language in bilingual children with ASD (Hambly and Fombonne, 2014), suggesting that children with ASD learn a 2nd language when given adequate exposure. However, relationships between exposure and proficiency in different language domains (e.g., vocabulary, morphology, sentence repetition) for children with ASD in bilingual environments have not been studied.
Objectives: We examine relationships between amount of language exposure and language proficiency in children with ASD with varying degrees of exposure to French via direct assessment on standardized measures. Based on Hambly and Fombonne (2014) we hypothesize that amount of exposure to the target language will be highly correlated with proficiency in that language. We explore the relationship between amount of exposure and two previously unstudied expressive language skills: morphology and sentence repetition, as well as receptive vocabulary.
Methods: Twenty five 5- to 10-year-old children with ASD were included. Participants were exposed to varying amounts of French throughout their lifetime, ranging from French monolinguals to balanced bilinguals in French and another language (English or Spanish). Parents completed a detailed language exposure questionnaire. Following Thordardottir's (2011) methodology, each child was classified in one of five French exposure groups (e.g., 0-20%, 80-100%). Across these 5 groups children were matched on nonverbal IQ, chronological age and socio-economic status (via maternal education). Language proficiency was assessed using the morphology and sentence repetition sub-tests of the French version of the Clinical Evaluation of Language Fundamentals (CELF-4; Semel et al., 2003). Vocabulary was evaluated through the French version of the Peabody Picture Vocabulary Test (*EVIP*; Dunn, Theriault-Whelan, & Dunn, 1993).
Results: Groups did not differ significantly on nonverbal IQ (p=.18), chronological age (p=.85) or SES (p=.08). We found marginally significant correlations on the expressive language measures of morphology (r=.40, p=.045) and sentence repetition (r=.39, p=.056). A strong, significant correlation was found for receptive vocabulary (r=.59, p=.002).
Conclusions: We found correlations between language exposure and proficiency on a range of standardized measures. As reported for typical development (e.g., Pearson et al., 1997), amount of language exposure was not perfectly correlated with language skills and other factors play a role, especially for expressive language. Some children who had low levels of exposure to the target language still performed in the normal range on language measures. Additional analyses will explore relationships between exposure and both parent and observer-rated proficiency in French. These results support previous findings suggesting that children with ASD acquire two languages when provided with optimal opportunities to do so.

Figures



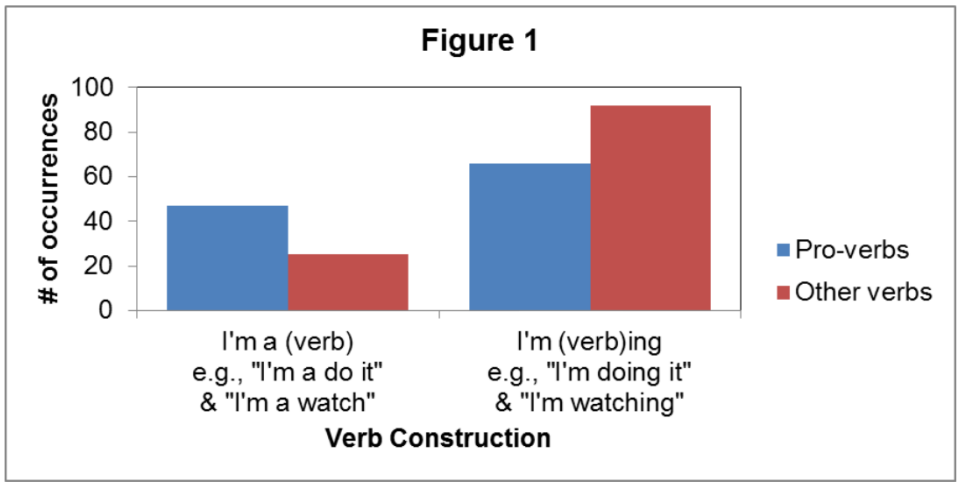


100 **164.100** Neologisms: A Case Study

N. N. Soja[1]*, M. S. Goodwin*[2] *and L. Naigles*[3]*, (1)Health Sciences, Northeastern University, Boston, MA, (2)Northeastern University, Boston, MA, (3)University of Connecticut, Storrs, CT*

Background: Children with Autism Spectrum Disorder (ASD) use neologisms (i.e., invented words or phrases) more frequently and more persistently than typically developing children (Volden & Lord, 1991). This unusual prevalence suggests a value to these made-up expressions and thus justifies and motivates the clarification of their function. One such neologism was found by Chin (2013) from a child, Audrey, with high-functioning ASD. Audrey said "I'm a (verb)," as in "I'm a watch," 72 times with 26 different verbs. Chin and colleagues (Chin et al., 2012, 2013) conjectured that the frame referred to the future, demonstrated that it was unattested in her input, and documented that it had mostly disappeared by the end of the study; however, the exact meaning of the frame is still unclear, as was Audrey's purpose in producing it.
Objectives: We investigated whether Audrey's "I'm a" frame was an alternative form of an existing expression by examining its privileges of occurrence relative to her future and present frames.
Methods: Audrey was a participant in the Speechome Project, which collected densely-sampled, high-quality audio-video recordings in homes during normal activities over four months (Vosoughi et al., 2012). At the time of the study, Audrey was 2;10-3;1, with a Mean Length of Utterance range of 2.2-3.5. Audrey's utterances of "I'm a (verb)" were compared with her uses of a conventional future frame ("I'm gonna (verb)") and a conventional present frame ("I'm (verb)ing"), as follows. First, her uses of "I'm a" and "I'm gonna" were coded as 'present' if they overlapped with their referent event or occurred within 30 seconds of it, because of children's difficulty with the boundaries of 'present'

(Harner, 1980). Referent events occurring more than 30 seconds later were coded as 'future'. Implications of this criterion are discussed further in the results. Second, her utterances of "I'm a (verb)" and "I'm (verb)ing" were coded according to the verbs they appeared with. Verbs were categorized as Pro-verbs (i.e., the verbs that children use first with multiple verb inflections: "go," "do," "make," "get," "eat," "sit," "ride," and "fix"; Bloom et al., 1980), or Other verbs (all others).
Results: (1) All but 1 of Audrey's uses of "I'm a" were produced in the context of 'present' activities, whereas 15 of 73 instances of "I'm gonna" referred to the future (chi2=12.12, p<.001). Moreover, those 15 cases of "I'm gonna" were not boundary cases, but referred to events happening in the distant future (e.g., bed time). (2) Audrey used "I'm a" more often with Pro-verbs, but "I'm (verb)ing" (N=158) more often with Other verbs (Figure 1, chi2=10.93, p<.001).
Conclusions: Audrey's usage of "I'm a" differed from both her use of the conventional future frame "I'm gonna" as well as of the conventional present frame "I'm (verb)ing". Thus, it does not appear to be an alternative form of either one, but possibly a wholly distinct construction. We continue to analyze its semantic/syntactic properties, as well as the contributions from Audrey's emotional state and cognitive demands, to discover just why it emerged.



K. J. Greenslade[1] *and R. Landa*[2]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)The Kennedy Krieger Institute, Baltimore, MD*

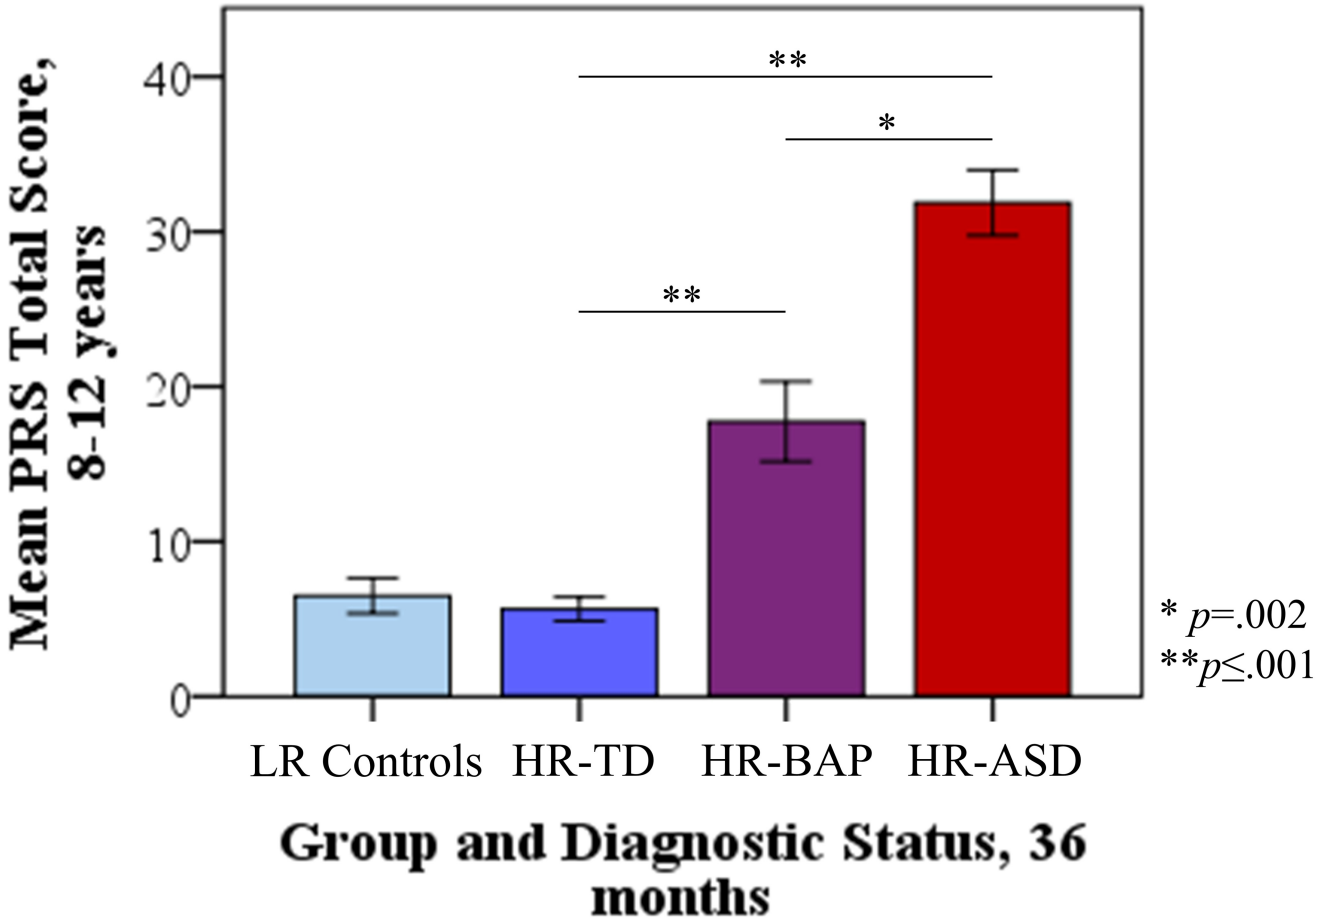
Background: Pragmatic language impairments are a hallmark of children with autism spectrum disorder (ASD; Simmons et al., 2014), and are sometimes observed in their parents (Hurley et al., 2007; Landa et al., 1992) and younger siblings (Ben-Yizhak et al., 2010; Miller et al., 2015). Limited research has examined predictors of later pragmatic language functioning (Gillespie-Lynch et al., 2015).
Objectives: To examine pragmatic language abilities in school-aged siblings of children with ASD, and identify early predictors of these abilities.
Methods: Between 8 and 12 years of age, 34 younger siblings of children with ASD (high-risk, HR) and 10 low-risk (LR) controls were assessed with the *Pragmatic Rating Scale–School-Age* (*PRS-SA*; Landa), scored based on behaviors observed during the *Autism Diagnostic Observation Schedule* (*ADOS*; Lord et al., 2002, 2012), Module 3 or 4. All participants also had been assessed at least twice between 14 and 36 months (14/18,24/30,and 36 months), with the *ADOS* and *Mullen Scales of Early Learning* (*MSEL*; Mullen, 1995). Based on 36-month assessments and clinical impressions, high-risk siblings were classified as ASD (HR-ASD,n=15), broad autism phenotype (BAP; HR-BAP,n=8), and typically developing (HR-TD, n=11). Nonparametric analyses compared *PRS-SA*scores across HR-ASD, HR-BAP, HR-TD, and LR controls; early predictors of later pragmatic language abilities were examined using Pearson's correlations and linear regression.
Results: A Kruskal-Wallis Chi-Square test revealed significant between-group differences in *PRS-SA* scores, $X(3)=33.28, p<.001$. Follow-up Mann-Whitney tests revealed:

- no significant difference between LR controls ($M=6.50, SD=3.60$) and HR-TD ($M=5.64, SD=2.58$), $Z=-0.57, p=.57$
- significantly lower (better) *PRS-SA* scores for HR-TD than HR-ASD ($M=31.87, SD=8.17$), $Z=-4.29, p<.001$, and HR-BAP ($M=17.75, SD=7.30$), $Z=-3.36, p=.001$
- significantly lower *PRS-SA* scores for HR-BAP than HR-ASD, $Z=-3.13, p=.002$.

Pearson's correlations were found between *PRS-SA* scores and 24-month:

- *ADOS* Communication+Social scores, $r=.60, p<.001, r^2=.36$.
- *MSEL* Receptive Language, Expressive Language, and Early Learning Composite scores, $r=-.60, p<.001, r^2=.36$; $r=-.51, p<.001, r^2=.26$; and $r=-.55, p<.001, r^2=.30$, respectively.

Linear regression analyses revealed that the *MSEL* Receptive Language score had a unique negative effect and *ADOS* Communication+Social scores had a unique positive effect on *PRS-SA* scores, ($b=-.35, SE=.15$), $t_{(36)}=-2.40, p=.02$ and ($b=.99, SE=.41$), $t_{(36)}=2.43, p=.02$, respectively. The model with both predictors accounted for a significant amount of variance in later pragmatic language functioning, $R^2=.45, F(2,39)=15.70, p<.001, R^2_{adjusted}=.42$.
Conclusions: The present data confirm poorer pragmatic language abilities in school-aged high-risk siblings with ASD and characteristics of the BAP, but not in siblings developing typically. These findings support recommendations to subdivide unaffected siblings into those who do and do not demonstrate BAP characteristics when examining pragmatic language (Ben-Yitzhak et al., 2011). Findings also suggest that autism-related social-communication and early learning abilities at 24 months are predictive of later pragmatic language functioning in high-risk siblings and low-risk controls. Continued investigation into the pragmatic language abilities of younger siblings of children with ASD and predictors of these abilities is warranted.



102 **164.102** Profiles of Pragmatic Language in Individuals with ASD and Their Parents

L. Bush[1]*, M. Lee*[1]*, N. M. Heckel*[1]*, A. Taylor*[1]*, A. L. Hogan-Brown*[2]*, G. E. Martin*[3] *and M. Losh*[4]*, (1)Northwestern University, Evanston, IL, (2)Psychology, University of South Carolina, Columbia, SC, (3)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (4)Department of Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Pragmatic (i.e., social) language abilities are universally impaired in individuals with autism spectrum disorder (ASD; Tager-Flusberg, 2002). Previous research indicates that parents of individuals with ASD may demonstrate subtle differences in pragmatic language that reflect genetic risk and comprise a component feature of the broad autism phenotype (BAP; Landa, 1991, 1992; Losh et al., 2008, 2012). This study aimed to build on these findings by examining parallel pragmatic language features in parents and children during semi-naturalistic conversation, using the Pragmatic Rating Scale (PRS; Landa, 1992) and Pragmatic Rating Scale-School Age (PRS-SA; Landa, 2011). We employed factor analyses in each sample to identify whether similar pragmatic language violations were observed in individuals with ASD and their parents. Further, we examined a range of potential phenotypic correlates in each group.
Objectives: To define potentially overlapping profiles of pragmatic language in individuals with ASD and their parents (with and without the BAP), and to explore correlated skills.
Methods: The PRS-SA and PRS consist of similar, operationally-defined pragmatic language features rated by blind coders from videotaped semi-structured conversational tasks (ADOS, and Life History Interview, respectively). To identify factors comprising pragmatic language characteristics of each group, Principal Component Analyses were completed on PRS-SA/PRS data from 53 school-aged individuals with ASD (IQ>80, age ≤19) and 186 parents of individuals with ASD. PRS-SA/PRS data were also included

from controls (22 children and 60 parents) to examine group differences and related correlates. Analyses controlled for differences in IQ and chronological age. Given prior research demonstrating links between social cognition and pragmatic language use (Losh & Piven, 2007), all participants completed a social cognition battery. BAP status was determined using the Modified Personality Assessment Scale (Tyrer, 1988).
Results: Findings indicated a two-factor model of pragmatic language in parents of individuals with ASD, characterized by Reserved and Dominant conversational features. A three-factor model emerged in individuals with ASD, which included nearly identical profiles as their parents plus an additional Disinhibited factor. Individuals with ASD scored significantly higher than controls and BAP+ parents scored significantly higher than BAP- and control parents across factors. In the ASD group, Reserved scores positively correlated with ADOS severity overall (r = .47) and social affect severity (r = .61), whereas Dominant (r = .54) and Disinhibited (r = .44) styles were positively associated with severity of restricted and repetitive behaviors. Finally, higher Dominant scores were negatively associated with social cognitive ability in parents and their children with ASD (rs > .3).
Conclusions: To our knowledge, this is the first study to employ factor analysis to identify overlapping pragmatic language profiles in individuals with ASD and their parents. Results suggest that qualitatively similar types of pragmatic language differences characterize ASD and the BAP, although these features are very subtly expressed in parents. Further, factors related to different aspects of ASD severity, and social cognition emerged as key correlates of pragmatic language across groups. Together, findings highlight pragmatic language as a valuable marker of genetic risk.

103 **164.103** Pronoun Interpretation Problems in Primary School-Aged Children with Autism Spectrum Disorder

J. Overweg[1]*, C. A. Hartman*[2] *and P. Hendriks*[1]*, (1)University of Groningen, Groningen, Netherlands, (2)University of Groningen and University Medical Center Groningen, Groningen, Netherlands*

Background: Personal pronoun reversal, i.e. saying *you* when meaning *I* and vice versa, is a well-known linguistic characteristic of children with Autism Spectrum Disorder (ASD). It is described as an idiosyncratic language problem in the DSM-5 diagnosis of ASD (American Psychiatric Association [APA], 2013). Pronoun reversals are viewed as manifest only in early development (Tager-Flusberg, 1994). However, Mizuno and colleagues (2011) showed that, in interpretation, even adults with high-functioning ASD have problems with personal pronouns and that these problems may be due to a failure in perspective-shifting between the roles of hearer and speaker.
Objectives: This study aimed to determine 1) whether primary school-aged children diagnosed with ASD show problems with pronoun interpretation in situations that require a perspective-shift and 2) which cognitive processes are needed to arrive at a correct interpretation of pronouns in these situations.
Methods: Forty-eight average functioning children with ASD and 43 typically developing (TD) children (age 6-12) participated in a larger study on language and communication in children with ASD. Clinical diagnosis of children in the ASD group was confirmed by the Autism Diagnostic Interview and/or Autism Diagnostic Observation Schedule. In a pronoun task children watched a short movie with three animals. An example of an item is: Pig whispered something in Frog's ear. After that Frog reported to Dog: "Pig said: 'You get the car'". The participant had to select the correct referent of *you*. To arrive at the correct interpretation of *you*, a perspective-shift is needed from the reporting context, where Dog is the referent of *you*, to the reported context, where Frog is the referent of *you*. In addition, cognitive tasks were administered to measure these children's Theory of Mind (ToM), cognitive inhibition, cognitive flexibility, working memory (WM), IQ and verbal ability.
Results: All children had problems interpreting pronouns in situations that required a perspective-shift. Whereas the TD children made less errors the older they were, the children with ASD did not show improved pronoun interpretation with age. An investigation of the cognitive processes involved in pronoun interpretation in perspective-shifting situations showed that, in all children, ToM, WM, IQ and verbal ability are needed for a better understanding of pronoun interpretation. Specifically for children with ASD, problematic pronoun interpretation was found to be related to second-order ToM understanding. Children with ASD with high second-order ToM understanding did not improve with age in pronoun interpretation, whereas TD children did.
Conclusions: Our findings suggest that primary school-aged children with ASD show a delayed development of pronoun interpretation. This delay seems to be due to problems with ToM. Our findings suggest that the pronoun interpretation problems in children with ASD should be seen as a perspective-taking problem in language, rather than an idiosyncratic language problem. Also, the pronoun problems in ASD should not be viewed as only manifest in early development, but in later development as well.

104 **164.104** Psychometric Properties, Classification, and Clinical Correlates of the Children's Communication Checklist – 2nd Edition in Autism Spectrum Disorder

J. Parish-Morris[1]*, A. de Marchena*[1]*, L. M. DePolo*[1]*, L. Bateman*[1]*, E. F. Ferguson*[1]*, K. J. Payton*[1] *and R. T. Schultz*[2]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The Children's Communication Checklist-2ndEdition (CCC-2; Bishop, 2006) is a widely used measure of structural and pragmatic language that has been shown to capture the social communication deficits of autism spectrum disorder (ASD). The CCC-2 is more sensitive to the pragmatic language impairments of ASD than the Test of Pragmatic Language (Volden & Philips, 2010), and distinguishes ASD from other disorders such as Attention Deficit Hyperactivity Disorder (Geurts et al., 2004) and Specific Language Impairment (Bishop, 2006). The CCC-2 consists of 10 subscales (A-J) of 7 questions each. Scales A-D measure structural language, E-H pragmatic language, and I-J behaviors specific to ASD. The General Communication Composite (GCC) and the Social Interaction Difference Index (SIDI) measure overall communication ability and special impairments not due to structural language problems, respectively. The original standardization sample from Bishop (2006) included just 62 participants with ASD, and internal consistency was not reported for any clinical population.
Objectives: Estimate the internal consistency of the CCC-2 scales in a large sample of individuals with and without ASD; provide descriptive data on CCC-2 performance in a subsample of ASD and TDC matched on age and race/ethnicity; determine the utility of the CCC-2 for classifying ASD, TDC, and Other (Rule Out ASD); assess relationships between CCC-2 scores and parent report/clinical observations of social impairment (Social Responsiveness Scale (SRS; Constantino, 2003) and ADOS calibrated severity subscores).
Methods: Parents/caregivers of children aged 6-18 provided CCC-2 data in the context of participation in several specific studies. Research reliable PhD-level clinicians classified children as having a diagnosis of ASD, Other (Rule Out ASD), or typical development (TDC). The analyzed sample consisted of 668 participants with summary scores; 473 with item-level scores, and 429 ASD/TDC matched on age, race, and ethnicity. Cronbach's coefficient alpha was used to estimate reliability and unidimensionality, logistic regression for classification; Pearson correlations assessed relationships to other parent/clinician ratings.
Results: Subscale reliability ranged from .62-.82 in the ASD group and .67-.83 in the Other group (Table 1). Estimated marginal means for subscale, GCC, and SIDI scores differed significantly between the ASD and TDC groups (Table 2). Logistic regression controlling for age, nonverbal and verbal IQ, sex, race, and ethnicity revealed a significant contribution of GCC to distinguishing ASD from TDC (Beta=-.27, p<.001), increasing sensitivity from 88% to 97% and increasing specificity from 46% to 94%; there was no classification benefit of the GCC for distinguishing ASD from Other. In all three groups, the GCC and SIDI correlated negatively with SRS scores (all ps<.05). The ADOS severity subscore for social affect correlated negatively with GCC in the ASD group and SIDI in Other (ps<.05). Correlations with the ADOS repetitive behaviors/restricted interests severity subscore were not significant.
Conclusions: The CCC-2 is a valuable tool for assessing pragmatic language in ASD, with most subscales and the GCC reaching internal reliabilities of >.7. The GCC distinguishes between ASD and TDC (but not ASD and Other), and correlates with clinician/parent measures of social impairment. 195 additional item-level sets will be included by May 2016.

Table 1. Cronbach's coefficient alpha for TDC, ASD, and Other (Rule Out ASD). Groups were not matched on age, sex, IQ, race, or ethnicity, so columns should interpreted independently. The current TDC group has lower subscale reliability than the original standardization sample, which may be attributable to different age ranges (6-18 vs. 4-16) and sample size.

	TDC (N=147)	ASD (N=264)	Other (N=62)
Scale A - Speech	0.68	0.80	0.83
Scale B - Syntax	0.26	0.82	0.80
Scale C - Semantics	0.48	0.71	0.74

105 **164.105** Rapid Automatized Naming As a Marker of Genetic Liability to Autism: An Eye Tracking Study

K. Nayar[1], *A. L. Hogan-Brown*[2], *C. La Valle*[3], *W. McKinney*[3], *P. C. Gordon*[4], *G. E. Martin*[5], *E. Norton*[3] *and M. Losh*[3], *(1)Northwestern University, Chicago, IL, (2)Psychology, University of South Carolina, Columbia, SC, (3)Northwestern University, Evanston, IL, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Communication Sciences and Disorders, St. John's University, Staten Island, NY*

Background: Rapid Automatized Naming (RAN) is a complex skill that indirectly measures the automaticity of cognitive and linguistic processes, associated with left hemispheric language and right cerebellar regions (Norton and Wolf, 2012). Evidence suggests that RAN is affected in autism spectrum disorder (ASD) and in the broad autism phenotype (BAP) among first-degree relatives (Losh et al., 2010; Hogan-Brown et al., 2014). Smaller eye voice span (EVS) (i.e., less lead in eye movement compared to speech) is associated with less fluent and automatized language processing in individuals with ASD and their siblings (Hogan-Brown, 2014). This study extends upon these findings by further examining eye movement during RAN in parents with and without the BAP, in addition to high functioning individuals with ASD. Comprehensive analyses of eye movements (e.g., EVS, saccades) in parents and individuals with ASD can provide fruitful clues into the automaticity and executive efforts exhibited during RAN and their genetic liability to ASD.

Objectives: To use eye tracking to examine underlying mechanistic processes of RAN abilities in individuals with ASD and their parents, and explore correlations with conceptually related clinical-behavioral phenotypes.

Methods: Fifty-five individuals with ASD, 43 controls, 136 parents of individuals with ASD, and 57 control parents completed RAN on an eye tracker. The RAN task involved quickly naming arrays of stimuli (letters, colors, numbers, objects). Naming time and errors were measured. Eye-tracking analyses included three indices of automaticity and efficiency: 1) *EVS*; 2) *average saccades per vocalization;* and 3*) perseverative saccades,* the number of repeated saccades made at the target or a previously-visited target during a vocalization. The BAP was measured in parents using the Modified Personality Assessment (Tyrer, 1988).

Results: Results indicate slower naming time and more errors in individuals with ASD and their parents (ps <.05), with differences in parents restricted to the less highly automated color and object trials. Eye movement analyses show smaller EVS in individuals with ASD (p <.01) and similar trends in their parents. Individuals with ASD and their parents made more perseverative saccades (ps <.05) than controls. Eye movement differences were evident specifically in the BAP(+) group, and predicted narrative ability in parents. In ASD, errors were associated with restricted and repetitive behaviors (RRBs) and errors and saccadic patterns were associated with poorer pragmatic language and narrative abilities (ps <.05).

Conclusions: Differences in RAN performance and associated eye movements indicate reduced automaticity in ASD and the BAP. This illustrates the reliance on greater attentional and executive resources during language processing among these groups. Further, associations between RAN time, errors, and perseverative saccades were associated with rigid personality traits in parents and restricted and repetitive behaviors in their children, highlighting perseverative tendencies commonly implicated in ASD

(Hill 2004). Together, results suggest that reduced automaticity is associated with downstream cognitive indices of executive flexibility and language, emphasizing automaticity as a critical precursor to complex language skills and a potential indicator of genetic liability to ASD.

106 **164.106** Relations Among Parent-Reported and Spontaneous Gestures, Fine Motor, and Language in Young Children with ASD: A Structural Equation Model Approach

D. L. Mead[1], *S. S. Manwaring*[2], *L. B. Swineford*[1] *and A. Thurm*[1], *(1)Pediatrics and Developmental Neuroscience Branch, National Institute of Mental Health, Bethesda, MD, (2)University of Utah, Salt Lake City, UT*

Background: Gestures and fine motor skills have been found to be related to language outcomes in young children with and without autism spectrum disorder (ASD). Evidence suggests some measurement variability between parent report and direct observation of gestures, resulting in research using either one mode of measurement or creating a standardized composite score for overall gesture use to predict language outcomes. To our knowledge, studies have not examined gesture use as an underlying, latent construct in a structural equation modeling framework, a powerful method of analysis that captures the variability and covariance of many individual components.
Objectives: This study examined the relationship among gesture, fine motor ability, and language in young children with ASD using structural equation modeling.
Methods: A total of 197 children were classified into three groups: ASD (n=110), non-spectrum developmental delay (DD; n=35), and typical controls (TYP; n=52) based on an evaluation conducted between the ages of 12 to 48 months (M=34.55, SD=8.41). Behavioral assessments included the Mullen Scales of Early Learning (MSEL) and the Autism Diagnostic Observation Schedule (ADOS), and parent-report measures included the Communication and Symbolic Behavior Scales Developmental Profile Caregiver Questionnaire (CSBS-CQ), the Vineland Adaptive Behavior Scales, Second Edition (VABS-II), and the MacArthur-Bates Communicative Development Inventories (CDI). CSBS-CQ and ADOS gesture items, MSEL and VABS-II age equivalents for fine motor, receptive, and expressive language, and CDI words understood/produced were used in analyses.
Results: A series of confirmatory factor analyses (CFA) was first run that found individual gesture items on the CSBS-CQ and the ADOS loaded significantly onto underlying gesture use. Next, a model testing the correlations between the factor scores from the CSBS-CQ, ADOS, and Fine Motor (MSEL, VABS-II) across all children revealed a strong, positive correlation (r=.70) between fine motor and parent-reported gestures (CSBQ-CQ), and strong, negative correlations between spontaneous gesture use (i.e., fewer gestures result in higher scores in ADOS) and both fine motor (r=-.52) and parent-report of gestures (r=-.80) (Figure1). The fit indices for the overall model revealed good fit; however, when models were run separately for the ASD and non-ASD groups (DD+TYP), the results indicated good model fit only for the ASD group. Finally, a model was run to identify if the CSBS-CQ, ADOS, and Fine Motor domains loaded significantly onto one, latent construct of “gestures” to predict concurrent language outcomes (MSEL and VABS-II, CDI). For expressive language, the model did not fit across the entire sample, or in either grouping. However, for receptive language, the ASD-only model revealed good fit, resulting in better overall gesture use predicting better performance on receptive language measures (Figure2).
Conclusions: An underlying construct of gesture use was found among parent-reported and spontaneous gestures, as well as fine motor, which differs from the traditional method of analyzing each domain separately or as with composite scores. Overall gesture use predicted concurrent receptive language in ASD, but not expressive language. The predictive model was not found in the non-ASD group, which may be due to reduced variability among gesture use.

Fit indices: ($\chi 2(6)=9.13$, $p=.17$; RMSEA=0.07, CFI=0.99)

107 **164.107** Relations Between Computerized LENA Recordings of Conversational Turns and Lab-Based Measures of Social Engagement in Children with Autism Spectrum Disorder

M. Sabatos-DeVito, *E. Paisley, C. H. Stoute, J. Newman, K. S. Davlantis and G. Dawson, Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC*

Background: Social communication impairments are core deficits and prognostic indicators of Autism Spectrum Disorder (ASD). A key challenge in the design and evaluation of ASD treatments is identifying measures of social communication that are ecologically valid, quantitative, and scalable for large clinical trials. Computerized home-based recordings of social communication, such as conversational turns, are promising alternatives to lab-based measures that require labor-intensive human coding. However, more research is needed to determine the extent to which such computerized recordings correlate with well-established, lab-based measures of social communication.

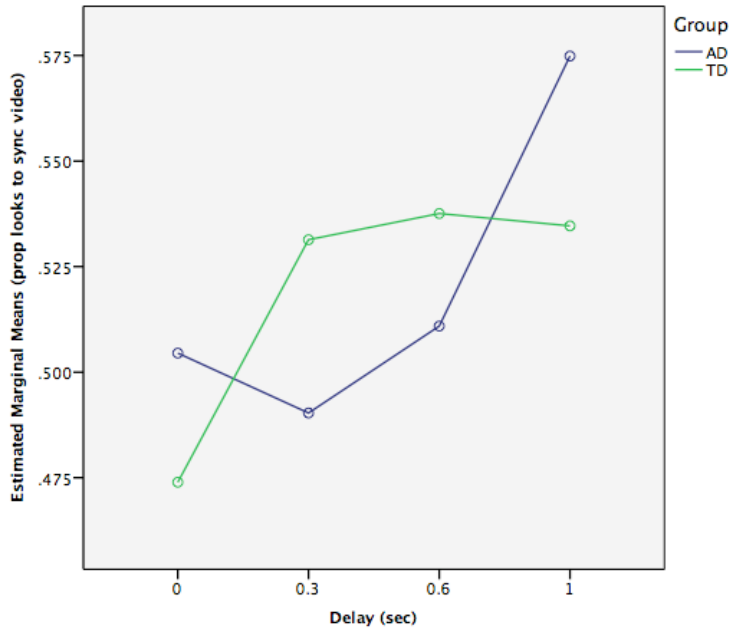
Objectives: Aim one of this study was to examine the correlation between a computerized home-based measure of social communication and a measure of social

communication derived from human coding of a laboratory-based parent-child play interaction. Aim two assessed the relationships between expressive language in children with ASD and both home-based computerized measures and lab-based coded measures of social communication.
Methods: Data were collected on children with ASD (N=25, Mean Age=4.47 years, Range=2.27-5.98 years; Mean Nonverbal IQ=64.3 +/- 24.6). ASD diagnosis was based on the ADOS-2 and ADI-R. Measures consisted of (1) a computerized measure of social communication collected with the LENA (Language Environmental Analysis) System at home, which automatically recorded adult and child word/vocalizations and conversational turns (Mean: 15.95 recorded hours; Range: 14.8 – 16 hours), (2) reliable human coding of the duration of child social engagement states during a lab-based, parent-child interaction, and (3) a standardized measure of expressive language (Expressive One Word Vocabulary Test). Parent-child play (8 minutes) was coded for six child-focused engagement states: Unengaged, Onlooking, Object, Person, Supported, Coordinated (Adamson et al. 1998). Using LENA, we calculated the average number of conversational turns during each conversation, the average duration of conversational blocks, and adult word count and duration during conversations. Data collection and coding are ongoing; final results will include additional data.
Results: Analyses of coded parent-child interactions (N=11) revealed that average parent-child conversational turns during conversational blocks at home (LENA) was significantly negatively related to the proportion of time in unengaged and supported engagement states (r=-0.701, p<0.05; r=-0.69, p<0.05, respectively), and positively related to the proportion of time in coordinated engagement (r=0.75, p<0.01) during lab-based play. Results were the same for average duration of conversational blocks. Adult word count during conversations (LENA) was significantly negatively correlated with proportion of time unengaged (r=-0.648, p<0.05) and positively related to coordinated engagement (r=0.661, p<0.05) during parent-child play. Child expressive vocabulary scores were significantly negatively related to supported engagement (r=-0.658, p<0.05) and positively related to coordinated engagement (r=0.916, p<0.001). Coding is ongoing and additional analyses will compare engagement states, conversational turns, and adult words of minimally verbal and verbal children.
Conclusions: This study is one of the first to investigate associations between home-based computerized measures and lab-based coded measures of social communication between a parent and child with ASD. Results suggest that home-based computerized measures of social communication may offer a scalable, reliable, and quantitative outcome measure for use in clinical trials of treatments for social communication impairments in young children with ASD.

108 **164.108** Sensitivity to Audio-Visual Synchrony and Its Relation to Language Abilities in Children with ASD

G. Righi[1], *E. Tenenbaum*[2], *D. Amso*[3] *and S. J. Sheinkopf*[4], *(1)Alpert Medical School of Brown University, rumford, RI, (2)Brown Center for the Study of Children at Risk at Women and Infants Hospital, Providence, RI, (3)Cognitive, Linguistic, and Psychological Sciences, Brown University, Providence, RI, (4)Brown Center for the Study of Children at Risk, Women & Infants Hospital The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Recent findings show that increased attention to the mouth is related to greater success in language learning among typically developing children and children with autism (Tenenbaum, Amso, Abar, & Sheinkopf, 2014; Tenenbaum, Sobel, Sheinkopf, Malle, & Morgan, 2014). What is not yet clear is the mechanism by which attention to the mouth may be related to language development. Children with impaired language abilities may have trouble processing speech because it is a complex multimodal signal comprised of both auditory and visual information. Hence, children might look away from the mouth in an attempt to simplify their perceptual experience. Previous findings suggest that children with autism show impaired recognition of audio-visual synchrony (Bebko, Weiss, Demark, & Gomez, 2006; Irwin & Brancazio, 2014; Irwin, Tornatore, Brancazio, & Whalen, 2011; Smith & Bennetto, 2007) and look less at the mouth than typically developing peers in audio-visual processing tasks (Irwin & Brancazio, 2014).
Objectives: (1) To replicate findings showing reduced sensitivity to audio-visual synchrony among children with autism; (2) To determine whether sensitivity in processing of audio-visual synchrony is related to language ability among children with autism.
Methods: Children with ADOS confirmed diagnoses of autism (AD; n = 23, M = 5.76 years, SD = 1.76) and typically developing children (TD; n = 19, M = 2.62, SD= 1.75) matched on language ability viewed twelve trials. Each trial was composed of two videos of a woman speaking in animated infant directed speech. One side of the screen displayed a video that was synchronized with the audio track and the other showed a video that was asynchronous at one of four delays (0ms, 330 ms, 660ms, and 1000ms). The dependent measure was proportion of looking time to the synchronous video.
Results: Repeated measure mixed general linear model was used with group (TD vs. AD) as a between subject factor and delay (0, 330, 660, 1000ms) as a within-subject factor. Results showed a significant main effect of delay ($F(3,37) = 11.8$, p<0.01). Post-hoc tests revealed a significant difference between the 0- and 1000-ms-delay conditions (p<0.05). No overall group differences or significant interactions were observed. Visual inspection of within group means suggests that TD children were sensitive to all delays whereas AD children were only sensitive to the 1000 ms condition (though differences were not statistically significant). Bivariate correlations revealed a marginally significant relationship between the dependent measure at 1000 ms delay and PLS Expressive Scores in the AD group (r = -.38, p<0.1); TD children showed the reverse pattern (r = 31, ns).
Conclusions: These preliminary results suggest that consistent with prior findings TD children are more sensitive to audio-visual synchrony than AD children. Contrary to predictions, AD children with higher expressive language abilities did not show a preference for synchronous videos. This surprising result may reflect differences in the mechanisms underlying language learning in ASD. Data collection is still underway and final analyses will explore this relationship further.



109 **164.109** Sensitivity to Subtle Changes: A Signal Detection Analysis of Memory for Faces, Objects, and Spoken Words in ASD

A. Hogstrom*, J. Green, A. Canfield, B. Castelluccio, M. Smith and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT*

Background:
Individuals with autism spectrum disorder (ASD) demonstrate hyperspecificity of information processing (McClelland, 2000). More detail in initial sensory/perceptual encoding (Mottron et al 1999) could potentially play a causal role in social and communicative deficits (Eigsti & Fein, 2013). A diagnosis of ASD will broadly impact recall for *socially-relevant* stimuli, but hyperspecific perceptual encoding might impact recognition of stimuli when presented with novel perceptual features.
Objectives:
The current study was designed to assess memory for stimuli that varied in social relevance and sensory modality. We predicted that individuals with ASD would be less accurate than their peers with typical development (TD) in recalling faces and spoken words, relative to non-social objects. The study also assessed the impact of enhanced sensory encoding in ASD on recall of non-meaningful changes in a memory task. We expected the ASD group to show greater effect of non-meaningful changes, across categories.
Methods:

Adolescents ages 12-18 with high-functioning ASD (*n*=10, IQs > 85) and TD (*n*=12; no group differences in gender or FSIQ) completed a stimulus recall task. Subjects were presented with, and asked to remember, three blocks of randomly-ordered stimuli: pictures of household objects, pictures of emotionally-neutral faces, and spoken high-frequency words. Order of block presentation was random. After a 30-minute delay, subjects were presented with the original and novel stimuli, and asked to report whether each item had been presented previously ("Old") or not ("New"), ignoring (with explanation) any changes. Of the Old stimuli, 50% were unchanged; 50% ("Change") were presented at 30° rotation (Faces, Objects) or spoken by a new talker (Words).

Results:

Accuracy was calculated using d'. Analyses revealed main effects of category and group, and a category-by-group interaction, *p*'s<.05. Across groups, accuracy was highest for Words, then Objects, and lowest for Faces (see Table 1). While the ASD group was generally less accurate, group differences were significant only for Faces. Second, a within-group analysis of accuracy for Old versus Change stimuli showed a near-significant (*p*=.07) difference in Word recall, for the TD group only. Across groups, Faces were most difficult to recall, with low accuracy regardless of Change status; recall for Objects was relatively unaffected by small changes. In contrast, the TD group was somewhat less accurate in recalling Change Words, whereas the ASD group showed no such decrement. Our final sample of 30 will be powered to reveal whether these preliminary results hold.

Conclusions:

As expected, the ASD group showed impaired recall; however, this deficit only appeared for Faces, and not for spoken Words. Faces accuracy was very low, obscuring effects of changes in orientation. Contrary to prediction, results for Objects and Words did *not* suggest heightened specificity of encoding in the ASD group. Indeed, the data suggested that any such effect was limited to the TD group, and to Words only. This suggests either that sensory information is not encoded with hyperspecificity in ASD, or that recall does not benefit from hyperspecific encoding. Future work will aim to disentangle these accounts.

Table 1. D' (accuracy) results for Old/New judgments by Category (Faces, Objects, Words) and Group

	ASD	TD	*F*	*p*	Cohen's *d*
Faces - Old	**-0.03 (0.47)**	**0.71 (0.73)**	**7.50**	**.01**	**1.21**
Faces - Change	**-0.11 (0.47)**	**0.47 (0.61)**	**6.15**	**.02**	**1.07**
Objects-Old	0.44 (0.44)	0.65 (0.55)	0.95	.34	0.42
Objects - Change	0.46 (0.32)	0.69 (0.52)	1.56	.23	0.53
Words-Old	0.80 (0.68)	0.90 (0.42)	0.17	.68	0.18
Words - Change	0.83 (0.46)	0.76 (0.33)	0.14	.71	0.17

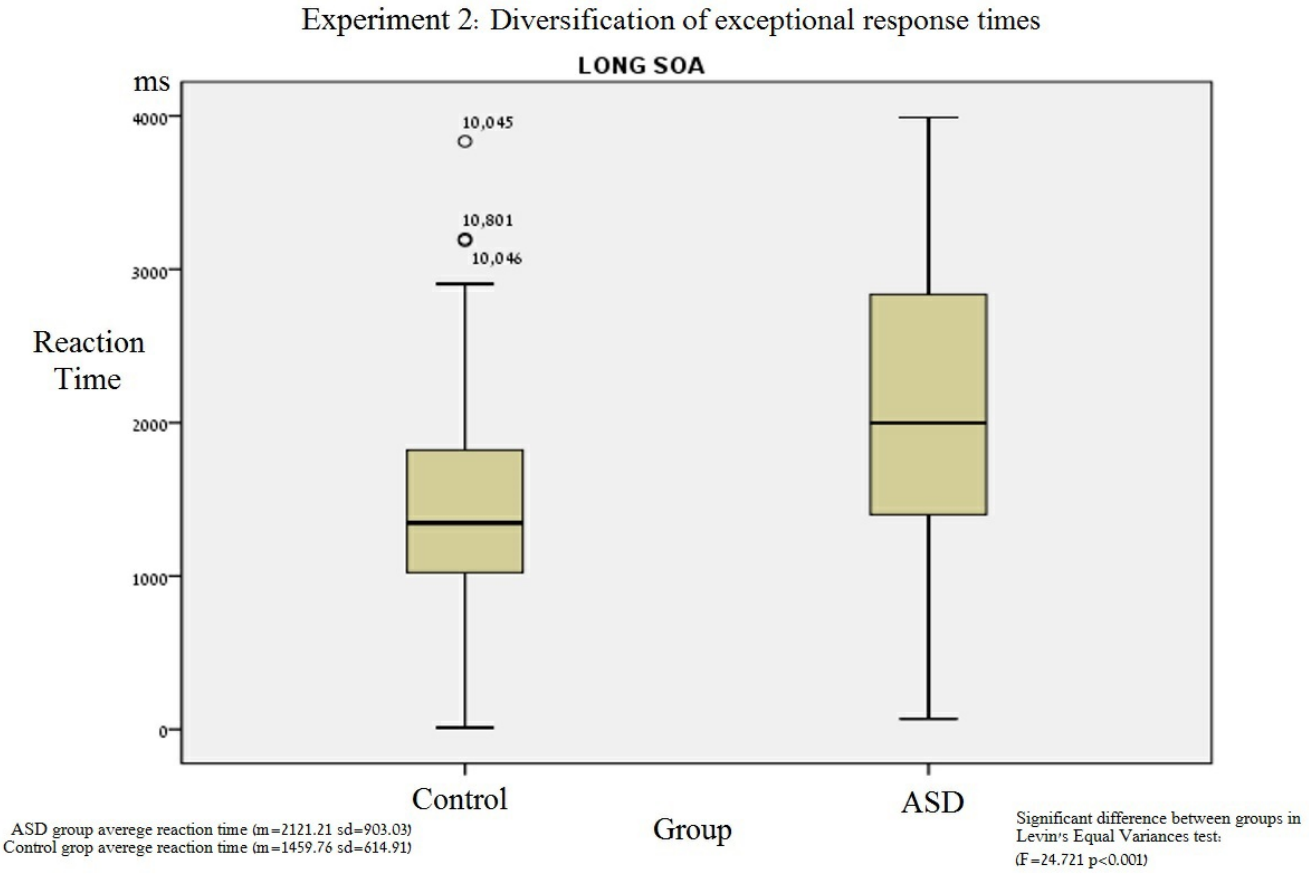
Data are shown as *M* (*SD*).

110 **164.110** Single Word Semantic Priming in High Functioning Individuals with Autistic Spectrum Disorder

ABSTRACT WITHDRAWN

Background:
Current research literature is controversial with regard to the higher-level linguistic processing capacity of young individuals with autistic spectrum disorder (ASD), and more specifically whether they utilize Semantic Priming similarly to neurotypical individuals (Lopez & Leekam, 2003; Kamio et al, 2006; Henderson et al, 2011; Norbury, 2013 in Dromi, Rum & Goldberg-Florian, in press).
No data was found with regard to the Semantic Priming Effect in young individuals with ASD who acquire and use a language other than English.
Objectives:
This study explores the Semantic Priming Effect, as well as the speed and accuracy of identifying words and non-words, in high-functioning Hebrew-speaking adolescents with ASD.
Methods:
We recruited two groups of participants: 22 adolescents with ASD in the age range of 14-27 (m=20.62 sd=2.59) comprised the experimental group, while 17 participants in the age range of 15-26 (m=21.13 sd=3.09) comprised the comparison group. A list of 36 semantically related word-pairs was constructed for use as stimuli for each experiment. A lexical chice task was administered using a computerized testing system that measured response time for a word versus that for non-word.
Two experiments were conducted. The first experiment was designed to encourage a quick, automatic, and subconscious response in determining the semantic relation

between paired words (Stimulus-Onset Asynchrony – SOA of 100 ms).The second experiment was designed to elicit strategic thought processes in making the judgment on the semantic relation between the same pairs of words (SOA of 1000 ms). The findings were analyzed several times in order to isolate the variables and examine their effect on the results.
Results:
In both experiments, the response time of participants in the experimental group was slower compared to the comparison group, and this was especially so when the target words were non-words.
The Semantic Priming Effect findings were different in the two experiments: In the first experiment, the experimental group demonstrated a Semantic Priming Effect similar to the comparison group. In the second experiment, a Semantic Priming Effect was not found in the experimental group, and the elimination of the subjects with reading difficulties did not change the outcome. Only the exclusion of cases of exceptional response times (±2 standard deviations) resulted in the experimental group demonstrating a Semantic Priming Effect similar to the comparison group. In all analyses, the heterogeneity and lack of uniformity in the responses of participants with ASD was evident.
Conclusions:
The findings suggest a need to differentiate between participants with ASD who exhibit linguistic impairment (Autistic with Language Impairment - ALI) and those who show efficient linguistic processing capacity even in highly demanding tasks (Autistic without Language Impairment - ALN). Moreover, in future research, more attention should be paid to the selection of participants, including controlling for those with and without reading difficulties. Finally, it is recommended that Semantic Priming experiments be administered to larger groups of individuals with ASD who learn and use different languages.



111 **164.111** Social-Communication Outcomes in Preschoolers Identified As at-Risk for ASD at 12 Months

S. W. Nowell[1], *L. R. Watson*[2] *and L. Turner-Brown*[3], *(1)UNC-Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Early social-communication weaknesses are associated with poor social inclusion outcomes in adulthood. Therefore, early identification and treatment of social-communication deficits is critical in order to optimize outcomes. Research in the area of child development has consistently linked mother's responsiveness to their young children with later developmental outcomes. The current study follows up on 3-5 year old children identified as at-risk for ASD on the First Year Inventory at age 12 months. The children participated in a RCT of an Adapted Responsive Teaching (ART) intervention between their 1st and 2nd birthdays, with families randomized to the ART group or a "referral to early intervention and monitoring" (REIM) control group.
Objectives: Our aim was to determine if parent responsiveness at 24 months in children identified as at-risk for ASD was predictive of social-communication skills at 3-5 years. We hypothesized that parents with higher Maternal Behavior Rating Scale (MBRS) scores on the factors of Responsiveness and Affect at 24 months would have children who show better social-communication skills at 3-5 years. Because parent responsiveness was a target of the ART intervention, and was significantly increased for parents in the ART group compared to the REIM group, we also hypothesized that children in the ART group would have reduced diagnostic severity in the dimension of social-communication at 3-5 years compared to children in the REIM group.
Methods: Families who had participated in the RCT were re-recruited for a follow-up study when the children were 3-5 years old. The original sample consisted of 87 children; so far, 55 families have returned for follow-up assessments. The following measures were used:
At 24 months

- ***Parent Responsiveness***: *Maternal Behavior Rating Scale- Revised* (MBRS)
- ***Social-Communication Skills:*** *Communication and Symbolic Behavior Scales* (CSBS)

At 3-5 years

- ***Structural Language*** *- Preschool Language Scales- Fifth Edition* (PLS-5), Children's Communication Checklist (CCC-2) Structural language subscales
- ***Social-Communication Skills***- The *Children's Communication Checklist – Second Edition* (CCC-2) Pragmatic Language subscales, the *Pragmatic Rating Scale – School Age* (PRS-SA), the Autism Diagnostic Observation Scales (ADOS-2), the *Vineland Adaptive Behavior Scales* (VABS-2), and the PLS-5 narrative retell task.

Results: Preliminary analyses were conducted with data on 32 children between 49-70 months old using the MBRS subscales of Responsivity, Affect, and Directiveness at 24 months to predict preschool outcomes on the CCC-2. The CSBS total standard score was used to control for baseline social-communication skills. All three MBRS subscales accounted for significant ($p<.05$) variance in the CCC-2 Structural Language subscales, above the variance accounted for by the CSBS (R^2 change=0.167), with Responsiveness having a positive effect as predicted, but the directions of effects for Directiveness and Affect opposite of what was predicted. The MBRS subscales did not significantly account for variance in the CCC-2 Pragmatic Language subscales. No intervention group differences were apparent in either structural or pragmatic language.
Conclusions: Preliminary findings support parent affect, responsivity, and directiveness at 24 months as significant predictors of preschool children's structural language. Future analyses will include additional participants and measures relevant to the aims of this study.

112 **164.112** Specific Language Impairment in ASD: Exploring Language Phenotypes Beyond Standardized Testing

K. Wittke[1]*, A. M. Mastergeorge*[2]*, S. Ozonoff*[3]*, S. J. Rogers*[4] *and L. Naigles*[1]*, (1)University of Connecticut, Storrs, CT, (2)University of Arizona, Tucson, AZ, (3)UC Davis MIND Institute, Sacramento, CA, (4)University of California at Davis, Sacramento, CA*

Background: Although current diagnostic criteria for ASD do not include language impairment, children with autism present with a wide-range of language abilities and deficits. Language can vary independently of IQ in autism (Kjelgaard & Tager-Flusberg, 2001), and some children with ASD evidently meet criteria for specific language impairment (SLI), as they present with impaired language despite intact nonverbal cognitive abilities (Tager-Flusberg, 2006). However, it is currently unknown how common the SLI phenotype is, and which linguistic markers differentiate those children from other language phenotypes in this population. Therefore, spontaneous language samples are an ideal method for investigating more detailed and comprehensive linguistic profiles (Dunn et al., 1996).
Objectives: To assess standardized-test subtyping of children with ASD by analyzing children's language samples for SLI-relevant linguistic markers.
Methods: 98 participants (M= 68.63 months, *SD* = 12.06) from a large-scale study of autism phenotypes were classified into 4 groups based on standardized test scores (DAS or MSEL for Nonverbal, a composite of EOWPVT, PPVT, MSEL, DAS for Verbal). Groups included: Low (nonverbal/verbal <70), Low Normal (nonverbal/verbal between 70-85), Possible SLI (nonverbal >70, verbal more than 15 points below nonverbal), and Normal (nonverbal/verbal >85). Recordings from the ADOS were transcribed, targeting tasks that afforded unprompted, spontaneous language production. 49 children were eliminated from further analysis because of video recording errors (*n*=16) and/or insufficient spontaneous language to transcribe (*n*=30); only 3 children in the Low group presented with sufficient language to transcribe so this group was excluded from further analyses. Therefore, 49 children were included in the final sample (M= 67.8 months, *SD* = 11.5), across 3 of the groups: Low Normal (*n*=6), Possible SLI (*n*=8), and Normal (*n*=35). Language samples were analyzed for frequency of language types and tokens, as well as MLU, grammatical errors, and omissions.
Results: One-way ANOVAs revealed significant effects of group for MLU, frequency of grammatical errors, total word and verb types, and frequency of article errors *(Fs* >3.5, *p*s <.04). However, post-hoc Scheffe tests revealed that the Possible SLI group differed from the Normal Group only in frequency of total grammatical errors (*p*=.003) and frequency of article errors/omissions (*p*=.03). Interestingly, the Low Normal and Normal groups differed significantly in total word types (*p*=.02), total verb types (*p*=.04), and frequency of article errors. Surprisingly, significant group effects were not observed for error frequencies with pronouns, plurals, and tense/agreement, which are the grammatical structures most often impaired in SLI.
Conclusions: Standardized test results pointed to a possible subgroup of SLI in a large ASD sample; however, grammatical analyses of their speech samples did not fully support this subgrouping. Overall, frequency of grammatical errors was higher in the Possible SLI group, but specific error types did not consistently reflect an SLI designation. Further analyses will scrutinize the grammatical error patterns for each child, exploring different subgroup assignments based on these language samples. Our results suggest that including spontaneous language samples is critical for capturing the full extent of language impairments as well as designing targeted interventions for children with ASD.

113 **164.113** Speech Acts during Spontaneous Peer Conversation in ASD and Typical Development

N. Bauminger-Zviely[1] *and A. Golan Itschaky*[2]*, (1)Bar-Ilan University, Ramat Gan, Israel, (2)School of Education, Bar Ilan University, Ramat Gan, Israel*

Background: In typical development (TYP), early peer talk is crucial for pragmatic development. Speech acts – the primary illocutionary values conventionally conveyed by utterances as acts – are a crucial component of children's conversational capabilities. The pragmatic deficit, reflected in remarkably deficient conversational capabilities, is considered the hallmark of the language deficit in autism spectrum disorder (ASD) (Stefanatos & Baron, 2011). Despite its importance for understanding the pragmatic deficit in ASD, preschoolers' speech acts during spontaneous peer talk has not been explored.
Objectives: The current study's major aim was to close this knowledge gap about characteristics of the pragmatic deficit in ASD by examining the speech acts of high-functioning preschoolers with ASD (HFASD, IQ>75) versus preschoolers with TYP during spontaneous peer talk. We were also interested in learning about the role of the conversational partner's friendship and disability status as contributing to pragmatic capabilities. Prior studies reported higher mutual social engagement, responsiveness, and reciprocal verbal exchanges in interactions with friends versus non-friends (Newcomb & Bagwell, 1995). Aadditionally, in the HFASD group, prior research showed higher social complexity and level of play in interactions with a typical partner (mixed dyads) versus a partner with HFASD (non-mixed dyads) (Bauminger et al., 2008).
Methods: We conducted comparative assessment of speech acts during spontaneous peer talk along 10-minute free-play scenarios in preschoolers (ages 3-6 years) with HFASD (*n*=21) versus with TYP (*n*=30). Groups were matched on SES, verbal IQ (VIQ), nonverbal IQ (NVIQ), and CA. Children's conversations were videotaped and coded to tap speech act capabilities. Acts' coding included: *Assertive* (e.g., evaluation, declaration); *Requestive* (e.g., questions, requests); *Responsive* (e.g., answers to WH questions); *Organizational Devices* (e.g., request for attention) (Dore, 1979); and also *Stereotypic Speech.* Correlations with CA, VIQ, and NVIQ were examined. We compared the two groups' interactions with a friend versus non-friend partner; additionally, in the HFASD group, we compared interactions in mixed versus non-mixed dyads.
Results: As predicted, analysis of observed speech acts during spontaneous peer conversations revealed fewer speech acts in HFASD versus typical age-mates, mainly in assertive (declarative) acts and organizational devices. Moreover, the HFASD group used stereotypic talk more often than TYP peers. However, in both groups, more frequent and diverse uses of speech acts emerged during interaction with friends versus non-friends, including: assertive (declaration, evaluation); requestive (request); responsive (replies); and organizational devices. Thus, friendship may enable children to converse in a more socially complex way. The comparison of mixed versus non mixed friendship in HFASD did not yield significant differences. CA correlated positively with frequency and variety of speech acts only in the TYP group, whereas VIQ correlated with speech acts' frequency in the HFASD group while interacting with a non-friend.
Conclusions: Despite the poor performance of speech acts in ASD, involvement in friendship relationships and VIQ were linked to more intact pragmatic capacities. Clinically, emphasis on friendship in early intervention may help elicit more adequate pragmatic capabilities and presumably fuller peer relations in preschoolers with ASD.

114 **164.114** Spontaneous Expressive Language Impairments in Clinic Referred Children for a Possible ASD

S. H. Kim[1] *and C. Lord*[2]*, (1)Yale Child Study Center, New Haven, CT, (2)Weill Cornell Medical College, White Plains, NY*

Background: Although impairments in spontaneous expressive language are prevalent in ASD and other communication disorders, standardized language measures currently available do not adequately capture these deficits, impeding our attempt to clearly quantify language profiles that are necessary for provisions of treatments. A newly developed language measure, the Observation of Spontaneous Expressive Language (OSEL) is a standardized, semi-structured clinician observation, which allows an assessment in children aged 2-12 years targeting: 1) Syntax, and 2) Pragmatic-Sematic skills under three domains: *Initiation of Reciprocal Communication*, *Narrative Skills*, and *Unusual Features* (**Table 1**).
Objectives: To examine spontaneous expressive language profiles during a standardized but natural, play-based setting targeting syntax (structure of language), semantics and pragmatics (social use of language) in clinic-referred children for a possible ASD.
Methods: Total of 66 children (57 ASD cases) were administered the OSEL (M*ean* Age=5, *SD*=2.3). The proportion of children showing delays were examined and the severity of delays were quantified based on language quotients ([age equivalent/chronological age]*100). The associations between the OSEL and autism symptom severity (Autism Diagnostic Observation Schedule [ADOS]) and standardized language scores (Comprehensive Assessment of Spoken Language [CASL] or Preschool Language Scale [PLS]) were examined using Pearson's Correlation.
Results: Out of 66 children, 38 (58%; 32 ASD cases) had their syntax language quotients less than 70. Out of 66 children, 55 (83%; 47 ASD) and 48 (72%; 41 ASD) had their language quotients less than 70 for *Initiation of Reciprocal Communication* and for *Narrative Skills* respectively. Notable gaps between chronological age and age equivalents (AE) were observed for all domains (e.g., mean Syntax AE=2.8 years (*SD*=0.7); mean chronological age=5.7 (*SD*=2.2); mean language quotient=53.6 [*SD*=16.6]). When verbal IQ and other language measures were examined, only 16-44% of all children who showed significant delays on the OSEL were identified as having delays (scores<2 *SD*s; **Figure 1**). A mild correlation was observed between the OSEL *Initiation of Reciprocal Communication* and ADOS *Social Affect* severity scores (*r*=-0.34, *p*<0.05). Moderate to strong correlations between OSEL and other language measures were observed (*r*'s 0.3-0.8; *p*'s<0.05).
Conclusions: Based on a measure of spontaneous expressive language, more than 80% of clinic-referred children for ASD showed significant delays in pragmatic language. Most children (90%) received a diagnosis of ASD, and their language scores were significantly associated with autism symptom severity. This may explain why these children demonstrated notable difficulties in initiating back-and-forth communication with a social partner and providing accounts of events, which is one of the hallmarks of ASD. About 60% of children also showed notable delays in syntax, suggesting that intervention may need to be tailored to target deficits in grammar in a subset of these children. The results also suggest that difficulties in spontaneous expressive language may be missed by other instruments measuring pre-determined answers that are highly tied to concepts. Moderate correlations between the OSEL and other measures also suggest that the assessment of language in a standardized but natural context has an additive value and should be used complementarily with other measures.

Table 1. OSEL Syntax, Pragmatic and Semantic Items

OSEL Syntax Items	OSEL Pragmatic and Semantic Items
Articles	**Initiation of Reciprocal Communication**
Regular Plurals	Verbal requests to get needs met
Irregular Plurals	Asks for information about thoughts, feelings, or experiences
Regular Past Verbs	Comments or offers information about thoughts, feelings, or experiences
Irregular Past Verbs	Maintains a conversation
Progressive Tense Verbs	(Absence of) Preoccupation with specific interests
Future Tense Verbs	
Copula Verbs	**Narrative Skills**
Modal Auxiliary Verbs	Repairs/Request clarification
Infinitive Phrases	Reports main ideas
Negation	Reports sequence of events/story
Prepositions	Comments on characters' emotional and/or mental states
Longest Sentence	Synthesizes cause-and-effect information
Subjective Pronouns	
Objective Pronouns	**Unusual Features**
Possessive Pronouns	Interrupts the examiner or dominates conversations
Subordination	Stereotyped/Idiosyncratic use of words or phrases
Coordination	Unspecific language and/or semantic errors
Adjectives	Immediate echolalia
Nouns	Impolite or inappropriate language
Verbs	
Responses to WH- questions	
Responses to Y/N questions	
Questions

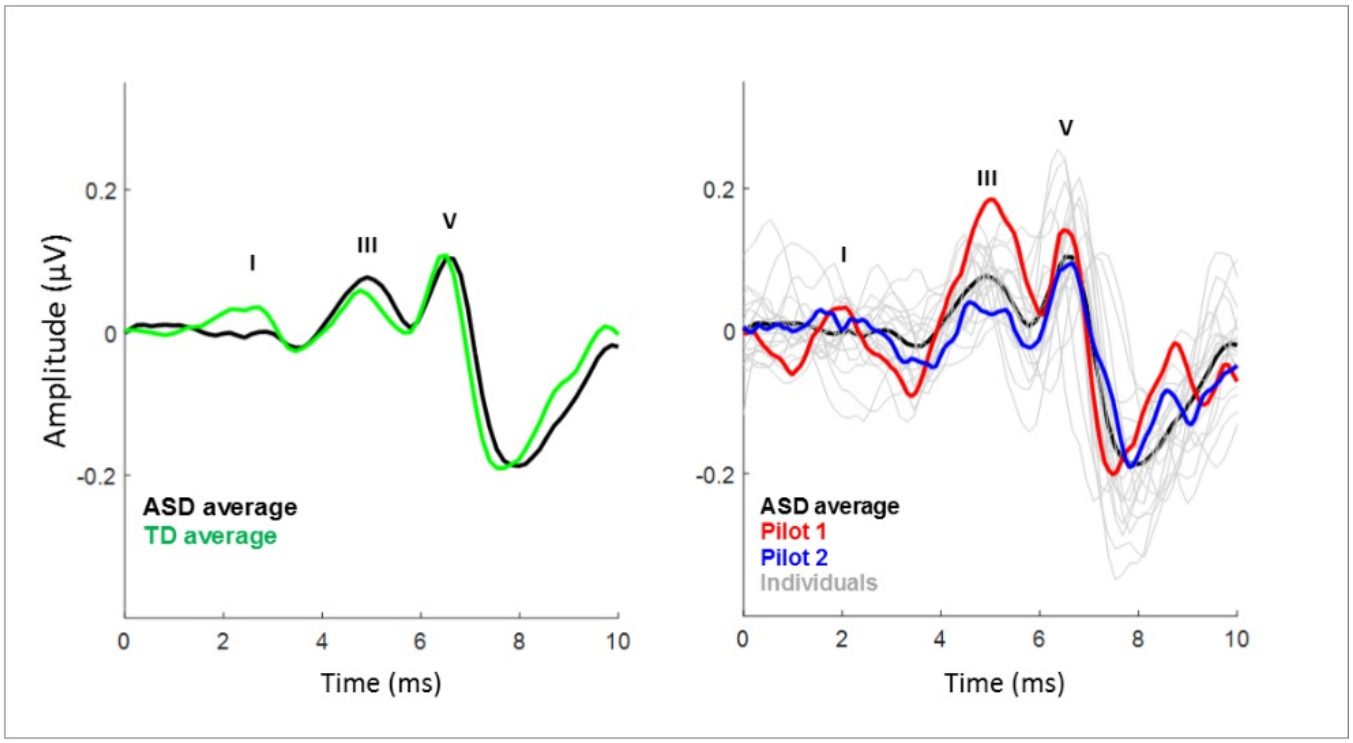
115 **164.115** Testing Auditory Brainstem Responses in Low-Functioning Children with ASD

Z. Johnson[1], *M. Spriegel*[2], *D. A. Fein*[3], *E. Skoe*[2] *and L. Naigles*[4], *(1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Speech Language Hearing Sciences, University of Connecticut, Storrs, CT, (3)Psychology, University of Connecticut, Storrs, CT, (4)University of Connecticut, Storrs, CT*

Background:
The neurological underpinnings of ASD language have long been sought, both to shed light on possible causes of the complex and multi-faceted behavioral presentation, and to identify targets for intervention. The purpose of our overall project is to explore whether abnormalities in language development can be attributed to breakdowns at an early stage of auditory processing, namely the auditory brainstem. Recent research with individuals with ASD has converged on the finding that abnormal neural conduction time, as revealed by prolonged latencies of auditory brainstem response (ABR), is a hallmark of the ASD central auditory system (Rosenhall et al., 2003; Roth et al., 2012; Russo et al., 2009). Most studies have involved high-functioning children tested in a lab setting; however, data collection from a wider range of children and in a home setting is desirable.
Objectives:
The purpose of the current study was to validate our ABR data collection protocol with low-functioning children tested at home.
Methods:
Two boys, aged 6 and 15 years, were tested. At their most recent assessment, their DAS NVIQs were 69 and 45 respectively, with TACL-Q standardized language scores of 57 and 61, respectively, and ADOS scores of 26 and 13, respectively. ABRs were recorded from scalp electrodes in response to a click stimulus (31.1/sec, 2000 trials) and a 40 millisecond "da" stimulus (10.9/sec, 6000 trials) presented at 80 dB SPL to the right ear. Wave V, the most robust peak within the ABR, serves as the primary dependent measure of sound encoding in this study.
Results:
Both boys were able to tolerate the electrode application and sound stimulation. Moreover, both provided useable ABR data, with minimal movement artifacts. In Figure 1, our pilot data is compared to the speech-evoked ABR waveforms of the TD and (high functioning) ASD groups from Russo et al., 2009. In our data, Wave V is clearly delineated; the latency and amplitude variability is also consistent with the ASD sample from Russo et al. (plotted as grey lines).
Conclusions:
Our procedures for collecting ABR data at home from two low-functioning boys with ASD proved successful, yielding waveforms that resembled those collected in lab settings, and demonstrating feasibility of collecting reliable ABR's in this setting and with this type of child. In the next 6 months we will collect ABR data from at least 8 more children with ASD, including both high- and low-functioning children, and assess the relationships between their ABRs and language abilities.



116 **164.116** The Discrepancy Between Receptive and Expressive Vocabulary in Preschoolers with ASD

P. J. Yoder[1], *L. R. Watson*[2] *and T. Woynaroski*[3], *(1)Vanderbilt University, Nashville, TN, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Vanderbilt University, Thompsons Stn, TN*

Background:
Some studies indicate receptive *age equivalencies* are lower than expressive age equivalencies in young children with autism spectrum disorder (ASD). In such children, the discrepancy between receptive - expressive vocabulary *size* should be atypically small, although this has not been shown. This could occur because children with autism attend less than other children to child-directed speech, which results in missing opportunities to learn to associate words with their referents. However, this association has not been tested.
Objectives:

1. Is there a lower receptive *age equivalency* than expressive age equivalency in preverbal children with ASD, and does this change over time?
2. Is there an atypically small receptive – expressive vocabulary *size* discrepancy?
3. Does early visual attention to speaker during child-directed speech predict the discrepancy between receptive – expressive vocabulary *size* 8 months later?

Methods:
Eighty-seven children with ASD participated in this study (see Table 1). Parent-reported (MacArthur-Bates Communication Development Inventory, MBCDI) receptive and expressive vocabulary was measured at four measurement periods, each separated by 4 months. The vocabulary size scores were transformed to age equivalencies using the median age or interpolated median age at which typically developing children achieved the raw score. The discrepancy between the mean receptive and the mean expressive vocabulary size in the typically-developing (TD) population was computed for four target ages. These ages were the rounded average of the mean receptive and mean expressive age equivalencies of the children with ASD at each measurement period (see Table 2). The visual attention to speaker during child-directed speech was quantified as the proportion of time that the child looked at the speaker out of the total time child-directed speech was presented at Time 2. The total duration of looking was coded from video records with inter-observer reliability > .9.
Results:
Children's receptive ages were significantly lower than their expressive ages at all four periods (within-subject Cohen's *d* values = .37, .34, .24, .24, respectively, all *p* values < .05). Table 2 indicates the atypically small discrepancy between receptive and expressive vocabulary size for the ASD sample. The difference between the normative gap for receptive versus expressive vocabulary size and that seen in the children with ASD grew over time. Time 2 visual attention to speaker during child-directed speech predicted the discrepancy between receptive and expressive vocabulary size at Time 4 (8 mos later), $r = .35$, $p = .01$. This association was significant, even after controlling for the receptive-expressive discrepancy at Time 1 ($p < .02$).
Conclusions:
Receptive vocabulary size was smaller than expected given the size of the expressive lexicon for this sample of young children with ASD, consistent with the finding that receptive vocabulary age equivalency was lower than expressive vocabulary age equivalency at each age point. Visual attention to the speaker during child-directed speech was associated with, and thus may have been one of the reasons for the atypically small discrepancy between, receptive and expressive vocabulary size. These findings suggest that enhancing attention to child-directed speech may be an important target of early language intervention.

Table 1.
Characteristics of Participants with ASD *at Time 1*

Variable	*Mean*	*Standard Deviation*
Chronological Age In Years	3.3 years	.6 years
MCDI Words Understood	115 words	110 words
MCDI Words Said	18 words	30 words

Table 2.

The Discrepancy Between Receptive and Expressive Raw Scores by Chronological Age in TD Children Comprising the MCDI Normative Sample and by Age Equivalency in ASD Children

Age group in mos of TD children in norming study	Average receptive-average expressive raw score difference for TD children at the target age	Rounded grand mean age equivalency in mos across modalities and participants at periods in ASD sample	Mean within-subject receptive-expressive raw score difference in ASD sample	TD – ASD difference in cross-modality discrepancy in vocabulary sizes
12	71	12	66	5
13	91	13	78	13
14	115	14	83	32

117 **164.117** The Early Language Environment and 9 Month “Hyper-Vocalizing” in Infants at Risk for Autism

M. R. Swanson[1], *B. Boyd*[1], *M. D. Shen*[1], *S. J. Paterson*[2], *J. C. Chappell*[1], *J. Pandey*[3], *J. Parish-Morris*[4], *R. Emerson*[1], *A. M. Estes*[5], *H. C. Hazlett*[6], *K. Botteron*[7], *R. T. Schultz*[8], *S. Dager*[9], *J. Piven*[1] *and .. The IBIS Network*[1], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Department of psychology, Temple university, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)University of Washington Autism Center, Seattle, WA, (6)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (7)Psychiatry and Radiology, Washington University School of Medicine, St. Louis, MO, (8)The Center for Autism Research, The Children’s Hospital of Philadelphia, Philadelphia, PA, (9)University of Washington School of Medicine, Seattle, WA*

Background: Studies on normative development have shown the substantial impact of the early language environment on a child’s later cognitive development (Hart & Risley, 1995; Ramirez-Esparza et al., 2014). Previous research on infants at-risk for ASD have been inconsistent with some reporting high-risk infants vocalizing less in the first year of life when compared to low-risk infants (Paul et al., 2010), while others report no group differences (Talbott et al., 2015; Northrup & Iverson, 2015). However, methodology has been limited to videotaped interactions of parents and infants playing.
Objectives: The goal of the current project is to extend prior literature by examining the early home language environment of 9 month old infants at high and low familial risk for ASD using naturalistic day-long in-home recordings.

Methods: This study includes data from 41 infants at high-risk (HR) for ASD (66% male), and 20 infants low-risk (LR) for ASD (50% male). As part of a larger ongoing longitudinal study, the Infant Brain Imaging Study, 9-month old infants wore LENA speech recorders for 2 full days in the home (yielding 32 hours of recording). The number of adult words, child vocalizations, and adult-child conversational turns were calculated. Infants and their families were also assessed during 4 clinic visits where infants were assessed using the Mullen: an intake assessment at 3 or 6-months, two randomly assigned follow-up assessments (6, 9, 12, or 15 months), and a 24-month outcome visit. Data collection is ongoing hence this analysis focused on the 12 and 15 month time-points.
Results: LR and HR infants did not differ on chronological age at 9-month LENA recording (Figure 1). The groups did significantly differ on Mullen early learning composite scores and receptive language scores at 12-15 months, but not on other Mullen subscales. LR and HR infants significantly differed on number of child vocalizations with HR infants vocalizing at a higher rate, $t(59)=2.76$, $p=.007$. The groups did not significantly differ in the number of adult words or conversational turns at 9 months. Given that previous studies have found maternal education and sex of the child to contribute to emerging language skills, additional analyses were run to control for these variables. We also controlled for Mullen composite. Results revealed a significant main effect of maternal education, $F(46)= 2.99$, $p=.05$, and group, $F(46)= 4.16$, $p=.04$, but not sex of the child or Mullen composite. This significant group difference in vocalization rate appears to be driven by a subgroup (25%) of HR "hyper-vocalizing" infants who vocalized at an extremely high rate (2 *SD*above the mean of LR infants, red diamonds in Figure 1).
Conclusions: We found that infants at HR and LR for ASD experience strikingly similar language environments in regards to adult words and adult-child conversational turns. However, we uncovered significant group differences in child vocalizations. This difference was driven by a subgroup of HR hyper-vocalizers who vocalized at a high rate. We will explore whether 9 month hyper-vocalizing is stereotypic in nature and if it is predictive of later ASD diagnosis.

	Low-Risk *M* (*SD*)	High-Risk *M* (*SD*)	*df*	*t*	*p*	Cohen's *d*

118 **164.118** The Problems with “Look, Don't Touch”: Designing Robots to Maximally Benefit Young Children with ASD

L. Boccanfuso[1], *L. Chen*[2], *C. Torres*[3], *B. Hudik*[4], *J. C. Snider*[5], *M. Sanfilippo*[6], *P. E. Ventola*[7], *K. Chawarska*[1], *J. M. O'Kane*[8], *B. Scassellati*[4] *and F. Shic*[1], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Mt. Holyoke College, South Hadley, MA, (3)Computer Science, Duke University, Durham, NC, (4)Yale University, New Haven, CT, (5)Yale Child Study Center, New Haven, CT, (6)University of California, Merced, Merced, CA, (7)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (8)University of South Carolina, Columbia, SC*

Background:
Despite the fact that the first five years of a child’s life are foundational for their social, emotional, behavioral, cognitive and communicative development, a paucity of robots exist that can withstand the physical interactions and play through which very young children naturally learn about the world. A common approach has been to employ expensive off-the-shelf robots with numerous degrees of freedom and sensors, many of which may be functionally unnecessary to achieve the end goal for which they are employed. This is deleterious to productive human-robot interaction (HRI) in two ways. First, child-robot interactions are restricted because children are either physically separated from the robot or are instructed not to touch the robot. Second, robots with many moving parts and behaviors can add unnecessary complexity, particularly for highly-targeted interventions with children who have behavioral, social and cognitive difficulties. In this work, we present 3 low-cost ($100- $300USD), field-tested robots and their fundamental design features that may help inform development of other robust and minimalistic robots suitable for use with very young populations of children with autism spectrum disorder (ASD).
Objectives:

To identify typical physical interactions that lead to hardware failures, describe the evolution of key design features and resulting design modifications to each of three robots used with individual groups of young children. Further, to evaluate the efficacy of three low-cost, robot prototypes that may help inform the development of other robust and minimalistic robots suitable for use with young populations of children with ASD.

Figure 1. Robots: CHARLIE, L-E and Sphero

Methods:

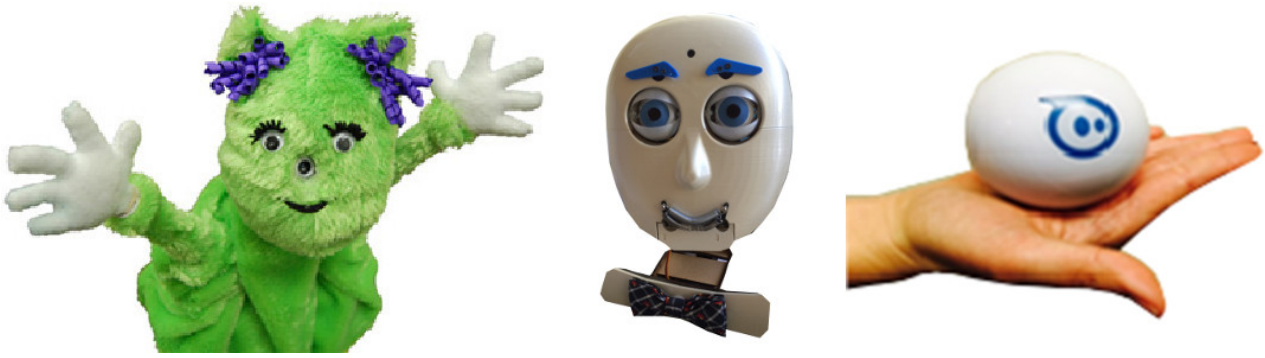
We analyzed child-robot interactions in each of three studies conducted with different subpopulations of children with ASD. Participant mean age for each study was 4.83 (CHARLIE, n_participants=8, n_sessions=96), 7.91 (L-E, n_participants=15, n_sessions=15) and 2.50 (Sphero, n_participants=12, n_sessions=12) years. Further, we summarized characteristics of interactions that lead to mechanical or hardware failure and identified specific design features that promoted maximal opportunities for unrestricted interactions and productive child-robot interaction. Finally, we evaluated the viability of low-cost robots with robust design features using empirical results obtained for each study.

Results:

Three generalizable, fundamental design features that directly contributed to promoting each study's aims resulted: (1) Simplified interface, with minimal DOF, and behaviors, (2) Securable base paired with break-away and/or compliant parts and, (3) Self-contained and impact-resistant. While low-cost and simple in design, these robot prototypes assisted in achieving significant improvements in speech (Mean Length Spontaneous Utterances), receptive language, interpersonal skills and play (Vineland Adaptive Behavior Scales – Parent/Caregiver Form). Additionally, one robot (Sphero) was used in unstructured scenarios to elicit and measure statistically significant differences in how typically developing children and a group of children with ASD play with a robot.

Conclusions:

Optimal HRI for young children requires robust robots. Simple, low cost design features can be easily integrated or added to robots employed to assist very young children with ASD while still contributing to significant improvements in several measures of communication and social skill proficiency.



119 **164.119** Looking and Language in Autism Spectrum Disorder: A Family Study

M. Lee[1], *N. M. Heckel*[1], *D. Hamburger*[2], *P. C. Gordon*[3], *G. E. Martin*[4] *and M. Losh*[5], *(1)Northwestern University, Evanston, IL, (2)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (3)Pyschology, University of North Carolina-Chapel Hill, Chapel Hill, NC, (4)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (5)Department of Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Converging evidence suggests that individuals with autism spectrum disorder (ASD) display atypical visual attention patterns that predict greater social impairment (Rice et al., 2012; Sasson et al., 2008; Klin et al., 2012). Unaffected relatives also demonstrate subtle differences in visual processing (Adolphs et al., 2008, Dalton et al., 2007). This study examines whether visual attention patterns relate to social language differences that characterize ASD, and which have been observed to express among unaffected relatives as well, though in milder form (e.g., Losh et al., 2008). Specifically, we examined visual attention during narration in ASD and first-degree relatives to investigate whether differences in perceptual strategies might relate to social communicative differences in ASD and subtler differences in social communication style in parents (i.e, the broad autism phenotype or BAP). Examining links between looking and speaking may inform how visual attention shapes the content and quality of social language.

Objectives: To examine relationships between visual attention and social language for individuals with ASD and their parents during two narrative tasks.

Methods: Thirty-four high functioning individuals with ASD (IQ>80) and 24 age-matched controls, as well as 147 parents of individuals with ASD and 61 control parents completed two narrative tasks presented on an eye-tracker: 1) a 24-page wordless picture book (PB), and 2) a series of six static images of emotionally ambiguous scenes drawn from the Thematic Apperception Test (TAT). During the PB task, participants narrated each page as it was presented on the eye-tracker. For the TAT task, individuals viewed six images from the TAT for eight seconds each. After each image was removed, participants were asked to tell a story about the image. Visual attention for narrative tasks was quantified as the proportion of fixations to different aspects of the images (e.g., social, background elements, white-space); Latent Semantic Analysis (LSA), a computational linguistic tool, measured narrative quality. Additionally, parents completed BAP assessments.

Results: Individuals with ASD demonstrated decreased attention to background elements during their narration of both tasks ($p < .05$). Whereas the ASD parent group did not differ from controls on the PB task, during the TAT BAP(+) parents looked significantly more at faces and significantly less at background elements of the scenes (ps < .05). Greater attention to non-social stimuli was positively correlated with semantic quality across narrative tasks in the ASD group and controls (rs > .4), as well as in parents (rs > .3).

Conclusions: This study is the first to assess the relationship between visual attention and narrative production in individuals with ASD and their parents. Results suggest that both individuals with ASD and their parents demonstrate different patterns of visual attention that may underlie differences in complex language use. In particular, reduced attention to the background of the scenes may result in narratives less rich in semantic content. Overall, this study provides further evidence of atypical visual processing as an index to genetic liability in ASD that may help explain the roots of differences in social language in ASD and the BAP.

120 **164.120** The Role of Parental Synchrony in the Language Abilities of Children with and without ASD

T. Ward[1], *T. Estrada*[1], *W. Mason*[1] *and B. Wilson*[2], *(1)Seattle Pacific University, Seattle, WA, (2)Clinical Psychology, Seattle Pacific University, Seattle, WA*

Background: Research suggests that up to 50% of children with autism spectrum disorder (ASD) have language impairments (Ganz, Lashley, & Rispoli, 2010). Parents play a critical role in the development of early language acquisition (Kamphaus, 1987; Mahoney, Kim, & Lin, 2007). Specifically, children with ASD whose parents demonstrated greater synchronous behaviors during a free play task had greater language gains longitudinally compared to parents with less synchrony (Siller & Sigman, 2002). These results have yet to be replicated using a typically developing (TD) control group.

Objectives: The aim of this study was to examine the moderating role of parental synchrony on the association between developmental status (ASD vs. TD) and verbal abilities.

Methods: Our sample consisted of 64 children, ages 3:0 to 6:11, and their parents. Thirty children were previously diagnosed with ASD and 30 children were TD. Parent-child dyads completed an eight-minute free-play task in a laboratory setting that was recorded for future coding. Parental synchrony was coded during the free-play task using a modification of Siller, Hutman, and Sigman's (2013) coding system. The *DAS-II*(Elliott, 2007) was also used to assess children's expressive and receptive language abilities.

Results: A multiple regression analysis was conducted using the SPSS macro add-on PROCESS (Hayes, 2008) to examine the moderating effect of parental synchrony on the association between developmental status and children's verbal abilities. Controlled variables included children's gender, age, and total number of parental phrases spoken. A significant main effect of status (B = -32.28, SE = 12.09, $p = .01$) and an insignificant main effect of parental synchrony (B = -.16, SE = .10 $p = .15$) on verbal abilities were detected. The interaction between status and parental synchrony was a significant predictor of verbal ability (B = .28, SE = .13 $p = .03$, $\Delta R^2 = .06$). When examining the significant interaction at the 10^{th}, 25^{th}, 50^{th}, 75^{th}, and 90^{th} percentiles, the conditional effect of status on verbal ability scores were significant at the 10^{th} (B = -15.96, SE = 5.54, $p = .006$) and 25^{th} (B = -12.75, SE = 4.54, $p = .007$) percentiles and insignificant at the 50th, 75th, and 90th percentiles. This indicates children with ASD whose parents used mean and high levels of parental synchrony may have comparable verbal abilities to their TD peers.

Conclusions: Our findings support our hypothesis that parental synchrony moderates the relation between developmental status and language abilities in children with ASD when compared to TD children. Children with ASD who experienced mean and high levels of parental synchrony did not have verbal abilities that were significantly different from their TD peers. In contrast, children with ASD whose parents engaged in low levels of synchronous behavior had significantly lower verbal abilities than TD children. These results suggest that moderate to high levels of parental synchrony potentially buffer against language deficits in children with ASD. This supports previous literature suggesting responsive parenting practices contribute to the acquisition of language during early childhood.

121 **164.121** The Wh-Questions Comprehension in Korean Children with Autism Spectrum Disorders

J. Park[1], *M. Nam*[2], *S. W. Cho*[3], *S. J. Lee*[2], *J. W. Jeong*[4] *and L. Naigles*[1], *(1)University of Connecticut, Storrs, CT, (2)Seoul Metropolitan Eunpyeong Hospital, Seoul, South Korea, (3)Sogang University, Seoul, South Korea, (4)Korea Institute for Developmental Disabilities, Seoul, South Korea*

Background: Producing wh-questions is frequently problematic for English-learning children with ASD[1]; comprehension emerges earlier but is nonetheless delayed relative to overall language level[2]. Researchers disagree on whether these difficulties are attributable to pragmatic vs. grammatical sources. Pragmatically, the desire to communicate with others is impaired in autism; therefore, children may not know when and how to ask questions appropriately[3]. Grammatically, English wh-questions deviate from the standard SVO word order ('What did John eat?' is OSV); therefore, it is possible that children with ASD who have acquired declarative SVO sentences have difficulties learning another order for questions. Korean provides a test of the grammatical perspective, because in Korean wh-questions the canonical word order (SOV) does not change[4]('John-NOM what-ACC eat-did-CM?')
Objectives: The current study tests whether Korean-learning children with ASD have advantages in wh-question acquisition. If grammatical complexity contributes to English-learning children with ASD's delay in wh-question acquisition, Korean-learning children with ASD might demonstrate earlier comprehension. In contrast, if the pragmatics of questions is the key source of wh-question difficulties in ASD, children learning Korean should show a similar delay to children learning English.
Methods: Typically developing(TD) Korean 2-year-olds (n=15, *MA*=28.35 months), and 4-year-olds (n=15, *MA*=51.68 months) participated. Korean children diagnosed with ASD and matched with the TD 2- and 4-year-olds on raw NVIQ scores (Leiter-3) were also recruited: 11 children with ASD (M_{age}=56.72 months) matched the TD 2-year-olds (TD_{Mean}=26.73; ASD-low_{Mean}=23.92) and 9 children with ASD (M_{age}=70.47 months) matched TD 4-year-olds (TD_{Mean}=45.88, ASD-$high_{Mean}$=45.85). Language levels were also comparable by group: (TD 2-year-olds M=267 words, ASD-low M=211.50 words; TD 4-year-olds $M_{expressivelanguageage}$=54.9 months, ASD-high $M_{expressivelanguageage}$=54.9 months). Children viewed a wh-questions video[2, 6] in which pairs of familiar items (apple, flower) appeared side-by-side in the baseline trial. Then the items appeared in transitive events (apple hitting flower); finally, they were again shown side-by-side, paired with object-what-questions, subject what-questions, or where questions: (1) (Sa-gwa-ga-Mu-eos-eul-Chyeo-seo "What did the apple hit?") (2) (Mueosi-Kko-cheul-Chyeo-seo "What hit the flower?") (3) (Eo-di-e-Kko-chi-I-seo "Where is the apple/flower?"). Children's eyegaze was coded offline. Percent looking to the named item ('apple' in (1)), were analyzed; children who understand the audio were expected to look longer to the correct items (compared to the named items).
Results: TD 4-year-olds demonstrated significant wh-question comprehension for both subject and object what-questions (*ts*>4.43, *ps*<.001); these children correctly looked at the named item *less* during the 'what' than 'where' trials. TD 2-year-olds only demonstrated this comprehension for the subject what-questions (*t*=3.78, *p*<.001). The ASD-high group demonstrated significant wh-question comprehension for the object what-questions (*t*= 2.43, *p*=0.02), but not for subject what-questions (*t*= 1.08, *p*>.05), while the ASD-low group did not demonstrate significant comprehension for either question type.
Conclusions: TD Korean 4-year-olds showed robust comprehension of wh-questions; however, the other groups all demonstrated some difficulties, with TD 2-year-olds succeeding only on subject wh-questions, ASD-high children succeeding only with object-wh-questions, and ASD-low children not succeeding on either. Therefore, the grammatically simpler form of Korean wh-questions do not appear to facilitate earlier acquisition of these forms, leaving open a role for pragmatics.

122 **164.122** Therapist Role-Reversals in an Autism Spectrum Pilot Study: Robot Malfunctions Prompt Enhanced Social Speech Performance

S. M. Walsh Matthews *and J. Pelkey, Languages, Literatures, and Cultures, Ryerson University, Toronto, ON, Canada*

Background: Recent studies (e.g., Kim et al. 2015) show increased social communicative behavior by children with Autism Spectrum Disorder (ASD) following human robot interaction (HRI). To test these results with a specific focus on social speech development, we designed and implemented a multi-month pilot study using HRI, hypothesizing that children with ASD would show improved linguistic and pragmatic communication skills through time. Tanaka and Matsuzoe (2013) find that using HRI in standard primary school settings enhances vocabulary, suggesting this may be due to role-reversal opportunities afforded by HRI, allowing children to serve as robot care-givers. This effect holds relevance for our findings.
Objectives: To use native NAO robot programming behaviors to elicit and observe social speech performance in three children with ASD through a pilot study hosted by an equal care (ABA, Therapy directed learning) center, allowing participants to interact with the small humanoid robot by playing semantic-domain card games, spontaneous dialogues and other routines.
Methods: The study used a grounded-theory, mixed-methods approach, combining ethnographic observation, with first language acquisition metrics, cognitive linguistic analyses and speech pragmatic analyses. Three investigators were required to facilitate each field data collection session, including an interface technician and two participant observers. Session programming was standardized across participants. Ethnographic field notes were rendered into project reports and compared with WAV audio recordings of HRI sessions to produce detailed transcripts coded to CHILDES CHAT standards (MacWhinney 2000). At least two investigators coded each transcript for multiple layers analysis, including Mean Length of Utterance (MLU) analysis, structural discourse analysis, content analysis of discourse pragmatics (with a focus on implicature), and cognitive semantic analysis of conceptual blends and script-frame dynamics.
Results: Relative levels of speech performance were operationalized after two visits to define varying degrees of proficiency per child: high [H], medium [M] and low-functioning [L], corresponding with preliminary MLU counts of 1.8[H], 1.0[M] and 0[L], further operationalized via successive layers of analysis. Modest net increases in MLU were apparent by the third visit (MLU=2.1[H] and 1.2[M]), and utterance counts increased substantially (n=82[H], n=69[M]). Speech pragmatic analyses indicated concrete instances of increased linguistic performance for social ends by participants H and M, including (1) increased usage of spontaneous vocatives, (2) increased verbal strategies to initiate conversation and (3) increased response rate to content questions. Linguistic strategies for the expression of concern, humor, empathy and care-giving also emerged following unplanned instances of robot malfunction, including unprompted assumption of overt role reversal by participant H, who offered a behavioral modification reward to the robot following technical correction of a software malfunction by investigators. Using insights from Cognitive Linguistics, such behavior is analyzed as a conceptual blend or interchange between Idealized Cognitive Models.
Conclusions: Using a range of fresh linguistic evidence, including first language acquisition metrics, cognitive linguistic analyses and speech pragmatic analyses, our study confirms that children with ASD who interact with robots demonstrate increased social communicative behaviors. We further find that robot malfunctions can give rise to care-giving role-reversals. Children assuming such roles improved in linguistic performance.

123 **164.123** Treatments Priorities of Saudi Parents for Their Children with ASD

F. Alnemary[1]*, H. M. Al Dhalaan*[2] *and F. Alnemary*[1]*, (1)UCLA, Los Angeles, CA, (2)King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*

Background:
Identifying parents' treatment priorities prior to treatment planning is critical. No information about parents' treatment priorities for their children with ASD in the Arab World.
Objectives:
To identify the treatment priorities that parents in the KSA have for their children with ASD. A second aim of the study was to determine whether child characteristics reflect on parent priorities.
Methods:
Data were collected from 156 caregivers of children with ASD who participated in a project aim to evaluate ASD in the KSA. The percentages of priorities were calculated identify the highest area of need. Chi-Square was used to examine the association between parent priorities and child characteristics.
Results:
The top treatment priorities were toileting and communication, followed by safety, school achievement, relationship with peers, sensory needs, problem behaviors, adaptive skills, relationship with siblings, feeding, community outings, compliance, sleeping issues, repetitive behaviors, parent-child interaction, and greeting. Parents' treatment priorities differed by child characteristics such age, gender, and severity of the ASD symptoms.
Conclusions:
Parent priorities tended to be higher in areas where children have the greatest deficits or show emerging skills, thus emphasizing on the importance on targeting the assessment of children's deficits and emergent skills for treatment planning.

124 **164.124** Understanding How Parent Pragmatics Influence Child Language

Y. S. Stern *and M. Y. Roberts, Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Quantity and quality of parents' child-directed language influence children's language development. Previous work has demonstrated that early language development is boosted by parents' use of certain strategies related to responsiveness. The delivery of verbal responses that are both temporally and topically contingent to a child's utterances facilitates language development. Since these response strategies are functionally similar to typical adult pragmatic norms, it is important to examine whether differences in parent pragmatic styles may affect the language input a child receives. As pragmatic differences have been identified in unaffected family members of individuals with autism, it is critical to understand how parental pragmatic differences might influence language learning in young children with ASD.
Objectives: The focus of this project was to determine how parent pragmatic profiles relate to early child language profiles of children with ASD. This project also aimed to

assess whether pragmatic profiles of parents predict parent use of language support strategies prior to participation in a parent-implemented language intervention. We explore the hypothesis that for parents of children with ASD, pragmatic profiles characterized by higher rates of pragmatic violations are negatively associated both with child language standard scores and parental use of language support strategies.
Methods: We adapted the Pragmatic Rating Scale (PRS; Landa et al., 1992) to assess the pragmatic quality of parent language during a semi-structured interview that was conducted prior to initiation of a parent-mediated language intervention. These conversations were coded for frequency and severity of pragmatic violations. A total of 20 parents of children between 24-42 months, were included in analyses (10 parents of children with ASD, 10 parents of children with a non-ASD language delay). The Preschool Language Scales (PLS-4) was conducted with each child to assess pre-treatment receptive and expressive language levels.
Results: An independent samples t-test revealed that parents of children with ASD scored significantly higher on the PRS (indicating more pragmatic violations), as compared to parents of children with a non-ASD language delay, $t(18) = -2.301$, $p < .001$. Partial correlations revealed that within the group of parents of children with ASD, PRS Totals were negatively correlated with child expressive language level, as measured by PLS-4 expressive language Standard scores, $r(7) = -.66$, $p < .05$. Additionally, within this group, PRS Totals were also negatively correlated with parent use of the expansions strategy in a pre-treatment play interaction, $r(7) = -.68$, $p < .05$.
Conclusions: Parent pragmatic style may contribute to difficulty with language learning in children with ASD. It may be challenging for parents with different pragmatic styles to naturally respond to child utterances in a topically contingent manner and implement the expansions strategy. This may indirectly influence child language development. The project highlights the responsibility of researchers and clinicians to consider parent language factors during design and implementation of parent-mediated language interventions for children with autism. Consideration of parent language may increase the likelihood that a parent-mediated language intervention will address both the needs of the child with ASD, as well as the parent's capacities.

125 **164.125** Uneven Language Acquisition in Mandarin-Learning Preschool Children with ASD: Comparing Vocabulary, Grammar, and Pragmatic Use Via the PCDI-Toddler Form

Y. E. Su[1], *L. Naigles*[2] *and L. Y. Su*[3], *(1)Institute for Applied Linguistics, School of Foreign Languages, Central South University, Changsha, China, (2)University of Connecticut, Storrs, CT, (3)Mental Health Institute, The Second Xiangya Hospital of Central South University, Changsha, China*

Background:
English-speaking children with autism spectrum disorders (ASD) have often been reported to demonstrate an uneven language profile, with strengths in vocabulary and grammar in contrast to the pragmatic deficits (Tager-Flusberg et al. 2005; Boucher 2012). Recent research has begun to delineate language profiles in non-English speaking children with ASD, to characterize the general language acquisition process of children with ASD across countries (Su et al. 2014; Terzi et al. 2014).
Objectives:
Using the Putonghua Communicative Development Inventory: Words and Sentences (PCDI-Toddler Form; Tardif et al., 2008), this study attempts to characterize expressive language profiles in Chinese preschool children with ASD, especially to compare vocabulary, grammar and pragmatic use.
Methods:
Parents of 110 2-6-year-old children with ASD (97 boys and 13 girls, mean age = 51.57 ± 15.34 months) completed the PCDI-Toddler Form. Children were divided into 3 subgroups - Low Verbal (LV, n=62), Middle Verbal (MV, n=30) and High Verbal (HV, n=18), based on a trimodal histogram of total vocabulary production scores (LV: 0–200 words; MV: 201 – 499 words; HV: 500+ words). Language abilities were compared among the subgroups and with the published norms of typically-developing (TD) children.
Results:
The LV, MV and HV subgroups were each significantly different in total vocabulary production as well as all five subcategories (nouns, verbs, pronouns, quantifiers and question words; ps < .01). The 3 subgroups also differed significantly in the four grammatical subcategories of serial verb construction, possessive, quantifier, and past tense marker (ps <.05 for 9/12 comparisons) and in the 5 pragmatic subcategories of abstract objects, possession, absent toys/animals, past events/people, and future events (ps <.05 for 12/15 comparisons). When matched on total vocabulary production scores with TD children aged 16 months, 20 months and 27 months, the three ASD subgroups didn't generally differ from the TD children on lexical subcategory scores (ps=.07-.75 for 13/15 comparisons), nor on grammatical subcategory scores (ps = .20 -.91 for 9/12 comparisons). In contrast, the vocabulary-matched groups did consistently differ on the subcategories of the pragmatic uses of language (ps <.05 for 12/15 comparisons), with the ASD groups showing lower scores. Correlations between the total grammatical and total pragmatic scores were not significant once vocabulary was partialled out, for the whole ASD group, nor for the three ASD subgroups (ps = .25 - .65).
Conclusions:
LV, MV and HV subgroups of Mandarin-speaking children with ASD differ on grammatical and pragmatic as well as vocabulary skills. However, compared to vocabulary-matched TD children, children with ASD seemed to have more difficulties in the pragmatic than in the grammatical uses of language. Furthermore, the grammatical and pragmatic uses of language were not significantly related, even in this large dataset of Mandarin-learning preschool children with ASD. These findings thus corroborate the uneven language profile reported in English-learning children with ASD.

126 **164.126** Validity Testing of a Social Communication Classification System of Functioning for Preschool Children with Autism Spectrum Disorder (ASD)

B. M. Di Rezze[1,2], *P. Stratford*[1], *P. Rosenbaum*[2], *L. Zwaigenbaum*[3], *M. J. C. Hidecker*[4], *H. Viveiros*[2] *and M. Law*[1], *(1)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (2)CanChild Centre for Childhood Disability Research, McMaster University, Hamilton, ON, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Communication Disorders, University of Wyoming, Laramie, WY*

Background: We have created an ASD functional classification system based on the WHO's International Classification of Functioning, Health and Disability (ICF). The Autism Classification System of Functioning: Social Communication (ACSF:SC) is a novel 5-level descriptive system with demonstrated consistency in ratings of both capacity (i.e., best) and typical performance by parents and professionals of preschool children with ASD.
Objectives: To examine the construct validity of the ACSF:SC across settings (i.e., home and clinic) and the spectrum of abilities of preschool children with ASD.
Methods: Support for ACSF:SC construct validation was proposed with a priori hypotheses by the research team based on Pearson correlation coefficients between ACSF:SC ratings (parents or professionals) and sub-domains of other measures. Construct validity was examined using concurrent ratings of the ACSF:SC with prominent ASD measures that evaluate function and/or social communication to assess: (1) convergent validity: how well the ACSF:SC correlates with measures possessing domains related to social communication; and (2) discriminant validity: weak correlations with unrelated functional domains. Professionals and parents completed the ACSF:SC ratings, and a concurrent self-report measure (Social Responsiveness Scale 2nd edition [SRS-2]). Parents also completed two interview-based measures: the Vineland Adaptive Behavior Scale-2 (VABS-2) and the Autism Diagnostic Interview-Revised (ADI-R) algorithm. For the ADI-R algorithm, only Social Interactions (section A) and Communication (section B) were completed.
Results: The sample included 36 children whose ACSF:SC and SRS-2 were completed by their parents. The mean age (SD) was 4.3 (0.9) years (85% male). 27 (75%) parents completed an interview to collect data for the VABS-2 and ADI-R algorithm. 33 professionals completed ACSF:SC and SRS-2 ratings. Descriptive data showed that children categorized as either verbal or non-verbal based on the ADI-R algorithm had an ACSF:SC across most of the 5 ability levels (Table 1). Mean composite scores for parent scores on the SRS-2 and VABS2 were generally increasing across improved functioning on the 5 ACSF:SC levels (i.e., ACSF:SC rating of 1 = highest ability) (Table 2). Convergent validity testing between the SRS-2 subdomain (Social Communication and Interaction [SCI]) and ACSF:SC showed statistically significant correlations for capacity (95% confidence interval[CI]), for parents: 0.52 (0.23,0.73) and for professionals: 0.63 (0.36,0.80), respectively. Discriminant validity comparing the ACFS:SC tool with an unrelated sub-domain of function on the VABS-2 (i.e., Motor Skills) demonstrated no significant correlations for capacity, -0.34 (-.64,0.04).
Conclusions: Without a gold standard, testing validity of a novel tool is challenging, requiring other measures that may be only partly related to its core construct (i.e., social communication functioning). These data demonstrated that ACSF:SC ratings by both parents and professionals were related to SRS-2-defined social communication. Parent ratings of children identified as having both verbal and non-verbal abilities also demonstrated abilities across most of the five ACSF:SC levels, indicating that social communication ability is not contingent on verbal ability. These data are promising starting point for an ongoing validation process of the ACSF:SC.

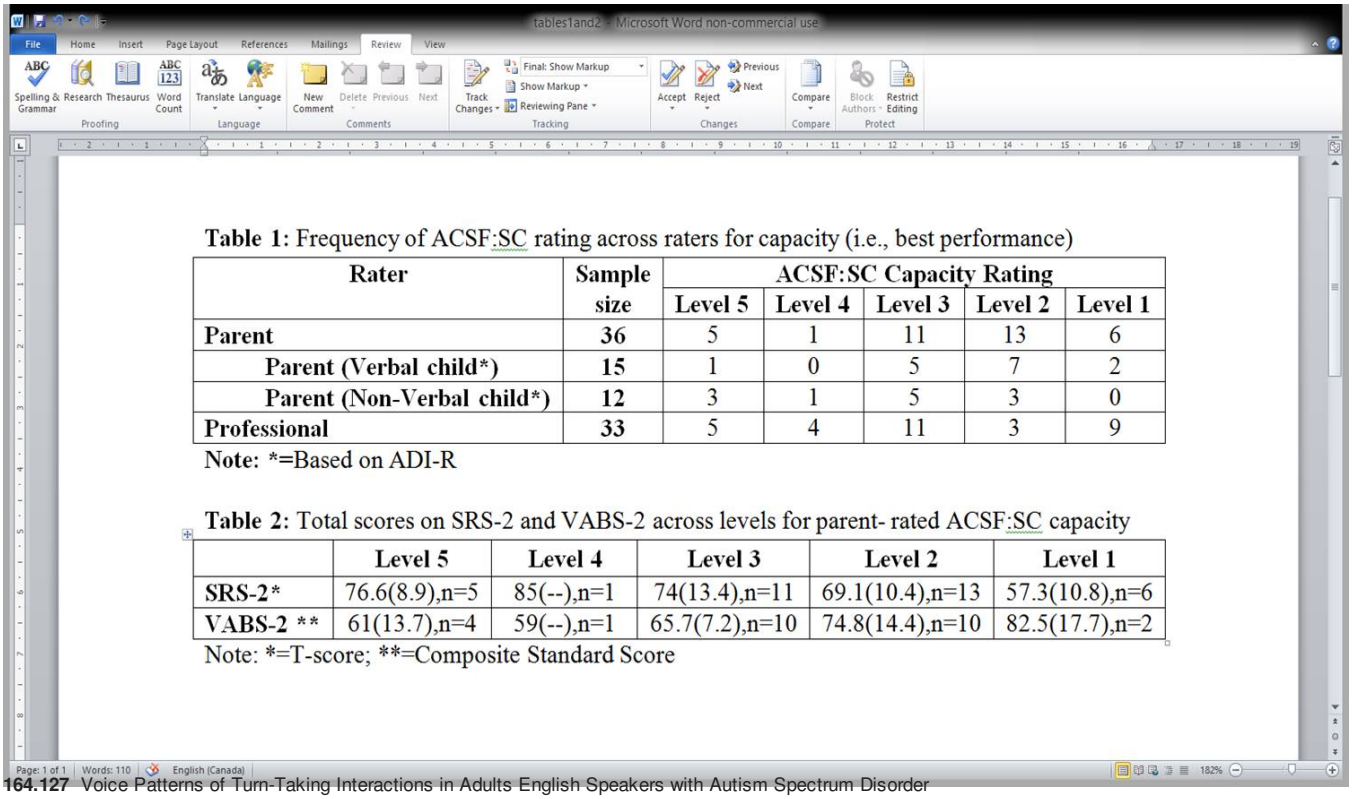

Table 1: Frequency of ACSF:SC rating across raters for capacity (i.e., best performance)

Rater	Sample size	ACSF:SC Capacity Rating				
		Level 5	Level 4	Level 3	Level 2	Level 1
Parent	**36**	5	1	11	13	6
Parent (Verbal child*)	**15**	1	0	5	7	2
Parent (Non-Verbal child*)	**12**	3	1	5	3	0
Professional	**33**	5	4	11	3	9

Note: *=Based on ADI-R

Table 2: Total scores on SRS-2 and VABS-2 across levels for parent- rated ACSF:SC capacity

	Level 5	Level 4	Level 3	Level 2	Level 1
SRS-2*	76.6(8.9),n=5	85(--),n=1	74(13.4),n=11	69.1(10.4),n=13	57.3(10.8),n=6
VABS-2 **	61(13.7),n=4	59(--),n=1	65.7(7.2),n=10	74.8(14.4),n=10	82.5(17.7),n=2

Note: *=T-score; **=Composite Standard Score

127 **164.127** Voice Patterns of Turn-Taking Interactions in Adults English Speakers with Autism Spectrum Disorder

R. Fusaroli[1,2], *A. Lambrechts*[3] *and K. L. Maras*[4], *(1)Interacting Minds, Aarhus University, Aarhus, Denmark, (2)Center for Semiotics, Aarhus University, Aarhus, Denmark, (3)City University London, Ruislip, England, United Kingdom, (4)University of Bath, Bath, United Kingdom*

Background: Individuals with Autism Spectrum Disorder (ASD) reportedly display atypical modulation of speech described as awkward, monotone, or sing-songy (Shriberg et al., 2001). These patterns are robust indicators of social communication deficit (Paul et al., 2005) and contribute to reaching a diagnosis of ASD. Fusaroli et al. (2013 ; IMFAR 2014 ; IMFAR 2015) showed that Recurrence Quantification analysis of acoustic features could be used to successfully identify voice patterns characteristic of adults with ASD and train machine learning algorithms to accurately (80-86%) discriminate autistic from non-autistic speakers in directed speech recordings.
Objectives: Our aim was to replicate and extend the results obtained by Fusaroli et al. (2013, 2014, 2015) in a turn-taking interaction, i.e. (1) characterise the speech patterns of adults with ASD in a Q&A setting, (2) characterise the corresponding changes in the interlocutor's speech patterns, and (3) employ the results in a supervised machine-learning process to determine whether acoustic features predict diagnosis and severity of the symptoms. We were also interested to evaluate how valid the model built based on directed speech data would be on turn-taking data
Methods: The context of a previously published study of memory in ASD (Maras et al., 2013) provided audio recordings of 17 ASD and 17 matched Typically Developing (TD) adults recalling details of a standardised event they had participated in. Part of the recording consisted in a Q&A between experimenter and participant, i.e. a turn-taking interaction. Transcripts were time-coded, and pitch (F0), speech-pause sequences and speech rate were automatically extracted. We conducted traditional statistical analysis on each prosodic feature. We then extracted non-linear measure of recurrence: treating voice as a dynamical system, we reconstructed its phase space and measured the number, duration and structure of repeated trajectories in that space (Marwan et al., 2007). The results were injected to train a linear discriminant function algorithm to classify the descriptions as belonging either to the ASD or TD group. The model was developed and tested using 1000 iterations of 10-fold cross-validation (to test the generalizability of the accuracy) and variational Bayesian mixed-effects inferences (to compensate for biases in sample sizes).
Results: Preliminary analysis of a subset of recordings suggest similar results to those obtained with directed speech: ASD individuals ASD produce highly regular speech patterns organized in frequently repeated short sequences (200-400 ms), supporting clinical reports of monotony. While features are similar across modes of communication, the coefficients discriminating individuals with ASD and controls need to be re-trained in the context of a turn-taking interaction. Interestingly, the interlocutor's speech patterns are as informative about diagnosis as the participants'.
Conclusions: The current data suggest than ASD adults produce highly regular patterns of speech in turn-taking interaction. Importantly this measurement captures some aspects of the clinical reports, which contribute to reaching a diagnosis of autism. Further analysis will establish whether voice patterns in turn-taking interaction are particularly distinct in ASD compared to directed speech, indicating whether interactive conversation exacerbates voice pattern atypicalities, reflecting the reported "awkwardness" in the interaction with ASD individuals ASD.

128 **164.128** Word Order Understanding Guides Wh-Question Comprehension

M. Jyotishi *and L. Naigles, University of Connecticut, Storrs, CT*

Background:
Wh-questions are challenging for children with ASD. Prior research has shown delays in both production and comprehension of questions like "What did the apple hit?" and "Who pushed the doggy?" in ASD compared with TD groups (1, 2). Some researchers have argued that children with ASD have particular difficulties with complex grammatical structures (3) while others have proposed that the impairments are related to pragmatics (4). We investigate the former possibility by examining whether early grammatical competence predicts later wh-question comprehension. One index of early grammar is word order; children who successfully process wh-questions must have abstracted the subject-verb-object (SVO) frame. Therefore, children's ability to successfully process SVO sentences could help them learn wh-question structures.
Objectives:
We investigated the degree to which comprehension of SVO word order at 2 years predicted wh-question comprehension at 3-4 years in a large sample of children.
Methods: Language comprehension of 35 TD children (MA_{visit1} =20.20 months) and 29 children with ASD (MA_{visit1}=33.16 months) was assessed via intermodal preferential looking every four months for two years in this longitudinal study. At visits 1-2, children viewed the word order video, in which they were shown side-by-side reversible actions involving a costumed horse and bird, paired with Baseline trials ("we can see both") and test trials ("The horse is washing the bird" vs. "the bird is washing the horse") (3,4). At visits 3-6, children watched the Wh-Question video, in which each horse-and-bird action was followed by trials in which the horse and bird appeared side by side. The test audios were e.g., "Where is the bird/horse?" for Where/Baseline trials, "What washed the horse?" for Subject wh-questions and "What did the bird wash?" for Object wh-questions. Children's eye movements were coded off-line. The dependent measures were difference scores of proportion looking to the target during the test minus baseline trials; larger differences indicated stronger comprehension. Word order scores were combined across visits 1 – 2; wh-question scores were analyzed for each visit.
Results:
In the TD group, a significant correlation was obtained between early word order and subject-wh-question at visit 5, $r = .359$, $p < .05$. In the ASD group, a significant correlation was obtained between early word order comprehension and object-wh-comprehension at visit 6, $r = .381$, $p < .05$. Stepwise regressions in which NVIQ (Mullen VR) and vocabulary (CDI:Communicative Development Inventory) were entered first revealed that word order was the only significant predictor of subject-question comprehension for the TD group, $F(1,30) = 4.43$, $p = .044$ ($R^2 = .129$). For the ASD group, NVIQ and early word order (but not vocabulary) jointly accounted for a significant amount of variance in object wh-question comprehension ($R^2 = .272$).
Conclusions:
Early performance on SVO word order predicted later wh-question comprehension in both group; thus, children's understanding of wh-questions seems to be emerging from their knowledge of English sentence frames. These findings lend support to the hypothesis that the sparse and delayed wh-question use of children with ASD has grammatical roots, perhaps in combination with pragmatic roots.

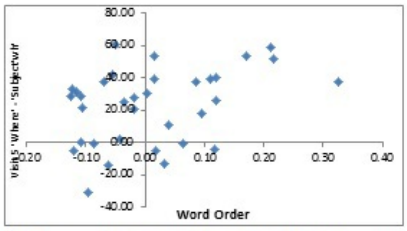

Figure 1. Word order significantly predicted Visit 5 'Where' – 'Subject-wh' in TD group.

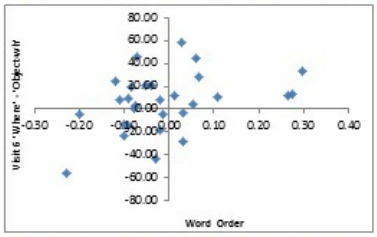

Figure 2. Word order significantly predicted Visit 6 'Where' – 'Object-wh' in ASD group.

129 **164.129** Writing Development in Higher-Functioning Children with Autism Spectrum Disorder with and without ADHD Comorbidity

M. C. Zajic[1], *N. S. McIntyre*[1], *L. E. Swain-Lerro*[1], *J. B. McCauley*[2], *H. K. Schiltz*[3], *T. Oswald*[2] *and P. C. Mundy*[4], *(1)University of California at Davis MIND Institute, Davis, CA, (2)University of California at Davis MIND Institute, Sacramento, CA, (3)Human Development, University of California at Davis, Davis, CA, (4)Education and Psychiatry, University of California at Davis, Sacramento, CA*

Background: Higher-functioning children with ASD (HFASD) often experience difficulty with writing. However, this problem also occurs for children with ADHD. Few studies have examined the effect of the co-occurrence of symptoms of ASD and ADHD on writing, and few studies have addressed the question of how well children with HFASD develop writing abilities across time in longitudinal research.

Objectives: To address these gaps in the literature, this longitudinal study examined writing ability in 8–16 year-old school-age children with HFASD compared to children with ADHD and typical development (TD). This study also examined the hypothesis that children with HFASD with comorbid elevations of ADHD would display poorer writing development than children with HFASD without comorbid ADHD.

Methods: The participants were 17 children with HFASD without ADHD symptoms (HFASD-L), 39 with HFASD and ADHD symptoms (HFASD-H), 24 children with only ADHD symptoms, and 25 children with TD. ASD symptoms were confirmed with the ADOS–2. ADHD symptoms (T-scores > 70) were confirmed with parent reports on the Conners-3. All groups were age matched at the first visit (T1) and re-assessed 15 months later (T2). IQ was assessed with the WASI-II, and FIQ was included as a covariate in all analyses due to group differences (Table 1). Writing was assessed with the Wechsler Individual Achievement Test–3 (WIAT-III). At T1, all children handwrote their responses; at T2, children were given the choice (their preference) to handwrite or type their responses.

Results: A mixed-design MANCOVA yielded a significant effect for time point on overall writing scores for all groups, $F(1,100)=7.0$, $p=.009$, $eta^2=.07$. Significant time point effects across groups were also observed on the WIAT-III word count and thematic content scores ($p=.027$ and $.009$, respectively; see Figure 1). Main effects for diagnostic group were observed for overall writing score, $F(3,100)=3.14$, $p=.03$, and word count, $F(3,100)=3.38$, $p=.03$, both $eta^2=.09$ (see Figure 1), but not for thematic content, $p=.15$. Children with HFASD-H performed poorest of all groups for overall writing score and word count (see Figure 1) but planned comparison revealed this difference was significant only versus the children with TD. Children with HFASD-H also performed poorly on thematic content at T1, but this effect was not apparent at T2 (see Figure 1).

Conclusions: This study provided evidence that many children with HFASD may be at risk for poor academic writing development, especially children with HFASD and comorbid ADHD symptoms. It was not clear if the writing risk of children with HFASD-H was appreciably greater than children with HFASD-L or ADHD; sample sizes may have limited the power of these comparisons. Alternatively, the results also provided evidence of improvement in writing across groups, suggesting that specific writing instruction may be a useful modality for communication intervention among children with HFASD or ADHD. Future research on measurement issues, such as handwriting versus typing and comparing the WIAT-III versus other writing assessments, will sharpen our understanding of writing development in children with HFASD and ADHD.

Table 1

Descriptive Statistics by Diagnostic Groups for Age, IQ, and Diagnostic Measures with One-Way Analysis of Variance (ANOVA) Comparisons

	TD		ADHD		HFASD-L		HFASD-H		ANOVA Comparisons	
N	25		24		17		39			
Measures	M	SD	M	SD	M	SD	M	SD	F	p value

C

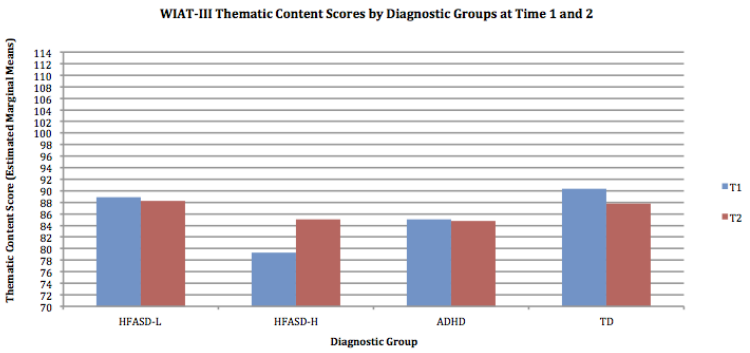

Figure 1. Age-based standardized WIAT-III writing scores for overall writing (A), word count (B), and thematic content (C) across the four-diagnostic group split across time points one and two. All estimated marginal means covary for FIQ = 102.92.

N. M. Heckel[1], *J. Barstein*[2], *G. E. Martin*[3] *and M. Losh*[1], *(1)Department of Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Northwestern University Feinberg School of Medicine, Chicago, IL, (3)Communication Sciences and Disorders, St. John's University, Staten Island, NY*

Background: Pragmatic language is universally impaired in individuals with ASD, and sub-clinical pragmatic language differences have been observed in a subgroup of first-degree relatives. Believed to constitute an endophenotype indicative of genetic risk to ASD, pragmatic language differences among relatives have been described as part of the broad autism phenotype (BAP). Prior investigations of pragmatic language in unaffected relatives revealed global differences in contingency and content in both narrative and conversational tasks (Landa et al., 1991, 1992; Losh et al., 2008, 2012). This study attempted to build on this work by applying a fine-grained discourse analysis to transcripts of conversational interactions from parents of individuals with ASD. In particular, we examined the use of conversational markers essential for cohering messages and maintaining the conversational floor, as well as the relevance and repetition of thematic content, which influences conversational reciprocity.
Objectives: To examine the patterns of discourse marker use and thematic content of conversational samples from parents of individuals with ASD and age- and IQ-matched controls.
Methods: Participants included 30 parents of individuals with ASD and 36 parents of typically-developing controls. A detailed coding scheme (adapted from Martin et al., 2012) was used to assess discourse marker use, thematic content, and topic repetition during a semi-structured conversation. Discourse markers included Back-Channeling (i.e., listener responses, 'okay', 'yeah') and Filled Pauses (e.g., 'uh', 'um'). Thematic content was evaluated by how related a topic was to ongoing discourse (i.e., Contingent vs Noncontingent). Topic repetition was derived by the proportion of topics that were spontaneously re-introduced by participants >2 times. BAP status (positive + or negative -) was determined using the Modified Personality Assessment Scale (MPAS; Tyrer, 1988) and global pragmatic language was assessed using the Pragmatic Rating Scale (PRS; Landa, 1992).
Results: Family diagnostic groups differed in their use of discourse markers. Specifically, the ASD parent group overall used Filled Pauses less than Control parents $F(1, 79) = 6.44$, $ps < .05$. When broken down by BAP status, however, the BAP (+) parents used Back-Channeling significantly less than control parents $F(2, 57) = 4.45$, ($p < .01$) and BAP (-) parents ($p < .02$). BAP (+) parents also demonstrated increased discussion of Noncontingent topics $F(2, 66) = 6.95$, $ps < .01$ relative to both groups. Greater discussion of Noncontingent topics was significantly related to a pragmatic language domain associated with talkativeness and overly detailed language ($r = .63$) in BAP (+) parents. Higher rates of repetitive topic introduction were observed in the BAP (+) group $F(2, 67) = 2.40$, $ps < .05$.
Conclusions: Differences in discourse marker use and thematic content in conversation were associated with subclinical features of genetic risk in parents of individuals with ASD. In particular, BAP (+) parents demonstrated word use patterns indicative of *reduced* reciprocity. Such discourse patterns may significantly, albeit subtly, influence communication styles relevant to interpersonal relationships. These findings underscore the subtle manifestation of pragmatic language differences as a possible endophenotype of ASD.

165 - Diagnostic, Behavioral & Intellectual Assessment II
5:30 PM - 7:00 PM - Hall A

131 **165.131** ABAS-II Adaptive Profiles and Correlates in Samples of Children with HFASD or LFASD

C. A. McDonald[1], ***B. C. Nasca***[2], *C. Lopata*[1], *J. P. Donnelly*[1], *M. L. Thomeer*[1] *and J. D. Rodgers*[1], *(1)Institute for Autism Research, Canisius College, Buffalo, NY, (2)Counseling, School, And Educational Psychology, SUNY at Buffalo, Buffalo, NY*

Background: There have been few studies that have used the ABAS-II to document adaptive profiles in homogeneous samples of high-functioning children with autism spectrum disorder (HFASD) and children with ASD and co-occurring intellectual disability (LFASD). Further, prior studies of predictors of adaptive functioning using either the VABS or ABAS-II have yielded mixed results (Lopata et al., 2012; McDonald et al., 2014).
Objectives: This study (a) examined the ABAS-II adaptive profile within each sample, (b) compared adaptive functioning and cognitive ability, and (c) assessed predictors (i.e., age, IQ) of adaptive skills.
Methods: Participants included 110 children (i.e., 55 with HFASD and 55 with LFASD), ages 6 to 12 years. The LFASD sample was recruited from a center-based school serving students with ASD and co-occurring cognitive and language deficits. Inclusion criteria included an independent diagnosis of an ASD and/or educational classification of autism and estimated IQ < 70. The second sample consisted of 55 children with HFASD recruited from prior clinical trials with an independent diagnosis of ASD and WISC-IV short-form IQ ≥ 85. The dependent measure used was the parent rating form of the Adaptive Behavior Assessment System - Second Edition (ABAS-II).
Results: Examination of the adaptive profile for the HFASD sample indicated a relative strength in the Conceptual domain (CON), followed by Practical (PRAC), and lastly Social (SOC) domains. Comparisons of cognitive and adaptive abilities within the sample indicated significantly lower scores on the GAC, $t(54) = 12.50$, $p < .001$, $d = 2.49$, and all of the adaptive domains [CON, $t(54) = 10.48$, $p < .001$, $d = 1.93$; PRAC, $t(54) = 9.64$, $p < .001$, $d = 1.95$; SOC $t(54) = 13.75$, $p < .001$, $d = 2.78$]. The majority of correlations between adaptive ability and cognitive ability and age were nonsignificant, with the exception of the relationship between age and SOC ($r = -.27$, $p < .05$), which was negative and significant. For the LFASD sample, no significant difference was found between cognitive ability and overall adaptive performance, GAC, $t(54) = 1.83$, $p = .073$, $d = 0.08$, or PRAC $t(54) = .54$, $p = .593$, $d = -1.00$. However, this sample performed significantly higher than expected on CON, $t(54) = -2.91$, $p < .005$, $d = -1.17$, and SOC, $t(54) = -6.35$, $p < .001$, $d = -1.33$, given their estimated cognitive ability. All correlations between age and adaptive abilities were nonsignificant ($p > .05$), while relationships between estimated cognitive ability and all adaptive areas for the LFASD sample were positive and significant ($p < .01$), with rs ranging from .35-.46.
Conclusions: The measurement of adaptive behavior is important both in diagnostic and psychological assessment. While individuals with LFASD displayed a relative strength in adaptive behavior in comparison to their estimated cognitive ability, individuals with HFASD displayed an overall cognitive strength with relative adaptive deficits. Results highlighted a need for intervention in the area of adaptive skills for children with ASDs, especially in the area of social skills for those with HFASD.

132 **165.132** Adaptive Behavior in Children with ASD with Monolingual and Bilingual Language Experience

S. B. Vanegas*, K. Acharya and L. Sandman, University of Illinois at Chicago, Chicago, IL*

Background:
Children with ASD typically present challenges across multiple areas of functioning. Adaptive behavior skills can yield practical information on the everyday functioning of children with ASD. The Vineland Adaptive Behavior Scales (Sparrow et al., 1984, 2005) has been developed as a parent interview to capture skills in communication, daily living, socialization, and motor domains and has been widely used in ASD research (e.g., McDonald et al., 2015). However, there is limited research on adaptive behavior skills among racial/ethnically diverse children with ASD. Evaluating adaptive behavior skills of children from diverse backgrounds can be a critical step in developing effective treatment goals.
Objectives:
The current study intends to fill a gap in empirical data on adaptive behavior skills in a diverse sample of children with ASD with monolingual and bilingual language experience.
Methods:
Clinical records for children with ASD between 3 and 12 years of age were reviewed from a developmental disabilities clinic located in a large diverse city in the United States. Data was extracted from the clinical record including demographics, language experiences, and scores for the Vineland Adaptive Behavior Scales and nonverbal IQ. Children were eligible for inclusion if they were verbal and had a nonverbal IQ score greater than 70. Children's language status was determined by review of clinician observations, parent-report of language use in the home/school, and language use reported in IEP reports. The preliminary sample included 57 children, with a mean age of 6.20 years. The monolingual group included 15 children (53% White, 47% African-American; 100% male) and the bilingual group included 42 children (100% Latino; 93% male, 7% female).
Results:
Preliminary analyses demonstrated that the bilingual group was older than the monolingual group and no differences were found in nonverbal IQ between groups. A MANOVA was then conducted on the standard scores for the Communication, Daily Living Skills, and Socialization subscales of the Vineland across child language groups, with age as a covariate. These analyses found that parent-reported communication skills did not differ between monolingual and bilingual children with ASD, $F(1, 54) = 1.30$, $p = .260$. Analyses also showed that bilingual children with ASD had more intact daily living skills, $F(1, 54) = 6.80$, $p = .012$, partial $\eta^2 = .11$, and more intact socialization skills, $F(1, 54) = 5.97$, $p = .018$, partial $\eta^2 = .10$, than monolingual children with ASD.
Conclusions:
The preliminary results finds that within a diverse sample of children with ASD, children with bilingual language experience had greater daily living and socialization skills when compared to children with monolingual language experience. These results are supported by one study comparing simultaneous and sequential bilingual children with ASD (Hambly & Fombonne, 2012). These results suggest that bilingual language experience may afford children with ASD additional opportunities for developing adaptive behavior skills. Additional data is needed to determine if adaptive behavior skills vary due to language experience or cultural values. These results contribute to the field by providing empirical evidence on diverse language experiences and adaptive behavior in children with ASD.

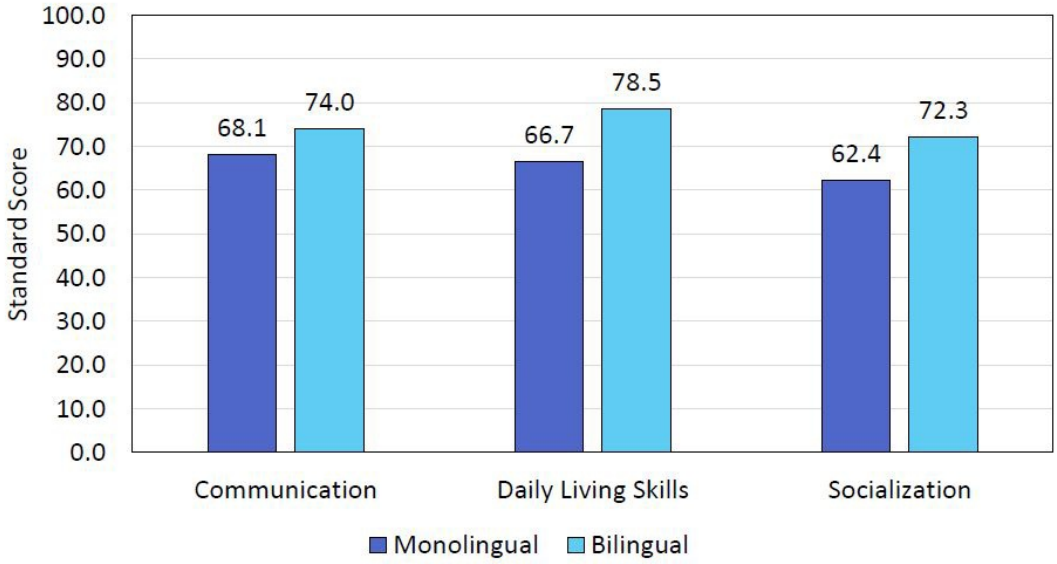

Figure 1. Standard Scores for subscales of the Vineland Adaptive Behavior by language group

133 **165.133** An Initial Evaluation of the Validity of the Gilliam Autism Rating Scale-Third Edition (GARS-3) in a Clinical Sample

*K. A. Hastings and **J. M. Campbell**, University of Kentucky, Lexington, KY*

Background: Third party rating scales are often used to support diagnostic decision making in Autism Spectrum Disorder (ASD) diagnostic evaluations. One such measure is the Gilliam Autism Rating Scale-Third Edition (GARS-3; Gilliam, 2014). The GARS-3 is a standardized norm-referenced instrument designed to assist in the diagnosis of ASD. The GARS-3 is keyed to correspond with DSM-5 diagnostic criteria and was standardized with a sample of 1,859 individuals with ASD 3 to 22 years of age. Gilliam (2014) provides psychometric support for the GARS-3 as evidenced by internal consistency of .79 - .94 for GARS-3 subscales and .93 - .94 for GARS-3 Autism Index scores. Gilliam also reports criterion-related validity in support of the GARS-3 as evidenced by significant correlations between the GARS-3 Autism Index and (a) the Childhood Autism Rating Scale, Second Edition (CARS-2) and (b) Autism Diagnostic Observation Schedule.
Objectives: The authors conducted an initial evaluation of the validity of the GARS-3 by correlating scores with well-established measures of autism symptomatology. Investigators also contrasted GARS-3 scores between individuals who met DSM-5 diagnostic criteria for ASD and those individuals who did not.
Methods: Participants were 20 individuals (*M* age = 8.23 yr; 80% Male; 80% Caucasian; 12 diagnosed with ASD, 8 diagnosed with another DSM-5 disorder) who participated in comprehensive diagnostic evaluation at a training clinic at a land grant university in the Southeast U.S. Diagnostic evaluation was established using results from the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) and CARS-2. Caregivers completed the GARS-3 as part of the diagnostic evaluation; GARS-3 ratings were collected for the purposes of research and were not used in diagnostic decision making.
Results: Preliminary results indicate significant relationship between ADOS-2 Module 3 Total Scores and CARS-2 T Score, $r(3) = .87$, $p < .05$. ADOS-2 Module 2 Total Score also correlated highly with the CARS-2 T Scores, $r(5) = .74$, $p < .05$. ADOS-2 Module 3 Total Score and the GARS-3 Autism Index were not correlated, $r(3) = -.04$, *ns*. CARS-2 T Score and the GARS-3 Autism Index were also uncorrelated, $r(18) = .06$, *ns*. CARS-2 T Scores differed across ASD and non-ASD groups, $t(18) = 3.42$, $p < .05$. Individuals with ASD diagnosis ($n = 12$) earned similar GARS-3 Autism Index scores ($M = 79.92$; $SD = 18.62$) to individuals without ASD diagnosis ($n = 8$; $M = 93.75$; $SD = 10.63$); $t(18) = -1.90$, *ns*.
Conclusions: Preliminary results suggest weak relationships between the GARS-3 Autism Index Score and the ADOS-2, and the GARS-3 Autism Index Score and CARS-2 T Score. ADOS-2 and CARS-2 T scores differed across diagnostic groups, with individuals with ASD earning significantly higher scores. GARS-3 Autism Index scores, however, did not differ between groups with ASD and those without ASD. Initial findings warrant caution in using the GARS-3; however, larger samples are needed to fully document the utility of the GARS-3 in diagnostic evaluation.

134 **165.134** Besides Normal Children, Can the Children and Adolescent Versions of Autism-Spectrum Quotient (AQ) Also Differentiate ASD from ADHD Children? a Validation Study of AQ in Hong Kong

P. W. Leung[1], *R. Chan*[2], *V. Wai*[1] *and P. Wong*[1], *(1)Dept of Psychology, The Chinese University of Hong Kong, Hong Kong, China, (2)Kwai Chung Hospital, Hospital Authority, Hong Kong, China*

Background:
The Children and Adolescent versions of Autism-Spectrum Quotient (AQ-Child and AQ-Adol) are respectively 50-item, parent-report questionnaires. They had been validated for assessing autism spectrum disorder (ASD), differentiating children with ASD from normal children. However, so far, few study reported on their ability to differentiate ASD from ADHD (attention-deficit hyperactivity disorder). Both neurodevelopmental disorders were common referrals to and presentation in child psychiatric clinics. It was important to test for practical reasons if AQ could aid clinicians in making differential diagnosis between ASD and ADHD.
Objectives:
This study aimed at testing whether the AQ-Child and AQ-Adol were not only capable in differentiating ASD children/adolescents from normal control, but also from ADHD children/adolescents.
Methods:
Two Chinese-speaking samples were recruited from child psychiatric clinics and mainstream schools to examine the psychometric properties of AQ-Child and AQ-Adol respectively in Hong Kong. They were translated into Chinese via the standard procedure of translation and back-translation. The first sample included three groups of children of 4 to 11 years for validating AQ-Child: (1) community control (N=1,196), (2) ASD children (N=124), and (3) ADHD children (N=82). A second sample included adolescents of 12 to 18 years for validating AQ-Adol: (1) community control (N=809), (2) ASD adolescents (N=78), and (3) ADHD adolescents (N=51). The AQ-Child and AQ-Adol were filled in by parents of the recruited samples.
Results:
The psychometric results found for AQ-Child and AQ-Adol were largely similar. Both did not find age and gender effects in their total scores. Factor analysis was able to replicate three of AQ-Child's five subscales, namely, Social Skills, Attention to Detail, and Communication, and four of AQ-Adol's five subscales, adding Imagination. The remaining subscale, Attention Switching, failed to be replicated in both AQ versions. The internal consistency of the total scores of AQ-Child and AQ-Adol were respectively 0.80 and 0.87, while test-retest reliability 0.80 and 0.95. There were significant group differences in the total scores of both AQ-Child and AQ-Adol across the three groups of participants with large effect sizes (>1.3) between ASD vs Control and ASD vs ADHD, but only small-to-moderate effect sizes (≤0.5) between ADHD vs Control. The AUCs for AQ-Child between ASD vs Control and ASD vs ADHD were respectively 0.91 and 0.87, while for AQ-Adol, the corresponding figures were 0.91 and 0.81. The performance of the five subscale scores of both AQ versions in the above psychometric indices varied. Instead, the total scores appeared to be the consistent good performers in them.
Conclusions:

The psychometric properties of AQ-Child and AQ-Adol in Hong Kong would be comfortably regarded as good to excellent. They were highly compatible to those of the original and other previous studies in AQ. Particularly, the added contribution of this study was to indicate that both AQ-Child and AQ-Adol were able to differentiate competently ASD from ADHD, underscoring the specificity of the AQ for ASD.

135 **165.135** Caregiver Concerns Prior to a Diagnostic Evaluation: Differences Between Children with and without Autism Spectrum Disorder

L. Little[1], *A. Wallisch*[2] *and B. Salley*[3,4], *(1)University of Kansas Medical Center, Kansas City, MO, (2)University of Kansas Medical Center, Kansas Clty, KS, (3)University of Kansas, Overland Park, KS, (4)Pediatrics, University of Kansas Medical Center, Kansas City, KS*

Background:
Research suggests that parental concerns precede an Autism Spectrum Disorder (ASD) diagnosis; it is unclear if specific types of concerns may be specific to children with ASD versus another developmental condition. While previous studies have gathered parent-report data from high-risk samples (Ozonoff et al., 2009) or used retrospective reports, caregiver concerns preceding a diagnosis of ASD in a large community based sample remain unexamined.
Objectives:
This study examined the extent to which parent concerns differentiate children with an eventual diagnosis of ASD versus those without in a community based sample aged 12 months-9 years.
Methods:
This secondary data analysis of caregiver report data gathered prior to a child's diagnostic evaluation resulting in a diagnosis of ASD (n=271) or non-ASD (including global developmental delay; n=314). We examined 3 groups of participants: (ages 0-3yrs; 3-6yrs; 6-9yrs; total of n=585 children). Concerns were coded from an intake form prior to diagnostic evaluations. Coding was adapted from Ozonoff et al. (2009), and included: 1) Externalizing; 2) Cognitive development; 3) Medical; 4) Motor; 5) Speech/communication; 6) Social interaction; 7) Stereotyped behavior; 8) Sensory aversions/preferences; 9) Unspecified autism; 10) Internalizing. We used binary logistic regression to determine the extent to which categories of caregiver concerns predicted diagnostic group (ASD/non-ASD) in 3 age groups of children.
Results:
In the youngest group, increased Externalizing (p<.05; OR=.334) and Cognitive development (p<.05; OR=.221) differentiated children in the non-ASD group. In children 3-6 yrs, increased Speech (p<.05; OR=1.640) and Social concerns (p<.01; OR=2.156) differentiated children with ASD. In the oldest group, increased Social concerns differentiated children with ASD (p<.05; OR=2.433). These four concerns correctly classified 74.5% of children 0-3yrs; 62.5% 3-6yrs; and 73.1% of children 6-9yrs.
Conclusions:
Results suggest that parental concerns may help predict a diagnosis of ASD, but distinct concerns differentiate ASD across age groups. Children that do not receive an ASD diagnosis in the 0-3yr group have a higher likelihood of Cognitive development and Externalizing concerns potentially due to the emphasis of reaching developmental milestones at this age. Among children aged 3-6 years that received an ASD diagnosis, the likelihood of Speech and Social concerns was increased. This may be due to the changing social demands on the child (e.g., preschool). At 3 years, many children are increasingly demonstrating complex language and social play, and this may be a potential differentiating factor and concern for parents of children with ASD. In children with a diagnosis of ASD aged 6-9 years, speech concerns diminish, and the likelihood of Social concerns is very high. By understanding the parental concerns that best differentiate those with an eventual ASD diagnosis, we can better monitor children at risk of a diagnosis and identify children more acuurately across development.

136 **165.136** Characteristics of Autism Spectrum Disorder Across Time: Comparing Cohorts of Birth Date and Time of Assessment

T. White*, T. E. Regan, K. Williams and M. R. Klinger, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Over the course of this century, the diagnosis of autism spectrum disorder (ASD) has drastically increased. In 2000, the rate of diagnosis was 1 in 150, and recent reports indicate the prevalence as 1 in 68 (Center for Disease Control, 2014). In addition to growing numbers in the population, the autism profile has changed. There has been an increase in the number of individuals diagnosed with normal to high intellectual functioning and adaptive behavior functioning (Freeman, Homme, Guthrie, & Zhang, 2009). There is a need to evaluate these changes across the ASD population over time.
Objectives: This study examined associations of autism diagnostic characteristics with date of birth and date of evaluation within a large clinical sample. Three diagnostic characteristics were included in analysis: autism symptom severity, adaptive functioning, and cognitive functioning. The goals were to (1) determine if changes in diagnostic profile appearance were tied to date of birth, indicating a birth cohort effect, and (2) determine if changes in diagnostic profile appearance were tied to date of evaluation, indicating changing diagnostic criteria across time.
Methods: This study used secondary data analysis of assessment data collected from the statewide UNC TEACCH Autism Program registry. A records review was conducted to compare profiles of individuals evaluated in clinics. The sample includes evaluations starting in 2000 through 2015. Data from nearly 3000 individuals were used in this study. A preliminary hierarchical multiple regression analysis was performed in order to investigate the ability to predict three facets of the autism profile (symptom severity, cognitive functioning, and adaptive functioning) based on date of diagnosis compared to date of birth, after controlling for both parent's date of birth and the child's gender.
Results: Data were analyzed separately for symptom severity (ADOS, N=1746 and CARS, N=1333), cognitive functioning (IQ, N=2929), and adaptive functioning (Vineland, N=2790). Hierarchical regression analyses were run for each variable with covariates (Parent 1 Date of Birth, Parent 2 Date of Birth, and Gender) entered first followed by predictor variables (Date of Evaluation and Child Date of Birth). Regression analyses found that both predictor variables contributed significant variance in the model for all four variables (ADOS: *Child Date of Birth*: beta = 0.315; p < .001; *Evaluation Date* beta= 0.265; p<.001) (CARS: *CDoB* beta= 0.237; p<.001; *ED* beta=0.117; p<.001) IQ: CDoB beta = .086; p < .001; ED beta = .357; p<.001) (Vineland: *CDoB* beta = .086; p < .001; *ED* beta = .357; p<.001).
Conclusions: Preliminary results indicate a relatively consistent pattern for both date of evaluation and date of birth cohorts influencing the characteristics of individuals seen in a large network of community clinics. Across the three domains (symptom severity, cognitive functioning, and adaptive behavior) all showed higher functioning for individuals diagnosed more recently and more adults. Part of this change may be due to changes in criteria (as indicated by evaluation date effects) and changes across birth cohorts (as indicated by child date of birth effects).

137 **165.137** Clincal Validation of a Test for Maternal Antibody Related (MAR) Autism

J. W. Amshey[1], *S. Hilt*[2], *J. Bue*[1], *A. Domingo*[1], *G. Landau*[1], *G. Korzus*[1] *and J. Van de Water*[3], *(1)Pediatric Bioscience, Inc., San Diego, CA, (2)University of California at Davis, Davis, CA, (3)University of California at Davis MIND Institute, Davis, CA*

Background: It has been reported based on Western Blot analysis (Braunschweig, et al., 2013), that approximately 23% of mothers of children with ASD have specific patterns of autoantibodies to brain proteins. These patterns are found in less than 1% of mothers of typically developing children. Thus, these autoantibodies are potential biomarkers for a newly identified subtype of autism, Maternal Antibody Related (MAR) autism, and may be risk factors for ASD. Validated biomarkers for ASD can potentially contribute to earlier diagnosis and intervention. We have converted the Western Blot to an ELISA method that is more suitable for clinical laboratory use.
Objectives: We set out to confirm that the ELISA method replicates the Western Blot findings and to determine the potential value of the test based on its sensitivity, specificity, and Positive Predictive Value [PPV]) in a large prospective-retrospective clinical study.
Methods: This study includes over 450 mothers enrolled in the CHARGE (Childhood Autism Risk from Genetics and the Environment) Study whose children (2-5 years old) have had a diagnosis of ASD confirmed on both ADI-R and ADOS, as well as case controls from mothers of typically developing children. Maternal plasma specimens collected at study enrollment were analyzed for the presence of multiple autoantibodies on a quantitative, high-throughput ELISA platform. These results are evaluated to provide a qualitative result for the presence or absence of the MAR autism subtype.
Results: The study is ongoing and results from the full study will be presented. Preliminary results on 123 samples with 6 of 7 known antigens show that the transfer of the MAR Autism Test to a high-throughput ELISA platform has been successful. We observed a 15% sensitivity (percent of ASD samples that tested positive) with 98% specificity (percent of TD samples that tested negative), consistent with previous results reported using the Western blot method. We will present the results of the decision algorithm training study of about 250 samples and a blinded validation study on about 200 samples, each set containing approximately 63% samples from mothers who have children with ASD, and 37% mothers of typically developing children.
Conclusions: These preliminary results suggest that the presence of MAR antibodies can be used to identify a substantial subtype of children with ASD with an actionable positive predictive value due to a low false positive rate. A positive result in a mother of a child where developmental delay is observed indicates a high probability of a future ASD diagnosis based on behavioral criteria. In such a case, behavioral therapy could be started immediately for the most effective outcome for the child. Samples from pregnant women are not included in the study, and the test is not validated for use during pregnancy.

138 **165.138** Clinical Characteristics of Children with Dup15q Syndrome and Comorbid ASD

C. DiStefano[1], *C. Kasari*[2], *S. Huberty*[3] *and S. S. Jeste*[4], *(1)Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)Psychiatry and Biobehavioral Sciences, UCLA Center for Autism Research and Treatment, Los Angeles, CA, (4)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background:
Duplication 15q syndrome (Dup15q), one of the most common genetic variants associated with Autism Spectrum Disorders (ASD) (Hogart et al., 2010), is characterized by intellectual disability (ID), hypotonia, motor delays, and social communication impairment (Battaglia et al., 2010). Because most research has consisted of retrospective chart

reviews or case studes, we lack in-depth information about clinical profiles of children with Dup15q syndrome, notably in comparison to children with non-syndromic ASD. Improved characterization of genetic syndromes associated with ID and ASD can inform not only prognosis, but also treatment, leading to the discovery of targeted, mechanism-based interventions that may improve individual outcomes.

Objectives:

Examine social-communication, adaptive and cognitive skills in children with Dup15q syndrome and compare these domains to chronological and mental age matched children with non-syndromic ASD.

Methods:

Participants included 13 children with Dup15q syndrome (22 months – 12 years) and 13 children with non-syndromic ASD, matched on chronological and mental age. In the Dup15q group, 10 participants had isodicentric duplications and 4 had active epilepsy. Participants were assessed for verbal and non-verbal developmental quotient, ASD characteristics and adaptive behavior. Group comparisons were performed between Dup15q and ASD participants, as well as within the Dup15q group (by duplication type and epilepsy status).

Results:

All Dup15q participants met criteria for ASD, but had significantly lower ASD severity scores (specifically on certain reciprocal social interaction items) than children in the ASD group (t=2.26, p=0.03). Dup15q participants demonstrated significantly more impaired motor (t=5.9, p<0.001) and daily living skills (t=2.41, p=0.03), and with significantly correlated scores across domains. In contrast, the ASD group showed scores that were largely independent of each other. Within the Dup15q group, there were no significant differences by duplication type. Participants with epilepsy were significantly more impaired than those without across all domains other than ASD severity (p-value range: <.001 - .03).

Conclusions:

All children with Dup15q syndrome met ADOS criteria for ASD, but showed relative strength in social interest with marked impairment in motor and daily living skills. Research is currently underway using electroencephalography (EEG) to examine neural correlates of social interest and language processing in Dup15q syndome in order to inform our understanding of how these processes interact with ASD symptoms. In the Dup15q group, motor skills were closely related to abiities across domains. Although children with ASD often show relative strengths in motor ability compared with other deveopmental domains (Yang et al., 015), recent studies have demonstrated the importance of early motor ability in predicting outcomes in children later diagnosed with ASD (Gernsbacher et al., 2008; Estes et al., 2015). Dup15q syndrome presents an ideal opportunity to examine developmental relationships between motor impairment and emerging ASD symptoms. Intervention recommendations for children with Dup15q syndrome include aggressive epilepsy treatment, focus on motor skills, and engagement based therapy building on social interest to further develop social communication abilities. Longitudinal research from early development is necessary to understand the temporal relationships between developmental domains, and multi-site studies will allow for larger sample sizes to examine subgroups with Dup15q syndrome.

Table 1: Relationships Across Skill Domains by Group

	ASD						Dup15q					
Skill Domain	1	2	3	4	5	6	1	2	3	4	5	6

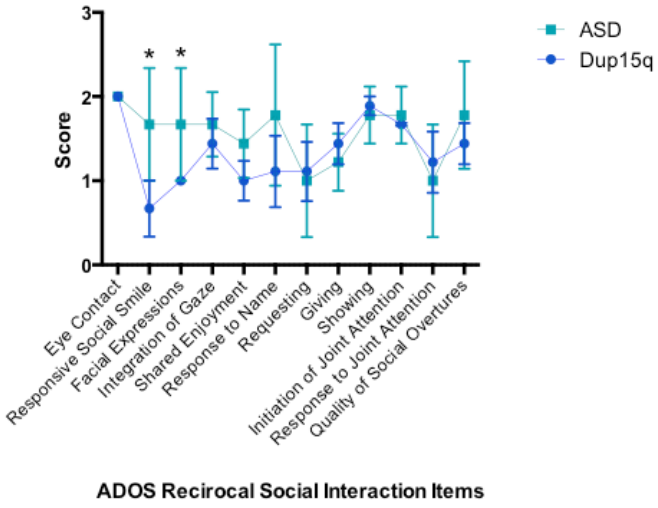
Figure 1: ADOS Reciprocal Social Interaction Item Scores by Group



Average ADOS RSI item scores by group, showing significant differences for two items: "Responsive Social Smile" (ASD *M*=1.67, Dup15q *M*=0.67; *t*=2.27, *p*=.04) and "Directs Facial Expressions to Others" (ASD *M*=1.67, Dup15q *M*=1; *t*=2.31, *p*=.04).

139 **165.139** Clinical Evaluation of Children with Autism at a Multidisciplinary Intervention Centre in India

D. R. Kanade, *A. Bondre and S. H. Dalwai, New Horizons Health and Research Foundation, Mumbai, India*

Background:
About 10 million individuals in India have Autism. The burden of disability is compounded by limited interventions and even fewer multidisciplinary approaches, targeting children in early life. Few studies in India have mapped clinical profiles of children with Autism.
Objectives:
This analysis aims to present results of clinical evaluations of children with features of Autism reporting to a multidisciplinary child development centre in Mumbai.
Methods:
Sample was derived from a published study (n = 1301) that obtained data on assessment and intervention for neurodevelopmental disorders at the aforesaid centre from 2009 to 2012. Children were trans-departmentally assessed across various clinical (developmental paediatric and paramedical) disciplines. Fourth edition of Diagnostic and Statistical Manual of Mental Disorders was referred. Data were descriptively analyzed using Microsoft Excel 2007 and Stata-10.
Results:
Out of 1301 children, 145 children (11.1%) were identified with features of Autism. Most children were referred by physicians and paediatricians (70.9%). Mean age at referral was 4.5 years. Only 3 children were referred at less than 2 years. The multidisciplinary centre was the first point of therapy for 60% of families. These findings indicate the delay by parents to seek care. Salient presenting concerns reported by parents were speech delay (88.1%), behavioural concerns (61.8%), and atypical socialization (36.1%) . About 69% of children attended school and most of them attended regular schools (94.5%) with English as medium of instruction (94.1%). However, English was spoken at only 35.4% of homes.
In developmental assessment (n = 134), solitary and destructive play was observed in 99.2% and 26.8% respectively. Thus, most children had not developed parallel play. Hypotonicity was observed in 63.4% of children. Hypersensitivity to tactile and auditory input was noted in 57.8% and 36.3% of children respectively. Hyposensitivity to vestibular and proprioceptive input was noted in 86.4% and 67.1% of children respectively. Toe-walking was present in 23.8% and mouthing of objects in 32% of children. Only 15.6% of children maintained eye-contact. Inability to perform activities of daily living was noted in 92.5% of children. In speech assessment (n = 96), sub-optimal oral-motor and vegetative functioning was present in 64.2% and 76% of children respectively. On assessment, non-verbal communication was noted in 75.6% of children. In speech milestones, delays in uttering one and two meaningful words were seen in 95.7% and 98.9% of children respectively. Receptive and expressive language ages were 16.2 and 14.8 months respectively and unpaired t tests provided statistically significant differences between these ages and the mean chronological age of 48 months. Thus, inability to communicate verbally was the most important reason for care-seeking. Comprehending single, dual and multi-step instructions (on 3rd edition of Reynell scale) was observed in 12.5%, 2% and 1% of children respectively.

Conclusions: Initial comprehensive evaluations allow developmental therapists to focus on multiple developmental domains, set feasible and individualized therapeutic goals and monitor functional changes, particularly in a multidisciplinary intervention model. Further research is needed to test the impact of these models in developing countries like India.Background:

140 **165.140** Cognitive and Adaptive Profile Differences Between Diagnostically Concordant and Nonconcordant Twins with ASD

J. Cash[1], *J. Mendelson*[2], *C. Hall*[3], *S. Hoffenberg*[3] *and T. Aronson*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA and The University of North Carolina at Greensboro, Greensboro, NC, (3)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA*

Background: Research on twins has demonstrated a strong genetic contribution to autism spectrum disorder (ASD), with monozygotic (MZ) twin ASD concordance rates ranging from 60 to 90% and dizygotic (DZ) ASD concordance rates ranging from 5 up to 20% (Bohm et al., 2009). Additionally, research suggests young children with ASD perform better on nonverbal tasks than language tasks (Hartley et al., 2009) and children with ASD tend to have the most substantial delays in socialization, slighter delays in communication, and relative strengths in daily living skills (Bolte and Poustka, 2002). However, little research has been done examining the developmental profiles of concordant and nonconcordant twins with ASD.
Objectives: The goal of the current study is to examine cognitive and adaptive profile differences between and among concordant and nonconcordant twins with ASD.
Methods: Participants included two MZ dyads and 12 DZ dyads, who were evaluated between the ages of 25 to 85 months (M=53.04 months, SD=19.56) in a diverse clinical setting. Twelve pairs of twins received concordant diagnoses of ASD.
Assessments included a developmental or cognitive measure (i.e., the Mullen Scales of Early Learning, Differential Abilities Scales-2nd Edition, or Stanford-Binet Intelligence Scales, 5thEdition), the Vineland Adaptive Behavior Scales, 2nd Edition, Survey Form, and the Autism Diagnostic Observation Schedule. Scores were converted to z-scores to compare group means.
Results: Overall diagnostic concordance was 86%. Diagnostic concordance in DZ twin dyads was 83%. Variability across cognitive and adaptive measures was examined by calculating a difference score for each twin dyad. Concordant twin dyads were highly consistent (i.e., less than 1 SD apart) in their adaptive skills (80-90%) as well as verbal (60%) and nonverbal (64%) cognitive abilities. Concordant twins demonstrated significantly lower verbal IQ than nonverbal IQ ($t(20)=-2.273$, $p<.05$). Nonconcordant twins demonstrated significantly higher verbal IQ ($t(23)=4.44$, $p<.01$), nonverbal IQ ($t(3.57)$, $p<.01$) and higher adaptive communication at a level that approached significance ($t(18)=1.832$, $p=.084$) than concordant twins. Additionally, nonconcordant twins were significantly older than concordant twins ($t(15)=3.99$, $p<.01$).
Conclusions: Data from the current study indicates DZ cognitive profiles among concordant twins are consistent with reported ASD profiles (Bohm et al., 2009). However, adaptive profiles among concordant twins are not consistent with the literature (Bolte and Poustka, 2002). Interestingly, concordant twins in this clinical sample have the most substantial delays in the area of adaptive communication and lesser delays in daily living skills and socialization. Nonconcordant dyads were significantly older at time of diagnosis and displayed better cognitive skills than concordant twins. Although they present with difficulties in the areas of socialization and daily living skills, they also present with stronger cognitive and adaptive communication skills. These profiles may lead to diagnostic ambiguity and later age of diagnosis. Findings indicate cognitive and adaptive profiles differ significantly between diagnostically concordant and nonconcordant twins. Future research should examine the relation between diagnostic concordance and cognitive/adaptive functioning, while controlling for zygosity, which will inform our understanding of heritable and shared environment contributions to cognitive and adaptive profiles in children with ASD.

141 **165.141** Concordance Between DSM-IV and DSM-5: Results from a Large-Scale Epidemiological Surveillance Study

L. A. Carpenter[1], *A. D. Boan*[1], *A. Wahlquist*[2], *A. P. Cohen*[3], *J. M. Charles*[1], *W. Jenner*[1], *J. Spinello*[1] *and C. C. Bradley*[1], *(1)Pediatrics, Medical University of South Carolina, Charleston, SC, (2)MUSC, Charleston, SC, (3)University of Illinois at Urbana-Champaign, Champaign, IL*

Background: In 2013 the American Psychiatric Association made significant revisions to the diagnostic criteria for Autism Spectrum Disorder (ASD), including moving from a series of related Pervasive Developmental Disorder (PDD) diagnoses in DSM-IV-TR to one ASD diagnosis in DSM-5. Changes were based on research suggesting poor distinction among DSM-IV-TR subtypes, and that social communication deficits and restricted repetitive behaviors are both core symptom domains in ASD. However there has been concern that the revised criteria may exclude more mildly affected children from clinical diagnosis.
Objectives: To determine concordance between DSM-IV-TR and DSM-5 ASD diagnoses among school-aged children at risk for ASD.
Methods: Data for this study is from the South Carolina Children's Educational Surveillance Study (SUCCESS), which is designed to assess the prevalence of ASD through population-based screening and evaluation. School-aged children 8-11 years of age were identified as being at risk for ASD using the Social Communication Questionnaire (SCQ). Participants (n=292) completed developmental assessments to determine ASD case status according to both DSM-IV-TR and DSM-5 criteria. Clinical best estimate diagnoses were based on lifetime history of ASD symptoms. Participants were 65% male, 42% white non-Hispanic, 35% black non-Hispanic, 9% non-native English speakers, and 62% from Title 1 public schools (schools with a high percentage of low income students). Average IQ was 93.97 (SD=19.03).
Results: All participants who met criteria for DSM-5 ASD (n=52) also met criteria for one of three DSM-IV-TR PDD diagnoses (Autistic Disorder, Asperger's Disorder, PDD-NOS). Forty percent of those with DSM-IV-TR PDD diagnoses did not meet criteria for DSM-5 ASD. Most discordant participants (30/35; 86%) had a DSM-IV-TR diagnosis of PDD-NOS. Demographic characteristics including gender, race, ethnicity, non-native English speaker status, and Title 1 school status were not associated with DSM-IV-TR/DSM-5 discordance. Those participants who were concordant for DSM-IV-TR PDD and DSM-5 ASD had significantly higher scores on autism-related assessment instruments (ADOS-2, SRS-2, & SCQ), and had significantly lower adaptive scores (Vineland-2). IQ was not significantly different between the two groups. Among those who met DSM-IV-TR but not DSM-5 criteria, 40% failed to fulfill at least 2 restricted repetitive behavior criteria, while 94% failed to fulfill all 3 social communication criteria for ASD.
Conclusions: Results suggest that, among school-aged children, DSM-5 ASD captures participants who have greater severity of ASD symptoms and more functional impairment than those captured under DSM-IV-TR. Individual demographics (SES, race, gender, ethnicity, IQ) do not appear to impact concordance. The majority of discordant participants met DSM-IV-TR criteria for PDD-NOS, a diagnosis that has been criticized for being overly broad and non-specific to ASD, and of these very few had a diagnosis of a PDD/ASD prior to participation in this study. Nonetheless, the fact that 40% of discordant participants met the autism/ASD threshold on the ADOS-2 suggests that some children with symptoms of ASD may not meet DSM-5 criteria for ASD. Particularly in regards to revisions in the social communication criteria, children with milder or fewer symptoms in this subdomain are less likely to be diagnosed with ASD under DMS-5 criteria.

142 **165.142** Confirmatory Factor Analyses of WISC-IV Scores of Children Diagnosed with ASD

L. Peacock, *J. Beck and M. South, Brigham Young University, Provo, UT*

Background: Confirmatory factor analyses confirmed the four-factor structure (verbal comprehension [VC], perceptual reasoning [PR], working memory [WM], and processing

speed [PS]) of the Wechsler Intelligence Scale for Chidren-4th edition (WISC-IV) in the publisher's large standardization sample (*N = 2,200)* of mostly typically-developing children age 6-16. Additional analyses confirmed the validity of interpreting a second-order general intelligence factor. Given that children and adolescents with ASD frequently have uneven IQ profiles, it is not clear that the four-factor structure is appropriate for this clinical population.
Objectives: We sought to investigate whether confirmatory factor analyses would validate or invalidate the four-factor structure of the WISC-IV in children and adolescents with ASD.
Methods: Data used reside in the NIH-supported NIMH Data Repositories, specifically in the National Database for Autism Research (NDAR). WISC-IV data was obtained for children and adolescents who had autism diagnoses confirmed by reported ADOS-2 scores above the diagnostic cut-off (≥7). The sample included 44 participants: 39 males and 5 females age 6-16 years (*M* 11.30) across a broad range of intellectual functioning (FIQ: *M* 96.96, range 48-131). We conducted maximum likelihood confirmatory factor analyses of two-, three-, and four-factor models of the ten core WISC-IV subtests. With more than four participants per observed indicator, our sample approaches the recommended five participants per indicator (Bentler & Chou, 1987). The two-factor model included verbal and nonverbal latent factors; the three-factor model included latent factors for verbal comprehension, perceptual reasoning and a combined factor of working memory and processing speed; and the four-factor model separated the working memory and processing speed factors. We also tested a second-order four-factor model which included a general intelligence factor. Goodness of fit indices were calculated for each model.
Results: All factor loadings in all models were significant ($p < .01$). The fit values for the two-, three- and four-factor models are shown in Table 1. The χ^2 statistics for all models were significant ($p < .05$), indicating poor model fit; however, the χ^2 statistic is notably sensitive to sample size. The conservative RMSEA indices indicated poor fit (> .08) for all models. The CFI values indicated adequate model fit (> .90) for all but the two-factor model, and showed the four-factor model to be significantly better than the three-factor model (difference > .01; Cheung & Rensvold, 2002). Of all the fit indices, the AIC is the most appropriate for comparing models (smaller AIC is better). The AIC values reveal the four-factor second-order model as best. Coding consistently had the smallest factor loading (β = .66 and .65 for the first- and second-order four-factor models).
Conclusions: This research confirms the four-factor model of the WISC-IV core subtests in a small sample of children and adolescents with ASD. Of all the core subtests, Coding should be interpreted most cautiously in terms of how it loads onto its respective composite score (Processing Speed). Future research with larger samples should investigate the validity of the four-factor structure across subgroups based on autism symptom severity.

Table 1

CFA Fit Values for Four Alternative WISC-IV Models (N = 44)

Models	*df*	χ^2	*p*	*RMSEA*	*CFI*	*AIC*
Two factor (V and NV)	34	93.93	< .001	0.20	0.79	2,135.02
Three factors (VC, PR, and WM + PS)	32	56.80	0.004	0.13	0.91	2,101.89
Four factors (VC, PR, WM, and PS), first-order	29	52.89	0.004	0.14	0.92	2,167.38
Four factors (VC, PR, WM, and PS), second-order	31	54.63	0.005	0.13	0.92	2,101.71

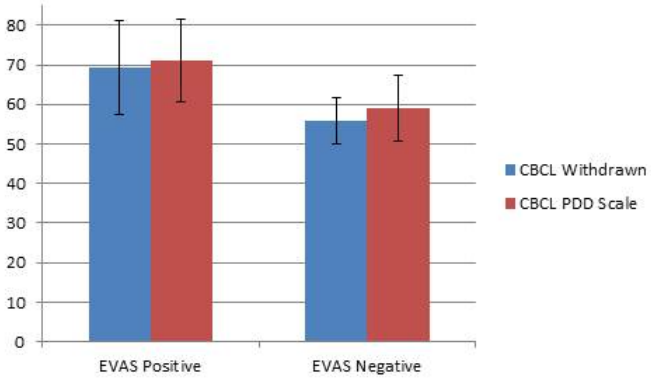
Note . WISC-IV=Weschler Intelligence Scale for Children–Fourth Edition; RMSEA = root mean square error of approximation; AIC = Akaike information criterion; CFI = comparative fit index; V = Verbal; NV= Nonverbal; VC=Verbal Comprehension; PR=Perceptual Reasoning; WM=Working Memory; PS=Processing Speed.

143 **165.143** Convergent and Divergent Validity of the Early Video Guided Autism Screener (EVAS) in a Clinically-Referred Sample

K. Sheperd[1], *K. Boswell*[2], *J. Neely*[3] *and R. Landa*[3], *(1)Kennedy Krieger Institute, Center for Autism and Related Disorders, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD, (3)The Kennedy Krieger Institute, Baltimore, MD*

Background: Although ASD can be detected as early as age 14 months (e.g., Landa, Gross, Stuart, & Faherty, 2013; Landa, Holman, & Garrett-Mayer, 2007), the average age of diagnosis is four years (ADDM, 2014). The American Academy of Pediatrics (AAP) recommends universal screening at ages 18 and 24 months, though screening and referral practices are inconsistent due to cost, lack of staff training, and time needed for screening. Access to a low-cost screening tool to promote completion of screening and referral can lead to earlier access to diagnosis and treatment. Existing autism-specific tools demonstrate modest sensitivity and specificity. The Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2000) has been evaluated as an efficient means to screen for ASD as well as other possible comorbidities, given the already widespread use of this tool. Several studies have shown that the Withdrawn and Pervasive Developmental Problems scales of the CBCL 1.5-5 version are useful in screening young children for ASD (Havadal et al., 2015; Muratori et al., 2011; Sikora et al., 2008).
Objectives: To examine the construct validity (i.e., divergent and convergent validity) of the EVAS in a clinically referred sample, relative to the CBCL, which shows growing evidence as a potential ASD screening tool.
Methods: Sample of 178 children aged 18-48 months (83.7% male, 52.2% White, Mean age = 33.24 months, SD = 8.43 months) referred to an autism specialty center for diagnostic evaluation due to concerns for possible ASD. Parents completed the EVAS and CBCL online during the clinic intake process prior to their diagnostic visits. A clinical best estimate (CBE) was assigned by the diagnosing clinician following the evaluation.
Results: To account for multiple comparisons, a Bonferroni correction was applied to evaluate differences between the EVAS cut-off and each CBCL syndrome and DSM-oriented scale (.05/13 = .0038). Using this correction, only the CBCL Withdrawn ($t(176) = 3.18$, $p = .002$) and PDD ($t(176) = 3.23$, $p < .001$) subscales differed according to EVAS screening results (See Figure 1). Children who screened positive on the EVAS had T scores over 1 SD higher on the Withdrawn and PDD scales than children who screened negative on the EVAS, suggesting convergent validity of EVAS screening results. Children who screened positive and negative on the EVAS were similar in terms of all other CBCL scales, child age, and child race (all $p > .0038$), suggesting evidence for divergent validity. See Table 1 for a summary of results.
Conclusions: Results provide evidence for construct validity of the EVAS, suggesting it is a valid tool to measure ASD-related concerns. Importantly, results suggest that the EVAS items are specific to ASD, rather than associated comorbidities (e.g., attention or affective concerns). Thus, the EVAS has strong potential as an ASD-specific screening tool.

Figure 1. T Scores of CBCL Withdrawn and PDD Scales by EVAS Screening Results.



Note: Error bars represent standard deviation of the mean

144 **165.144** Creating an Observation System to Quantify Symptomatology Progress during Treatment in Children with Autism Spectrum Disorders

***M. V. Cornejo**, M. V. Van Dyke and J. J. Wood, University of California Los Angeles, Los Angeles, CA*

Background:
Self-reported or parental reported paper and pencil measures are typically used in research settings to generate behavioral profiles of child participants and to quantify changes in their behaviors and symptomatology. Evidence suggests that the change of emotional or maladaptive responses has been difficult to measure using these standard paper and pencil tasks in the ASD population. Currently there is no known system that can assess the progress during therapy through the use of an unbiased observation system.
Objectives:

- To create a reliable observation system that can document change as it is occurring across time during treatment sessions in children with ASD.
- To assess the degree of overlap between a new observation system (PASTOS) and other scales that measure similar constructs such as the Multidimensional Anxiety Scale for Children (MASC), the Social Skills Rating System (SSRS) and the Self-Efficacy Questionnaire for Children (SEQ-C).

Methods:
This study examined treatment session transcripts of twenty-two elementary school-aged children who were participating in a randomized controlled trial of cognitive behavioral therapy (M = 9.0 years, SD = 2 years) diagnosed with high functioning autism spectrum disorder (IQ above 70) and anxiety disorders. In order to assess the therapeutic process, treatment sessions 2, 4, 10, and 15 were chosen to be coded by observers. Coders listened to the entire treatment session while reading the transcript; at the conclusion of an audiotaped session, the coders assigned an extensiveness rating for various symptoms, from 1 to 7, with 1 = not at all, 3 = some of the time, 5 = considerably and 7 = extensively for 27 items divided into 5 subscales. The five subscales consisted of: 1) anxiety and related emotional states, 2) self-help skill mastery, 3) core autism symptoms, 4) child coping strategies, 5) parent-child interactions. Correlations were run using the five subscales and total PASTOS scores with MASC, SSRS and SEQ-C scores.
Results:

- Significant correlations were found between PASTOS and MASC scores at both baseline and post treatment.
- No significant correlations were found between PASTOS scores and SEQ-C ratings at baseline, but total PASTOS scores correlated with total SEQ-C scores at post treatment. At the subscale level, total SEQ-C positively correlated with PASTOS's social communication subscale at post treatment. Self-perception and parental communication subscales also correlated with SEQ-C ratings at post treatment in expected directions.
- SSRS' self-control subscale positively correlated with PASTOS' anxiety and self-perception scales at post treatment.

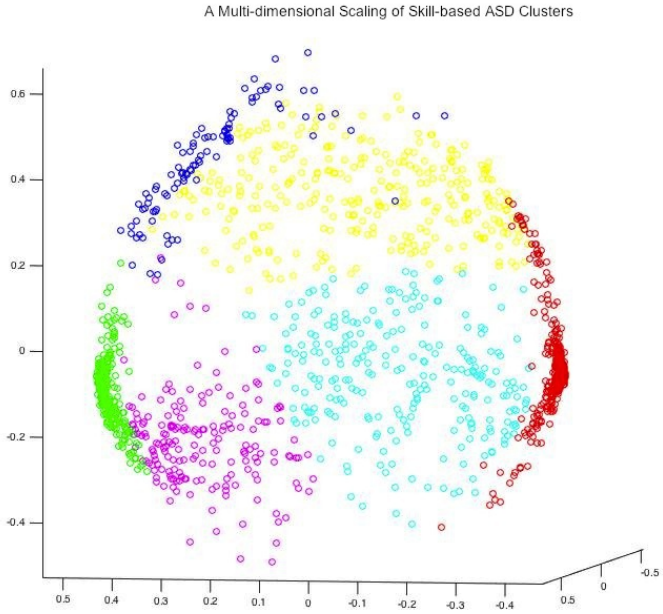
Conclusions:
This investigation sought to create an alternative system to evaluate progress of children with ASD during treatment sessions. The results suggest that PASTOS is a promising system for tracking changes in anxiety and related emotional states, child coping strategies, and self-skill mastery when compared to parental reports. Further research should explore additional alternatives to tracking progress of symptomatology and methods to make observation systems efficient and usable by coders within a standardized training regimen.

145 **165.145** Defining Behavioral Phenotypes in Autism Spectrum Disorders

***D. Dixon**[1] and E. J. Linstead[2], (1)Center for Autism and Related Disorders, Tarzana, CA, (2)Chapman University, Lakewood, CA*

Background: Autism spectrum disorder (ASD) is a heterogeneous disorder. Presentation and severity of symptoms as well as response to treatment vary widely among individuals with ASD. Because of the heterogeneous nature of ASD, individualization of treatment is critical to treatment success. In recent years, the scale and ease at which fine-grained behavioral data can be collected has grown dramatically, providing new avenues of research in predictive analytics for behavioral treatment of ASD. Behavioral phenotyping of ASD is one such avenue that may advance targeted treatment methods, improving treatment efficacy.
Objectives: The purpose of the present study was to identify whether distinct behavioral phenotypes could be defined in a large geographically diverse sample of children with ASD receiving community-based behavioral intervention services.
Methods: A high-dimensional cluster model of ASD was built for 1,619 patients with confirmed diagnoses. Nonparametric techniques were used to statistically determine latent group structure among the population based on responses to a standardized comprehensive assessment of developmental functioning. Unsupervised machine learning methods were utilized to infer cluster membership assignments. Both the classic K-means clustering algorithms with hard cluster assignment output, as well as a

more sophisticated Gaussian mixture model based on expectation maximization were considered. The latter provided a probabilistic framework on which to measure and differentiate clusters.
Results: Results of this study statistically detected the existence of distinguishable subgroups of ASD. Each of these subgroups displayed distinct deficits across developmental domains, including academic, adaptive, cognition, executive functioning, language, motor, play, and social skills. While memberships were significant and statistically distinct for all subgroups, some subgroups displayed clearly unique patterns of deficits while other subgroups showed marked similarities. Profiles for like subgroups suggested a hierarchical relationship, revealing high, moderate, and low levels of functioning for a single composition of deficits.
Conclusions: Findings indicate the existence of distinct behavioral phenotypes within a large sample of children with ASD. It is encouraging that such distinctions were be made using the results of a standardized assessment that can be easily administered. Future research should investigate whether these phenotypes display measurable differences in treatment response. These profiles serve as preliminary templates upon which targeted behavioral treatment programs may be built. The significance of these phenotypes may span beyond behavioral treatment. Further exploration of other distinctions between these groups (e.g., genetic, medical, environmental, etc.) are warranted.



146 **165.146** Defining in Detail and Establishing Consensus on DSM-5 Autism Spectrum Disorder (ASD) Criteria for Case Review

C. E. Rice[1], *L. A. Carpenter*[2], *A. D. Boan*[3], *M. J. Morrier*[4], *C. Skowyra*[5], *S. L. Bishop*[6], *N. Hobson*[7], *A. Thurm*[8], *W. W. Zahorodny*[9] *and C. Lord*[10], *(1)Emory Autism Center, Decatur, GA, (2)Medical University of South Carolina, Charleston, SC, (3)Pediatrics, Medical University of South Carolina, Charleston, SC, (4)Emory University, Atlanta, GA, (5)Washington University in St. Louis, St. Louis, MO, (6)Department of Psychiatry, University of California San Francisco, San Francisco, CA, (7)Independent Consultant, Texas, TX, (8)Pediatrics and Developmental Neuroscience Branch, National Institute of Mental Health, Bethesda, MD, (9)New Jersey Medical School, Westfield, NJ, (10)Weill Cornell Medical College, White Plains, NY*

Background: The diagnostic criteria for autism and related conditions has changed based on clinical and empirical findings; however, the current *DSM-5* diagnosis of ASD remains complex and behaviorally-defined. Diagnosis relies on professional evaluation of a person`s developmental history in light of the specified criteria. Most research into ASD and Pervasive Developmental Disorder (PDD) diagnostic criteria has been on the agreement of overall diagnosis, the validity of subtypes, or on factor analysis of the primary domains and specific criteria representing those domains. Within the given diagnostic taxonomy, little research has been done to specify the concepts and exemplars that serve as evidence for the criteria.
Objectives: To describe a process to define a comprehensive list of exemplars for each of the 7 core *DSM-5* ASD criteria, and report on interrater reliability in applying these exemplars to determine ASD case status.
Methods: The methods followed a format used for population-based prevalence record review. A team of clinicians completed an iterative process to identify specific exemplars for each of the 7 diagnostic criteria and associated features specified in *DSM-5*. This included mapping exemplars to the *DSM-5* ASD criteria from the following sources: the Autism and Developmental Disabilities Monitoring (ADDM) Network *DSM-IV-TR* PDD criteria mapping; the *DSM-5* text; *Autism Diagnostic Observation Scale, Second Edition* (*ADOS-2*); and *Autism Diagnostic Interview-Revised (ADI-R)*. After each phase of mapping, expert input was sought and differences resolved. Use of the detailed criteria was piloted in South Carolina as part of a supplemental study to compare *DSM-IV-TR* and *DSM-5* record review and direct screening with clinical evaluation on a population-based cohort of children. For the initial pilot, composite records detailing developmental evaluations (n=79) of 10 children were independently reviewed by 2 clinician reviewers to determine whether the individual behavioral exemplars could be reliably coded according to *DSM-5* criteria. Primary and blinded reliability review of evaluations for approximately 210 children are underway as is piloting for use in the larger multi-site ADDM Network.
Results: The process resulted in a case review manual detailing concepts and specific behavioral examples (over 300 exemplars) within each criteria (e.g., the example of 'touching or acting on others without regard to other's involvement or reaction" would be an example of "abnormal social approach" under "A1. Deficits in social emotional reciprocity"). For the first 10 cases, interrater reliability averaged 93% agreement on the DSM-5 criteria (range 80-100%), 92% on early developmental concerns, 87% on associated features, 90% on earlier PDD diagnosis, and 90% on final ASD case status. Ratings of severity levels were less consistent. Data (% agreement and Kappas) on the full reliability sample will be presented.
Conclusions: Application of the *DSM-5* ASD criteria is not well-specified in clinical practice, and both researchers and clinicians may be inconsistent in terms of mapping individual behavioral exemplars to diagnostic criteria. More detailed application of exemplars within criteria and domains can be reliably defined and applied. This framework can be further evaluated for improving consistency of ASD diagnoses.

147 **165.147** Development of a Diagnostic Algorithm for the PDD Behavior Inventory Based on Classification Trees

I. L. Cohen[1], *X. Liu*[2], *M. Hudson*[3], *B. Z. Karmel*[4] *and J. M. Gardner*[5], *(1)1050 Forest Hill Rd, New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (2)Queen's University, Kingston, ON, Canada, (3)asd-carc, Kingston, ON, Canada, (4)Infant Development, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (5)Infant Development, New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY*

Background: The PDD Behavior Inventory (PDDBI) is a reliable and valid assessment tool that has been shown to yield excellent sensitivity and specificity for children whose diagnoses were confirmed by the ADOS-G and ADI-R (Cohen et al. 2010). Recently, we have shown that the PDDBI can differentiate children with ASD from those with Attention Deficit Hyperactivity Disorder using a Classification Tree, a non-parametric type of machine learning (Cohen, 2013). Due to these results and need for Level 2 screeners for ASD, we explored the use of Classification Trees as a means of developing a diagnostic algorithm for the PDDBI.
Objectives: To develop a reliable and valid diagnostic algorithm for the PDDBI.
Methods: To date, 649 parent and 202 teacher PDDBI forms have been collected from the NYS Institute for Basic Research (IBR), and from Queens University. Approximately 83% of cases have been diagnosed with "ASD" with the remainder ("OTHER") having ASD ruled out as a diagnosis after extensive clinical evaluation or identified by parents as unaffected siblings or who were toddlers taking part in a longitudinal investigation of at-risk infants.
The Classification and Regression Trees module (Statistica, Version 12) was used to develop the algorithm. Inputs included the Repetitive, Ritualistic and Pragmatic Problems Composite T-score, the Approach-Withdrawal Problems Composite T-score, the Expressive Social Communication Abilities Composite T-score, the Autism Composite T-Score, the Social Discrepancy score, and the Semantic-Pragmatic Problems Discrepancy score. Sixty percent of the dataset was used for training and 20% for testing during the development process. The remaining 20% (the "validation set" not used in the model development process) helped validate the final model.
Results: A number of models were explored and yielded similar results. The selected model divided the ASD sample into two parts, a "typical" ASD group and a "high social-functioning" ASD group while the OTHER sample was divided into three groups, a relatively unaffected group, and two smaller sets: 1) a "rigid" group, and 2) a "severe

behavior problem" group.
The two ASD groups differed on IQ, Vineland, and ADOS severity scores; parent reports of seizures; and association with a gene polymorphism linked to autism severity (Cohen et al. 2003).
Sensitivity and Specificity were 83% and 87% for the training set, 86% and 81% for the test set, and 82% and 81% for the validation set. Sensitivity and specificity were 80% each for cases <4 years and 85% and 89%, respectively, for cases >4 years.
Overall agreement between parent and teacher global algorithm diagnoses (ASD vs OTHER) was 78% (Kappa = 0.47) and was 66% (Kappa = 0.52) for the more fine grain groupings. Using only cases in which parent and teacher forms yielded identical groupings, increased sensitivity and specificity to 90% each.
Conclusions: Results confirm previous studies suggesting two forms of ASD, a classic presentation (often associated with intellectual delays and seizures), and a group with better social and language skills having a more optimal outcome. These results suggest that the PDDBI can serve as a useful Level 2 screener.

148 **165.148** Developmental Profiles of Children Missed By Early Autism Screening Compared to Early-Identified Peers

C. Cordeaux[1], *M. Barton*[2] *and D. A. Fein*[2], *(1)University of Connecticut, Storrs, CT, (2)Psychology, University of Connecticut, Storrs, CT*

Background: The American Academy of Pediatrics recommends that all children be screened for ASD at 18 and 24 months of age. ASD-specific screening and diagnostic tools for toddlers such as the M-CHAT and the M-CHAT-R/F make it possible for clinicians to make stable diagnoses at younger ages. However, no screening instrument can identify all cases at 18-24 months. Children who screen negative at 18-24 months old but later screen positive at 30-48 months old with the M-CHAT and M-CHAT-R/F are "potential miss" cases and provide important information about the natural course of ASD as well as the types of children likely to be missed by ASD-specific screening instruments.
Objectives: This study presents data from a two-year follow-up screening with the M-CHAT and the M-CHAT-R/F examining the developmental and sociodemographic profiles of "potential miss" cases.
Methods: Participants were screened at pediatric well-visits at 18-24 months of age. Approximately 2 years after initial screening, children were rescreened with the M-CHAT-R/F; Children who screened positive at 18-24 months and/or 48 months were invited to complete an evaluation. Some children who screened negative at 18-24 months but positive at 48 months received an ASD diagnosis (Missed) (N=27) at 48 months. A subset of children maintained an ASD diagnosis from their initial evaluation to their 48 month evaluation (ASD; N=164).
Results: At 48 months, groups did not differ by age, gender, or race/ethnicity. Groups differed significantly on cognitive ability, adaptive skills, and symptom severity, with the Missed group showing stronger cognitive and adaptive skills and lower symptom severity. There was no difference between groups in the number of DSM-IV criteria met, though Missed children were more likely to receive a PDD-NOS diagnosis compared to the ASD children. Additionally, the groups significantly differed by the age at which first words and phrase speech developed, with the Missed group more likely to develop first words and phrases on time. Sibling status also differed between groups, with children in the Missed group more likely to be the oldest child or first child with ASD. Parent-reported age of first concern or regression did not differ between groups.
Conclusions: These findings indicate that a subset of children with ASD are more likely to be missed by ASD parent-report screening at 18-24 months, may not present with full symptom profiles, or may present with less severe symptoms and milder developmental delays at 18-24 months. These results also emphasize the importance of ASD screening at multiple time points, as a single screening may miss cases, or initial diagnosis may change. Understanding profiles of children who are not diagnosed until late toddlerhood can inform best practices for screening in the community and aid in measure development for ASD-specific screening tools.

149 **165.149** Does Age of ASD Diagnosis Produce Differential Outcomes in Middle Childhood

M. Clark[1], *C. Dissanayake*[2] *and J. Barbaro*[3], *(1)Kingsbury Drive Bundoora, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)La Trobe University, Melbourne, Victoria, Australia*

Background: To date, no other studies have investigated the development pathways of children with an ASD prospectively ascertained from a community sample. Research that has studied children with an ASD from infancy to school age, has relied on high-risk and infant sibling cohorts (Landa et al., 2013; Landa & Garrett-Mayer, 2006). Further, although it is considered best practice to diagnose ASDs by 2 years of age where possible, the average age of diagnosis in Australia remains between 4 and 6 years of age (Bent, 2015). Research is yet to investigate the impact age of diagnosis has on later outcomes (cognitive and behavioural). Specifically, this study is interested in whether children who receive an earlier diagnosis (at 24 months) experience more positive develpmental outcomes in middle childhood, relative to those who were detected later.
Objectives: The primary focus in this investigation is to assess the developmental progress at school age, of children diagnosed with an ASD at 24 months, first identified through the SACS study. A longitudinal design is employed here. A secondary objective is to compare the outcomes of the SACS cohort at school age, to those children who were formally diagnosed with an ASD after 3 years of age, using a cross sectional design
Methods: All children were involved in a throrough developmental assessment at school age. Cognition was assessed using the Wechsler Abbreviated Scale of Intelligence (WASI) while the Autism Diagnostic Observation Schedule (ADOS) was administered to assess social communication development and autism severity at school age.
Results: Children in the SACS cohort made significant gains in cognition from toddlerhood to school age, with only few meeting criteria for an ID at outcome (7%). Despite changes in severity of autism symptoms, diagnoses of ASD were highly stable over time with 73% of children retaining their early ASD diangosis from toddlerhood to middle childhood. Preliminary between group comparisons reveal that children diagnosed early are demonstrating higher Full Scale IQ (FSIQ) and Verbal IQ (VIQ) and lower ASD severity at school age, relative to children diagnosed later. However, at this stage, these between group differences are not significant.
Conclusions: This research illustrates the cognitive and behavioural trajectories of children at school age, who were identified and diagnosed with an ASD at 24 months as part of the Social Attention and Communication Study (SACS; Barbaro & Dissanayake, 2009). Further, these findings, although preliminary at this stage, will highlight the importance of *age* of ASD diagnosis and will identify whether the timing of diagnosis contributes to differential developmental outcomes in middle childhood.

150 **165.150** Early Intervention Participation in Families with Toddlers with or at-Risk for an Autism Spectrum Disorder

J. Page[1], *S. Zheng*[2], *C. Wong*[1,2] *and K. C. Gallagher*[3], *(1)UNC Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)FPG Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:
Research has shown that accessing Part C Early Intervention (EI) services at younger ages can alter the trajectory of disability for children with, or at-risk for, autism spectrum disorder (ASD). In studies using quantitative methods intervention services focused on types of services received, parents' satisfaction, with parents of older children with various disabilities. Qualitative investigations with a sufficient sample would help understand family experiences and decisions related to EI service participation, particularly for families with young children that have or are at-risk for autism. It is important to identify families' decisions for accessing services, identify additional services they are not receiving, and possible barriers impacting families' perceptions and experiences with EI.
Objectives:
The current study explores EI service participation and experiences of families with toddlers with or at-risk for ASD, with the following questions:

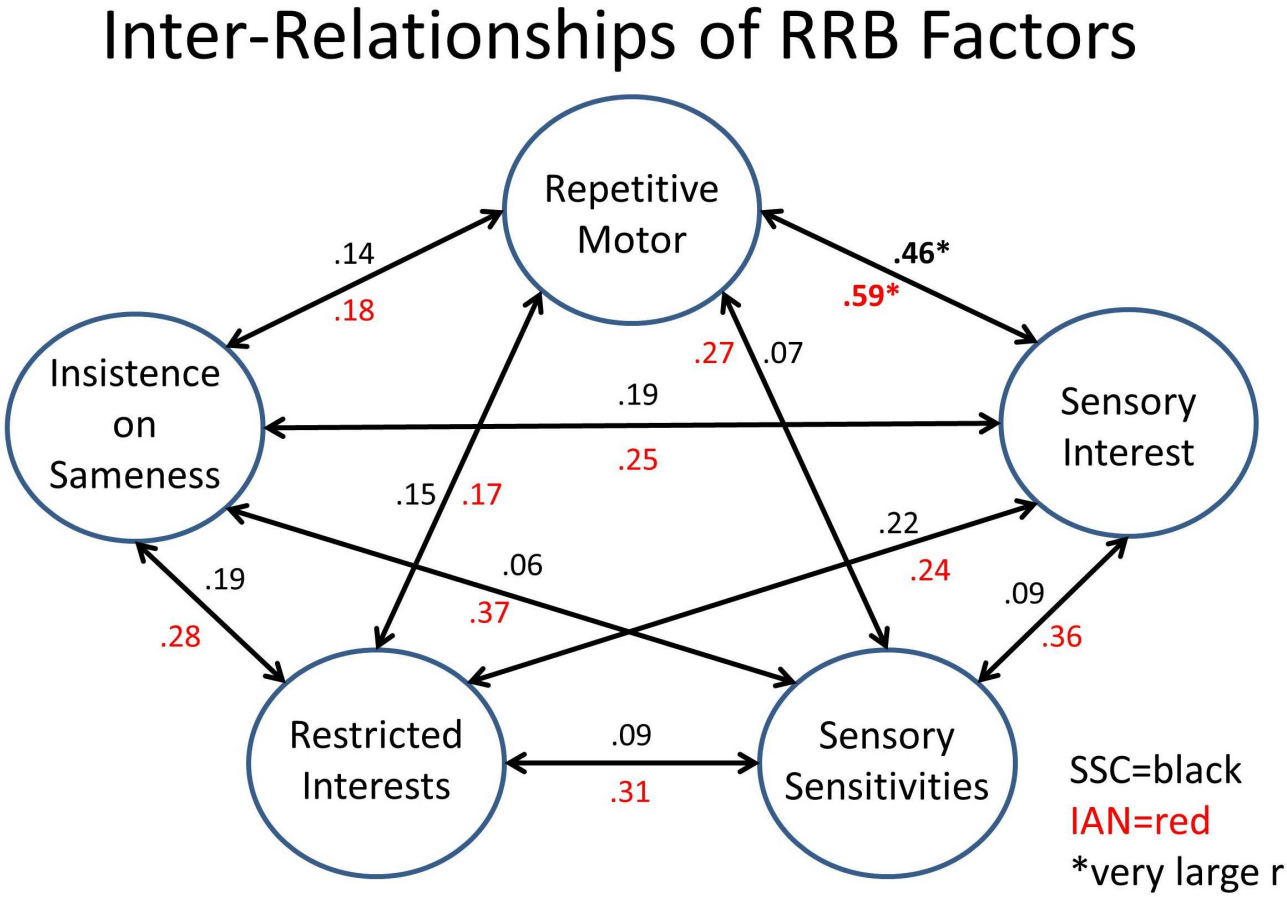
1. What factors impact a family's decision to participate in the EI services that they and their child receive?
2. What services do parents want to receive, and what quantity of services do they desire?

Methods:
Thirty seven semi-structured, 20-minute interviews were conducted with families who participated in a larger randomized control study. Families had a child between 16-36 months of age, failed MCHAT, and were ethnically and racially diverse. Interviews were video recorded and coded by two graduate research assistants, who had established reliability on the codes. Using grounded theory, they generated themes from the data and coded for axial codes (sub-themes within the data).
Results:
Thirty-three of the 37 families were receiving at least one EI service, with speech therapy being the most accessed. On average, children were referred at 20 months, although many parents reported concerns at 12 months. Many families were referred to local EI agencies by pediatricians. Factors impacting families' decision for services accessed include child qualified for service (based upon delay) and services that targeted the specific delay. Many families reported that the most positive part of service was reflected in their child's progress. All of the families reported that they wanted more services for their child; only three mentioned parent support groups for themselves. TEACCH, play group, and occupational therapy were the services parents desired most. By investigating desired and additional resources for families with toddlers, our study identified discrepancies between EI service and parental expectations. Many families cited time, coordinating with service providers, financial burden, a lack of service choices for their child, as barriers to accessing specific services.
Conclusions:
Our findings confirm and extend the literature by interviewing families of toddlers with or at-risk for ASD, in that we identified factors impacting a families' decision to access specific EI services. Parents reported that additional funding and accessing research-based interventions would help their child. Additional research investigating the impact of services for parents is warranted. Identifying and understanding families' preference and decisions to access EI services can help identify gaps in service and practice

151 **165.151** Empirically-Identified Restricted Repetitive Behavior Domains: Informing DSM-6

T. W. Frazier[1] *and A. Y. Hardan*[2]*, (1)Cleveland Clinic Center for Autism, Cleveland, OH, (2)Stanford University, Stanford, CA*

Background:
Restricted, repetitive behavior (RRB) is one of the two symptom domains used to diagnose autism spectrum disorder. Diagnostic and Statistical Manual of Mental Disorders – Fifth Edition (DSM-5) criteria include 4 sub-domains of RRB, including repetitive motor/speech, sameness/inflexibility, restricted interests, and abnormal sensory experience. In contrast, empirical studies of RRB suggest two broad domains – insistence on sameness and repetitive sensory motor behavior. However, diagnostic criteria are based on limited empirical work and previous factor analytic studies of RRB have been restricted to single instruments, limited item sets, or single samples.
Objectives:
To empirically-identify RRB sub-domains using confirmatory factor analyses based on two instruments within each of two separate samples.
Methods:
Parent-reported symptom data were obtained from 2,643 children with ASD included in the Simons Simplex Collection (SSC) using the Social Responsiveness Scale and Repetitive Behavior Scale-Revised and 3,907 children with ASD from the Interactive Autism Network (IAN) using the Social Responsiveness Scale and Social Communication Questionnaire. In each dataset, items were a priori chosen to represent one of five constructs: repetitive motor behavior, insistence on sameness, restricted interests, sensory interests, and sensory sensitivities. A series of confirmatory factor analyses (CFA) were conducted using item-level data with increasingly complex models, including a 1-factor model merging all items, a 2-factor model merging repetitive motor with sensory interests and the remaining three constructs, three 3-factor models iteratively separating restricted interests, sensory interests, and sensory sensitivities from the prior 2-factor model, and a 5-factor model with all five constructs as separate factors. Improved fit across increasingly complex models was evaluated using changes in the Bayesian Information Criterion (BIC), Root Mean Square Error of Approximation (RMSEA), and Confirmatory Fit Index (CFI).
Results:
In both samples, the 5-factor model fit best (smallest absolute improvement: ΔBIC=424, ΔRMSEA=.004, ΔCFI=.024). Absolute fit was marginal for the 5-factor model, as would be expected by multi-item factor analyses without cross-loadings based on complex psychopathology questions. Factor correlations indicated that all RRB constructs had positive, but modest, inter-relationships (SSC r=.06-.22; IAN r=.17-.37), with the exception of the very large relationship between repetitive motor behavior and sensory interests (SSC r=.46, 95%CI=.41-.51; IAN r=.59, 95%CI=.55-.63). Qualitative examination of item loadings revealed that the restricted interests and sensory sensitivities factors, while clearly distinct from other factors, included only a few salient loadings.
Conclusions: Additional large sample studies are needed to confirm and extend the present findings. If confirmed, future revisions of diagnostic criteria may benefit from separating sensory interests and sensory sensitivities, as these two constructs appear only modestly correlated. The present data indicate that sensory interests may be a statistically separable from repetitive motor behavior, although the high correlations observed across samples suggests that future investigations evaluate the clinical and diagnostic utility of this distinction. Only a small number of items were available to evaluate restricted interests, yet this construct clearly separated from other insistence on sameness items, supporting current diagnostic criteria. Future instrument revisions should focus on beefing up measurement of restricted interests and sensory sensitivities.



152 **165.152** Engaging and Adaptive Assessment for Attention in 16p11.2 Deletion Syndrome

A. Brandes-aitken[1]*, S. N. Skinner*[2]*, E. Martucci*[3]*, J. Bower*[3]*, J. A. Anguera*[4]*, A. Gazzaley*[5] *and E. J. Marco*[6]*, (1)Neurology, University of California, San Francisco, San Francisco, CA, (2)University of California, San Francisco, San Francisco, CA, (3)Akili Interactive, Boston, MA, (4)Neurology, UCSF SNAP, San Francicso, CA, (5)Neurology, UCSF, San Francisco, CA, (6)University of California in San Francisco, San Francisco, CA*

Background:
16p11.2 deletion syndrome is associated with a wide range of neurodevelopmental conditions including Attention Deficit and Hyperactivity Disorder (ADHD) and Autism. Despite the high prevalence of ADHD in this population, estimated to be at least 19%, their cognitive control deficits have not been directly measured. Traditional measures of selective attention are often limited by floor effects and lack of participant engagement. Consequently, we hypothesize that a digital platform assessment, with engaging game-like function and adaptive algorithms, would be a more powerful measure of selective attention deficits.
Objectives:
In this study, we aim to determine if children with 16p11.2 deletion show deficits in visual motor processing and sustained attention using the Project: EVO™ (EVO) cognitive assessment. We further investigate sustained and selective attention using standard cognitive measures to investigate whether a difference in delivery platform changes our ability to detect deficits in this clinical population.
Methods:
We recruited children with and without 16p11.2 genetic copy number variations for this cognitive assessment study. Twenty children had a 16p11.2 deletion (mean age 10.1 years +/- 3.9, 6 females) and they were compared with 91 children without known 16p11.2 copy number variation, 16 of which were siblings of the affected individuals (mean age 10.7 years +/-2.2, 41 females). We recruited carrier children and their non-carrier siblings at the Simons VIP annual meetings (Orlando, 2013 and Tyson's Corner, 2015). Neurotypical controls and one family with 16p11.2 deletion were recruited from the UCSF Sensory Neurodevelopment & Autism Program and collaborations with Akili

interactive. Children were administered two traditional measures of selective attention, the Flanker Task and the Visual Search Task and the EVO assessment. EVO consists of three assessment components: visuomotor tracking (participants must steer the iPad through winding paths), perceptual discrimination (responding to relevant targets while ignoring distractors), and multitasking (preforming tracking and discrimination, simultaneously). In addition, we assessed basic motor speed with an iPad tapping assessment.

Results:

Using an ANCOVA analysis (controlling for age), we found no significant difference between response time or response time variability in children with or without 16p11.2 deletions on standard, non-adaptive, assessment tools: the Flanker Task and the Visual Search Task. Using the EVO platform, children with 16p11.2 deletions displayed significantly lower visuomotor tracking level, slower response time, and higher response time variability relative to their siblings and unrelated children without 16p11.2 deletion. A group effect was not present for multitasking abilities. In a subset of children who were able to complete these tasks, we found no statistical difference in motoric tapping speed between groups, suggesting that observed performance disparities using EVO for response time and response time variability are not simply a result of impaired motoric control or familiarity with iPad use.

Conclusions:

These findings suggest that children with 16p11.2 deletion have measurable performance deficits in selective attention and visuomotor tracking compared to related and un-related children without this genetic mutation. Furthermore, an engaging, adaptive assessment tool may be a more powerful assessment strategy than traditional measures.

153 **165.153** Exploration of ASD Symptoms Among Individuals with Pitt-Hopkins Syndrome

S. E. O'Kelley[1], *K. C. Guest*[2], *C. O. Leonczyk*[1], *E. Rahn*[3], *K. D. Krubinski*[4], *B. A. Modi*[4], *A. Kennedy*[3] *and D. Sweatt*[3], *(1)University of Alabama at Birmingham, Birmingham, AL, (2)University of Alabama, Birmingham, AL, (3)Neurobiology, University of Alabama at Birmingham, Birmingham, AL, (4)Psychology, University of Alabama at Birmingham, Birmingham, AL*

Background: Pitt-Hopkins Syndrome (PTHS) is caused by disruption (mutation or deletion) of transcription factor 4 (TFC4, located on chromosome 18). Haploinsufficiency, or inheriting only one working copy of TCF4, causes PTHS. Approximately, 200-300 documented cases of PTHS exist worldwide. Available clinical studies describe individuals with PTHS as exhibiting some of the core symptoms of Autism Spectrum Disorder (ASD), including difficulties in verbal and nonverbal communication, sensory sensitivity, and social interaction difficulties. Significant developmental delays, including motor delays, and intellectual disability are also reported in individuals with PTHS.
Objectives: The current study focused on obtaining specific caregiver-reported descriptions of individuals with PTHS to clarify and characterize the presence of ASD symptoms in this population, with particular emphasis on the social, communication, adaptive, developmental, and repetitive behaviors of individuals with PTHS.
Methods: Parent/caregiver participants were recruited through the Pitt Hopkins Research Foundation and completed questionnaires over the telephone and by mail, including a detailed demographic and background questionnaire, the Modified Checklist for Autism in Toddlers-Revised (M-CHAT-R), Communication and Symbolic Behavior Scales-Infant Toddler Checklist, Repetitive Behavior Questionnaire, Short Sensory Profile-2, and Vineland Adaptive Behavior Scales- II. Additional measures of ASD symptomatology and behavioral difficulties were also obtained.
Results: Data are currently available for 18 individuals with confirmed PTHS, including 11 males. The mean age of the individuals with PTHS at the time of the caregiver interview was 7.67 years (range of 2 to 17 years), and adaptive skills were well below average (mean Vineland-II Adaptive Behavior Composite standard score = 47.9, SD = 10.35), indicating developmental delays across skill areas. On rating scales, individuals with PTHS were described as exhibiting delays in early emerging social-communication skills on the CSBS-ITC (mean total raw score = 21.63, consistent with a range of concern for a child at a 10-month level) and the presence of significant ASD "red flags" on a brief screening tool developed for very young children (mean "failed" M-CHAT-R items = 9.73, considered "high risk"). On the RBQ, a tool that has demonstrated good validity in measuring repetitive behaviors in several genetic syndromes as well as ASD, individuals with PTHS received elevated scores for overall repetitive behaviors and in particular, the presence of clinically significant stereotyped behaviors in 83% of the sample (mean SB score = 9.17, SD = 4.33). A range of sensory differences were also endorsed by caregivers on the SSP-2 for their children. Data collection and analyses are ongoing and will provide additional information about relations between variables and will seek to clarify whether level of functioning and/or level of social-communication impairments better predict the ASD symptom profiles of individuals with PTHS.
Conclusions: Information regarding ASD symptoms and patterns of behavior within genetic syndromes such as PTHS may be helpful in characterizing a broader ASD phenotype. Further, a better understanding of social communication and behavioral difficulties in individuals with known genetic differences and developmental delays may help guide more informed recommendations for intervention.

154 **165.154** Exploring Personality in Children with ASD: Correlations Between Observed, Self-Report, and Parent-Report Measures

A. R. Osuna[1], *D. Delgadillo*[1] *and J. J. Wood*[2], *(1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA*

Background: While personality is a widely accepted framework used to study behavior in typical populations, studying personality in those with ASD is a relatively novel focus. A few studies have indicated that adults self-report behaviors low in openness to experience and extraversion (Anckarsäter et al., 2006), and high in neuroticism (Kanai et al., 2011). In a parent-report study of children aged three to five years, Fortenberry et al. (2011) found that children with ASD scored lower in extraversion, conscientiousness, and openness to experience than those typically developing. There are two significant gaps in this literature. First, studies in this subfield have relied solely on parent- and self-report measures. Secondly, the subjects of ASD personality research are typically adults with the disorder. The present study addresses these gaps by looking at school-aged children and supplementing self- and parent-report measures with an observational approach.
Objectives: The purpose of this study was to: 1) Test a novel observational approach to evaluating personality in children with ASD using the ADOS; and 2) Correlate observational scores, self-reports, and parent-reports of the child's personality.
Methods: The personalities of 43 school-aged children (6 to 13 years) with ASD were examined. Participants completed Module 3 of the ADOS, which was then assessed for personality using a novel observational personality coding scheme (OPS). The OPS looked at the following personality factors: openness to experience, conscientiousness, extraversion, agreeableness, neuroticism, and intelligence. Children self-reported personality using the Big Five Questionnaire for Children (BFQ-C), while parents rated their child's personality using the Hierarchical Personality Inventory for children (HiPIC).
Results: Each of the six OPS personality factors consisted of four or five observable items that yielded reliable internal consistencies ($\alpha > .650$). The OPS and HiPIC significantly correlated within the domains of extraversion and emotional stability, $r(35) = .351$, $p < .05$. Observed extraversion was significantly negatively correlated with agreeableness, $r(35) = -.549$, $p < .01$, and conscientiousness , $r(35) = -.409$, $p < .05$. Furthermore, observed openness to experience was significantly correlated with agreeableness, $r(35) = -.423$, $p < .01$ and observed conscientiousness was marginally significantly correlated with agreeableness , $r(35) = -.316$, $p = .057$. BFQ-C scores did not significantly correlate with any corresponding factor on the OPS or HiPIC.
Conclusions: Our results indicate that the ADOS may be a valuable source of information in regard to assessing the personality of children with ASD. Furthermore, discrepancies between measures on corresponding factors infer that it can be problematic to rely on a single questionnaire. Personality offers an additional lens of evaluating the heterogeneous behavior of children with ASD that is traditionally underutilized. Our forthcoming work will look at psychopathology scores in order to cross-validate the OPS measure. Future research should expand on this work and further explore the personality of individuals with ASD.

155 **165.155** Expressive Language As Predictor for Amount of Assessment Required to Evoke Challenging Behavior

P. Juarez[1], *J. E. Staubitz*[2], *N. Houchins-Juarez*[3], *J. Torelli*[1], *K. M. Simcoe*[1] *and J. L. Staubitz*[3], *(1)Vanderbilt University Medical Center, Nashville, TN, (2)Pediatrics, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University, Nashville, TN*

Background:
When behavior analysts are enlisted to reduce challenging behavior, valid assessments are needed to develop individualized treatment. The functional analysis (FA) is the most valid measure for this purpose; it methodically tests and confirms hypothesized functions of challenging behavior. The Latency-Based Functional Analysis (LBFA) is an expedited FA model validated for confirming evocative and reinforcing variables of challenging behavior. Length of the LBFA is predicated on the amount of time required to systematically evoke and reinforce challenging behavior, then replicated with experimental control.
Within a randomized controlled trial (RCT) assessing for potential cost-benefit of behavior analytic services within typical inpatient hospital settings, we conducted latency-based FAs of the challenging behavior of [SJ1] 18 children diagnosed with autism and with varying communicative abilities.
Objectives:
Test the hypothesis that patient expressive language skill may predict the speed with which challenging behavior can be evoked within LBFAs.
Methods:
Eighteen children (17 male, 1 female) ages 6-16 (mean 10.3) with autism participated in this study. Twelve were admitted to a university-based child and adolescent psychiatric hospital and six were admitted to a medical floor of a university-based children's hospital. All had history of chronic challenging behavior. We conducted all assessments in inpatient units of these settings; either in participants' rooms or multi-purpose rooms.
Definitions for each participant's target behaviors were operationalized based on caregiver report during pre-FA interviews. LBFAs were conducted using procedures based on Thomasson-Sassi, et al. (2011). Minimum numbers of assessment series required to evoke target behaviors for each participant were recorded. A series was defined as the total set of 2-4 assessment session types (e.g. attention, play, tangible, escape) to be presented within the LBFA. Patients' expressive language skills were rated based upon direct observations by behavior analysts during patient interviews, assessments, and informal observations within the hospital setting. Patient utterances were sorted into two categories: "limited vocal" (patients used approximations of sentences or shorter phrases with limited vocabulary) or "fully vocal" (speaking primarily in full sentences

and using expansive vocabulary).
Finally, we evaluated the degree to which expressive language rating predicted the number of series needed to evoke challenging behavior within the LBFA using a point-biserial correlation.
Results:
Results indicated expressive language rating was positively correlated with the number of series needed to evoke challenging behavior (r_{pb} = .58). Higher verbal ability predicted a higher number of series.
Conclusions:
Results suggest patients demonstrating high levels of expressive language skill may require adaptation of LBFAs for improved results. Limitations of this study include small sample size, and pilot iteration of a language skills assessment. Because language performance was rated based on post-hospitalization reviews of videos capturing participant interactions within behavioral assessments, the experimenters did not have the opportunity to conduct a validated language assessment with the participants. Future research should use previously-validated language measures, further test the expressive language skills rating scale used within this study, verify which adaptations to behavioral assessments can be useful to rapidly evoke and study challenging behavior for verbally skilled patients, and examine replicability.

156 **165.156** Factor Analysis of the Parent Stress Index in Children with Autism Spectrum Disorder and Serious Behavioral Problems

V. Postorino[1], *C. McCracken*[2], *S. E. Gillespie*[3] *and L. Scahill*[4], *(1)Marcus Autism Center, Emory University, Atlanta, GA, (2)Depertment of Pediatrics, Emory University School of Medicine, Atlanta, Georgia, (3)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (4)Pediatrics, Marcus Autism Center, Atlanta 30329, GA*

Background: Children with autism spectrum disorder (ASD) may exhibit a range of disruptive behaviors including tantrums, noncompliance, aggression and self-injury. These behaviors often pose extraordinary strain on parents. The Parent Stress Index-Short Form (PSI-SF) is a common measure of parental stress that has been used across a wide range of children with psychiatric and developmental disorders including those with ASD. In most studies, investigators used the original three factors developed by Abidin (Abidin, 1995). However, a recent factor analysis of the PSI-SF by Zaidman-Zait and colleagues (2011) raised questions about the relevance of the original three factor model in children with ASD.
Objectives: The aim of this study was to examine the factor structure of the PSI-SF in a large sample of parents of children with ASD and disruptive behaviors.
Methods: We used data from two federally-funded, multisite, randomized clinical trials conducted by the Research Units on Pediatric Psychopharmacology (RUPP) and Research Units on Behavioral Intervention (RUBI) Autism Networks. To be included in these trials children had to have: 1. ASD with moderate or greater disruptive behavioral problems as measured by the Aberrant Behavior Checklist-Irritability subscale and the Severity scale of the Clinical Global Impression; 2. IQ of 35 or greater as assessed by the Abbreviated Stanford-Binet 5, the Leiter-R or the Mullen Scales. Parents of 304 medication-free children with ASD completed the PSI-SF at baseline. Preliminary factor analysis with promax rotation was performed using maximum likelihood estimation on all 36 questionnaire items of the PSI-SF. Three factors were retained and items with factor loadings greater than 0.3 were kept. Cronbach's α was calculated to verify each factor as measuring in the direction of a single construct, using a cutoff of 0.7.
Results: The sample of 304 children (263 males; 41 females) had a mean age of 5.8 ± 2.2 years (range 3.1-13.8); 81.3% were white, 10.9% were African American, 10.9% were listed as "Other" (e.g., Asian, Alaskan, Pacific Islander or multi-racial). The mean score on the ABC Irritability subscale was 26.1 ± 7.0. Preliminary factor analysis revealed that 3 items did not load on any factor. The remaining 33 items loaded on factors that were similar to the original three factor structure of the 36-item PSI-SF. The deletion of these three items improved the alpha coefficient for each of the three factors with no change in the alpha value for the total score (Figure 1).
Conclusions: To our knowledge no previous study has examined the factor structure of the PSI-SF in a large sample of children with ASD and serious behavioral problems. In this sample, our preliminary factor analysis suggests that a three factor solution with 33 items may have advantages over the original 36 item measure in this clinical population. Additional exploratory factor analyses may provide further support for this new factor structure of the PSI-SF. We will also examine correlations of these new factors with other measures (e.g., Vineland, ABC, IQ, Home Situations Questionnaire) in this well-characterized population.

Table 1: Cronbach's Alpha, the reliability for the 3 sub-scales in 33 items and the 36 items

Model	Parental Distress	Parent -Child Dysfunctional Interaction	Difficult Child	Total Scale
36 items	12 items: 0.86	12 items: 0.73	12 items: 0.77	0.83
33 items	14 items: 0.87	9 items: 0.90	10 items: 0.90	0.84

Table 2: Preliminary 33-item PSI-SF structure

PSI Factor Results	Factor 1	Factor 2	Factor 3
27) I feel that my child is very moody and easily upset.	**0.806**	0.187	-0.181
30) My child gets upset easily over the smallest thing.	**0.804**	-0.089	-0.051

24) Sometimes my child does things that bother me just to be mean.	0.035	**0.528**	0.131
5) Since having a child, I feel that I am almost never able to do things that I like to do.	0.097	-0.048	**0.764**
12) I don't enjoy things as I used to.	0.019	0.082	**0.747**
9) I feel alone and without friends.	-0.129	0.030	**0.671**
3) I feel trapped by my responsibilities as a parent.	0.064	0.084	**0.616**
4) Since having this child, I have been unable to do new and different things.	0.296	-0.092	**0.613**
11) I am not as interested in people as I used to be.	-0.185	0.108	**0.592**
7) There are quite a few things that bother me about my life.	0.239	-0.025	**0.579**
10) When I go to a party, I usually expect not to enjoy myself.	-0.282	0.131	**0.574**
8) Having a child has caused more problems than I expected in my relationship with my spouse.	-0.027	0.226	**0.475**
6) I am unhappy with the last purchase of clothing I made for myself.	-0.217	0.212	**0.367**

157 **165.157** Factors That Promote Early ASD Diagnosis Among Simplex Families in an Urban Setting

M. Thompson[1], *E. A. Fox*[2], *T. Ward*[3], *J. Gerdts*[4] *and R. Bernier*[4], *(1)University of Washington Autism Center, Seattle, WA, (2)University of Washington Center for Human Development and Disability, Seattle, WA, (3)Seattle Pacific University, Seattle, WA, (4)University of Washington, Seattle, WA*

Background:
Early diagnosis of ASD and subsequent intervention have been found to significantly and positively impact child outcomes (Zwaigenbaum et al., 2015). It is unclear, however, which factors promote early diagnosis. Studies have focused on environmental factors (e.g., poverty, accessibility of services, presence of an older sibling with ASD), but little is known about the biological and behavioral factors that may impact early diagnosis (Herlihy et al., 2015; Liptak et al., 2008). Recent advances in the understanding of the genetic factors implicated in autism also necessitate an examination of the relationship between genetic status and age at diagnosis.
Objectives:
To determine the factors that promote early ASD diagnosis for children in simplex families within a homogeneous socio-demographic community.
Methods:
Participants included 182 children with ASD (79.9% male, mean age = 9.41 years) from the University of Washington's Simons Simplex Collection (SSC) site. 28 children had an identified Likely Gene-Disrupting Mutation (LGD), while 154 were without an LGD. Age of diagnosis was extracted from an interview used to qualify subjects for study participation. Child variables hypothesized to impact age at diagnosis included gender, presence of an LGD, developmental regression, and intellectual ability. Presence of regression was extracted from the ADI-R, as was age at first parental concern. Intellectual ability was assessed via full-scale IQ. Demographic characteristics hypothesized to affect age at diagnosis were obtained from the SSC Background History Form. To account for multiple comparisons during correlation and regression analyses, a stricter p-value of p<.008 was used.

Results:
Bivariate correlations were performed using variables of interest and age at diagnosis. Significant positive correlations between age at diagnosis and both age at parental concern and intellectual ability were identified ($r(166) = .25$, p=.000; $r(166) = .353$, p=.000). Results indicated significant negative correlations between age at diagnosis and regression, $r(166) = -.30$, p=.000. Multiple linear regression was performed to assess which variables had the strongest effect on age at diagnosis. There was a main effect of intellectual ability on age at diagnosis ($B = .448$, $t(128) = 3.31$, p=.001). A trend suggested age at parental concern also predicted age at diagnosis ($B = .596$, $t(128) = 2.37$, p=.02). There was no main effect for any demographic characteristic.
Conclusions:
When environmental factors like income, education, and geographic access to services are consistent, children's intellectual ability, a characteristic not specific to autism, may affect when children are diagnosed. Additionally, while parental concern has not, historically, been shown to promote early ASD diagnosis, it appears to contribute to age at diagnosis in this sample, likely driven by similar factors (e.g., intellectual impairments are identified earlier). Since having an older sibling with ASD has been shown to promote early diagnosis, focusing on simplex families gives important insight into the factors that impact diagnosis when families do not have prior ASD experience. The results indicate a need for parent education to help parents recognize ASD symptoms, specifically for those children who may not exhibit other developmental delays.

158 **165.158** Informant Discrepancies in Externalizing and Internalizing Symptoms and Adaptive Skills of High-Functioning Children with ASD

C. A. McDonald[1], *C. Lopata*[1], *J. P. Donnelly*[1], *M. L. Thomeer*[1], *J. D. Rodgers*[1] *and A. K. Jordan*[2], *(1)Institute for Autism Research, Canisius College, Buffalo, NY, (2)University at Buffalo, SUNY, Buffalo, NY*

Background: Assessment of clinical symptoms requires information from multiple informants. However, informant discrepancies may have significant repercussions when performing evaluations (i.e., access to services, treatment planning, progress monitoring; De Los Reyes & Kazdin, 2004). Understanding informant discrepancies may be more important for children with ASD, who often have difficulty generalizing across settings (Stratis & Lecavalier, 2015). Despite potential effects on access to services and intervention planning, there is a paucity of research that has comprehensively examined informant discrepancies for scales assessing externalizing, internalizing, and adaptive behaviors for children with HFASD.
Objectives: This study examined parent-teacher discrepancies for ratings of externalizing and internalizing symptoms and adaptive skills of children with HFASD.
Methods: This study included a total of 236 BASC-2 ratings of children with HFASD from two informant groups (parents and teachers). Each parent-teacher pair (n = 118 parents/caregivers and n = 118 teachers) rated the same child. The children with HFASD, ages 6 to 11 years, were recruited from clinical trials and had a prior clinical diagnosis of ASD, WISC-IV short-form IQ > 70, and VCI or PRI factor score >80. All diagnoses were confirmed using the ADI-R. The dependent measure used was the *Behavior Assessment System for Children-2 (BASC-2), Parent (PRS) and Teacher (TRS) Rating Scales*. Protocols were scored using the BASC-2 ASSIST Plus computer scoring software. Scores on the Internalizing Problems, Externalizing Problems, and Adaptive Skills Composites were examined for mean differences, level of agreement, linear relationships, and moderators of discrepancies.
Results: Mean difference comparisons were non-significant for the Externalizing Composite and its Aggression and Conduct Problems scales (negligible-to-small effect size *d*s, .02 - .25). Only the Hyperactivity scale within this composite yielded a significant between-groups difference ($d = .45$). For the Internalizing Composite and its scales, all between-groups comparisons were non-significant and the effect sizes were small-to-negligible (*d*s < .17). Parent-teacher ratings on these Composites and scales were significantly correlated (generally moderate). In contrast, teacher ratings were significantly higher than parents for the Adaptive Skills Composite and several of its constituent scales. Effect sizes on these significant comparisons ranged from small ($d = .48$) to large ($d = 1.06$), with the Adaptive Skills Composite difference reflecting a medium effect size ($d = .73$). Between-groups comparisons for non-significant scales resulted in small effect sizes (*d*s = .20-.30). Correlations between informants on the Adaptive Skills Composite were significant (low-to-moderate), with variability in the correlations among its constituent scales. Parent-teacher discrepancies were not moderated by child or parent variables.
Conclusions: This study suggests a reduced likelihood of informant discrepancies for externalizing and internalizing symptoms, with larger discrepancies expected when assessing adaptive skills. Reasons for the inconsistent pattern of findings are unknown but may involve more diversity in skills making up the adaptive skills construct or greater salience of behavioral symptoms. Poor agreement may have treatment and progress monitoring implications (e.g., difficulties identifying targets, establishing baselines, assessing intervention efficacy).

159 **165.159** Intelligence Profile and Diagnosis Model in Children with Autism Spectrum Disorder (ASD)

B. Chen[1], *H. Deng*[1], *X. Zou*[1], *J. He*[1] *and B. Wu*[2], *(1)Children Developmental & Behavioral Center, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China, (2)School of Mathematics & Computational Science, Sun Yat-Sen University, Guangzhou, China, Guangzhou, China*

Background:
Differences in intelligence profile for ASD and other developmental disabilities such as ADHD are commonly observed in clinical practice. Some studies indicate that the intellectual-indicators may contribute to diagnostic discrimination. This study establishes a novel computerlearning-model for ASD diagnosis, which is demonstrated to have satisfied performances in discriminating ASD from ADHD individuals.
Objectives:
1. To explore diagnostic prediction accuracy of ASD and ADHD base on individual intelligence profile.
2. To provide informative models for decision making for ASD diagnosis based on performance pattern differences on intelligence measurement.
Methods:
The study population consisted of 605 children from Chinese Han population, which includes 275 children diagnosed as ASD by clinical-judgments according to DSM5 criteria, 192 with ADHD, 104 with Intellectual-Disabilities, and 36 Typically-Developed individuals. Chinese-Wechsler Intelligence Scale for Children (C-WISC) was administered between 01/2013 to 01/2015 in all subjects. We built a Random-Forest model to make diagnostic classification by randomly taking 2/3 samples as the training dataset and 1/3 as the test, then applied bootstrap strategies to re-sample 100 times. The Random-Forest method is used to build the diagnostic model, where each factor's contribution to diagnostic classification are evaluated and the important factors are selected to build the prediction model. We presented the decision tree for ASD diagnosis using intellectual-indicators.
Results:
In those with Full-Scale IQ ≥70 , Arithmetic, Comprehension and Similarities were the most important factors for ASD diagnosis, with the general prediction accuracy for ASD of 0.537 and ADHD 0.74. With the threshold of Arithmetic Standard score (S-score) ≥8.5, plus | VIQ – PIQ | >10, the prediction accuracy for ASD increases to 82% if Picture Arrangement S-score is <8.5 plus Information S-score ≥14. With the Arithmetic S-score < 8.5 and Block Design S-score ≥12, the prediction of ASD diagnosis shows 77% accuracy without requirement of VIQ and PIQ differences. In those with Full-Scale IQ <70, Comprehension became a primary component in the ASD decision making process, followed by Block Design and Object Assembly. General prediction accuracy is 0.822 to separate ASD from others including ADHD, ID and TD. With | VIQ – PIQ | >5, predicting accuracy for ASD diagnosis could reach to 100% in a total of an 18 case subset, with Comprehension S-score <1.5 and Block Design S-score ≥7.5. In the subgroup without Verbal IQ and Performance IQ differences requirement, predicting accuracy for ASD diagnosis is 93% with Comprehension S-score <1.5 and Block Design S-score ≥6.5.
Conclusions:
Our findings suggest that a low Comprehension level shows promising predictive accuracy in low functioning children with ASD, with an individual's visual learning abilities remaining at a similar level. This may contribute to the effectiveness for rescreening ASD missed-diagnosis in other developmental-disabilities population, especially children who receive a prior diagnosis of intellectual disability. In higher functioning children with ASD, the predictors include normal visual learning skills and cognition, but abilities related to logic or reasoning are poor. Risk factors in other intellectual assessments which may contribute to ASD diagnosis should be explored in further research.

160 **165.160** International Survey of Autism Spectrum Disorder Diagnostic Procedures

W. M. Weikum[1], *J. Shen*[2] *and N. E. Lanphear*[1], *(1)Sunny Hill Health Centre, University of British Columbia, Vancouver, BC, Canada, (2)Child & Family Research Institute, Vancouver, BC, Canada*

Background: Efficient diagnosis of Autism Spectrum Disorder (ASD) is essential for timely access to intervention services. The "gold standard" diagnosis of ASD is often multidisciplinary teams with structured observation and diagnostic interviews. However, differences in timing, personnel and diagnostic tools exist among centers.
Objectives: Since no universally accepted diagnostic method exists, we surveyed ASD centers to better understand current international practices.
Methods: A diagnostic tool and protocol survey was emailed to centers serving children with ASD. We collected 178 surveys from all world regions that correspond in English.
Results: Most children (42%) are assessed between 3-6 years of age. Multiple disciplines are used in 97% of centers, with an average of 4 (SD=2) disciplines used at each center. Psychologists (89%), Speech/Language Specialists (71%), Pediatricians (63%) and Psychiatrists (48%) are the most commonly used disciplines. Centers (n=90) from non-English speaking countries (N-ENG) use more Psychiatrists ($p<.05$) and centers (n=88) from English speaking countries (ENG) use more Pediatricians ($p<.05$). When questioned about their assessment protocols, 80% of centers report using standard procedures. The most frequently reported diagnostic tools are the Autism Diagnostic Observation Schedule (ADOS/ADOS-2; 84%), Autism Diagnostic Interview (ADI-R; 57%), Modified Checklist for Autism in Toddlers (48%) and Childhood Autism Rating Scale (CARS/CARS-2; 46%). The ADI-R is used more in N-ENG countries ($p=.05$), but the ADOS is used more in ENG countries ($p<.05$). Additional psychological testing is done in 78% of centers. The most common tests reported examine Intelligence (62%), General Development (50%) and Adaptive Behavior (38%), while Speech/Language specific tests are only reported by 17% of centers. The most frequently used tests are the Wechsler Scales (57%) and Vineland Adaptive Behavior Scales (28%). N-ENG countries

report more appointments [3.3 visits (SD=1.7) vs. 2.5 visits (SD=1.6); $p< .05$], however, both ENG countries [5.9 hours (SD=2.7)] and N-ENG countries (6.1 hours; SD=4.3) spend similar numbers of hours in appointments. The average number of weeks from referral to diagnosis is 25 weeks (SD=21) for all centers. Although wait time from first assessment visit to diagnosis is similar for ENG [7.5 weeks (SD=9.5)] and N-ENG countries [7.2 weeks (SD=6.5)], ENG countries have significantly longer wait times between referral and the first assessment visit [26.3 (SD=21) weeks vs. 9.5 (SD=12) weeks; $p<.05$]. Specifically, Canada [45 (SD=23) weeks] has significantly longer referral wait times ($p<.05$), even when compared to other ENG countries such as the United States [19 (SD=13) weeks], and other Commonwealth countries [23 (SD=21) weeks].
Conclusions: The majority of centers use multidisciplinary teams and report using interview and child observation tools. Results show ENG centers have significantly longer referral wait times, use more Pediatricians and use the ADOS more often. Conversely, N-ENG countries report using more Psychiatrists and the ADI-R more frequently. Despite more appointments in N-ENG countries, there are similar amounts of time spent in appointments and nearly equivalent wait times between first appointment and diagnosis for both ENG and N-ENG countries. ASD diagnostic centers will be interested in comparing their own procedures to our findings.

161 **165.161** Investigating Symptom Overlap Between Individuals with High-Functioning Autism Spectrum Disorder and Schizophrenia

S. Brocke[1], *K. Cook*[2], *L. Rabany*[1], *S. Corbera*[1,2], *K. Pelphrey*[3], *M. Bell*[2,4] *and M. Assaf*[1,2], *(1)Olin Neuropsychiatry Research Center, Hartford, CT, (2)Yale Psychiatry, New Haven, CT, (3)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (4)Department of Veteran Affairs, West Haven, CT*

Background: Autism Spectrum Disorders (ASD) and Schizophrenia (SZ) are traditionally conceptualized as separate clinical entities. However, recent findings have suggested that they might overlap, as both are neurodevelopmental disorders characterized by negative affect, reduced social interaction and deficits in social cognition. Importantly, the symptom overlap profile, as defined by standard clinical assessments is not clear.
Objectives: Compare scores on standard symptom assessments, focusing on positive and negative symptoms as well as social and communication deficits in individuals with high-functioning ASD, SZ and in healthy controls (HC).
Methods: 29 individuals with ASD, 36 individuals with SZ, and 45 HC ages 18-32 were recruited to date. We administered a battery of clinical assessments to confirm diagnosis and quantify symptoms, including: Structured Clinical Interview for DSM-IV TR (SCID), Positive and Negative Syndrome Scale (PANSS) and the Autism Diagnostic Observation Schedule (ADOS). One way ANOVAs were performed to assess the differences in scores between the groups and correlation analyses to assess the relationship between positive and negative psychotic symptoms and social and communication deficits.
Results: One way ANOVAs showed main effect of group on ADOS Total, Communication (C) and Social Interaction(SI) subscale scores($p <.001$). Post-hoc Tukey HSD tests demonstrated that HC showed significantly lower scores than the patient groups with no significant differences between the patient groups on all scores. The PANSS Total score showed a main effect for group ($F(1,57)=11.93$, $p=.001$) as did the subscale scores(positive, negative and general)($p <.05$). However, SZ participants showed significantly higher (worse) scores compared to the ASD group on all PANSS scores.
SZ participants showed a significant correlation between PANSS and ADOS scores, including positive correlations between PANSS Negative and ADOS C, SI and Total scores ($r(33) = .494$ $p =.003$, $r = .746$, $p< .001$, and $r = .71$, $p <.001$, respectively). This group also exhibited a trending inverse correlation between PANSS Positive and ADOS SI and Total ($r (34) = -.311$, $p = .065$, $r = -.321$, $p =.056$, respectively). Finally, PANSS total scores also showed a correlation with SI ($r(33) = .342$, $p = .044$) and a trend with ADOS Total ($r = .319$) $p = .062$).
ASD participants showed significant correlations between PANSS general and ADOS C, SI and Total scores ($r(22) = .410$, $p = .046$, $r(22) = .481$, $p =.017$, $r(22) = .585$. $p=.003$, respectively). In addition, this group showed a significant correlation between the PANSS total score and the ADOS SI and total ($r(22)= .480$, $p = .018$, $r(22) - .427$, $p = .037$, respectively). There were no significant correlations between PANSS Negative and ADOS scores.
Conclusions: Our data support the hypothesis that social and communication deficits in SZ are similar to those of ASD. However, the pattern of correlation between these deficits and symptoms related to psychosis, especially negative symptoms, is different between these groups. These results have implications for future research on the underlying biology of both diagnoses as well as to patient assessment in clinical setting in order to fully characterize individual symptoms and their severity.

162 **165.162** M-CHAT Screening in Toddlers Referred to Early Intervention

B. L. Eaton[1], *K. L. Traub*[2], *D. Thao*[2], *N. Basu*[2], *S. E. Levy*[3], *A. Bennett*[4], *H. Kruger*[5] *and D. L. Robins*[2], *(1)Autism, Chester County Intermediate Unit, Downingtown, PA, (2)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA, (4)Developmental & Behavioral Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:
Early detection of autism spectrum disorder (ASD) is a priority to facilitate early intervention. The Childhood Autism Team CHeck (CATCH) Team is a cross-system specialized screening and assessment process in Chester County, PA for children in Early Intervention. Children are referred to the CATCH team if they screened positive on the Modified Checklist for Autism in Toddlers (M-CHAT) at 18-36 months and/or if the early intervention providers and parents express concerns about ASD. Referral to the CATCH team (including developmental pediatrics, school psychologist, and behavioral health professionals) results in a diagnostic evaluation.
Objectives:
The objectives of the current study were to (1) evaluate the utility of the M-CHAT to detect ASD in a community-based high-risk sample, (2) compare M-CHAT scores to final diagnosis, and (3) examine the preliminary psychometric properties of the M-CHAT among children referred to the CATCH team for ASD assessment.
Methods:
Archival data (2005-2014) from CATCH included 246 toddlers who screened positive on the M-CHAT and 12 who screened negative but were referred by a provider due to concerns of ASD. From this sample, 197 were diagnosed with ASD (79.8% male; mean age=2.20 years, *SD*=.51, range: 1.10-2.90) and 61 were diagnosed with other developmental delays (69.6% male; mean age=2.32 years, *SD*=.45, range: 1.11-2.90). Diagnoses in the non-ASD group included language delay (n=40), global developmental delay (n=19), and other (n=2, separation anxiety, behavior concern). Evaluation tools included ADOS(2), CARS(2), medical history and parent interview to inform a DSM(-IV/5) checklist. Data were extracted from clinical evaluation records. M-CHAT scores included total and/or critical score (note: some children had only one score available); final diagnosis was a clinical best estimate considering all available data.
Results:
Total M-CHAT score was not significantly different between ASD (mean=7.13, *SD*=3.8) and non-ASD (mean=6.50, *SD*=3.7), $t(225)=-1.50$, $p=.294$. However, critical score was significantly higher for the ASD group (mean=3.30, *SD*=1.6) compared to the non-ASD group (mean=2.32 *SD*=1.4, $t(108)=-2.89$, $p=.005$. The M-CHAT was positive (based on either total or critical score) for 190 (96.4%) of the ASD cases, indicating high sensitivity among those children referred for specialized ASD assessment by the CATCH team. Similar to other studies, the M-CHAT was not specific to ASD, but in the current sample, positive predictive value (PPV) was .77 indicating that positive screens were much more likely to be diagnosed with ASD than in low-risk samples (e.g., .06 PPV for the single-stage M-CHAT in Chlebowski et al., 2013).
Conclusions:
ASD screening tools may perform differently in high-risk samples compared to low-risk samples. Examining utility of ASD screeners in community-based settings facilitates the implementation of research tools in real-world settings. In a high-risk sample of toddlers, the M-CHAT critical score may be more useful in differentiating ASD from non-ASD delays, rather than the total score. PPV indicated high confidence that positive screens are likely to have ASD. Findings from the current study corroborate that standardized screening paired with referrals for diagnostic evaluation can facilitate identification of young children with ASD.

163 **165.163** Non-Binary Gender Is Associated with Higher Autistic Traits

T. Loucas[1], *P. Beaman*[1], ***L. E. Martin***[2] *and M. Younas*[2], *(1)Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)University of Reading, Reading, United Kingdom*

Background: There is a relationship between autistic traits and gender: it is well-established that they are higher in males than females and ASD is more commonly diagnosed in males. There is now also evidence that individuals attending gender identity clinics for gender re-assignment score highly on measures of autistic traits, but those self-identifying as of non-binary gender need not be seeking gender re-assignment, and the incidence of autistic traits in this broader case of non-binary gender experience is unknown
Objectives:
This study aims to provide initial data on autistic traits in those who experience their gender as non-binary.
Methods:
An online survey advertised to students at University of Reading and through social media sites used by individuals identifying as of non-binary gender. The Autism Spectrum Quotient (AQ) was used as a measure of autistic traits. Respondents were asked to report their gender and male, female or other. The other category offer a list of further options based on self-identification: agender,androgyne, bigender, genderfluid, genderqueer, neutrois, pangender, trans*female, trans*male, trans*person, two-spirit, and a “prefer not to say” option. Respondents were also asked basic demographic questions, including age, country, first language, educational level and fluency in English and whether they had a diagnosis of ASD.
Results:
329 adults started the survey, 39 individuals completed gender questions but not AQ. 273 completed the AQ and the gender questions, of these 40 respondents reported receiving an ASD diagnosis and 12 chose not to disclose this information. 221 respondents reporting no ASD diagnosis were included in the analysis: N=33 male, N=119 female, N=69 non-binary. Mean (SD) AQ scores for male = 22.9 (8.2), female = 17.4 (8.2), non-binary = 28.3 (7.4). Multinomial logistic regression was used to look at the association between gender and AQ score, controlling for reported ASD diagnosis and demographic variables. The model was significant ($\chi^2(12) = 91.0$, $p < .001$). Only AQ

score was a significant predictor of reported gender. An increase in AQ score was associated with an increased likelihood of reporting male gender relative to female (odds ratio = 1.08; 95% confidence interval = 1.037-1.136). An increase in AQ score was also associated with an increased likelihood of respondents their gender as non-binary relative to female (odds ratio = 1.183; 95% confidence interval = 1.124-1.245).
Conclusions: We replicate the association between higher ASD traits in males relative to females and extend the association to adults who self-identify as non-binary. This is consistent with reports from clinical samples and suggests, further, the broader experience of non-binary gender is also associated with higher reported autistic traits. The causes of this association are unclear, but suggestions have included: prenatal androgen exposure and interpreting a problem relating to others, and associated feelings difference, as a problem of being in the wrong gender. Differences in interoception reported in ASD may also be implicated in gender dysphoria. It is also possible that the association we find is because everyday social interactions experienced by individuals identifying with non-binary gender results in increased reporting of autistic traits.

164 **165.164** Online Remote Verbal IQ Testing for Large-Scale Autism Studies and the Issue of Cheating

A. Zoltowski[1], *C. C. Clements*[2,3], *L. Bateman*[1], *N. Stein*[4] *and R. T. Schultz*[5,6], *(1)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Psychology, University of Pennsylvania, Philadelphia, PA, (4)Department of Statistics, Wharton School, University of Pennsylvania, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Departments of Pediatrics and Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: Online phenotyping for autism research has many attractive properties, especially when the desired sample size is large and in-person testing burdensome. For skill testing, computer adaptive testing (CAT) based on item response theory can be an accurate and efficient alternative. We have developed an online Verbal IQ test (CARAT-V; Clements et al., 2015) that can be conveniently taken remotely with the precision of a standard IQ test. However, remote testing without study personnel supervision leaves open the possibility that test-takers will ignore directions to do the test without seeking help from others or the internet.
Objectives: To develop and test an algorithm for detecting item responses suggestive of cheating during an online test.
Methods: We collected CARAT-V data from N=3383 anonymous participants, excluding N=151 who sped through the test at such a rate that effort was compromised (response faster than median on >80% of items; accuracy <30%). The current analyses focused on developing a detection algorithm using self-reported cheating as the gold standard. In the final analyses to be reported at IMFAR, we will refine the algorithm using the more reliable gold standard of participants recruited for a randomized trial who receive instructions that cheating is permitted or not. For a subset of participants aged 8-10 years, the data noted whether the participant left the "full-screen test mode" during a question (allowing internet searching), and this feature will be extended to adult samples in upcoming trials.
Results: Incidence of self-reported cheating differed significantly between adults, adolescents, and children ($\chi^2 = 49.74$, $p < .001$). Self-reported cheating among adults was so infrequent (Table 1) that further investigation is needed. For adolescents, an algorithm was created which i) divided items into quintiles by response time and ii) flagged participants whose accuracy on items in the slowest quintile was more than 1 standard error greater than for all other quintiles combined, correctly capturing 45% of adolescents who self-reported cheating. For children, leaving full-screen mode during the item was a compelling indication of potential cheating, since item accuracy was 7.3% higher when the participant did so instead of staying on the testing screen ($t = 3.85$, $p < .001$). Self-reported cheating was not associated with total score for any age group, as baseline abilities and the frequency of this behavior may vary.
Conclusions: Our analyses suggest that tracking when participants exit full screen mode and our response time algorithm are promising tools to help researchers determine if and when an online result is suspect for child and adolescent participants. A limitation of our approach, however, is that our current gold standard leads to an all or none detection strategy, and we would ideally eliminate select data as suspect from each test taker. We will address these problems and further refine our algorithms in upcoming trials. The ability to screen for cheating is a prerequisite to confidently deploying a test remotely to study samples, thus allowing wider adoption and larger scale data collection, which is especially attractive for genetic studies.

Table 1. Sample size and incidence of self-reported cheating by age group

	Children (8-13 years)	Adolescents (14-17 years)	Adults (18+ years)
N	1720	558	954
Incidence	6.0%	4.0%	0.4%

165 **165.165** Outcome Summaries of Latency-Based Functional Analyses Conducted in Inpatient Units of Hospital Settings

P. Juarez[1], *J. Lambert*[2], *J. E. Staubitz*[3], *J. Torelli*[1], *M. Mahoney Hopton*[1], *K. M. Simcoe*[1] *and N. Houchins-Juarez*[2], *(1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN, (3)Pediatrics, Vanderbilt University Medical Center, Nashville, TN*

Background:
Latency-based functional analysis (LBFA) may be a viable alternative to traditional Functional Analysis (FA) when evoking and reinforcing high rates of problem behavior is not advisable, or when client time, appropriate and safe assessment space, and/or staffing are limited. In practice, this means that the conditions under which families reported seeing problem behavior were systematically presented for the participant and that data collectors measured how soon problem behaviors occurred when different conditions and potential reinforcers were applied. Comparing this latency to problem behavior across different conditions is a valid way to confirm the functional reinforcer(s) for a behavior. Embedded within a randomized controlled trial (RCT) to assess for potential cost-benefit of behavior analytic services within typical inpatient hospital settings, we conducted LBFAs of the problem behavior of 18 children diagnosed with autism in inpatient hospital settings.
Objectives:
The purpose of this study was to provide preliminary descriptive evidence of the capability of LBFAs to identify functional reinforcers for problem behavior when conducted within typical inpatient hospital settings.
Methods:
Eighteen children (17 male, 1 female) with autism ages 6-16 years (mean 10.3) participated in this study. Twelve had been admitted to a university-based child and adolescent psychiatric hospital and six had been admitted to a medical floor of a university-based children's hospital. Additionally, all had a reported history of chronic problem behavior. We conducted all assessments in inpatient units of the above-mentioned hospital settings; either in subjects' rooms or in multi-purpose rooms found within these units.
Definitions for each subject's target response(s) were operationalized based on caregiver report during pre-FA interviews (definitions available upon request). A preference assessment was conducted with the patient, followed by initiation of a latency-based FA. Assessment procedures were based on those described by Thomasson-Sassi et al. (2011).
Therapists also tracked latency to occurrence of non-targeted problem behavior during FA trials when subjects engaged in multiple topographies of problem behavior. Because latencies for these topographies were obtained within the context of highly controlled antecedent manipulations, we conceptualized data obtained from this secondary analysis as a structured descriptive assessment (SDA; Freeman, Anderson, & Scotti, 2000), with latency to unconsequated problem behavior as its dependent variable.
Results:
Eighteen latency-based FAs were conducted in inpatient hospital settings to identify the function of problem behavior of 15 subjects diagnosed with ASD. Eight latency-

based FAs successfully identified the functions of eight response topographies. Conversely, eight latency-based FAs produced inconclusive results. Four latency-based SDAs were simultaneously conducted on the secondary responses of four subjects. Differentiated response patterns emerged for two patients.
Conclusions:
Despite some limitations, which were specific and unique to the study settings and therapeutic contexts, results indicate it is possible to identify behavior function through latency-based FAs conducted by novel therapists in inpatient hospital units after evoking and reinforcing a minimal number of target responses. Furthermore, we outlined a latency-based strategy for collecting descriptive data on non-targeted problem behavior during FA sessions.

166 **165.166** Parents' Concerns As They Relate to Their Child's Development and Later Diagnosis of Autism Spectrum Disorder

M. Richards[1] *and D. L. Robins*[2]*, (1)Drexel University, Philadelphia, PA, (2)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: An important part of developmental and autism specific surveillance in toddlers is when physicians elicit parents' concerns. The relationship of parents' concerns and an autism spectrum disorder (ASD) diagnosis has been examined based on age at and nature of first concern, however the difference in parents' concerns between children diagnosed with ASD compared to children who are diagnosed with other developmental delays has not been studied.
Objectives: Data from children evaluated as part of a toddler screening study were used to examine: 1) differences between the ASD and non-ASD groups in the categories of developmental concerns reported by parents prior to diagnostic evaluation, 2) congruence of parent concerns with their child's later diagnosis, 3) the extent to which parent concern(s) predicted the therapies their child received and type of specialists consulted, and 4) the association between the number of parental concern categories and clinical measures.
Methods: Toddlers who screened positive for autism spectrum disorder (ASD) risk on the Modified Checklist for Autism in Toddlers (-Revised) during well-child check-ups received a diagnostic evaluation. Prior to evaluation, but after screening, parents completed a history questionnaire about their child (n=532). Parents' reports of concerns about their child's health and development, therapy received, and specialists consulted were coded into discrete categories.
Results: Most parents (>90%) had concerns about their child's development. The most common concern in both the ASD and non-ASD diagnostic groups was speech/communication (78.6%). Parents of children with ASD were significantly more likely than parents of non-ASD children to endorse speech/communication (p<.001), restricted and repetitive behaviors (p=.001), and social concerns (p=.001). Parents of non-ASD children were significantly more likely than parents of children with ASD to have behavior (p=.005) and medical concerns (p=.004). The mean number of concern categories was not significantly different between the ASD parents (mean=2.2, SD=0.072) and the non-ASD parents (mean=2.02, SD=0.075), (t(530)=1.82, p=.62), indicating that the ASD parents did not have more concerns overall. Parents of children diagnosed with ASD were more likely to have an autism specific concern (speech, restricted and repetitive behaviors including sensory, behavior, or autism label) compared to parents of a child diagnosed with non-ASD (p<.001). Parent concerns predicted type of therapy received and specialists consulted. Parents who reported a speech concern were 1.6 times more likely to receive speech therapy compared to a child whose parents did not have a speech concern. The number of concern categories endorsed was positively associated with several ASD scores: M-CHAT score (r=.279, p<.001; n=176), M-CHAT-R score (r=.146, p=.006; n=356), CARS (r=.130, p=.003). Number of concern categories was not associated with the ADOS severity score (r=.023, p=.705).
Conclusions: The developmental concerns expressed by parents of undiagnosed toddlers were highly consistent with the diagnosis the child later received. Based on their areas of concerns, parents made contact with the appropriate professionals and their children received some therapy prior to diagnosis. Finally, parents who reported concerns across different developmental areas endorsed more symptoms during screening. Results emphasize the importance of incorporating parent concerns during the referral and diagnostic processes.

167 **165.167** Performance of M-CHAT and ITC Screeners in High-Risk Siblings

E. Schriver[1]*, D. L. Robins*[2]*, L. A. Croen*[3]*, M. D. Fallin*[4]*, I. Hertz-Picciotto*[5]*, R. Landa*[6]*, S. E. Levy*[7]*, S. Ozonoff*[8]*, J. Pandey*[7] *and C. J. Newschaffer*[1]*, (1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (5)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (6)The Kennedy Krieger Institute, Baltimore, MD, (7)Children's Hospital of Philadelphia, Philadelphia, PA, (8)UC Davis MIND Institute, Sacramento, CA*

Background: It is important to examine screening efficacy in determining children at risk for ASD. Most studies have included low-risk toddlers; younger siblings of children diagnosed with ASD are a high-risk population of particular interest, given their elevated ASD prevalence of 1 in 5.4 (Ozonoff et al, 2011) compared to the general population's prevalence of 1 in 68 (CDC, 2014).
Objectives: To examine two screening tools, the Infant-Toddler Checklist (ITC) and the Modified Checklist for Autism in Toddlers (M-CHAT), and to examine concordance between screening outcomes and ASD classification at 36 months.
Methods: Parents of high risk siblings (n=166; 74 females, 92 males) completed the ITC at 6, 12, and/or 18 months and/or the M-CHAT at 18 and/or 24 months. Sensitivity, specificity, and positive likelihood ratios were examined for each screener at each timepoint, combinations of timepoints for each screener, and both screeners at 18 months using clinical best estimate for classification.
Results: As children got older, the percent who screened positive on each tool decreased (37.9%, 25.5%, and 22.4% for ITC, 25.8% and 21.6% for M-CHAT). The ITC sensitivity ranges from 48.5-69.2% and specificity from 65.2-91.1% for ages 6-18 months. The M-CHAT sensitivity ranges from 53.8-62.1% and specificity from 81.9-92.7% for ages 18-24 months. Sensitivity for ITC at any age from 6-18 months is 83.9% and for M-CHAT from 18-24 months is 82.1%. At 18 months, screening positive on one or both screens yielded 71.4% sensitivity and 76.4% specificity, while screening positive on *both* at 18 months resulted in 50.0% sensitivity and 95.8% specificity. The ITC at 18 months, the M-CHAT at 24 months, and screening positive on both the M-CHAT and ITC at 18 months had the highest positive likelihood ratios of 7.8, 8.5, and 11.9 respectively, meaning that children with ASD are that much more likely to screen positive than those without ASD. The combination of screening positive on the M-CHAT at 18 or 24 months and the combination of screening positive on both the M-CHAT and ITC at 18 months had both sensitivity and specificity >70%.
Conclusions: High-risk siblings are at elevated risk of ASD and also elevated risk of other developmental disorders. Therefore, it is important to examine the performance of tools that have been validated in low-risk samples to determine their utility in identifying siblings at the greatest risk of ASD. Performance on both tools was better in older children than in younger children, consistent with the literature (e.g., Pandey et al., 2008). Both the ITC and the M-CHAT demonstrated moderate sensitivity and moderate to good specificity at various ages; there was not a single tool at a specific age that was notably best at detecting ASD. However, the combination of M-CHAT at either age and the combination of either tool at 18 months met thresholds for adequate sensitivity and specificity; this suggests that in the complex developmental trajectories of siblings at risk for ASD, it will be important to consider multiple tools or multiple ages to best assess risk for ASD.

168 **165.168** Presentation of ASD in Females: Examining DSM Criteria in a Clinical Sample

R. Jamison*, Center for Child Health and Development, University of Kansas Medical Center, Kansas City, KS*

Background: Prevalence rates of a 4:1 male to female ratio for autism spectrum disorder results in narrow population of study, with females representing less than 15% of participants in ASD samples across published intervention studies (Watkins et al., 2014). Early research suggested girls with ASD were more likely to have an intellectual disability as compared to boys with ASD. However, recent research suggests that girls and women with ASD may present with different symptoms as compared to boys and men, resulting in a delayed diagnosis for females or missing high functioning females (Head et al, 2014; Lai et al, 2011; Begeer et al, 2013; Niller, 2014).To date, much research focuses on sex differences between males and females with ASD on specific measures with less emphasis on characteristics that may influence diagnosis or changes in symptoms over time.
Objectives: The primary objective is to examine the presentation of ASD in a clinic sample of females referred for an autism evaluation. The secondary objective is to consider potential sex differences in diagnostic criteria and to identify variables for further study and hypotheses regarding manifestation of ASD in females.
Methods: We examined characteristics of ASD through a retrospective analysis of a clinical sample, including potential sex differences in diagnostic variables (age at diagnosis, co-existing symptoms) as well as a descriptive analysis of DSM criteria in females with ASD as compared to males. Our sample includes data from our clinical database (n > 1300) of patients referred for an autism evaluation in our interdisciplinary clinics across the past three years. Analysis includes descriptive statistics, frequencies, and t-tests to compare groups. DSM criteria is examined in a subsample of males and females.
Results: Females are less likely to receive a diagnosis of ASD as compared to males with a significantly lower rate of diagnosis. Although we did not find a significant difference for age of ASD diagnosis in our clinical sample, females that did not receive a diagnosis were significantly older compared to males that did not receive a diagnosis. Similar to Hiller et al. (2014), females in our sample demonstrated low rates of restricted interests. We also found fewer symptoms related to deficits in nonverbal communication, play, or stereotyped behaviors.
Conclusions: Females in our clinical sample demonstrate some differences in diagnostic criteria as compared to males, with some symptoms predicting an increased likelihood of diagnosis in females. These data provide direction for further study and potential hypotheses related to how ASD manifests differently in females.

169 **165.169** Profiles of Classroom Active Engagement Among Early Elementary Students with Autism Spectrum Disorder

N. J. Sparapani[1]*, V. P. Reinhardt*[2,3]*, L. Morgan*[2]*, C. Schatschneider*[2] *and A. M. Wetherby*[2]*, (1)Arizona State University, Tempe, AZ, (2)Florida State University Autism Institute, Tallahassee, FL, (3)JFK Partners Universiy of Colorado School of Medicine, Aurora, CO*

Background: Classroom active engagement is essential for effective educational programming for students with Autism Spectrum Disorder (ASD; National Research Council, 2001). However, students with ASD display constellations of challenges that may interfere with active engagement in classroom activities. A recent study using the

Classroom Measure of Active Engagement (CMAE), a multidimensional observational tool, reported a pattern of overall limited yet variable active engagement in elementary students with ASD in classroom activities (Sparapani, Morgan, Reinhardt, Schatschneider, & Wetherby, 2015). Identifying profiles of active engagement may guide effective programming for students with ASD by describing patterns of skills and behaviors that influence classroom performance and learning.
Objectives: The purpose of this study was to identify profiles of active engagement within a sample of elementary students with ASD using the CMAE.
Methods: Participants included 196 students with ASD and their educators (n = 126) in kindergarten through second grade (M = 6.36 years, SD = 1.01) who were video-recorded in their classrooms at the beginning of the school year. This study used latent profile analysis (LPA), a statistical method for identifying subgroups of individuals that share characteristics (Jung & Wickrama, 2008) to define distinct profiles of active engagement in elementary students with ASD. LPA was used to compare models with two, three, four, and five profiles based on seven components of active engagement from the CMAE including productivity, eye gaze, responding, directed communication, generative language, flexible behavior, and flexible attention.
Results: Preliminary findings indicated that four latent profiles best described classroom active engagement within the sample (Entropy =.94), showing excellent overall model fit, the best fit in comparison to competing models, and strong overall membership probability (0.93 to 0.98). Below is a brief description of each profile.
Profile 1, the largest profile (64%), was characterized by limited eye gaze (1.5 SD below the mean) and less frequent directed communication and generative language (0.5 SD below) than each of the other profiles. Students in **Profile 2** (12%) exhibited greater classroom active engagement than each of the other profiles, showing the highest frequency of eye gaze (5.5 SD above), directed communication (2 SD above), and generative language (1.5 SD above). **Profile 3** (18%) was also characterized by a higher frequency of eye gaze (5 SD above); however each of the other active engagement components appeared to be within the typical range compared to the total sample. **Profile 4**, the smallest profile (6%), was characterized by a higher frequency of generative language (1.5 SD above) than directed communication and responding (approaching 1 SD above), and students' frequency of eye gaze was below the sample mean (approaching 0.5 SD).
Conclusions: These findings indicate that components of active engagement form constellations of skills and behaviors that vary among elementary students with ASD. This study provides preliminary data about a promising method to identify profiles of active engagement, which may help guide educational programming and support educational outcomes in elementary students with ASD.

170 **165.170** Prospective Clinical Evaluation of a Machine-Learning Based Test for Rapid Detection and Triage of Autism

M. Duda[1], *J. Daniels*[2] *and D. Wall*[1], *(1)Department of Pediatrics, Stanford University, Stanford, CA, (2)Stanford University, Palo Alto, CA*

Background:
The incidence of autism has increased dramatically over recent years, making this mental disorder one of the greatest public health challenges of our time. The standard practice of diagnosis is based on behavioral characteristics, as the genome has largely proved intractable for diagnostic purposes. Yet, the most commonly used behavioral instruments take up to 3 hours to administer by a trained specialist, contributing to the substantial delays in diagnosis experienced by many children, who may go undiagnosed and untreated until ages beyond when behavioral therapy would have had more fundamental positive impacts. In an effort to mitigate these challenges, we have developed a machine-learning based system for accurate classification of autism that requires minutes to administer and that can be delivered via mobile technologies.
Objectives:
Enabled in part by the 2013 Slivka/Ritvo Innovation Award, we completed a clinical study at the Developmental Medicine Center at Boston Children's Hospital. The objective was to test the sensitivity and specificity of a new, electronically administered, 7-question autism spectrum disorder (ASD) screen to triage those at highest risk for ASD in a prospective clinical population of children at risk for autism and/or other developmental delays between the ages of 16 months and 17 years.
Methods:
We created a mobilized web-accessible system for obtaining answers to a parent-directed classifier and a short home video of the child for machine classification. We administered the test in advance of the clinical team's evaluation at the DMC (via iPhone, iPad, or personal computer). All subjects were recruited from a convenience sample of children referred for consultation of developmental/behavioral concerns. Once the predetermined sample size of 200 was exceeded, we abstracted data from the medical record to compare the best estimate clinical diagnosis against the outcome from the ML classification tool.
Results:
A total of 222 families participated in the study, with a 69% rate of assent. The children assessed ranged in age from 1 to 16 years of age, with a median age of 5.8 years. 76.1% were male, and most participants had an intelligence/developmental quotient score >85; 69 of participants (31%) received a clinical diagnosis of ASD. The sensitivity of the MCDC in detecting ASD was 89.9% [95% CI = 82.7-97]; the specificity was 79.7% [95% CI = 73.4-86.1].
Conclusions:
Approaches that enable families to bridge the gap between initial warning signs of developmental delay and clinical diagnosis of autism quickly and effectively are critically needed for the field. The results from this clinical trial in a representative tertiary care facility suggest that the ML approach has clinical reliability across a range of ages and likelihood of high adoption by families. The study demonstrates the feasibility of accurate pre-clinical assessments and highlights the possibility of using mobile techniques for clinical triage, to reduce bottlenecks and reach a larger percentage of the population in need.

171 **165.171** Psychometric Properties of the Dimensional, Diagnostic and Dimensional Interview Version for Adults (3DIVA)

K. Clarke[1], *M. McKenner*[2], *C. Allison*[3], *S. J. Wheelwright*[4], *S. Baron-Cohen*[3], *D. H. H. Skuse*[5] *and* ***W. Mandy***[6], *(1)Clinical Psychology, UCL, London, United Kingdom, (2)UCL, London, United Kingdom, (3)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (4)Department of Psychiatry, Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (5)Institute of Child Health, London, United Kingdom of Great Britain and Northern Ireland, (6)University College London, London, United Kingdom*

Background:
A substantial number of cases of autism spectrum conditions (ASC) (also know as 'autism spectrum disorder', or 'autism') go undetected in childhood, and people do not grow out of ASC as they become adults. Therefore a number of individuals with autism progress to adulthood without receiving a diagnosis, in particular those with subtle symptoms, occurring in the context of a normal-range IQ and fluent language. As a result there is increasing acknowledgement amongst policy makers and healthcare professionals of the need to develop valid means of assessing autism in adults, to inform targeted support and intervention.
A cornerstone of autism assessment is informant report, preferably from someone (such as a parent) who knew the assesse in childhood. A valid assessment requires that such informant reports be integrated with self-report and direct observational information. Currently there are no validated, standardised informant-report measures designed for assessing adult autism, as defined in DSM-5.
The Dimensional, Diagnostic and Dimensional Interview version for adults (3DIVA) comprises 71 questions, 24 of which are historical, covering the assessee's life between birth and adolescence. Its algorithm outputs scores for the two DSM-5 domains of 'social communication and social interaction' and 'restricted repetitive patterns of behaviour, interests or activities'. The 3DIVA is intended for use with adults who have an IQ above 70, reflecting the increased risk of such individuals being missed in childhood and so presenting to adult services for assessment. It is a highly structured interview, and so is suitable for administration both in person and by telephone, as in the assessment of adults, parental report can sometimes be attained over the telephone but not face-to-face.
Objectives: To measure the reliability and validity of the 3DIVA, including its ability to discriminate autism from mental disorders such as anxiety, psychosis and depression.
Methods: Participants (N=86) were: (1) adults with autism (n=39); (2) adults without autism who were receiving clinical intervention for a mental health problem ('clinical comparison group') (n=20); and (3) adults without autism from the general population ('non-clinical comparison group') (n=27). The groups did not differ on IQ, number of years in education, or age. In the majority (85%) of cases the informant completing the 3DIVA was the index participant's mother.
Results: The 3DIVA showed excellent reliability (Cronbach's alpha's >.93, inter-rater reliabilities >.98). Criterion validity was shown by the strong sensitivity and specificity of the instrument, which correctly identified 93% of those with autism (sensitivity), and 92% of the non-autism participants (specificity). Evidence for construct validity was shown by the lack of association between 3DIVA DSM-5 algorithm scores and age or IQ.
Conclusions: The 3DIVA shows promise as a quick (< 40 minutes), reliable and valid informant-report tool for assessing whether an adult has high-functioning autism. It was able to discriminate between autism and conditions such as anxiety, psychosis and depression, and so could be used in general adult mental health settings, as well as in specialist neurodevelopmental services.

172 **165.172** Reaching the Other Half: Moving Towards Symptom-Based Referral Methods in a Community-Derived Sample

C. K. Kraper[1], ***C. Rothwell***[2,3], *J. L. Martucci*[4], *A. Verbalis*[5], *S. Seese*[2], *J. Safer-Lichtenstein*[6], *A. B. Ratto*[7], *L. Kenworthy*[8] *and L. G. Anthony*[5], *(1)Children's National Health System, Rockville, MD, (2)Center for Autism Spectrum Disorders, Children's National Medical Center, Rockville, MD, (3)Catholic University of America, Washington, DC, (4)Neuropsychology, Children's National Health System, Rockville, MD, (5)Children's National Medical Center, Rockville, MD, (6)Georgetown University, Washington, DC, (7)Children's National Medical Center, Silver Spring, MD, (8)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Current research practices typically limit participation to individuals with prior clinical diagnoses. This limits findings and generalizability to families who have sought care (Durkin et al., 2015). In answer to this, approaches that do not require a previous diagnosis, as supported by Patient-Centered Outcomes Research (PCOR) health disparities methodology, reach families who have not previously accessed mental health services by sampling underserved communities referred for symptoms rather than diagnosis. This approach has the potential to broaden the generalizability of research findings and directly impact underserved children and families.
Objectives: This study seeks to understand differences between previously-diagnosed and newly-identified children with ASD and/or ADHD in a community-based sample.
Methods: Participants include 160 families referred by high-poverty schools in the Washington, DC metropolitan area for participation in a comparative effectiveness trial of

two school-based executive function interventions. At this time, 94 cases have been assessed and entered. In this sample, race/ethnicity was reflective of the community (48.7% Latino, 22.7% White, 15.9% Black, 6.8% other). 27.4% of families were primarily Spanish speaking. 45.8% of the ASD group (n=24) and 52.9% of the ADHD group were newly-identified through gold standard assessment. FSIQ did not differ between children with and without prior diagnosis. At baseline, demographic information, behavioral/emotional functioning (CBCL), and family strain were measured.
Results: Independent samples t-tests and chi-square analyses revealed no significant differences in family income and parent education level between children with and without prior diagnosis. For children with prior diagnosis, families reported significantly more strain (t(75)=-2.12, p=.037) and greater child externalizing problems (t(70)=-2.67, p=.009). There was a higher proportion of English-speaking families within children with prior diagnosis (χ^2(1, N=75)=8.361, p<.006). Multiple linear regression analyses showed language spoken in the home significantly predicted prior diagnosis after accounting for behavioral/emotional problems (CBCL Total Problems; R^2=.189, F(1, 67)=8.037, p=.006). Importantly, within the ASD group, neither ASD symptom severity (ADOS-2), Total Problems, family strain, nor language spoken in the home differed between those who were previously identified vs. newly diagnosed.
Conclusions: Children previously identified as ADHD were more likely to have parents who spoke English, reported feeling more parenting strain, and noticed more problems in their children. In contrast, children previously diagnosed with ASD did not differ from those newly-identified on these variables or in autism-specific symptomatology. Thus, there is value in symptom-based referral methodology for ASD studies, as these methods allow for accurate identification of individuals who meet full diagnostic criteria. Additionally, roughly half of both final diagnostic groups were newly identified. Although ADHD can be reliably diagnosed by community providers, ASD diagnosis continues to be difficult to access, and children are being missed despite showing the same degree of symptomatology. Further research should explore factors related to difficulty accessing specialized ASD diagnosis. In sum, studies allowing for symptom-based referrals, rather than diagnosis-based referrals, have the potential to impact communities and better capture the full ASD population.

173 **165.173** School Refusal Behavior in Students with Autism Spectrum Disorder, an Exploratory Study of Prevalence and Associated Factors

***E. K. Munkhaugen**, Oslo University Hospital, Oslo, Norway*

Background:
School refusal behavior refers to unauthorized absenteeism in compulsory school; it is defined as child-motivated refusal to attend school and/or difficulties remaining in class for an entire day. Failure to attend school might negatively influence the student's academic, psychological and social development and increase the risk for dropping out of school.
Despite increased research in factors associated with quality of school experiences less attention has been directed to absenteeism and school refusal behavior in students with ASD. The research is to our knowledge sparse, however, parent reports from the Danish and the Swedish Autism Association found a prevalence of school refusal behaviour in students with ASD, 39% and 36.5%, respectively. A better knowledge of the prevalence and the individual risk factors can be important for professionals to prevent and treat school refusal behavior in students with ASD.
Objectives:
This study aimed to explore the prevalence of school refusal behaviour in students with ASD aged 9-16 years without intellectual disability (IQ > 70), compared to typically developing (TD) students in Norwegian schools. Further, to explore if individual characteristics can predict risk for displaying school refusal behavior in the students with ASD.
Methods:
A cross-sectional study involving 80 students with a confirmed diagnosis of ASD without intellectual disability, and a comparison group of 138 children and adolescents at the same age, sex and classes with no disabilities are included in the study. The participants were recruited from schools, child and adolescent psychiatric and pediatric outpatient clinics or via the Norwegian Autism Association website. The diagnoses were assessed and confirmed by specialists in child and adolescent psychiatric and paediatric outpatient hospital clinics. Teachers and parents registered absences and school refusal behavior over 20 days. Parents answered a socioeconomic questionnaire. To assess data characterizing the students with ASD, parents answered the Behavior Rating Inventory of Executive Function (BRIEF), the Child Behavior Checklist (CBCL) and the Social Responsiveness Scale (SRS) questionnaires. Information regarding demographic factors was collected via the Norwegian educational information system.
Results:
School refusal behaviour was revealed in 42% of students with ASD compared to 7.1% of TD students based on teachers collected data. Parent registrations showed a prevalence of school refusal behaviour in 52.6% of the students with ASD and 2.3% of the TD students. Strong associations were found between school refusal behaviour and illness in other family members and in those attending junior high school. Preliminary results in total scores from the BRIEF, the SRS and the CBCL showed significant differences between students with ASD and students with ASD and school refusal behavior.
Conclusions:
Findings showed that school refusal behaviour in students with ASD is most prevalent and associated with illness in other family members, and attending eight to tenth grade. Further, students with ASD and school refusal behaviour tend to have more problems assessed with the BRIEF, the SRS and the CBCL.

174 **165.174** Screening Practices and Factors Influencing Autism Spectrum Disorder Screening By Community Paediatricians

***A. Ip**[1], A. Dupuis[2], E. Anagnostou[3,4,5], A. Loh[6], A. Munoz[7], T. Dodds[7] and S. Smile[7,8], (1)Developmental Paediatrics, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)University of Toronto, Toronto, ON, Canada, (4)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Paediatrics, University of Toronto, Toronto, ON, Canada, (6)Surrey Place Centre, Toronto, ON, Canada, (7)Bloorview Research Institute, Toronto, ON, Canada, (8)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background:
Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder which affects 1% of the population. Research has shown that ASD can be diagnosed in children 2 to 3 years of age with some accuracy. High risk children have been identified prior to 24 months of age. In Canada the median age of diagnosis of ASD is 39 to 55 months, which suggests a later time to diagnosis than seen in other developed countries. Screening is important for early identification of children with ASD, potentially leading to earlier intervention. Research has identified some potential barriers to early identification of ASD; however, information regarding general paediatric practices around ASD screening in Canada is lacking.
Objectives:
The aim of the study is to examine the use of ASD screening tools and developmental screening tools by community pediatricians. We also evaluated facilitators and barriers to ASD screening by community paediatricians.
Methods:
A cross sectional survey of community paediatricians was conducted. A questionnaire was developed based on previous survey data. The survey was reviewed by developmental paediatricians and community pediatricians to ensure clarity and ease of use. The questionnaire was distributed to five hundred and sixty paediatricians.
Results:
There was a 48% response rate (267/560)of whom 132 were eligible. Ninety three percent of responders use a developmental screening tool, namely the Nipissing Developmental Screen, Rourke Baby Record and Ages and Stages Questionnaire. Seventy one percent (71%) of responders use an ASD screening tool when there are concerns for ASD noted. Only 15% of community paediatricians routinely use ASD screening tools, and 14% never use an ASD screening tool. The most commonly used ASD screening tool is the Modified Checklist for Autism in Toddlers, Checklist for Autism In Toddlers and Social Communication Questionnaire. Community paediatricians refer a child who they suspect of having ASD to a clinical specialist primarily to confirm the diagnosis and to facilitate access to resources and interventions. Community paediatricians are keen to incorporate a formal ASD screening tool in their practice but identified the need for clearer guidelines for ASD screening.
Conclusions:
The majority of community paediatricians use an ASD screening tool when there are specific concerns for ASD. The time to screen for ASD and the ability to navigate ASD resources and interventions are important barriers for community paediatricians. Clarity around guidelines as to when and how to screen for ASD is needed.

175 **165.175** Screening for Autism Spectrum Disorder: A Measurement Agreement Study

***D. Kamara**[1], K. M. Walton[1] and A. N. Witwer[2], (1)The Ohio State University, Columbus, OH, (2)The Ohio State University, Gahanna, OH*

Background: Children with Autism Spectrum Disorder (ASD) often show developmental delays prior to their diagnosis of ASD (Zwaigenbaum et al., 2009). Autism screening for children with developmental delay (DD) can help identify children that are in need of autism-specific services. The Modified Checklist for Autism, Revised with Follow-up (M-CHAT-R/F; Robins et al., 2014) is a widely accepted screening tool for autism in toddlers. In addition to the M-CHAT-R/F, there are also measures in place for identifying problems with behavior problems and social-emotional competence (i.e. social-emotional functioning). Some of these social-emotional screening tools, including the Ages and Stages: Social-Emotional (ASQ:SE; Squires, Bricker, & Twombly, 2002), the Brief Infant Toddler Social Emotional Assessment (BITSEA; Briggs-Gowan & Carter, 2006), and the Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2000), are also used as screening tools for autism and are commonly given in early intervention settings. The ASQ:SE contains items that are meant to flag for autism, but has not yet been validated as an autism-specific screening tool. Despite this, in a survey of birth to three providers, the ASQ:SE was reported to be the most commonly administered screening tool for ASD (Shaw & Hatton, 2009). The BITSEA also includes items that are meant to flag for ASD. An Autism score derived from these items has demonstrated promise in identifying children with ASD (Kruizinga et al., 2014). The CBCL has a pervasive

developmental problems (PDP) scale that can be used to identify children with ASD. A recent meta-analysis suggests that the CBCL PDP scale may be sensitive, but not specific at identifying ASD (Hampton & Strand, 2015). Given the varied use of these tools in community settings, it is worthwhile to know how much these measures agree with each other in terms of identifying children with DD who are at-risk of ASD.
Objectives: To examine the agreement between the M-CHAT-R/F, the BITSEA Autism score, the CBCL PDP scale, and the ASQ:SE in classifying children as at-risk for ASD in a sample of toddlers with developmental delay.
Methods: Participants were young children between the ages of 18-36 months, and their parents, enrolled in early intervention services in Ohio. Parents completed a packet of questionnaires on their child's social-emotional functioning. All measures were completed within one month of each other. Agreement was calculated based on dichotomous risk outcomes (at-risk or not at-risk) with Cohen's Kappa, which corrects for chance agreement. Each social-emotional screening tool was compared individually to the M-CHAT-R/F.
Results: Preliminary results suggest moderate to substantial agreement between measures. So far, the CBCL PDP scale appears to have the strongest agreement with the M-CHAT-R/F. Data collection is ongoing. We expect to have results from approximately 50 children and parents by IMFAR.
Conclusions: Within a population of toddlers with developmental delays, the social-emotional screening tools, particularly the CBCL PDP scale had good agreement with the M-CHAT-R/F. These results suggest that these tools may be appropriate for screening children with developmental delays for ASD. Further research needs to examine the sensitivity and specificity of these measures.

176 **165.176** Screening for Autism Spectrum Disorders in Childcare Centers Using the M-CHAT-R/F

B. Ferreira[1], *D. Thao*[1], *A. Spiller*[1], *N. Tomy*[1], *T. Scott*[2] *and D. L. Robins*[1], *(1)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Delaware Valley Association for the Education of Young Children, Philadelphia, PA*

Background: Early detection of autism spectrum disorders (ASD) leads to early intervention which in turn leads to better outcomes. The average age of diagnosis is 4 years old. Pediatricians are mandated to complete ASD specific screenings at 18 and 24 months, but with the multitude of tasks that must be performed during a short check-up, ASD specific screenings may not be offered. Early Childhood Education Providers (ECEPs) may be an ideal source to increase access to screening.
Objectives:

1. Assess the feasibility and acceptability of autism screening in childcare centers.
2. Evaluate the concordance of M-CHAT-R/F results from parents and teachers.

Methods: A mixed method approach included focus groups to serve as a needs assessment and to provide data on acceptability of screening completed by ECEPs. Ten childcare sites were recruited; ECEPs participated in a 90-minute training about symptoms of ASD, a demonstration of the web-based system, and an interactive discussion. A questionnaire was administered to ECEPs to understand perceptions about developmental screening and monitoring. To support screening, researchers attended parent events, and were available at pick-up and drop-off times to help parents complete the M-CHAT-R/F. ECEPs also completed M-CHAT-R/F. Children that screened positive were invited for a diagnostic evaluation; parents received oral and written feedback about their child.
Results:
Nine primary caregivers (mean age=42, *SD*=12.8, range:20-56 years) of young children participated in the first focus group. Participants were predominately African American (88.89%), and 44% of participants held some type of college degree. Approximately one-third of participants voiced familiarity with autism. Caregivers felt benefits of childcare included socialization and learning foundational skills. Caregiver concerns about ECEPs included lack of training and familiarity, and lack of a relationship with their children.
Seven ECEPs participated in the second focus group; they were enthusiastic about the role of childcare providers in developmental monitoring and screening, and endorsed use of continuous monitoring for children. 57.1% of participants held an advanced degree. Methods for monitoring varied across centers. 28% reported using the Ages and Stages Questionnaire, 14% reported a mixture of methods, but 57% consider their monitoring techniques to be "informal".
Over half of ECEPs (*n*=57) who completed pre-study questionnaires indicated they have experience monitoring development of children in the classroom, yet over 25% have never talked with parents about concerns related to their child's development.
Although more than 700 children within our qualifying age range were enrolled across all 10 childcare centers, uptake has been low. Of the 95 children who have completed screening, 10 children screened positive: 6 based on parent report, 3 based on teacher report, and 1 child screened positive on both reports. Concordance for screening results was 76%.
Conclusions: ECEPs are accepting of screening for ASD, but low participation rates among parents indicate barriers to screening in childcare settings. Concordance among ECEPs and parents is high when children are screened by multiple informants. With strong teacher support, screening is more widely accepted by parents, and the use of M-CHAT-R/F can contribute to the early detection of autism.

177 **165.177** The Faison-Quality of Life Questionnaire: A Brief Survey of Outcome and Indicators for Individuals with Autism Spectrum Disorder

E. T. Newcomb[1] *and* ***R. K. Gilbert***[1,2], *(1)The Faison School for Autism, Richmond, VA, (2)University of Richmond, University of Richmond, VA*

Background: Given the high and increasing incidence rate of autism spectrum disorder (ASD), it is key for providers, families, and other stakeholders to possess a tool to measure an individual with ASD's quality of life (QOL). Further, given the challenges and resources required to deliver and receive treatment, it is also important that such tool expeditiously capture important information within pivotal areas. Although a number of QOL survey tools and structured interview rating forms currently exist, none satisfied the general criteria set by the investigators, which included: a) Identifying something brief (to administer), b) Capturing information from a variety of important domains, and c) Utilizing something carefully tailored to individuals with ASD and related developmental disorders.
Objectives: To assess student health and wellness outcomes
Methods: A 25-item questionnaire was created to quickly assess a student's QOL. The QOL questionnaire contained five subsections: 1) Physical, 2) Emotional, 3) Behavioral, 4) Social, and 5) Independence. Questions were each arranged on a 4-point Likert scale ranging from strong agreement to strong disagreement, resulting in a range of scores from 25 (high QOL) to 100 (low QOL).The questionnaire was administered to 62 parents of children who attended a school for students with autism.
Results: Preliminary results indicated a number of commonalities between gender and age bracket subsets, as well as from subsection to subsection across participants. Further, results are discussed in terms of individual-family level implications as well as additional steps required to validate the questionnaire and assess reliability.
Conclusions: This study is a strong preliminary step in exhibiting trends across physical, emotional, behavioral, social, and level of independence, quality of life-related outcomes amongst individuals with Autism Spectrum Disorder. It also offers a viable metric tool that can be utilized in an educational setting to inform service providers.

178 **165.178** The Importance of Visually Guided Screening: An Examination of an Autism Screener with and without Video Depiction of ASD Symptomology

K. Boswell[1], *K. Sheperd*[2] *and R. Landa*[3], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Center for Autism and Related Disorders, Baltimore, MD, (3)The Kennedy Krieger Institute, Baltimore, MD*

Background: Autism Spectrum Disorder may be detected during the second year of life (e.g., Landa et al., 2007; 2014), though average age of diagnosis is after 4 years (ADDM, 2014). At present, screeners for ASD do not possess adequate sensitivity and specificity to detect subtle behavioral manifestations. Emerging research shows that video referencing improves accuracy of caregiver behavioral ratings and may improve caregiver-professional communication about behavior (Sices et al., 2008, Marrus et al., 2015).
Objectives: Preliminary findings demonstrated that a new web-based video-guided screener for detecting the risk of ASD in young children (the Early Video-Guided Autism Screener [EVAS]) has moderate predictive power when compared to the current diagnostic gold standard, the Autism Diagnostic Observation Schedule (ADOS) and clinical judgment. The present study aims to examine the added value of video examples on the EVAS.
Methods: Parents of 103 children aged 12-60 months (mean age 24.57 months (11.51 SD), 52.4% male, 70.9% Caucasian) completed a paper-based question-only version (no videos) of the EVAS screener prior to their child receiving an evaluation that included the ADOS. Receiver operating curves (ROC) analysis utilized a diagnostic classification of ASD vs No-ASD generated through the ADOS and clinical judgment to determine this sample's cut-off for classification and to examine the effect of removing video guidance (using just the EVAS questions) on performance of the screener by comparing results with existing data previously obtained using the full video-guided tool (EVAS).
Results: Using the questions-only version of the screener, findings paralleled some aspects of previously obtained results involving use of the questions with video-guidance. In both versions of the tool, ROC analyses suggested a cut-off of 53 as the optimal selection for classification (Figure 1). A comparison of the area under the curve (AUC) in the two datasets was not significantly different (p=0.23), though the video-guided sample performed slightly better. Further examination of the criterion validity of the questions-only version relative to the video-guided version suggested lower sensitivity (27.6%, 95% CI: 19.0-36.2 vs. 89.4%, 95% CI: 83.6-95.2) and a moderate, but slightly lower, positive predictive value (80.0%, 95% CI: 72.3-87.7 vs. 92.2%, 95% CI: 87.2-97.2). The specificity performed slightly higher at 97.3% (95% CI: 94.2-100.4 vs. 88.4%; 95% CI: 82.4-94.4). See Table 1.
Conclusions: These findings suggest that while the EVAS questions help informants to differentiate between having ASD-related concerns from typical development, video guidance appears to enhance parents' ability to differentiate ASD-specific concerns from other general developmental concerns. This supports the budding literature highlighting the need for well validated, video-guided, screeners to enhance parent report of behavior and facilitate early detection of ASD.

Figure 1. Comparison of Classification Performance Utilizing a Cut-off of 53.

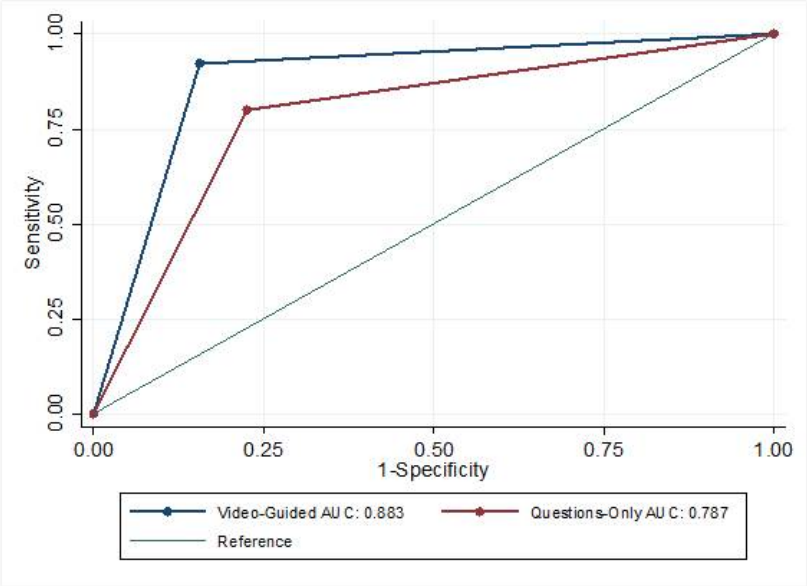

Table 1. Sensitivity and Specificity Analyses by Sample

	% (95% CI)			
	Sensitivity	Specificity	PPV	NPV
Video-Guided	89.4 (83.6-95.2)	88.4 (82.4-94.4)	92.2 (87.2-97.2)	84.4 (77.6-91.3)
Questions-only	27.6 (19.0-36.2)	97.3 (94.2-100.4)	80.0 (72.3-87.7)	77.4 (69.3-85.5)

179 **165.179** The Social Communication Questionnaire (SCQ) As a Population-Based Screening Instrument for Autism Spectrum Disorder

C. C. Bradley[1], *A. D. Boan*[1], *A. Wahlquist*[2], *A. P. Cohen*[3], *J. M. Charles*[1] *and L. A. Carpenter*[4], *(1)Pediatrics, Medical University of South Carolina, Charleston, SC, (2)MUSC, Charleston, SC, (3)University of Illinois at Urbana-Champaign, Champaign, IL, (4)Medical University of South Carolina, Charleston, SC*

Background: The Social Communication Questionnaire – Lifetime Version (SCQ) is a 40-item parent-report screening measure for Autism Spectrum Disorder (ASD) that is widely used in research and clinical practice. Although the SCQ has been studied in both clinical and general population samples, the sample sizes have been small and there is limited data available regarding how demographic factors, such as gender, race, or SES might impact parent responses on the SCQ.
Objectives: (1) To determine the sensitivity and specificity of the SCQ as a screening instrument for ASD in a large, epidemiological sample of youth; (2) To examine the impact of various demographic factors on SCQ scores.
Methods: Data for the present study comes from the South Carolina Children's Educational Surveillance Study (SUCCESS) which was designed to assess the prevalence of ASD in children born in 2004 (aged 8-10 at the time of participation) through direct screening and evaluation. SCQs were distributed to all children in the study area through schools. Participants with SCQ≥15, as well as 20% of those with scores between 8 and 14 were invited to participate in a diagnostic assessment.
Results: Of the 8246 SCQ's that were distributed, 4085 (50%) were returned. Total SCQ scores were available for 3720 participants (91%) with a mean of 6.09 (SD = 5.44, Range: 0 to 36) and a median score of 5. Over 7% of the sample had an SCQ score of 15 or higher, with another 23% of SCQs falling between 8 and 14. Participants were 49% male, 52% white non-Hispanic, 23% black non-Hispanic, 4% Hispanic, and 51% from Title 1 public schools (schools with a high percentage of low income students). Unsurprisingly, males had significantly higher mean SCQ scores than females (6.87 vs. 5.34, p<.0001). Title 1 school status was also associated with higher SCQ scores (7.35 vs. 5.03, p<.0001). Race and ethnicity data was available for less than half of the sample due to differences in data availability in each school district. Non-Hispanic black families reported higher SCQ scores than non-Hispanic white families (7.65 vs. 5.08, p<.0001) and families who identified as Hispanic also had significantly higher SCQ scores (9.41 vs. 6.24, p<.0001). For youth with SCQ≥15 who completed an in-person assessment, the unadjusted OR = 1.32, indicating a 32% increase in risk for meeting DSM-5 criteria for ASD for each additional SCQ point above 15. The mean SCQ score amongst youth diagnosed with DSM-5 ASD was 23.54.
Conclusions: This study includes one of the largest samples ever to utilize the SCQ for population-based screening for ASD. Significant mean score differences based on demographic factors including race, ethnicity, and Title 1 school status suggest that this instrument may perform differently in different populations. Further sensitivity and specificity analyses are ongoing, as well as analyses focusing on the extent to which completing the Spanish-language SCQ impacts the association between ethnicity and the SCQ as many Hispanic families elected to complete the Spanish-langauge SCQ.

180 **165.180** The Utility of the ADOS-Toddler Module in an Independent Sample

L. B. Swineford[1,2] *and A. Thurm*[2], *(1)Department of Speech and Hearing Sciences, Washington State University, Spokane, WA, (2)Pediatrics and Developmental Neuroscience Branch, National Institute of Mental Health, Bethesda, MD*

Background: Calibrated severity scores (CSS, also termed comparison scores) have been developed for the Autism Diagnostic Observation Schedule, second edition (ADOS-2) and the two diagnostic domains, Social Affect (SA) and Restricted and Repetitive Behaviors (RRB) (Gotham et al., 2009; Hus, Gotham, & Lord, 2014). These scores are published for modules 1-3 of the ADOS-2 in an attempt to provide a metric of ASD severity not conflated by cognitive and language abilities. With the recent addition of the toddler module (ADOS-T), there is now a version of the ADOS available for children between 12 and 30 months of age. Sensitivity, specificity, and predictive value of raw ADOS-T scores support the use of the ADOS-T in early diagnostic practices (Luyster et al., 2009; Guthrie et al., 2013). However, the ADOS-T is still new compared to the other ADOS modules. The recent publication of the ADOS-T CSS scores (Esler et al. 2015) highlights the need for further examination of its utility using independent samples.
Objectives: The aim of the present study was to examine the utility of the CSS scores for the ADOS-T in an independent sample of children with ASD, non-ASD delays, or typical development.
Methods: Participants included 116 toddlers (mean age: 21.44 months; range 12.60-29.76 months) who screened for autism research in the Pediatrics and Developmental Neuroscience Branch of the National Institute of Mental Health. Of the 116 toddlers, 21 met criteria for ASD, 37 for non-ASD delays, and 58 for typical development. All participants received the ADOS-T and the Mullen Scales of Early Learning as part of the screening evaluation.
Results: In the ASD group, 95% (n=20) of participants had raw scores that fell into the moderate-to-severe concern range. In contrast, 81% (n=30) of children in the non-ASD group and 93% (n=54) of children in the typical development group fell in the little-to-concern range. The mean CSS score in the ASD group was 8.38 (SD 1.62, range 4-10) which was significantly higher than the CSS scores for the non-ASD delay (mean = 2.59, SD = 1.65, range 1-7) and typical development (mean = 1.86, SD = .963, range 1-5) groups. The same pattern was observed for the SA and RRB CSS scores (see Figures 1 and 2). In the ASD group, neither the raw nor CSS scores (SA, RRB, total score) correlated with nonverbal or verbal DQ.
Conclusions: This study provides further support for the use of the clinical concern ranges on the ADOS-T. Further, results suggest that the CSS and even raw scores of the ADOS-T are an independent metric of ASD symptom severity, as the raw scores were also not related to measures of language and cognitive ability. These findings contrast the original ADOS-T CSS publication which suggested the raw and CSS scores (less so for the latter) were influenced by language abilities. Overall, while longitudinal studies need to compare CSS scores from the ADOS-T to other modules, the ADOS-T CSS scores will be useful in allowing for comparison of ASD symptoms over time.

Figure 1. ADOS-T Social Affect Calibrated Severity Scores by Diagnostic Groups.

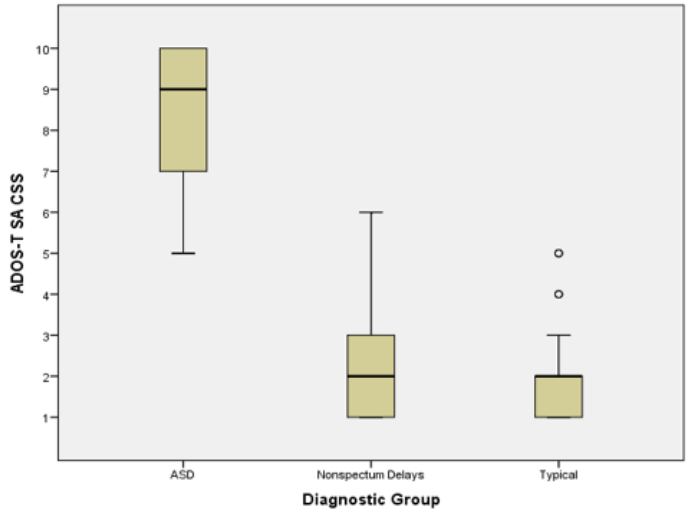

Figure 2. ADOS-T Restricted and Repetitive Behavior Calibrated Severity Scores by Diagnostic Groups.

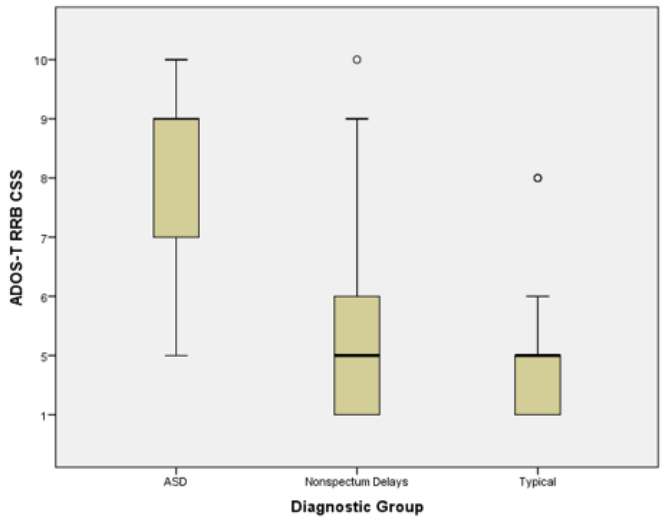
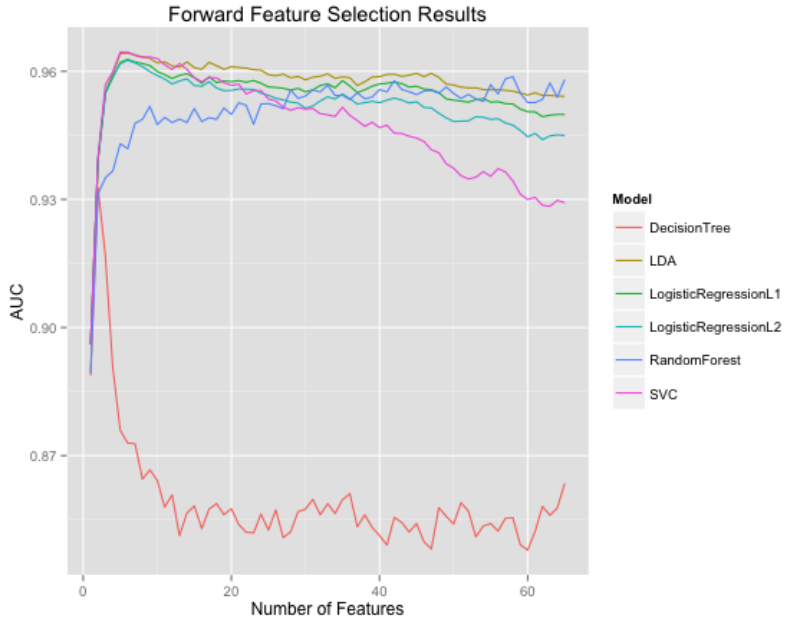


181 **165.181** Use of Machine Learning for Behavioral Distinction of Autism and ADHD

M. Duda[1], *R. Ma*[2], *N. Haber*[2] *and D. Wall*[3], *(1)Department of Pediatrics, Stanford University, Stanford, CA, (2)Pediatrics, Stanford University, Stanford, CA, (3)Stanford University, Palo Alto, CA*

Background: Though autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) continue to rise in prevalence, together affecting >10% of today's pediatric population, the methods of diagnosis remain subjective, cumbersome and time intensive. Furthermore, considerable behavioral overlaps between the two disorders, including impulsivity and trouble with social interactions, can complicate differential diagnosis for clinicians. Methods to quickly and accurately assess risk for these, and other, developmental disorders are necessary to streamline the process of diagnosis and grant families access to much-needed therapies sooner.
Objectives: In light of our prior success in applying machine learning to gold-standard diagnostic tools distinguish ASD from non-ASD, we elected to apply similar methodology for the distinction of ASD and ADHD. The aims of this study were to determine 1) whether machine learning can be used to discern between autism and ADHD with high accuracy and 2) whether this distinction can be made using a small number of commonly measured behaviors.
Methods: Using forward feature selection, as well as undersampling and ten-fold cross validation, we trained and tested six machine learning models on complete 65-item Social Responsiveness Scale (SRS) score sheets from 2925 individuals with either ASD (n = 2775) or ADHD (n = 150).
Results: We found that only 6 of the 65 behaviors measured by the SRS were sufficient to distinguish ASD from ADHD with high accuracy (AUC = 0.964).
Conclusions: These results support our previously stated hypotheses, providing a method for accurate classification of ASD and ADHD with a minimal set of behavioral

features. This classification system shows promise for use as an electronically administered, caregiver-directed resource for preliminary risk evaluation and/or pre-clinical screening and triage that could help to speed the diagnosis of these disorders.



182 **165.182** Utility of the SCQ and RBS-R to Confirm Caseness of Adolescents and Adults in ASD Research

L. A. Pepa[1] *and V. Hus Bal*[2]*, (1)Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY, (2)Department of Psychiatry, University of California San Francisco, San Francisco, CA*

Background: Better tools are needed to screen and diagnose adolescents and adults with ASD (IACC, 2013). The Autism Diagnostic Interview-Revised (ADI-R; Rutter et al., 2003a) may be useful to establish “caseness,” but is cost and time-intensive and often infeasible for parents of older individuals. Less is known about the predictive validity of the Social Communication Questionnaire Lifetime and Current forms (SCQ-L, SCQ-C; Rutter et al., 2003b) in older samples. The original SCQ validation (Berument et al., 1999) included individuals from 4-40 years, but did not report findings separately by age group. In a study of adults with ID, both SCQs yielded good sensitivity (79-89%), but low specificity (SCQ-C=66%; SCQ-L=48%; Sappok et al., 2015). No study has examined the predictive validity of the SCQ in adolescent or adult ASD samples spanning the full range of cognitive ability.
Objectives: This study aims to 1) compare sensitivity and specificity of the SCQ-L, SCQ-C and ADI-R and 2) assess whether combination with the Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 2000) improves predictive validity.
Methods: Participants were drawn from a study focused on improving ASD diagnostic methods for adolescents and adults. Analyses included 49 individuals with diagnoses of ASD and 12 participants with non-ASD diagnoses (Age M=19.70, SD=3.43; NVIQ M=79.54, SD=32.57) who had an ADI-R, SCQ-C, SCQ-L and RBS-R completed at a single time point. ADI-R sensitivity and specificity were based on standard algorithm cutoffs and CPEA criteria (Lainhart et al., 2006); for both SCQ forms, cutoff=15. ROC analyses were used to derive cutoffs for SCQ-C, SCQ-L and RBS-R.
Results: For both groups, the SCQ showed moderate to strong correlations with the ADI-R and IQ. The ADI-R yielded the best balance of sensitivity (78-88%) and specificity (67-71%) using standard or CPEA criteria, respectively. The SCQ-L offered comparable sensitivity (76%), but poorer specificity (58%); a cutoff of 16 yielded somewhat better specificity (67%) without significant reduction in sensitivity (73%). In contrast, the SCQ-C yielded superior specificity (92%), but poor sensitivity (47%); lowering the cutoff to 13 reduced specificity (67%) and only improved sensitivity to 61%. Combining SCQ-L and SCQ-C did not improve predictive validity over either form alone. Although not intended as a screener, an RBS-R cut-off of 10 yielded results comparable to the SCQ-L (sensitivity=71%, specificity=58%). Requiring participants to meet on the SCQ-L or RBS-R provided the same balance of sensitivity (78%) and specificity (67%) as the standard ADI-R. Combining the SCQ-C and/or the RBS-R resulted in good specificity (>83%), but sensitivity remained below 62%.
Conclusions: Combining the SCQ-L and RBS-R yielded comparable sensitivity and specificity to the ADI-R, suggesting this combination may be a useful alternative to confirm “caseness” in adolescent and adult ASD research. In a sample of more diverse cognitive abilities, SCQ-C provided higher specificity, but lower sensitivity than studies of individuals with ID (Sappok et al., 2015); similar results with the SCQ-L were achieved, albeit with a lower cutoff. Future directions include replicating results in an independent sample and exploring whether combination with the ADOS further improves predictive validity.

183 **165.183** Validation of the Early Video-Guided Autism Screener (EVAS) in a Clinically-Referred Sample

J. Neely[1], *K. Sheperd*[2], *K. Boswell*[3] *and R. Landa*[1], *(1)The Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Center for Autism and Related Disorders, Baltimore, MD, (3)Kennedy Krieger Institute, Baltimore, MD*

Background: Although ASD can be detected as early as 14 months (e.g. Landa et al., 2007, 2013), the average age of diagnosis is four years (ADDM, 2014). The American Academy of Pediatrics (AAP) recommends universal screening at ages 18 and 24 months, though screening and referral practices are inconsistent due to cost, lack of staff training, and time needed for additional in-person evaluation. Access to a low-cost and efficient screening tool to promote further assessment can lead to earlier access to diagnosis and treatment. Existing ASD screeners have modest sensitivity and positive predictive value, and lack video examples of specific behaviors. Evidence is emerging that video guided examples of child development behaviors activate parents' evaluative thinking about their child's developmental well-being and may improve accuracy of parent report (Lievens et al., 2008; Marrus et al., 2015; Sices et al., 2008).

Objectives: The present study sought to validate the Early Video-guided Autism Screener (EVAS) in a clinically-referred sample. The EVAS is an innovative, accessible, and cost-efficient screener for children ages 18-48 months. The EVAS previously demonstrated strong sensitivity (SN), specificity (SP), positive predictive value (PPV), and negative predictive value (NPV) in a relatively small, but developmentally diverse sample (n=109). The present study will evaluate the previously derived EVAS cut-off score, and compare it with the gold-standard diagnostic tool the Autism Diagnostic Observation Schedule Second Edition (ADOS-2), and clinical best estimate (CBE) diagnoses.

Methods: A cut-off score of 53 was derived in a sample of 109 children with typical development (n=29), suspected developmental delays (n=15), suspected ASD (n=35), and diagnosed ASD (n=30) (Landa et al., 2014). The present sample included 170 children aged 18-48 months (mean age 2.75 years (.75 SD), 84.1% male, 55.9% Caucasian) clinically referred for ASD evaluation due to suspicion of ASD. All were administered the EVAS online as part of their clinic intake. The ADOS was completed during diagnostic evaluations. Examiners rated CBE following the evaluation. Most (74.1%) received an ASD diagnosis; 7.7% had CBE of 'at-risk for ASD'.
Results: The EVAS cut-off score for ASD risk of 53 was replicated resulting in moderate SN (84.1%; 95% CI: 78.6-89.6), SP (71.4%; 95% CI: 64.6-78.2), and strong PPV (98.6%; 95% CI: 96.8-100.4). Additionally, EVAS scores correlated moderately with the ADOS Toddler Module algorithm score ($n = 54$, $r = .29$, $p < .05$) and the Module 1 algorithm score ($n = 84$, $r = .24$, $p < .05$). The correlation between the EVAS and ADOS Module 2 algorithm score failed to reach significance ($n = 32$, $r = .32$, $p = .07$).
Conclusions: Results provide strong evidence of the criterion validity of the EVAS suggesting it could be a valid, efficient, and cost-effective tool for ASD screening in specialty clinic settings. This tool provides a convenient and efficient method for caregivers to consider the degree to which their child exhibits signs of ASD and may improve caregivers' communication about their child's behavior during diagnostic evaluations.

184 **165.184** Validation of the Electronic 2-Stage Modified Checklist for Autism in Toddlers, Revised, with Follow-up (M-CHAT-R/F)

D. L. Robins[1], *K. A. Haynes*[2], *R. K. Ramsey*[3] *and L. B. Adamson*[3], *(1)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Georgia State University, Atlanta, GA, (3)Psychology, Georgia State University, Atlanta, GA*

Background: Currently, the AAP recommends universal screening for ASD in toddlers. However, barriers have limited implementation, and median age of diagnosis remains after the fourth birthday (CDC, 2014). Simplifying procedures for administration and scoring of tools like the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F) may improve uptake and sustained use in community settings.
Objectives: Although the M-CHAT-R/F has been validated (Robins et al., 2014), it is important to examine validity when changing mode of delivery. The goal of the current study was to validate the adaptation of M-CHAT-R/F for electronic delivery.
Methods: Four private practices and one urban public clinic offered electronic M-CHAT-R/F screening during routine toddler check-ups at 18 and 24 months. Parents completed screening on a Chromebook in the office or using an at-home portal prior to the check-up. All participants completed consent, demographics, and the initial 20 M-CHAT-R items; when children scored in the moderate risk range (total score 3-7), the appropriate Follow-Up items were launched automatically during the same screening session. Follow-Up items were adapted for self-report by converting open-ended questions to forced-choice. Children who screened positive (initial score ≥8, or Follow-Up score ≥2) or had physician concerns about ASD were invited for diagnostic evaluation. The screening sample was divided based on clinic type, considering the effect of maternal education, which is a marker for socioeconomic status, on screening (e.g., Khowaja et al., 2015). The sample included 1719 children from private practices (49.2% male; 75.2% Caucasian, 10.6% African-American; 83.3% mothers had a college degree) and 687 children from an urban public clinic (53.4% male; 2.8% Caucasian, 88.1% African-American; 13.0% mothers had a college degree). Results were compared to published M-CHAT-R/F data (Robins et al., 2014), in which parents completed the initial M-CHAT-R on paper, and the Follow-Up via phone interview with research staff.
Results: The screen positive rate on the initial electronic M-CHAT-R was commensurate between the paper sample (7.2%) and the private practices (7.6%), but notably higher in the public clinic (14.7%). Drop-out at the Follow-Up stage was eradicated (1 family (<1%) failed to complete needed Follow-Up, compared to 18% dropout in the paper sample). A higher percentage of children who completed electronic Follow-Up continued to screen positive (4.3% private, 7.9% public) compared to phone Follow-Up (2.2%). The ASD detection rate was comparable across electronic and paper samples (7.9 and 6.7 per 1,000, respectively). Nineteen children were diagnosed with ASD (13 private; 6 public); 18 were detected by M-CHAT-R/F, one from physician concern.
Conclusions: Initial screen positive results are consistent across mode of delivery (electronic vs. paper), when participants using the electronic assessment in private practices were compared to published norms for the paper version. The elevated screen positive rate after Follow-Up using the electronic version may indicate differences in parent responses during an interview vs. on computer, interviewer deviation from the Follow-Up script, or differences in findings due to eradication of the dropout at the Follow-Up phase of screening. Commensurate ASD detection rate supports the validity of the electronic M-CHAT-R/F.

185 **165.185** Validity of Standardized Diagnostic Instruments for Autism Spectrum Disorders in Toddlers Recruited from a Population-Based Cohort: The Influence of Parental Concern

A. Havdahl[1,2,3], *S. L. Bishop*[4], *P. Suren*[3], *A. S. Oyen*[2,3], *C. Lord*[1], *A. Pickles*[5], *S. von Tetzchner*[6], *S. Schjolberg*[7], *N. Gunnes*[3], *M. Hornig*[8], *M. Bresnahan*[8], *W. I. Lipkin*[8], *E. Susser*[9], *P. Magnus*[3], *N. Stenberg*[10], *T. Reichborn-Kjennerud*[3,6] *and C. Stoltenberg*[3,11], *(1)Weill Cornell Medical College, White Plains, NY, (2)Lovisenberg Diaconal Hospital, Oslo, Norway, (3)Norwegian Institute of Public Health, Oslo, Norway, (4)Department of Psychiatry, University of California San Francisco, San Francisco, CA, (5)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (6)University of Oslo, Oslo, Norway, (7)Mental Health, Norwegian Institute of Public Health, Oslo, Norway, (8)Columbia University, New York, NY, (9)Epidemiology and Psychiatry, Columbia University, New York, NY, (10)Oslo University Hospital, Oslo, Norway, (11)University of Bergen, Bergen, Norway*

Background:
Diagnostic instruments for autism spectrum disorders (ASD) have been validated primarily in samples of children referred to ASD specialty clinics for suspected ASD, and there is little information about the performance of these instruments when used with children identified in other ways.
Objectives:
This study examined the validity of widely used diagnostic instruments for ASD among toddlers recruited from a population-based study, and the influence of the identification route.
Methods:
Participants were 679 toddlers (age 35-47 months) who received multi-disciplinary diagnostic evaluations of ASD. We examined agreement of the Autism Diagnostic Interview-Revised (ADI-R) (Toddler algorithms) and the Autism Diagnostic Observation Schedule (ADOS) (ADOS-2 algorithms) with clinical best-estimate diagnoses. Receiver operating characteristic and logistic regression analyses were used to assess the diagnostic accuracy of the ADI-R and ADOS scores and cutoffs, and the additive value of combining the instruments. The analyses were carried out in the overall sample as well as for the comparison of toddlers identified based on 1) parental concern about ASD and 2) parent-reported behavioral signs of ASD (screening) *without* a specific concern about ASD.
Results:
The ADOS cutoffs showed consistently well-balanced sensitivity and specificity, whereas the ADI-R cutoffs missed a substantial proportion of toddlers ultimately diagnosed with ASD, especially among toddlers whose parents did not have a specific concern about ASD (43%). However, continuous scores from both the ADI-R and ADOS agreed well with clinical diagnoses (AUC=0.87-0.95), and contributed additively to their prediction ($p<0.001$). When applying modified ADI-R cutoffs, good balance between sensitivity and specificity was found also among toddlers without parental concern about ASD.
Conclusions:
The results underscore the utility of combining standardized instruments based on parental interview and clinician observation in diagnosing ASD. The established ADI-R cutoffs had low sensitivity among toddlers whose parents did not have a specific concern about ASD. Future studies should examine the utility of adjusting classification criteria on the ADI-R and other parental report-based ASD instruments to account for the influence of parental ASD concern.

186 **166.186** A Prospective Birth Cohort Study on Intra-Uterine Inflammation and Developmental Disabilities Including Autism Among Preterm- and Term- Born Children

M. Li[1], *M. D. Fallin*[2], *R. Landa*[3], *L. K. Hironaka*[4], *L. Sices*[4], *T. Stivers*[4], *D. M. Caruso*[5], *J. L. Kaczaniuk*[1], *C. Pearson*[4], *B. Zuckerman*[4] *and X. Wang*[6], *(1)Wendy Klag Center for Autism and Developmental Disabilities and Center on Early Life Origins of Disease, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (3)The Kennedy Krieger Institute, Baltimore, MD, (4)The Boston University Medical Center, Boston, MA, (5)Center on the Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD, (6)Center on Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD*

Background: Maternal intra-uterine inflammation (IUI) is suspected to play a role in the development of autism spectrum disorder (ASD); limited epidemiologic evidence has linked indirect markers of IUI such as maternal infection and inflammatory cytokines with risk of ASD. However, the effect of IUI may not be specific to ASD, but general to any neurodevelopmental disorder. Studies on IUI and neurodevelopmental disorders mostly included children born extremely preterm; the effect of IUI among children born with longer gestation is unknown.
Objectives: Using a prospective birth cohort enriched by preterm birth, we sought to examine the effect of IUI, measured by clinical chorioamnionitis (CA), in combination with a range of gestational ages, in the development of ASD. We also included analyses on other developmental disorders (DD) in parallel to examine if the effects are specific to ASD or common across various DDs.

Methods: This study included 2359 children (87 ASD cases) with clinical CA data, a subset of the Boston Birth Cohort who completed at least one postnatal study visit at Boston Medical Center between 1998 and 2014. Cases of ASD, intellectual disabilities (ID), attention-deficit hyperactive disorder (ADHD) and other DD were identified based on ICD9 codes of physician diagnoses in electronic medical records. Gestational age was defined by an algorithm based on prenatal ultrasound before 20 weeks of gestation and date of last menstrual period. CA was identified if the mother and the child had at least two of the clinical signs and symptoms of CA. Using Cox proportional hazard regression model controlling for potential confounders, risk of each type of DD was compared among children with different gestational age and CA status.
Results: Controlling for gestational age, CA was associated with increased risk of ASD (Hazard Ratio: 1.9 [95% confidence interval: 1.0-3.6]) and ID (Hazard Ratio: 3.7 [95% confidence interval 2.1-6.4]), but not ADHD or other DD in children. Jointly, early preterm birth (less than 34 weeks of gestation) without and with CA were both associated with greatly increased risks of ASD (Hazard Ratio: 4.6 and 6.3) and ID (Hazard Ratio: 3.2 and 8.5), and moderately increased risks of ADHD (Hazard Ratio: 2.1 and 2.7) and other DD (Hazard Ratio: 1.7 and 3.0). Term birth with CA and late preterm birth (34 to 36 weeks of gestation) without CA were also significantly associated with increased risk of ID (Hazard ratio: 4.7 and 1.9), while late preterm birth with CA was significantly associated with increased risk of other DD (Hazard ratio 2.1).
Conclusions: This is the first prospective study on the effect of IUI on DDs across gestational ages. We found IUI to have heterogeneous associations with DDs independent of preterm birth: it is a risk factor for ASD and ID, but not ADHD and other DD. We also found IUI to be a risk factor for ID among term children.

187 **166.187** ASD Screening in Primary Care: 10 Years of the M-CHAT Program in Spain

*P. Garcia Primo[1], M. V. Martín Cilleros[2], M. Magan Maganto[2], B. Esteban Manjón[2], M. Posada[1], M. T. Sáez Martín[2], G. Bueno Carrera[2] and **R. Canal-Bedia**[2], (1)Carlos III National Health Institute, Madrid, Spain, (2)University of Salamanca, Salamanca, Spain*

Background: Great efforts have been put into developing methods for early identification of toddlers with autism spectrum disorder (ASD) (Zwaigenbaum et al 2015). Despite the recommendation from the American Academy of Pediatrics (AAP) to do population-based screening (first-level) for ASD (Johnson & Myers, 2007) applied specifically at least in two occasions to all children before two years of age, it has hardly been approached from the public health system (PHS) perspective. Moreover there is a need to validate the usage of standardized instruments as a cost-efficient strategy in the PHS.
Objectives: The main goal of this study is to evaluate the "M-CHAT and M-CHAT-R ASD Early Screening Program" in community settings, after 10 years ongoing in two regions of the North of Spain (Salamanca and Zamora), in terms of feasibility, reliability and costs with the purpose of extending the program at regional and national levels.
Methods: Parents of 18 months and/or 24 months aged children residing in the selected geographical area during the study period (October 2005-October 2015), were asked to fill the Spanish version of the M-CHAT (updated version M-CHAT/R since April 2014) at the outpatient health services (compulsory vaccination programme and well-child check-up programme respectively) by a professional working at any of the total 54 pediatric teams (nurses and pediatricians) of the PHS that received training and agreed to participate (every team in the area). Scripted phone follow-ups were performed for positive (failed) screens and, differential diagnosis was done following a standardized protocol, using Vineland, Merril-P and ADOS-G. A well stablished coordination with the ASD early intervention centres and the Hospital diagnosis units in the area served as surveillance for tracking false negatives of both provinces.
Results: A total of 17332 M-CHAT were administered considering both M-CHAT and M-CHAT/R Spanish versions. Out of the total, 1600 (9.2%) resulted as ASD high-risk, of which 156 (9.7%) were confirmed as positive with the follow-up interview. Out of these, 54 children received a diagnosis of any ASD and 88 other disorders of childhood onset according to DSM-IV . The 74% of the participant professionals felt the program was totally feasible and 22% felt it was viable but with reservations (n = 54). Lastly, false negatives surveillance system identified 8 ASD cases out of the total of screened children. These results show a sensitivity of 0.87, a specificity of 0.99 and a PPV of 0.38 for ASD cases in this screening program (PPV of 0.94 when considering other DD).
Conclusions: This study has been able to show for the first time in Spain, the feasibility of a long lasting ASD screening program within the PHS. The current findings suggest that training on social and communicative development and dissemination of ASD early signs among pediatric teams, besides the use of a standardized tool, is essential for progress in the early detection of these disorders. The feasibility of this program should be considered for future strategies regarding ASD early detection by Health Policy makers at international level.

188 **166.188** An Expanded Examination of Neonatal Cytokines and Chemokines As Predictors of Autism Risk: The Early Markers for Autism (EMA) Study

L. S. Heuer[1], *K. L. Jones[2], C. K. Yoshida[3], R. Hansen[4], O. Zerbo[3], P. Ashwood[5], L. A. Croen[3], J. Van de Water[6] and R. Yolken[7], (1)UC Davis, Davis, CA, (2)University of California at Davis, Sacramento, CA, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)Pediatrics and the MIND Institute, University of California Davis, Davis, CA, (5)UC Davis, Sacramento, CA, (6)University of California at Davis MIND Institute, Davis, CA, (7)Johns Hopkins, Baltimore, MD*

Background: Previous work by our group identified cytokines and chemokines (CyChs) in neonatal bloodspots as potential biomarkers for evaluating autism risk. Obtaining

an early biomarker is crucial to preventative medicine in autism spectrum disorder (ASD), allowing for earlier identification and earlier intervention, potentially leading to improved outcomes.
Objectives: Utilizing a more sensitive and expansive immunoassay, we aimed to expand upon our earlier findings in the characterization of newborn bloodspot profiles of CyChs in a larger sample population of children with autism spectrum disorders (ASD), children with developmental delay (DD) without ASD, and children considered to be typically developing.
Methods: Data are from the Early Markers for Autism (EMA) study, a population-based nested case control study that utilizes archived maternal mid-pregnancy and neonatal blood specimens from mother-baby pairs. Birth records were linked to the California Department of Developmental Services (DDS) client databases to identify children with ASD (N=370) and children with DD without ASD (N=140). General population controls (GP, N=378) were randomly selected from the remaining birth records, matched to ASD cases on child month and year of birth and gender. Final diagnostic status, based on DSM-IV-TR criteria, was determined by expert clinical review of abstracted diagnostic and clinical information in DDS client records. Newborn bloodspots were eluted and assayed for 42 different CyChs using a multiplex platform. CyChs that had significant non-detects or that remained non-normally distributed after natural log transformation were broken into quartiles. Comparisons of CyChs concentrations between groups were carried out on a cytokine by cytokine basis using a multivariate logistic regression models, adjusting for birth type (cesarean vs vaginal), gestational days at birth, age at time of newborn bloodspot collection, infant gender, birth weight, and birth season, as well as parental (maternal and paternal) age, education, race, and plate number to control for plate to plate variation. Normally distributed CyChs were subjected to a linear regression model incorporating the aforementioned covariates. The corresponding residuals from each CyCh were used in partial least squares discriminant analysis (PLS-DA), a multivariate approach to derive combinations of CyChs that would discriminate between cases and controls.
Results: Children with ASD had significantly increased neonatal levels of IL-4, IL-6, IL-8, IFN-g, and Eotaxin-1 compared to GP controls. In addition, children with ASD had significantly decreased levels of Eotaxin-1 and increased IL-12p70 levels relative to DD children. We observed no significant differences in CyChs levels between the DD and GP groups. After adjusting for multiple comparisons by FDR, all associations were no longer statistically significant. Furthermore, the PLS-DA multivariate approach did not identify any combinations of CyChs that discriminated between study groups.
Conclusions: Elevated levels of some cytokines and chemokines measured in newborn bloodspots indicated a higher level of immune activation at birth in children who were subsequently diagnosed with ASD. However, this expanded sample set was not sufficient to determine if the CyCh analytes noted herein will constitute reliable biomarkers of ASD risk, and thus should be repeated in future studies.

189 **166.189** Androgens and Neurodevelopmental Disorders: Maternal Polycystic Ovarian Syndrome As a Risk Factor for ASD and ADHD

R. M. Gardner[1], *L. Widman*[2], *C. Dalman*[3] *and K. Kosidou*[4], *(1)Tomtebodavagen 18A, Karolinska Institutet, Stockholm, Sweden, (2)Centre for Epidemiology and Community Medicine, Stockholm County Council, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, Sweden, (4)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden*

Background:
ASD and ADHD are neurodevelopmental disorders that are becoming increasingly common in childhood. The two conditions are highly co-morbid and are skewed by sex, with rates being considerably higher for boys. It may be that the two conditions share genetic and environmental risk factors. It has been hypothesized that ASD and ADHD are partially caused by prenatal androgen exposure. Recent evidence supports the hypothesis that fetal steroid exposure is associated with the risk of ASD.
Objectives:
We hypothesized that maternal polycystic ovary syndrome (PCOS), a condition associated with excess androgens, would increase the risk of ASD in the offspring. We furthermore tested whether risk attributable to PCOS is specific for ASD or if the condition is also associated with risk of ADHD.
Methods:
Here we compare the results of two matched case-control studies, for ASD and ADHD, both nested within the total population of Sweden (children aged 4-17 who were born in Sweden from 1984 to 2007). PCOS, ASD, and ADHD were defined from ICD codes through linkage to healthcare registers. Controls were matched by birth month and year, sex, and region of birth. Conditional logistic regression was used to evaluate the association between maternal diagnosis with PCOS and offspring outcomes.
Results:
We identified 23 748 ASD cases and 208 796 matched controls, as well as 58 938 ADHD cases and 504 983 matched controls. 16% of ADHD cases also had a diagnosis of ASD. Maternal PCOS increased the odds of ASD in the offspring by 59%, after adjustment for confounders (OR 1.59, 95% CI 1.34 – 1.88). However, maternal PCOS increased the odds of ADHD in offspring by 41% (OR 1.41, 1.26 – 1.58). After exclusion of the 16% of ADHD cases who also had a diagnosis of ASD, the OR for maternal PCOS was somewhat attenuated, though the association remained (OR 1.32, 1.17 – 1.51).
Conclusions:
These studies indicate that maternal PCOS is a risk factor for both ASD and ADHD, independent of co-morbidity between the disorders. Further studies are necessary to determine the mechanisms by which the metabolic and hormonal disturbances of maternal PCOS may influence fetal neurodevelopment.

190 **166.190** Antidepressants during Pregnancy and Autism Risk: Update from the Stockholm Youth Cohort

D. Rai[1], *B. Lee*[2], *C. Dalman*[3], *C. J. Newschaffer*[4], *G. Lewis*[5] *and C. Magnusson*[3], *(1)University of Bristol, Bristol, United Kingdom, (2)Drexel University, Philadelphia, PA, (3)Karolinska Institutet, Stockholm, Sweden, (4)A.J. Drexel Autism Institute, Philadelphia, PA, (5)UCL, London, United Kingdom*

Background: It is still uncertain whether exposure to antidepressants during fetal life is causally linked with autism spectrum disorders (ASD). All seven epidemiologic studies published to date found crude associations between antidepressant use during pregnancy and offspring ASD. However, there was evidence of confounding, raising concern that the observed association reflected the risk of autism due to the underlying condition for which the medications were prescribed. One study reported that the risk of ASD with antidepressant use during pregnancy attenuated after adjustment for maternal depression, but an association with attention deficit hyperactivity disorder (ADHD) persisted. Further research is required to establish whether these associations are causal in order to inform clinical guidance.
Objectives: To assess the association between maternal antidepressant use during pregnancy with offspring ASD (with and without intellectual disability), ADHD and intellectual disability; ii) to carry out analyses to strengthen causal inference, including using paternal antidepressant use during the period of pregnancy as negative control exposures, and propensity score matching methods to account for confounding by indication.
Methods: Cohort study using the subset of the Stockholm Youth Cohort born between 1 January 1996 and 31 December 2010 (n=414,105). Data on parental depression and other potential confounders were prospectively recorded before the birth of the child. The sample was divided into two sub-cohorts: first the children with data on maternal report of medication use collected at the first antenatal interview (cohort born between 1996 and 2004, n=194,466); and second those with information on parental antidepressant use extracted from prescription records using the national patient register (cohort born after 2006, n=135,189). Children born in 2005 were excluded due to lower quality coverage of medication use in the registers. A total of 4,184 ASD cases were identified within these sub-cohorts using multisource case-ascertainment. Cluster robust logistic regression was used for primary analysis.
Results: In both sub-cohorts, a maternal history of depression was associated with an increased risk of offspring ASD but this association was not present for paternal depression. Maternal use of antidepressants was associated with higher risk for ASD in both cohorts after adjustment for birth-year, sex, parity, parental ages, family income, parental country of birth, education and history of depression (adjusted OR sub-cohort 1: 2.07 (1.62, 2.65); OR for subcohort 2: 2.13 (1.24, 3.67)). A higher risk of ADHD was also observed with maternal antidepressant use during pregnancy in both cohorts (subcohort1: OR=1.89 (1.54, 2.33); subcohort2: OR=2.13 (1.01, 4.50)) after adjustment for the above covariates, but there was no heightened risk observed for individuals with intellectual disability. The negative control and propensity score matched analyses are underway.
Conclusions: The associations mirror previous findings of associations between antidepressant use during pregnancy and offspring ASD, and were observable using both maternal self report and prescription records data. The results of our ongoing analyses will be informative in relation to the causal meaning of these findings.

191 **166.191** Are Mothers of Children with Autism More Likely to Have Studied a STEM Degree? a Study of 2,000 Women

S. Baron-Cohen, *P. Smith and C. Allison, Autism Research Centre, University of Cambridge, Cambridge, United Kingdom*

Background:
