Abstract Book

Oral Session -
100 - Welcome Address and INSAR President Address
8:30 AM - 9:00 AM - Hall B

8:30 Welcome Address and INSAR President Address

Keynote Address
101 - Environment and Autism: Understanding Causes from an Epidemiologic Perspective
9:00 AM - 10:00 AM - Hall B

Speaker: I. Hertz-Picciotto, Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA

By the end of the 20th century, very little rigorous research had been conducted to uncover the causes for autism, although a few studies provided compelling clues. This evidence pointed to several conclusions: first, that both genetic and environmental factors could play a role, and second, that the non-heritable causes might include both microbiologic (rubella, influenza) and pharmacologic (thalidomide, valproic acid) agents. Even as theories and myths have multiplied, the past decade has witnessed a new wave of increasingly rigorous epidemiologic research, some of it quite robust. This presentation will summarize: current knowledge on specific exposures in early prenatal or postnatal life that are potential or likely contributing factors to ASD; parallels with the literature on neurotoxins and cognitive impairment; and promising approaches for integrating environmental epidemiology with advances in molecular genetics. To meaningfully assess the current science, key concepts will be interwoven, including the challenges to causal inference from observational studies, and some under-appreciated implications of multifactorial causation. Reflections will be offered for future directions in research on etiologies of autism.

9:00 Environment and Autism: Understanding Causes from an Epidemiologic Perspective

***I. Hertz-Picciotto**, Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA*

By the end of the 20th century, very little rigorous research had been conducted to uncover the causes for autism, although a few studies provided compelling clues. This evidence pointed to several conclusions: first, that both genetic and environmental factors could play a role, and second, that the non-heritable causes might include both microbiologic (rubella, influenza) and pharmacologic (thalidomide, valproic acid) agents. Even as theories and myths have multiplied, the past decade has witnessed a new wave of increasingly rigorous epidemiologic research, some of it quite robust. This presentation will summarize: current knowledge on specific exposures in early prenatal or postnatal life that are potential or likely contributing factors to ASD; parallels with the literature on neurotoxins and cognitive impairment; and promising approaches for integrating environmental epidemiology with advances in molecular genetics. To meaningfully assess the current science, key concepts will be interwoven, including the challenges to causal inference from observational studies, and some under-appreciated implications of multifactorial causation. Reflections will be offered for future directions in research on etiologies of autism.

Panel Session
102 - Pushing the Boundaries for Understanding Environmental Influences on Neurodevelopment
10:30 AM - 12:30 PM - Hall B

Panel Chair: Irva Hertz-Picciotto, *Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA*

Often, attention is drawn to the potential for neurodevelopmental damage after a man-made disaster or accidental poisoning event, as occurred with PCBs, methyl-mercury, and most recently, with lead in Flint, Michigan. Those earlier tragedies, which led to serious mental and physical disabilities, served as warning signs and led to in-depth research on lower level exposures to the same substances, levels for which clinical signs are not obvious, yet large epidemiologic studies have now uncovered the adverse consequences. In this panel, Dr. Lanphear describes how low-level exposures have been dismissed, even when comparisons with known toxins or drugs that trigger problems at similarly low doses indicate reasons for concern. His presentation outlines what clinicians and scientists need to know about the biologic impacts from lead, arsenic, and other exposures in early development. Dr. Rauh uses novel approaches in a longitudinal study to examine how commonplace prenatal exposures may have long term impacts, and how imaging studies are showing changes that correlate with gestational pesticide exposures. Her team has also identified surprising neurologic outcomes in school-aged children. Dr. Engel takes a step back to consider various biomarkers and how to circumvent the common pitfalls in environmental epidemiology and strengthen the inferences that can be made with regard to causal relationships, based not only on consistency and replication across studies but also on temporality, mechanistic considerations, dose-response, and other attributes of observational studies. Dr. Fallin will lay out a framework for integrating research on genetics with environmental epidemiology to harness the power of -omics technology with large-scale well-designed epidemiologic studies to advance the science of etiology in its multi-factorial complexity.

10:30 **102.001** Little Things Matter: The Impact of Toxins on the Developing Brain

***B. Lanphear**, Simon Fraser University, Burnaby, BC, Canada*

The impact of toxic chemicals on brain development is usually subtle for an individual child, but they can be substantial at the population level. Low-level exposures to toxic chemicals - such as lead, tobacco, pesticides and flame retardants - are implicated in the development of intellectual deficits, behavioral problems and preterm birth. Yet, too little has been done to protect children from these ubiquitous, but insidious toxins. This session will provide an overview of the population impact of toxic chemicals on children's health to set the stage for dialogue about ways to articulate their impact and importance for brain development.

11:00 **102.002** Atypical Neuropsychological Profiles, Attention Deficit Disorder, Brain Anomalies and Environmental Insecticide Exposure

***V. Rauh**, Columbia University, New York, NY*

Background: Underlying variability in neuropsychological profiles has been demonstrated among children with attention deficit disorders, and this may contribute to the differences in behavioral phenotype and clinical disorders in this population.
Objectives: This study investigated the contribution of prenatal exposure to chlorpyrifos, a widely used organophosphate pesticide, to neuropsychological patterns and clinically defined ADHD-type outcomes at 12 years of age. Observed patterns were associated with anatomical MRI findings.
Methods: An inner-city community-based cohort was followed prospectively from the prenatal period through 12 years of age (n=250), including repeated biomarkers of environmental exposures, full neuropsychological test battery, and structural MRI.
Results: Highly exposed children showed a unique neuropsychological profile, with significant deficits (all ps<0.01) in auditory attention and fine motor performance, but no deficits on more complex visual attention and inhibitory control tasks. Children with pesticide exposure and the signature profile were at increased risk of clinically-meaningful ADHD, as measured by the DuPaul-Barkley ADHD Rating Scale. These findings were consistent with abnormalities in morphological measures of the cortical surface, including the posterior temporal region, subserving attention and receptive language.
Conclusions: Findings suggest that prenatal organophosphate pesticide exposure, at relatively modest doses common in agricultural regions of the US, result in a signature pattern of neuropsychological deficits, accompanied by disturbances in brain morphology by MRI, persisting into the early school years. Furthermore, highly exposed children with this atypical profile were at significantly increased risk of ADHD-type symptoms.

11:30 **102.003** Strengthening Inferences in Environmental Epidemiology

***S. M. Engel**, Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Environmental chemical exposures are increasingly recognized as contributors to the development of neurological diseases. However, exposure measurement is frequently challenged by uncertainty in the relevant etiological window, and the retrospective nature of study designs for rare developmental outcomes, like Autism.
Objectives: This talk will describe the principals of causal inference in molecular environmental epidemiology, opportunities for exposure assessment that take advantage of new developments in environmental biomarkers, and will consider other conventional approaches to exposure assessment that may be implemented in case-control and prospective study designs.
Conclusions: Attention to causal inference methods will strengthen the impact of the literature linking environmental exposures to developmental outcomes. Replication and consistency, temporality, and dose-response will be discussed in connection with standard criteria for evaluating biomarker validity, using a series of conventional and novel biomarkers of environmental toxicants as case studies. Examples of persistent and non-persistent contaminants measured in conventionally collected matrices, such as urine

and blood, will be examined. In addition, biomarkers that make use of novel matrices, including blood spots, hair, and exfoliated deciduous teeth, will be discussed. Exposure assessment methods that strengthen the evidence linking environmental exposure to health outcomes will contribute to a better understanding of the relevant etiological pathways.

12:00 **102.004** The Power of "Omics" for Environmental Epidemiology of ASD

***M. D. Fallin**, Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background:
There is clear evidence that both genetic and environmental factors influence ASD risk. However, much more work has been done in genetic discovery and resulting mechanistic insights. The "omics" revolution offers multiple opportunities to combine efforts and inform environmental discovery, which is critical for policy and prevention efforts regarding modifiable risk.
Objectives:
To review the current opportunities for integration of "omics" measurement into studies of the environmental risk factors for ASD.
Methods:
Large scale measurement of the genome, epigenome, transcriptome, proteome, and metabolome are now feasible for epidemiologic studies. Now, epidemiologic methods must be applied with specific goals in mind for the integration of these measures into questions of environmental risk.
Results:
Associations have been observed between environmental exposures and epigenomics, transcriptomics, proteomics, and metabolomics, and there is some evidence for the influence of the genome on environmental susceptibility. We provide a framework for how to integrate these pairwise relationships to provide insight on mechanistic questions for environmental epidemiology of ASD as well as to develop potential biomarkers that can enable even larger scale environmental epidemiology investigation. We also present the methodologic challenges that must be overcome to realize the potential of such integration.
Conclusions:
The omics revolution is a great opportunity to maximize discovery in environmental health through both mechanistic work and development of new biomarkers. There are multiple methodologic challenges to overcome, but these are now surmountable opening the door for important discovery that can have prevention and policy implications.

Panel Session
103 - Transcranial Magnetic Stimulation (TMS) in Autism Spectrum Disorder

10:30 AM - 12:30 PM - Room 307

Panel Chair: Peter Enticott, *Deakin University, Burwood, Australia*

Discussant: Stewart Mostofsky, *Johns Hopkins School of Medicine, Baltimore, MD*

Transcranial magnetic stimulation (TMS) is an emerging neuroscience technique that can be used to probe in vivo brain function. When applied repeatedly, TMS also has therapeutic applications in a number of psychiatric and neurological conditions, most notably depression. In recent years a number of research groups have begun to use TMS in autism spectrum disorder (ASD). This has included studies of neuroplasticity, neurochemical systems, and cortical excitability, but also the interventional use of repetitive TMS (rTMS) in an attempt to elicit a therapeutic response. In 2013, an international group of leading ASD and brain stimulation researchers formed a consensus group for TMS in ASD, and are currently working toward a coordinated approach for advancing basic and clinical science in this area. This panel will provide an overview from four different labs that conduct TMS research in ASD, and will feature both investigative and therapeutic studies.

10:30 **103.001** Transcranial Magnetic Stimulation Provides a Means to Investigate Cortical Excitability and Plasticity in Autism Spectrum Disorder

***L. Oberman**, Bradley Hospital, East Providence, RI*

Background: The etiology and neurobiology of Autism Spectrum Disorder (ASD) is complex and insufficiently understood. Recent studies across multiple research areas, including genetics, animal model research, and human studies have implicated mechanisms of cortical excitability and plasticity in the pathophysiology of ASD. Our group has pioneered the development of transcranial magnetic stimulation (TMS) and repetitive TMS (rTMS) metrics of cortical excitability and plasticity as putative endophenotypes in ASD. However, both the intraindividual and interindividual reliability of these measures has not been clearly established. Additionally, how abnormalities at the local circuit level impact developmental and experience-based functional brain connectivity and how the functioning of these circuits impact behavior is still a mystery.
Objectives: To use TMS to explore cortical excitability and plasticity in ASD.
Methods: Our published and ongoing studies employ TMS-based measures of cortical excitability and plasticity in children and adults with ASD including single-pulse, paired-pulse, and rTMS protocols.
Results: Across multiple studies, application of an rTMS protocol proposed to index non-Hebbian plasticity and GABAergic inhibitory tone (theta burst stimulation (TBS)) results in a prolonged modulation of corticospinal excitability in adults with ASD. Specifically, while controls show a modulation of the TMS-induced motor evoked potentials (MEPs) for approximately 30-40 minutes following TBS, the effect lasted for over 60 minutes in individuals with ASD. This finding is quite reliable at the group level, but has proved elusive to replicate at the individual level. State-dependent factors relating to expectation and attention likely impact the reliability of this measure. Additionally, we find that a subgroup of individuals with ASD show paradoxical responses to paired pulse and rTMS protocols thought to be related to GABAergic tone.
Conclusions: We continue to explore the utility of TMS and rTMS indices of excitability and plasticity in an effort to develop a valid and reliable endophenotype that would facilitate ASD diagnosis early in life, enable efficient study of ASD risk factors, and eventually serve as a useful biomarker to inform the development of effective therapies and assess treatment response in future clinical trials, however, given the heterogeneity of this disorder (both at the behavioral and physiological level) individual and subgroup analyses, rather than group averages, need to be considered when determining the validity of these measures.

10:55 **103.002** Transcranial Magnetic Stimulation Treatment: Focusing on Core Pathological Features of Autism Spectrum Disorders

***M. F. Casanova**, Pediatrics and Biomedical Sciences, University of South Carolina School of Medicine, Greenville, SC*

Background: Recent evidence suggests the symptoms of autism spectrum disorder (ASD) may be related to an increased ratio of cortical excitation to inhibition. Using specific parameters of stimulation, rTMS has been shown to increase cortical inhibition by selectively activating interneurons.
Objectives: In a number of investigations, our group evaluated the effects of rTMS on indices of selective attention and executive functioning, as well as measures of social awareness, hyperactivity, irritability, and repetitive/stereotyped behavior.
Methods: Subjects with ASD were assessed at baseline and following rTMS with electroencephalographic (EEG) and event-related potential (ERP) measures of selective attention and executive functioning. Subjects were also assessed for ASD symptomatology using neuropsychological questionnaires.
Results: Our preliminary findings in experimental studies using 6-, 12, or 18 session-long, low frequency rTMS courses in children (age<18 years) with ASD indicate significant improvement in EEG and ERP measures of selective attention and executive functioning, and also showed significant improvement in measures of irritability and repetitive/stereotyped behavior.
Conclusions: rTMS has the potential to become an important therapeutic tool in research and treatment and may play an important role in improving the quality of life for many individuals with ASD.

11:20 **103.003** Repetitive Transcranial Magnetic Stimulation for Executive Function Deficits in Autism Spectrum Disorder and Effects on Brain Structure and Function

***S. H. Ameis**, University of Toronto, Toronto, ON, Canada*

Background: There are no satisfactory treatments for executive functioning (EF) deficits that predict real-world disability and long-term morbidity in individuals with high functioning autism spectrum disorder (HF-ASD). Our randomized, double-blind, sham-controlled pilot study results suggest that four weeks of repetitive transcranial magnetic stimulation (rTMS) applied to dorsolateral prefrontal cortex (DLPFC) can significantly improve EF performance in adults with schizophrenia (Cohen's d=0.91). As there may be overlapping etiology resulting in EF impairments in HF-ASD and in schizophrenia, the same biological treatments may improve performance deficits in both conditions.
Objectives: To complete a pilot study exploring the novel application of rTMS to DLPFC for treatment of EF deficits in adolescents and young adults with HF-ASD. This pilot study focuses on evaluating the feasibility of implementing our rTMS treatment protocol in HF-ASD. Our primary aims are to: (i) determine if our rTMS protocol can be successfully applied in people with HF-ASD, (ii) examine whether active rTMS improves EF performance in HF-ASD, and (iii) use structural and functional MRI in a pre/post design to identify mechanisms of treatment response .
Methods: We are using a randomized, double-blind, sham-controlled design comparing active (20Hz) vs. sham rTMS applied 5 days per week for 4 weeks bilaterally to DLPFC in young people with HF-ASD (active, N=20 vs. sham, N=20, 16-35 years). Outcome measures of EF performance (measured using Cambridge Neuropsychological Test Automated Battery) are being evaluated before and after the 4-week intervention. Structural and functional neuroimaging measures (MRI/DTI/rs-fMRI and task-based

fMRI) will also be acquired at baseline, and at the end of the 4-week rTMS trial in HF-ASD subjects to assess for biomarkers of treatment response.
Results: We have now completed year 1 of our 2-year clinical trial. 20 subjects have now successfully completed our study protocol. Over the past 12 months, we have demonstrated feasibility and tolerability of our rTMS protocol in HF-ASD, having successfully recruited ~2 HF-ASD subjects/month (total N=20) to our study, retaining 100% of randomized subjects, with only transient and mild side-effects reported following rTMS.
Conclusions: At IMFAR 2016, we will present our novel protocol, as well as preliminary data regarding the feasibility of implementing our study protocol in HF-ASD participants. In addition, we will present preliminary neuroimaging results including: associations between baseline measures of cognitive performance and DLPFC structure and DLPFC activation, as well as microstructure of white matter tracts connecting to the DLPFC.

11:45 **103.004** Clinical Trials of Deep Repetitive Transcranial Magnetic Stimulation (rTMS) to Bilateral Dorsomedial Prefrontal Cortex in Autism Spectrum Disorder

***P. Enticott**, Deakin University, Melbourne, VIC, Australia*

Background: Autism spectrum disorder (ASD) is characterised by impairments in social relating, which have been linked to abnormal activation within 'social brain' networks that include dorsomedial prefrontal cortex (dmPFC).
Objectives: Across two clinical trials, we investigated whether high-frequency (5 Hz) stimulation of bilateral dmPFC, using a deep rTMS coil to achieve the necessary depth of stimulation, could induce clinical, cognitive, and neurobiological changes among 'high-functioning' adults with ASD.
Methods: Study One involved a randomised, sham- controlled clinical trial of deep rTMS to bilateral dmPFC in 28 adults with ASD. Participants received active or sham deep rTMS each weekday for two weeks. Clinical and cognitive assessments were conducted before, after, and one-month following the treatment phase. Study Two was an open-label study where 20 adults with ASD received 16 active treatments over 4 weeks. Participants underwent positron emission tomography (PET) to assess brain glucose metabolism before and after the treatment course, while clinical and cognitive assessments were conducted before, after, 1-month, 3-months, and 6- months following treatment.
Results: In Study One, there was a significant decrease in self-reported clinical ratings of social impairment for those in the active condition, but no change for participants allocated to sham stimulation. In Study 2, there was again a decrease in clinical ratings of social impairment, and evidence for enhanced glucose metabolism (mid cingulum) following deep rTMS.
Conclusions: These data provide preliminary support for the safety and efficacy of deep rTMS to dmPFC in ASD, and suggest effects on neural networks that support the integration and understanding of social information. The clinical significance of these findings will be explored.

Panel Session
104 - Improving Early Access to Autism Screening and Specialized Services: Reaching Historically Underserved Communities
10:30 AM - 12:30 PM - Room 308

Panel Chair: Ivy Giserman Kiss, *University of Massachusetts Boston, Boston, MA*

Discussant: Alice Carter, *Department of Psychology, University of Massachusetts Boston, Boston, MA*

Presentations in this panel present strategies for identifying and addressing health disparities in the early detection of ASD, with a focus ranging from evaluating psychometric properties of specific screening tools (BITSEA, M-CHAT) in diverse populations to qualitative and systems-level visual analysis of multiple aspects of service delivery in community-based settings. The use of methods such as machine learning (M-CHAT) and receiver operating characteristic analyses (BITSEA) to optimize screener effectiveness highlights the availability of psychometrically-sound screening instruments for use in diverse populations. However, broader systems analyses of completing multi-stage screening, obtaining referrals for diagnostic evaluations, participating in diagnostic evaluations, and receiving services reveal challenges to implementation of ASD screening in community-based settings. Challenges include limited capacity of the service delivery system, family factors such as hesitance to acknowledge a child's problem, and finances. Implementation of ASD screening is best understood as a dynamic process that is shaped by organizational setting and mission and the unique characteristics of the populations being served. Therefore, it is important to document variations in practices designed to reach racial and ethnic minorities. Multiple contextual factors must be considered and multiple stakeholders engaged when supporting families attempting to navigate service delivery systems for children with possible ASD.

10:30 **104.001** Examining the Influence of Race and Gender on Autism Spectrum Disorder Screening Using the M-CHAT-R: A Self-Organizing Map Approach

***R. S. Factor**[1], L. E. Achenie[2], A. Scarpa[1,3], M. V. Strege[1], D. L. Robins[4] and S. McCrickard[5], (1)Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Department of Chemical Engineering, Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Virginia Tech Center for Autism Research, Blacksburg, VA, (4)Drexel University, Philadelphia, PA, (5)Department of Computer Science, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Early screening of Autism Spectrum Disorder (ASD) has been found to facilitate early intervention. The Modified Checklist for Autism in Toddlers-Revised (M-CHAT-R; Robins, Fein, & Barton, 2009) is a 20 item revised version of an evidence-based parent-report instrument recommended by the American Academy of Pediatrics (Johnson & Myers, 2007). One survey found only 60% of pediatricians reported using formal ASD screening at 18 months and only 50% at 24 months (Arunyanart et al., 2012).
Further, differences in diagnosis based on demographic characteristics (i.e., race and gender) can impact the age of diagnosis. One study indicated White children received a diagnosis earlier than African-American children (Mandell et al., 2002). In addition, there may be gender differences in ASD presentation, as ASD is diagnosed later and less frequently in females—especially high functioning females (Head, et al., 2014; Hiller, Young, & Weber, 2014). Since current screening practices rely on clinician training and subjective judgment, machine learning (ML) may be a powerful complementary scoring tool to examine race and gender group differences. Self Organizing Maps (SOM) is a type of ML that clusters data according to similar responses (Bock, 2003).
Objectives: This study examined the use of ML to 1) simplify the administration and scoring of the M-CHAT-R, and 2) improve performance across demographic groups, while examining item-level differences.
Methods: This study used SOM to classify groups based on archival data of 14,995 toddlers (46.51% male; 15 years average maternal education), ranging from 16-30 months, collected during their 18- or 24- month well visit. Children at risk were referred for diagnostic assessment. Comparisons of group assignment and item analysis were conducted based on race (Whites versus African-Americans) and gender. MATLAB script was created to interface with the SOM Toolbox (SOM Toolbox Team, Helsinki University of Technology, Finland) and run for different data sets. All 20 M-CHAT-R items were included as inputs and SOM selected the most informative questions to create clusters based on similar traits.
Results: SOM was able to separate toddlers into risk status groups based on fewer items (12/20 items) and identify symptom presentation differences. Three risk status groups emerged: Typically Developing (TD), Low Risk (LR), and High Risk (HR). Risk status indicates that a toddler may be at risk for any developmental disability, including ASD. In all groups, 100% of ASD cases (determined by follow-up testing) fell into HR clusters. Similar cluster results emerged for Whites and African-Americans, and item analysis indicated deficits in joint attention (JA; i.e., pointing, coordinated gaze) differentiated HR from other groups. While SOM also resulted in three risk status levels in males, SOM failed to provide these differentiations for females, resulting in only LR and HR clusters. This indicates inconsistencies in capturing ASD symptoms in females, such that both the M-CHAT-R and SOM might not as acutely capture at-risk females.
Conclusions: This illustrates the potential utility in using ML in ASD screening and the need to target JA in screeners, although different items or algorithms may be needed to improve screening in females.

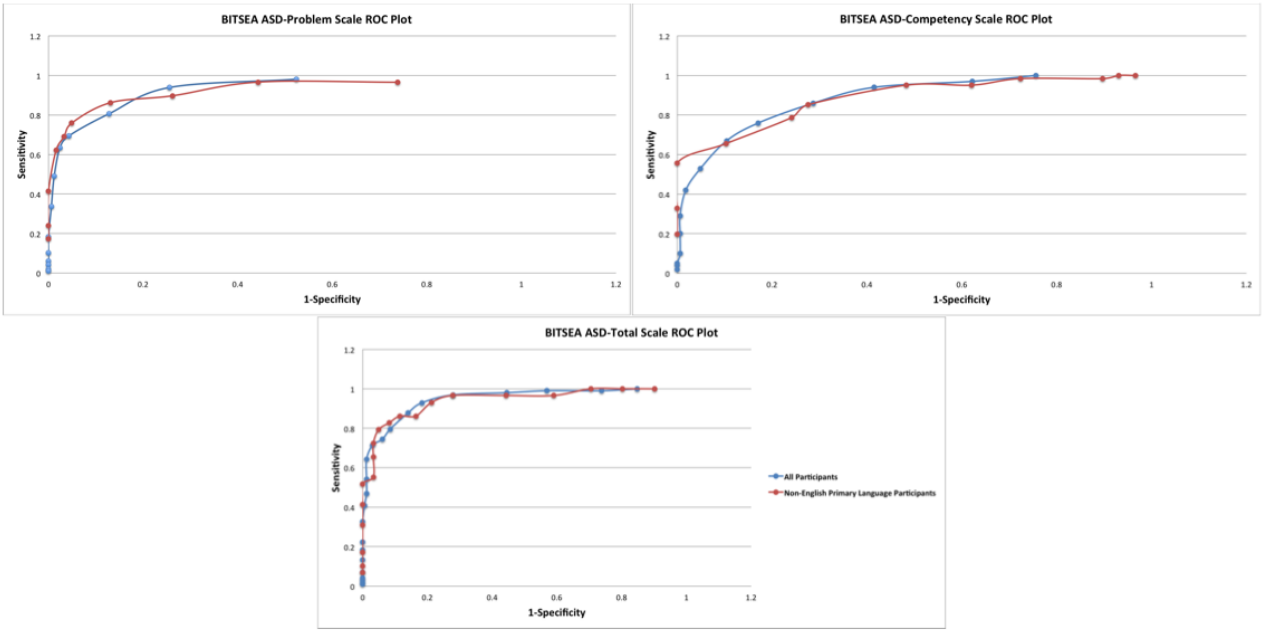
10:55 **104.002** Using the BITSEA to Screen for ASD in Young Diverse Populations

***I. Giserman Kiss**, F. Martinez-Pedraza and A. S. Carter, Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background: Retrospective and prospective studies confirm that symptoms of ASD emerge during the first two years of life (Ozonoff et al., 2011). Yet, the national average age of diagnosis is above 36 months (CDC, 2012), with a greater delay for children from minority backgrounds, non-native English speaking families, and low socioeconomic statuses (Valicenti-McDermott et al., 2012). With increasing evidence that early intervention (EI) significantly improves outcomes for children with ASD, early detection and diagnosis is critically needed (Seida et al., 2009). The AAP and CDC recommend administering developmental screeners at routine visits; universal screening can potentially ameliorate health disparities regarding age of diagnosis. The Brief Infant Toddler Social Emotional Assessment (BITSEA) (Briggs-Gowan & Carter, 2006) is a screening tool designed to identify toddlers with social-emotional/behavioral problems and/or delays/deficits in social-emotional competencies. Eighteen of the 42 items on the BITSEA reflect behaviors consistent with ASD symptoms. In previous work, we determined that the BITSEA ASD scales were highly effective in identifying children with ASD in a sample of 436 toddlers (mean age: 29 months), with sensitivity, specificity, and PPV rates all over 80% for the optimal cut-point.
Objectives: The goals of this study included: determining how the BITSEA functioned in a younger sample of toddlers with diverse backgrounds, and exploring possible health disparities in the utility of the screening instrument.
Methods: Data are presented on a diverse sample of 276 toddlers (mean age: 25 months, 55% male, 41% diagnosed with ASD) enrolled in EI services. 53% of toddlers were from historically underserved racial/ethnic minority backgrounds (21% Black/African American, 22% Latino/Hispanic, 4% Asian, and 6% multiracial) and 33% of toddlers came from families with a primary language other than English (16% Spanish, 17% other). Caregivers completed the BITSEA in either English or Spanish. Analyses

examined the following subscales: ASD-Problem (including nine items focused on ASD negative symptoms), ASD-Competence (including nine items focused on ASD positive symptoms), and ASD-Total (sum of the ASD-Problem and reverse-scored ASD-Competence subscales).
Results: ROC plots were developed for the BITSEA ASD subscales for the entire sample (see attached figure). The ASD-Total subscale with a cut-point of -9.5 was determined as the most effective for identifying children with ASD and demonstrated 93% sensitivity and 82% specificity. To explore health disparities in the utility of the screening instrument, we ran the same analyses for the participants with primary languages other than English (see attached figure), and found comparable results; a cut-point of -9.5 on the ASD-Total subscale yielded 93% sensitivity and 79% specificity in this subsample.
Conclusions: The BITSEA ASD-Total scale appears to be an effective screening measure for ASD in young children from diverse backgrounds. Moreover, the scale was equally effective for children from English and non-English speaking families. These findings suggest universal BITSEA screening in EI could reduce the significant health disparity in age of first diagnosis. Challenges and successes in screening diverse populations will be presented in conjunction in a separate presentation in this panel.

ROC Plots of Effectiveness of BITSEA ASD Scales



11:20 **104.003** Systems-Level Analysis of Implementing a Two Stage Screening Protocol for Autism Spectrum Disorders in a Community-Based Setting

T. I. Mackie[1,2], *R. C. Sheldrick*[3], *C. Tan*[3] *and A. S. Carter*[4], *(1)Institute for Health, Health Care Policy and Aging Research, Rutgers University, New Brunswick, NJ, (2)Department of Health Systems and Policy, School of Public Health, New Brunswick, NJ, (3)Department of Pediatrics, Tufts Medical Center, Boston, MA, (4)Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background:
Disparities in delay to diagnosis of Autism Spectrum Disorders may be effectively addressed by implementing evidence-based screening protocols in community based settings, such as Early Intervention (EI). Optimizing the efficiency of screening protocols among underserved populations can benefit by engaging implementation and systems sciences to examine factors influencing administration of ASD screening tools.
Objectives:
We present the development, validation and evaluation of a process map—a systems-level visualization of the process logic and flow for screening implementation. We use process maps as the basis for analyses of organizational, administrator, and client characteristics that influence administration of the two-stage ASD screening process at an EI site. This case study emphasizes the value of process evaluation when assessing implementation of complex interventions.
Methods:
To examine process efficiency of a two-stage screening for ASD, we employ multiple qualitative methods to examine administration, scoring, and informing families of findings for each of the instruments used in the two stage screening process. To improve the validity of process maps, we utilized respondent triangulation through inclusion of multiple samples. To date, these include: (1) trainers who provided support for implementation (n=10) and (2) EI service providers who administered the two stage screening (n=15). All participants were asked to develop a process map of the screening process from point of initiation until time of completion. For trainers, we conducted two concurrent focus groups to develop independent process maps and a subsequent member-checking focus to reconcile differences and validate findings. For EI providers, process maps were created during semi-structured interviews. Once collected, we individually analyzed EI provider and trainer process maps, coded associated discussions, and examined findings in regard to process efficiency.
Results:
We highlight three notable findings. First, clinical judgment played a significant role in process efficiency. For example, EI service providers described time delays to screen families that were driven by their ascertainment of families' 'readiness to screen' for ASD. Second, departures from protocol resulted in both negative "drift" from fidelity of administration, but also positive "adaptation" that supported provider's ability to follow protocols. For example, respondents articulated unique challenges in administering screening given the educational, linguistic and cultural diversity of clients served. Respondents identified both positive adaptations, such as hiring additional staff to support screening, but also possible "drift," such as adaptation of screening protocols in an attempt to facilitate understanding. Third, the unique roles of the trainers and EI providers led to work flows that are 'invisible' to other stakeholders unless careful efforts are undertaken to assess and monitor process.
Conclusions:
Our findings suggest that implementation of ASD screening in community-based settings to reach racial and ethnic minorities requires careful documentation of the variation that may emerge to accommodate the organizational setting, administrator priorities, and the unique characteristics of the populations being served. Moreover, these points of variation may remain 'invisible' to the trainers and implementation team if efforts are not taken to engage other stakeholders in assessment of implementation.

11:45 **104.004** Service Providers' Perspectives of Obstacles to ASD-Specialized Services

E. A. Karp, *L. V. Ibanez, S. R. Edmunds, C. M. Harker and W. L. Stone, Department of Psychology, University of Washington, Seattle, WA*

Background: Children's early access to ASD-specialized intervention is associated with better long-term outcomes. However, access to ASD-specialized intervention is often impeded by delays in referral and long waitlists for diagnostic confirmation. This study analyzed service providers' perceptions of obstacles that families face as they navigate three stages of the service delivery system: (1) obtaining a referral for an ASD diagnostic evaluation; (2) obtaining the diagnostic evaluation; and (3) obtaining ASD-specialized intervention.
Objectives: To identify: (1) prominent obstacles to each stage of service delivery; and (2) the extent to which county demographics (i.e., percentage of the population living below the Washington State [WA] poverty line, percentage of the population that is Hispanic, and whether the county is rural or urban) predict obstacles at each stage of service delivery.
Methods: Service providers (*n*=128) from 12 demographically diverse WA counties attended one-day workshops on the use of an ASD-specialized intervention. Providers responded to open-ended questions about obstacles that families face at each stage of the service delivery system. Grounded theory was used to identify themes that emerged for each stage. Responses were grouped into system-level obstacles (e.g., limited capacity within the service delivery system) and family-level obstacles (e.g., parental knowledge about ASD) for each stage (Table 1). Six hierarchical linear regressions were conducted to examine the effects of the three county-level predictors on system- and family-level obstacles.

Results: Six identical obstacles emerged for the referral and diagnostic evaluation stages, and 7 obstacles emerged for the intervention stage (Table 1). For the referral stage: (1) system-level obstacles were associated with counties that were rural (β=-.47, p<.01), had larger Hispanic populations (β=.30, p=.03), and had lower levels of poverty (β=-.47, p<.01), R^2 =.15; and (2) family-level obstacles were associated with urban counties (β=.28, p<.01), R^2 =.08. For the diagnostic evaluation stage: (1) system-level obstacles were associated with counties that had larger Hispanic populations (β=.19, p=.04), R^2 =.03; and (2) family-level obstacles were associated with urban counties (β=.33, p<.01), R^2 =.10. For the intervention stage: (1) system-level obstacles were associated with higher levels of poverty (β=.18, p<.05), R^2 =.03; and (2) family-level obstacles were associated with urban counties (β=.31, p<.01), R^2 =.10.
Conclusions: Limited capacity of the service delivery system, as well as family factors such as knowledge about ASD, hesitance to acknowledge a problem, culture, and finances were reported as obstacles for all three stages, suggesting that these areas may be particularly salient for families navigating ASD service delivery systems. At the intervention stage, additional barriers related to complex, difficult-to-navigate systems and family logistical constraints. At all stages, family-level obstacles were generally associated with urban counties, and system-level obstacles were associated with counties with either large Hispanic populations or high levels of poverty. Hispanic ethnicity was associated with system-level challenges at the referral and evaluation stages but not the intervention stage. These findings suggest that multiple contextual factors must be considered when supporting families attempting to navigate service delivery systems for children with possible ASD.

Table 1. System-level and family-level obstacles reported for each stage of the service delivery system.

Referral & Diagnostic Evaluation Stages
System
Limited capacity of the service delivery system
Limited provider knowledge and training regarding early signs of ASD
Family
Limited parental knowledge about early signs of ASD
Hesitance about accepting a possible problem
Cultural differences
Families' economic resources
Intervention Stage
System
Limited capacity of the service delivery system
Complicated service delivery system that is difficult to navigate
Family
Limited parental knowledge about ASD interventions and referral follow-through
Logistical constraints (e.g., scheduling treatment sessions)
Hesitance about accepting a possible problem
Cultural differences
Families' economic resources

Panel Session
105 - Outcome Measures for Early Intervention Studies in Autism Spectrum Disorder
10:30 AM - 12:30 PM - Room 309

Panel Chair: Catherine Lord, *Weill Cornell Medical College, White Plains, NY*

Discussant: Tony Charman, *Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

The field of ASD intervention research is in dire need of treatment response measures that adequately capture subtle changes in social communication behaviors. This panel presents recent findings from different research groups, introducing several advances in the development of outcome measures. We open with a presentation that reviews early intervention literature and underscores the need for the development of outcome measures. The next two presentations provide initial validity of a newly developed treatment response measure known as the Brief Observation of Social Communication Change (BOSCC) in two independent samples. We close with a presentation that extends this work to explore whether automated analyses of child vocalizations using the LENA voice recorder can be useful in identifying treatment response. Together this panel provides both an overview of our current challenges and of initial cutting-edge results for future researchers to expand upon. Implications for intervention research, behavioral phenotyping, and clinical practice will be discussed.

10:30 **105.001** Evidence Synthesis: Outcome Measures for Early Intervention Studies in ASD
H. McConachie, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: One problem for researchers evaluating early intervention, and for providers of services for young children with autism spectrum disorder (ASD), is the multitude of outcomes assessed and tools used to measure children's progress. How can we best decide what outcomes to measure and how to measure them?
Objectives: To synthesise the evidence about tools used to measure outcomes in children with ASD up to age 6. Further, to explore how to identify what outcomes to prioritise, and report outcome areas in which robust tools are lacking.
Methods: A number of steps were completed as part of evidence synthesis:
A: Recent summary papers about outcome measurement for young children with ASD were reviewed.
B: Ways of working towards defining a core outcome set for early intervention studies in ASD were reviewed.
C: The methods and findings of the MeASURe review (McConachie et al 2015) were considered. MeASURe identified tools used in ASD early intervention and longitudinal studies, and systematically reviewed papers addressing the measurement properties of the tools when used with young children with ASD, using the COSMIN checklist (Consensus-based Standards for the selection of health Measurement Instruments).
D: Synthesis of evidence and identification of gaps in the tools available to measure outcomes.
Results: Recent papers have considered the 'best' tools for measurement of repetitive behaviours, anxiety and social-communication, usually by expert consensus. Others proposed batteries of tests. No fully systematic process for identifying how best to measure outcomes has been agreed.
Conceptual frameworks for deciding what to measure have been proposed, based on the International Classification of Functioning, Disability and Health, including domains of 'impairments', 'activity limitations', 'participation restrictions', and family measures. Ways of integrating the differing perspectives of the autism community, clinicians, educators and researchers have been proposed.
In the MeASURe review, 129 tools were identified. 2,793 papers on the measurement properties of tools were sifted and data extracted from 128 concerning 52 (40%) tools; for 60%, no measurement properties study including children with ASD was found. The most robust 12 tools were identified, and gaps in the evidence and array of tools

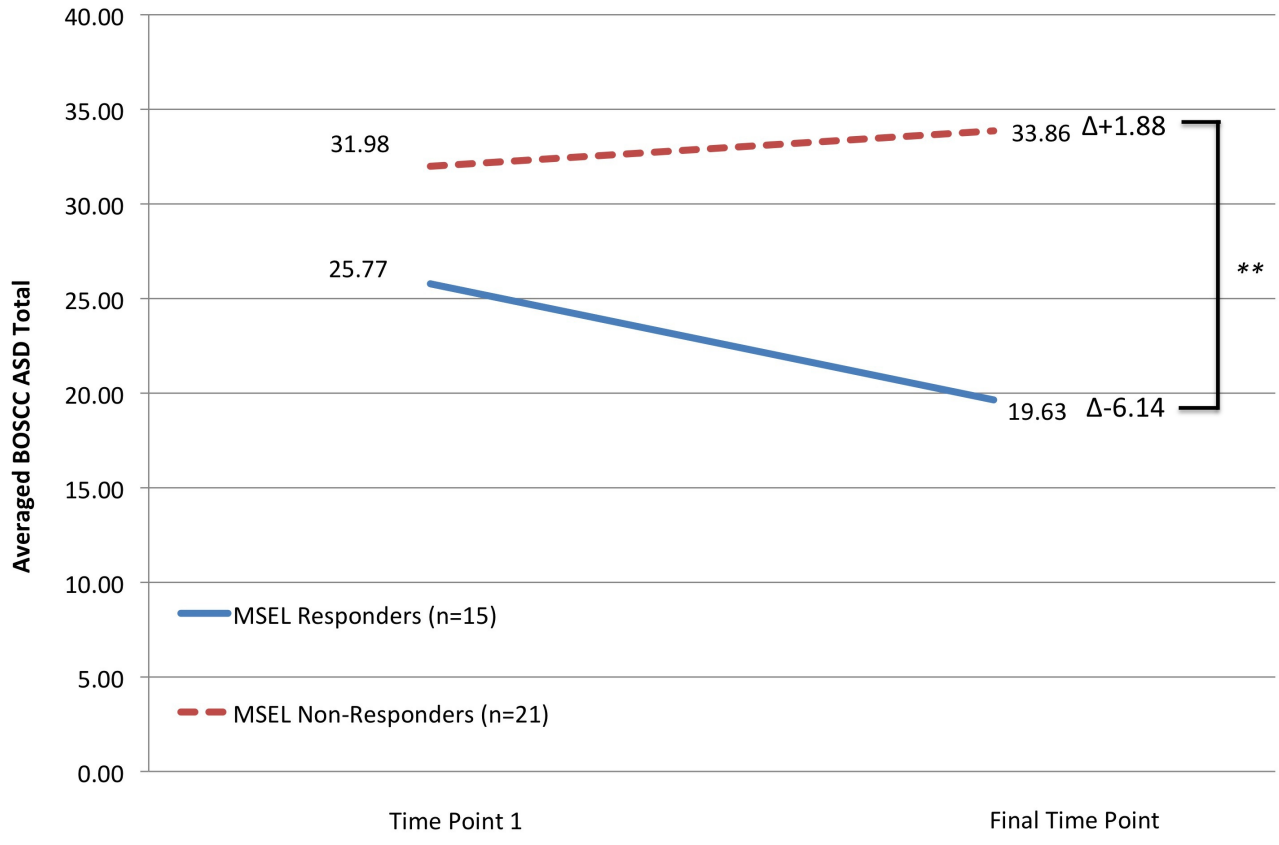
pinpointed, such as measurement of wellbeing and participation outcomes for children. The lack of a reliable and valid tool to measure core autism impairments, with proven responsiveness to treatment, is a clear hindrance to early intervention research.
Conclusions: An agreed core set of outcomes, and battery of robust tools, are goals for the future; in the interim a process for reaching such conclusions could be agreed. For some important outcome areas, good tools are lacking. Further review of established and newer tools is still required, with input from parents and other stakeholders, before consensus can be reached about a recommended battery to be used by researchers and service providers.
This presentation includes evidence synthesis commissioned by the National Institute for Health Research (NIHR) under the Health Technology Assessment programme (HTA Project:11/22/03). The views expressed are those of the author and not necessarily those of the National Health Service, NIHR or Department of Health.

10:55 **105.002** Preliminary Reliability and Validity of the Brief Observation of Social Communication Change (BOSCC)

R. Grzadzinski[1], *C. Carberry*[2], *A. Hamo*[2], *K. M. Frost*[3], *M. Heyman*[4], *C. Dick*[4], *S. Manevich*[5], *N. Hong*[5], *A. Pickles*[6] *and C. Lord*[2], *(1)Center for Autism and the Developing Brain, New York, NY, (2)Weill Cornell Medical College, White Plains, NY, (3)Center For Autism and the Developing Brain, White Plains, NY, (4)Center for Autism and the Developing Brain, White Plains, NY, (5)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (6)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background: The field of ASD intervention research lacks adequate outcome measures to assess the utility of treatments (Anagnostou et al., 2015). Although standard measures of social communication behaviors exist, these measures are often not sensitive enough to subtle changes over short periods of time (e.g., the Autism Diagnostic Observation Schedule; ADOS), capture only very specific behaviors (e.g., Early Social Communication Scales), or rely on parent report leading to potential reporter bias. To address these limitations, our group developed the Brief Observation of Social Communication Change (BOSCC), an observation-based measure coded by a blind researcher/clinician that is intended to be sensitive to slight changes in social communication and restricted, repetitive behaviors.
Objectives: To provide preliminary reliability and validity for the BOSCC.
Methods: The BOSCC coding scheme was applied to 177 parent-child free-play videos from 56 toddlers and pre-schoolers with diagnoses of Autism Spectrum Disorder (ASD). All children were using phrase speech or less and were participating in various intervention trials active at two sites. Exploratory Factor Analyses (EFA) were conducted, providing BOSCC domains, as well as intraclass correlations (ICCs) for Test-Retest (TRT) and Inter-rater reliability (IRR). Growth curve models were fit to all available data for each child's BOSCC score and ADOS Calibrated Severity Score (CSS). Exploratory analyses were also conducted comparing BOSCC scores in children who did and did not demonstrate changes on metrics that have successfully measured change in other research (Wetherby et al., 2014) including the Vineland Adaptive Behaviour Scales- Communication domain (VABS) and Mullen Scales of Early Learning Receptive Language domain (MSEL).
Results: EFA results support a two-factor model, consistent with the social communication and Restricted, Repetitive Behavior (RRB) domains seen in the ASD symptom literature. ICCs computed for TRT and IRR data ranged from 0.79-0.91 and 0.94-0.96, respectively. Results of whole sample (including responders and non-responders) random effects analyses indicate that the average rate of change each month in the ADOS CSS score was 0.055, which corresponded to an effect size of -0.026 per month. The average rate of change in the BOSCC ASD total score was -0.711 corresponding to a substantially larger, though small effect size for the rate of change of -0.068 per month. However, compared to children who did not show improvements on the VABS and MSEL, children who showed improvements (increases) on the on VABS and MSEL also demonstrated significantly larger decreases in BOSCC scores (see Figure 1).
Conclusions: This work provides preliminary evidence for the utility of the BOSCC as a treatment response measure. The BOSCC demonstrates more change than the ADOS CSS over the course of months of intervention. The BOSCC may be an additional tool which is sensitive enough to capture slight changes and also standard and flexible for use across studies. We hope that the BOSCC can aid in identifying efficacious treatments, monitoring progress, and tailoring individualized treatment plans for children with ASD.

Figure 1. BOSCC ASD Total Across Time Points for Responders and Non-Responders (defined by improvements in MSEL Receptive Language).
[MSEL Receptive Language Standard Score increase ≥5= Responders (n=15), Non-Responders (n=21)]



11:20 **105.003** A Preliminary Evaluation of the Brief Observation of Social Communication Change (BOSCC) As Candidate Outcome Measure in an Independent Dutch Sample

M. K. J. Pijl[1,2], *J. K. Buitelaar*[2,3], *N. N. J. Rommelse*[2,4] *and I. J. Oosterling*[2], *(1)Cognitive Neuroscience, Radboud University Medical Centre, Nijmegen, Netherlands, (2)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (3)Radboud University Medical Centre, Nijmegen, Netherlands, (4)Department of Psychiatry, Radboud University Medical Centre, Nijmegen, Netherlands*

Background: The Autism Diagnostic Observation Schedule (ADOS) is commonly used as outcome measure. However, it has not primarily been designed for measuring change. A recently developed measure that is aimed to detect change in ASD symptoms, the Brief Observation of Social Communication Change (BOSCC), may be more apt for such purposes. The current study includes a head to head comparison between both measures, comparing ability of detecting behavioral change based on a 10-minute

unstructured parent-child interaction (BOSCC) versus a 40-60 minute standardized semi-structured examiner-child interaction (ADOS).
Objectives: To evaluate the usefulness of the BOSCC in detecting ASD symptom change in comparison to the ADOS, focusing on 1) inter- and intra-rater reliability; 2) construct validity; and 3) sensitivity to capture change.
Methods: Participants encompassed 48 toddlers diagnosed with ASD who were involved in an early intervention study (Oosterling et al., 2010). In that study an intervention was tested in a randomized controlled trial; parents in the experimental group received parent (Focus) training in addition to care-as-usual, whereas parents in the control group received care-as-usual alone. The current study conducted a secondary analysis; applying the BOSCC coding scheme on 96 videotaped parent-child dyads. At baseline and after one year of intervention the ADOS, non-verbal IQ, MacArthur-Bates Communicative Development Inventory (MCDI) and Child Behavior Checklist (CBCL) were also assessed. The Autism Diagnostic Interview (ADI-R) was only applied at baseline. Group-based and individual analyses were done.
Results: 1) Excellent inter-and intra-rater reliability was obtained for total and sub scores of the BOSCC; intraclass correlations were 0.96–0.99 and 0.77–0.98, respectively. This is comparable to the established reliability of the ADOS. 2) With regard to convergent validity, the BOSCC total score showed a moderate Spearman's correlation with the ADI-R (r_s=0.46), whereas the ADOS total score showed a weak correlation with the ADI-R (r_s=0.39). With regard to discriminant validity, weak correlations were found between the BOSCC and CBCL scores (r_s=-0.04–-0.30), whereas the ADOS showed weak to moderate correlations (r_s=-0.05– -0.41). In contrast, for both the BOSCC and ADOS moderate to strong correlations were found with non-verbal IQ (BOSCC: r_s= -0.44–-0.57; ADOS: r_s=-0.54–-0.60) and MCDI scores (BOSCC: r_s=-0.41–-0.60; ADOS: r_s=-0.50–-0.65). However, overall, construct validity of the BOSCC and the ADOS did not significantly differ. 3) Both the BOSCC and the ADOS total scores were significantly lower at follow-up than at baseline. When considering the clinical reliability of change for each individual separately, using Reliable Change Indexes, the BOSCC was able to capture more reliable change (29% showed significant change on the BOSCC compared to 10% on the ADOS). Change measured by the BOSCC was weakly correlated with change on the ADOS, and with change on other measures.
Conclusions: Our preliminary results indicate that the BOSCC, used in a naturalistic setting to measure change in social communicative behavior, seem to be a promising outcome measure, and has greater potential in measuring individual change as compared to the ADOS. Explanations for findings and recommendations for future research will be discussed.

11:45 **105.004** The LENA System in Clinical Trials: Evidence from Pivotal Response Treatment Studies

***A. Y. Hardan**, Stanford University, Stanford, CA*

Background: Treatment research in autism spectrum disorder (ASD) has been limited by the lack of objective indicators of symptom improvement. Thus, there is a critical need to develop validated, objective outcome measures for assessing treatment-mediated changes in core autism symptoms. The Language ENvironment Analysis System collects large samples of speech from the child's natural environment and automates analysis of child utterances and conversational turns. This system is ideal to assess any changes in clinical trials involving interventions that aim at assessing language improvement in ASD.
Objectives: This presentation will review data from two different clinical trials examining the effectiveness of two pivotal response treatment (PRT) programs in targeting language deficits in minimally verbal young children with ASD between the ages of 2 and 6 years.
Methods: The first dataset was obtained from an uncontrolled trial examining the effectiveness of a group parent training in PRT (PRTG) in children with ASD between the ages of 2 and 6 years. The second dataset is being collected as part of a randomized controlled trial of a PRT package treatment (PRT-P), which combines parent training with clinician-delivered in-home treatment. PRT-P is being compared to a delayed treatment group (DTG) that is receiving community services. In both trials, LENA recordings were obtained at baseline and post-treatment.
Results: Eleven children with ASD participated in the first study. Preliminary analyses revealed improvement in language abilities with increases in child vocalization during structured laboratory observation (SLO) with increase in the number of utterances between baseline (32 ± 21) and post-treatment (51 ± 26; t= -3.572, p=.009). This improvement was associated with changes in the average frequency of child vocalization per hour as assessed by in-home LENA recordings (Baseline= 205 ± 77; Post-treatment=244± 96; t= -1.882, p=.089). Data is available from 25 participants in the PRT-P trial, and preliminary analyses revealed significant improvement in language deficits as measured by the clinical global impression scale-improvement (CGI-I) (N=16; PRT-P= 9; DTG = 7; X^2= 9.363; p=0.025), and the MacArthur-Bates Communicative Development Inventories with the active group showing more improvement than the control group on the words produced out of 680 (PRT-P: 10; Baseline=126.6 ± 111.2; week 24: 281.0 ± 194.3; DTG = 7; BL: 111 ± 110; Week 24: 140 ± 148; F=5.267; df (1;15); p=0.037). LENA recording were also obtained and findings from a small subset of participants, revealed a non-significant increase in the conversational turn count in the active group (N=11; Baseline 144.7 ± 94.1; Week 24: 149.0 ± 97.3). Additional LENA data will be available and further analyses will be completed.
Conclusions: These preliminary findings illustrate the value of including objective measures obtained in the natural environment using the LENA system in assessing improvement in language in response to two different PRT programs. Potential benefits and challenges of the LENA system will be discussed in comparisons to structured laboratory observation and standard language measures.

Panel Session
106 - Behavioral Interventions for Adults with ASD
10:30 AM - 12:30 PM - Room 310

Panel Chair: Caitlin Conner, *Department of Psychology, Virgina Tech, Blacksburg, VA*

While research on adult outcomes in ASD has been an area of recent focus, intervention research has not kept pace, leaving the field fairly uninformed regarding best practices. There is a critical need for treatment research given outcome data suggesting that adults often struggle with psychiatric comorbidity, unemployment and underemployment, and overall diminished quality of life. In this panel, four clinical scientists from different institutions present original research on intervention studies for adults with ASD with diverse targets. McVey and colleagues present data on a replication of the PEERS-Young Adult social skills intervention and investigate how the program affects related issues such as anxiety. Eack and colleagues present data on an RCT of Cognitive Enhancement Therapy, where social and nonsocial cognitive rehabilitation is conducted, and have found effects in both neurocognitive and social domains. Next, Schall and her colleagues present outcome data from Project Search, an intervention focusing on training and maintaining vocational work. Lastly, Conner presents data on an adapted mindfulness-based intervention for young adults with ASD focusing on emotion dysregulation. Together, these presentations present preliminary results of wide ranging intervention foci and implementation approaches. Collectively, the studies suggest that clinically significant change is possible for adults.

10:30 **106.001** A Replication and Extension of the UCLA PEERS® for Young Adults Social Skills Intervention

***A. McVey**, B. Dolan, K. A. Schohl, C. Caiozzo, E. Vogt and A. V. Van Hecke, Marquette University, Milwaukee, WI*

Background:
Research shows that the UCLA PEERS® for Young Adults social skills intervention is effective at helping young adults with ASD make and keep friends (Gantman, Kapp, Orenski, & Laugeson, 2012; Laugeson, Gantman, Kapp, Orenski, & Ellingsen, 2015), however, these findings have not yet been replicated outside of the site of development. Further, the developers utilized relatively small sample sizes, limited diagnostic criteria for ASD, and did not evaluate the intervention's impact on social anxiety.
Objectives:
The objectives of this study were to examine the effectiveness of the PEERS® for Young Adults intervention by conducting a direct replication and extension by recruiting a larger sample size, utilizing more stringent diagnostic criteria, and examining social anxiety outcomes.
Methods:
Forty-seven young adults with high functioning ASD (N = 47; 38 male) between the ages of 17 and 28 participated in this study. Participants were screened using the Autism Diagnostic Observation Schedule (ADOS-G; Lord, Rutter, DiLavore, & Risi, 2002) as it represents the gold-standard in ASD evaluation. Participants were randomly assigned to either the Experimental Treatment Group (EXP) or the Waitlist Control Group (WL). All participants and parents/caregivers completed a battery of questionnaires to assess social skills behavior, social responsiveness, social skills knowledge, quality of socialization, empathy, loneliness, and anxiety at two time points (pre- and post-intervention for the EXP group) approximately 15 weeks apart.
Results:
Young adults in the EXP group demonstrated significant improvements in social skills, specifically problem behavior (SSIS-RS Competing Problem Behavior, $F(1, 45)$ = 11.952, p = .001, partial η^2 = .210), social responsiveness (SRS, $F(1, 45)$ = 7.651, p = .008, partial η^2 = .145), social skills knowledge (TYASSK, $F(1, 45)$ = 92.010, p =.001, partial η^2 = .672), and empathy (EQ, $F(1, 45)$ = 6.960, p =.011, partial η^2 = .134) compared to the WL group at post-intervention. Quality of socialization, as measured by the number of direct peer interactions, approached significance (QSQ-YA, $F(1, 45)$ = 3.449, p = .070, partial η^2 = .071). Improvements were seen for social and emotional loneliness (SELSA), but they did not reach significance. Exploratory analysis uncovered a significant improvement in social anxiety over time (LSAS, $F(1, 45)$ = 9.302, p = .006, partial η^2 = .297). Social phobia (SPIN) improved as well, but not to the point of significance.
Conclusions:
Results provide further support for the effectiveness of the UCLA PEERS® for Young Adults intervention, specifically in the domains of social skills behavior, social responsiveness, social skills knowledge, and empathy. Further evaluation is merited to examine the effects of the intervention on social and emotional loneliness and anxiety, though trends demonstrate improvement in these areas as well. These results have important implications for the overall mental health and well being of young adults with

ASD. Improvements in social skills are likely to relate to improvements not only in the development of social relationships, but also mood, adaptive functioning, and self-efficacy.

11:00 **106.002** Cognitive Enhancement Therapy for Adults with Autism Spectrum Disorder: Results from an Ongoing Randomized-Controlled Trial

S. M. Eack[1,2], *D. P. Greenwald*[2], *S. S. Hogarty*[2], *M. Y. Litschge*[2], *S. S. Porton*[2], *C. A. Mazefsky*[2] *and N. J. Minshew*[2,3], *(1)School of Social Work, University of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Department of Neurology, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Adults with autism spectrum disorder (ASD) experience significant disability due to pervasive social and non-social cognitive impairments. Cognitive rehabilitation has emerged as an effective set of approaches for addressing cognitive deficits in numerous neurological and psychiatric populations, yet little is known about their efficacy in adults with ASD.
Objectives: The purpose of this research was to conduct the first adequately-powered randomized-controlled trial of Cognitive Enhancement Therapy (CET) in adults with ASD. CET is a promising social and non-social cognitive rehabilitation intervention that has shown significant benefits in patients with schizophrenia and in preliminary uncontrolled studies in adult autism.
Methods: Verbal adults with ASD were randomized to an 18-month controlled trial of CET or an active Enriched Supportive Therapy (EST) comparison treatment, which addresses psychoeducation, stress management, and emotion regulation. Comprehensive measures of cognitive and behavioral outcomes were collected prior to treatment and at 9 and 18 months of treatment by raters who were blind to treatment assignment.
Results: Analyses of the first 40 adults randomized to this trial are indicating significant and medium-to-large levels of differential improvements in neurocognitive and social-cognitive functioning favoring CET. The greatest domains of neurocognitive improvement in CET have included visual learning and processing speed, and the greatest area of social-cognitive improvement has been in the domain of facial emotion perception. Most importantly, these cognitive gains observed in CET are translating into large improvements on blinded measures of adaptive function, particularly major role and vocational functioning. Significant improvements in anxiety and depressive symptomatology, as well as functional outcome are also being observed in EST.
Conclusions: Cognitive rehabilitation may be an effective avenue for addressing core cognitive deficits that limit adaptive function in adults with ASD. CET represents a comprehensive and promising approach to cognitive rehabilitation in adult autism that may be able to significantly improve neurocognitive and social-cognitive information processing, with considerable benefits to real-world adaptive function. EST alone or in combination with CET also represents a feasible and potentially effective individual approach for improving symptom and functional outcomes in adults with ASD.

11:30 **106.003** The Impact of Project Search Plus ASD Supports on Employment and Social Responsiveness in 18 to 21 Year Old Youth with ASD

C. M. Schall*, Virginia Commonwealth University, Richmond, VA*

Background: For most individuals with autism spectrum disorder (ASD), graduation from high school represents a time of worry with few future options and a lack of hope for college or post high school employment (Wehman, Schall, Carr, Targett, et al., 2014). Adolescents with autism aging out of high school are unemployed and under employed at higher rates than other similar disability groups (Howlin et al., 2013; Newman et al., 2011; Roux et al., 2013; Schall et al., 2014; Shattuck et al., 2011). Unfortunately, for the most part, they remain unemployed, underemployed, or chronically change low wage jobs through adulthood (Cimera and Cohen, 2009; Cimera et al., 2012; Henninger and Taylor, 2013; Schall, et al., 2014; Shattuck et al., 2011, 2012). Further, families, individuals with ASD, health care professionals, and educators are unclear about their future with limited employment options on the horizon (Holwerda et al., 2012, Schall et al., 2013, 2014; Shogren and Plotner, 2012; Watson et al., 2013; Wehman, Schall, Carr, et al., 2014). While this situation is likely to grow in intensity due to the increasing prevalence of ASD, few intervention studies have addressed this tremendous treatment need (Buescher et al., 2014; Hansen et al., 2015).
Objectives: The objective of this study was to measure the impact of Project SEARCH plus ASD Supports (PS-ASD) on the social communication, behavioral, and employment outcomes of youth with ASD across three vocational domains (employment status, wage, number of hours worked per week) and three personal domains (social responsiveness, physical and mental health, and self-determination).
Methods: This is a randomized controlled study of the efficacy of the PS-ASD Model in 82 adolescents and young adults aged 18 to 21 with autism spectrum disorder across four different sites. Of the 82 enrolled subjects, 42 were randomly assigned to the control group, while 40 were assigned to the treatment group. Data collection is ongoing and will be updated as it is collected.
Results: There were no differences between the groups on demographic variables of age, gender, ethnicity, or medical diagnosis. The majority of both groups were individuals with a diagnosis of autism. Outcomes were significantly different as measured on employment where 84% of the treatment group were employed within a year of graduation from high school and earned a mean wage of $8.44 per hour for a mean of 20.2 hours per week. The control group, on the other hand, were employed at much lower rates with only 11% were employed within one year of graduation and earned a mean wage of $8.99 per hour while working a mean of 12 hours weekly. Significant differences were observed on supports intensity, social responsiveness, and psychological empowerment with employed participants demonstrating more independence, increased social responsiveness, and greater psychological empowerment than those who were unemployed.
Conclusions: Employment outcomes were excellent and follow up data highly promising as was the concomitant independence, self-determination, and social responsiveness of students in the treatment group. This data suggests there may be treatment benefits associated with employment for youth with ASD.

12:00 **106.004** Mindfulness-Based Therapy for Adults with Autism Spectrum Disorder: A Pilot Study

C. M. Conner[1,2] *and S. W. White*[3], *(1)Department of Psychology, Virgina Tech, Blacksburg, VA, (2)Department of Psychology, Virginia Tech, Blacksburg, VA, (3)Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background:
Prior research has shown that individuals with ASD experience difficulties in emotional functioning and emotion regulation (ER). Furthermore, aggression, irritability, anxiety, and tantrum-like behaviors are common among individuals with ASD (Mazefsky et al., 2013; Samson, Huber, & Gross, 2012). MA-based interventions have been shown to be beneficial in targeting ER difficulties (e.g., inflexibility, rumination, or reappraisal and perspective taking) frequently seen in individuals with ASD (Eack et al., 2013; Rieffe et al., 2011; Samson et al., 2013).
Objectives:
Given high levels of ER difficulties among individuals with ASD, the development of effective interventions is imperative. The purpose of the current study was to determine the feasibility of a new, mindfulness-based intervention targeting ER difficulties in ASD.
Methods:
Nine young adults aged 18-25 years (mean= 19.56; 7 males= 77.78%) participated. All had ADOS-2 confirmed ASD diagnosis and IQ> 80. After eligibility determination, participants were randomly assigned to a three- or four-week baseline period, then completed six hour-long weekly individual therapy sessions where Mindfulness-based Cognitive therapy (MBCT) techniques and ER strategies were covered. Participants completed the Difficulties in Emotion Regulation Scale (DERS; Gratz & Roemer, 2004) and the Satisfaction with Life Scale (SWLS; Diener, Emmons, Larsen, & Griffin, 1985) at eligibility and endpoint. Reliabile Change Indices (RCI; Jacobson & Truax, 1991) and clinically meaningful change scores were used to assess within-person change over the course of intervention.
Results:
On the DERS, two of the nine participants had RCI scores above the cutoff of +/- 1.91, while an additional participant had a clinically meaningful change score from eligibility to endpoint. Four participants were below clinical cutoffs at eligibility and remained below cutoffs at endpoint, and two participants remained above clinically significant cutoffs. Seven of the nine participants' DERS scores decreased, indicating improving ER, from eligibility to post-treatment.
For the SWLS, none of participants demonstrated a significant RCI; however, one of the participants displayed meaningful change from pre- to post-treatment. Three other participants remained above the meaningful change cutoff throughout treatment.
Conclusions:
Results indicate that mindfulness-based intervention significantly lowers ER difficulties for adults with ASD who reported elevated ER difficulties prior to beginning intervention. The intervention did not have a significant effect on quality of life for most of the participants. Further research on ER and mindfulness-based interventions for ASD is warranted. Clinical implications related to ER and these interventions for ASD will be discussed.

Poster Session
107 - Brain Function (fMRI, fcMRI, MRS, EEG, ERP, MEG)
11:30 AM - 1:30 PM - Hall A

1 **107.001** 22q11.2 Deletion Syndrome Is Associated with Altered Resting State Networks

C. M. Pretzsch[1], *E. Daly*[2], *C. M. Murphy*[2], *C. Ecker*[2], *G. M. McAlonan*[3], *M. Gudbrandsen*[2], *R. H. Wichers*[2], *L. Kushan*[4], *C. Bearden*[5], *M. Craig*[2] *and D. G. Murphy*[2], *(1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,*

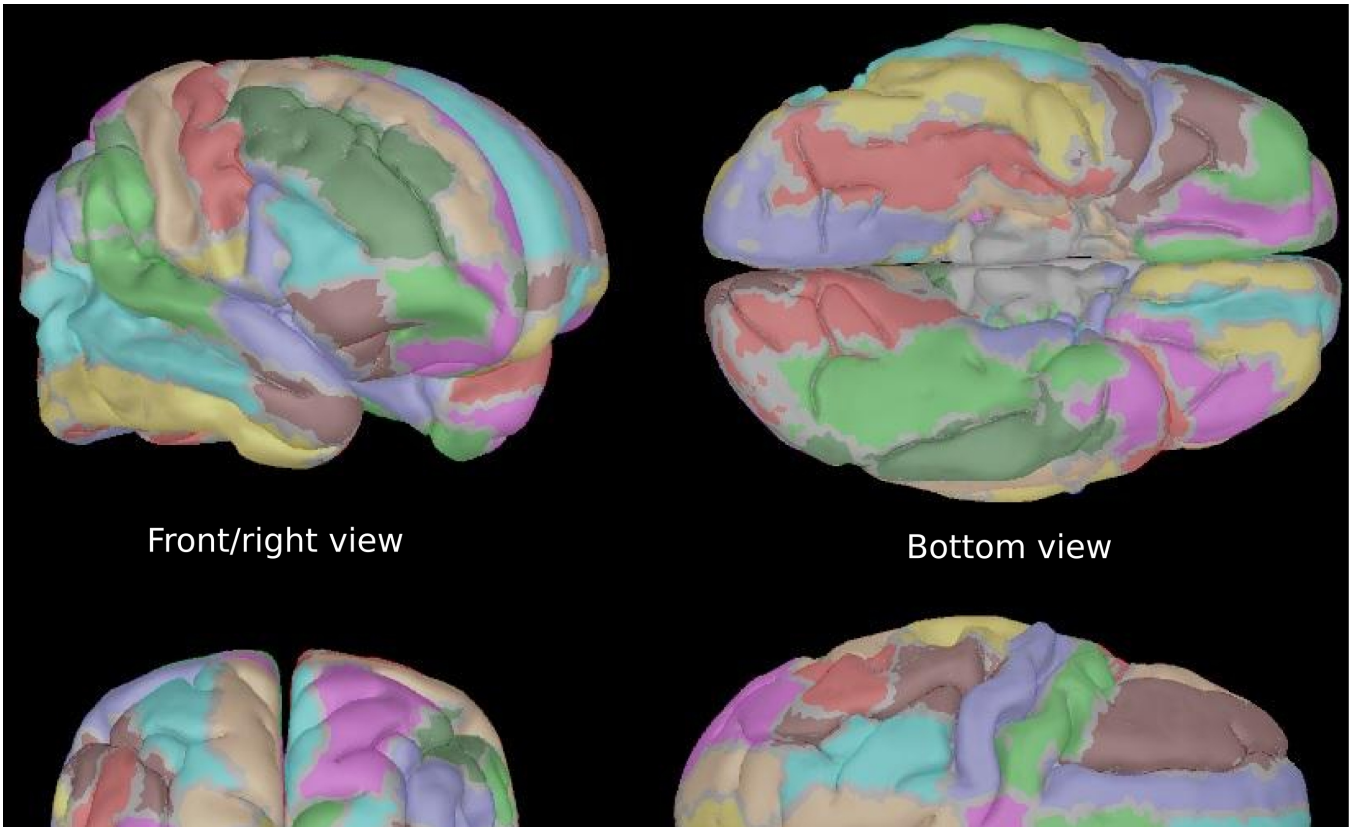
(2)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (3)Department of Forensic and Neurodevelopmental Science, IoPPN, KCL, London, United Kingdom, (4)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA, (5)Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

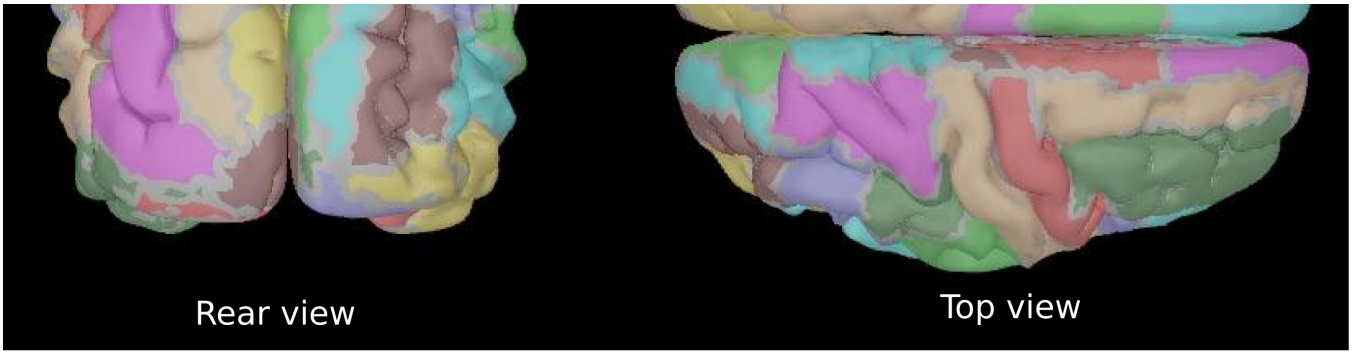
Background: The biological basis of Autism Spectrum Disorder (ASD) is still not fully understood. The study of conditions with a clearly identified genetic risk for neurodevelopmental disorders, such as 22q11.2 deletion syndrome (22q11DS), may help identify important biological pathways which are intermediate between risk genes and disorder. Therefore, we tested the hypothesis that the 22q11.2 deletion would impact upon the functional integrity of core resting state networks in brain.
Objectives: Functional magnetic resonance imaging (fMRI) was used to investigate neural resting state networks (RSNs) in the brain at rest in individuals with and without 22q11DS. This study had two aims: (1) To identify RSNs shared among individuals with 22q11DS and healthy controls: These RSNs were predicted to be in line with those established by previous research. (2) A between-group comparison of RSNs: Significant group-differences across widespread RSNs were predicted.
Methods: Thirteen individuals with 22q11DS and 34 healthy controls matched for age and sex underwent resting state fMRI. The data were analysed using spatial independent component analysis (Infomax algorithm). One-sample and two-sample t-tests were used to identify across-group networks and between-group differences, respectively. Although groups were matched on age, as brain maturation trajectories can be quite distinct in neurodevelopmental disorders, beta-values from regions of significant group-differences were also extracted and potential correlations with participants' ages were explored.
Results: Recognised RSNs were identified in all participants, including the Anterior Salience, Auditory, Default Mode (dorsal and ventral part), Higher Visual, Language, Left Executive Control, Primary Visual, and Visuospatial Network. All RSNs except for the ventral part of the Default Mode Network showed significant between-group differences, which were similar to differences reported in studies of idiopathic neurodevelopmental conditions. There was no effect of age in either group.
Conclusions: 22q11DS alters RSNs. This may constitute an intermediate phenotype and further analyses will examine the possible clinical correlates of these differences.

2 **107.002** A New Open-Source Tool for EEG Source Reconstruction in Infants

C. O'Reilly[1], *M. Elsabbagh*[2] *and T. B. Team*[3], *(1)Blue Brain Project, École Polytechnique Fédérale de Lausanne, Geneva, Switzerland, (2)McGill University, Montreal, PQ, Canada, (3)Birkbeck, University of London, London, United Kingdom*

Background: EEG studies in autism have been so far limited to scalp signals even though this kind of analysis has known limitations (e.g., noisier patterns, impossibility to relate observations to brain structures). Tools for performing cortical source estimation are now widely available. However, limited availability of structural recordings of the infant's head is among the factors hindering the adoption of latter techniques.
Objectives: With increasing availability of EEG recordings from infants at-risk for autism, our goal was to develop novel tools allowing progress in this area. We developed a population-averaged template allowing source reconstruction in one year-old infants without the need for individual participant MRI.
Methods: We used the BrainVisa pipeline to estimate a mesh surface of the cortical ribbon and some deep structures (e.g., the thalami) from the dataset of Shi et al. (2011) [PLoS One, 6(4), e18746] which contains an MRI template (average from 90 infants recorded at 1 year), tissue probability maps, and brain parcellation [Tzourio-Mazoyer, et al., (2002). NeuroImage, 15(1), 273-289]. Poor gray/white matter discriminability (typical for MRI at this age) and fuzziness due to inter-participant averaging of MRI volumes required additional manipulations to guide BrainVisa. Thus, a gray/white matter mask was computed using a Python toolbox (NiBabel) to merge the information from the gray and white matter probabilistic maps (voxels intensity < 25% of maximal intensity were set to 0; remaining voxels were classified as gray or white matter depending on the respective maps where their intensity was higher). The MRI-space Tzourio-Mazoyer parcellation was propagated to the cortical and subcortical mesh by coregistering every vertex with the corresponding voxel. BrainVisa provided a poor skull reconstruction, so Brainstorm was used for that purpose. As suggested by experimental results showing skull thickness of 1.5 to 4 mm in one year-old infants [Li et al., (2015) PLoS One, 10(5), e0127322], an 2.75 mm skull thickness was used for reconstructing the scalp, outer skull interface, and inner skull interface with boundary-element method.
Results: The resulting template is available online in the Matlab Brainstorm package and can freely be used for EEG source analysis of high-density EEG recordings.
Conclusions: Availability of these new tools will promote analyses of topologically-resolved functional connectivity in the study of autism through the estimation of EEG sources. Moreover, as data from large scale MRI studies of infants at-risk becomes available, it will be possible to improve validity of these EEG tools for infants across the first three years of life.





Reconstructed surfaces along with the projected regions of the Tzourio-Mazoyer, et al. (2002) altas.

3 **107.003** A Pharmacological MRI Study of Response Inhibition in Autism Spectrum Disorder Using Tianeptine

R. H. Wichers[1], *J. L. Findon*[1], *E. Daly*[1], *K. Rubia*[2], *C. Ecker*[1] *and D. G. Murphy*[1], *(1)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
Hyperserotonaemia is frequently reported in autism spectrum disorder (ASD). However, current drug treatments with selective serotonin reuptake inhibitors (SSRI's) further increase brain serotonin, and it is controversial whether they are effective. We recently demonstrated that an alternative approach – reducing brain serotonin using tryptophan depletion (ATD) - 'normalizes' fronto-cerebellar dysfunctions in ASD during tasks of inhibitory control that were associated with restricted, stereotyped and repetitive behaviours (Daly et al. 2014). Hence, repurposing existing drugs that reduce brain serotonin may offer a new therapeutic opportunity that can be rapidly translated to the clinic.
Objectives:
This study aimed to test the effect of the selective serotonin reuptake enhancer (SSRE) tianeptine, on inhibitory control networks in ASD.
Methods:
We included 10 right-handed adult males with ASD and 10 age- and IQ- matched controls. Pharmacological magnetic resonance imaging (phMRI) was used to compare brain activity during a Go/No-Go task under an acute dosage of 12.5 mg tianeptine and placebo in a randomised, double blind procedure. The fMRI data were analysed using a nonparametric approach to minimize assumptions (c.f. http://brainmap.it) and significance was defined as $p < .05$ corrected for multiple comparisons.
Results:
Following tianeptine dosage, adults with ASD showed a significant increase in activation compared to placebo in key inhibitory regions including left medial prefrontal gyrus, right cerebellum and right cuneus.
Conclusions:
We report proof of concept that tianeptine modulates abnormal brain activation during response inhibition in ASD. Further work is required to determine if it can be repurposed to reduce repetitive behaviours.

4 **107.004** Aberrant Brain Network Dynamics in Childhood Autism and Its Relation to Behavioral Inflexibility

K. Supekar*, S. Ryali and V. Menon, Stanford University School of Medicine, Stanford, CA*

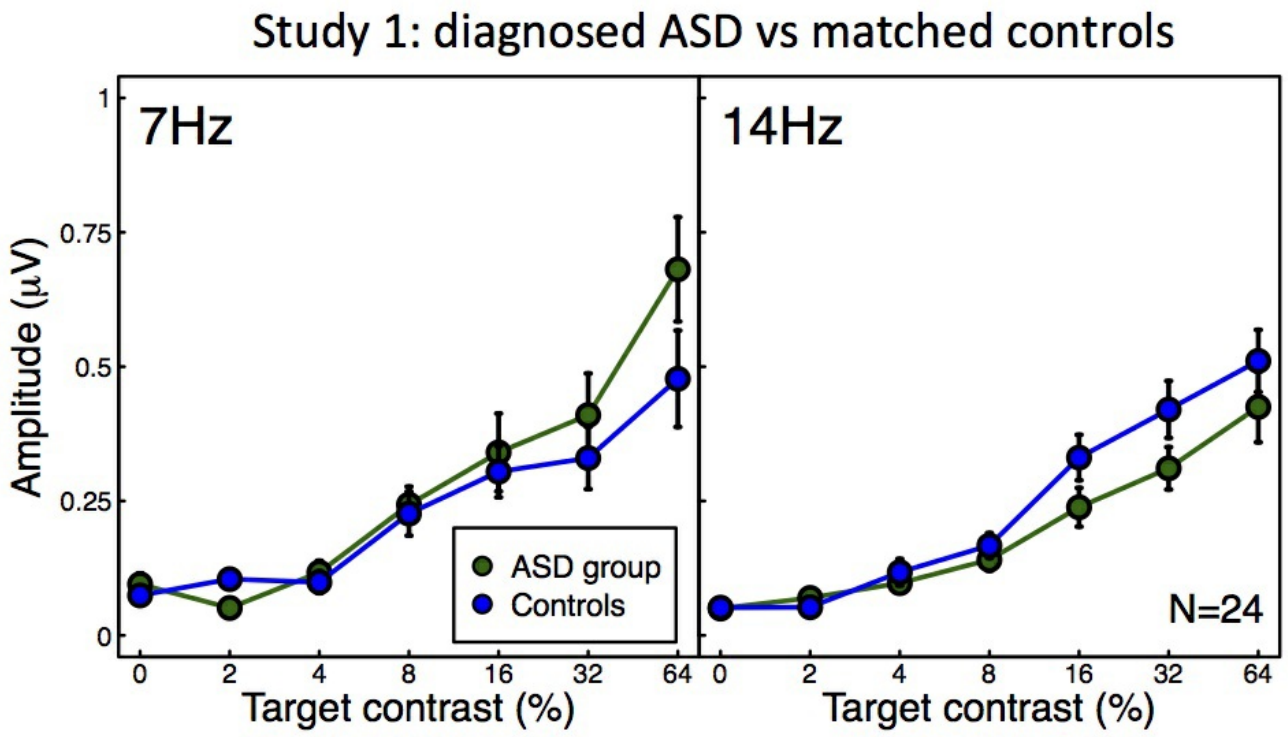
Background:
There is a growing consensus that the underlying neurobiological disturbance associated with autism spectrum disorder (ASD) is aberrant large-scale brain networks. Remarkably, to date, there have been no systematic attempts to characterize dynamic/time-varying functional interactions among these networks in children with ASD, work that is critical for understanding the etiology of this complex neurodevelopmental disorder.
Objectives:
To characterize dynamic functional interactions within a triple-network saliency model, and test the hypothesis that dynamic functional interactions among the salience (SN), central executive (CEN), and default mode (DMN) networks are dysregulated in children with ASD. We also determine whether dynamic network dysregulation measures can differentiate children with ASD from typically-developing (TD) children and predict clinical symptoms.
Methods:
One cohort of 40 children (ASD=20,age:10.1±1.6;TD=20,age:10±1.6) and a second cohort of 60 children (ASD=30,age:10.3±1.8;TD=30,age:10±1.7) participated in the study. Task-free fMRI was acquired from both cohorts.
Regional fMRI timeseries were extracted from six key network-nodes: right anterior insula and anterior cingulate cortex (SN); right posterior parietal cortex and right dorsolateral prefrontal cortex (CEN); posterior cingulate cortex and medial prefrontal cortex (DMN). We developed a novel Hidden Markov (HMM)-based method that overcomes limitations of existing approaches for estimating dynamic/time-varying functional interactions between distributed brain regions. For each participant, we applied the HMM method to the regional timeseries to identify brain states and estimate probability of each brain state at each timepoint; each brain state is characterized by distinct intrinsic functional connectivity structure. The states and dwelling times of each state calculated as frequency of occurrence of that state across time, was compared between the two groups. To determine whether the learned HMM models can be used to discriminate children with ASD from TD children, we compared the likelihood of observing the TD data given the ASD model and vice-a-versa. Lastly, we measured the relationships between the state dwelling times and the ASD symptom severity.
Results:
In Cohort 1, in both groups we found two prominent brain states: 'segregated state' characterized by strong within-network coupling and no cross-network coupling, and 'integrated state' characterized by strong cross-network coupling. Notably, brain dynamics of ASD children were characterized by less frequent 'integrated state', than TD children. HMM-based classifiers differentiated children with ASD from TD children with 84% accuracy. ASD children who showed the lowest dwelling time in the 'integrated state' had the most severe restricted/repetitive behavior.
We repeated our entire analysis on the second cohort. In spite of differences in scanner and acquisition protocols, results from this analysis replicated our findings observed in Cohort 1.
Conclusions:
Our findings provide not only provide novel evidence that alterations in dynamic coupling among the SN, CEN and DMN networks is a reproducible neurobiological signature of childhood autism but also show a link to core ASD symptomatology demonstrating for the first time that at earlier ages closer to disorder onset, the brain in children with ASD is inflexible in ways that contribute to behavioral inflexibility. More generally, the triple-network model provides a novel, replicable and parsimonious systems neuroscience framework for characterizing childhood ASD and predicting clinical symptoms in affected children.

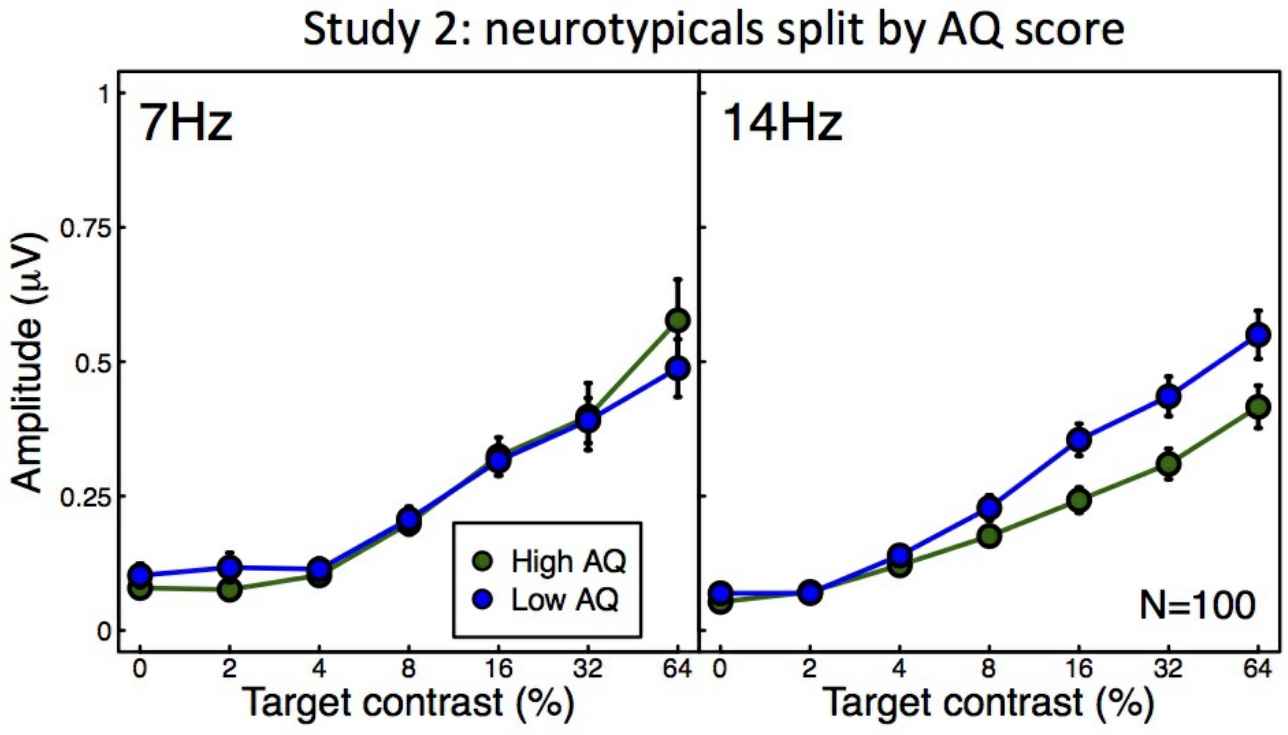
5 **107.005** Abnormalities in the Steady-State Contrast Response of Adults with High-Functioning Autism

D. H. Baker *and G. Vilidaite, Department of Psychology, University of York, York, United Kingdom*

Background:
Individuals with autism spectrum conditions (ASCs) often report hypersensitivity to intense sensory stimuli, such as loud sounds and high contrast patterns. This might be due to an abnormality in the neural transduction of sensory signals, perhaps involving differences in gain control.
Objectives:
Here we looked for objective evidence of atypical contrast responses both in adults with a clinical diagnosis of an ASC, and in the general population as a function of autistic traits.
Methods:
We used a steady-state VEP paradigm, in which observers viewed on-off flickering sine wave grating stimuli of 0.5c/deg at a range of contrasts (0-64%) whilst their EEG activity was recorded from 64 scalp electrodes. The dependent variable was the EEG amplitude at the target frequency (7Hz) or the second harmonic of the target frequency (14Hz). In study 1, 12 adult participants (1 female) had a clinical diagnosis of an ASC, and 12 participants were age- and gender-matched controls. Clinical diagnoses of ASC were confirmed by an ADOS interview, which was also completed on control participants. In study 2, 100 neurotypical adults completed the same EEG paradigm. Participants

also completed the autism quotient (AQ) (study 1) or short-AQ (study 2) questionnaire, and stated that they did not suffer from epilepsy.
Results:
In study 1, a 2x2x7 mixed ANOVA revealed a significant frequency by group interaction. Individuals with a clinical diagnosis of an ASC (mean AQ 31) had increased responses at the first harmonic, but weaker responses at the second harmonic frequency ($F_{1,22}$=4.41, p<0.05), compared with controls (mean AQ 17). These effects emerged at higher stimulus contrasts, and were not evident at baseline. In study 2, we performed a median split by AQ score. There was again a significant interaction between frequency and group ($F_{1,98}$=5.59, p<0.05), with the high AQ group (mean AQ 21) having lower amplitudes at the second harmonic than the low AQ group (mean AQ 10). This was confirmed by a significant negative correlation between AQ and the second harmonic amplitude at the highest contrast tested (r=-0.21, p<0.05).
Conclusions:
In two studies, we found a reduction in the amplitude of the second harmonic response that was associated with both clinically diagnosed autism, and higher levels of autistic traits. Second harmonic responses are believed to originate from complex cells in primary visual cortex that code for changes in contrast. This finding might therefore explain the poorer performance of children with ASC on a contrast discrimination task (Greenaway et al., 2013, *Neuropsychologia*). We also observed increased first harmonic responses in individuals with an ASC diagnosis. This is similar to findings in individuals with epilepsy (though none of our participants had ever experienced a seizure), and may be related to feelings of discomfort elicited by intense visual stimuli. In a companion study, we have found analogous effects in a fly genetic model of ASC, involving mutations of the sodium-hydrogen exchanger gene, Nhe3. This suggests that the cellular processes mediated by this gene might be responsible for sensory abnormalities commonly experienced in autism.





6 **107.006** Adaptive Neural Mechanisms in Individuals with Autism for Integrating Multisensory Real-World Stimuli

P. J. Webster[1], *C. Frum*[1], *C. Bauer*[1], *A. Kurkowski-Burt*[2], *N. Mardmomen*[3], *M. Gray*[4] *and J. W. Lewis*[1], *(1)Neurobiology & Anatomy, West Virginia University, Morgantown, WV, (2)Occupational Therapy, West Virginia University, Morgantown, WV, (3)Biology, West Virginia University, Morgantown, WV, (4)Psychology, West Virginia University, Morgantown, WV*

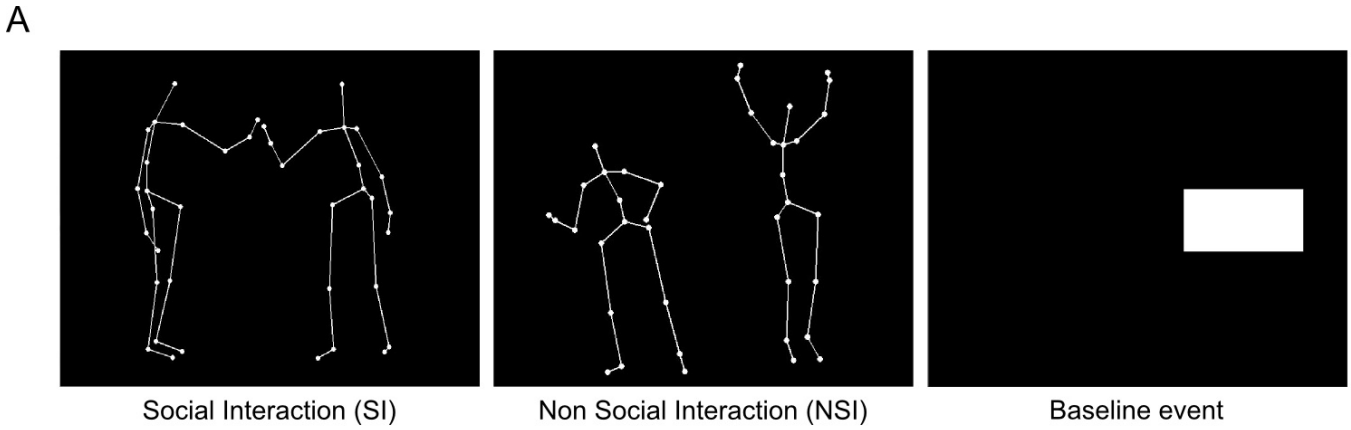
Background: Individuals on the autism spectrum can over respond or under respond to every-day sights, sounds, smells, etc. This sensory processing dysfunction is a pervasive aspect of autism that increases anxiety and negatively impacts language development and social interactions. The ability to appropriately process sensory

information is developed early in life based upon our experiences. After birth our brain learns to integrate what we see and hear so that information comes together in the correct timeframe, e.g. listening to someone speak while watching their mouth move. It is critical that the brain processes auditory information in synch with the visual information as this increases attention and is crucial for language development. Individuals with autism have been shown to integrate sensory information, but over a wider timeframe than their peers. This wider temporal binding window can impact their brain's ability to benefit from multiple sensory inputs and may contribute to aberrant sensory processing. Exactly how the brain can be re-organized to process audiovisual interactions remains unresolved.
Objectives: We are using functional magnetic resonance imaging (fMRI) to characterize adaptive cortical mechanisms for processing audiovisual information in high-functioning individuals with autism. Neuroimaging results will be correlated with behavioral measures of sensory processing and integration. We also sought to use socially relevant stimuli in order to more precisely examine how the brain responds when processing real-world events in the environment.
Methods: While in the 3T MRI scanner, participants watched a video of someone bouncing a basketball (a socially relevant stimulus). Their task was to press a button when they perceived the ball to touch the ground. The video included an audiovisual condition (bi-modal; see and hear the action), a visual only condition (uni-modal; only see the ball dribbled), and a resting condition (baseline control; actor holding basketball). Participants included high-functioning individuals with autism (aged 18-28 years) as well as individuals without autism matched for age and gender. Brain regions activated during the unimodal and bimodal conditions, relative to the baseline condition, were modeled using multiple linear regression analyses (NIH AFNI software). Individual datasets were transformed into Talairach coordinate space, and groups were compared and contrasted across conditions using t-tests.
Results: Both groups showed similar activation in primary auditory and primary visual cortices when processing audiovisual information. However, differences were seen between the two groups across the two conditions (uni-modal vs. bi-modal; $p<0.01$, corrected). The group with autism revealed increased activation in portions of cingulate cortex and middle temporal gyrus compared to individuals without autism. Conversely, individuals without autism showed increased activation in left inferior medial-posterior insula, which persisted in all individual datasets.
Conclusions: The functional roles of the cortical regions differentially activated provide important clues as to possible adaptive mechanisms that high-functioning adults with autism are using at a systems level to cope with audiovisual interactions. Correlations between neuroimaging results and sensory profile sub-scores may reveal autism subtypes that can be explored further.

7 **107.007** Altered Connectivity Between Brain Regions Involved in Social Body Motion (BM) Perception in Adults with Autism: A fcMRI Study

P. Duret[1,2], *M. V. Kujala*[3], *G. Riot*[4], *S. Sonié*[2], *D. Meunier*[2], *N. Georgieff*[4], *M. A. Hénaff*[2], *L. Mottron, M.D.*[1], *P. Fonlupt*[2] *and C. Schmitz*[2], *(1)Centre d'Excellence en Troubles Envahissants du Développement, Montréal, QC, Canada, (2)Lyon Neuroscience Research Center, Lyon, France, (3)Department of Equine and Small Animal Medicine, Faculty of Veterinary Medicine, Helsinki, Finland, (4)CH Le Vinatier, Bron, France*

Background:
Atypical comprehension of, and attention to social communication are core symptoms characterizing the Autism Spectrum (AS). Among other aspects, social communication includes processing information provided by body language, or Body Motion (BM). BM can be depicted using point-light displays, a minimalistic presentation of humans in action. Previous studies evidenced that autistic people were able to recognize simple actions through BM (Paron et al., 2008), but were less accurate when BM carried an emotional or social content (Centelles et al., 2013). Processing Social BM involves a large set of cerebral regions belonging to the mentalizing (MN) and the Mirror Neuron (MNS) systems, the basal ganglia and parts of the cerebellum.
Objectives:
We investigated putative autistic vs non-autistic group differences in regional activity and connectivity, in brain regions involved in BM processing. Altered activity and connectivity were predicted among the components of MN and MNS networks in the AS group, in parallel with superior involvement of the visual regions.
Methods:
Using fMRI, we recorded brain activity when participants watched point-lights videos of two actors either engaged in a Social Interaction (SI) or moving without interacting (NSI). Fifteen AS (diagnosed according to the DSM-IV criteria using the ADI-R and/or ADOS) and fifteen non-AS participants matched on age, IQ and gender performed a SI/NSI recognition task. Groups were compared in terms of behavioral performance, cerebral activity and functional connectivity. The connectivity analysis was performed on regions of interest (ROI) selected in the functional contrasts based on their reported implication in social BM processing. Regions belonging to the MN, MNS, the striatum and the cerebellum were included together with visual areas that are known to be over-implicated in visual social and non-social tasks in autism. Clusters detected in each group were pooled, resulting in one set of ROI which individual time-series were extracted. A General Linear Model was designed to take into account the variations due to the task. Finally, correlation coefficients were extracted for each pair of ROI, for all-task, and for each condition: SI, NSI, BM (SI+NSI) and Control. Non-parametric statistical tests were used and False Discovery Rate correction was applied.
Results:
AS were significantly slightly less accurate than non-AS participants to recognize SI only (93% and 86% correct for non-AS and AS respectively). Functional activations in non-AS were found in expected regions. The AS group showed sparser activation, with a strong implication of the striatum and primary visual cortex, the latter being nevertheless under-connected to the other ROI in the connectivity analysis. We also found evidence of atypical MNS involvement in the task and significant under-connectivity of the medial pre-frontal cortex (MPFC) during social processing. Surprisingly, a striatal over-connectivity was associated with the processing of BM and its social clues in autism.
Conclusions:
By investigating the neural correlates of BM processing in AS, this work evidenced the use of atypical mechanisms by autistic people, who seemed to rely more on the strong implication of striatal and visual systems that might compensate for the under-implication of the MPFC in this task.



8 **107.008** Altered Recruitment of the Brain's Reading Network in Children with Autism

H. Bednarz, *J. O. Maximo, D. Murdaugh and R. K. Kana, University of Alabama at Birmingham, Birmingham, AL*

Background: Autism spectrum disorders (ASD) are characterized by language deficits, which often entail difficulties in reading comprehension. Reading consists of decoding (the ability to translate letters into spoken language) and comprehension (the ability to understand what spoken words mean). While a proportion of children with autism show intact decoding skills, many exhibit significant deficits in comprehension (Nation et al, 2006). Such deficits may underlie altered recruitment of the language association cortex. Only a few neuroimaging studies have examined reading comprehension and its underlying neurobiology in autism.
Objectives: To examine the functional integrity of the brain's reading network in children with ASD and to relate it to their neuropsychological profile.
Methods: Nineteen high-functioning children with ASD and 16 typically developing (TD) control children participated in this study. The participants were matched on age (8-13 years), gender, handedness, full-scale IQ, verbal IQ, and fluency/decoding. Children completed a word similarities task in the scanner, in which they read a set of four words and determined whether the fourth word was similar to the previous three words presented (e.g. *orange, apple, mango,* table). fMRI data collected on a 3T Siemens Allegra scanner were analyzed using SPM12. Brain activation in regions within a previously identified reading network (Koyama et al., 2011) was examined.
Results: A 2-sample t-test revealed significantly decreased activity in ASD children, relative to TD children, in the left superior-temporal gyrus (LSTG), left supramarginal gyrus/angular gyrus (LSMG/AG), and middle occipital area ($p<0.05$, 300 voxels). ASD participants had significantly lower reading comprehension scores ($M = 77.6$, $SD = 13.3$) than TD controls ($M = 99.7$, $SD = 14.1$); $t(33) = 4.74$, $p<.001$, as measured by the Gray Oral Reading Test (GORT-4). In addition, the GORT comprehension scores predicted activation patterns in ASD participants in bilateral frontal and thalamic regions, a trend not seen in TD participants. Similarly, the accuracy of ASD children in the word similarities task was positively correlated with their GORT comprehension scores ($r = 0.559$, $p <0.05$).
Conclusions: Reduced activation in LSTG and LSMG/AG in ASD children may suggest difficulty in phonological as well as semantic processing (Bigler et al, 2007; Buchsbaum, 2001; Hickok & Poeppel, 2007). Since fluency was relatively intact in our sample, it is possible that ASD subjects used alternate methods to decode the words (e.g. memorization of words, pattern recognition). The relationship between GORT comprehension and bilateral frontal and thalamic activation in ASD children in our study may suggest a moderating effect of the thalamus on language comprehension in ASD (Klostermann, Krugel, & Ehlen, 2013). Thus, the results of this study provide evidence for altered recruitment of language areas in ASD children with intact fluency accompanied by poor comprehension; this may underlie differences in phonological and semantic processing. These findings have important implications for developing neurobiologically informed and targeted reading interventions in ASD.

9 **107.009** Altered Timing of Event Related Potentials in the Praxis Network of Children with High Functioning Autism

D. McAuliffe[1], *T. L. Johnson*[2], *M. Hallett*[3], *N. E. Crone*[4], *A. Pillai*[1], *S. H. Mostofsky*[5] *and J. B. Ewen*[6], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Neurology and Developmental Medicine, Kennedy Krieger Institute, Baltimore, MD, (3)National Institute of Neurological Disorders and Stroke, Bethesda, MD, (4)Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, (5)Johns Hopkins School of Medicine, Baltimore, MD, (6)Kennedy Krieger Institute/JHUSOM, Baltimore, MD*

Background: Autism Spectrum Disorders (ASD) cardinally affect social and cognitive function, but motor domain deficits are also prominent and offer a well characterized window to observe altered brain physiology. Performance of learned skill movement – praxis – is deficient in children with ASD and is correlated with deficiencies across other domains. Altered connectivity hypotheses suggest information transmission may be impaired in ASD; specific hypotheses, such as *slowed* transmission, however, have rarely been tested directly. EEG can shed light on the timing and activation of left central and parietal regions that constitute the praxis network.
Objectives: To identify timing differences in various components of the praxis network in ASD, during tool-use motor preparation and pantomime (execution), using event-related potentials (ERPs).
Methods: 25 children with high functioning autism (HFA) and 33 typically-developing (TD) controls, aged 8-12 years, pantomimed the use of tools while EEG was recorded. Each participant observed a picture of a tool for 3 seconds and then was signaled to pantomime the tool use for 3 seconds. Event related potentials (ERPs) were time locked to the onset of stimulus picture, with the Prepare phase computed at 0-1s and the execution phase at 3-4s relative to the stimulus picture onset. The signal was analyzed in 2 channels each from left parietal (LP1, LP2) and 2 from left central (LC1, LC2) scalp regions. Timing of ERPs was assessed using rectified area latencies, calculated using time to reach 50% of total area within the praxis tool Prepare and Execution windows. *Post hoc*,we examined relative latencies between parietal and central regions.
Results: We first examined group differences in mean latencies of each of the 4 channels, separately in both Prepare and Execution phases. Only one of the left central channels (LC1) showed significant group differences, and only during Execution: children with HFA showed slower activation by an average of 67ms ($p = 0.03$). *Post hoc,* we found that LC1 activation followed LP1 (77ms, $p = 0.04$) activation significantly during the Execution in the HFA group. No parietal-central lag differed from zero in the TD group.
Conclusions: In children with HFA, activation of central, motor regions during tool-use gesture pantomime was delayed compared with controls. Further, controls showed zero-lag parietal-central activation, whereas children with HFA showed a significant delay in central activation compared with parietal regions. These findings are consistent with the literature that suggests slowed transmission in the central nervous system in ASD. These findings motivate further studies of information transfer characteristics in ASD and their relationship to clinical findings.

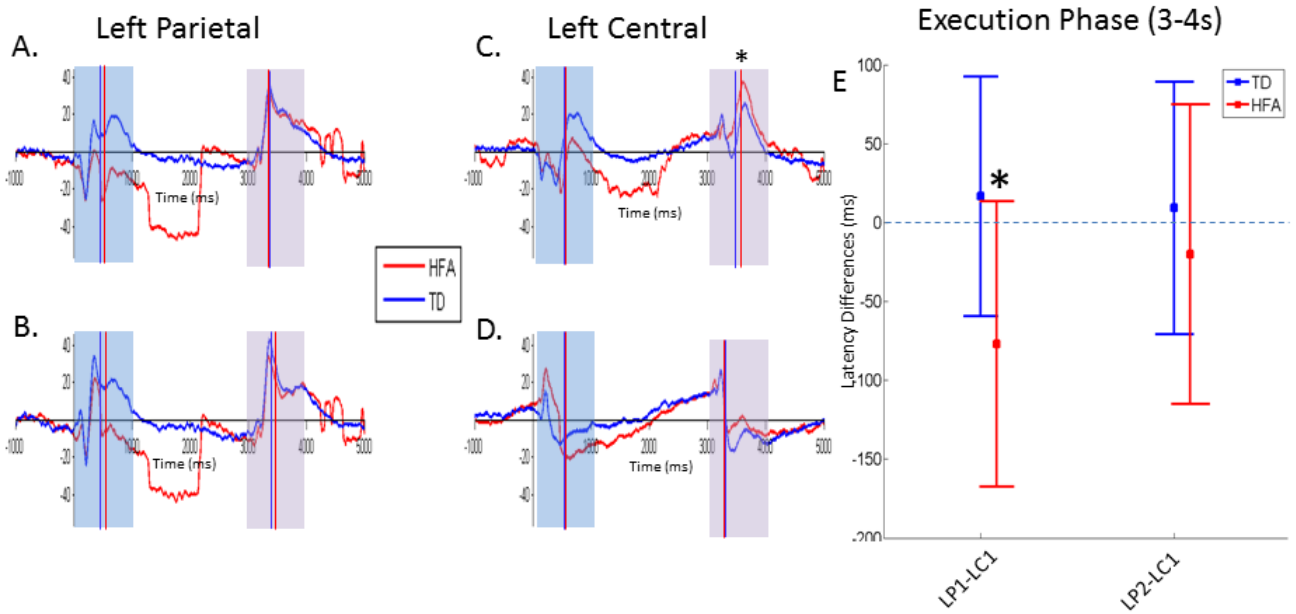


Figure 1: Panels A-D show the grand averaged ERP for the left parietal (LP1, LP2) and left central (LC1, LC2) channels. The vertical bars indicate the measured mean 50% fractional area latency. Highlighted regions are the Preparation phase (blue, 0-1s) and the Execution phase (purple, 3-4s). The only group difference was in LC1, with HFA showing significantly delayed activation in this central channel in Execution, compared with controls.

Panel E shows the relative latency differences between the significant central channel (LC1) and the two parietal channels (LP1, LP2). LC1-LP1 in the HFA group was significantly different from zero lag. * Indicates significance $p<0.05$.

10 **107.010** Atypical Working Memory-Related Brain Activation and Connectivity in Adolescents with Autism Spectrum Disorders

K. R. Bellesheim[1], *J. P. Stichter*[2], *K. E. Bodner*[1,3], *J. L. Sokoloff*[1] *and S. E. Christ*[1], *(1)University of Missouri, Columbia, MO, (2)Department of Special Education, University of Missouri, Columbia, MO, (3)Department of Health Psychology, Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO*

Background: Recent studies have reported atypical functional brain connectivity (i.e., correlations in neural activity between brain regions) in individuals with autism spectrum disorder (ASD; Koshino et al., 2005; Cherkassky et al., 2006). Research on healthy non-ASD individuals suggests that the degree of functional connectivity between brain regions is often not static but rather varies as a function of the task being performed. For example, when transitioning from a period of rest to the performance of a working memory task, the synchronization of activity within the 'working memory' network of brain regions may increase. One such working memory-related region is the left intraparietal sulcus (IPS), which previous research suggests is a 'core' critical region for working memory (Cowan et al., 2010).
Objectives: The goal of the present study was to evaluate potential ASD-related disruptions in patterns of rest-based and task-based activation and interrelations involving the left IPS. To accomplish this, functional activation and psychophysiological interaction (PPI) connectivity analyses were utilized in individuals with and without ASD during rest and during performance of a non-verbal working memory task.
Methods: A sample of 19 adolescents with ASD (mean age = 13.1 yrs; range: 11-15 yrs) and 21 typically developing adolescents without ASD (mean age = 13.2 yrs; range: 11-16 yrs) participated. Functional MRI scans were obtained while participants completed two conditions (2-back and 0-back) of an *n*-back non-verbal working memory task using a series of novel face stimuli. Each participant completed two functional runs, with each including 6 counterbalanced task epochs (3 per condition). PPI connectivity analysis was conducted to assess for differences in patterns of functional connectivity between a seed region, the left IPS, and the rest of the brain during task versus rest periods.
Results: Whole brain analysis revealed several regions-of-interest (ROIs) demonstrating significant condition (0-back and 2-back) x group (ASD and non-ASD) interactions in neural activation. ROIs included the left IPS, left ventrolateral prefrontal cortex, right superior temporal cortex, and left fusiform gyrus [$F(1,38) > 7.94$, $p < .005$ cluster-thresholded, in all instances]. A significant PPI was observed between the left IPS and the anterior cingulate cortex (ACC) [$F(1,38) = 14.59$, $p< .005$ thresholded]. Whereas the non-ASD group showed a decrease in functional connectivity between the aforementioned regions during task performance compared to rest, the ASD group showed the opposite pattern (increased connectivity during task compared to rest).
Conclusions: Consistent with past neuroimaging studies, individuals with ASD demonstrated altered neural activation and functional connectivity compared to individuals without ASD both during a non-verbal working memory task and during resting period. Results of the current analysis further suggest ASD-related disruptions in the extent to which connectivity between regions changes as a function of task demands. Further analyses will examine the potential relationship between this phenomenon and cognitive, social, and behavioral functioning.

11 **107.011** Amygdala Hyperconnectivity during Adaptive Executive Control of Social Information Processing in Autism Spectrum Disorders (ASD) Children

J. B. Cherry[1], *X. You*[2], *R. Ludlum*[3], *W. D. Gaillard*[2], *L. Kenworthy*[4] *and C. J. Vaidya*[5], *(1)Psychology, Georgetown University, Washington, DC, (2)Children's Research Institute, Childrens National Medical Center, Washington, DC, (3)Department of Psychology, Georgetown University, Washington, DC, (4)Children's Research Institute, Children's National Medical Center, Rockville, MD, (5)Georgetown University, Washington, DC*

Background:
Social communication, an area of impairment in ASD, involves dynamic interaction between social information processing (e.g., eye gaze) and flexible executive control of actions in the service of goals. We have reported that ASD children engage a more widespread network of regions connected to the amygdala during executive control of social cues in a novel Stroop-like interference task, suggesting difficulty suppressing emotional reactivity during executive control (Murphy et al., 2012). Here, we examine *context-adaptation* reflecting dynamic executive control of social cues, manifested in trial-to-trial adjustments in control evoked by variable proportion of incongruent and congruent trials – higher adjustment is needed in a block of 25% incongruent and 75% congruent trials relative to a block with 75% incongruent and 25% congruent trials. Such adaptive executive control is reflective of real-world social interaction.
Objectives:
To examine amygdala functional connectivity during adaptive executive control of socially significant information processing in 7-14 year-old ASD and control children.
Methods:
Imaging was performed at 3T in 73 children (age, gender, and IQ matched 38 ASD, 35 controls) during 2 runs of the Stroop-like task requiring a left/right handed response to the direction indicated by a word (LEFT or RIGHT) positioned on the nasion of faces appearing in color with neutral facial expression. Across trials, eye-gaze direction varied such that relative to the target word, it was either congruent (leftward gaze and "LEFT" word) or incongruent (leftward gaze and "RIGHT" word). Unbeknownst to the subjects, the proportion of incongruent (I) and congruent (C) trials varied across blocks (25I-75C%; 50I-50C%; 75I-25C%) with jittered trials within blocks to allow selective averaging of incongruent and congruent trials.
Images were slice-time and motion-corrected, normalized and resliced to 3mm, smoothed with 8mm FWHM and using stringent motion-criteria retained 38 children (16 ASD, 22 controls). Functional connectivity was analyzed using psychophysiological interaction in SPM8, for right and left amygdala ROIs based on the AAL brain atlas, separately

for Incongruent and congruent trials. Regions showing differences between ASD and control groups for 25I-75C% vs. 75I-25C% contrast were identified with a whole-brain ANOVA in SPM 8 (p < .05 Monte Carlo corrected; p<.001, k=24 voxels).
Results:
Performance was slower for incongruent than congruent trials indicating interference suppression associated with greater executive control. Interference was higher for 25I-75C% relative to 75I-25C% blocks but did not differ by group. For both left and right amygdala, connectivity was greater in ASD than control children for incongruent trials, with right superior temporal sulcus and precuneus, important for gaze processing. Additionally, left amygdala also had greater connectivity with bilateral supplementary motor and striatal regions, involved in response inhibition and superior and inferior parietal cortex involved in spatial attention. Connectivity for congruent trials did not differ between groups for the left amygdala, but was greater with the left lingual gyrus, a visual processing region in ASD than control children.
Conclusions:
These findings draw attention to hyperconnectivity of the amygdala with striatal and temporo-parietal regions as loci of network disturbances contributing to social interaction difficulties in ASD.

12 **107.012** An Analysis of Resting EEG Data in Infants at High-Risk for Developing ASD

***T. Y. Kim**, A. Naples, M. Rolison and J. McPartland, Child Study Center, Yale School of Medicine, New Haven, CT*

Background:
Clinical diagnoses of autism spectrum disorder can be made as early as two years of age, but experimental evidence suggests that atypical patterns of attention and brain activity in infants who later develop autism may be present in the first months of life. Measurement of EEG in infancy provides a direct, non-invasive measure of cortical activity. Differences in EEG spectral power during rest have successfully discriminated children with ASD from controls and have been shown to correlate with clinical characteristics. Recent studies suggest that ASD can be characterized by atypical neural oscillations, such as decreased alpha power and increased theta power in adults relative to children. By measuring resting brain activity in infants at high (HR; older sibling with ASD) and normal risk (NR; no family history of ASD) for ASD, it may be possible to identify anomalous brain activity preceding emergence of behavioral symptoms.
Objectives:
The current study compared resting EEG spectral power in 6-24 month old HR and NR infants to assess (a) overall oscillatory power differences and (b) patterns of relative power within groups. We further assessed different patterns of age-related change in the EEG between groups.
Methods:
In a longitudinal design, HR (n = 28, 46 sessions) and NR (n = 21, 31 sessions) infants were assessed at 6, 9, 12, and 24-months of age. EEG was recorded for 2 minutes with a 128-channel Hydrocel Geodesic Sensor net while infants observed bubbles blown by an experimenter. Data from electrodes over frontal scalp were processed with Netstation v4.5 through a first-order high-pass filter, a 100 Hz low-pass filter, and segmented into 120 1s epochs hand-edited for artifacts. The cleaned data was subjected to a Hann window and spectral power was estimated using a Fast Fourier Transform.
Results:
Preliminary analyses indicated that the ratio of alpha-to-theta (HR mean = -.4330, NR mean = -.3751, mean difference = .05787, p = .024) and the ratio of alpha-to-beta power (HR mean = .2671, NR mean = .3083, mean difference = .04121 in direction of NR, p = .017) differed between HR and NR infants. In NR infants, power in the beta frequency band was significantly correlated with age (r = .366, p = .043) but not in HR infants (r = .099, p = .513). Ongoing analyses explore patterns of coherence across scalp regions.
Conclusions:
Results indicate different patterns of oscillatory brain activity with different maturational trajectories in HR versus NR infants. HR infants displayed decreased levels of alpha relative to both beta and theta activity. The lack of developmental change in beta activity in HR infants suggests atypical maturation of feedback connectivity in children at a higher risk of ASD. By identifying differences in neural oscillations in early life before behavioral symptoms emerge, differences in oscillatory power have the potential to serve as early biomarkers of ASD, as well as to provide insight into neural mechanisms of ASD that may inform novel forms of early intervention.

13 **107.013** An Effective Connectivity Approach to Autism Spectrum Disorders

***S. Vettori**[1,2,3], D. Marinazzo[2], B. Boets[1,3] and R. Siugzdaite[2,4], (1)Child and Adolescent Psychiatry, KU Leuven, Leuven, Belgium, (2)Data analysis Department, Ghent University, Gent, Belgium, (3)Leuven Autism Research consortium (LAuRes), KU Leuven, Leuven, Belgium, (4)Experimental psychology department, University of Ghent, Ghent, Belgium*

Background:
Many neuroimaging studies indicate that autism spectrum disorders (ASD) are characterized by aberrant functional connectivity. However, the nature and directionality of these aberrant connections remain largely unknown and under-investigated.
Objectives:
With a novel combination of advanced neuroimaging data analysis methods, we aim to understand the directionality of these aberrant functional connections.
Methods:
We used resting state fMRI data of the Autism Brain Imaging Data Exchange database (ABIDE) from 21 participants with ASD and 21 IQ-matched typically developing (TD) children (age range: 7-12 years). First, we used functional connectivity density mapping (FCD), a whole-brain data-driven method, to identify local and global differences in functional connectivity density between resting-state fMRI data of the ASD and the TD group. Then we used partially conditioned Granger causality analysis to investigate the directionality of those connections that showed group differences in functional connectivity density. With this method, a reliable estimate of group differences in directed connectivity was obtained.
Results:
Local and global functional connectivity density mappings reveal clusters with more dense short-range local and global connections in four subcortical and five frontal regions in the ASD group, as compared to the TD group. Granger causality indicates that both the incoming and the outgoing information flow is increased in ASD in 7 of these 9 regions. However, in the right caudate and the left inferior frontal gyrus (two regions known to be involved in ASD), the incoming information flow is higher than the outgoing flow in ASD, while this pattern is reversed in the TD group.
Conclusions: With a novel combination of advanced neuroimaging data analysis methods, we investigated differences in dynamical functional connectivity and in the directionality of information flow between children with ASD and TD controls. For the right caudate and the left inferior frontal gyrus (relevant for respectively sensorimotor control and language processing), we found that children with ASD show more incoming and less outgoing functional connections than TD controls. Accordingly, this may indicate that information from these two regions is less transferred to control other regions in a top-down manner, which may relate to deficits in sensorimotor control and language processing in ASD. We conclude that this pattern of inverted effective connectivity in right caudate and left inferior frontal gyrus in ASD may explain some of the inconsistencies in the literature, and that this novel finding provides important insights in the neurobiological origin of ASD.

14 **107.014** Attention and Brain Response during Simulated Social Interactions in ASD

***A. Naples**, M. Rolison, J. H. Foss-Feig, K. K. Stavropoulos, T. Winkelman and J. McPartland, Child Study Center, Yale School of Medicine, New Haven, CT*

Background:
Difficulties with eye-contact represent some of the earliest observable symptoms of autism spectrum disorder (ASD). While difficulties with eye-contact are clinically diagnostic, experimental investigations of gaze processing have yielded mixed results. Prior work has focused primarily on experiments in which individuals with ASD passively observe faces. Our preliminary work assessing response to mutual gaze has revealed ERP markers of eye-contact. The N170 and P300, temporally early electrophysiological components, show variability in response to shared gaze that track with clinical characteristics. Further, eye movements to interactive faces distinguish between groups and reflect variability in the clinical phenotype.
Objectives:
To investigate neural processing of interactive eye-contact; investigate attention by measuring eye-movements during interaction with an onscreen face; and evaluate the relationship between neural and attentional markers of eye-contact and clinical characteristics.
Methods:
ERPs were recorded from 44 children with ASD (M =14.5 years, mean IQ =103) and 44 controls (M =13.7 years, mean IQ=107) using a 128 electrode Geodesic Net. Eye movements were recorded with an SR-Research Eyelink 1000 integrated with EEG recording. Through co-registered and time-locked ET and EEG, the experiment was controlled by participant gaze. Trials began with a centrally presented face displaying direct or averted gaze. Contingent upon participant fixation, the face responded by either looking at (eye contact) or away (averted gaze) from the participant. ERPs were time-locked to face movement.
Results:
Preliminary analyses of eye-tracking data using linear mixed models indicated that, when initially looking to faces, individuals with ASD show longer gaze latency than controls [B = 83.10, p = .02], but an interaction between condition (gaze direction) and group [B = 49.5 p = 0.08] revealed that control participants looked more slowly to faces showing averted gaze. Region of interest analyses indicated that children with ASD looked less to the left eye of the face [B = 40.0, p = .06]. Analyses of pupil size revealed an interaction [B = 4.1, p = .06], such that individuals with ASD exhibited pupil dilation following direct gaze whereas controls exhibited constriction. Preliminary analyses of

ERP data revealed that averted gaze elicited a more positive P300 in both groups [$p < .05$], although an interaction revealed that increasing levels of anxiety predicted more positive P300s for direct gaze [B = 0.063, $p = 0.06$]. Analyses in progress investigate brain response to mutual gaze and the relationship between attentional dynamics and clinical characterization.

Conclusions:

We demonstrate an electrophysiological marker of reciprocal gaze perception that is sensitive to clinical characteristics and a pattern of attenuated attention, but increased arousal, to direct gaze in individuals with ASD. Our ERP findings suggest that direct gaze perception is associated with anxiety regardless of group assignment. Relationships between pupillary dilation and anxiety suggest that mechanisms of arousal associate with social brain response and reflect meaningful variability in the clinical phenotype. By linking both eye-tracking and EEG during social interactions, we can gain insight into the complex interrelationship between attention and brain response to social information during the course of an interaction.

15 **107.015** Atypical Functional Heterogeneity of the Right Temporo-Parietal Junction in Autism Spectrum Disorders

D. Moraczewski[1] *and E. Redcay*[2]*, (1)University of Maryland, College Park, MD, (2)Department of Psychology, University of Maryland, College Park, MD*

Background:

The right temporo-parietal junction (rTPJ) sits at the border of the dorsal and ventral attention and fronto-parietal networks. This region is associated with increased activation during social-cognitive and attention tasks in neurotypical (NT) individuals, whereas individuals with ASD display atypical activation. Deficits in these behaviors are a core phenotype of ASD, thus the rTPJ is a crucial region to understand the relationship between brain and behavior in this disorder. In NT, the rTPJ displays a heterogeneous organization of distinct sub-regions, each of whom show differential task activation and intrinsic functional connectivity. This functional organization has also been shown to specialize with age. Thus, regional heterogeneity may reflect optimal age-related local and network-wide specialization for efficient task engagement. Atypical specialization of this region in ASD may contribute to the social and attention deficits seen in the ASD phenotype. However the relationship between heterogeneity of the rTPJ and the behavioral deficits in ASD are unknown.

Objectives:

The objectives of the current study are to compare intrinsic rTPJ heterogeneity in NT and ASD. We also examine regional organization for age-related changes and relationships with diagnostic assessment scores in the ASD group.

Methods:

We used a large, multi-site sample (N = 240, 107 ASD) of NT and ASD resting-state data from the Autism Brain Imaging Database Exchange. We started with a rTPJ region defined within the default mode network from the Yeo et al., 2011 functional atlas and progressively dilated the original ROI three times in order to progressively expand the borders into other networks. Then, using principal component analysis, we extracted the percent variance explained by the first eigenvector of time-series at each ROI level as a measure of regional heterogeneity (i.e., reduced percent variance is associated with greater heterogeneity). We expect this measure to be inversely related to ROI size, a pattern that highlights increased heterogeneity as the ROI expands. However, we hypothesize that the ASD group will show less heterogeneity compared to the NT group, suggesting less functional specialization. We then examined regional heterogeneity for age-related changes and relationships with diagnostic scores in ASD.

Results:

A within-group main effect was detected for ROI size ($F(3,948) = 5.04$, $p < .002$), which demonstrates that region dilation yields increased heterogeneity. Between-group differences were only detected at the largest two ROIs (second dilation: $t(240) = 1.95$, $p < 0.05$; third dilation: $t(240) = 2.17$, $p < 0.03$) showing that the ASD group displayed less heterogeneity at the largest two ROI sizes. No relationship was detected with respect to age. Also, no relationships with diagnostic scores were detected, however there was large variability between sites.

Conclusions:

We found that as region size increased, regional heterogeneity decreased in both groups. In addition, the ASD group displayed less heterogeneity than the TD group in the largest two ROI dilations. This suggests that there may be less functional specialization at the network borders surrounding the rTPJ, which could have important implications for understanding brain organization in ASD.

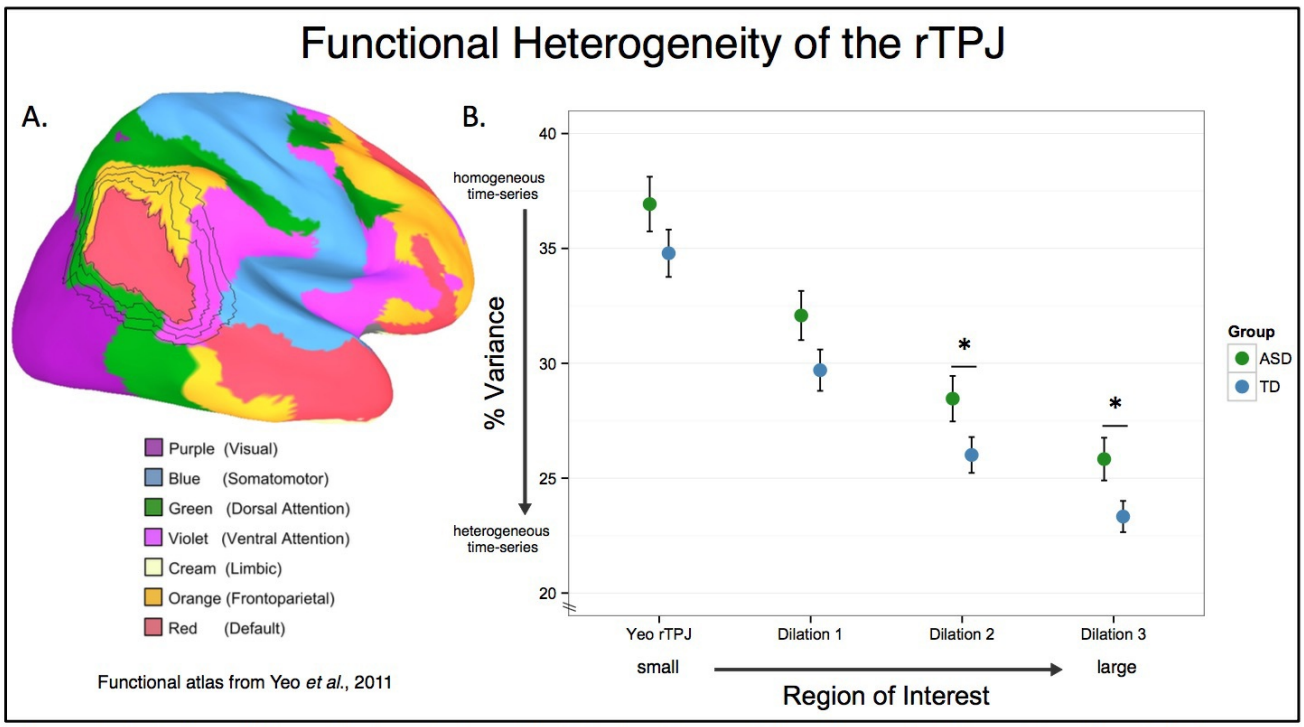

Figure 1: **A**. Starting with the original rTPJ region of the default mode network from Yeo, *et al.*, 2011, we dilated the ROI 3 times (black outlines) in order to capture the borders of other resting-state networks (see color legend for network specification). **B**. Percent variance explained by the first eigenvector of time-series from each ROI is shown by group. Lower variance denotes greater heterogeneity. Bars denote standard error. Significant between-group differences using Welch's *t* are denoted with * (Dilation 2: $t(240) = 1.95$, $p < 0.05$; Dilation 3: $t(240) = 2.17$, $p < 0.03$).

16 **107.016** Atypical Intrinsic Functional Connectivity of Core Face Perception System Is Associated with Symptom Severity in ASD

W. Zhao[1]*, I. Fishman*[2]*, R. J. Jao Keehn*[2] *and R. A. Müller*[2]*, (1)Psychology, San Diego State University, San Diego, CA, (2)San Diego State University, San Diego, CA*

Background: One of the core symptoms of Autism Spectrum Disorder (ASD) is a deficit in social communication. Individuals with ASD have impairments in face processing, a crucial component of reciprocal social interactions, including deficits in gaze processing and face identification. Face processing relies on the core face perception system, which includes the fusiform face area (FFA), occipital face area (OFA), and the posterior superior temporal sulcus (pSTS).

Objectives: Given the observed deficits in face perception in ASD and the prevalent theory that ASD is a disorder of network dysfunction and abnormal brain connectivity, we examined the functional network organization of the core face perception system in children and adolescents with ASD using intrinsic functional connectivity (iFC).

Methods: We performed whole-brain iFC analysis using bilateral FFA, OFA and pSTS as seed regions (Tahmasebi et al., 2012) in 35 children and adolescents with ASD (aged 8-17 years) and 36 typically developing (TD) participants matched for age, gender, IQ, and in-scanner head motion.

Results: Between-group comparisons revealed two main clusters of differential iFC shared across most seeds. Underconnectivity (ASD < TD) with the right IFG, part of the extended face perception system (Fairhall & Ishai, 2007), was found for bilateral FFA, right OFA, and bilateral pSTS seeds. The degree of underconnectivity between right IFG and right FFA, and between right IFG and right OFA was correlated with ADOS-2 Total scores, such that weaker connectivity, compared to TD, was associated with greater symptom severity. Overconnectivity (ASD > TD) with the PCC was found for the bilateral FFA and OFA seeds. Additionally, right FFA seed also yielded overconnectivity in or close to default mode network (DMN) nodes, including the mid orbital gyrus and bilateral angular gyri. The extent of overconnectivity between right FFA and DMN regions was also correlated with ADOS-2 Total scores: Individuals with ASD with greater connectivity between right FFA and DMN regions had more ASD symptoms.
Conclusions: Our findings indicate atypical iFC patterns of core face perception regions in children and adolescents with ASD. Individuals with ASD exhibited reduced segregation between the core face perception system and out-of-network regions, such as the DMN, and reduced integration between the core and extended face perception systems. The link between increased ASD symptomatology and atypical connectivity patterns of the core face perception system suggests that compromised face perception network integrity may contribute to social communication deficits observed in ASD.

17 **107.017** Atypical Novelty Detection ERP Responses Associated with Genetic but Not Idiopathic ASD Etiologies

***C. M. Hudac**, T. DesChamps, S. J. J. Webb and R. Bernier, University of Washington, Seattle, WA*

Background: Recurrent disruptive likely gene disrupting (LGD) mutations such as *CHD8* and *DYRK1A* have been implicated as contributing to approximately 10% of autism spectrum disorders, (ASD; Iossifov et al., 2014). To better describe the known genetic and phenotypic heterogeneity in ASD, recent work has begun to target specific neural phenotypes related to specific genotypes. One such study integrating a "genetics-first" approach with cognitive neuroscience discovered unique social phenotypes related to genetic and idiopathic etiologies of ASD (Hudac et al., 2015). However, it is still unclear how genetic disruptions impact associated aspects of ASD, such as cognitive delay.
Objectives: We aimed to characterize the neural patterns associated with idiopathic and genetic ASD etiologies during an auditory oddball task that is known to capture both attention orientation and novelty processing mechanisms. Recruitment targeted children with ASD who had completed genetic testing in prior studies and either had a known ASD-associated truncated likely gene-disrupting mutation (LGDM; Sanders et al., 2015; Iossifov et al., 2014) or no LGDMs (Idiopathic). Prior studies have found that children with ASD exhibit attenuation of the P3 component in response to novel and infrequent stimuli (e.g., Salmond et al., 2007; Donkers et al., 2015). However, we hypothesized that children with ASD with distinct genetic etiologies may showcase differences in neurophysiological functioning.
Methods: Gender-matched children age 6 to 18 (M=13.5 years, SD=2.5) were enrolled in the LGD Mutation group (n=11, ASD with LGDM), Idiopathic group (n=12, ASD without LGDM), or the Typical development group (n=11, no ASD). During electroencephalography acquisition, children watched a video of a trip to the zoo while passively attending to frequent tones, infrequent tones, and novel sounds (adapted from Salmond et al., 2007). Tone stimuli (1000 or 750 Hz) were counterbalanced between subjects. Maximum amplitude at scalp electrode clusters around C_z and F_z were extracted for the P300 component (180-350 ms). We focused on difference comparisons for attention orientation (infrequent minus frequent) and novelty detection (novel minus frequent).
Results: Repeated measures general linear models (SPSS 19) indicated an interaction between region, condition, and group, $F(2,17)=8.50$, $p=.024$, such that the LGDM group exhibited a reduced P300 novelty detection responses (i.e., a smaller response after accounting for the response to the frequent tone) at C_z compared to TYP children, (difference = 4.26 uV, SD = 1.5, p = .031). There were no significant amplitude differences between the Idiopathic and TYP groups at F_z or C_z for either attention orienting or novelty detection comparisons (p's>.17).
Conclusions: Here, children with idiopathic ASD and those with LGDMs exhibit typical patterns of attention orienting. However, children with ASD and a LGD mutation have reduced novelty detection responses, compared to typically developing children. These results indicate that the contribution of genetic etiology on functional neural mechanisms in ASD may impact specific cognitive functions more so than others.

Figure 1. Event-related potentials waveforms for LGD M, Idiopathic, and Typical development groups at central electrodes for frequent tone (black), infrequent tone (blue), and novel sound (red) conditions for the C_z region.

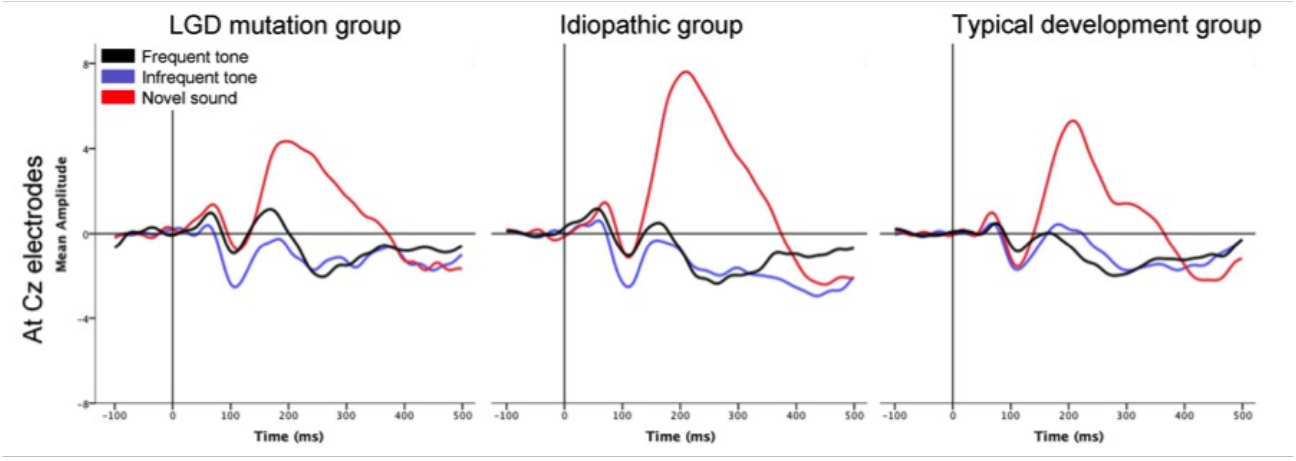

Figure 2. Novelty detection response (novel sounds minus frequent tones) are plotted for each group for the C_z region. Individual responses for children in the LGDM group are annotated with each child's corresponding gene event.

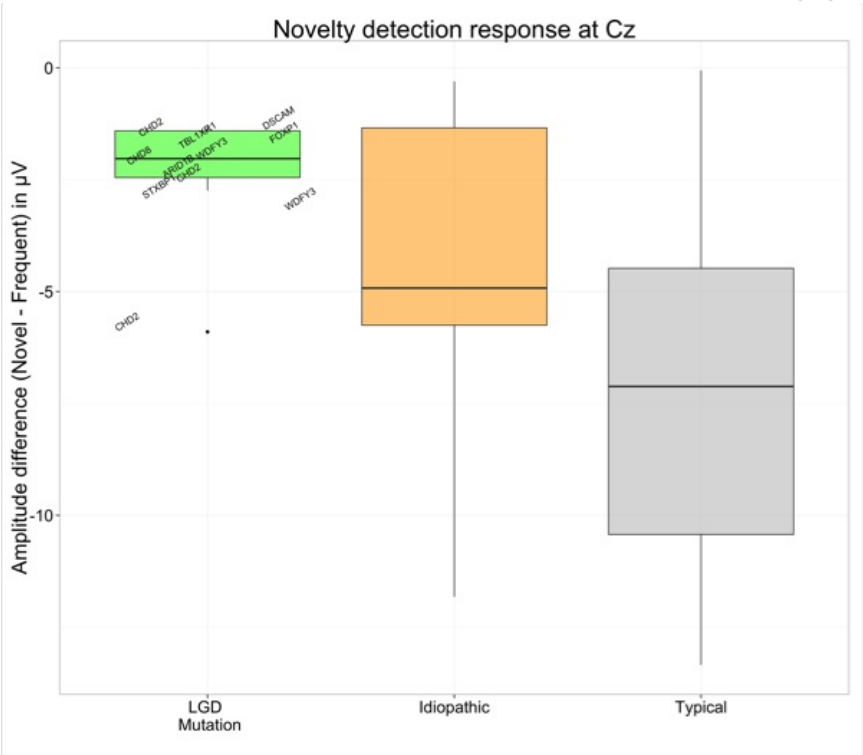


18 **107.018** Atypical Pattern of Frontal EEG Asymmetry to Direct Gaze in Young Children with Autism Spectrum Disorder

A. Kylliainen[1], *T. M. Helminen*[1], *J. Lauttia*[1], *S. Yrttiaho*[1], *K. Eriksson*[2], *J. K. Hietanen*[3] *and J. M. Leppänen*[2], *(1)University of Tampere, Tampere, Finland, (2)School of Medicine, University of Tampere, Tampere, Finland, (3)School of Social Sciences and Humanities / Psychology, University of Tampere, Tampere, Finland*

Background:
It has been suggested that another person's direct gaze is not socially motivating for individuals with autism spectrum disorder (ASD) and therefore they ignore it. This assumption has gained psychophysiological support from previous findings indicating that, contrary to typically developing children, children with ASD did not show greater relative left-sided, approach-related frontal EEG activity to direct gaze in comparison to shut eyes. Relative right- and left-sided asymmetries in the frontal alpha-band EEG activity have been associated with activation of the avoidance- and approach-related motivational brain systems, respectively. The children in the previous study were, however, school-aged and high-functioning children with ASD, leaving it open whether a similar pattern of responses would be observed already at an earlier age, and whether the findings could be generalised to low-functioning ASD.
Objectives:
The aim of the study was to investigate motivation-related brain responses to direct gaze in young, low-functioning children with ASD. In order to ensure that the possible abnormal findings were autism-specific, we also investigated an IQ-matched comparison group of children without ASD in addition to a normative comparison group of age-matched typically developing children.
Methods:
Twenty young (2.5-5.5 years of age) children with ASD, 20 typically developing children and 18 children with developmental delay without ASD participated in the study. The frontal alpha-band EEG (EGI Geodesic 128 channel system) activity was measured whilst the children viewed photos of faces with direct or downcast gaze and cars pictured from front or back view. On each trial, the stimulus was static for the first 2 seconds and then loomed towards the child for 3 seconds, creating an impression of an approaching person (or a car). Frontal EEG asymmetry was analysed separately to the static and moving phases of the stimuli.
Results:
The results showed that the typically developing children showed greater approach-related frontal EEG activity to direct gaze compared to downcast gaze. In children with ASD, the downcast gaze elicited greater approach-related frontal EEG activity compared to the direct gaze. In the children with developmental delay without ASD, there was no significant difference between the gaze conditions in the frontal EEG activity. These patterns of activity were obtained for the moving but not static phases of the stimuli.

Conclusions:
The pattern of frontal EEG activity to direct gaze was different in children with ASD compared to the other groups. The findings suggest that the lack of normative approach-related motivation towards another person´s direct gaze is evident early in the autistic development. It also strengthens the role of eye contact in abnormal social development of children with ASD. Interestingly, the dynamic stimuli seemed to be more sensitive than static stimuli to reveal differences in the motivation-related brain responses.

19 **107.019** Atypical Pupillary Light Reflex in 2 – 6 Year Old Children with Autism Spectrum Disorders

D. M. Dinalankara[1], *J. H. Miles*[2], *T. N. Takahashi*[3] *and G. Yao*[1], *(1)University of Missouri, Columbia, MO, (2)Thompson Center at the University of Missouri, Columbia, MO, (3)University of Missouri Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

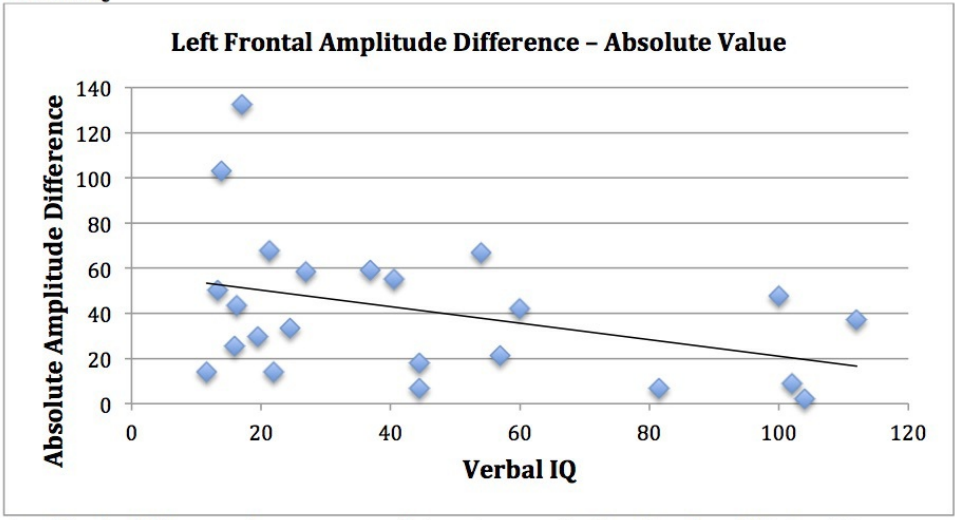
Background: Atypical pupillary light reflex (PLR) was previously observed in children age 6 – 17 years with autism spectrum disorders (ASDs). Abnormal PLR parameters were also reported in “high risk” 10-month-old infants who have siblings diagnosed with ASD. However, the group differences in PLR parameters appeared to be age dependent. To better understand the age effect, there is a need to evaluate PLR in children 2 – 6 years old, which is lacking in the literature.
Objectives: To investigate whether atypical PLR parameters also exist in 2 – 6 year old children with ASD.
Methods: Pupillary light reflex was measured in 55 children with ASD (54.1±16.2 months) and 54 children in the typical development (TD) group (55.0±17.8 months). Tests were conducted using a remote PLR device under two room illuminance levels: 5.6 lux (L1) and 2.7 lux (L2). We measured the following PLR parameters: baseline pupil radius, PLR latency, constriction, and constriction time. In addition, a questionnaire was used to evaluate symptoms related to autonomic nervous system (ANS) and their potential correlations with PLR parameters. A mixed model was used to study the group, age-group, and illuminance level effect on PLR parameters. Linear regression was used to investigate the change of PLR parameters with age.
Results: The mixed model indicated a significant group effect ($F_{1,205}$=31.10, p<0.0001) and age effect ($F_{1,205}$=21.37, p<0.0001) on the PLR latency. Overall PLR latency was longer in the ASD group than in the TD group; the latency in ASD group was 246.17 ± 18.20 ms in L1 and 261.27 ± 15.74 ms in L2 whereas it was 235.76 ± 16.01 ms in L1 and 248.05 ± 12.64 ms in L2 in the TD group. Linear regression confirmed that PLR latency decreased with age in the TD group (r=–0.41, p=0.0026 in L1 and r=–0.31, p=0.023 in L2) and baseline pupil radius increased with age in the TD group (r=0.36, p=0.0084 in L1 and r=0.28, p=0.042 in L2). However these age trends were not observed in the ASD group (p>0.05 in L1 and L2). There was a significant difference between the ASD and TD groups in the averaged ANS score (t_{80}=6.85, p<0.0001). Two-way ANOVA indicated a significant interaction between the group (ASD vs. TD) and abnormal ‘sweat’ symptoms on PLR constriction ($F_{1,100}$ =9.84, p=0.0022 in L1 and $F_{1,102}$=7.63, p=0.0068 in L2).
Conclusions: Atypical PLR parameters were also observed in 2 – 6 year old children with ASD. In the TD group, PLR latency decreased with age and baseline pupil radius increased with age; whereas these trends were not observed in the ASD group. Children with ASD showed more symptoms of autonomic nervous system dysfunction. We observed an association between abnormal sweating and PLR constriction in the TD group but not in the ASD group.

20 **107.020** Auditory Statistical Learning in Children with ASD Relates to Verbal IQ: An ERP Study

C. DiStefano[1], *E. Baker*[2], *J. McCracken*[3] *and S. S. Jeste*[4], *(1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

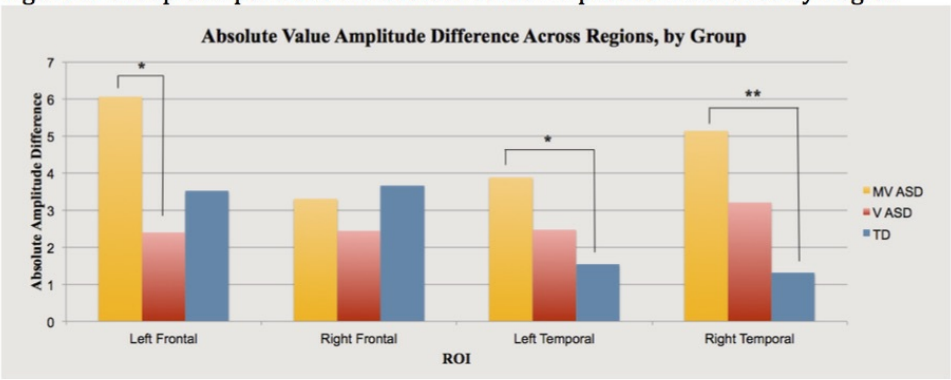
Background:
Approximately 30% of children with autism spectrum disorder (ASD) remain minimally verbal (MV) despite receiving intervention (Anderson et al., 2007). Examining cognitive skills that underlie language learning may help reveal reasons for this impairment. One crucial precursor to language development is auditory statistical learning (ASL), where infants are able to detect word boundaries by determining transitional probabilities between syllables in the speech stream (Kuhl, 2004). Although impaired ASL in high-functioning children with ASD has been documented using fMRI (Scott-Van Zeeland et al., 2010), no studies have examined ASL in minimally verbal children. Electroencephalography (EEG) represents an ideal methodology for studying this population because it gathers information about cognitive processing without requiring overt responses.
Objectives:
Evaluate ERP evidence of ASL in MV and verbal children with ASD, compared with typically developing children. Examine the relationship between ASL and language ability.
Methods:
30 children with ASD (17 MV; age 5-10) and 7 age-matched TD children participated in an ASL event-related potential (ERP) paradigm. Participants heard a 4-minute acoustic stream of 4 pseudo-words (constructed from 12 syllables), followed by a test phase in which pseudo-words (high transitional probabilities between syllables) were interspersed with non-words (low transitional probabilities). The mean ERP amplitude 400-600ms after word offset was calculated for each condition, for 4 regions of interest (ROI; left/right, frontal/temporal). ASD group analysis was performed using repeated measures ANOVA, with correlations to examine relationship between ERP results, verbal and non-verbal IQ. ERP results were directly compared across groups (verbal ASD, MV ASD, TD) using t-tests.
Results:
Repeated measures ANOVA yielded a main effect of region (F=5.01, p=.007) but no condition effect or region-by-condition interaction, indicating that ASD participants as a group did not show ERP evidence of ASL. Group comparisons showed that the MV ASD group showed significantly larger amplitude differences in: left frontal ROI compared with verbal ASD (t=-2.5, p=.02), left and right temporal ROI compared with TD (t=2.23, p=.04; t=3.11, p=.005). There were no significant differences between verbal ASD and TD groups. Amplitude difference was negatively correlated with VIQ (r=.46, p=.01), but was not related to NVIQ or chronological age.
Conclusions:
There is variability across individuals with ASD in the magnitude of their ERP response to an ASL paradigm, where participants with a lower VIQ show more condition differentiation. TD participants performed similarly to verbal ASD participants with neither group differentiating conditions. ASL may be a more immature process, and so not reliably detectable in participants with a higher developmental age. Minimally verbal children with ASD may continue perform this cognitive process but fail to develop other necessary cognitive-linguistic processes. Because ERP evidence of ASL is related to VIQ but not NVIQ, it is likely related specifically to language ability rather than overall developmental level. Research including a mental age matched comparison group as well as longitudinal research is necessary to fully interpret these findings. Further research into ERP correlates of ASL as well as other language-related cognitive processes will further elucidate pathways to language impairment in minimally verbal children with ASD.

Figure 1: Absolute Value Amplitude Difference Between Conditions Related to Verbal IQ



Amplitude difference between conditions is negatively related to VIQ (r=-.50, p=.005) and remains significant when the two participants with the highest difference values (possible outliers) are removed (r=-.46, p=.01).

Figure 2: Group Comparisons of Absolute Value Amplitude Difference By Region



The minimally verbal ASD group showed significantly larger amplitude differences in: left frontal ROI compared with the verbal ASD group (t=-2.5, p=.02), left temporal ROI compared with the TD group (t=2.23, p=.04) and right temporal ROI compared with the TD group (t=3.11, p=.005). There were no significant differences between the verbal ASD and TD groups.

21 **107.021** Baseline EEG Recordings in Young Children with ASD: Stimulus Type Matters

X. A. Tran[1], *E. Baker*[2], *J. Frohlich*[3], *S. Huberty*[4] *and S. S. Jeste*[3], *(1)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (4)Psychiatry and Biobehavioral Sciences, UCLA Center for Autism Research and Treatment, Los Angeles, CA*

Background: Baseline EEG has been increasingly studied as a biomarker of baseline brain activity in children with autism spectrum disorders (ASD). Characterization of baseline EEG in this population often requires the presentation of a visual stimulus to maintain a child's attention; stimuli range from live examiners interacting with the child to abstract videos (Machado 2015, Gabard-Durnam 2015). Stimulus type may impact a child's overall state and level of engagement with the testing environment, altering the child's EEG oscillations, leading to variability in signal that reflects "state" and not "trait' of a child.
Objectives: We asked if there were differences in baseline EEG power at specific frequency bands when children with ASD watched a video of abstract shapes compared to a segment of their favorite video. We hypothesized that neural correlates of attention and engagement, as quantified by higher theta power, would occur when children watched a more appealing stimulus like their favorite video.
Methods: We examined data from 27 children with ASD ages 2-6 years old (37% female; mean age = 55.6±13.2 months, IQ 49-114), recruited from the Early Childhood Partial Hospitalization Program. Baseline EEG was recorded using a high density system (EGI Inc. 128-channels). Children watched a video of an abstract screen saver

followed by their favorite cartoon video (varied based on each child's preference). Each video was presented for 2 minutes. EEG data were processed per prior protocols (McEvoy 2015). Relative spectral power for delta (1-3 Hz), theta (4-7 Hz), alpha (8-12 Hz), beta (13-30 Hz), and gamma (31- 48 Hz) frequency bands were calculated using Welch's method, in 9 regions of interest (ROIs) across the scalp. For statistical analysis, we used a general linear model with repeated measure design for 3 within-group comparisons (video, frequency, ROI); we further examined significant main effects using paired samples t-tests.
Results: There was a significant interaction of stimulus type with group ($F_{4, 23}$ = 4.878, P = 0.005). Post hoc analysis showed relative power in the delta frequency band was significantly higher (P_{delta} = 0.003) in the abstract video (mean = 0.495±0.087) compared with the favorite video (mean = 0.473±0.077). Relative power in the theta and beta frequency bands was significantly lower (P_{theta} = 0.019, P_{beta} = 0.043) in the abstract video ($mean_{theta}$= 0.252±0.067, $mean_{beta}$ = 0.107±0.028) than in the favorite video ($mean_{theta}$ = 0.271±0.078, $mean_{beta}$= 0.113±0.031). There were no significant differences in alpha or gamma power between stimulus types.
Conclusions: Baseline EEG power can change based on stimulus type, with greater theta and beta power that may reflect increased attention and engagement during a preferred video. Preferred video also has a social salience that may elicit greater attention. These findings support the importance of reporting stimulus type during baseline EEG recording and maintaining consistent testing parameters during recordings. In ongoing analyses, we will examine these findings in relation to the child's IQ, age, ASD severity, and rating of a child's behavior during the EEG session.

22 **107.022** Brain Dopamine D1 Receptor Binding in Young Adults with Autism Spectrum Disorder

K. Suzuki[1], *K. Nakamura*[2], *Y. Ouchi*[1], *K. Takebayashi*[1], *M. Yokokura*[1], *K. Nakaizumi*[1], *M. Tsujii*[3], *T. Sugiyama*[1] *and N. Mori*[1], *(1)Hamamatsu University School of Medicine, Hamamatsu, Japan, (2)Hirosaki University Graduate School of Medicine, Aomori, Japan, (3)Chukyo University, Toyota, Japan*

Background: Autism spectrum disorder (ASD) is characterized by repetitive and/or obsessive interests and behavior and by deficits in sociability and communication. Previous neuroimaging studies using positron emission tomography (PET) found the dopaminergic dysregulation in the orbitofrontal cortex and microglial activation in more diverse brain regions in adults with ASD, although the relationship between the two phenomena remains unclear.
Objectives: To determine a possible association between the dopamine D1 receptor availability and microglial activation in living subjects with ASD.
Methods: We measured the binding of dopamine D1-like receptors with the radio-ligand ^{11}C-SCH23390 in the brain of subjects with ASD (n=20) and age- and sex-matched control subjects (n=20). The binding of radio-ligand ^{11}C-PK11195 was also measured as a representative index of microglial activation. Whole-brain voxel-based analyses as well as regions of interest-based methods were used for between-subjects analysis and within-subjects correlation analysis with respect to clinical variables.
Results: We found significantly higher ^{11}C-SCH23390 binding potentials in the orbitofrontal cortex and midbrain of subjects with ASD compared to control (corrected P<.05). A previous finding of elevated ^{11}C-PK11195 binding in the brain of ASD was confirmed. The levels of ^{11}C-SCH23390 binding in the orbitofrontal cortex was positively correlated with ^{11}C-PK11195 binding in the midbrain, but not the orbitofrontal cortex per se. There was no significant correlation between PET data and clinical valuables evaluated.
Conclusions: The results suggest that the availability of D1 receptor at the resting state is elevated in the orbitofrontal cortex of subjects with ASD. The increased availability of D1 receptor may reflect a possible pathophysiological aspect intrinsic to the ASD brain with extensive microglial activation.

23 **107.023** Cerebellar Contributions to Whole-Brain Resting-State Networks: A Combined Tdcs-Fmri Study

A. M. D'Mello[1], *P. E. Turkeltaub*[2,3] *and C. J. Stoodley*[1], *(1)American University, Washington, DC, (2)Georgetown University Medical Center, Washington, DC, (3)Research Division, MedStar Rehabilitation Hospital, Washington, DC*

Background: Differences in cerebellar structure and function are amongst the most consistent neural findings in autism spectrum disorder (ASD). In particular, right lobule VII of the cerebellum (including Crus I/II) show grey matter reductions and differences in activation patterns in ASD individuals. This region is structurally and functionally connected to association regions of the cerebral cortex, participating in cerebro-cerebellar loops that form part of cognitive control and default mode networks. It has been proposed that the cerebellum is important in both the optimization of structure and function in the cerebral cortex during development, providing a framework for understanding a potential role for the cerebellum in ASD. However, the effects of cerebellar activity on these broader cerebro-cerebellar circuits is not yet clear, even in typically-developing (TD) adults.
Objectives: Here, we examined the effects of cerebellar transcranial direct current stimulation (tDCS) on resting-state functional connectivity patterns in TD young adults. We hypothesized that right cerebellar tDCS would modulate neural activation patterns throughout the brain, particularly in frontoparietal and default mode networks (DMN).
Methods: We combined 20min of 1.5 mA anodal or sham tDCS over the right posterolateral cerebellum with functional MRI in TD adults (n=27; μ=24.4 years old). Sixteen participants received active tDCS, and 11 participants received sham tDCS, where the current is ramped up over 15s and then ramped down before any clinically significant current is applied. The active (anodal) electrode was placed over the right posterolateral cerebellum (1cm down and 4cm over from inion; estimated to be over lobule VII) and the reference electrode was placed on the right pectoral muscle. Seven minutes of resting-state functional images were acquired both pre- and post-tDCS (47 interleaved slices, 168 volumes, TR 2500ms, TE 30ms, 3.2mm isotropic voxels, flip angle 90º, FOV 205mm).
Results: Relative to sham, anodal tDCS increased activation in right cerebellar Crus I/II. When functional connectivity was examined between right Crus I and the rest of the brain (seed-to-voxel analysis), we found that tDCS modulated cortical resting-state connectivity, shifting right Crus I connectivity patterns outside of canonically connected networks. Specifically, within frontoparietal networks, anodal tDCS increased functional connectivity between right Crus I of the cerebellum and the anterior cingulate cortex, regions that are typically anti-correlated in the frontoparietal network. Within the DMN, anodal tDCS increased functional connectivity between the right Crus I of the cerebellum and the bilateral precuneus (a DMN node) as well as occipital regions.
Conclusions: These preliminary results are consistent with the proposed role of the right posterolateral cerebellum in the modulation of broader cerebro-cerebellar networks. When anodal tDCS is applied over the right cerebellum in TD adults, the functional connectivity acquires an ASD-like pattern – increased out-of-network functional connectivity within frontoparietal cognitive control networks, and increased cerebro-cerebellar functional connectivity both within the DMN as well as outside of canonical DMN nodes. These findings are consistent with the deficits in resting-state network segregation found in ASD and provide testable hypotheses for future application of cerebellar tDCS in ASD populations.

24 **107.024** Cerebellar Metabolite Levels and Social-Communication Impairments in Twins with Autism Spectrum Disorder

J. P. Hegarty II[1], *M. Gu*[1], *D. Spielman*[1], *S. Cleveland*[1], *J. Hallmayer*[1], *L. Lazzeroni*[1], *M. Raman*[1], *T. W. Frazier*[2], *J. M. Phillips*[1], *A. L. Reiss*[1] *and A. Y. Hardan*[1], *(1)Stanford University, Stanford, CA, (2)Cleveland Clinic Center for Autism, Cleveland, OH*

Background:
Cerebellar circuits are important for providing regulatory feedback to other regions of the brain. Traditionally the cerebellum was thought to be exclusively involved with motor control, but imaging and lesion studies have implicated higher-order cognitive domains as well. The cerebellum is of particular interest in ASD because neuronal circuits in the cerebellar hemispheres have consistently been implicated in the disorder with multiple studies also reporting either hypo- or hyper- plasia in the vermis.
Objectives:
The goal of this study was to examine neurochemical profiles of the cerebellum to determine whether individuals with ASD exhibit differences in neuronal density, neurotransmitter signaling capability, or metabolic activity that are related to social-communication impairments.
Methods:
Data were acquired from a neuroimaging study of same-sex twin pairs that included monozygotic (MZ) and dizygotic (DZ) twin pairs with ASD and MZ and DZ control twin pairs. Cognitive/behavioral assessment included measures of intelligence (SB-5) and social-communication impairments (SRS). An oblique MR spectroscopy chemical shift imaging slab that covered portions of the cerebellar hemispheres and vermis was acquired. A subset of individuals with ASD and controls with valid spectra from the cerebellum was included in the present preliminary study and consisted of 25 individuals with ASD and 25 controls. Voxels (4.5 mL) included primarily grey matter (GM) or white matter (WM) in the right cerebellar hemisphere (R Cere Hemi) and a combination of GM and WM in the vermis. Metabolites were assessed in relation to internal creatine levels and adjusted for tissue composition. Compounds containing n-acetyl aspartate (NAA), glutamate (Gln), choline (Cho), and myo-inositol (mI) were examined.
Results:
Individuals with ASD exhibited the anticipated cognitive/behavioral profile including social-communication impairments (M_{ASD}=69.88,SD=19.73; M_{CTRL}=44.58,SD=10.89) and lower IQ (M_{ASD}=84.88,SD=31.13; M_{CTRL}=109.88,SD=16.49); but groups did not significantly differ in age (M_{ASD}=11.44,SD=2.76; M_{CTRL}=10.40,SD=2.38) or gender (M/F_{ASD}=19/6, M/F_{CTRL}=16/9), indicating sufficient control matching. Metabolites in the R Cere Hemi did not significantly differ between groups; however, there was a trend towards a difference in choline-containing compounds such that individuals with ASD exhibited higher concentrations in GM (M_{ASD}=0.29,SD=0.06; M_{CTRL}=0.26,SD=0.04), F(1,47)=3.509, p=0.067, η^2=0.069, and WM (M_{ASD}=0.31,SD=0.05; M_{CTRL}=0.28,SD=0.07), F(1,47)=3.197, p=0.080, η^2=0.064. R Cere Hemi GM and WM concentrations of NAA, Gln and mI did not differ between groups, and there were also no differences across metabolites in the vermis. Within individuals with ASD, there was a strong positive association between social-communication impairments and GM Cho (r=0.58) and a moderate association with WM Cho (r=0.39).
Conclusions:
Preliminary data from this investigation show that individuals with ASD may be more likely to present elevated choline-containing compounds in the right cerebellar hemisphere. Choline is a precursor of acetylcholine and marker of cellular membrane turnover. Elevated choline may indicate membrane degradation or increased cellular proliferation and is also present in less mature neuronal circuits. Therefore, our findings may suggest greater perturbation or less maturation of cerebellar circuits in some

individuals with ASD that are related to social-communication impairments. The examination of additional participants and the assessment of heritability will allow further elucidation of potential differences in cerebellar choline in individuals with ASD.

25 **107.025** Change of Neurophysiological Correlates of Biological Motion Processing By the Group Based SOSTA-FRA Intervention in High Functioning Children and Adolescents with ASD

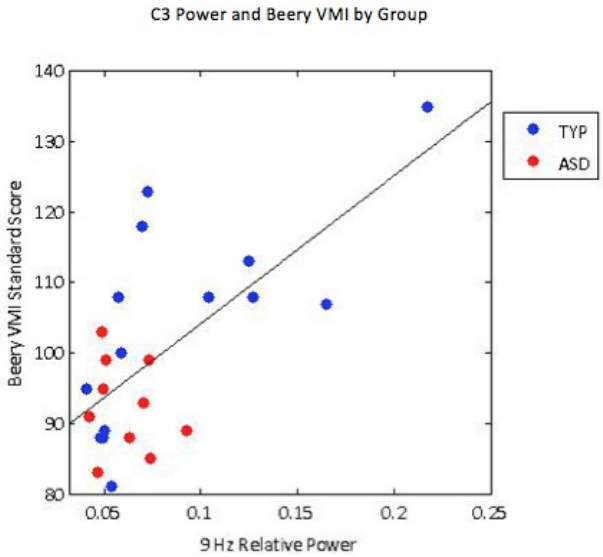
C. Luckhardt[1], *A. Kröger*[1], *S. Bender*[2] *and C. M. Freitag*[3], *(1)Autism Research and Intervention Center of Excellence Frankfurt, Goethe University Hospital, Frankfurt, Germany, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Cologne, Cologne, Germany, (3)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Johann Wolfgang Goethe-University Frankfurt/Main, Frankfurt, Germany*

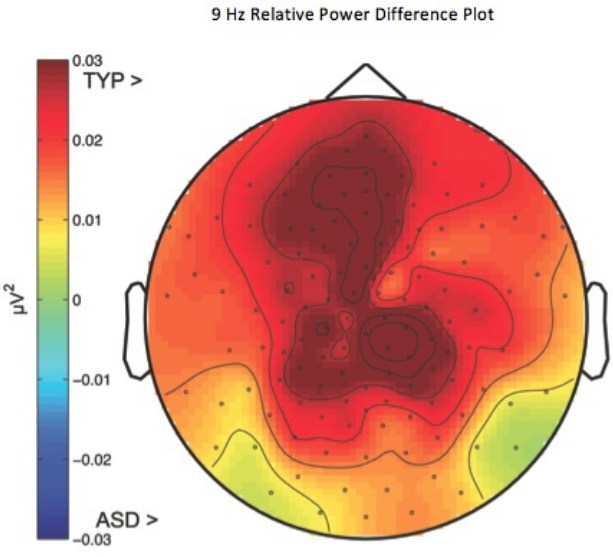
Background:
Group based psychotherapy focusing on improvement of social and self-regulation skills is the intervention of choice in high functioning children and adolescents with autism spectrum disorder (ASD). Systematic empirical evaluation of such interventions aims at elucidating mechanisms by which they improve social skills in ASD. Neurophysiological studies can contribute by assessing neural correlates of behavioral change. Biological motion processing is a fundamental skill required for almost all social interactions, as we need to interpret dynamic social signals such as gestures, body language or facial expressions. Biological motion processing therefore seems well suited for evaluating perceptual and cognitive changes following social skills trainings in ASD.
Objectives:
We hypothesized that the group based SOSTA-FRA intervention would change neural correlates of visual and cognitive biological motion processing in individuals with ASD.
Methods:
Data was collected within a randomized controlled trial. The intervention group received twelve sessions of the manualized SOSTA-FRA training, while the control group continued to receive treatment as usual (TAU). Both groups were assessed three times (t1=baseline, t2=post intervention, t3=3-months follow-up), completing both questionnaires and the neurophysiological assessment at all time points. In each group 17 matched children participated in the neurophysiological assessment at all three time-points and provided sufficient artifact free data for analysis. The task comprised two conditions in which pointlight-displays of biological (walking human figure) and non-biological motion (scrambled stimulus derived from the human stimulus) were shown and participants were instructed to discriminate between the two motion types. Taking into account hemisphere and condition we compared amplitudes and latencies of the P100, N200 and P400 event related potentials (ERPs) between the two groups across all three measurements.
Results:
Both groups showed a constant high performance on the motion discrimination task and no changes across time ($F_{2,60}$=.273;p=.762) or between groups (group*time: $F_{2,60}$=.791; p=.458) were evident. Still, ERP analysis revealed reduced N200 latencies at three months follow-up for the SOSTA-FRA but not the TAU group ($F_{2,64}$= 4.067; p=.022).
Conclusions:
While no improvement in task performance could be observed, likely due to ceiling effects, ERP results point towards change of neural function following the intervention. The intervention led to faster early neural processing of complex visual stimuli, which has been discussed as a deficit typical for ASD. While the exact mechanisms that lead to this change need to be investigated in further detail, results indicate improved visual processing strategies by SOSTA-FRA.

26 **107.026** Characterizing the Cortical Basis of Motor Impairments in ASD Using EEG

S. T. Major[1], *B. P. Rardin*[1], *R. Bernier*[2] *and M. Murias*[3], *(1)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (2)University of Washington, Seattle, WA, (3)Duke University, Durham, NC*

Background:
Atypical visual motion perception is a feature of autism spectrum disorders (ASD) and may contribute to the abnormal development of motor milestones observed in this population. The EEG Rolandic mu rhythm, related to motor cortex function, has reduced suppression during action observation in ASD. Individuals with ASD also exhibit reduced global alpha (Berger) power; the alpha rhythm shares a frequency range, but not topography, with the mu rhythm. Exploring the relationship between mu and alpha rhythms and motor performance may help to better characterize the cortical basis of motor deficits seen in ASD.
Objectives:
The present study investigated relative power at each frequency in the mu and alpha band (8-12 Hz) in children with and without ASD during a visual motion task. Differences in motor performance between the two groups were assessed using the Movement Assessment Battery for Children (M-ABC) and the Beery-Buktenica Developmental Test of Visual-Motor Integration (Beery VMI). Power at each frequency was correlated with performance on these motor tests.
Methods:
Participants were 11 females and 18 males (n=29) between 7-8 years old, all but 2 were right handed. The ASD group's mean age was 95.2 months (+/- 6.3) and mean FSIQ was 100.1 (+/- 12.1). The control group's mean age was 95.1 months (+/- 7.6) and mean FSIQ was 107.6 (+/- 23.9). ASD diagnosis was based on ADOS and ADI-R. EEG was recorded as subjects watched sand fall through an hourglass. Time series data were transformed via FFT with 1 Hz resolution and standard electrodes were considered (C3, C4, P3, P4, F3, F4, O1, O2).
Results:
The ASD group had lower standard scores on Beery VMI (t=3.22, p<0.01) and M-ABC Total (t=3.88, p<0.001). At 9 Hz, the ASD group had lower relative power at C3 (t=1.82, p<0.05) and F3 (t=2.37, p<0.05). At 10 Hz, the ASD group had lower relative power at F3 (t=2.43, p<0.05) only. Combining ASD and TYP groups, the Beery VMI scores correlated with 9 Hz relative power at C3 (r=.67, p<0.001), F3 (r=.68, p<0.001), and F4 (r=.64, p<0.001). No correlations were observed at 8 Hz, 10 Hz, 11 Hz, or 12 Hz. Separately, the ASD group revealed no correlation between performance and 9 Hz power, while the TYP group showed strong positive correlations at C3 (r=.70, p<0.01), F3 (r=.67, p<0.01), and F4 (r=.65, p<0.05).
Conclusions:
Children with ASD scored lower on both motor tests, highlighting a motor execution deficit in the autism group. The ASD group exhibited lower 9 Hz power in left central (C3) and left frontal (F3) scalp regions and lower 10 Hz power in a left frontal (F3) region. No group differences were observed at 8 Hz, 11 Hz, or 12 Hz, at occipital or parietal electrodes (O1, O2, P3, P4), or in the right hemisphere (C4, F4). The group differences in 9 Hz power at C3 and F3 and the strong correlations with a visuo-motor integration assessment suggest that EEG power at this frequency may serve as an index of visual motor impairment in 7-8 year old children.





27 **107.027** Children with ASD Fail to Downregulate Visual Cortex during Auditory Processing

R. J. Jao Keehn[1], *S. Sanchez*[1], *C. R. Stewart*[1], *W. Zhao*[1], *E. Grenesko*[1], *B. Keehn*[2] *and R. A. Müller*[1], *(1)San Diego State University, San Diego, CA, (2)Speech, Language, and Hearing Sciences, Purdue University, West Lafeyette, IN*

Background: Autism Spectrum Disorders (ASD) are predominantly characterized by impairments in two core domains: social communication, and restricted and repetitive behaviors (RRB) that encompass atypical responses to sensory stimuli. Research has indicated a high prevalence of sensory issues in ASD; some children with ASD are easily overwhelmed while others seem unaware of their environment. Given the importance of sensory input during development, particularly from vision and audition (two of the main sensory modalities involved in social interactions and language), impairments in these systems may have cascading effects that contribute to disturbances in higher-order cognitive and sociocommunicative abilities.
Objectives: We assessed the neural mechanisms underlying basic sensory processing of visual and auditory information in ASD. Specifically, we examined the effects of auditory processing on visual cortical activity in nonlinguistic contexts.
Methods: Functional magnetic resonance imaging (fMRI) was used to test children and adolescents with ASD (n = 16) and typically developing (TD) participants (n = 16) matched for age, gender, nonverbal IQ, and handedness during a sensory discrimination task. Participants were presented with visual (dot located high or low in the display) and auditory stimuli (4000 or 1600Hz), and were instructed to indicate whether each stimulus was “high” or “low”. Measures of accuracy and reaction time were also recorded during the scan.
Results: Functional MRI findings indicated divergent patterns of activity in visual cortex during auditory processing. The TD group showed downregulation, whereas the ASD group showed upregulation in visual cortical areas, which was associated with symptomatology. Moreover, ASD children and adolescents had lower auditory discrimination accuracy than their TD counterparts.
Conclusions: Our findings (i) support the notions of basic auditory impairment, but visual sparing in ASD. They further indicate (ii) that individuals with ASD fail to downregulate visual cortex during simple auditory processing, and (iii) that this impaired crossmodal modulation is linked to sociocommunicative symptomatology. These results add to the existing evidence of atypically enhanced recruitment of visual cortices during a variety of cognitive and perceptual tasks (Samson et al., Hum Brain Mapp., 2012), suggesting that such atypical visual recruitment also occurs during sensory processing in non-visual modalities. They are also in line with the general hypothesis of atypical sensorimotor building blocks as developmental precursors of sociocommunicative impairments in ASD.

28 **107.028** Common CNTNAP2 Variant Relates to Altered Functional Connectivity of the Striatum

K. E. Lawrence[1], *L. M. Hernandez*[2], *D. H. Geschwind*[3], *S. Y. Bookheimer*[1] *and M. Dapretto*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)Department of Neurology, UCLA, Los Angeles, CA*

Background: Contactin associated protein-like 2 (*CNTNAP2*) plays an important role in the development of frontostriatal networks and has previously been associated with language endophenotypes in autism spectrum disorder (ASD) and specific language impairment (Penagarikano & Geschwind, 2012). *CNTNAP2* messenger RNA is expressed in frontostriatal networks of the human brain, and common variants in *CNTNAP2* have previously been related to brain connectivity (Dennis et al., 2011; Tan et al., 2010), as well as activity during language processing (Koeda et al., 2015; Whalley et al., 2011) and implicit learning (Scott-Van Zeeland et al., 2010a). However, no studies to date have investigated how *CNTNAP2* may relate to functional connectivity of brain structures that are involved in language learning. A prior study from our lab demonstrated that, unlike typically developing (TD) controls, individuals with ASD do not display increased striatal activity during an implicit language-learning task (Scott-Van Zeeland et al., 2010b). Therefore, in order to characterize how this neural circuitry may be influenced by genetic risk, we investigated the relationship between *CNTNAP2*rs2710102 (previously associated with age at first word in ASD) and striatal connectivity in youth with and without ASD.
Objectives: Examine how a common *CNTNAP2* variant (rs2710102) relates to functional connectivity of the striatum, an important structure for implicit language learning.
Methods: Thirty-seven children and adolescents with ASD and 30 matched TD controls completed a 6-minute resting-state functional MRI scan. Resting-state functional connectivity analyses were conducted using the left caudate and the left putamen as seeds. As prior imaging genetics studies have used either dominant or recessive modes of inheritance (Dennis et al., 2011; Scott-Van Zeeland et al., 2010a; Whalley et al., 2011), we analyzed the data separately using each model. Initial group comparisons were completed in FSL, prethresholded with a joint mask of the within group results and thresholded at Z>2.3 with a cluster threshold of p=.05.
Results: Under the dominant and recessive models, the risk and non-risk groups both displayed robust functional connectivity between the left caudate and frontal, temporal, and parietal regions. In the dominant model, the non-risk group displayed significantly greater connectivity than the risk group to the medial prefrontal cortex, a region in which *CNTNAP2*is known to be expressed (Abrahams et al., 2007). When using a recessive model, the risk group showed significantly greater connectivity to bilateral frontal pole regions than the non-risk group. With regards to left putamen connectivity, both groups displayed robust connectivity to frontal and temporal areas for the dominant and recessive models. There were no significant between-group differences in putamen functional connectivity regardless of model.
Conclusions: Connectivity of the striatum, an area previously associated with language learning differences between ASD and typical development, is significantly modulated by a common genetic variant that has been linked to language in ASD.

29 **107.029** DNA Methylation of the Oxytocin Receptor Gene Predicts Variability in Brain Response to Social Stimuli Among Children with Autism Spectrum Disorder

A. Jack[1], *T. S. Lillard*[2], *D. R. Oosting*[1,3], *J. P. Morris*[2], *K. Pelphrey*[1] *and J. J. Connelly*[2], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Department of Psychology, University of Virginia, Charlottesville, VA, (3)Psychology, University of Massachusetts, Boston, MA*

Background: The hormone oxytocin influences social perception, and variants of the oxytocin receptor gene (*OXTR*) have been associated with autism spectrum disorder (ASD)[1]. However, epigenetic modifications that impact gene transcription also impact phenotypic variability. One such modification is DNA methylation, which allows for transcriptional silencing as well as temporal control of gene expression. Previously, we (JJC) found elevated *OXTR* DNA methylation (*OXTR*m) in individuals with ASD[2] accompanied by decreased oxytocin receptor transcription in superior temporal sulcus (STS), a site associated with social perception. Subsequently, we (AJ, JPM, JJC) demonstrated that blood-derived *OXTR*m in healthy adults predicts variability in response to social stimuli in key brain sites, including STS[3,4]. These findings suggest that *OXTR*m is atypical in ASD, and variability in *OXTR*m within the typical range predicts social brain function. However, the relationship between *OXTR*m and functional brain outcomes within ASD is yet unexplored. Here we describe associations between *OXTR*m and brain response to human motion, among children with and without ASD.
Objectives: To characterize 1) how *OXTR*m interacts with ASD diagnosis to predict brain response to human motion, and 2) how sex differences in *OXTR*m interact with diagnostic status to predict brain response to human motion.
Methods: We enrolled 11 children with ASD (5 girls) and 14 typically developing (TD) children (6 girls). Blood was collected in mononuclear cell separating tubes and samples spun to separate the mononuclear cell fraction as per product protocol, and DNA was isolated. *OXTR*m was assessed at CpG sites -860, -924, and -934. Epigenotyping procedures are described in[3,4]. Scans included a T1-weighted anatomical image and a BOLD fMRI scan. The Biological Motion paradigm features interleaved blocks of coherent (BIO) and scrambled (SCRAM) point-light displays of human movement and recruits brain regions involved in social perception, including STS[5]. We assessed where BIO > SCRAM brain activity varied as a function of *OXTR*m, and where this relationship differed by diagnosis and sex ($z = 2.3$, $p = 0.05$, whole-brain cluster-corrected).
Results: Children with ASD with higher methylation at sites -934 and -924 had weaker response to human motion in social brain regions including bilateral STS, while TD children with higher methylation showed stronger response in these regions (Fig1). This finding suggests compensatory social brain activity in children with higher epigenetic risk but no expression of the disorder, and a lack of such compensation in ASD. Additionally, at sites -860, -924, and -934, higher methylation was associated with a weaker response in occipitotemporal regions including STS and fusiform gyrus, but only in girls with ASD.
Conclusions: These results suggest that variability in *OXTR*m holds promise for helping to explain processes of ASD risk and protection, including those that may differ by sex.

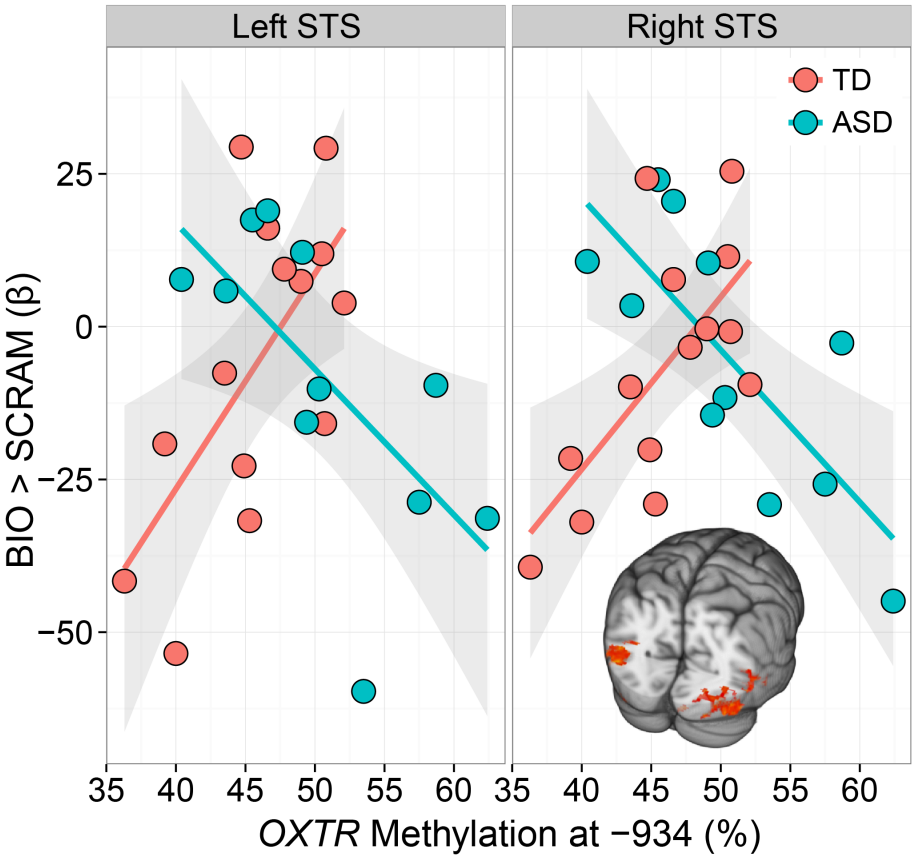
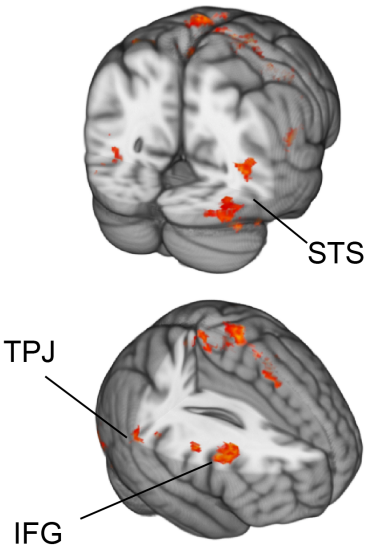
Fig. 1 | DNA methylation of the oxytocin receptor gene (*OXTR*) interacts with ASD diagnosis to predict brain response to displays of human motion.



While higher *OXTR* methylation at **CpG site -934** predicts stronger superior temporal sulcus (STS) response to biological motion in TD children, it predicts weaker STS response in children with ASD.



Right hemisphere view

A similar pattern is found at **CpG site -924** within right STS, right inferior frontal gyrus (IFG) and right temporo-parietal junction (TPJ).

30 **107.030** Default Mode Network - Insight into Disruptive Behaviour in Autism Spectrum Disorder

J. Lei[1,2], P. E. Ventola[1], E. Dayan[3], K. Pelphrey[1] and D. Yang[1], (1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Psychology and Language Sciences, University College London, London, United Kingdom, (3)National Institute of Neurological Disorders and Stroke, National Institutes of Health, Human Cortical Physiology Section, Bethesda, MD

Background: One third of children with autism spectrum disorder (ASD) exhibit comorbid disruptive-behaviour, anxiety, and attentional-deficit problems. Disruptive-behaviour in ASD may be linked to poor self-regulation, and the neural correlates have not yet been established. Moreover, poor self-regulation may compromise social functioning. The Default Mode Network (DMN) is a set of brain regions typically deactivated during cognitive tasks and may be related to self-regulation. DMN may provide a neural window to study disruptive behaviour and social functioning in children with ASD, and may help clarify how disruptive behaviours are linked with comorbid anxiety or attentional-deficit-problems at the brain level.
Objectives: To examine how disruptive behaviour in children with ASD is related DMN deactivation, to determine how much this relationship is mediated by comorbid anxiety and/or attentional deficit problems, and to explore the link between DMN deactivation and social functioning.
Methods: Participants included 31 children (all male) with ASD between the ages of 4 and 18 years. Age appropriate versions of Child/Adolescent Symptom Inventory-4 (CSI-4/ASI-4) was used to assess comorbid symptoms of anxiety, attentional deficit, and disruptive behaviour (Cronbach's α= .75 to .91). Social Responsiveness Scale (SRS) was used to measure social functioning. All participants underwent functional magnetic resonance imaging (fMRI) whilst passively viewing alternating clips of biological (BIO) and scrambled point-light displays (12 blocks in total, 24 s each block) in a 3-Tesla scanner. The experiment began and ended with 20-s fixation interval, which were combined to create fixation (FIX) condition for all contrast analyses. A whole-brain group analysis was conducted using mixed-effects modelling (FSL's FLAME1+2), voxel-level thresholding $Z > 1.96$, and cluster-level thresholding $p < .05$, while controlling for age.
Results: At the group level and as expected, DMN deactivations in medial prefrontal cortex (MPFC), posterior cingulate cortex (PCC), and precuneus (PC) were observed in BIO<FIX contrast (Fig 1-top). DMN deactivation was negatively correlated with disruptive behaviour in MPFC and PCC/PC (Fig 1-bottom), suggesting that disruptive behaviours reduced the DMN deactivation in these regions. Furthermore, anxiety partially mediated the disruptive behaviours' effect of reduced DMN deactivation in a region within MPFC (Fig 2). There was no evidence supporting attention deficit problems mediated. DMN deactivation was also negatively correlated with SRS total raw score.
Conclusions: This study demonstrated that DMN deactivation provides a useful window to study the role of self-regulation in children with ASD. Reduced DMN deactivation in children with ASD who displayed disruptive behaviour suggests poorer self-regulation when engaged in a social perception task. The effect within MPFC is partially mediated by anxiety, suggesting interventions aimed to reduce disruptive behaviour via improving self-regulation may be more successful by simultaneously targeting comorbid anxiety in children with ASD. Reduced DMN deactivation is also linked to greater social impairment. To our knowledge, this study is the first to provide a neuromarker for disruptive behaviour in ASD, which describes a key brain-based dimension that may be used to facilitate the development of tailored treatment to reduce disruptive behaviour in ASD in the future.

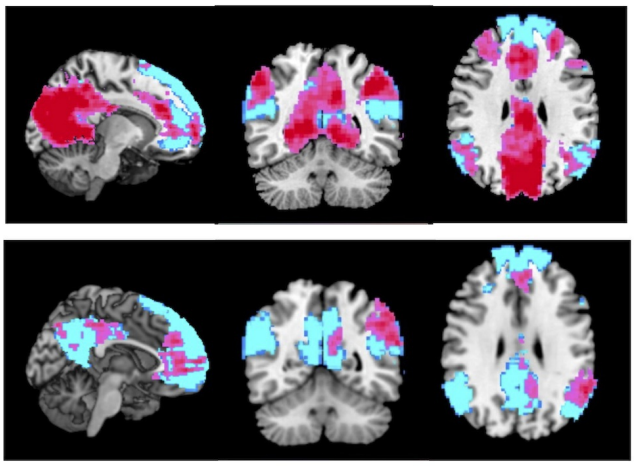


Fig 1. Activation overlaid on top of DMN template. **Top row:** BIO<FIX deactivation observed in posterior cingulate cortex, precuneus and medial prefrontal cortex (**pink**; voxel-level Z > 1.96, cluster-level p < .05 corrected). Slices taken at MNI 152 2mm coordinate: (-12, -54, 30). Cyan regions indicate the regions of DMN established in the previous literature (Yeo et al., 2011). **Bottom row:** BIO<FIX deactivation in DMN was weaker in children with greater disruptive behaviour (**pink**; mixed-effects, voxel-level Z > 1.96, cluster-level p < .05 corrected). Slices taken at MNI 152 2mm coordinate: (-12, -54, 30).

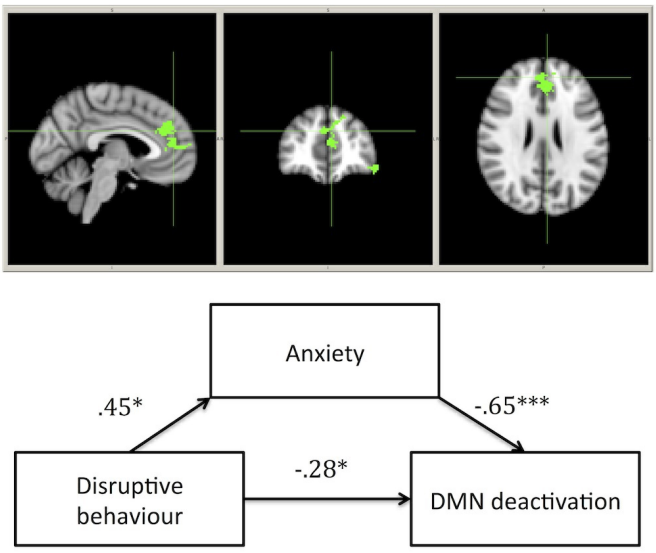

Fig 2. The effect of reduced BIO<FIX DMN deactivation with greater disruptive behaviour was partially mediated by anxiety in children with ASD in a DMN brain region within MPFC, shown in **green** (mixed-effects, voxel-level Z > 1.96, cluster-level p < .05 corrected), Sobel's Z = -2.39, p = .02. Slices taken at MNI 152 2mm coordinate: (-4, 46, 26). Coefficients were standardized estimates. *p < .05 **p < .01

31 **107.031** Developmental Changes in Learning to Predict Others' Preferences: Implications for Autism Spectrum Disorder

G. Rosenblau[1], *C. W. Korn*[2], *B. C. Vander Wyk*[1] *and K. Pelphrey*[1], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Department of Psychiatry, Psychotherapy, and Psychosomatics, University of Zurich, Zurich, Switzerland*

Background:
Many of our efforts in social interactions are dedicated to optimizing our predictions of others' preferences, mental states, and behaviors, an ability referred to as Theory of Mind (ToM). Research over the past two decades has established that children with autism spectrum disorder (ASD) show significant developmental delays in ToM. . In consequence, behavioral interventions for ASD focus mostly on improving ToM skills. However, a mechanistic understanding of how we improve our predictions of others' mental states over time, and an understanding of developmental changes in these learning processes are lacking.
Objectives:
We aim to gain a mechanistic understanding of how humans optimize predictions of others' preferences over the course of typical development. Optimizing predictions is defined as reducing the difference between expected and actual outcomes, i.e., prediction errors. In a next step, we will investigate developmental differences in encoding and updating social prediction errors between typically developed adolescents and adolescents with ASD.
Methods:
We utilize a novel preference task to investigate the behavioral and neural mechanisms involved in updating social predictions and learning from prediction errors. To ensure high ecological validity, the task involves real social feedback. Typically developed adults (N=21) and adolescents (N=23) are asked to predict the preferences of three different people for a number of items (food types, beauty products and leisure activities). They subsequently receive trial-by-trial feedback about others' actual preference ratings. After completing the task, participants rate their own preferences for the same items (see Figure 1 A). We use reinforcement learning (RL) models to describe participants' changes in ratings over time. On the neural level, we model participant's trial-by-trial prediction errors (the absolute difference between participant's rating of the other person's preference and the person's actual preference rating) and the perceived self-other difference (the absolute difference between participant's ratings of their own preference versus that of the other person). We also used estimated prediction errors and estimated ratings from the winning RL model to predict trial-by-trial changes in brain activity.
Results:
Estimating others' preferences relies on two components: reinforcement learning based on past feedback and participants' own preferences for an item. Learning processes differ across development. Adolescents are slower at updating their predictions based on past feedback (see Figure 1 B); older adolescents show more updating (i.e., smaller prediction errors). Paralleling the developmental differences on the behavioral level, brain regions typically assigned to the ToM network support distinct processes in adolescents and adults. For instance, medial prefrontal cortex (MPFC) and posterior cingulate cortex (PCC) activity are less related to estimated predictions and more strongly correlated with estimated prediction errors in adolescents compared to adults (see Figure 1 C).
Conclusions:
We show that adolescence is marked by substantial developmental changes in social learning. We are currently investigating differences between the developmental trajectories of TD and ASD adolescents. This could help identify behavioral and biological markers of treatment change, which could help predict behavioral treatment outcomes for adolescents with ASD.

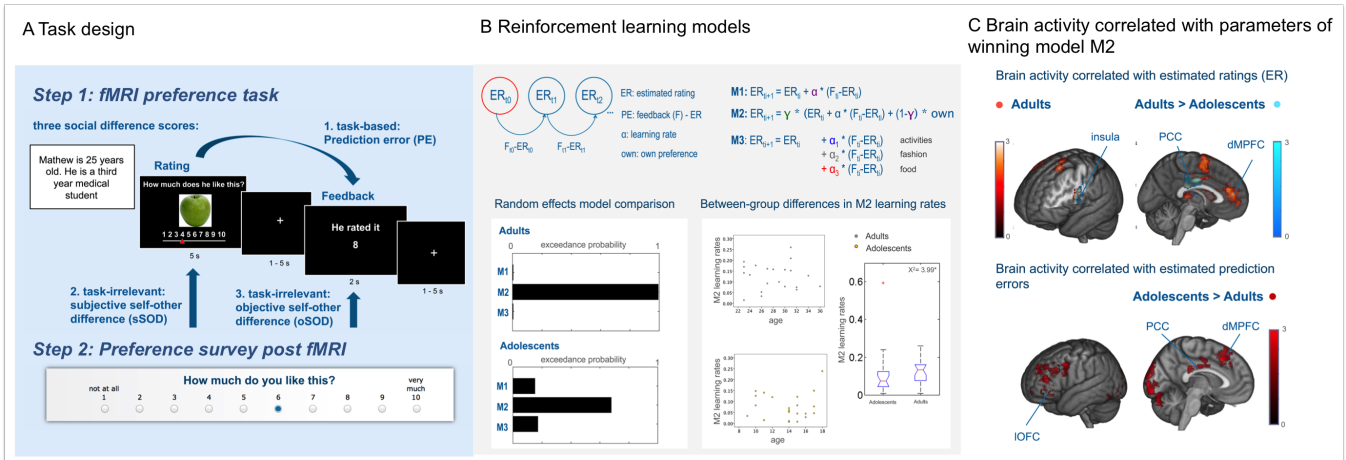

Figure 1 | **A)** Study design steps: Step 1 - participants predict the preferences of three different people in three consecutive fMRI task runs. Step 2 - participants rate how much they themselves like the items after the fMRI experiment. **B)** Reinforcement learning models tested in the adult and adolescent groups. Left panel: In the adult group the winning model (M2) is a combination of the classical reinforcement learning model based on past information and participants' own preferences for the items. In the adolescent group the difference between the tested models is less pronounced. Right panel: Adolescents show lower learning rates in M2 than adults. **C)** Upper panel: Brain regions that show significantly higher correlations with estimated ratings in adults versus adolescents. Lower panel: Brain regions that show significantly higher correlations with estimated prediction errors in adolescents versus adults. The results are whole brain cluster level FWE corrected at z = 1.7, p < 0.05.

32 **107.032** Differences in Auditory Evoked Potentials Between Children with Autism Spectrum Disorder with Versus without Language Impairment: A Methodological Comparison

E. Kwok, *E. Dovigi and J. Oram Cardy, Communication Sciences and Disorders, University of Western Ontario, London, ON, Canada*

Background: Atypical auditory processing is commonly reported in individuals with *autism spectrum disorder (ASD),* particularly in those with co-occurring *language impairment (LI).* One method commonly used to investigate these processes is recording of *auditory evoked potential (AEPs)*using electroencephalography. There is considerable interest in understanding whether atypical auditory cortical processing underlies LI in individuals with ASD, however, findings are inconsistent. Bomba and Pang (2004) identified two factors that explain some discrepancies in the literature: the heterogeneity of individuals diagnosed with ASD and the lack of an appropriate control group. A third possibility receiving little consideration in the literature to date is whether the choice of data analysis method contributes to discrepancies across studies.
Objectives: To compare differences in AEPs between children with ASD with normal language development (ALN) and those with language impairment (ALI) using three analysis methods: peak amplitude/latency, time-frequency, and global waveform resemblance.
Methods: Seventeen children aged 7-11 years (ALN: n=10, ALI: n=7) participated in a passive AEP paradigm where 225 trials of a 50ms, 490Hz tone were presented binaurally. A 128-channel EGI system recorded AEPs during stimulus presentation. Children with ALN had standard scores ≥ 85 on the *Clinical Evaluation of Language Fundamentals – 4*, while those with ALI scored < 85 (< 1 *SD*below the mean). The AEPs of children with ALN and ALI recorded at channel Fz were compared across three analysis methods. **1) Peak amplitude/latency analysis**: P1 and N2 AEP components were identified from the grand averaged waveform of all participants. The mean amplitude and peak latency within 60ms (±30ms) around the maximum of P1 and N2 were calculated and compared across groups. **2) Time-frequency analysis**: The AEPs of all participants underwent wavelet transformation from 5-100Hz in steps of 0.98 Hz using Morlet wavelets. The power and circular variance of AEPs at the gamma oscillation range (30-50Hz) were calculated and compared for both 200ms pre- and 200ms post-stimulus intervals. **3) Global waveform resemblance analysis**: An AEP segment from 0-400ms post-stimulus presentation was compared between children with ASD to our previously established normative AEPs of children with typical development aged 7-10 years. Using the intraclass correlation coefficient as an indicator of overall resemblance, the AEPs of children with ASD were assigned an age-equivalent based on the comparison that yielded the highest resemblance score.
Results: In amplitude/latency analysis, only the N2 mean amplitude was significantly different between ALI and ALN (p<0.005). Neither power nor circular variance of gamma-oscillation were significantly different between the two groups. Despite having the same mean chronological age, children with ALI had a younger AEP-age-equivalent than children with ALN (7.4 and 8.4 years respectively, p<0.01) on the global resemblance analysis.
Conclusions: Our results demonstrate that different AEP analyses can lead to different conclusions about putative auditory processing differences between children with ALI and ALN. Interpretation of the relation between AEPs and language functioning in ASD should take into consideration the choice of data analysis method and the neural processes thought to underlie different cortical responses.

33 **107.033** Differential Engagement of Prefrontal Cortex Underlies Local Bias in Children with Autism

A. J. Herringshaw, *S. L. Kumar and R. K. Kana, University of Alabama at Birmingham, Birmingham, AL*

Background: Visuospatial information processing in Autism Spectrum Disorders (ASD) is often described in terms of an inability to “see the forest for the trees.” The Weak Central Coherence (WCC) account of ASD (Frith, 1989) posits that a detail-oriented information processing bias exists in ASD, which can manifest as strength or as weakness depending on the task at hand. For example, in social cognition tasks where strong coherence is the norm, people with autism may falter, as opposed to visual search tasks where they perform well. Differences in brain responses in frontal versus posterior regions may underlie this cognitive and behavioral profile.
Objectives: To examine the neural correlates of WCC in children with ASD in the context of visual and social processing.
Methods: ASD (N=17) and Typically Developing (TD) (N=17) children and adolescents completed an emotion and shape judgement task in a Siemens 3.0 Tesla fMRI scanner. The task consisted of stick-figure human characters made up of geometrical shapes displaying different emotions. In the shape/local condition, participants indicated whether or not a given geometric shape (e.g., a rectangle) was present in the figure. In the emotion/global condition, participants recognized the emotion conveyed by the stick figure (e.g., sad). Whole-brain within-and-between-group activation and seed-to-voxel functional connectivity analyses were conducted in SPM12 and the CONN toolbox.
Results: 1) Significantly increased activity in ASD children, relative to TD, in posterior regions, including the middle occipital and middle temporal areas for both emotion and shape processing; 2) ASD children showed decreased activity (ASD<TD) in right superior and middle frontal regions (RSFG/MFG) while recognizing local shapes (p< 0.01; cluster =174 voxels); 3) Significantly weaker connectivity for emotion recognition in ASD participants (ASD<TD) between left extra-striate body area (EBA) to frontal pole (FP) and MFG (p< 0.05, cluster-level FDR corrected); and 4) The ASD group was significantly faster in the local/shape processing condition (ASD mean= 2871 milliseconds, TD mean= 3381 milliseconds; t(32)= 2.41; p< 0.05), while the TD group was significantly more accurate in the emotion condition (ASD mean= 88.2%, TD mean= 95.6%; t(32)= 2.63; p< 0.05).
Conclusions: Longer reaction times and greater recruitment of frontal regions in TD children during shape identification may suggest the need to override a global-processing bias that is not seen in ASD. Poorer accuracy of ASD children in recognizing emotions indicates that a default local bias may be a weakness in this context, and the decreased EBA-Frontal connectivity in ASD may underlie this weakness. While this local bias provided the ASD group with an advantage in faster processing of shapes, the TD group still performed the task with equal accuracy. Overall, our findings support weak central coherence in autism manifesting as a deficit and strength in social and visual tasks respectively, along with evidence for increased occipital recruitment and weaker connectivity. Clinical implications include targeting global visual processing in improving emotion recognition abilities.

34 **107.034** Dynamic Whole-Brain Functional Connectivity and Connectopathy in Autism: A Population-Based Neuroimaging Study of Brain Development

R. L. Muetzel[1], *L. M. Blanken*[1], *B. Rashid*[2], *R. Miller*[3], *F. Verhulst*[4], *H. Tiemeier*[4], *V. Calhoun*[3] *and T. J. White*[5], *(1)Child and Adolescent Psychiatry, Erasmus Medical Center - Sophia Children's Hospital, Rotterdam, Netherlands, (2)Electrical and Computer Engineering, University of New Mexico, Albuquerque, NM, (3)University of New Mexico, Albuquerque, NM, (4)Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC-Sophia, Rotterdam, Netherlands, (5)Erasmus University Medical Centre, Rotterdam, Netherlands*

Background: Deficits in brain connectivity have been proposed to underlie symptomatology in autism spectrum disorders (ASD). Functional brain connectivity has been extensively studied in children and adults with ASD since the introduction of resting-state functional MRI (RS-FMRI). Despite the presence of an extensive and expanding

literature, both in terms of brain function and structure, the neurobiological etiology of ASD remains elusive. Traditional connectivity studies operate under the assumption that the characteristics of connectivity remain stationary throughout the measurement period. Dynamic functional connectivity (DFC), a new technique that relaxes this stationarity assumption and allows states to change over time, may show promise in the study of connectopathy in children with ASD.
Objectives: ASD has traditionally been conceptualized categorically, but is increasingly recognized as the end of a continuum of traits that extends into the general population(1). While these two constructs of the disorder clearly compliment one another in the search for the underlying neurobiology, there is an overrepresentation of case-control studies in the literature. The current study aims to expand the current functional connectivity literature in ASD in two ways: First by using a dimensional measure of autistic traits and second by using a novel metric of functional connectivity, namely DFC, in both globally 'disconnected' and default-mode states.
Methods: The present work utilizes a large, population-based cohort of children ages 6-to-10 years (mean age = 7.9 years). 774 children (52% boys / 48% girls) participated in the study. Mean non-verbal IQ was 102±14. Autistic traits were measured using the short form (18 item) Social Responsiveness Scale. Children underwent a 5½-minute RS-FMRI scan with a 3 Tesla GE MRI system. MRI data were pre-processed using the Statistical and Parametric Mapping Software, and group independent component analysis was performed using the GIFT-toolbox. Special care was taken to account for movement artifact(2). Traditional static connectivity was first estimated, followed by DFC using a sliding-window approach and k-means clustering(3). Summary metrics, including mean dwell time were computed for each participant and dynamic state. Multiple linear regression analyses were conducted to assess the association between DFC and autistic traits.
Results: Figure 1A illustrates the average, static connectivity state, and the 4 dynamic connectivity states observed in the current sample. Linear regression analyses, accounting for age, sex, and non-verbal IQ, show that autistic traits are positively associated with average time spent in a globally disconnected state (state 2, Figure 1B). Conversely, low levels of autistic traits were associated with a greater average time spent in a default-mode state.
Conclusions: For the first time, we demonstrate associations between autistic traits on a continuum and aspects of DFC in a large, population-based study of children. Specifically, we show evidence of children with high levels of autistic traits spending more time in a globally 'disconnected' functional state, relative to children with lower levels of autistic traits.

35 **107.035** EEG Findings Processed By Next Generation Artificial Adaptive Systems Can Perfectly Distinguish ASD Children from Typically Developing Children: A Proof of Concept Pilot Study

E. Grossi[1], *M. P. Buscema*[2] *and C. Olivieri*[1], *(1)Autism Unit, Villa Santa Maria Institute Neuropsychiatric Rehabilitation Center, Tavernerio, Italy, (2)Semeion Research Centre*

of Sciences of Communication, Roma, Italy

Background:
To our knowledge, this is the first study that applies an artificial adaptive system to extract interesting features in computerized EEG that distinguishes ASD children from typically developing ones. The new system, named MS-ROM/I-FAST, belongs to the family of systems developed by The Semeion Research Institute in Rome. MS-ROM/I-FAST is a new, complex algorithm used for blind classification of the original EEG tracing of each subject. This is accomplished by recording and analyzing a few minutes of their EEG without any preliminary pre-processing. A proof of concept study published in *The Artificial Intelligence Journal* in 2015 showed accuracy values ranging from 94%-98% in discerning subjects with Mild Cognitive Impairment and/or Alzheimer's Disease from healthy elderly people.
Even if the neuropathology related to autism is markedly different from that of Alzheimer disease, simple reasoning would support the idea that the atypical organization of the cerebral cortex present in autism should result in an EEG signature open to detection through potent analytical systems like ANNs.
Objectives:
The aim of the study is to assess how effective this methodology distinguishes ADS subjects from typically developing ones.
Methods:
Fifteen definite ASD subjects (age range 8 -22) and ten typically developing subjects (age range 7-12) were included in the study. Patients received independent Autism diagnoses according to DSM-V criteria, then subsequently confirmed by a qualified psychiatrist at Villa Santa Maria, where the patients reside, using the ADOS scale (overall severity score had a range from a minimum of 4 to a maximum of 10 points, average = 7.9). No autistic child was affected by genetic conditions and/or cerebral malformations documented by neuroimaging and epilepsy.
A continuous segment of artefact-free EEG data lasting 60 s in ASCCI format was used to compute multi-scale entropy values and for subsequent analyses.
A Multi-scale ranked organizing map (MS-ROM), based on the self-organizing map (SOM) neural network, coupled with the TWIST system (an evolutionary system able to select predictive features) created an invariant features vector input of EEG on which supervised machine learning systems acted as blind classifiers.
Results:
After MS-ROM/I-FAST preprocessing, the overall predictive capability of different machine learning systems in deciphering autistic cases from normal ones consistently amounted to 100% (Table 1). These results were obtained at different times in separate experiments performed on the same training and testing subsets. The similarities among the ANN weight matrixes measured with apposite algorithms were not affected by the age of the subjects. This suggests that the ANNs do not read age-related EEG patterns, but rather invariant features related to the brain's underlying disconnection signature.
Conclusions:
This pilot study seems to open up new avenues for the development of non-invasive diagnostic testing for the early detection of ASD.

36 **107.036** ERP Correlates of Inhibitory Control and Theory of Mind Are Associated with Each Other and with ASD Symptoms

***A. D. Nijhof**, M. Brass and J. R. Wiersema, Ghent University, Ghent, Belgium*

Background:
Both Theory of Mind (ToM) and Executive Functioning (EF) impairments have been argued to play a causal role in ASD. Interestingly, over the years, there has been growing support for a link between EF and ToM, and EF has been mentioned as an 'enabling factor' in the development of ToM. It is suggested that specifically inhibitory control is needed for successful ToM, as mentalizing almost always requires overriding a prepotent response (e.g., overriding own belief in false-belief tasks). Indeed, some studies have shown correlations between ToM and inhibitory ability, and fMRI studies have shown overlapping brain activation during ToM and inhibition tasks. Still, studies attempting to directly test the link between inhibitory control and ToM are scarce, especially at the neural level, but may be of much importance to better understand ToM deficits in ASD.
Objectives:
The aim of the current study was to investigate the relationship between neural correlates of inhibitory control and ToM, using EEG. In addition, correlational analyses were conducted to relate the ERP findings to ASD symptoms in a neurotypical population.
Methods:
22 neurotypical participants carried out a ToM task and a Go/No-Go task while their EEG activity was being recorded. The Go/No-Go task required participants to respond to a certain letter (80%, Go), and to inhibit responding to another letter (20%, No-Go). The ToM task consisted of watching short videos, in which both the participant and another agent formed a belief about the location of a ball. During the outcome phase, participants had to respond in accordance with what the agent had believed, enabling false- versus true-belief analyses. ERP components were calculated for No-Go versus Go trials, and for false- versus true-belief trials. These were subsequently related to ASD symptomatology assessed by means of the Autism Spectrum Quotient (AQ).
Results:
For the Go/No-Go task, the typical pattern of N2 and P3 components was found, with expected differences between Go- and No-Go-trials. In the outcome phase of the ToM task, a P3-like component could be observed at the midline, for the false-belief versus true-belief trials. A strong positive and specific correlation was found between the false-belief (versus true-belief) related P3 component and the No-Go (versus Go) P3 component ($r = 0.50$); no link was found with the N2. In addition, both the false-belief P3 and No-Go P3 were moderately and negatively correlated with ASD symptoms ($r = -0.35$ and $r = -0.32$ respectively).
Conclusions:
The finding that ERP indices of inhibitory control and mentalizing are positively correlated suggests that general inhibitory control plays a significant role in Theory of Mind tasks. Both ERP indices were found to be associated with ASD symptoms, with smaller amplitudes for adults with more ASD symptoms. Although we used a dimensional approach in a neurotypical population and replication of the findings is warranted in individuals with a formal diagnosis of ASD, these findings may help to better understand ToM deficits in ASD.

37 **107.037** Effects of Age and Social Function on Voice-Processing Systems in Autism

***A. E. Baker**[1], A. Padmanabhan[1], P. Odriozola[2], D. A. Abrams[2] and V. Menon[3], (1)Stanford University School of Medicine, Palo Alto, CA, (2)Stanford University, Palo Alto, CA, (3)Stanford University School of Medicine, Stanford, CA*

Background:
Children with autism spectrum disorders (ASD) often show a lack of engagement with social communication cues, including speech, perhaps due to diminished attribution of reward to social stimuli, which may impact the development of social skills. In adolescence, increased importance is placed on social interactions as individuals begin to make a world for themselves outside of the home. Social communication impairments thus may leave individuals with ASD uniquely vulnerable during the transition from childhood to adulthood. Neuroimaging research suggests that children with ASD show weaker connectivity between voice-selective superior temporal sulcus and reward and affective brain regions compared to typically developing (TD) children, and that the strength of connectivity is associated with individual differences in social communication abilities. However, little is known about the development of speech processing in the social brain during adolescence, or its relationship to social communication deficits in ASD.
Objectives:
We examined the neural basis of 1) processing unfamiliar voices compared to non-vocal sounds and 2) processing unfamiliar voices compared to mother's voice, a familiar vocal source associated with the home environment, in children and adolescents with ASD compared to their TD peers. Specifically, we explored age- and social function-related effects to better understand how voice processing in ASD deviates from typical development and correlates with social communication abilities.
Methods:
We used fMRI to measure brain activity in 31 individuals with high-functioning ASD (8-18 y/o) and 39 age- and IQ-matched TD controls (7-17 y/o) in response to nonsense words produced by both unfamiliar female speakers and their own mothers, as well as energy- and duration-matched non-vocal environmental sounds. We also administered the social responsiveness scale (SRS) to measure social function.

Results:
The ASD group showed less activity in reward and social brain regions compared to the TD group in response to vocal stimuli. Moreover, unfamiliar voices, compared to both environmental sounds and mother's voice, elicited increased activity in the brain's reward circuit as a function of age in the TD group, suggesting increased reward attribution to novel vocal sources in adolescence. This relationship was absent in the ASD group, who showed no age-related change but did show variability in brain activity in voice-selective and affective regions as a function of SRS score, with increased activity correlating with more severe social impairments.
Conclusions:
Our results support previous findings by showing that both familiar and unfamiliar vocal sources elicit reduced brain activity in reward and affective circuits in individuals with ASD compared to their TD peers. Moreover, the absence of age-related changes in response to unfamiliar voices in the ASD group suggests a deviation from typical development. Such impairments may play a role in the ability of adolescents with ASD to experience novel vocal sources as salient and pleasurable stimuli, thereby impacting social skill development in this population. Our results also suggest a neural basis for individual differences in social function in ASD, with immature brain responses correlating with behavioral impairments.

38 **107.038** Electrophysiological Signatures of Visual Statistical Learning in Three-Month Old Infants at Risk for Autism Spectrum Disorder

A. Marin[1], *T. Hutman*[2], *M. Dapretto*[3], *C. Ponting*[1], *S. P. Johnson*[4] *and S. S. Jeste*[1], *(1)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)UCLA, Los Angeles, CA*

Background: Visual statistical learning (VSL) refers to implicitly extracting commonalities and transitional probabilities within the visual environment (Bulf et al., 2011), and may be a precursor to later cognition and social communication (Romberg & Saffran, 2010). We previously demonstrated impairments in VSL in preschool-age children with ASD using a novel electrophysiological (EEG) paradigm (Jeste et al., 2015). No studies have examined VSL in infants at risk for ASD.
Objectives: We asked whether EEG signatures of VSL could be quantified at 3-months of age, and whether VSL distinguished high- and low-risk infants (HR infants have an older sibling with ASD), and whether there was an association between VSL at 3-months and later cognitive function.
Methods: Three-month-old infants (n=22, high-risk (HR): n=11, low-risk (LR): n=11) were exposed to a continuous stream of shapes based on a modified version of the Kirkham et al. (2002) VSL task. High density EEG was recorded (128 electrode, EGI inc) and the event-related potential (ERP) of interest was the frontal Positive Slow Wave (PSW). A general linear model evaluated within-subject effects of region and condition and between-subject effects of group with respect to PSW mean amplitude. Learning was operationalized as differentiation between conditions (expected vs. probabilistic). Whole group correlations between ERP markers of learning and cognitive skills at 6-months (Mullen Scales of Early Learning, 1995) were also performed.
Results: There was a significant group by condition interaction ($F(1, 20) = 7.393$, $p = .013$, partial $h^2 = .270$) and a significant main effect of region ($F(2, 19) = 5.302$, $p = .015$, partial $h^2 = .358$). Post-hoc tests revealed greater mean amplitude within the middle region as ($M = 2.560$, $SD = 4.162$) compared to the right ($M = 2.039$, $SD = 3.155$) and left ($M = .687$, $SD = 3.841$). Post-hoc tests revealed that HR infants significantly differentiated conditions ($t(10) = 2.967$, $p = .014$), while LR infants did not ($t(10) = -.793$, $p = .446$). An independent samples t-test returned significant differences between HR ($M = 3.282$, $SD = 3.669$) and LR ($M = -.809$, $SD = 3.384$) groups in PSW difference amplitudes ($t(20) = 2.719$, $p = .013$). The absolute value PSW difference amplitudes correlated with six-month visual receptive skills ($r(21) = .49$, $p = .02$) and mental age ($r(21) = .48$, $p = .03$), but groups did not differ on mental age at 6 months.
Conclusions: EEG correlates of VSL seem to differentiate HR from LR infants as early as 3-months of age, with HR infants displaying evidence of VSL. EEG signatures of learning predict both visual receptive skills and mental age at six months. The relationship between VSL and cognitive function suggest a role of pattern learning in later cognitive development. Group differences in VSL suggest that infants at risk for ASD demonstrate strengths in processing visual patterns—a strength that may occur at the expense of later social attention or learning. As we confirm diagnostic outcomes, we will better understand the predictive nature of this cognitive domain in infants at risk for ASD.

39 **107.039** Engagement of Language and Theory-of-Mind Networks during Self-Other Processing in Autism Spectrum Disorders

E. Sartin[1], *C. E. Stevens*[2], *C. L. Klein*[3], *M. R. Klinger*[4], *L. G. Klinger*[5] *and R. K. Kana*[6], *(1)UAB, Trussville, AL, (2)Psychology, University of Alabama at Birmingham, Birmingham, AL, (3)Psychology, Marietta College, Marietta, OH, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (6)University of Alabama at Birmingham, Birmingham, AL*

Background: Autism Spectrum Disorder (ASD) is characterized by difficulties in social interaction and social communication (American Psychiatric Association, 2013). Self-referential processing, critical in interpersonal interactions, entails the ability to process information by incorporating self-awareness, self-judgment, and self-memory. Self-referential processing has been linked to several brain areas, including the medial prefrontal cortex (MPFC), inferior parietal lobule (IPL), anterior cingulate cortex (ACC), and left inferior frontal gyrus (LIFG). Individuals with ASD have been found to show atypical brain responses in some of these areas when engaged in self-other representation tasks (Craik et al., 1999; Chiu et al., 2008; Lombardo et al., 2010).
Objectives: The primary objective of this fMRI study is to examine the role of language and theory-of-mind (ToM) brain networks in self-other processing across ASD and typically developing (TD) individuals.
Methods: 15 high-functioning adults with ASD and 15 age-and-IQ-matched TD control participants (mean age= 21.7; mean IQ: ASD=105, TD=111, p=.124) took part in this study. All participants were right-handed males. Participants made "yes" or "no" judgments of whether an adjective, presented visually, described them (*self*) or their favorite teacher (*other*). There was also a case judgment control condition where the participants determined whether the adjective contains the letter "e". The data were collected using a Siemens 3T Allegra scanner and analyzed using the SPM 12 software. Participants also completed the Reading Mind in the Eyes (RMIE) task outside of the scanner to asses ToM.
Results: The main results of this study are: 1) Both ASD and TD participants showed significant activity in left superior temporal gyrus (LSTG), LIFG, MPFC, and LIPL during *self* as well as *other* processing (p= .001, voxels=78); 2) Between-group analyses showed significantly decreased activity in RSTG in ASD for both *self* as well as *other* processing (p= .05, voxels= 579); 3) Other related processing also elicited significantly reduced activation in the precuneus in ASD participants(p=.001, voxels=78); 4) When *self* and *other* processing were directly contrasted, ASD participants showed reduced activation in the ACC, putamen, caudate, and cerebellum (p=.001, voxels 78); and 5) A regression analysis with MIE scores as covariate significantly predicted RIFG activation for self-processing in ASD participants (p=.01, voxels=253).
Conclusions: Increased activity in LIFG and LSTG for self and other processing, but not for case judgment, suggests greater levels of semantic processing; this is consistent with the findings of previous imaging studies (Kelley et al., 2002). Reduced RSTG and precuneus activation during *other* processing in ASD participants reflects poor engagement of regions that are part of the ToM network. Recent meta-analysis data underscore the role of these regions in other-related processing (Murray et al., 2015). Comprehending *self*-related words also seems to recruit temporal and IFG areas differently in ASD participants, as seen in previous studies (Lombardo et al., 2010, D'Argembeau et al., 2007). Overall, the findings of this study emphasize the role of social and semantic processing brain networks and their alterations in the neurobiology of autism.

40 **107.040** Evaluation of Mismatch Negativity As Biomarker for Language Impairment in Autism Spectrum Disorder

H. L. Green[1], *L. C. Goodwin*[2] *and K. Froud*[3], *(1)Columbia University, New York, NY, (2)Columbia University, Staten Island, NY, (3)Biobehavioral Sciences, Columbia University Teaches College, New York, NY*

Background: Currently, autism spectrum disorder (ASD) is diagnosed using the Diagnostic Statistical Manual of Mental Disorders-Fifth Edition (DSM-V) and children often go undiagnosed until around the age of three. Moreover, current language assessments are designed to behaviorally measure language skills, therefore requiring that a child have language or be "of language age" in order to participate. As a result of these diagnostic limitations, speech and language interventions for children with ASD plus language impairment (ASD+LI) are often not initiated until a child is of preschool age. Finding an early and objective way to identify language impairment (LI) in ASD has the potential to lead to earlier speech and language intervention for individuals "at risk" for the disorder. Magnetoencephalography (MEG) studies use the Mismatch Field component (MMF) to investigate how the brain processes speech sounds. Previous MEG studies by Roberts et al. (2011) utilizing the MMF component have shown that increased MMF latency (i.e., longer processing time) is a predictor of LI in children with ASD (sensitivity 82.4%; specificity 71.2%).
Objectives: Since MEG is expensive and not widely used with infants or young children, we attempted to replicate these results using the mismatch negativity (MMN), the electroencephalography (EEG) equivalent of MMF. EEG is inexpensive and can be used with children of all ages making it an appropriate method to identify LI in children on the autism spectrum. We explored increased MMN latency as a potential biomarker for LI in autism.
Methods: EEG was recorded in children ages 5-10 with ASD+LI, ASD-LI and typically developing controls (TD) during a passive auditory oddball experiment presenting speech sounds. During the recording children were instructed to watch a movie and ignore the sounds.
Results: Contrary to previous MMF findings, individuals with ASD+LI demonstrated decreased MMN latency in the left hemisphere in response to vowel sounds compared to those with ASD-LI and TD controls. A positive correlation between left hemisphere MMN latency and language scores on the Clinical Evaluation of Language Fundamentals-Fifth edition was found when combining both ASD groups. No correlation between MMN latency and language score was found in the control group. Parent report revealed that all individuals with ASD who participated in this study were hyper-sensitive to sounds.
Conclusions: Our results show that children with ASD+LI and hyper-sensitivity to auditory stimuli detect change in the auditory stream faster than children with ASD-LI and TD controls. Our results support the theory that children with ASD+LI have increased connectivity in primary sensory cortices at the expense of computational connectivity between association areas of the brain (Belmonte et al., 2004). This may account for faster auditory processing time despite low language scores in these children. Further

research needs to be done in order to determine if grouping children by hyper- versus hypo-sensitivity to auditory stimuli could explain conflicting results between studies and elucidate a neurophysiological biomarker of language impairment in subgroups of children with ASD.

41 **107.041** Evaluation of the Pupillary Light Reflex As a Potential Biomarker in Children with Autism Spectrum Disorder

V. Y. Kang[1,2], *M. Pereverzeva*[1], *S. T. Geller*[1,2], *S. Lo*[1], *L. V. Ibanez*[1,2], *W. L. Stone*[1,2] *and S. O. Murray*[1], *(1)Department of Psychology, University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA*

Background:
Previous studies have found differences in autonomic nervous system (ANS) functioning between children with ASD and typically developing (TD) children. The pupillary light reflex (PLR) is one measure of autonomic functioning that has revealed a longer latency, faster constriction velocity, and lower constriction amplitude for individuals with ASD compared to those with TD between 7 and 20 years of age (Daluwatte et al., 2012; Fan et al., 2009). Evaluation of the PLR in a younger age group could provide insight into the early development of the ANS in ASD and be useful in discovering potential early biomarkers of ASD.
Objectives:
This study investigated PLR parameters in younger ASD and TD children than have been studied previously, using a simplified paradigm. The goal of the study was to examine differences in the PLR between groups of ASD and TD children between the ages of 3 and 10 years, and to develop a simple testing procedure that could be used for young, pre-verbal children.
Methods:
Children with ASD (n= 34, male=28; $M_{age=}$ 5.79 years) and TD children (n= 33, male=21; $M_{age=}$ 6.06 years) participated in two testing sessions. Each session lasted under 5 minutes and included four to six 21-second-long trials. The visual stimuli were large black and white circles, presented on a uniform gray background, and alternating every second. A standard LCD monitor (Vizio SV420M), calibrated with a spectroradiometer (PR 650), was used to present the stimuli. Pupil size was measured by an infrared-based eye tracker (Tobii X120). The PLR parameters, measured from the white circle onset, included the means of baseline pupil size (pupil size prior to the presentation of the stimulus, in millimeters), PLR latency (time point when the change in the pupil size over the change in time is maximum, in milliseconds), and dilation time (time point at the maximum pupil size, in milliseconds).
Results:
Children with ASD (M=3.83, SD=.38) had significantly larger average baseline pupil size than controls (M=3.59, SD=.31), $F(1)$=8.22, $p < .01$, and had significantly longer mean PLR latency (M=402.88, SD=37.64) than controls (M=382.48, SD=27.10), $F(1)$=6.10, p=.016. In addition, children with ASD (M=260.44, SD=20.58) had marginally significantly longer mean dilation time than controls (M=250.76, SD=18.16), $F(1)$=3.91, p=.052.
A similar pattern was present in the youngest, previously untested age group (ages 3 to 6). The ASD group (n= 23, M=262.96, SD=21.64) had significantly longer mean dilation time than controls (n= 18, M=251.28, SD=11.73), $F(1)$=4.25, p=.046 and had significantly longer mean PLR latency (M=410.00, SD=40.40) than controls (M=385.00, SD=23.81), $F(1)$=5.40, p=.025.
Conclusions:
There were significant differences in PLR parameters between children with ASD and TD in an age group that was younger than previously studied. The results are consistent with previous findings in older children, which suggest that PLR measures could be extended to younger ages and potentially serve as an early biomarker for ASD.

42 **107.042** Evidence for Early Divergence of Thalamocortical Networks in High-Risk Siblings of Individuals with Autism Spectrum Disorder (ASD)

A. Nair[1], *T. Tsang*[2], *C. Ponting*[3], *J. Liu*[2], *S. Y. Bookheimer*[2] *and M. Dapretto*[2], *(1)Psychiatry, University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: The thalamus is an important subcortical relay structure, through which most sensory information is routed. It plays a crucial role in modulation of visual, auditory, and somatosensory functions, as well as attention and motor control. Various lines of evidence have suggested thalamic abnormalities in ASD (e.g., Chugani et al. 1997, Friedman et al. 2003). Highly specific patterns of thalamocortical connectivity have been demonstrated in typically developing (TD) individuals using functional connectivity MRI (fcMRI; Zhang et al. 2008, 2010; Fair et al. 2010). In prior studies (Nair et al., 2013; Nair et al., 2015), we demonstrated that children and adolescents with ASD showed mostly reduced connectivity especially for prefrontal-thalamic networks, accompanied by overconnectivity within temporal-thalamic networks.
Objectives: Given the importance of early identification of biomarkers and endophenotypes of ASD, it is crucial to understand how early in the developmental process these differences in thalamocortical networks emerge.
Methods: Resting-state fcMRI (rs-fcMRI) data were acquired during natural sleep for 8 minutes on a 3T Siemens scanner for 19 infant siblings (6 weeks post-birth) of children with ASD (i.e., high-risk group; HR) and 21 infants at low risk (LR) for ASD. Data were preprocessed using AFNI and FSL, and included motion correction, spatial smoothing, isolation of low frequency fluctuations (.008<f<.08), and normalization to the UNC Infant 0-1-2 neonate atlas (Shi, 2011). The same atlas was used to obtain masks for prefrontal cortex, motor cortex, somatosensory cortex, parietal lobe, occipital lobe, temporal lobe and thalamus (see Nair et al., 2013). Time-series were extracted from each of these cortical regions, and submitted to partial correlation analyses with field of view restricted to thalamus. Results were normalized using Fisher R-to-Z transformation and submitted to paired t-test analysis for comparison between groups. Additional rs-fcMRI data were obtained for 10 HR and 11 LR participants at 9-months post-birth. Similar preprocessing and statistical analyses were used on these data, except that these data were normalized to the UNC Infant 0-1-2 1-year atlas.
Results: Rs-fcMRI results showed aberrant patterns of thalamocortical connectivity in the HR group compared to LR groups at 6-weeks post-birth. These patterns mostly indicated underconnectivity effects for all regions in the HR group, except for the parietal lobe, which showed bilateral overconnectivity effects with the thalamus. At 9 months post-birth, the HR group showed thalamocortical patterns similar to older ASD children and adolescents in our prior studies (Nair et al., 2013; Nair et al., 2015). More specifically, as compared to the LR group, the HR group demonstrated marked bilateral underconnectivity within prefrontal-thalamic networks, and bilateral overconnectivity within temporal-thalamic networks.
Conclusions: Our findings suggest that aberrant subcortical-cortical connectivity may be disrupted as early as the first weeks of life in infants at higher risk of developing ASD. Further longitudinal assessment is required to determine if these thalamocortical connectivity differences can predict which individuals within the HR group will later meet criteria for diagnosis of ASD.

43 **107.043** Examination of the Role of Social and Sensory Factors in Atypical Speech Processing in Autism Spectrum Disorder

L. Latterner, *J. Pandey, J. E. Maldarelli, R. T. Schultz and J. McCleery, The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Language and social development are intimately linked. Individuals with Autism Spectrum Disorder (ASD) display differences in language processing, including atypicalities in speech sound discrimination and lateralization of speech processing. It is unclear, however, whether these differences are related to the inherent social nature of speech or its unique sensory features. In light of evidence for both broad sensory and specific auditory processing abnormalities in ASD, further research is necessary to determine how atypicalities in language processing are related to social and sensory aspects of speech.
Objectives: To investigate brain responses to speech and non-speech stimuli in children with ASD using event-related potentials, in order to elucidate how abnormalities in speech processing relate to social and sensory factors associated with speech.
Methods: Participants are children with ASD aged 3-5 years and chronological age-matched typically developing (TD) controls (see Table 1 for sample characteristics). ASD participants were diagnosed by research-reliable doctoral level clinicians using best clinical judgment based on a variety of measures (ADOS-2, Mullen Scales of Early Learning, Vineland Adaptive Behavior Scales). Speech stimuli in this on-going study consist of short nonsense phrases spoken with angry or neutral prosody, selected based upon affect ratings (interrater reliability ≥.875). Non-social sensory-matched controls for the speech sounds were created by synthesizing a complex tone with the same pitch, amplitude, and overtones as the original speech. Speech and non-speech stimuli are presented in separate blocks, each contrasting prosody (angry, neutral). This experimental design allows for analysis of broad (speech vs. non-speech) and specific (angry vs. neutral) social factors while controlling for sensory features. Analyses focus on the P2 component and a late positive component (P450) over frontal cortex, in order to examine both perception and cognitive evaluation of the stimuli. ANOVAs with Stimulus Type (Human, Non-Human), Emotion (Angry, Neutral), and Hemisphere (Left, Right) as within-subjects factors and Group (ASD, TD) as a between-subjects factor were conducted on the amplitudes of these components.
Results: Perceptual P2 component amplitudes exhibited a significant Group by Hemisphere interaction whereby P2 amplitudes were larger in the left hemisphere for ASD participants but larger in the right hemisphere for TD participants ($F(1, 13) = 6.265$, p<.05, η_p^2=.325). Amplitudes of a frontal P450 cognitive component also displayed an interaction effect between Stimulus Type and Group in which TD participants exhibited larger discrimination of speech and non-speech stimuli, ($F(1, 13) = 6.838$, p<.05, η_p^2=.345).
Conclusions: Preliminary analyses found that ASD participants exhibit atypical left-lateralization of auditory perceptual processing regardless of the stimulus, suggesting the possibility that abnormal hemispheric specialization is independent of both social and prosodic factors. However, these preliminary results suggest that ASD participants also exhibited reduced discrimination of speech and non-speech sounds relative to control participants at a later cognitive stage of processing. Because the speech and non-speech stimuli were carefully matched on physical properties, this finding suggests that impairments in later cognitive processing of speech versus non-speech in ASD may be driven by social factors. Data collection is on-going and full sample ASD and TD data will be reported.

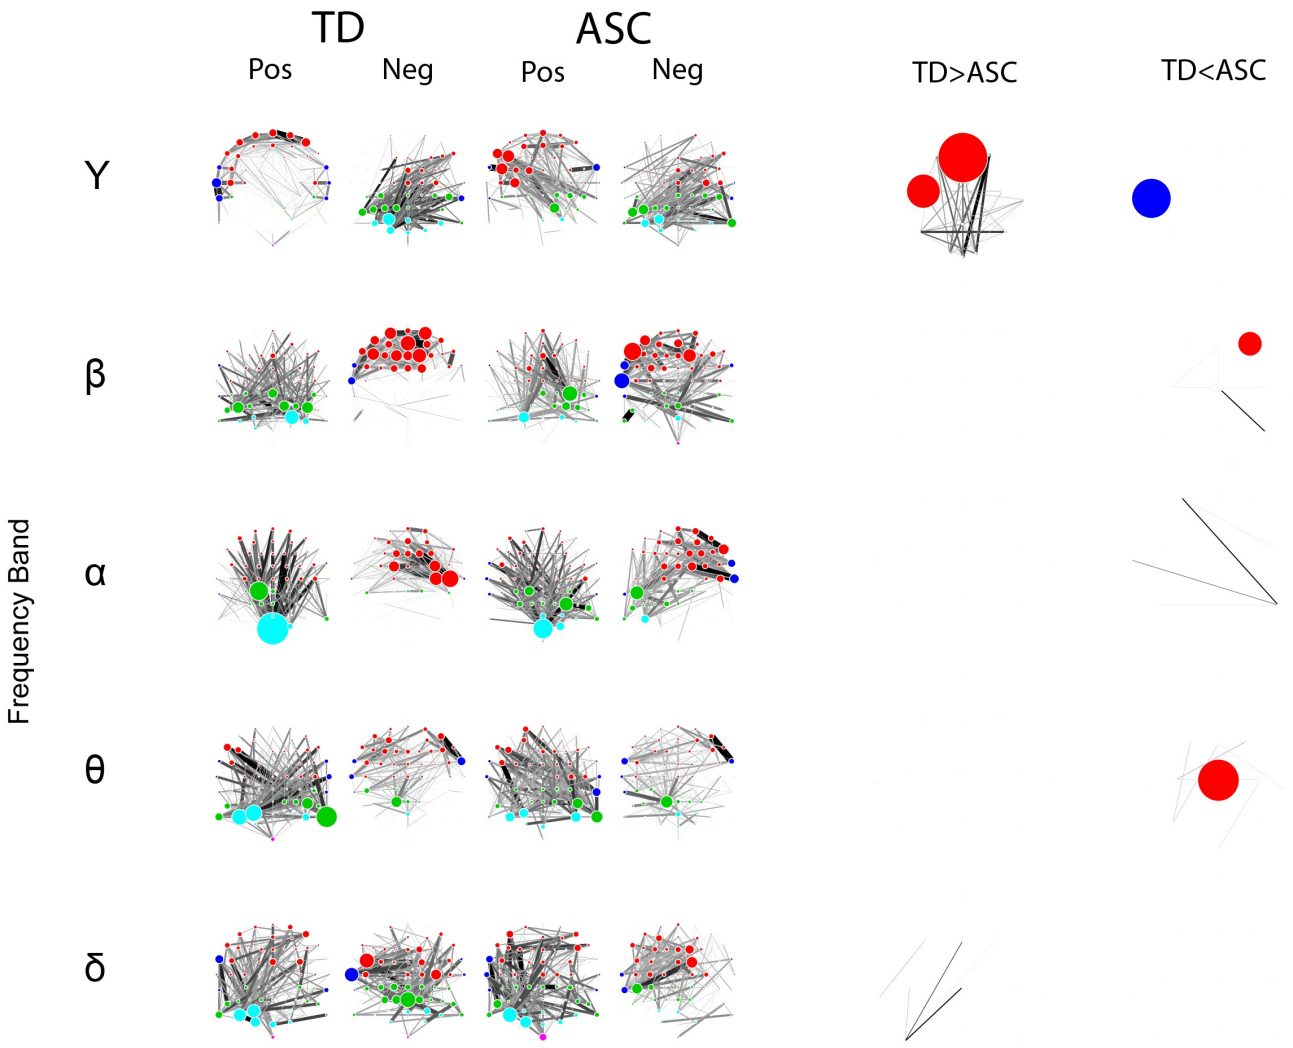
Table 1: Participant characteristics.

	ASD	TDC
N	11	4
Age (months) *mean (SD)*	57.5 (9.4)	59.25 (14.3)
% female	18.2%	50.0%
Early Learning Composite (Mullen Scales of Early Learning) *mean (SD)*	75.3 (13.4)	92.8 (12.8)
Race (% Caucasian)	54.5%	50.0%

44 **107.044** Exploring Atypical Connectivity in Autism Using Graph Theory and Electroencephalography

R. A. Bethlehem[1], *M. G. Kitzbichler*[2], *J. Freyberg*[1], *E. Ruzich*[1], *S. K. Crockford*[1] *and S. Baron-Cohen*[1], *(1)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (2)Department of Psychiatry, Brain Mapping Unit, University of Cambridge, Cambridge, United Kingdom*

Background:
Atypical neural connectivity has been proposed to be a potential hallmark of autism, with hypotheses including decreased fronto-posterior and enhanced parietal-occipital connectivity, reduced long-range and increased short-range connectivity, and temporal binding deficits. However, empirical findings vary substantially depending on the aspects of connectivity examined, the developmental stage of the individual, the spatial and temporal scales, task versus no-task conditions, how motion artefacts are handled, and the specific neural systems under consideration.
Objectives:
To explore the atypical connectivity hypothesis of autism with functional connectivity (FC) analysis of resting-state electroencephalography (EEG) data, using graph theoretical analysis, a non-biased, model-free, data-driven approach.
Methods:
Resting-state EEG data (4-minute with 1-minute alternating eyes-closed, eyes-open) were recorded from 14 adults with autism and 34 neurotypical controls matched for age and IQ. We used data-driven graph theory methods to study FC during the eyes-closed condition of these data. Functional connectivity was estimated using envelope correlations that are more robust against the problem of volume conduction in EEG. In contrast to fMRI, EEG data arguably suffer less from head-motion artefacts and provide a much higher temporal resolution to study network dynamics.
Results:
There were weak whole-brain effects combined with heterogeneous local effects. Consistent with prior literature, differences were found in the alpha and beta frequency range. Specifically, in the alpha frequency range there was a trend towards increased clustering of positive correlations in occipital regions in the neurotypical group, relative to the autism group. Conversely, in the beta frequency range there was increased clustering of negative correlations in central and frontal regions in the neurotypical group relative to the autism group. Most prominently we found higher absolute coupling between frontal and occipital regions in the gamma frequency range in the control group. As the sign of this coupling in the gamma frequency is negative, it means there was less decreased coupling and this is thus interpreted as relative increased functional connectivity between occipital and frontal regions in ASC, that was most prominent in frontal regions.
Conclusions:
The results reveal no clear whole-brain connectivity pattern associated with autism. There are numerous local differences between the neurotypical and autism groups. Most prominently there was a slight but robust increase in functional connectivity between occipital and frontal regions in ASC in the gamma frequency range. Gamma osciliations have previously been associated with a possible excitation-inhibition balance in visual cortex and it is possible the present hyperconnectivity during resting state conditions is the result of a similar excitation-inhibition imbalance.



45 **107.045** Functional Connectivity in the Salience Network Differs Between Infants at High- and Low-Risk for ASD

T. Tsang[1], *C. Ponting*[2], *R. McCarron*[1], *K. E. Lawrence*[1], *S. Y. Bookheimer*[1] *and M. Dapretto*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: Autism spectrum disorders (ASD) are characterized by deficits in social communication and sensory processing. Disruptions in brain connectivity have been implicated in ASD (Geschwind & Levitt, 2007), which may result from altered prenatal neural development (Stoner et al., 2014). In particular, hyperconnectivity of the salience network (SN) has been associated with symptom severity in children with ASD (Uddin et al., 2013). The SN is involved in modulating attention to salient aspects in the internal and external environment. Social stimuli represent salient features of an infant's environment (Johnson & Morton, 1991) and atypical attention allocation to social stimuli has been observed among infants who develop ASD (e.g., Shic, Macari, & Chawarska, 2104). This feature of ASD may stem from altered functional connectivity within the SN during infancy.
Objectives: Here we examine functional connectivity in the SN in 6-week-old infants at high- (HR) and low-risk (LR) for ASD in order to identify how early patterns of connectivity may relate to social cognitive development.
Methods: An 8-minute rs-fcMRI scan was acquired during natural sleep in 6-week HR and LR infants on a 3T Trio Scanner. Risk status was determined by virtue of having one or more older siblings with a confirmed ASD diagnosis. The rs-fcMRI data were motion scrubbed and preprocessed using FSL. The SN was identified using the right insula region-of-interest from an infant atlas (Shi et al., 2011) as the seed. The Autism Observation Scale for Infants was administered 12 months.
Results: HR and LR infants were matched on age ($t(32) = .44$, $p = .65$) and head motion ($t(32) = .37$, $p = .71$).Whole-brain correlation maps generated from the insula seed demonstrated that the SN was detectable in all infants ($p < .05$, cluster corrected). In comparison to LR infants, HR infants exhibited hyperconnectivity between the right insula and somatosensory areas; in comparison to HR infants, LR infants showed stronger connectivity between the right insula and frontal regions of the SN ($p < 0.05$, cluster corrected). Hyperconnectivity between the right insula and sensory cortices among HR infants was associated with the severity of early ASD symptomatology ($r = -.83$, $p < 0.001$).
Conclusions: These preliminary findings indicate that risk status is associated with significant differences in SN connectivity as early as 6 weeks of age. The right insula has been identified as the hub of the SN, which is involved in modulating attention to interoceptive and exteroceptive stimuli (e.g., Uddin & Menon, 2009). Hyperconnectivity between the right insula and somatosensory cortices in the HR group may cascade to altered developmental trajectories characterized by diminished attention to external social stimuli and increased attention to internal sensory perception (e.g., sensory over-responsivity—Green et al., 2013). Although diagnoses cannot be confirmed until 36 months, these findings suggest that disruptions in SN connectivity may provide early reliable biomarkers of ASD before observable social and cognitive symptoms are present.

46 **107.046** Functional Near-Infrared Spectroscopy of Neural Responses to Speech at Three Months

N. M. McDonald[1], *J. A. Eilbott*[2], *H. M. Fichtenholtz*[3], *M. L. Braconnier*[4], *C. A. Wall*[5], *C. A. Paisley*[4] *and K. Pelphrey*[4], *(1)Yale Child Study Center, New Haven, CT, (2)Yale University, New Haven, CT, (3)Yale University School of Medicine, West Haven, CT, (4)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (5)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Infants show a behavioral preference for speech vs. other human and environmental sounds within the first months of life. This preference for speech sounds is an important factor in social development, with a lack of preference potentially indicating risk for social deficits, such as in autism spectrum disorder (ASD). While several studies have identified specialized neural circuitry for processing speech vs. non-speech sounds in adults, it is less clear whether this specialization is evident in the first months of life. A previous study from our group using functional magnetic resonance imaging (fMRI) found increased activation to speech vs. non-speech sounds in the left temporal cortex in one- to four-month-old infants during natural sleep. We sought to replicate these findings using functional near-infrared spectroscopy (fNIRS) in awake infants at three months of age.
Objectives: In preparation for developing less-invasive risk biomarkers for ASD, we examined whether 3-month-old infants showed increased neural activation in response to

infant-directed speech vs. other human sounds using fNIRS.
Methods: Infants were seated in their parent's lap across from a screen and wearing the infant fNIRS headgear (optodes covering right and left temporal cortices; see Figure 1). Auditory stimuli were adapted from Shultz et al. (2014). Infants heard five 10-s blocks (pseudorandom order) for each of the three conditions: infant-directed speech (IDS), human communicative non-speech vocalizations (HCM), and human non-communicative vocalizations (HNC). Speech sounds were comprised of a set of phrases in Japanese to allow for a focus on the social, rather than language-related, aspects of speech. While the sounds played, an infant-friendly video depicting non-social stimuli played to maintain infant attention. Changes in oxygenated hemoglobin (Oxy-Hb) within the speech condition were contrasted with the non-speech conditions.
Results: Data from 14 infants were included in analyses. As depicted in Figure 2, grand average waveforms within each hemisphere indicated increased activation in the right temporal cortex in response to infant-directed speech. A *t*-test contrasting the speech vs. non-speech conditions revealed a significant difference in mean Oxy-Hb concentration at 4.5 to 7.5 s post stimulus, $p = .02$.
Conclusions: Infants exhibited increased activation to speech sounds within the first three months of life. We found increased activation to infant-directed speech within the right temporal cortex, an area often found to be sensitive to social stimuli. These findings offer important implications for understanding ASD. Specifically, it may be that a lack of neural specialization for social stimuli, including speech, within the first months of life places infants at risk for the disruptions in social development apparent in ASD. As a next step, we plan to examine whether individual differences in neural sensitivity to speech are associated with concurrent parent reports of early sociability. Future directions include longitudinally examining whether infants who are more sensitive to speech at three and six months of age are more social at 12 months and whether these early neural responses are associated with risk for ASD.

Figure 1. Optode configuration by hemisphere

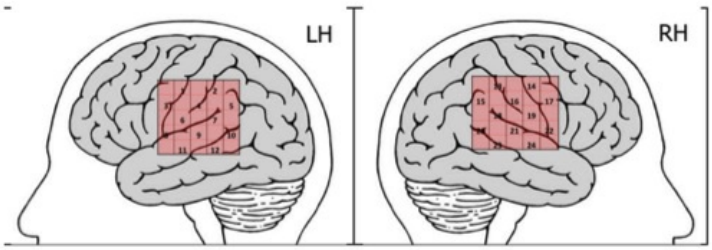


Figure 2. Comparison of post-stimulus Oxy-Hb concentrations by hemisphere and condition

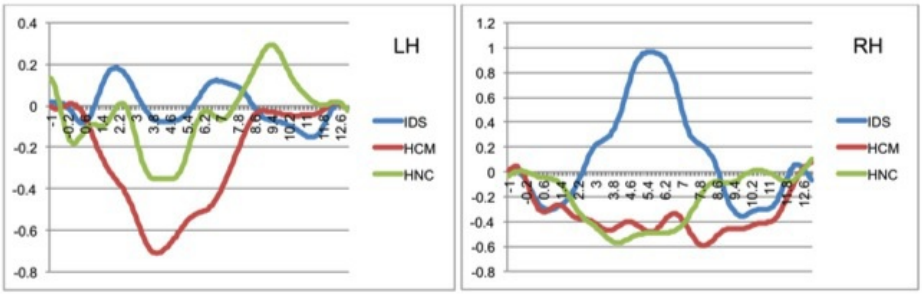
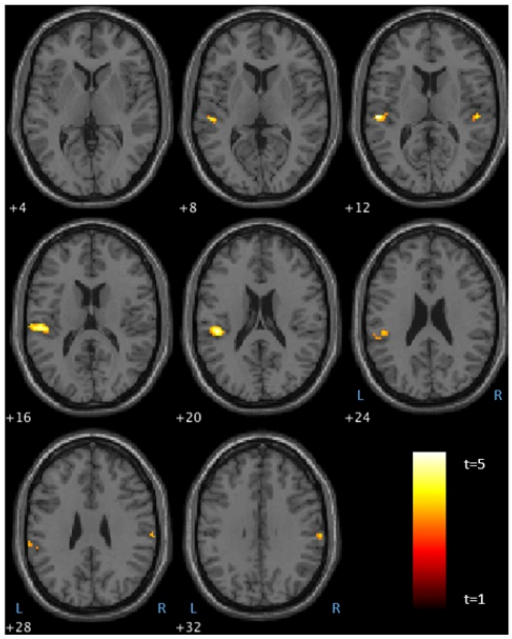


Note. IDS = Infant-directed speech, HCM = Human communicative non-speech vocalizations, HNC = Human non-communicative vocalizations

47 **107.047** Hemispheric Differences in Auditory Complexity Processing in ASD

L. A. Sand[1], *E. Redcay*[2], *T. Zeffiro*[3], *F. Samson*[4] *and D. J. Bolger*[1], *(1)Human Development & Quantitative Methodology, University of Maryland, College Park, MD, (2)Department of Psychology, University of Maryland, College Park, MD, (3)Neurometrika, Potomac, MD, (4)Department of Psychology, University of Western Ontario, London, ON, Canada*

Background: Autism Spectrum Disorder (ASD) can be accompanied by delays in speech acquisition and a puzzling combination of auditory abilities, with enhanced pitch processing abilities often coexisting with atypical spoken language processing, particularly involving prosody. Speech has complex auditory characteristics and there is evidence for hemispheric specialization of auditory processing, with temporal processing more lateralized to the left hemisphere and spectral processing to the right. It is possible that some aspects of autistic individuals' atypical auditory behavior results from lateralized differences in complex sound processing in both primary and non-primary auditory cortex.
Objectives: N/A
Methods: We employed fMRI to explore the neural basis of complex sound processing in 12 ASD and 15 typical participants, ages 16-30. Participants performed a simple visual discrimination task while hearing 7 sec trials of parametrically varying complex auditory stimuli with a random spectrogram that had 5 levels each of spectral and temporal complexity. These stimuli are noise-like and do not resemble speech sounds. We used an accelerated multiband (MB) echo planar imaging (EPI) pulse protocol providing both high temporal and spatial resolution, thus enabling more accurate measurement of functional responses. Single subject fixed effect regression models were used to compute parameter estimates for each of the 25 spectral/temporal sound complexity combinations. Head motion covariates and motion outlier exclusion were used to minimize the effects of participant head motion. Group mixed effects models were used to identify group and groupXtask interaction effects.
Results: Both groups showed strong bilateral activity modulations with increasing spectral complexity in the planum temporale (PT; secondary auditory cortex), and transverse temporal gyri (TTG; primary auditory cortex). Increasing temporal complexity had a weaker modulatory effect and was only seen in the left PT. Averaging across all levels of spectral and temporal complexity, ASD participants exhibited higher activity in the PT and TTG, with the effect larger on the left than the right.
Conclusions: While we observed similar spatial patterns of hierarchical functional organization for auditory processing in both groups, the ASD participants exhibited higher task-related activity in left primary and non-primary auditory cortex when listening to complex sounds. This lateralized difference was largest in auditory cortex lateral to TTG. Greater auditory stimulus complexity effects in regions sensitive to acoustic temporal features could represent atypical left hemisphere processing of complex auditory stimuli in ASD, possible related to atypicalities in spoken language processing.



T-values for regions showing significantly greater BOLD signal in ASD > TYP contrast for average of all levels of spectral and temporal complexity displayed on a template brain. Relative to typical controls, ASD participants exhibited higher activity in planum temporale (PT) and transverse temporal gyri (TTG), with the effect larger on the left than the right. Axial slices are displayed.

48 **107.048** Increased Gamma Oscillatory Activity within the Salience Network: Relationship to Social and Attention Functioning in ASD

T. Andersen[1], *A. M. Flores*[1], *C. Swick*[1], *J. Brennan*[2], *I. Kovelman*[2], *S. Bowyer*[3] *and R. Lajiness-O'Neill*[1], *(1)Eastern Michigan University, Ypsilanti, MI, (2)University of Michigan, Ann Arbor, MI, (3)Henry Ford Hospital, Detroit, MI*

Background: Autism spectrum disorders (ASD) are characterized by deficits in social and attention functioning. Research to date has failed to clarify the pathogenesis, and there is an urgent need to identify biomarkers to aid earlier diagnosis given its escalating prevalence. Deficits in the salience network (SN) have been shown to distinguish between children with autism and neurotypical children; however, links to clinical symptoms have not been established. The insula is a key node of the SN, responsible for "selecting" stimuli for additional processing. Disruptions in connectivity are believed to lead to aberrant salience processing, which may contribute to core symptoms of ASD (i.e. lack of attention to social stimuli).
Objectives: This study investigated relationships between neural synchrony within the SN and social/attention functioning.
Methods: Twelve children with ASD (Age: M = 9.2; SD = 1.0) and 13 neurotypical (NT) controls (Age: M = 9.3; SD = 1.3) underwent magnetoencephalography at rest. Synchronization of activity was quantified by calculating coherence (0 to 1) between the insula and other cortical regions of the SN. Group differences were computed using t-tests for each region pair. Kendall Tau correlations were computed to examine relationships between coherence and social/attention functioning, as measured by NEPSY-II Auditory Attention (AA)/Response Set (RS) and Social Responsiveness Scale-2 (SRS-2), respectively.
Results: Within gamma, higher coherence was noted in NT between L Insula (LI) to: R Angular Gyrus (p = .02), R Middle Occipital Gyrus (p=.05), and R Superior Occipital Gyrus (p = .04). In ASD, significant positive relationships were noted between SRS-2 Cognitive subscale and coherence from LI to: L Cingulate (p=.003), L Inferior Frontal Gyrus (IFG) (p=.04), L Superior Frontal Gyrus (SFG) (p=.03), R Cingulate (p=.007), R Insula (RI) (p=.04), and R SFG (p=.03). Significant relationships between SRS-2 Restricted and Repetitive Behavior (RRB) subscale and coherence from RI to L Cingulate (p=.05) and LI to: L Cingulate (p=.003), L SFG (p=.03), R Cingulate (p=.02), RI (p=.05), and R SFG (p=.03), were noted. Within NT, significant negative relationships between NEPSY RS and coherence from LI to L IFG (p=.04) and LI to L MFG (p=.05) was noted. SRS-2 Communication and Motivation were positively related between coherence and LI to L Cingulate (both p=.04).
Conclusions: In NT, higher gamma band synchrony is noted in cross-hemispheric connections between LI and R parieto-occipital regions. In ASD, greater deficits in social cognition/RRB are related to higher gamma band synchrony, specifically within the left hemisphere and between insula and cingulate/frontal gyri. A similar relationship is reflected in heightened coherence between bilateral insula, cingulate and SFG. Better complex attention is related to lower gamma coherence between left insular and frontal regions in NT, while no relationship was found in ASD, suggesting alternate "selection" pathways. Overall, findings suggest enhanced frontal gamma oscillatory activity between the insula, a vital component of the SN, and other frontal regions may contribute to core symptoms of ASD.

49 **107.049** Increased Trial-By-Trial Neural Variability Associated with Increased Autistic Traits in Healthy Adults

M. H. Puglia*, J. J. Connelly and J. P. Morris, Department of Psychology, University of Virginia, Charlottesville, VA*

Background: The Noisy Brain Theory suggests that the unique constellation of symptoms present in autism spectrum disorder (ASD) might be the result of a single widespread abnormality in neural functioning. Specifically, the evoked response to stimuli across multiple sensory modalities is less reliable and shows greater variability among individuals with ASD when compared to neurotypical controls (Dinstein et al., 2012; Milne, 2011).
Objectives: As it is increasingly understood that autistic traits are expressed on a continuum in the general population, the current study expands upon these results to examine whether trial-by-trial variability in neural response is also associated with the occurrence of autistic traits in healthy adults. We utilize a biological motion perception paradigm to explore how response variability is associated with autistic traits under both social and nonsocial contexts.
Methods: Eighty-six healthy adults (49 males) aged 18 to 25 years passively viewed alternating 24-s blocks of point-light-walker displays of biological motion or random motion while undergoing fMRI. Autistic traits were assessed with the Autism Spectrum Quotient Questionnaire (AQ) (Baron-Cohen et al., 2001). An independent components analysis (ICA) was first performed to identify regions of interest (ROIs) with a model-free, data-driven approach. To assess the evoked response to each stimulus type (biological, random), the peristimulus timecourse from each ROI was extracted separately for each trail (5 per stimulus type), with onset aligned to the onset of the stimulus, and a duration of 44 seconds capturing the entire hemodynamic response to the stimulus including recovery. Neural variability was calculated as the standard deviation of each time point within each individual's timecourse for each ROI and stimulus type.
Results: AQ scores showed a normal distribution and ranged from 4 to 32 in the current sample. The first component of the ICA accounted for 46.57% of variance in data and consisted of 12 spatial clusters encompassing bilateral fusiform gyrus, posterior superior temporal sulcus, precuneous, rostromedial prefrontal cortex, superior frontal gyrus, left orbitofrontal cortex and rostrolateral prefrontal cortex, and right inferior frontal gyrus. Across both conditions and all ROIs, AQ score and neural variability showed a significant positive association (all p's < 0.0001). For the biological condition, variability of neural response across ROIs accounted for 5 to 28% of variance in autistic traits. Similarly, for the random condition, variability of neural response across ROIs accounted for 7 to 59% of variance in autistic traits.
Conclusions: Previous research has indicated that poor response reliability may be a fundamental neural characteristic of autism. The current study expands upon this hypothesis by demonstrating that healthy adults with a high occurrence of autistic traits show a similar "noisy" neural response across repeated trials of stimulus presentation as indicated by increased standard deviations within the timecourse. Within healthy populations, neural noise has been associated with developmental processes (Misiæ, et al., 2010), and may therefore prove to be a particularly useful metric for informing differential developmental trajectories among individuals with ASD.

50 **107.050** Integrated Study of Joint Attention in Autism Spectrum Disorders By High-Density EEG and Eye-Tracking

L. Billeci[1,2], *A. Narzisi*[2], *A. Tonacci*[3], *S. Calderoni*[4], *G. Pioggia*[5] *and F. Muratori*[2], *(1)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (2)IRCCS Stella Maris Institute, Pisa, Italy, (3)Clinical Physiology Institute - National Research Council, Pisa, PI, Italy, (4)Magnetic Resonance Laboratory, Division of Child Neurology and Psychiatry University of Pisa; Stella Maris Scientific Institute, Pisa, Italy, (5)National Research Council of Italy (CNR), Pisa, PI, Italy*

Background: Autism Spectrum Disorders (ASD) are characterized by a strong impairment in joint attention (JA) development. This deficit is associated with difficulties in social

learning and has consequences on the subsequent behavioral and neural development of children with ASD. For this reason the implementation of protocols for the study of brain-behavior correlation of JA are crucial in understanding and treating ASD. Electrophysiology (EEG) can provide cues about the behavioral correlates of JA with an excellent temporal resolution. To our knowledge no study in literature have explored yet the neurophysiological correlates of JA in ASD using EEG. Moreover eye-tracking can provide additional information about the direction of the gaze during the task.
Objectives: The aim of this study was to describe the neurophysiological and gaze correlates of JA in children with ASD during responding and initiating joint attention tasks. A further aim was to use this quantitative assessment to evaluate the eventual modifications in EEG and eye-tracking measures due to the treatment.
Methods: Data were acquired in 10 children with ASD at T0 and after six months of treatment (T1). Stimuli consisted in video sequences, with an actor between two identical toys placed on the floor in front. The experiment involved two conditions: the responding to joint attention (RJA) and the initiating joint attention (IJA). A control condition without objects was also added. EEG data were acquired using a high-density 128-channels system (HCGSN 128; Electrical Geodesics Inc) while children' gaze was recorded with SMI Eye Tracking device by SensoMotoric Instruments (Germany). A switch connected to the stimulus PC allowed sending the events simultaneously to the two systems. EEG data epochs, in which the child attended the screen, were pre-processed to remove artifacts and analyzed using quantitative methods (QEEG) to obtain power, asymmetry and coherence. For eye-tracking data analysis three regions of interests (ROIs) were selected: model's face, target object and non-target object. Gaze duration within each ROI and transitions between different ROIs were computed.
Results: In the IJA condition treatment induced an increased in frontal gamma activity and a decrease in alpha and delta activity in frontal, temporal and occipital areas. Coherence in gamma band increased in frontal and occipital areas while delta and alpha coherence decreased in occipital areas. In the RJA condition power decreased in frontal regions in theta and alpha bands, in right temporal area in alpha and in left occipital area in delta. Coherence increased in delta band between occipital and temporal areas and in parietal area in theta and alpha bands. Eye-tracking analysis revealed an increased attention at face and a decreased attention at objects at T1. In addition in the IJA task transitions from both target and non-target object to face increased compared with T0. Significant correlations were observed among QEEG measures and eye-tracking parameters.
Conclusions: The integrated protocol realized allowed to explore neurophysiological and gaze correlates of the different components of JA. The results of this study suggest that IJA and RJA subtend two different neural circuitries, which can be modified by treatment.

51 **107.051** Interactive Social Neuroscience to Assess Reward Processing in the Broad Autism Phenotype: An Event-Related Potential Study

M. Rolison[1], *A. Naples*[1], *J. Herrington*[2] *and J. McPartland*[1], *(1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Autism Spectrum Disorder (ASD) is hallmarked by interpersonal difficulties, yet scant published neuroscience research investigates actual social interactions. Atypical reward processing is implicated in ASD, but ecologically valid studies dissociating social versus non-social reward in ASD are lacking. This study utilized interactive social neuroscience methods to examine reward processing in a social context and its association with autistic traits in typically developing (TD) adults. Using simultaneous recording of electroencephalogram (EEG) and electrocardiogram (ECG) in pairs of people competing in a computer game, we examined reward processing (indexed by event-related potentials [ERP]), heart rate variability, and their association with autistic symptomatology.
Objectives: Characterize neural and cardiac markers of reward and feedback processing and their association with autistic traits during face-to-face social interactions.
Methods: 16 TD adults, grouped in same-sex dyads, (a) sat quietly apart versus together while making eye contact, and (b) played a competitive treasure hunt game against a computer and against each other. EEG and ECG were recorded from each member of the dyad using wireless recording devices. ERP components marking early visual processing (P1, N2) and reward processing (FRN, P3) were contrasted based on competitor (computer/human), outcome (win/loss), and player (self/opponent). To quantify social function and dysfunction, the Autism Quotient (AQ) and Broad Autism Phenotype Questionnaire (BAPQ) were administered.
Results: Preliminary analyses of heart rate variability and resting data revealed differences associated with the presence of another person. Autistic traits were associated with attenuated FRN and P3 indices of reward processing. Sensitivity to feedback, indexed by the FRN, during live, not computer, competitors was correlated with autistic traits. There was a significant correlation between the differences in FRN amplitude between self-win and opponent-win when playing against another person and AQ (r=-0.505, p=0.046) and BAPQ (r=-0.558, p=0.025) scores. Additionally, BAPQ score was correlated with differences in FRN amplitude between self-win and opponent-miss when playing against another human (r=-0.544, p=0.030), as well as with the difference in FRN amplitude for opponent-win and self-miss (r=0.526, p=0.036). Sensitivity to reward during live interaction, indexed by the P3, was correlated with autistic traits. For the P3, BAPQ scores were correlated with the difference in amplitude between self-win and opponent-win conditions when playing against another person (r=-0.516, p=0.041), as well as between opponent-win and self-miss conditions when playing against another person (r=0.524, p=0.037). There were no significant effects of outcome, player, competitor, or interactions for low-level sensory components (P1 and N2; all ps>0.10).
Conclusions: This study applied interactive social neuroscience to investigate reward processing during live interaction in TD adults. This was the first study to examine electrophysiological indices of reward-feedback monitoring during live dyadic interaction. Results reveal task-specific modulation of brain activity during live interaction that is absent during computer interaction. Individuals with lower levels of autistic traits exhibited greater sensitivity to outcome during live interaction versus playing alone. Our findings provide new insight into differences in reward processing mechanisms associated with autistic traits and further emphasize the import of utilizing more ecologically valid approaches in neuroscientific studies of social brain function.

52 **107.052** Investigation of Face Processing in Autistic Spectrum Disorder (ASD) for the Development of Clinically Useful Biomarkers: An Electroencephalographic Approach

N. Mc Devitt[1], *L. Gallagher*[2] *and R. B. Reilly*[3], *(1)Trinity College Dublin, Dublin, Ireland, (2)Psychiatry, Trinity College Dublin, Dublin, Ireland, (3)Department of Engineering, Trinity College Dublin, Dublin, Ireland*

Background: Autistic Spectrum disorders (ASDs), are characterized by social deficits and restricted/repetitive behaviours. Underlying mechanisms are unclear, though they are thought to be caused by an interaction between genetic and environmental factors. Using imaging methods such as electroencephalography (EEG) to understand more about the neural mechanisms of ASDs may aid in the development of clinically useful biomarkers for earlier diagnosis as well as for drug treatment endpoints.
Objectives: To conduct behavioural and electrophysiological endophenotyping to probe core social deficits of ASD to facilitate improved knowledge regarding underlying neural mechanisms of ASD.
Methods: 5 participants with ASD and 10 typically developing (TD) participants have completed this research currently, data collection is ongoing. ASD participants have an unambiguous clinical diagnosis of ASD. EEG was recorded continuously using a high density 64 electrode array. Analysis was carried out offline. The paradigm consisted of schematic faces representing different emotions. There were three stimulus categories: Standard, Target and Deviant. The deviant varied between conditions A (Angry) and B (Happy). This paradigm was adapted from a study by Kreegipuu et al (2013). For this research particular focus was paid to the parietal region as this area is consistently associated with P300 generation.
Results: A within group analysis comparing the difference between stimuli in the ASD group was carried out. All mean amplitudes between the time period of interest (250-550ms) were found to be significantly different from each other ($p<0.001$), a between group analysis compared mean P3 amplitudes, between the two groups, each stimulus

response was compared. All three were found to be statistically significant from each other ($p<0.001$). A within group analysis of amplitude differences for each stimulus between the two conditions, exhibited that there was no significant differences found in mean P3 amplitudes in the ASD group ($p<0.05$). The control group conversely exhibited a significant difference in mean amplitudes in response to the deviant between conditions.
Conclusions: The aim here was to probe the core social deficits in ASD utilising EEG in TD individuals in comparison to individuals with ASDs. The significant differences in P3 amplitudes exhibited between the two groups suggest mechanistic differences in emotional processing between the two groups. Additionally, within group analysis of Condition A and B revealed a significant difference in amplitudes between the deviant stimuli in TD adults ($p<0.001$). There was no difference observed in the ASD group between the two conditions ($p>0.05$). Angry faces have been shown previously to elicit higher amplitudes than happy faces (Martens, Leuthold, & Schweinberger, 2010). There are several reasons this may have occurred, the ASD group have been more focused on details of the faces rather than the global representation, this more detail oriented observation has been exhibited in ASD previously. Secondly, ASD group may not be able to differentiate between the emotions on the schematic faces as easily as the TD group. Overall, significant differences in emotional face processing between the two groups were exhibited, further investigation into these differences could lead to the development of clinically useful biomarkers for earlier diagnosis.

53 **107.053** Mental Imitation and Mirroring in Children with Autism

*J. O. Maximo, **R. J. Donnelly**, H. M. Wadsworth and R. K. Kana, University of Alabama at Birmingham, Birmingham, AL*

Background: Although a deficit in imitation has been reported in autism spectrum disorders (ASD) (Williams et al., 2001; Rogers et al., 2003; 2008), recent studies have reported intact imitation skills in this disorder (Bird et al., 2007; Dinstein et al., 2010; Hamilton et al., 2007). Mental imitation, perhaps a precursor to motor imitation, involves visual perspective-taking and motor imagery (Jeannerod, 1994; Goldman, 2005). Research on mental imitation in autism has been rather limited compared to that on motor imitation. Considering the proposed role of impairments in the mirror mechanism and mentalizing ability in autism, we hypothesize that children with autism will have altered patterns of brain responses coupled with poorer task performance in mental imitation of actions.
Objectives: The main objective of this study is to determine the differences in brain responses underlying mirroring and mentalizing networks during mental imitation in children and adolescents with ASD
Methods: Thirteen high-functioning children and adolescents with ASD and 16 age-and- IQ-matched typically developing (TD) control participants took part in this fMRI study. In the MRI scanner, participants were shown cartoon pictures of people performing everyday actions (*Transitive actions*: e.g., ironing clothes but with the hand missing; and *Intransitive actions*: e.g., clapping hands with the palms missing) and were asked to identify which hand or palm orientation (of three answer choices) would best fit the gap (Mozaz et al., 2002). Neuroimaging data was analyzed using AFNI and SPM12 to examine brain activation and functional connectivity.
Results: The main findings of this study are as follows: 1) Processing both transitive and intransitive actions yielded activation in the bilateral inferior frontal gyrus (IFG) and inferior parietal lobule (IPL) in both ASD and TD groups; 2) Between-group analysis yielded hypoactivation in the ASD children, relative to TD, in the right angular gyrus and cerebellum for both conditions; 3) Hyperactivation in ASD, relative to the TD group, in the left middle occipital gyrus, left IFG, and IPL for both transitive and intransitive actions; and 4) whole-brain functional connectivity analysis revealed underconnectivity (ASD < TD) between the RIFG seed with left cerebellum, right insula, and the right fusiform gyrus and between the right IPL seed and right precentral gyrus (All analyses are reported at a statistical threshold of $p < 0.05$, cluster size $k = 100$; FWE corrected).
Conclusions: Increased activation in IFG and IPL in both groups suggests possible role of mirroring mechanism in mental imitation of actions. Hypoactivation in RIPL and its hypoconnectivity with motor areas in ASD suggest limited and/or altered engagement of the mirroring/motor network. This pattern of activation difference may have implications for understanding social movement and in social development through modeling in ASD. Hypoconnectivity of IFG with several regions also underscores the limited engagement of social brain areas in autism. Overall, our findings suggest that mirroring and mentalizing brain networks respond differently in children with ASD during tasks of mental imitation.

54 **107.054** Neural Adaptation during Learning in ERPs to Visual Target Detection in Children with ASD

S. E. Schipul[1]*, G. T. Baranek*[2]*, A. M. Campbell*[1] *and A. Belger*[1]*, (1)University of North Carolina, Chapel Hill, NC, (2)UNC Chapel Hill, Chapel Hill, NC*

Background: Previous fMRI studies have demonstrated reduced neural adaptation in adults with autism spectrum disorder (ASD) during short term learning tasks (Schipul et al., 2012; Schipul & Just, 2015). Reduced neural adaptation may impair learning abilities in ASD and possibly play a role in the emergence of behavioral characteristics of ASD. However, it is critical to examine the neural processing underlying learning throughout development in ASD. Therefore, in the present study we use electroencephalography (EEG) to examine neural adaptations during learning in children with ASD during performance of a visual target detection task.
Objectives: The current study examines changes in event-related potentials (ERPs) over time during a visual target detection task in children with ASD and typically developing (TD) children, in order to gain insight into neural adaptability in children with ASD.
Methods: Participants include children with ASD and TD children, ages 8 to 12 years old and with IQs in the normal range. EEG data was collected while participants performed a visual target detection task for 30 minutes. Data was collected from 128 electrode sites and was analyzed using EEGLab. EEG waveforms were compared for both non-targets (red circle, 85% of trials) and targets (blue square, 15% of trials) between Early and Late blocks of the experiment. Data collection is ongoing and currently includes 10 ASD and 12 TD participants.
Results: Preliminary results suggest that the ASD group (n=4) and TD group (n=4) show similar EEG waveforms to Non-Targets in Early blocks, but that the ASD group shows a similar pattern in Late blocks, while the TD group shows significant attenuation in Late blocks in both the P1 and N2 (Fig. 1). In response to Targets, the ASD group shows an attenuated P3 response relative to the TD group in Early blocks (Fig. 2). Group adaptations in the response to Targets is currently unclear. Behavioral accuracy and reaction time was similar across groups and well above chance.
Conclusions: These preliminary findings suggest reduced adaptation over time in ERP responses to visual non-target stimuli in children with ASD. This may reflect reduced neural adaptability in ASD that may affect the learning process throughout development. Furthermore, we found blunted ERPs to targets in ASD (despite intact behavioral performance). Future analyses will include the full final participant groups and will relate neural measures to clinical measures of ASD symptom severity and sensory features. Reduced neural adaptability in ASD may affect the learning of a variety of behaviors throughout development and may play a role in the emergence of ASD symptoms.

55 **107.055** Neural Bases of Hierarchical Shape Processing in Autism Spectrum Disorder

T. DeRamus[1], *K. N. Rody*[2], *S. L. Kumar*[3] *and R. K. Kana*[3], *(1)Psychology, University of Alabama at Birmingham, Birmingham, AL, (2)Psychology, University of Alabama Birmingham, Birmingham, AL, (3)University of Alabama at Birmingham, Birmingham, AL*

Background: Enhanced visuospatial processing (Mottron et al., 2006) and Weak central coherence (WCC) (Frith & Happe, 2006) accounts argue that individuals with autism spectrum disorders (ASD) may focus on featural aspects of information more than the configural aspects. Nevertheless, there is increasing evidence that the "local bias" in ASD is not always present when other developmental factors (such as age and metrics of IQ) are taken into account (Pellicano et al., 2006). Furthermore, a number of experiments have found enhanced recruitment of frontal, parietal, and occipital brain regions in ASD, but studies reporting how these regions are interconnected during such visuospatial processing tasks in ASD is limited.
Objectives: To obtain a greater understanding of brain circuitry involved in visuospatial functions in individuals with ASD.
Methods: Fifteen children and adolescents with ASD and sixteen typically developing (TD) control participants (age 8-17 years) performed a hierarchical shape stimuli task (Navon, 1977) in the fMRI scanner. The task utilized a blocked design with trials that require the participant to name the larger shape composed of the smaller shapes (Global), and to name the smaller shapes that compose the large shape (Local). Data collected from a Siemens 3T Allegra scanner were analyzed using SPM12; functional connectivity analyses were performed using the CONN Toolbox, with 28 seed regions of interest (ROIs) selected from previous literature and from meta-analysis data. Connections were grouped and familywise error corrected using Network Based Statistics (NBS) in CONN. ANCOVAs were used to assess group differences in mean reaction time (RT) with age and full scale IQ (FSIQ) as covariates.
Results: While processing global shapes, ASD children displayed greater activity in the middle and superior temporal (MTG/STG), middle occipital, and lingual, superior and middle frontal gyri (SFG/MFG), and inferior parietal lobule (IPL), along with putamen and thalamus. A similar effect was found while identifying local shapes, with greater lingual, posterior cingulate, MTG, and SFG activation, along with putamen thalamus in ASD. ASD participants showed hyperconnectivity during local processing between the STG seed with the fusiform, inferior occipital, lingual, postcentral gyri and the thalamus. The thalamic seed revealed increased connections in ASD between the insula, inferior frontal, and postcentral gyrus. Faster RTs were found in the Local compared to the Global condition. Task accuracy did not differ by trial type or between ASD and TD individuals, but there was a significant main effect of FSIQ on task performance.
Conclusions: Our functional results are consistent with some previous findings of increased activation among visual-spatial regions of the brain in ASD (Gadgil et al., 2013; Kana et al., 2013). Increased connectivity between these regions and the thalamus in ASD may suggest an altered pattern of perceiving and integrating visual stimuli in ASD. The behavioral results from this study do not support the hypothesis of enhanced perceptual processing for local stimuli in ASD, and suggest that performance for such tasks may be more influenced by other factors such as IQ. Future experiments with additional measurements are needed to explore this hypothesis further.

56 **107.056** Neural Correlates of Sociocognitive Processing in Infants with Congenital Visual Impairment

N. J. Dale[1], *M. O'Reilly*[2], *E. Sakkalou*[2], *A. Salt*[2] *and M. De Haan*[3], *(1)Clinical Neurosciences, UCL Institute of Child Health/ Great Ormond Street Children's Hospital, London, United Kingdom, (2)Clinical Neurosciences, UCL Institute of Child Health, London, United Kingdom, (3)Developmental Cognitive Neuroscience, UCL Institute of Child Health, London, United Kingdom*

Background:
Young children with congenital profound or severe visual impairment (VI) have a high risk of developing difficulties in social communication and interaction. However the electrophysiological mechanisms underlying socio-cognitive processes in infants with VI remains unknown. The Subject's Own Name (SON) is a powerful and unique auditory social stimulus; behavioural, imaging and ERP studies in healthy infants have shown that the SON response can be detected as early as 4-5 months (Mandel, 1995, Grossmann *et al*., 2010; Blasi *et al*., 2011, Lloyd-Fox *et al*., 2012). The SON is considered a reliable measure of socio-cognitive processing (Carmody *et al*., 2006) and has the potential to demonstrate abnormalities in atypical populations.

Objectives:
We set out to examine ERP responses to the SON in infants with VI at 1 year of age compared to age-matched typically sighted controls. Based on previous SON ERP findings, we predicted that the SON would elicit greater amplitudes compared to the other name in typically sighted infants. We predicted atypical ERP responses in infants with VI compared to sighted controls based on the evidence that children with VI have socio-cognitive difficulties (Dale & Salt, 2008).
Methods:
23 infants with severe and profound VI (mean 12.7 ± 2.5 months) with 'simple' peripheral disorders of the congenital visual system and 14 age-matched typically sighted infants (mean age mean 12.5 ± 2.4 months) underwent ERP recording using a 128-channel EGI Sensor Net. SONs and 'other' names spoken by the mother's voice were presented in an equiprobable design at 70 dB intensity. Two ERP components were identified by selecting peak amplitudes (± 30 ms) of grand averages per group: *P300* (213-273 ms) component and *N500* (484-544 ms) component.
Results:
Repeated-measures ANOVAs revealed no effect of the SON on P300 responses in the infants with VI or in the typically sighted control group (all *p*'s >.05). A significantly larger N500 amplitude (greater response) for the SON compared to Other name at frontal and central sites was observed (Name x Location: $F(3,39.1) = 2.5$, $p<0.05$) in the typically sighted control group. However in the infants with VI, no significant name effect on the N500 component was found, with similar magnitude of response to both SON and other name observed ($p>.05$).
Conclusions:
This finding for the N500 component in typically sighted group was consistent with Parise *et al.* (2010), who also found significantly larger negative-going amplitudes (N200-600) at frontal and central sites in response to the SON in 5-month-old typically sighted infants. However, infants with VI showed an atypical response to the SON, showing a reduced SON effect and not localized in the same sites, compared to the typically sighted control group. Therefore, as early as 1 year of age, infants with congenital VI appear to be processing socially salient information differently to age-matched sighted infants and we can detect this at neural level. Further investigation will identify if the ERP SON response acts as an early biomarker for later socio-communicative difficulties in children with VI who are most at risk of emerging autism.

57 **107.057** Neural Mechanisms of Emotion Regulation with Circumscribed Interests in Adults with ASD

***L. Antezana**, M. Coffman and J. A. Richey, Virginia Tech, Blacksburg, VA*

Background: Restrictive and repetitive behaviors (RRB) are a core feature of autism spectrum disorder (ASD), and circumscribed interests (CI) are one of the core characteristics of RRB. Individuals with ASD also evidence increased affective responses (i.e. hyperarousal and positive valence) toward CI (Sasson, Dichter, & Bodfish, 2012). Intensity of CI are known to impact difficulties in executive function and social responsiveness (Anthony et al., 2013). The ability to modulate one's affective responses is known as emotion regulation (ER) and deficits in ER around CI may therefore be related to impairment with these day-to-day difficulties arising from CI. Although there are noted atypical neural mechanisms of ER with social information in ASD (Richey et al., 2015), mechanisms of ER have not been studied in the context of CI. We hypothesize that the lateral prefrontal cortex (PFC), a core area in modulating behavior, may underlie altered ER for CI in ASD.
Objectives: To examine activation of the PFC in the context of CI under varying states of ER in ASD and control groups.
Methods: A total of 27 adults (ASD=13; Control=14) participated in this study. Groups were matched on age (ASD M=26.1; Control M=27.4) and IQ (ASD M=113.3; Control M=116.3). ASD diagnosis was confirmed with the Autism Diagnostic Observation Schedule. Functional magnetic resonance imaging (fMRI) data were collected during a cognitive appraisal task on a 3T General Electric Signa Excite HD scanner. Each individual was asked to bring in ten photographs of their CI, which were used as stimuli for the task. After receiving standardized training in cognitive emotion regulation techniques, participants viewed each image for 4 seconds (free viewing period) and were then asked to "Think Positive," or "Think Negative" about CI images while undergoing fMRI. Whole group activation for the pre-instruction [<] post-instruction periods contrast showed activation of the medial PFC (mPFC). A region of interest (ROI) was identified using a 40-voxel sphere in the mPFC from which parameter estimates were extracted.
Results: Contrary to predictions, significant clusters of activation were observed in the medial, rather than lateral prefrontal cortex. ROI analyses of mPFC clusters revealed no group differences between ASD and control subjects during the baseline (pre-instruction) or think-negative conditions ($p>0.25$). However, for the think-positive condition, the control group showed significantly increased activation in the mPFC, compared to the ASD group, $t(17.78)=2.12$, $p<0.05$, $d=0.85$.
Conclusions: Individuals with ASD showed diminished function in mPFC during think-positive instructions for CI. These findings may indicate impairment in constraining positive affect toward CI, and thus provide evidence for targeting emotion regulation in the context of treatment.

58 **107.058** Neural Mechanisms of Uncertainty Processing in Children with Autism Spectrum Disorder

***C. R. Damiano**[1,2], E. Hanna[3], D. Cockrell[4], K. L. Dunlap[5], S. Miller[1], M. L. Kovac[1], L. Turner-Brown[6], J. Kinard[1] and G. S. Dichter[1], (1)Carolina Institute for Developmental Disabilities, University of North Carolina School of Medicine, Chapel Hill, NC, (2)Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC, (3)Department of Psychology and Neuroscience, Duke University, Durham, NC, (4)Virginia Tech Carilion School of Medicine and Research Institute, Roanoke, VA, (5)Vanderbilt Kennedy Center, Nashville, TN, (6)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Autism spectrum disorder (ASD) is often characterized by a preference for predictability and difficulty coping with unpredictable or unexpected circumstances referred to as insistence on sameness. This behavioral tendency may also have an impact on other core symptoms of ASD as a preference for sameness and aversion towards uncertainty may bias individuals with ASD to prefer predictable circumscribed interests versus inherently unpredictable social interactions. Yet, despite the prevalence of such symptoms and their potential role in core ASD symptomatology, uncertainty processing and its neurobiological mechanisms have yet to be studied empirically in children with ASD
Objectives: The present study had the following aims: (1) to better understand the neural circuitry involved in processing uncertainty using functional magnetic resonance imaging (fMRI) in both a social and non-social context and (2) to investigate how neural activation during uncertainty processing might be related to caregiver-reported aversion to uncertainty (i.e., intolerance of uncertainty) and insistence on sameness symptoms.
Methods: This study included 25 children with ASD and 21 typically developing (TD) children who were matched on age, IQ, and gender. An fMRI task previously used to measure neural responses to uncertainty (Grupe & Nitschke, 2011; Sarinopoulos et al., 2010) was adapted to include positively valenced social stimuli (i.e., faces with positive affect) and positive non-social stimuli (i.e., monetary compensation). All fMRI analyses were corrected for multiple comparisons to obtain a cluster-corrected threshold of $p< .05$ using a frontolimbic small volume correction. Structurally defined frontolimbic regions of interest were also correlated with caregiver-reported measures of intolerance of uncertainty and insistence on sameness.
Results: During the processing of uncertainty in a non-social context, the ASD group demonstrated attenuated activation of the bilateral putamen, nucleus accumbens, insula, and anterior cingulate cortex relative to the TD group. During uncertainty in social context, the ASD group demonstrated enhanced activation of the bilateral anterior cingulate cortex and frontal medial cortex. Frontolimbic activation during uncertainty processing was also found to be positively correlated with caregiver-reported levels of intolerance of uncertainty and insistence on sameness in children with ASD.
Conclusions: These results suggest that differential neural mechanisms are involved in the processing of uncertainty in children with ASD versus TD children and that these mechanisms may be influenced by a social versus nonsocial context. In addition, atypical processing of uncertainty may be related to elevated intolerance of uncertainty and insistence on sameness symptoms. An improved understanding of the mechanisms underlying atypical processing of uncertainty in ASD may ultimately provide insight into core ASD symptomatology, help differentiate these symptoms in ASD versus other clinical populations, and work towards developing interventions to address this symptom domain in ASD.

59 **107.059** Neurodevelopmental Indices of Theory of Mind and Their Relations to Everyday Social Functioning

***C. E. Mukerji**[1,2], S. H. Lincoln[1,2], A. V. Torricelli[3], N. Kleeman[1], S. Hasselmo[1], C. I. Hooker[4] and C. A. Nelson[1,2], (1)Harvard University, Cambridge, MA, (2)Boston Children's Hospital/Harvard Medical School, Boston, MA, (3)Rutgers University, New Brunswick, NJ, (4)Rush University Medical Center, Chicago, IL*

Background: Theory of mind, the capacity to reason about others' mental states, is a fundamental social cognitive ability affected in children with autism spectrum disorder (ASD). Prior research indicates that the functional specialization of neural mechanisms supporting ToM is related to social cognitive task performance in typically developing (TD) children. Preliminary evidence from a study of adolescents and adults with ASD suggests that activation in the right temporoparietal junction (rTPJ), a key node of the ToM network, may be related to symptom severity in ASD. Although influential theories of child development posit that ToM is central to social functioning, the relation between neural ToM mechanisms and the broad spectrum of daily social functioning observed across typical (TD) and atypical child development remains unclear.
Objectives: This study aimed to (a) isolate neural activation specifically elicited by ToM reasoning and (b) investigate, for the first time, the relations between these neural ToM mechanisms and individual variation in children's daily social functioning. We predicted that school-age TD children would demonstrate enhanced activation in the neural ToM network during mental state reasoning. Moreover, we predicted that activation at key nodes of this ToM network (e.g., rTPJ and precuneus) would be associated with individual variation in children's social functioning in daily life.
Methods: Participants were 31 TD children between 9 and 13 years old. Functional neuroimaging (BOLD) data were collected on a 3T Siemens Tim Trio scanner while participants completed a false belief task developed for school-age children. In the experimental (ToM) condition, children listened to vignettes describing social scenarios and then evaluated characters' beliefs. In the control condition, they listened to non-social scenarios and then made inferences about physical causality. In addition, parents completed a multidimensional interview measure assessing their children's daily social functioning (Vineland Adaptive Behavior Scales, 2ndedition).
Results: Whole-brain analyses indicated enhanced activation to ToM reasoning relative to the control task at key nodes of the ToM network: the right temporoparietal junction (rTPJ), precuneus, and right anterior superior temporal sulcus ($p<.05$, FWE-corrected). Controlling for the effects of general cognitive ability (IQ), activity in the precuneus

(r=0.51, p=0.035) and rTPJ (r=0.46, p=0.05) correlated with children's daily social play and leisure functioning.
Conclusions: Results revealed that, during mental state reasoning, school-age children engage key nodes of a distributed ToM network previously identified in adults. Moreover, our results elucidated key relations between social brain and behavior: activity in the precuneus and rTPJ was associated with daily social functioning in play and leisure activities, such that greater activation was linked to better functioning. These findings indicate that neural ToM mechanisms index variation in children's everyday social functioning, demonstrating value as a biological metric of functional heterogeneity in child development. Neural activation in the ToM network may also serve as a useful biomarker of social intervention change that may be detectable before meaningful behavioral differences emerge. Ongoing work investigates relations among neural activity in the ToM network, social cognitive ability, and daily social functioning in children with ASD.

60 **107.060** Neuromodulation Therapy Integrating Prefrontal rTMS and Neurofeedback for the Treatment of Autism

E. M. Sokhadze[1], *A. S. El-Baz*[2], *A. Tasman*[2], *Y. WANG*[3] *and M. F. Casanova*[4], *(1)Biomedical Sciences, University of South Carolina School of Medicine, Greenville, SC, (2)University of Louisville, Louisville, KY, (3)State Key Laboratory of Cognitive Neuroscience and Learning,BeiJing Normal University, Beijng, China, (4)Pediatrics and Biomedical Sciences, University of South Carolina School of Medicine, Greenville, SC*

Background: The study is based on an underlying neuropathological model of autism (Casanova et al. 2006) which emphasizes "minicolumnar" pathology and cortical lateral inhibition deficits resulting in behavioral abnormalities and executive dysfunctions. We propose that neuromodulation based on repetitive Transcranila Magnetic Stimulation (rTMS) over prefrontal area will enhance lateral inhibition through activation of inhibitory double bouquet interneurons and will be accompanied by positive EEG alteration that can be operantly conditioned using neurofeedback (NFB) training immediately after each rTMS session. In our studies using rTMS we demonstrated improvements in executive functions, as well as positive effects of prefrontal neurofeedback training in autism (Sokhadze et al., 2014; Wang et al., 2014). In the current study each rTMS session was followed by NFB, and this was predicted to result in synergetic response.
Objectives: The overall aim of the study was to investigate behavioral responses, ERP indices of information processing, and coherence of induced gamma oscillations in children with autism enrolled either in 18 weekly sessions of combined rTMS -NFB training group or in the wait-list group. The goal of our study was to investigate whether behavioral, EER and EEG indices, and behavioral evaluation outcomes will show positive changes in the treatment group (N=20) as compared to wait-list group (N=22).
Methods: We used 18 weekly sessions of 0.5 Hz rTMS bilaterally over dorsolateral prefrontal cortex followed by prefrontal neurofeedback in 20 children with autism (14.9 yrs). Another group of children with autism (N=22, 15.6 yrs) was tested twice within 4 months. Baseline and post-treatment assessments used selective attention tests with EEG/ERP recording and behavioral evaluations (Aberrant Behavior Checklist [ABC] and Repetitive Behavior Checklist [RBS-R]).
Results: Post-TMS-NFB evaluations showed decreased irritability and hyperactivity on ABC, and decreased stereotypic and total repetitive behaviors scores on RBS. The TMS-NFB group showed decrease of error rate (F=5.62, p=0.02). Magnitude of the frontal N100 decreased, while amplitude of the P200 to target stimuli increased post-TMS-NFB. Similar effects were expressed as well in the parietal P3b. The treatment group showed increase coherence of induced gamma to targets between frontal and temporal sites (e.g., F3-T7, F=6.67, p=0.014). NFB sessions resulted in linear regression of the theta-to-beta ratio and increase of gamma power over 18 sessions of integrated treatment.
Conclusions: Improved clinical behavioral evaluation outcomes along with functional EEG/ERP measures post-TMS-NFB are indicative of more efficient information processing post-treatment. The study represents a pilot translational clinical research exploration where rTMS and neurofeedback were combined, and treatment effects were compared with a wait-list group using clinical, behavioral and cognitive outcome measures. Preliminary results are very encouraging and warrant further more rigorous randomized controlled clinical trials.

61 **107.061** Object Selectivity or Motivational Relevance: Fusiform Activation to Faces and Food

K. M. Adamson[1], *C. Hyde*[1,2] *and V. Troiani*[1], *(1)Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA, (2)Bucknell University, Lewisburg, PA*

Background: While activation of the fusiform gyrus is most commonly linked to face processing, this region is also activated when viewing pictures of food and increases its responsivity following a period of fasting. Because objects must compete for our visual attention, an intriguing hypothesis is one in which parts of the ventral visual stream respond to salient objects, determined by individual preferences or item value. To our knowledge, no study has been conducted viewing activation to the ventral visual stream to both faces and food. Here, we examine whether altered motivation in one domain, such as food, will have an impact on another domain, such as faces.
Objectives: To characterize category-selectivity and brain-behavioral correlates in the ventral visual stream in response to various categories of objects in a cohort of 48 healthy college age adults using fMRI (24 female; mean age=22.33).
Methods: In an fMRI study acquiring BOLD images, we used a block design in which 4 categories of objects were presented, including faces, scenes, clocks, and highly palatable food. *Prior to the imaging session, participants also completed the Broader Autism Phenotype Questionnaire (BAP-Q). Body mass index (*BMI) was calculated based on self-reported measurements of height and weight and used as a measure of food motivation. We implemented a region of interest (ROI) analysis using parcellation maps generated by a watershed algorithm with an independent data set (Julian et al., 2012). We calculated face-selectivity in bilateral FFA by contrasting face and food blocks and correlated this with phenotyping metrics.
Results: We find a positive correlation between BMI and the BAP-Q Aloof subscore ($r(46)=0.494$, $p<0.001$), indicating that as body mass increases, social motivation decreases. We also show a significant impact of food motivation on face-selectivity in the right fusiform ($r(46)=-0.288$, $p<0.024$). That is, with increasing BMI, the right fusiform shows less of a differential response to faces relative to food. To further explore this effect, we ran analyses separately for each gender. When genders were split, we find the BMI:BAP-Q Aloof relationship was only present in females ($r(22)=0.648$, $p<0.001$) and the relationship between food motivation and face-selectivity in the right fusiform was only present in males ($r(22)=-0.550$; $p=0.003$).
Conclusions: These findings suggest that the fusiform may not be specific to only perceptual aspects of face processing, but may also respond to other items of motivational relevance. One possibility is that the fusiform is part of a relevance detection system that typically serves the role of face processing, but can be hijacked in cases of chronically altered motivation (i.e. towards food as chronic food motivation increases). Our findings also indicate some degree of differentiation between how atypical motivational and social relevance systems interact with gender, a finding that warrants future exploration in autism and other developmental disabilities.

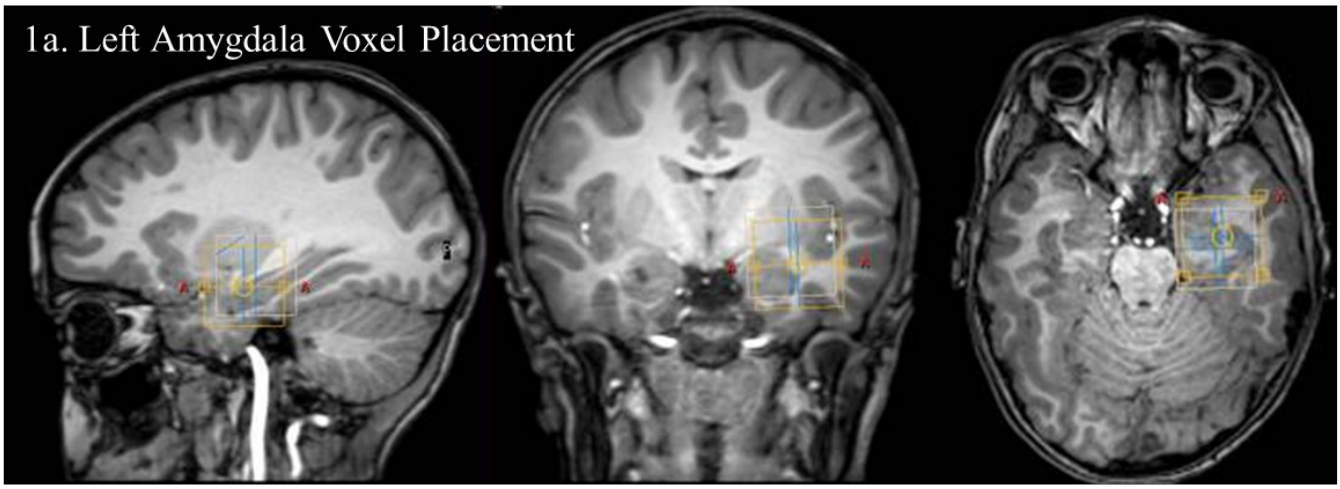
62 **107.062** GABA and Glutamate Concentrations in the Amygdala Modulate BOLD Response to Rapidly Presented Fearful-faces and Houses

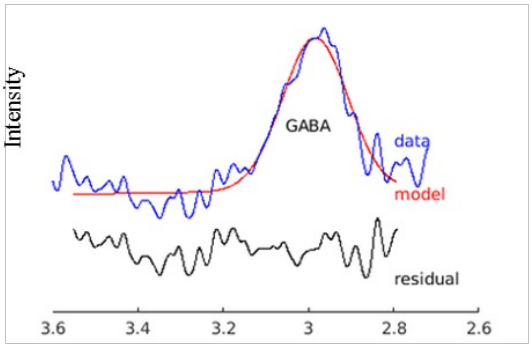
M. A. Reiter[1], *K. Kolodziej*[2], *T. L. Richards*[2], *N. M. Corrigan*[2], *K. Sambrook*[1], *T. St. John*[3], *M. Reilly*[1], *E. Shankland*[1], *R. A. Edden*[4], *S. Dager*[5] *and N. M. Kleinhans*[2], *(1)Radiology, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA, (3)University of Washington Autism Center, Seattle, WA, (4)Johns Hopkins University School of Medicine, Baltimore, MD, (5)University of Washington School of Medicine, Seattle, WA*

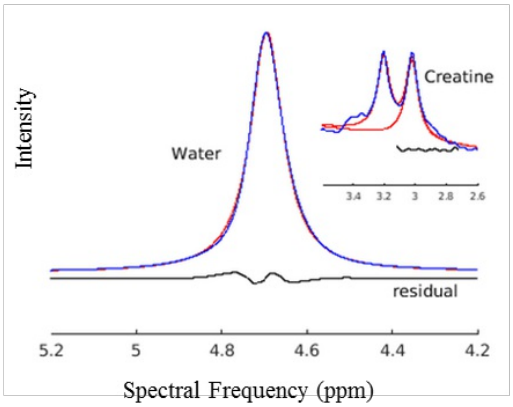
Background:
Abnormal face-processing is a pervasive deficit in individuals with ASD, which may be driven by amygdala dysfunction. Although the relationship between atypical functional and structural characteristics of the amygdala and abnormal face processing has been widely reported in ASD, the role of biochemical characteristics is largely unknown. Both glutamatergic and GABAergic mechanisms are thought to underlie experience-dependent plasticity of neural circuits, including those involved in emotional face processing. However little is known about the role of GABA and Glutamate (Glu) in modulating the BOLD response to fearful-faces and objects in humans.
Objectives:
Investigate the relationship between GABA and Glu concentrations in the amygdala and BOLD response to fearful-faces and houses in a sample of children with ASD and other sensory difficulties.
Methods:
T1-weighted 3DMPRAGE, fMRI, and magnetic resonance spectroscopic (MRS) data were acquired on a 3T Philips Achieva. Data were collected for 17 individuals and after quality control 14 were included in the analysis (mean age:10.4(1.64), IQ: 123.5(19.9)).
Data acquisition, fMRI: 54 volumes of high resolution data ($2.3mm^3$) were collected. Participants were shown blocks of rapidly-presented fearful-faces, houses and scrambled images. MRS: Single-voxel MRS data were acquired from the left amygdala-hippocampal region at two echo times (TE=30 and 80ms) using a MEGA-PRESS pulse sequence (TR 2000, 2048 complex time points, spectral width 2000 Hz, 32 averages, voxel size 30x30x30mm). A similar sequence, with a modification for GABA-editing, was acquired from the same voxel location (TR/TE 2000/68ms).
Data processing: fMRI data were processed using FSL. MRS: The LCModel software package (Provencher, 1993), with water-signal referencing, was used to derive concentration estimates for Creatine and Glu. The GABA-edited data were processed using the "Gannet" software toolkit.
Analysis: FMRI analyses were conducted using FLAME. Concentrations of GABA and Glu were entered as covariates in the GLM to test the correlation between chemical concentration and activation to fearful-faces and houses. Data were corrected for multiple comparisons using cluster-thresholding set at $z>2.3$ (voxel height) and $p<.05$ (cluster extent), whole brain corrected.

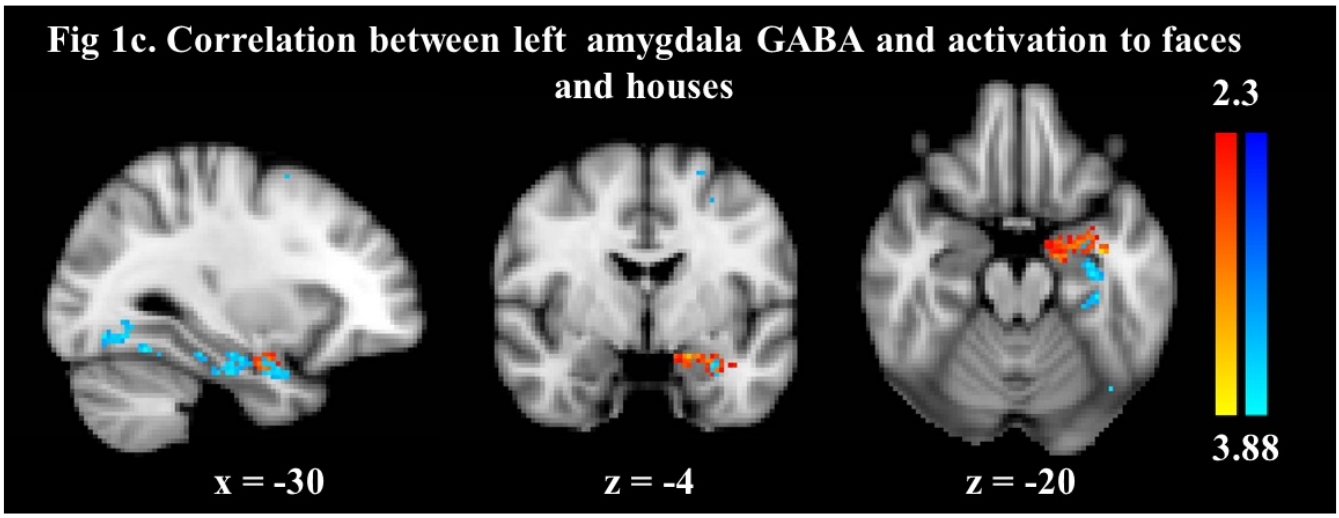
Results:
Fearful-faces: Higher concentrations of amygdala GABA were associated with decreased activation to fearful-faces in the amygdala. Amygdala Glu concentration was positively correlated to activation in the prefrontal cortex, superior parietal lobule, lateral occipital cortex, and cerebellar vermis and negatively correlated to activation in the striatum and subcallosal cortex.
Houses: Higher concentrations of amygdala GABA were associated with increased activation to houses in the prefrontal cortex, and with decreased activation in the hippocampus and fusiform gyrus. Higher concentrations of Glu were associated with increased activation to houses in the frontal-pole and frontal eye fields.
Conclusions:
Higher levels of Glu were associated with widespread increases in cortical activation to both fearful-faces and houses. Higher amygdala GABA levels were specifically associated with decreased activation to fearful-faces in emotional face-processing areas, and with decreased activation to houses in areas involved in object-processing and memory. This suggests that interactions between GABA and Glutamatergic mechanisms within the amygdala may underlie some of the emotional face-processing deficits experienced by individuals with ASD.

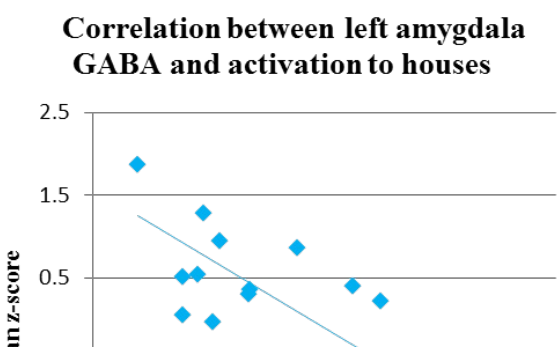


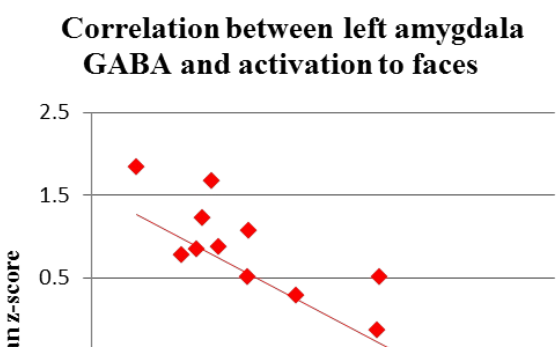
1b. Example of GABA, Water, and Cre Spectra for an 8 Year old Child











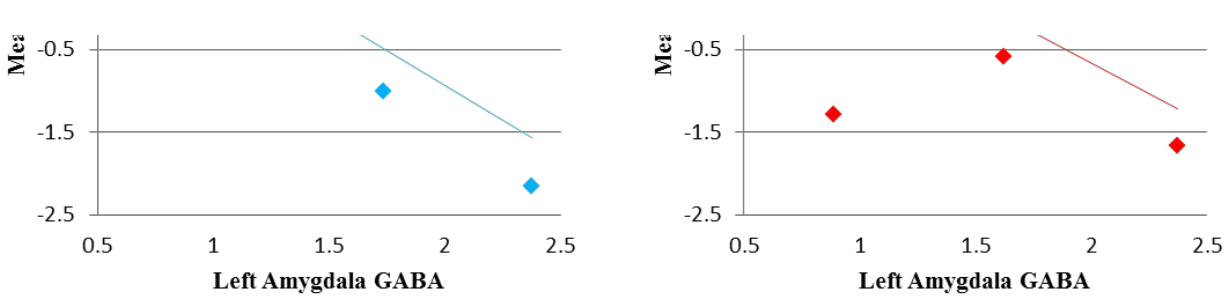


Figure 1.a. Example of left amygdala voxel placement acquired during data acquisition. The orange borders represent the area covered by the 30x30x30mm voxel. **1.b** shows the representative MEGA-PRESS spectra of GABA, Cre, and water in the left amygdala processed using the "Gannet" toolkit (Edden et al. 2013). The red curve in the panels shows the GannetFit curve-fitting results. The blue curve shows the postphase and frequency aligned GABA, Cre and water data. The black curve below the red and blue curves depicts the residual difference between the experimental data and the curve fit. **1.c** The correlation between left amygdala GABA and activation to faces and houses. Higher levels of GABA in the left amygdala were associated with decreased activation to faces in the left amygdala (red) and with decreased activation to houses in the left hippocampus (blue). Images are presented in radiological convention (R=L). Scatter plots in the lower panel are presented for illustrative purposes.

63 **107.063** Phase-Locked Frequency Contributions to Executive Functioning in Children with and without ASD

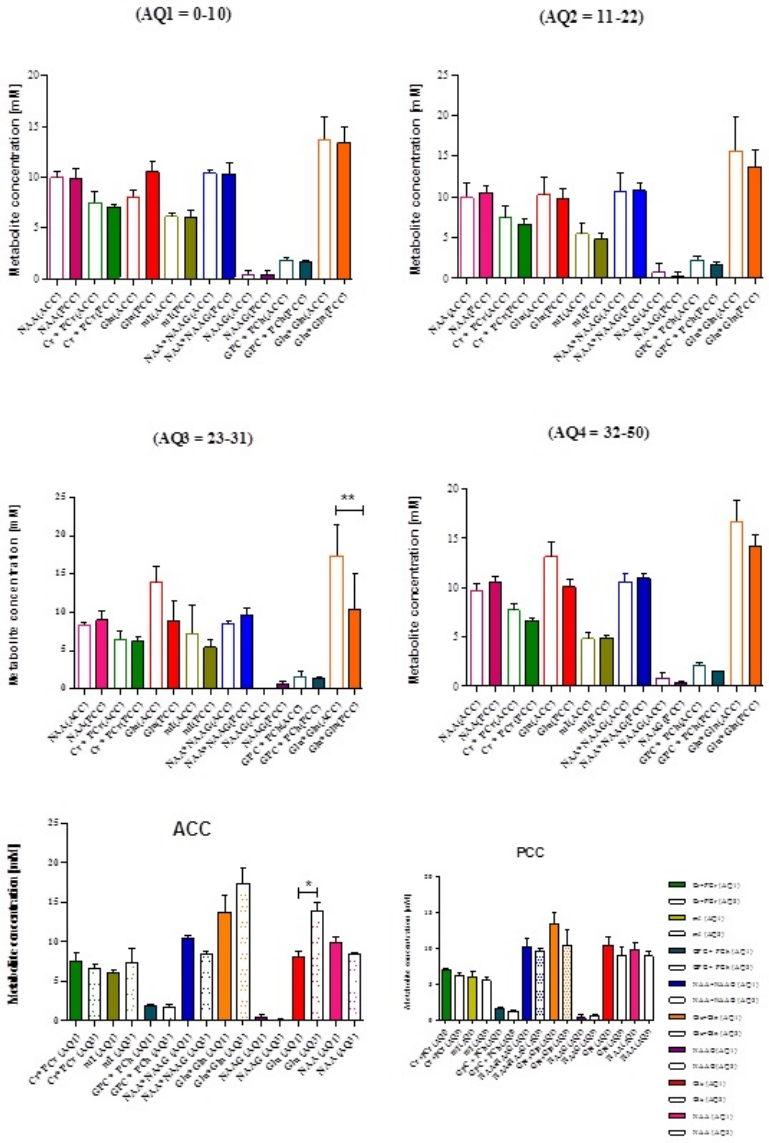
T. Clarkson[1], *A. R. Bhandarkar*[2] *and S. Faja*[3], *(1)Boston Children's Hospital: Harvard Med School, Boston, MA, (2)Laboratories of Cognitive Neuroscience, Boston Children's Hospital: Harvard Med School, Boston, MA, (3)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background:
Executive Functioning (EF) is the ability to manage complex or conflicting information in the service of a goal. Children with autism spectrum disorders (ASD) show deficits in EF but little is known about what neural networks contribute to this phenotype. One region implicated in conflict monitoring and working memory is the Anterior Cingulate Cortex (ACC), which is a known theta oscillatory generator (Tsujimoto, et al. 2006). Event-related time-frequency analysis can be used to help determine phase-locked frequency contributions to the neural signal, which help elucidate regional activation based on known oscillatory generators (Roach, & Mathalon, 2008). A developmentally appropriate flanker task was used for measuring phase-locked frequency responses in the N2 component in typically developing (TYP) children compared to children with ASD.
Objectives: To determine whether phase-locked frequency band activities during the N2 ERP component predict EF performance in children with and without ASD.
Methods: 19 children with ASD and 29 TYP children between the ages of 7-11 years participated. Additional children with ASD are being recruited. All had an IQ > 85 and there were no group differences on IQ, age or gender. The EF Battery included the Stroop task to measure inhibition of interfering information, the Change task to examine monitoring, the Backwards Digit Span to measure working memory, and the Flanker task as another measure of inhibition. Time-frequency analysis using the Fourier Transform on averaged ERP waveforms was used to examine phase-locked spectral data within the N2 component in the incongruent condition.
Results: In the TYP group, higher theta and beta power predicted of worse monitoring, ($F(2, 28) = 11.67$, $p < 0.001$) with an $R^2 = .46$. Additionally, higher theta and alpha power predicted worse inhibition ($F(2, 21) = 3.54$, $p < 0.049$) with an $R^2 = .27$ on the Stroop task, and higher theta and beta power predicted worse inhibition on the Flanker task ($F(2, 29) = 3.61$, $p=0.04$). Theta power alone predicted worse working memory ($F(1,29) = 4.09$, $p=0.05$). In the ASD group, theta and beta power trended towards predicting poor working memory performance ($F(2, 18) = 3.23$, $p = 0.06$), $R^2 = .29$.
Conclusions: Overall within the TYP group, increased theta power within the N2 predicted worse EF performance on our tasks that measured monitoring, inhibition, and working memory. This is consistent with previous literature that demonstrated increased ACC activation, which is a theta oscillatory generator, is associated with increased conflict monitoring activity on more difficult tasks. More involvement of the ACC indexed by theta suggests more effortful neural response, thus worse overall performance. Within the TYP group these findings suggest that phase-locked time-frequency analysis could be a powerful tool for examining specific neural activity and brain networks that are important for EF performance. Specifically, an increase in phase-locked theta power during the N2 is a good indicator of poor EF abilities. Within the ASD group, our initial examination did not show this pattern, only a trend in theta and beta power related to working memory. However data collection is ongoing for children with ASD to increase statistical power.

64 **107.064** Phenotypic Plasticity in the Cingulate Cortex in Autism Spectrum Disorders: Target on Etiology?

C. D. Jimenez de Espinoza[1], *F. Marcano*[2] *and J. L. González-Mora*[3], *(1)San Cristobal de La Laguna, Universidad de La Laguna, Lab. Neuroquímica y Neuroimagen., Santa Cruz de Tenerife, Spain, (2)Research units ULL, Magnetic Resonance Center IMETISA, La Laguna, Spain, (3)Neurochemistry and neuroimage laboratorie, University of La Laguna, La Laguna, Spain*

Background: Phenotypic plasticity is the ability of the human brain to change its morphological patterns, interactions in its sensory modalities and patterns of release of neurotransmitters. In previous studies, we observed changes in the levels of the neurotransmitters in the cingulate cortex in adult autism spectrum disorders (ASD) using ^{1}H-MRS techniques and this led us to further investigate these changes.
Objectives: The purpose of this study was the detection of a possible secretion pattern of specific neurotransmitters in the cingulate cortex in adults with Autism Spectrum Disorder.
Methods: In this case-control study, *in vivo* single-voxel proton magnetic resonance spectroscopy signals (^{1}H-MRS) were recorded in 12 right-handed young adults with ASD (median age, 22 years ± 2.2), and 19 typically developing (TD) controls (mean age, 22.80 ± 3.25) who were well matched for age, IQ and different AQ score groups: (AQ1=0-10; AQ2=11-22; AQ3=23-31) and AQ4=32-50. The diagnosis of autism was established by a neurologist, psychiatrist and psychologist in every case. The Autism Spectrum Quotient (AQ) designed by Baron-Cohen et al., 2001 to assess Autistic Spectrum traits in intellectually competent adults in both the general population and the Autism Spectrum community. Imaging was performed on a 3.0-T scanner using a single-voxel point-resolved spectroscopy technique. The volume of interest (VOI) was located in the anterior and posterior bilateral cingulate cortex. The absolute concentrations of creatine + phosphocreatine (Cr+Pcr), N-acetyl-aspartate (NAA), N-acetyl-aspartate+N-acetyl-aspartyl-glutamate (NAA+ NAAG), N-acetyl-aspartyl-glutamate (NAAG), glycerophosphocholine + phosphatidylcholine (GCP+PCh), myo-inositol (mI), glutamate (Glu) and glutamate+glutamine (Glu+Gln) were processed by the LC Model 6.2-3A.
Results: A significant increase glutamate + glutamine (Glu+Gln) was observed, $F=20.77$; $t= 4.73$, in the subject group with AQ3 = 23-31 between the bilateral anterior cingulate cortex (ACC) and the posterior bilateral cingulate cortex (PCC). While, this group (AQ3 = 23-31) showed a significant increase in the level of glutamate (Glu) in the anterior cingulate cortex (ACC), $F=23.43$; $t=4.06$, compared with the control group (AQ1=0-10). One-way ANOVA and Bonferroni's Multiple Comparison Test. $P < 0.05$ were applied to perform the statistical analysis.
Conclusions: The presence of an imbalance in the glutamate (Glu) system between the anterior and posterior cingulate cortex was apparent in the ASD group with AQ3 = 23-31. The elucidation of the etiology of this difference in this brain region studied in autism spectrum disorders is and will be a research goal for our team.



65 **107.065** Pivotal Response Treatment Increases Neural Processing Efficiency of Faces in Children with Autism Spectrum Disorder

Z. J. Williams[1], *M. Rolison*[2], *K. K. Stavropoulos*[2], *J. H. Foss-Feig*[2], *S. M. Malak*[1], *A. Naples*[2], *K. Pelphrey*[1], *P. E. Ventola*[1] *and J. McPartland*[2], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT*

Background:
Pivotal Response Treatment (PRT) is an empirically validated, naturalistic behavioral intervention that uses the principles of Applied Behavior Analysis (ABA) to address core deficits in social communication in individuals with Autism Spectrum Disorder (ASD). Originally developed to promote language acquisition in nonverbal children with ASD (Koegel et al., 1987), PRT has been expanded to target other developmental areas. Recent work has demonstrated improvements in pragmatic language, social engagement, and adaptive functioning skills (Ventola et al., 2014), as well as normalization of neural activation (Ventola et al., 2015) following a 16-week course of PRT. Effects of PRT on the temporal dynamics of neural activation have yet to be studied. By utilizing the precise temporal resolution of electroencephalography (EEG), this study aims to assess changes in the efficiency of neural processing of social information following a 16-week course of PRT.
Objectives:
To identify changes in temporal dynamics of the neural processing of social information following a 16-week course of PRT.
Methods:
Seven children with ASD between the ages of 4 and 6 years received PRT (6 hours with the child and 2 hours with the parent per week) for 16 consecutive weeks. Participants completed an EEG session, recorded with a 128-channel Hydrocel Geodesic sensor net, before and after treatment and at 16-week follow-up. A subset of participants (n = 3) completed an additional EEG 16 weeks prior to the start of treatment as a waitlist control group. During EEG recording, participants were presented with 73 computer-generated faces that displayed either neutral or fearful expressions. Event-related potentials (ERPs) were measured over the right occipitotemporal region. The latency and amplitude of ERP components that reflect early visual processing and face processing (P100 and N170, respectively) were examined at each time point.
Results:
An overall main effect of treatment on N170 latency was observed [$F(1,6) = 11.34$, $p = .015$], signifying a change in the efficiency of face processing. Post-hoc paired samples t-tests revealed that a significant reduction in N170 latency occurred to both neutral ($p = .027$) and fearful ($p = .029$) face stimuli following treatment. There were no significant changes in N170 amplitude or in either P100 latency or amplitude ($ps > .05$). Additionally, no significant change in N170 latency was observed over the 16-week period prior to treatment in the waitlist control group [$F(1,2) = 2.45$, $p = .26$]. Preliminary analyses of follow-up data suggest stability in increased efficiency of N170 latency.
Conclusions:
These preliminary findings suggest that a 16-week course of PRT is associated with increased processing efficiency of socially salient stimuli. The improvements were seen only in brain responses associated with social perception (N170), as opposed to lower-level visual processes (P100), suggesting focal treatment effects on social processing. Waitlist control data indicate that this is unlikely to related to practice effects, and follow-up data suggest that these effects endure beyond treatment. Results suggest specific and persistent action of PRT on neural systems subserving social perception.

66 **107.066** Processing of Facial Expressions and Their Mental Imagery in ASD: An EEG Study with Feasibility Analysis for a Neurofeedback Approach

M. Simoes[1], *J. Andrade*[1], *R. Monteiro*[1], *S. Mouga*[1], *P. Carvalho*[1], *G. G. Oliveira*[2] *and M. Castelo-Branco*[1], *(1)University of Coimbra, Coimbra, Portugal, (2)Hospital Pediátrico de Coimbra, Coimbra, Portugal*

Background:
Facial expression (FE) processing deficits have been identified in ASD. Studies on this topic usually use static photographic stimuli of facial expressions. Here we explored induced brain dynamics of facial expression morphing. These stimuli may be potentially relevant in helping attributing mental states to others in ASD, by facilitating the capability of imagining another person performing an action such as a facial expression.

Objectives:
In this study we investigated brain responses to dynamic FE stimuli. Additionally, we searched the neural correlates of imagery of a third person performing FEs, and assessed the viability of a neurofeedback approach based on such correlates.
Methods:
EEG data on 58 scalp locations were so far collected from eleven male teenagers with high-functioning ASD (16.91 ± 2.51 years old) and seven neurotypical male teenagers (15.57 ± 3.31 years old), performing a task divided in two parts: visual stimulation and mental imagery. On the visual stimulation part, a virtual male teenager (always present on the screen) performed dynamic happy and sad facial expressions, starting and returning to the neutral expression (morphing duration: 250ms and FE duration: 1500ms). On the mental imagery task, the participant was asked to imagine the virtual person performing the FE (happy or sad), after a visual instruction and an auditory trigger. EEG data were preprocessed and cleaned from noise and artifacts. Event-related potentials (ERP) for each FE stimulus were computed, and their peak and respective latencies were extracted. For the imagery part, event related spectral perturbation (ERSP) was computed for each FE. Finally, a linear Support Vector Machine (SVM) was used to discriminate EEG segments as FE imagery or no imagery, using power variations from a neutral baseline as feature after the application of a Common Spatial Patterns algorithm on the train data. Cross-validation was used to assess the accuracy of the classifier in the cleaned and original data, as simulation for an online application.
Results:
ERP responses to sad expressions were more sustained than for happy stimuli. Peak responses for sad stimuli were found delayed for the ASD group in frontal and left central cortex ($p<0.05$). ERSP analysis showed power decreases in theta rhythms during the imagery process, mainly in fronto-temporal and parieto-occipital areas. ASD group theta power deactivations were statistically significantly smaller than controls ($p<0.05$), but yet significantly different than baseline in the occipital region. Regarding the classifier, an accuracy of 74(±2)% was achieved in single-trial level for both groups. Those results were statistically different from the chance level for every participant ($p<0.01$).
Conclusions:
Results from the ERP analysis suggest abnormal responses to sad facial expressions in the ASD group. Theta event-related desynchronization in frontal and parieto-occipital areas was present during the FE imagery task on both groups, although with significantly lower intensity in the ASD group. That group difference opens the possibility of using theta band as target for neurofeedback approach using FE imagery, as validated by the SVM classifier which identified imagery segments with an accuracy of 74% in single-trial level.

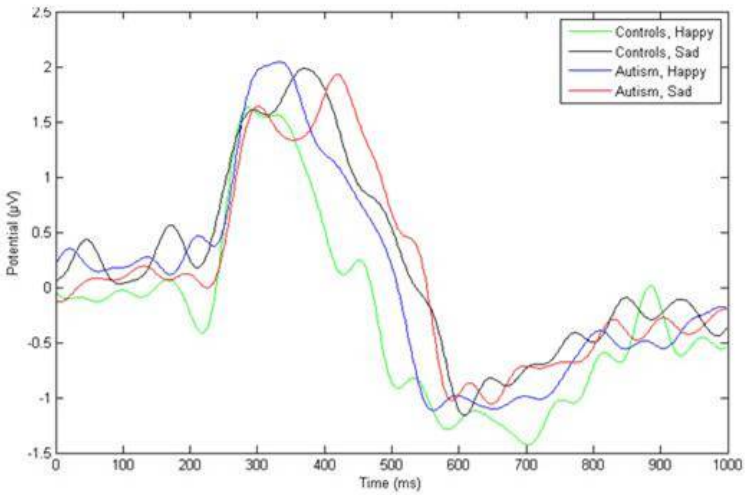


Figure 1 – ERP example for the frontal midline cluster, showing responses to Happy and Sad stimuli for both ASD and Control groups.

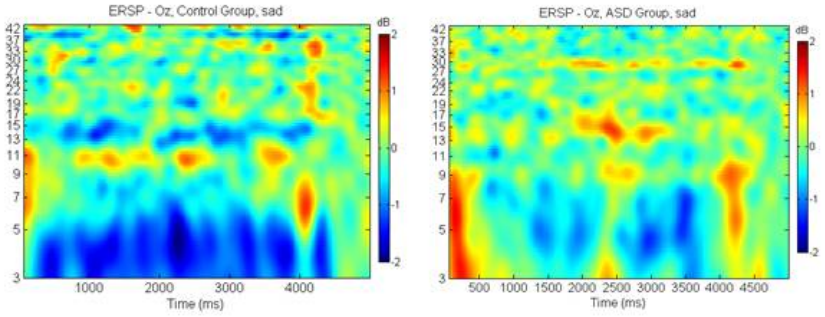

Figure 2 – Group ERSP of sad facial expression imagery in Controls and ASD, captured from the Oz channel, showing different theta power deactivations.

Brammer*[4], *S. Baron-Cohen*[3], *A. Popma*[2], *D. G. Murphy*[1] *and C. Ecker*[1], *(1)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Department of Child and Adolescent Psychiatry, VU University Medical Center, Amsterdam, Netherlands, (3)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (4)Department of Neuroimaging, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background: Although the cerebellum is widely recognised to be primarily involved in motor function, accumulating evidence indicates that it also plays a crucial role in mediating wider cognitive functioning. Differences in cerebellar neuroanatomy have been well documented in males with Autism Spectrum Disorder (ASD), but have not yet been examined in females. The neuroanatomy of ASD in females therefore remains insufficiently understood.
Objectives: (1) To examine differences in cerebellar neuroanatomy in females with ASD compared to female neurotypical controls, and (2) to establish the relationship between cerebellar neuroanatomy and the severity of autistic symptoms within the ASD group.
Methods: Structural Magnetic Resonance Imaging (sMRI) data were acquired in 49 females with an Autism Diagnostic Interview Revised (ADI-R)-confirmed diagnosis of ASD, and 47 neurotypical female controls who did not differ significantly in age (28±7 and 27±7 years, respectively) and full-scale IQ (118±11 and 115±7, respectively). These participants were recruited as part of the MRC UK Autism Imaging Multicentre Study (MRC AIMS), and scanned at the Institute of Psychiatry, Psychology and Neuroscience in London, and the Autism Research Centre, University of Cambridge, UK. To examine between-group differences in regional cerebellar neuroanatomy, we utilized the SUIT-toolbox (http://www.diedrichsenlab.org/imaging/suit.htm), which provides a high-resolution template of the human cerebellum and a parcellation for different functionally defined cerebellar subregions. Following cerebellar isolation and normalisation, data were analysed using a voxel-based approach to examine between-group differences at each cerebellar voxel. A cluster-threshold was used to assess cluster-level significance at a P-value that provided the expected number of false positive clusters by chance to be smaller than one (i.e. p=.003). We also examined Pearson correlation coefficients between the individual's cluster volumes and the different subdomains of the ADI-R, and the Autism Diagnostic Observation Schedule (ADOS).
Results: Individuals with ASD showed significant reductions in regional cerebellar volume in (1) the left lobules Crus II, IX, VIIB, VIIIb, (2) the right lobules IX and VIIIb, and (3) parts of the vermis (VIIb, VIIIa, VIIIb). These clusters functionally sub-serve the default-mode network and the frontoparietal network. Significant negative correlations were found between the cluster volume (1) in the left hemisphere and the ADI-R social (r=-0.313, p=0.44) and communication domain scores (r=-0.396, p=0.009); and (2) between the volume of the right-hemisphere cluster and the ADI-R social domain (r=-0.39, P=0.011), and ADOS social (r=-0,396, P=0.006) and communication scores (r=-0,3, P=0.041). Both clusters also correlated with the total ADI scores (i.e. lower regional volumes were associated with more severe autistic symptoms).
Conclusions: This is the first large-scale multicentre MRI study to investigate differences in cerebellar neuroanatomy between females with ASD and female controls, and to relate neuroanatomical findings to clinical outcomes. We found that females with ASD – like their male counterparts – have regional differences in cerebellar neuroanatomy, and that these are associated with clinical symptom severity. Future research is, however, warranted to compare males and females with ASD directly in order to determine whether these neuroanatomical differences are shared or distinct across sex.

68 **107.068** Regulation of Brain Excitatory/Inhibitory Balance through the Mu-Opioid System Depends on the Extent of Autistic Symptoms

J. L. Findon[1], *R. H. Wichers*[2], *J. Horder*[3], *E. Daly*[2], *R. A. Edden*[4], *D. G. Murphy*[2] *and G. M. McAlonan*[5], *(1)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, England, United Kingdom, (2)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (3)Institute of Psychiatry, King's College London, London, England, United Kingdom of Great Britain and Northern Ireland, (4)Johns Hopkins University School of Medicine, Baltimore, MD, (5)Department of Forensic and Neurodevelopmental Science, IoPPN, KCL, London, United Kingdom*

Background: There is accumulating evidence that ASD involves an imbalance between excitatory (E) glutamate and inhibitory (I) GABA transmission. E/I balance can be modulated through multiple signalling pathways, including the opioid system. For example, genetic abnormalities in the mu-opioid receptor gene are linked to ASD; and the social behaviour abnormalities of the mu-opioid receptor 'null' mouse can be rescued by a glutamate acting drug (mGluR4 positive allosteric modulator; Becker et al, 2014). However, whether E/I balance can be regulated through the mu-opioid system in adults with and without ASD has not been directly examined.
Objectives: To provide Proof of Concept evidence for a difference in E/I response to mu-opioid activation in adults with and without symptoms of ASD.
Methods: We used MEGAPRESS proton magnetic resonance spectroscopy ($[^1H]$-MRS) to measure levels of Glx (glutamate + glutamine) and GABA from the dorsomedial pre-frontal cortex of 19 unmedicated adult men with (n=8) and without (n=11) ASD. Individuals were scanned twice, once after oral administration of 12.5mg of tianeptine (a mu-opioid receptor agonist; Gassaway et al, 2014) and once following matched placebo in a randomised double blind procedure. Scans were at least 8 days apart to ensure full washout of the drug. An 'Inhibitory Index' was defined as GABA/(GABA + GLx), and the percentage (tianeptine-induced) change in Inhibitory Index from baseline (placebo) was calculated. ASD symptoms were rated in the entire cohort using the Autism Quotient (AQ). We conducted a preliminary analysis of group differences in the change in Inhibitory Index; and tested the prediction that the change in Inhibitory Index would be correlated with the extent of autistic symptoms rated using the Autism Quotient (AQ) across the entire cohort.
Results: There was a trend-level group difference in the tianeptine induced change in the inhibitory index ($p = 0.08$). This masked a highly significant negative correlation between AQ score and the change in inhibitory index ($r = -.617$, $p < 0.01$). Scrutiny of this relationship revealed that there was essentially 'no change' in inhibitory index in individuals with AQ = 24, a recognised population 'cut-off' score for ASD. However, tianeptine decreased the inhibitory index in individuals with AQ > 24; and those with the highest AQ scores had the greatest decrease. In contrast, tianeptine increased the inhibitory index in individuals with AQ < 24; and those with the lowest AQ had the greatest increase.
Conclusions: Thus, E/I balance can be shifted acutely in the adult brain through the mu-opioid system. However, the direction and extent of E/I change depends on the extent of autistic features measured using the AQ. This study is still in progress. A larger sample size will allow us to assess whether modification of E/I balance through the mu-opioid system could provide a means to identify more 'pharmacologically homogeneous' sub-groups of people with ASD. It may also support further work to confirm the mu-opioid system as a treatment target for ASD. In that event, repurposing well-tolerated drugs with a known safety profile, including tianeptine, should be explored.

69 **107.069** Repetitive TMS Effects on Autonomic Balance in Children with Autism

M. F. Casanova[1], *Y. WANG*[2], *E. L. Casanova*[3] *and E. M. Sokhadze*[4], *(1)Greenville Campus Greenville Health Systems, University of South Carolina School of Medicine, Greenville, SC, (2)State Key Laboratory of Cognitive Neuroscience and Learning,BeiJing Normal University, Beijng, China, (3)Biomedical Sciences, University of South Carolina, Greenville, SC, (4)Biomedical Sciences, University of South Carolina School of Medicine, Greenville, SC*

Background:
Autism is a pervasive developmental disorder marked by difficulty in social interaction, impairments or lack of communication, and restricted range of interests. In addition, many children with autism exhibit symptoms associated with autonomic dysfunctions, which are presented as abnormalities in regulation of blood pressure, temperature, heart rate, and other body functions by the autonomic nervous system (ANS). The main findings of autonomic abnormalities studies in Autism Spectrum Disorders (ASD) point at reduced baseline parasympathetic activity in association with evidence of increased baseline sympathetic tone resulting in an autonomic imbalance, which negatively affects physiological functions and manifests in alterations of various electrophysiological measures.
Objectives:
The aim of the study was to investigate electrophysiological measures reflecting ANS activity in two cohorts of children with ASD during 12 and 18 weekly sessions of low frequency repetitive Transcranial Magnetic Stimulation (rTMS) over the dorsolateral prefrontal cortex (DLPFC). The underlying hypotheses were: (1) low frequency (0.5 Hz) rTMS over the prefrontal cortex lowered ANS hyper-activation in children with autism through activation of frontal inhibitory tone controlling ANS, and (2) lower ANS arousal post-TMS will be manifested as a decrease of skin conductance level (SCL), heart rate (HR), and increased HR variability and in improvement of behavioral evaluation scores.
Methods:
We investigated autonomic activity in 30 children with ASD during 12 sessions of rTMS and 18 children with ASD during 18 sessions of rTMS over DLPFC. Physiological activity measures such as skin conductance level (SCL), heart rate (HR), HR variability (HRV) were recorded during rTMS sessions with a C-2 J&J Engineering Inc. physiological monitoring system. Behavioral evaluations were conducted using the Aberrant Behavior Checklist (ABC) and the Repetitive Behavior Scale (RBS-R).
Results:
Post-12 rTMS measurements showed a decrease of low frequency (LF) component of HRV with statistical significant changes in HR regression and standard deviation of HR, though without any significant changes in SCL. Post 18 session rTMS outcomes showed slower heart rate accompanied by increase of high frequency (HF) component of HRV (as indicated by R-R intervals of ECG), higher deviation of R-R, and lower LF/HF ratio.
Conclusions:
Our findings show reduced sympathetic activation after rTMS resulting in lower HR predominantly through withdrawal of sympathetic tone (LF of HRV) and increase of parasympathetic cardiac neural control activity post 12 rTMS sessions. Neuromodulation using prolonged 18 session rTMS course in children with ASD resulted in a more pronounced HR slowing, a higher power of HF of HRV and time domain measures of HRV. Behavioral evaluations based on ABC and RBS-R scores showed similar improvements in 12 and 18 sessions of rTMS. Low frequency rTMS activates inhibitory tone of the frontal cortex resulting in a lower excitation of the ANS probably through inhibitory fronto-limbic circuits.

70 **107.070** Salience Network Connectivity Is Related to Brain and Behavioral Markers of Sensory over-Responsivity in ASD

S. Green[1], *L. M. Hernandez*[2], *K. E. Lawrence*[3], *S. Y. Bookheimer*[3] *and M. Dapretto*[3], *(1)UCLA, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Children with autism spectrum disorders (ASD) often exhibit sensory over-responsivity (SOR), which may cause them to react negatively to sensory stimuli such as noisy environments or scratchy clothing (Liss et al., 2006), and SOR is associated with increased functional impairment (e.g., Liss et al., 2006; Pfeiffer et al., 2005). Previous research from our lab suggests that SOR may be related to an overattribution of salience to extraneous sensory information, as individuals with ASD and SOR have hyperactivation and reduced habituation in the amygdala and sensory cortices in response to mildly aversive sensory stimuli (Green et al., 2015). The salience network, an intrinsic brain network which is thought to modulate attention to internal versus external stimuli, has been consistently found to be atypical in ASD (Uddin et al., 2013). Salience network abnormalities during resting-state are thought to underlie some of the difficulties intrinsic to ASD, such as atypical allocation of attention to extraneous sensory stimuli rather than relevant social stimuli (Uddin et al., 2013). However, to-date there is little research on how differences in salience network organization in ASD relates to differences in brain function during information processing. Thus, in the present study we sought to examine how intrinsic connectivity in the salience network relates to SOR by integrating resting-state fMRI, task-based fMRI, and behavioral data.
Objectives: To examine how connectivity with the salience network (with anterior insula as the hub) during resting state relates to symptoms of SOR and to brain response to mildly aversive sensory stimuli.
Methods: Participants were 28 children and adolescents with ASD and 33 TD matched controls, between 8-17 years of age. Children underwent a 6-minute resting-state scan as well as a separate fMRI paradigm, where they were presented with simultaneous mildly aversive auditory stimuli (noisy traffic sounds) and tactile stimuli (scratchy sweater rubbed from wrist to elbow). Parents completed the tactile, auditory, and visual scales of the Short Sensory Profile (REF) and SenSOR Invenstory (REF) and scores were standardized and combined into an SOR composite. Whole-brain connectivity with a 5-mm spherical seed in the right anterior insula (AI) was examined, with SOR composite scores as a regressor to determine resting state connectivity as a function of SOR severity. Correlations between resting-state salience network connectivity and brain response to mildly aversive tactile and auditory stimuli were examined.
Results: SOR in youth with ASD was related to increased resting-state functional connectivity between salience network nodes and brain regions implicated in primary sensory processing and attention (somatosensory cortex and amygdala). Further, the strength of this connectivity at rest was related to the extent of brain activity in these same areas in response to auditory and tactile stimuli.
Conclusions: Results support an association between intrinsic brain connectivity and specific atypical brain responses during information processing. Additionally, findings suggest that basic sensory information is overly salient to individuals with SOR, leading to over-attribution of attention to this information. Clinical implications include incorporating sensory coping strategies into social interventions for individuals with SOR.

71 **107.071** Specificity of Atypical Neural Response to Language in Infants at Risk for ASD

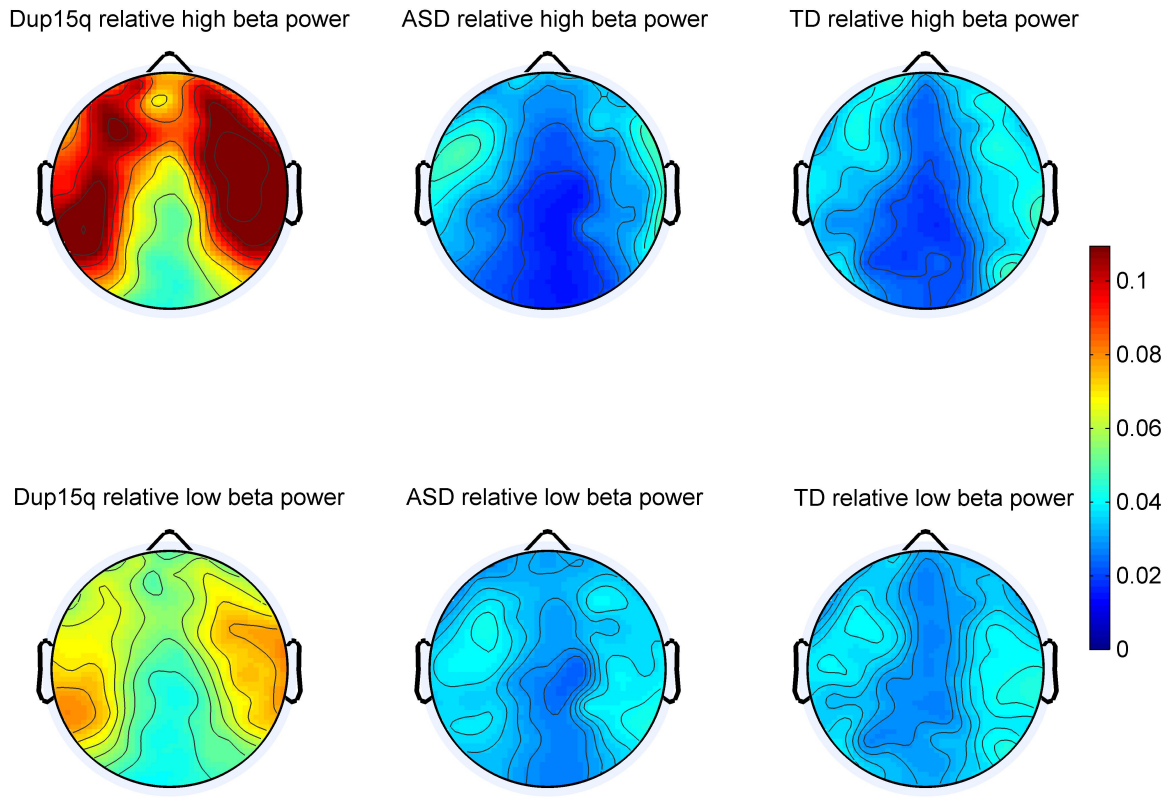
C. Chuang[1], *M. Rolison*[1], *J. F. Yang*[1], *E. D. Brooks*[1], *P. Hashim*[2], *R. Travieso*[3], *J. Terner*[4], *K. K. Stavropoulos*[1], *D. M. Steinbacher*[3], *N. Landi*[5], *L. C. Mayes*[1], *J. A. Persing*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)Department of Dermatology, Mount Sinai School of Medicine, New Haven, CT, (3)Section of Plastic Surgery, Yale School of Medicine, New Haven, CT, (4)Division of Plastic Surgery, Montefiore Medical Center, Bronx, NY, (5)Department of Psychological Sciences, University of Connecticut College of Liberal Arts and Sciences, Storrs, CT*

Background: Language delay impairing communication is a primary feature of autism spectrum disorder (ASD). Children with ASD display social and communicative impairments, and present with varying levels of language functioning (Kjelgaard et al., 2001). One approach to studying language processing in infants at high risk for ASD is the use of auditory event-related potentials (ERPs). Previous work has demonstrated irregularities in the P150 component in infants at high risk for ASD as an indicator of abnormal speech processing (Guiraud et al., 2011). Outside of ASD, study of language development is of interest in craniosynostosis, a congenital condition of premature skull fusion in infants causing abnormal skull shape and distribution of brain volume. Craniosynostosis (CSO) has been associated with delayed speech and decreased abilities in both reading and spelling (Knight et al., 2014). This study seeks to compare language processing in infants across two disorders associated with language impairment—infants at high-risk for ASD with infants with CSO.
Objectives: Compare auditory ERPs during an auditory oddball paradigm in infants at high risk for ASD (HR), infants with craniosynostosis (CSO), and infants at normal risk for ASD (NR).
Methods: 49 infants (12 HR, 13 CSO, and 24 NR) completed an EEG recorded with a 128-channel Hydrocel Geodesic sensor net. Infants listened to a series of 100 speech sounds – the dental /da/ versus the retroflex /da/ phoneme, each presented 50 times. Data was segmented to 100ms pre-stimulus, and ERPs were extracted over 100-300ms post-stimulus for the P150 component and 400-550ms for the N450 component. Magnitudes of the P150 and N450 component amplitudes were compared between the study groups. Statistical analyses were performed using repeated measures analysis of variance (ANOVAs) with participant group as a between-subjects factor and brain hemisphere as a within-subjects factor.
Results: No significant differences ($p>0.05$) were observed in the P150 or N450 component amplitudes in response to the dental versus retroflex phonemes within each of the HR, CSO, and NR groups. At the N450, a significant hemisphere by group interaction was observed ($p<0.05$). NR infants displayed lateralized response to language ($p<0.01$), while HR and CSO infants did not evidence significant hemispheric lateralization ($p=0.32$ and $p=0.60$, respectively). At the P150 ERP, a marginal hemisphere by group interaction was observed ($p=0.06$). NR infants displayed lateralized response to language ($p=0.04$), while HR and CSO infants displayed no detectable hemispheric lateralization ($p=0.25$ and $p=0.57$, respectively).
Conclusions: This study compared infants at high risk for autism with infants with craniosynostosis, another congenital condition characterized by language impairments. We found that both HR and CSO infants lacked hemispheric lateralization of neural response to language at multiple auditory ERPs, in contrast with control infants who displayed expected patterns of lateralization. Shared patterns of abnormal auditory processing in these two clinical populations suggest that atypical language lateralization may reflect a general disruption in language development, not specific only to ASD.

72 **107.072** Spontaneous Beta Oscillations Are a Biomarker of Duplication 15q11.2-q13.1 Syndrome

J. Frohlich[1], *D. Senturk*[2], *P. Golshani*[3], *R. Sankar*[4] *and S. S. Jeste*[5], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Biostatistics, University of California, Los Angeles, Los Angeles, CA, (3)Neurology, University of California, Los Angeles, Los Angeles, CA, (4)Pediatrics, Neurology, University of California, Los Angeles, Los Angeles, CA, (5)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: Duplications of 15q11.2-q13.1—referred to as Dup15q syndrome—account for roughly 1% of autism spectrum disorder (ASD) cases while also conferring strong risk for intellectual disability (ID) and epilepsy. Interstitial cases of Dup15q syndrome feature extra copies of duplicated genes on the q-arm of chromosome 15, generally resulting in partial trisomy. Isodicentric cases of the same disorder feature an extranumerary chromosome and generally result in partial tetrasomy as well as greater overall clinical impairment [Battaglia 2008]. All cases of Dup15q syndrome include duplications of gamma-aminobutyric acid($GABA)_A$ receptor subunit genes *GABRA5, GABRB3,* and *GABRG3*. Recently, case reports have identified spontaneous beta oscillations (SBOs) resembling benzodiazepine-induced activity in clinical electroencephalography (EEG) recordings from children with Dup15q syndrome [Ageeli et al 2014; Urraca et al 2013].
Objectives: Herein, we sought to quantify SBOs in resting-state EEG recordings from children and compare a cohort of children with Dup15q syndrome with (A) a comparison group of age-matched typically developing (TD) children and (B) another comparison group of age and intelligence quotient (IQ) matched children with nonsyndromic ASD.
Methods: We measured SBOs from resting-state EEG recordings of children with Dup15q syndrome ($n = 11$) using 129 channel high-density EEG nets and compared these recordings to those from TD children ($n = 9$) and children with nonsyndromic ASD ($n = 10$). Because beta is traditionally examined as two frequency bands, we quantified SBOs as both low beta and high beta power. Relative power in delta (1 – 4 Hz), theta (4 – 8 Hz), alpha (8 – 12 Hz), low beta (12 – 20 Hz), high beta (20 – 30 Hz), and gamma (30 – 48 Hz) frequency bands was computed for 9 scalp regions of interest (ROIs). Any child being treated with benzodiazepines—drugs which induce beta oscillations and enhance inhibitory currents through $GABA_A$ receptors—was excluded from analysis.
Results: High beta power was significantly higher in children with Dup15q syndrome compared with both the TD ($p < 1.0 \times 10^{-4}$, FDR corrected) and ASD ($p < 1.0 \times 10^{-4}$, FDR corrected) comparison groups. Similarly, resting low beta power was significantly higher in children with Dup15q syndrome than in either comparison group (TD, $p = 0.0108$, FDR corrected; ASD, $p = 6.5 \times 10^{-3}$, FDR corrected). Delta power was also significantly lower in children with Dup15q syndrome than in either comparison group (TD, $p = 8.1 \times 10^{-3}$, FDR corrected; ASD, $p= 0.0126$, FDR corrected).
Conclusions: SBOs represent a clear diagnostic biomarker of a genetically distinct subgroup of children with neurodevelopmental disorders. Given evidence that beta oscillations relate to GABAergic tone [Gaetz et al., 2011; Van Lier et al., 2004], these SBOs represent a potential biomarker of cortical inhibition in this population that may facilitate not only the diagnosis but also treatment monitoring in a subgroup of children within the autism spectrum. Our finding of lower delta power in children with Dup15q syndrome may relate to a shift in spectral energy from slow to fast frequencies (i.e., delta to beta) resulting from $GABA_A$ receptor gene upregulation in this disorder.



73 **107.073** State-Dependent Reductions in Brain Network Modularity and Behavioral Inflexibility in Childhood Autism Spectrum Disorder

C. J. Lynch[1], *A. Breeden*[2], *X. You*[3], *R. Ludlum*[1], *W. D. Gaillard*[3], *L. Kenworthy*[3] *and C. J. Vaidya*[1], *(1)Department of Psychology, Georgetown University, Washington, DC, (2)Interdisciplinary Program in Neuroscience, Georgetown University, Washington, DC, (3)Children's Research Institute, Childrens National Medical Center, Washington, DC*

Background: Behavioral inflexibility, the inability to shift to a different thought or action following a change in a situation, is a hallmark of autism spectrum disorders (ASD). Emerging evidence in healthy adults suggests that the dynamic nature of the brain's large-scale functional network architecture enables adaptive goal-oriented behaviors. With this principle in mind, we hypothesized that behavioral inflexibility in ASD is associated with an aberrant adaptation of brain networks during cognitive states requiring this ability. Graph theory metrics, such as modularity, may be particularly well-suited to capture these atypical patterns of whole-brain communication.
Objectives: Use a multi-state approach to test for state-dependent brain network modularity reductions in ASD children.
Methods: Seventeen children with ASD and age-, IQ-, gender-matched typically developing (TD) children performed three functional magnetic resonance imaging (fMRI) tasks. The first task consisted of passive fixation (i.e., resting-state). The second task required monitoring a central visual stream of shapes and responding to a target shape. The third task utilized visual stimuli that were identical to those used in the second but imposed behavioral flexibility demands through an alternative set of instructions. This manipulation allowed testing whether differences in brain network modularity between ASD and TD children are specific to a cognitive state requiring behavioral flexibility (Task 3) versus a perceptually invariant cognitive state not requiring behavioral flexibility (Task 2) or a resting-state (Task 1). For each participant, a whole-brain functional connectivity (FC) matrix was generated for each state using the regions-of-interest created by Power et al. (2011) with the effects of participant motion, physiological noise, and task structure regressed. FC matrices were decomposed into distinct modules by implementing the Newman–Girvan quality function *Q*. This function was optimized using the Louvain algorithm, as implemented in the brain connectivity toolbox (https://sites.google.com/site/bctnet/), and iterated 1000 times. Independent sample t-tests were applied to test for differences in modularity (i.e., *Q*) between ASD and TD children for each state. In addition, average ASD and TD FC matrices were entered into network visualization software to compare how network topologies, represented as spring graphs, reconfigured between states.
Results: Brain network modularity was reduced in ASD children relative to TD children [$t(33) = 1.70$, $p<0.05$] in the cognitive state requiring behaviorally flexibility (Task 3), but not in the cognitive state requiring no behavioral flexibility (Task 2) or the resting-state (Task1). In line with this finding, spring graphs revealed a striking pattern of cross-module signaling specific to Task 3 in the ASD group.
Conclusions: Our results suggest that behavioral inflexibility in ASD may be associated with reductions in brain network modularity (i.e., less segregation of networks). However, this work has broader implications for ASD brain connectivity research, which often assumes the resting-state captures intrinsic brain network abnormalities. In contrast, our findings highlight the importance of understanding the influence of specific cognitive states on brain networks in ASD.

74 **107.074** Subtype Classification of Autism Spectrum Disorder Via Resting-State fMRI Reveals Distinct Brain Network Endophenotypes

J. A. Richey[1], *K. M. Gates*[2], *S. Lane*[2], *A. D. Valdespino*[3], *R. A. Müller*[4] *and A. Di Martino*[5], *(1)Virginia Tech, Blackbsurg, VA, (2)Psychology, University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)Psychology, Virginia Tech, Blacksburg, VA, (4)San Diego State University, San Diego, CA, (5)NYU Child Study Center, New York, NY*

Background: Phenotypic heterogeneity has presented a significant obstacle to MRI/fMRI-based diagnostic classification because most optimization algorithms assume a single, mutually exclusive distinction between ASD and typically developing groups. However, extant literature very clearly indicates that autism is not a single clinical entity, but a manifestation of dozens or more likely hundreds of genetic and genomic disorders (Betancur, 2011). Lack of information about subgroups of ASD is a problem in both diagnostic and treatment domains, because effects of interest may only be observed in only a subset of cases, thereby reducing statistical power and obscuring mechanisms of change in currently available treatments.
Objectives: The primary objective of this project was to apply a novel group search algorithm (Group Iterative Multiple Model Estimation [GIMME]; Gates & Molenaar, 2013) to resting-state fMRI data to determine whether brain-based heterogeneity within ASD can actually be *useful information*, that facilitates the identification of subgroups whose brain network properties are similar. A second objective is to then identify whether ASD symptoms within subgroups also cluster together.
Methods: We evaluated resting-state fMRI from individuals with ASD (N=70) from the NYU site in the Autism Brain Imaging Data Exchange (ABIDE; DiMartino et al., 2014). Data were preprocessed in AFNI (motion corrected, censored/scrubbed[0.05 FD], lowpass filtered). We applied GIMME to timeseries data extracted from seven brain regions in the default mode network (DMN). GIMME identifies contemporaneous and temporally lagged paths that are (1) common to all members of the sample and (2) unique to subsets of cases.
Results: Three distinctive subgroups of ASD emerged from our analysis of the DMN. Consistent with previous work on brain connectivity of DMN related to social-cognitive deficits (Lynch et al., 2013; Uddin et al., 2013), group 1 demonstrated hyperconnectivity of posterior cingulate, precuneus and left angular gyrus, perhaps relating to deficits in theory of mind and difficulty in episodic memory and self-related processing. Group 2 demonstrated increased connectivity between midline regions (dorsomedial PFC, rostral anterior cingulate), which has been previously linked to repetitive behaviors (Weng et al., 2010). Finally, group 3 demonstrated similar patterns to groups 1 and 2, but also enhanced connectivity of rostral anterior cingulate and posterior cingulate/precuneus. Preliminary analysis of phenotyping data indicates that groups differ on Vineland

subscales (Deficits in Daily Living Skills domain: Grp 1; Deficits in Socialization domain: Grp 2).
Conclusions: Effective connectivity maps at the individual level can be aggregated into verifiably homogeneous subgroups/communities, which share similar brain network properties. Analyses relating phenotyping data available through ABIDE are ongoing, and indicate that brain-derived subgroups meaningfully map onto symptoms.
Funding: This work was supported by R03 MH102651 "*Data Mining for Autism Endophenotypes in a Large-Scale Resting State fMRI Repository.*" PI: Richey.

75 **107.075** Temporal and Spatial Neural Correlates of Theory of Mind in Children with ASD

V. Yuk[1,2]*, R. Leung*[1,2]*, E. Anagnostou*[3,4] *and M. J. Taylor*[1,2,4]*, (1)Diagnostic Imaging, The Hospital for Sick Children, Toronto, ON, Canada, (2)Psychology, University of Toronto, Toronto, ON, Canada, (3)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Paediatrics, University of Toronto, Toronto, ON, Canada*

Background: Theory of mind (ToM), or the ability to recognize the different mental states of others, is characteristically impaired in children with autism spectrum disorder (ASD), which is thought to contribute to their social cognitive deficits. Functional MRI studies have investigated the neural mechanisms underlying ToM, implicating the precuneus, temporoparietal junction (TPJ), and the medial prefrontal cortex (mPFC) as core regions of the ToM network. Studies in adults with ASD have shown atypical activation in these areas. However, only a few studies have examined the timing of brain activity during ToM reasoning, and none have explored this aspect in ASD, nor how it differs in children, even though deviations in the latency and duration of brain activity during development can also be responsible for the social impairments observed in ASD.
Objectives: This study determined the temporal and spatial properties of brain regions active during a false-belief ToM task in children with and without ASD using magnetoencephalography (MEG).
Methods: Participants included 22 typically-developing (TD) children and 19 age- and sex-matched children with ASD between the ages of 8 and 12 years. We studied the timing of ToM-related neural processes using a false-belief task adapted from Dennis et al. (2012) for MEG, which has precise temporal and spatial resolution on the order of milliseconds and millimetres, respectively.
Results: While the two groups of children did not differ in performance on the false-belief task, whole-brain analyses revealed distinctive neural patterns. Whereas TD children activated familiar ToM regions, such as the right precuneus (150-225 ms and 325-400 ms) followed by the left TPJ (300-400 ms and 425-475 ms), children with ASD appeared to utilize verbal abilities to complete the same task, activating the left inferior frontal gyrus (IFG; 275-375 ms and 450-600 ms), while simultaneously relying on working memory, attention, and inhibition areas, such as the right dorsal TPJ overlapping with the right superior parietal lobule (275-375 ms and 450-600 ms) and the right IFG (300-600 ms).
Conclusions: Using MEG, we were able to detect a unique temporospatial recruitment of brain regions involved in understanding false belief in our participants with ASD, which suggests that children with ASD make use of alternative strategies to compensate for their deficits in ToM. As our group of children with ASD did not differ from controls on measures of working memory and inhibition, and given that the brain areas they activated are typically involved in these processes, these children may have employed these preserved executive functions to perform similarly to their peers on the ToM task. These results not only inform how ToM can be conserved in some children with high-functioning ASD, but they also demonstrate processes that could be harnessed in interventions to improve ToM and social cognition in children with ASD. Future work will expand our findings to the connectivity domain, as individuals with ASD have been shown to have atypical patterns of connectivity, and the interaction between executive functioning and ToM will be explored.

76 **107.076** The Impact of Child Characteristics on EEG Data Quality in Infants at Risk for and Children with ASD

E. Baker[1] *and S. S. Jeste*[2]*, (1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background:
Electroencephalography (EEG) is a promising functional imaging method to identify biomarkers of outcome in children at risk for and with ASD. EEG data are susceptible to artifact and can be rendered unusable due to slight movements, such as head turning, blinking, or even smiling. During initial stages of data processing, artifacts commonly result in trial loss. Currently, no standardized measures exist to quantify participant behavior and its effects on data quality. Additionally, it is undetermined if variability in social communication impairment and cognitive function impacts data quality.
Objectives:
We asked whether cognitive ability and behavior of children with or at risk for ASD related to percentage of useable trials garnered from session. We developed a rating of child's behavior during session through a 5-point likert scale of perceived mood. Primary use of the scale was to quantify in-session perceived mood and overall compliance. We investigated two samples of children from the Autism Centers for Excellence (ACE) study. The two groups included: (1)"ACE Project 2:" 12-24 month-old infants at risk for ASD, defined by elevated scores on the Autism Diagnostic Observation Schedule-Toddler Version (ADOS-T) and (2) "ACE Project 3:" children aged 6-11 years-old with ASD who are minimally verbal. We focused on these cohorts due to marked cognitive impairment and varied symptom expression, resulting in challenges during EEG recording.
Methods:
Forty-seven children from ACE Project 2 (mean age=18.6 months) were presented with familiar and novel photos of faces while EEG was recorded. Sixteen children from ACE Project 3 (mean age=88.2 months) listened to an auditory statistical learning task while EEG was recorded. EEG recording was performed using a high-density system (128-channel, EGI Inc.). Developmental quotients (DQ) were acquired from the Mullen Scales of Early Learning and social communication impairment was calculated with the total score from the ADOS-T and ADOS-2. Behavior rating was performed during EEG tasks. Useable data were defined as the percentage of trials available after automated artifact detection; channels were rejected if amplitude difference was greater than 150 mV.
Results:
ACE Project 2 and ACE Project 3 participants did not differ in amount of useable data provided (t=1.36,p=.262). Within ACE Project 2, age (r=.128,p=.509), ADOS-T score (r=-.12,p=.536), and DQ (r=-.083,p=.668) did not relate to amount of usable data collected from participants. Similarly, within ACE Project 3, age (r=.200,p=.950), ADOS-2 score(r=.074,p=.747), and DQ (r=-.465,p=.128) did not significantly relate to useable data. Behavioral rating significantly correlated with amount of useable data in both groups [ACE Project 2 (r=-.404,p=.030) and ACE Project 3 (r=-.734,p=.01)].
Conclusions:
Clinical characteristics, including cognitive ability and social communication impairment, are not useful constructs to measure data quality in EEG. However, perceived mood and behavior of the child during session does predict useable data. As EEG and other experimental measures serve as functional biomarkers in ASD, measurement of a child's behavior and mood during testing sessions will be critical to improve signal quality. Practices to standardize behavior and improve mood during recording should be implemented. Future directions involve measuring impact of behavioral regulation techniques on data quality.

77 **107.077** The Influence of Biological Sex on Neurobiological Mechanisms Underlying Autism Spectrum Disorder

M. Kirkovski[1,2]*, P. Enticott*[1]*, N. Rogasch*[3]*, T. Saeki*[4]*, B. Fitzgibbon*[2]*, J. Maller*[2]*, M. Hughes*[5]*, S. Rossell*[5] *and P. Fitzgerald*[2]*, (1)Deakin University, Melbourne, VIC, Australia, (2)Monash Alfred Psychiatry Research Centre, Monash University, Melbourne, Australia, (3)Monash Biomedical Imaging, Monash University, Clayton, Australia, (4)Monash University, Melbourne, Australia, (5)Swinburne University, Hawthorn, Australia*

Background: Autism spectrum disorder (ASD) is highly heterogeneous condition, particularly when considering neurobiological function. There is, however, evidence to suggest that biological sex contributes to this neurobiological heterogeneity, and that females may be more profoundly affected.
Objectives: This study investigated the role of biological sex on neural mechanisms underlying ASD, including neural activity and connectivity, with a specific focus on brain regions and mechanisms underlying social cognition.
Methods: 66 males and female adults with high-functioning ASD and age, sex and IQ matched controls took part in this study. Participants completed various measures, including: neurocognitive/neurobehavioural assessment; structural (anatomical and diffusion weighted imaging [DWI]), functional (resting state [investigating the default mode network; DMN], and task related [investigating ToM]) magnetic resonance imaging (MRI); and combined transcranial magnetic stimulation (TMS) and electroencephalography (EEG; TMS-EEG) of right lateralised dorsolateral-prefrontal cortex (rDLPFC), primary motor cortex (rM1) and temporo-parietal junction (rTPj).
Results: : DWI data revealed no differences between groups in any major white matter (WM) tracts throughout the brain. At rest, we did not identify any differences in functional connectivity (FC) between the key DMN structures, between groups, nor any effect of sex. Reduced FC in the ASD group, however, was noted between the posterior cingulate cortex (PCC) and the right lateralised somatosensory and temporal cortices. While processing social interactions, there were no group differences in hemodynamic response in core "mentalising" regions (medial prefrontal cortex, rTPj), but the ASD group displayed a reduced response in the neighbouring right posterior superior temporal sulcus (pSTS). Gender analysis indicated that this was apparent for males with ASD, but not females with ASD. TMS-EEG data did not reveal any group differences in neurobiological response to TMS at any of the sites investigated, or any effect of sex.
Conclusions: These findings provide important information with regard to the heterogeneity of ASD, specifically around the notion of a mediating role of biological sex in ASD. The findings of this study indicate that the perceived sex differences in ASD are not consistently replicated across measures of neurobiological mechanisms. This highlights the importance of investigating sex differences in ASD across a variety of measures and mechanisms, and also across different domains implicated in the autism spectrum.

78 **107.078** Voice Processing in High-Functioning Autism Spectrum Disorder: Neuronal and Behavioral Mechanisms

S. Schelinski[1], *C. Roswandowitz*[1,2], *K. Borowiak*[1,3] *and K. von Kriegstein*[1,4], *(1)Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, (2)International Max Planck Research School on Neuroscience of Communication, Leipzig, Germany, (3)Berlin School of Mind and Brain, Humboldt University of Berlin, Berlin, Germany, (4)Humboldt University of Berlin, Berlin, Germany*

Background: The ability to recognize the identity of others is an evolutionary conserved process and a key requirement for successful communication. In autism spectrum disorder (ASD), a condition that is associated with difficulties in social interaction, there is good evidence that the ability to identify another person by face is deficient (Weigelt et al., 2012). Previous research suggests that voice identification processing is also impaired in ASD (Schelinski et al., 2014). However, the underlying neuronal and perceptual mechanisms of this voice processing deficit are unknown.
Objectives: Here, we systematically investigated the behavioral and neuronal mechanisms of voice processing in high-functioning ASD.
Methods: Sixteen adults with high-functioning ASD and sixteen typically developed controls (matched pairwise on age, gender, and IQ) participated in two fMRI experiments and a comprehensive behavioral test battery on voice recognition. In the first fMRI experiment (vocal sound experiment), participants passively listened to blocks of vocal (speech and non-speech) and non-vocal sounds (e.g. musical instruments, nature, animals) (Belin et al., 2000). In the second fMRI experiment (voice recognition experiment), participants performed voice identity recognition and speech recognition tasks on the same stimulus material (von Kriegstein & Giraud, 2004). The behavioral test battery included tests on (i) recognition of newly learned voices, unfamiliar voice discrimination and famous voice recognition, (ii) acoustic processing abilities that are associated with voice recognition (i.e. tests on vocal pitch and timbre discrimination), (iii) control tasks (i.e. tests on musical pitch and timbre perception, and face identity recognition). Results were considered as significant at $\alpha = .05$ (fMRI: $p < .05$ family wise error (FWE) corrected for region of interest).
Results: The behavioral results showed that the ASD group had particular difficulties with discriminating, learning, and recognizing unfamiliar voices, while recognizing famous voices was comparable to controls. Difficulties with unfamiliar voices correlated with similar difficulties in recognizing unfamiliar faces. Tests on acoustic processing abilities showed that the ASD group had a specific deficit in vocal pitch discrimination that was dissociable from otherwise intact acoustic processing (i.e. musical pitch, musical timbre, and vocal timbre perception). The vocal sound experiment showed that passive listening to vocal sounds in contrast to non-vocal sounds elicited similar activity in voice-sensitive cortices in the superior temporal sulcus and gyrus (STS/STG) in the ASD and the control group. The voice recognition experiment showed reduced BOLD responses to the voice identity recognition in contrast to the speech recognition task in the ASD compared to the control group in the right posterior STS/STG—a region that has been previously implicated in processing acoustic voice features.
Conclusions: Our results allow, for the first time, a characterization of the voice recognition deficit in ASD: Both the behavioral and neuronal findings indicate that in high-functioning ASD, the ability to recognize voices is impaired because of difficulties with processing acoustic aspects of voices, that is, difficulties with integrating the acoustic characteristics of the voice into a coherent percept. A deficit in voice processing might contribute considerably to the development of communication difficulties - a core hallmark of ASD.

79 **107.079** White and Grey Matter Abnormalities in Autism Spectrum Disorder Associate with Verbal Performance

S. V. Huemer[1], *F. Kruggel*[2], *V. Mann*[2] *and J. Gehricke*[3], *(1)University of CA - Irvine, Rancho Palos Verdes, CA, (2)University of California, Irvine, Irvine, CA, (3)University of California, Irvine, Santa Ana, CA*

Background: Recent diffusion tensor imaging (DTI) studies point to impairments in most or all major neural networks rather than isolated, discrete brain regions in ASD (McAlonan et al., 2005; Mueller, 2007; Shukla, Keehn, & Mueller, 2011). Several brain regions have been implicated consistently in ASD but results often differ on whether there are increased or decreased brain volumes and whether differences can be found at all in certain regions. The discrepancies may result from differences in imaging protocols, data analysis, subject ages, and samples sizes, but the overall inhomogeneity of ASD samples, which disregard neurological and diagnostic subtypes, may play a bigger role than generally assumed.
Objectives: ASD subjects may vary in the extent of verbal impairment, and the potential anatomical correlates of this are a concern of this paper along with the general profile of white and gray matter anomalies associates with ASD.
Methods: Twenty participants (ages 12 – 20 years 5 female, 15 male) with a previous diagnosis of an autism spectrum disorder and 10 typically developing (TD) participants (ages 12 – 18 years, 1 female, 9 male) were enrolled in our study. This whole-brain structural magnetic resonance imaging (MRI) investigation used voxel-based morphometry to analyze white and grey matter concentration (VBM-GM and VBM-WM) and tensor based morphometry (TBM) to analyze shape differences. Diffusion tensors were computed from the registered diffusion-weighted images using a nonlinear procedure and tensors were converted into fractional anistropy (FA), mean diffusivity (MD), and radial diffusivity (RD) values (method DTI-FA, DTI-MD, DTI-RD).
Results: For adolescents with ASD, VBM and TBM revealed regions of lower GMC alongside higher WMC in the left and right precentral gyrus, lower GMC with decreased WMC in the left anterior cingulate, as well as lower GMC in the left operculum, the left superior frontal gyrus, the right and left superior temporal gyrus, and WM shape differences in the left frontal lobe and the right and left claustrum. TBM also indicated significant expansion in areas that are in overprojection with the uncinate fasciculus. When subjects were defined by a measure of receptive verbal ability (PPVT-III), we found increased GMC in the parahippocampal gyrus, along with an increased WMC and increased FA in the adjacent WM of the temporal lobe. Increased WM density, increased FA, and decreased MD and RD were also found in the lower scoring subjects in frontal WM of both hemispheres, along the left and right arcuate fascicle and the uncinate fascicle.
Conclusions: Our findings of significant differences in white and grey matter concentration and shape largely support prior research. We found even more pronounced differences when we used verbal ability as an independent variable, which also revealed FA and RD differences widely described in previous DTI studies.

80 **107.080** Working Memory Load-Dependent Activation Differences Between ASD and TD Children: An fNIRS Study

F. A. Fishburn[1], *R. Ludlum*[2], *K. M. Dudley*[3], *A. B. Ratto*[4], *A. V. Medvedev*[5], *L. Kenworthy*[6] *and C. J. Vaidya*[2], *(1)Interdisciplinary Program in Neuroscience, Georgetown University, Washington, DC, (2)Department of Psychology, Georgetown University, Washington, DC, (3)Children's National Medical Center, Center for Autism Spectrum Disorders, Ellicott City, MD, (4)Children's National Medical Center, Silver Spring, MD, (5)Center for Functional and Molecular Imaging, Georgetown University Medical Center, Washington, DC, (6)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Autism Spectrum Disorder (ASD) is characterized by difficulties with social interaction, communication, and restricted and repetitive interests – however the disorder also manifests as disturbances in executive function. ASD subjects have been shown to have atypical brain activation on executive function tasks even where there are no differences in task performance. These studies have typically used fMRI, which is of limited use in children due to its sensitivity to head motion. In this study, we use fNIRS (functional Near-Infrared Spectroscopy), a method robust to head motion, to measure activation differences between ASD and typically-developing (TD) children during a working memory task. In addition, we examine whether brain activation correlates with executive function in daily-life using the Behavior Rating Inventory of Executive Function (BRIEF).
Objectives: Determine whether activation in response to increasing working memory load differs between ASD and TD children, and whether activation differences correlate with real-world measures of executive function in daily life.
Methods: Forty-one age- and IQ-matched subjects (19 ASD, 22 TD) of ages 7-15 and IQ >80 were given a 7-minute n-back task with loads of 0-, 1-, and 2-back. Each load condition contained 3 blocks of 9 consonant letter stimuli, with block sequence pseudorandomized. Optical data were recorded on a two-wavelength (690 and 830 nm) continuous-wave CW6 imaging system (TechEn, Inc., Milford, Massachusetts). The 60 optical channels covered the anterior and lateral frontal, temporal, parietal, and occipital cortices. *Preprocessing:* Raw signals were corrected for motion by spline interpolation, band-pass filtered, and converted to changes in deoxygenated hemoglobin concentration. *Activation:* Subject reaction times for correct target trials were z-scored and an average was taken for each condition. These values were then used to create a load-dependent regressor for each subject. A GLM was performed at each channel using NIRS-SPM and the t-statistic for load-dependent activation was computed, regressing out the covariates age, gender, and IQ. Group difference was statistically evaluated by 2-sample t-test. P-values were corrected using the false discovery rate (FDR) procedure. The channel with peak group difference in activation was then correlated with the Behavioral Regulation (BRI) and Metacognition (MI) indices from the BRIEF.
Results: Group x load ANOVAs on task accuracy and reaction time both revealed a main effect of load ($F_{(2,74)} = 9.144$, $p < .0005$; $F_{(2,74)} = 7.616$, $p < .001$) but no significant main effect of group or group x load interaction. ASD subjects exhibited greater load-dependent activation than TD in left lateral prefrontal cortex ($t_{(39)} = 3.893$, $p < .05$; Figure 1). Activation in this region correlated with the BRI in ASD subjects ($r_{(15)} = .542$, $p < .05$) but not controls.
Conclusions: ASD subjects showed greater load-dependent activation than TD subjects in left lateral PFC while completing the task with equivalent performance. Activation in this area correlated with daily-life executive functioning for ASD subjects. These data suggest that executive functions require greater effort from ASD subjects than their TD counterparts and these differences may extend to everyday tasks and behaviors.

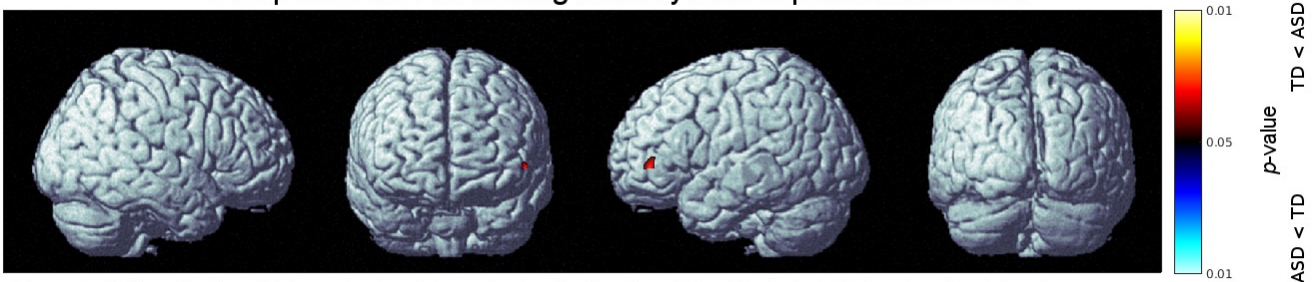


Figure 1. ASD subjects exhibit greater load-dependent activation than TD subjects in left lateral prefrontal cortex.

81 **108.081** Are Fathers Active Playmates with Their Children with ASD, and Why This Is Relevant for Therapy?

P. Venuti[1]*, A. Bentenuto*[2] *and C. Furlanello*[3]*, (1)University of Trento, Trento, Italy, (2)University of Trento, Trento, TN, Italy, (3)FBK - Fondazione Bruno Kessler, Trento, Italy*

Background:
Healthy parent-child interaction is essential for child development. In particular, parents play a central role in the acquisition of social and communicative skills, both in typical as well as in atypical children (Flippin & Crais, 2011). While mothers tend to rise play level (both for exploratory or symbolic play), fathers usually tune their play level closer to the child one (de Falco et al. 2009, 2010) . It is thus relevant, also for potential application, to assess quantitatively the relevance of fathers engagement with children with Autism Spectrum Disorders (ASD), who are characterized by social and communication deficits.
Objectives:
The aim of the study is to evaluate comparatively interactive behaviours and play of mothers and fathers with their children with ASD in a structured experimental setup. We search for patterns of interaction that are consistently tuned closely to child actual level and does can serve sustaining long interaction time.
Methods:
This study involved 60 parent-child dyads: 30 children with ASD (M chronological age= 45.7 months [range: 23-68]; SD=12.80; M mental age = 34 months, [range: 13-72],SD=15.43) in interaction with their mothers and their fathers, separately. To assess parent-child interaction, data were collected during two consecutive video recorded 10 min play sessions. A play code (Bornstein et al 1997, Venuti et al, 2008) was applied to the child's play and to the parent's play. Finally, the emotional profiles in parent-child dyads were evaluated using the Emotional Availability Scales (EAS4thEdition, Biringen 2008).
Results:
Regarding the construct of emotional availability, in this study no significant difference was found between mothers and fathers. Children with ASD mainly engaged in exploratory play, both with fathers and mothers. We found that mothers prefer symbolic play levels, while fathers use significantly more exploratory play. As a consequence, we measured longer average interaction time with fathers.
Conclusions:
As fathers are active playmates with their ASD children, they can achieve longer and richer interaction also when symbolic level is not attained and it is hard to engage the child. Taking into account this advantage, the involvement of the father should became a solid base ground in early autism intervention.

82 **108.082** Brief Parent Training in PRT during Jumpstart, a Community Implemented Parent Education and Empowerment Program: Parent and Child Outcomes

N. L. Matthews*, B. C. Orr, B. Harris and C. J. Smith, Southwest Autism Research & Resource Center, Phoenix, AZ*

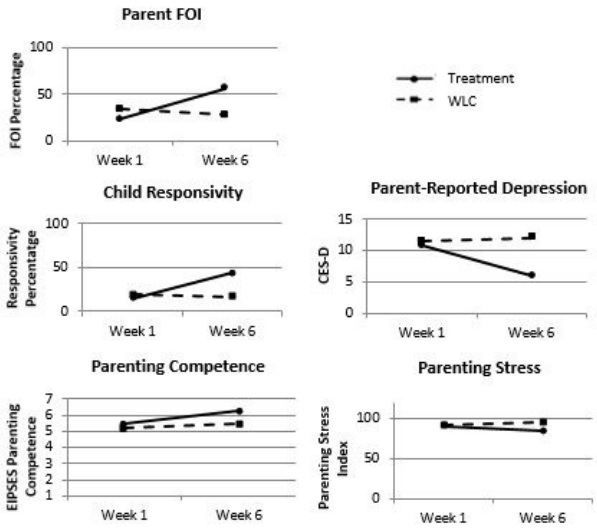
Background: Beginning behavioral intervention for autism as early as possible is important for facilitating optimal outcomes (e.g., Dawson et al., 2012). This effort is often hindered by long waitlists, lack of qualified interventionists, and cost. JumpStart is a short-term, group-format education and empowerment program for parents of recently diagnosed children. It is implemented by community practitioners at a non-profit autism center, includes brief parent training in pivotal response treatment (PRT), and equips families to navigate service systems.
Objectives: (1)To compare change in parent fidelity of implementation (FOI) of PRT, child responsivity, parent-reported well-being, and parent-reported self-efficacy between treatment and waitlist control (WLC) groups, and to determine the percentage of parents who achieved FOI within the full sample; (2) To discuss strengths and challenges of this program.
Methods: Participants were 36 parent-child dyads recruited from the JumpStart waitlist, matched on child age, and enrolled in the treatment (n = 18) or WLC (n= 18) group. Children had an ASD diagnosis (83%) or an 'at-risk for autism' classification. Diagnostic distributions were identical and Vineland composite scores did not differ between groups at study entry. See Table 1 for participant demographics.
JumpStart meets twice weekly over a 4-week period (weeks 2-5). It includes didactic lessons on autism, obtaining services, and brief training in PRT (i.e., 1.25 hours didactic, 5 hours guided observation, and 5 hours in-vivo coaching). At a study visit 4-6 weeks prior to the program (WLC group only), orientation (week 1), 1-week follow up (week 6), and 3-month follow-up (week 18), parents completed the Parent Stress Index (Abidin, 1995), the Early Intervention Self-Efficacy Scale (Guimond et al., 2008), the Center for Epidemiological Studies Depression Scale (Radloff, 1977), and a 10-minute videotaped probe with their child coded for child responsivity and parent FOI. Of note, 'week 6' probes were collected during week 5 due to program restraints and thus reflect only 3.75 hours of in-vivo coaching. Parents completed 1.25 additional hours of coaching after probes were collected.
Results: Depicted in Figure 1, the treatment group demonstrated greater increases in parent FOI (F(1, 33) = 40.43, p < .001) and child responsivity (F(1, 33) = 26.80, p < .001) and decreases in parent-reported depression (F(1, 33) = 4.19, p = .05) compared to WLC. Approaching statistical significance were increases in parenting competence (F(1, 32) = 3.95, p = .06) and decreases in parenting stress (F(1, 33) = 2.99, p = .10). Within the full sample, average FOI at week 6 was 57% (SD = 17.57) and 23% of parents achieved FOI (> 75%).
Conclusions: Parents who participate in JumpStart can begin intervention earlier while arranging a more comprehensive treatment program. Findings suggest that JumpStart yields meaningful outcomes, including gains in child responsivity, parent FOI, and parenting competence, and decreased parent depression and stress. Three-month follow-up data will indicate whether these changes are maintained. Additionally, strengths and challenges of the program will be discussed, including number of families served (60-84 annually), quality of parent training, funding, and a growing waitlist.

Table 1. Participant Demographics

Variable		Treatment (n = 18) $M(SD)$	WLC (n = 18) $M(SD)$
Child			
	Age (months)	40.83 (11.30)	40.72 (11.61)
	Gender (percent male)	100.00	94.44
	Vineland ABC	65.67 (8.60)	67.83 (11.85)
	Race (percent)		
	Caucasian	77.77	66.67
	Hispanic	5.55	22.22
	Asian	11.11	11.11
	African American	5.55	0.00
Parent			
	Age (years)	34.61 (5.61)	36.77 (7.05)
	Percent mothers	83.33	88.90

Note. WLC = Waitlist control group. ABC = Adaptive Behavior Composite.

Figure 1. Change in Primary Outcome Variables



Note. WLC = Waitlist control group. FOI = Fidelity of Implementation. CES-D = Center for Epidemiological Studies Depression Scale. EIPSES = Early Intervention Parenting Self-Efficacy Scale. For WLC, data represent change over 4-6 week period prior to JumpStart participation.

83 **108.083** Comparative Efficacy of Parent Training Plus Individual Targeted-ABA Therapy Versus Parent Training Alone: A Preliminary Analysis

R. Embacher[1], *T. W. Frazier*[1], *T. N. Gray*[2] *and A. Y. Hardan*[3], *(1)Cleveland Clinic Center for Autism, Cleveland, OH, (2)Center for Autism, Cleveland Clinic Children's, Cleveland, OH, (3)Stanford University, Stanford, CA*

Background: Extensive support exists in the literature for early intensive behavioral intervention following an autism spectrum disorder (ASD) diagnosis. Demand for services far exceeds availability, especially for young children with a recent diagnosis. Low access and high expense of intensive behavioral intervention programming creates the need for effective treatment modalities. Parent training has been shown to be effective for improving child skills and decreasing challenging behavior; however it is not yet clear to what extent simultaneous individual behavior therapy adds to this model. In addition to the type and frequency of services provided, a number of variations on behavior therapy teaching approaches exist and have been implemented as both parent training and individual therapy packages. These include structured Applied Behavior Analysis (ABA) approaches and methods that are more child-led and involve the use of natural opportunities and reinforcers, such as Pivotal Response Training and the Early Start Denver Model. A known weakness of structured ABA is that the therapist-driven structure of sessions can decrease spontaneous responding. Conversely, a weakness of child-led, naturalistic approaches is that low functioning children may not be able to lead interaction and instead prefer to engage in repetitive sensory motor behavior. Targeted ABA (T-ABA) blends structured ABA and naturalistic, child-led approaches by emphasizing the approach which matches most closely to the child's abilities and needs.
Objectives: The primary aim was to compare the efficacy of T-ABA therapy delivered using a combination of parent-training and individual sessions versus parent-training alone.
Methods: The study uses a 20-week, randomized, two-group, cross-over design. During the first 10 weeks of the study, both groups received five T-ABA parent training sessions followed by five parent-therapist in vivo coaching sessions (1 hr each). The T-ABA parent training plus individual therapy group also received eight individual therapist-child sessions (1 hr each). During the final 10 weeks, the T-ABA parent training alone group crossed-over to receive individual therapy sessions. Eight outcome measures were examined in this preliminary analysis including measures of autism symptoms, communication skills, and quality of life.
Results: To date, 15 parent-child pairs have been recruited and completed treatment and an additional 8 parent-child pairs are in progress. Preliminary analyses indicated that both treatment arms produced improved manding, tacting, echoic behavior, motor imitation, and listener responding measured by the Verbal Behavior Milestones Assessment and Placement Program (VB-MAPP), and improved overall quality of life ($p<.05$) as measured by the Child and Family Quality of Life-Second Edition. Adding individual therapy resulted in greater improvements in autism symptoms ($p<.001$) as measured by the Social Responsiveness Scale and a trend toward greater improvements in visual matching ($p=.082$) as measured by the VB-MAPP relative to the T-ABA parent-training alone group.
Conclusions: T-ABA parent-training alone or in combination with individual therapy appears to be an effective less-intensive treatment approach for young children with ASD. Improvements in autism symptoms may be stronger with the addition of individual therapy sessions. Sample size is small and results should be considered very preliminary.

84 **108.084** Consensus Among Early Intervention Autism Experts Regarding Context for Success and Strategies for Suddenly Inclusive Early Education Childcare Settings

M. P. Maye[1], *A. K. Stone-MacDonald*[2], *V. E. Sanchez*[2], *J. A. Galler*[2] *and A. S. Carter*[3], *(1)University of Massachusetts Boston, Boston, MA, (2)University of Massachusetts, Boston, Boston, MA, (3)Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background: A recent national survey of parents of preschool aged children found that 91% of children with ASD were receiving care in community settings (e.g., family-based child care, preschools, child care centers). Compared to parents of typically developing children (9%) and parents of children with developmental delay (16%), parents of children with ASD (39%) were significantly more likely to report that childcare challenges contributed to employment accommodations (e.g., quit a job, did not take a job, greatly changed their job) at a significantly elevated rate (Montes & Halterman, 2008). Thus, many community early educators in childcare settings may not be prepared to meet the needs of children with ASD. Working towards the development of an intervention that targets strategies early educators can use within the context of a center-based childcare setting could be a partial solution to this problem. Such an intervention should focus on identifying and including *active ingredients* of early interventions for children with ASD (Kasari, 2002) that can be integrated with best practices for early education.
Objectives: To identify potential active ingredients of early interventions that can be taught to early educators working in childcare settings to support toddlers with ASD.
Methods: Sixteen of 26 early intervention autism experts, identified based on published early intervention autism research articles over the past 20 years, participated in

semi-structured interviews regarding early intervention development (e.g., key strategies, training of early educator/child care provider interventionists). Two additional expert interviews will be completed for the final poster presentation. These interviews were one part of a larger project to develop a brief intervention for early educators in child care settings. Interviews were independently transcribed and coded by three people. Ongoing analysis with NVIVO is focused on exploring themes. Thorough systematic coding, categories and themes will be generated and researchers will check for saturation.
Results: Preliminary analysis highlights the following two themes: 1. creating a context for success (including sub-themes such as child engagement [e.g., toy options, child choice] and awareness of child developmental level [e.g., play above and below child's developmental level, activities at different levels] and 2. specific strategies critical to the intervention process (including sub-themes such as pausing [e.g., expectant pausing, waiting] and using routines [e.g., routines to the third power, structure]). Additional sub-themes as well as quotes to substantiate each of these themes will be provided in the final presentation.
Conclusions: A number of early intervention models were represented in the expert interviews (e.g., ESDM, Children's Toddler School, JASPER, LEAP, Walden School). The level of consensus regarding the context required for a successful intervention is compelling. These themes lend support for common training needs among early educators that could be addressed by an intervention for use in suddenly inclusive early education childcare settings. Additionally, the level of agreement present regarding "the most important intervention strategies" provides researchers with a potential starting point for future studies that should analyze the relative impact of individual intervention strategies and their interaction with one another when used simultaneously.

85 **108.085** Earlier Intervention Is Better for Toddlers with ASD: Evidence from a Randomized Controlled Trial of the Early Social Interaction Project

W. Guthrie[1,2], *A. M. Wetherby*[1], *J. Woods*[1], *C. Schatschneider*[1], *R. Holland*[1], *L. Morgan*[1] *and C. Lord*[3], *(1)Florida State University Autism Institute, Tallahassee, FL, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Weill Cornell Medical College, White Plains, NY*

Background: Early diagnosis of autism spectrum disorder (ASD) is on the rise, spurred by advances in early detection methods and recommendations for screening at 18 and 24 months (Johnson & Myers, 2007). Naturalistic developmental behavioral interventions (NDBIs) have been shown to improve language, cognitive, and/or social outcomes for toddlers diagnosed with ASD (Dawson et al., 2010; Kasari et al., 2010; Wetherby et al., 2014). Although there is agreement that intervention before age three is important, empirical evidence for the notion that "earlier is better" is limited and comes almost entirely from observational studies (Granpeesheh et al., 2009; Harris & Handleman, 2000). There is a critical need for experimental treatment studies that test timing effects to guide the optimal age of intervention for ASD.
Objectives: To report on findings from a randomized controlled trial (RCT) designed to test timing effects of early intervention for toddlers with ASD under age three. This study compared improvement during Early Social Interaction (ESI) between toddlers randomized to receive individualized treatment early (~18 months) or 9 months later (~27 months).
Methods: A complete crossover RCT design was employed in which toddlers (*N*=82) received ESI-Individual at either 18 or 27 months of age. At 18 months, toddlers were randomly assigned to either ESI-Individual or ESI-Group as their first treatment condition. After 9 months, children received the other treatment condition for an additional 9 months, totaling 18 months of treatment. Child outcome measures were administered at baseline, crossover, and end of treatment: Communication and Symbolic Behavior Scales (CSBS), Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales, Second Edition (VABS-II), and Autism Diagnostic Observation Schedule (ADOS).
Results: Generalized linear models revealed that toddlers who received ESI-Individual at 18 months showed greater gains during this treatment than those who received ESI-Individual at 27 months. These timing effects were demonstrated for receptive language (MSEL and VABS-II), expressive language (VABS-II), social communication (CSBS), symbolic skills (CSBS), and daily living skills (VABS-II). Timing effects were not observed for autism symptoms (ADOS), motor skills (MSEL and VABS-II), or visual reception skills (MSEL).
Conclusions: These findings extend current knowledge on efficacy of NDBIs by demonstrating that ESI-Individual treatment leads to greater gains when initiated at 18 months compared to 27 months. This study represents the first effort to use RCT methods to rigorously test whether earlier is better for toddlers with ASD, allowing for strong causal conclusions to be made. This study is also the first to examine timing effects under age two. Previous studies have generally examined the effect of treatment started by age three, but this study examined even younger children in order to determine the optimal age for treatment. Results provide strong support for treatment beginning at 18 months and suggest that even a narrow window of 18 versus 27 months may have a critical impact on early intervention. These findings also underscore the importance of screening for ASD early in the second year of life and referring toddlers to autism-specific intervention programs by 18 months.

86 **108.086** Early Intervention Program Participation By Preschool Children with Autism Spectrum Disorder

J. Shenouda[1], *J. Solis*[2], *K. Sidwell*[1], *D. Lincer*[2], *R. Baltus*[2] *and W. W. Zahorodny*[3], *(1)Rutgers University, Newark, NJ, (2)Pediatrics, Rutgers University, Newark, NJ, (3)New Jersey Medical School, Westfield, NJ*

Background: Early Intervention Programs (EIP) are critical to the overall outcome of children with Autism Spectrum Disorder (ASD). Through early intervention, children make gains in cognitive ability, social functioning and even in the core symptoms of ASD. The efficacy of EIP is also increased when at-risk children are placed early.
Objectives:
This study endeavored to investigate the number, proportion and demographic distribution of preschool age children with ASD receiving services through Early Intervention Programs (EIP) in a large, metropolitan, population-based, sample and analyzed demographic differences among children receiving EIP services.
Methods:
Data were from the New Jersey Autism Study (NJAS), a population-based ASD surveillance investigation carried out in Essex and Union Counties. The current findings represent 4-year olds (2006-born) with surveillance-defined ASD, in 2010. ASD ascertainment was by an active, retrospective, multiple-source, Centers for Disease Control and Prevention (CDC)-designed case-finding method, based on review and analysis of information contained in health and education records. Demographic variables and case-specific data, including information on use of EIP services, were analyzed. Chi-square tests were used to test associations.
Results:
We identified 352 four-year-old children with ASD in 2010. Of those, 211 ASD children (60%) received EIP services. Overall, sex, race/ethnicity and SES were not associated with receipt of EIP services. We found no variation EIP service by cognitive impairment. Children with a mild degree of impairment due to ASD were less likely to receive EIP services ($p<.05$). Children with the Autistic Disorder pattern were more likely to receive EIP services than children with the PDD-NOS pattern (92% vs. 8%, $p<.001$, respectively). Children with ASD receiving EIP services were more likely to be diagnosed with ASD before school age (64% vs. 35%, $p<.01$). Our findings showed that the average age of ASD diagnosis of preschool children with ASD receiving EIP services was 30 months, while the average age for children not receiving EIP services was 38 months ($p<.001$). Also, children with ASD receiving EIP services had their first evaluation at 23 months, while children not receiving EIP services had their first evaluation by 36 months ($p<.001$).
Conclusions:
Our findings show that a significant minority of children with ASD (40%) do not receive Early Intervention Program services. Our findings also indicate that children with ASD receiving EIP services are likely to have a higher degree of impairment than other ASD children.

87 **108.087** Early Start Denver Model (ESDM) Informed Treatment in Israeli ASD Preschools – a Pilot Study

T. Gev[1,2], *Y. Gavrilov-Sinai*[1,2], *C. Colombi*[3], *I. Mor Snir*[2] *and O. Golan*[1,2], *(1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel, (3)Psychiatry, University of Michigan, Ann Arbor, MI*

Background:
The Early Start Denver Model was previously shown to be effective as an intensive home-based intervention (Dawson et al., 2010). However, in Israel, the majority of young children diagnosed with ASD attend state funded autism daycares and preschools. It is therefore of high importance to assess the efficacy of the ESDM when applied in this setting. Recent attempts to implement this model in a preschool setting have shown encouraging results in terms of children's developmental gains and the overall feasibility and practicality of the program (Vivanti et al., 2014).
Objectives:
The current pilot study aimed to examine an ESDM informed adaptation to an existing ASD preschool setting in Israel.
Methods:
The intervention included 12 children (aged 36-45 months) from three ASD preschools, and was comprised of 2 hours/week of individual ESDM-informed sessions with a therapist in training and a weekly session of parent-child "live-training". Integration of the ESDM-informed adaptation in the daily preschool routine included presentation of the model, the curriculum and learning objectives to the therapeutic and educational staff, and an ongoing demonstration of teaching techniques at various contexts (1:1 sessions, group activities, playground, mealtimes etc). Changes in children's social communication (BOSCC), cognitive ability (MSEL) and adaptive behaviors (VABS-II) were measured before and after 6 months of intervention.
Results:
After 6 months, children showed significant gains in MSEL receptive language, expressive language and visual reception developmental quotients. Significant gains were also shown in VABS-II scales of communication, socialization and daily living skills, and the Adaptive Behavior Composite. Significant improvements on BOSCC total score were found, as well as improvement in child responsiveness to parent and a reduction in unusual sensory interests.
Conclusions:
Results indicate the ESDM may be adapted successfully for use in preschools for children with ASD, with positive child outcomes. Future research should focus on parent,

and child-parent interaction outcomes, as well as on cultural adaptation and widespread dissemination of the model in a controlled study-design.

88 **108.088** Effectiveness of a Parent-Child Developmental Behavioral Training Program in a Community-Based Clinic

M. Kinnear[1], *M. J. Baker-Ericzen*[2], *N. Murphy*[3], *R. Linn*[1], *M. Fitch*[4], *S. M. Kanne*[5] *and M. O. Mazurek*[6], *(1)Rady Children's Hospital San Diego, San Diego, CA, (2)Child and Adolescent Services Research Center, Rady Children's Hospital San Diego, San Diego, CA, (3)Research, Rady Children's Hospital San Diego, San Diego, CA, (4)Child & Adolescent Services Research Center, Rady Children's Hospital, San Diego, San Diego, CA, (5)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (6)University of Missouri - Columbia, Columbia, MO*

Background: There has been increasing support for the efficacy of parent-mediated interventions to improve social communication in young children with Autism Spectrum Disorder (ASD)(Kasari et al., 2010). An initial efficacy trial for a specific model of parent-child developmental behavioral training (PCDBT) demonstrated an increase in child language associated with increased parent use of intervention techniques (Ingersoll & Dvortcsak, 2010). There continues to be a need for studies of effectiveness of interventions when implemented in diverse community settings (e.g., National Advisory Mental Health Council, 2001; National Research Council, 2001; Rogers, 1998). Thus, this study examines the effectiveness of PCDBT implemented in an ethnically diverse community-based clinic.
Objectives: To investigate 1) treatment outcomes in a community clinic parent training therapy program, and 2) child characteristics that may moderate treatment outcomes.
Methods: Preliminary data are drawn from a comprehensive baseline assessment of an ongoing R01 study conducted in a community clinic parent training therapy program. Parents completed the Autism Impact Measure (AIM; Kanne et al., 2014), Social Responsiveness Scale, 2nd edition (SRS-2; Constantino & Gruber, 2012) and demographic forms. The Autism Diagnostic Observation Schedule, 2nd edition (ADOS-2; Lord et al., 2012) and Vineland Adaptive Behavior Scales, 2nd edition (Vineland-II; Sparrow, Cicchetti & Balla, 2005) were administrated by trained, research reliable project staff. This sample includes 34 children (82% male) ages 2-9 years (M = 4.4 years; SD = 2.2) and their primary caregivers. All children had a diagnosis of Autism Spectrum Disorder (all cases validated by positive ADOS-2), and 63% identified as racial or ethnic minority. Paired sample t-tests were conducted to examine treatment outcomes on selected measures. Hierarchical blocked regressions were conducted to identify predictors for treatment outcomes.
Results: There was significant improvement post treatment as measured by the ADOS-2 Social Affect subscale, the ADOS-2 overall score, the AIM frequency total score, the AIM impact total score, and the Vineland-II Communication domain (see Table 1 for results). Other measures of social functioning and behavior did not capture significant change. Additionally, age, minority status, and IQ were tested as potential predictors of treatment outcome. None of these variables were significant predictors after controlling for baseline functioning (Age: β=-0.08, p=0.63; Minority: β=0.08, p=0.62; IQ: β=-0.29, p=0.14).
Conclusions: Findings demonstrate that parent-child developmental behavioral training offered in a community clinic results in moderate improvements in social functioning and communication. This finding is consistent with the literature demonstrating effectiveness of parent training programs targeting social communication in community settings (e.g., Baker-Ericzén, Stahmer, & Burns, 2007). Further, the treatment outcomes are consistent with efficacy trials of other parent-mediated training programs (Oono, Honey, & McConachie, 2013). It is also important to note that individual characteristics, such as age, minority status, and IQ, did not moderate treatment outcomes in this diverse community sample. A current limitation of this study is the small sample size; the sample will be doubled by the submission of the poster.

Table 1

Differences on outcome measures pre- and post- treatment

Measures	n	Pre (*M*)	Post (*M*)	Effect Size (Cohen's d)
ADOS: Social Affect	33	11.3	9.21	**0.48****

89 **108.089** Effects of School-Based Early Literacy Interventions for Preschoolers with ASD

R. Hudson*, E. Sanders, R. Greenway, C. Gasamis and J. Martini, University of Washington, Seattle, WA*

Background:
It is well-established that readers need to develop proficiency in word reading and general language comprehension to read with comprehension (Oakhill, Cain, & Bryant, 2003). This study compares two school-based interventions that target one side of the simple view of reading. Both interventions were 1:1, 4 days a week for 20 weeks. One intervention was Interactive Book Reading (IB), hypothesized to increase expressive and receptive vocabulary. The other intervention was phonological awareness (PA), hypothesized to increase PA skills.
Objectives:
What are the immediate effects of treatments for preschool children with Autism Spectrum Disorder?
Methods:
This study followed a sequential cohort design. Across the three years, children diagnosed with ASD were randomly assigned to IB (n = 48), PA (n= 43) or BAU control (n = 44) group. The inclusion criteria were (a) a medical diagnosis of ASD or an educational identification, (b) an active IEP and receive services for ASD, (c) enrolled in their last year of preschool, (d) no known co-occurring neurological or genetic disorders, and (e) a minimum standard score of 55 on the OWEPVT.
Results:
A multilevel modeling approach for testing differences among three conditions was employed to account for dependencies in the data due to classroom and site. Although some teachers participated in more than one cohort, teachers and sites were treated as separate for each cohort for the purpose of controlling for cohort differences. No child participated in more than one year. Standard scores were employed in all analyses to ensure comparability of scores across cohorts and provide a similar scale across all measures. After controlling for classroom and site, pretest differences were detected on the Woodcock Johnson Understanding Directions subtest. This is not surprising that one measure found one difference among the three groups, since random assignment does not guarantee group equivalence across a number of measures. The subsequent posttest analyses controlled for pretest to provide greater precision in estimating group mean differences. Ultimately, results showed that Interactive Book Reading (IB) group significantly outperformed the BAU control group on two language measures (oral communication and listening comprehension) and further, showed a consistent trend ($p < 0.10$) to have higher scores on expressive vocabulary as well. There were group differences favoring the IB group over the PA group on three of the five language measures: expressive vocabulary, receptive vocabulary, and listening comprehension.
Given that early language measures – rather than early literacy measures – have been shown time and again to more accurately predict later reading comprehension outcomes in typically developing students, these findings indicate that interactive book reading may be a more promising intervention for children with autism in particular (compared with phonological training or business-as-usual) since these are the students who traditionally can decode but have difficulty comprehending text.
Conclusions:
Our next steps are to test whether treatment effects are moderated by pretest (baseline) scores, as well as to incorporate fidelity and classroom observation data into our

models. These future models will help pinpoint whether treatment effects are maximized under varied conditions.

90 **108.090** Effects of a Parent-Implemented Developmental Reciprocity Program for Children with Autism Spectrum Disorder

G. G. Baldi[1], *C. Ardel*[2], *R. A. Libove*[2], *S. Schapp*[3], *S. Burton*[3], *J. M. Phillips*[2], *A. Y. Hardan*[2] *and G. W. Gengoux*[2], *(1)Children's Health Council, Palo Alto, CA, (2)Stanford University, Stanford, CA, (3)PGSP-Stanford PsyD Consortium, Palo Alto, CA*

Background: Developmental approaches to autism treatment are based on the premise that establishing strong interpersonal relationships through natural play will foster developmental progress and reduce symptomatology. A variety of developmental approaches are used in community treatment; however, there is limited empirical literature documenting the procedures or demonstrating their effectiveness. Well-designed studies using standardized outcome measures are needed to better understand whether these treatments are effective and how they compare to other available interventions for ASD.
Objectives: The current pilot study evaluated the effectiveness of a 12-week parent-delivered Developmental Reciprocity Program (DRP) on standardized outcome measures including Vineland Adaptive Behavior Scales-Second Edition (Vineland-II), Social Responsiveness Scale (SRS), MacArthur Communicative Development Inventories (CDI), Short Sensory Profile (SSP), and the Clinical Global Impression: Improvement scale (CGI-I).
Methods: Twenty-four children with ASD (mean age=45.5 months, SD=13.4) and a primary caregiver participated in 12 weekly sessions (90 minutes each) of parent training in the DRP model, covering topics including introduction to developmental approaches, supporting attention and motivation, sensory regulation and sensory-social routines, imitation/building nonverbal communication, functional language development, and turn taking. Parent questionnaires and a structured lab observation were completed at baseline, week 6, and week 12.
Results: Twenty-four subjects completed baseline measures and began the DRP treatment program. Twenty-two subjects completed the 12-week treatment and post treatment assessments; two subjects ended their participation in the study after week 6 and all available data were included in the analyses. Preliminary findings revealed improvement in communication skills (Vineland-II Communication Domain standard score; Baseline: 78.0 ± 14.5; Week 12: 81.2 ± 18.9; F(1,16): 6.251, p=.024). Trends toward significance were found in the overall Vineland-II Adaptive Behavior composite score (Baseline: 73.6 ± 10.5; Week 12: 77.1 ± 13.9; F(1,19): 4.116, *p*=0.061). Differences on the SRS raw scores were observed (Baseline: 80.8 ± 21.5; Week 12: 72.1 ± 18.7; F(1,19):7.620, *p*=.012) but not on the SRS T-scores (Baseline: 75.0 ± 9.9; Week 12: 73.6 ± 10.3; F(1,19):1.218, *p*=.284). Differences were also observed on the words produced out of 680 on CDI (Baseline: 243.4 ± 145.1; Week 12: 310.3 ± 237.3; F(1,18):18.104, *p*=.000). No significant differences in sensory sensitivity were observed as measured by the SSP. Finally, overall improvements were measured using the CGI-I, with 10 participants being judged as “Much Improved”, 13 as “Minimally Improved”, and only 1 showing “No Improvement.”
Conclusions: Preliminary findings from this pilot study indicate that the DRP model shows promise in the treatment of children with ASD with possible improvement in communication deficits and adaptive skills. Randomized controlled trials are needed to determine whether the effects observed here will be replicated in a larger sample. These results will be discussed with respect to the need for future research in the area of developmentally-based interventions and the implications for autism early intervention services including parent training programs.

91 **108.091** Evaluating a Coach-the-Coach Model with Community Childcare Providers to Support Social Communication Development with Children

C. Watts, ***N. D. Bond****, T. Nelson, J. Stapel-Wax and E. Wang, Marcus Autism Center, Atlanta, GA*

Background:
The National Research Council (2001) found that early detection and 25 hours a week of active engagement promoted and encouraged success for all children entering Kindergarten. Using principles guided by the SCERTS framework, (Prizant et.al,2005), a coach-the-coach model was implemented to guide front-line workers by training and providing feedback related to their use of transactional supports. Using strategies for adult learning to enhance collaboration amongst providers and coaches has been successful in early intervention to support positive developmental trajectories for children (Friedman & Woods, 2012).
Objectives:
This project looked at improving the coaching abilities within Georgia’s Bright from the Start (BFTS) Department of Early Care and Learning (DECAL) professionals by utilizing a multi-phase coach-the-coach model focusing on increasing knowledge of typical child-development and detection of ASD and developmental disabilities using transactional supports to promote active engagement in early childcare settings.
Methods:
This project tracked the progress of 14 ECP’s (Early Childcare Providers) from Bright from the Start and 5- Infant Toddler Specialists and 9- Inclusion Specialists from the second year. Through the coaching and collaboration strategies to promote adult learning, the project focused on increasing active engagement in the classrooms and an increased awareness of red flags for ASD to provide the support the children needed to be successful. Coaching was conducted in three (3) 12-week phases that started out with heavier support and moved to less frequent support. Classrooms were observed at the start of the project and after a three-month period in order to determine if practices increased or decreased and sustained in community settings. Effectiveness of practice 1) rate of support and coaching provided by the ECP’s during video-recorded independent-classrooms sessions with childcare providers throughout the coaching process. period and (2 number of children identified at risk for ASD. The Social Emotional Engagement-Knowledge Skills (SEE-KS) rating form was used to determine an increase or decrease in the following domains; Fostering Engagement, Presenting Information in Multiple Ways, and Allowing Students to Act and Express Themselves in Multiple Ways(Prizantet.al,2005)
Results:
The data from this coaching model yielded an increase in all three areas of that were measured. Fostering engagement increased by <0.0001, presenting information in multiple ways increased by 0.0002 and allowing students to act and express themselves in multiple ways 0.00018. Over two years of coaching, 14 children were identified as showing red flags for ASD.
Conclusions:
These results show the coach-the coach model enhanced the use of the transactional supports used in the childcare settings. Seeing an increase in the amount of this coaching model yielded an increase in the coaching and support provided by the ECP’s increased awareness of red flags for ASD. Throughout this coaching project, the ECP’s were proficient coaching and collaborating with others and used this to increase the knowledge in the childcare settings.

92 **108.092** Evaluating a Coach-the-Coach Model with Early Childcare Providers to Support Children with Social Communication Impairments

N. D. Bond[1], *C. Watts*[1], *T. Nelson*[1], *T. Ryan*[2], *M. Costo*[1], *E. J. Wang*[3], *J. Stapel-Wax*[1] *and S. K. Fuhrmeister*[1], *(1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Duluth, GA, (3)Pediatrics, Emory University, Atlanta, GA*

Background: The National Research Council (2001) found that early detection and 25 hours a week of active engagement promoted and encouraged success for all children entering Kindergarten. Using principles guided by the SCERTS framework, (Prizant et.al,2005), a coach-the-coach model was implemented to guide front-line workers by training and providing feedback related to their use of transactional supports. Using strategies for adult learning to enhance collaboration amongst providers and coaches has been successful in early intervention to support positive developmental trajectories for children (Friedman & Woods, 2012).

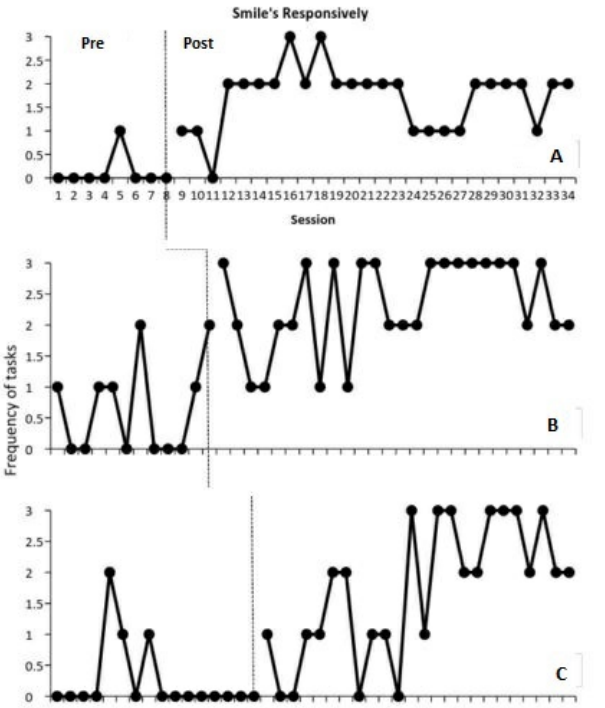
Conclusions: These results show the coach-the coach model enhanced the use of the transactional supports used in the childcare settings. Seeing an increase in the amount of this coaching model yielded an increase in the coaching and support provided by the ECP’s increased awareness of red flags for ASD. Throughout this coaching project, the ECP’s were proficient coaching and collaborating with others and used this to increase the knowledge in the childcare settings by applying the transactional supports to promote active engagement with children at risk for ASD in the classrooms.

93 **108.093** Evaluation of a Novel Curriculum Targeting Early Social Communication Skills in Minimally Verbal, Preschool Aged Children with Autism Spectrum Disorder (ASD): A Pilot Study

K. T. Sterrett[1], *K. Hayashida*[2], *J. Kim*[3], *T. Paparella*[4] *and S. Freeman*[4], *(1)Graduate School of Education and Information Studies, University of California Los Angeles, Los*

Angeles, CA, (2)Child Psychiatry, Semel Institute for Neuroscience, Los Angeles, CA, (3)Semel Institute for Neuroscience, Los Angeles, CA, (4)University of California Los Angeles, Los Angeles, CA

Background: Some of the most enduring impairments in children with autism spectrum disorder (ASD) fall within the domain of social communication. Distinguishing characteristics of delays include difficulties with social orienting and joint attention (Dawson et al., 2004). Preverbal social communication skills have been linked to improved developmental trajectories including spoken language and adaptive functioning that may be maintained throughout adolescence (Kasari et al., 2008; McGovern & Sigman, 2005). However, only a small amount of research has been devoted to the treatment of preverbal social communication skills in minimally verbal children with ASD. With such potentially promising outcomes, there is a clear need for empirically-based early interventions targeting this core deficit domain. As a good portion of time for young preschool-aged children takes place in a classroom environment, these interventions need also be easily implemented and generalized by classroom personnel.
Objectives: To carry out a pilot study evaluating the efficacy of The Preverbal Communication and Social Expressive Skills (PCSES) curriculum, a newly manualized intervention targeting behavior regulation, joint attention, and interaction skills in minimally verbal preschool children with ASD. Each target skill required 5 consecutive days of lessons that included behavioral modeling, rehearsal and feedback.
Methods: Three children with ASD ages 4-5 years were recruited from an early intervention preschool program to participate in the PCSES curriculum and subsequent evaluation. Each day, PCSES was carried out using two non-consecutive didactic sessions. These small group sessions were composed of naturalistic lessons based on the principles of ABA and Milieu based treatment. Pilot data were collected on all three participants. Pre-treatment assessments included the Early Social Communication Scales (ESCS) and a semi-structured play assessment (SSPA). The SSPA was designed to provide opportunities for the children to exhibit each targeted PCSES skill (attending to adults face, smiling responsively, regarding self in mirror, orienting to adults, following points, reaching and giving to request). All children were then given the SSPA following the five days of treatment to monitor the acquisition and maintenance of the skill. The ESCS was then re-administered post-maintenance.
Results: A non-concurrent multi-baseline design was used to analyze pre- and post-treatment SSPA data. Pre-treatment skills varied per child but overall, all children performed better following the implementation of the PCSES curriculum, with the frequency of target skills trending in a therapeutic direction (see Figure 1). These conclusions were further supported by an analysis of effect size using percentage of data exceeding the median (PEM) (Lenz, 2013). For two children, intervention was shown to be moderately to very effective (effect sizes .66-1) on 5/5 needed skills. For the other child, intervention was very effective (.83-.92) for 4/5 skills, with one showing debatable effectiveness (.5). Preliminary analysis of the ESCS demonstrates a positive change in early social gestures.
Conclusions: The current findings show that the PCSES curriculum may result in positive trends of growth in certain behavior regulation and joint attention skill that have been shown to impact developmental trajectory. A RCT with additional standardized measures is needed to explore these results further.



94 **108.094** Examining the Potential Reach and Engagement with a Self-Directed Telehealth Parent-Mediated Intervention for Children with ASD in Community Settings

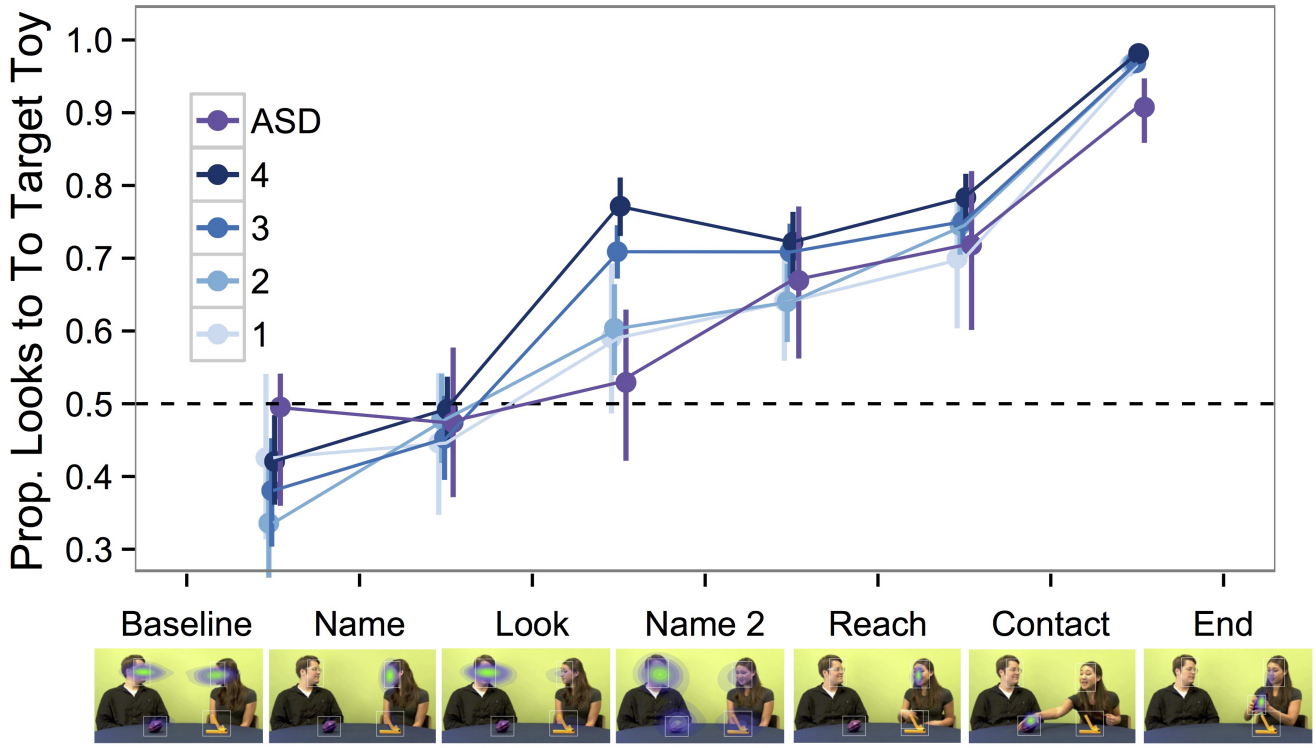
K. F. Shannon[1], *N. I. Berger*[2], *B. E. Holtz*[3] *and B. Ingersoll*[2], *(1)Psychology, Michigan State University, Ada, MI, (2)Michigan State University, East Lansing, MI, (3)Department of Advertising & PR; Department of Media & Information, Michigan State University, East Lansing, MI*

Background: Initial lab-based trials of self-directed, telehealth parent-mediated interventions (SDT-PMIs) for families of children with ASD demonstrate high levels of program acceptability, program engagement, and improvements in parent and child behaviors, indicating their potential as a low-cost universal intervention. However, little is known about the potential reach of and parent engagement with such programs outside of a lab setting.
Objectives: This study conducted a field trial of ImPACT Online, a SDT-PMI for families of children with ASD to: 1) Examine the potential reach of the program; 2) Compare the demographics of families who enrolled in a field trial (FT) to families who enrolled in lab-based trial (LT) of ImPACT Online; 3) Compare metrics of program engagement for FT and LT families; and 4) Examine the relationship between program engagement and changes in parents' intervention knowledge.
Methods: FT families were recruited by: 1) a flyer with a link to the program website which was provided to families during the feedback session at several community autism diagnostic clinics; 2) a link to the program website which appeared on a Statewide autism center website; or 3) word of mouth and/or internet search. Parents enrolled through the program website, and did not have direct contact with research staff. One diagnostic clinic tracked referrals to obtain an estimate of reach. Sixty-two parents completed a survey of family demographics and intervention knowledge at intake and 21 (34%) completed a 6-month follow-up survey. Program engagement (% of program components completed) was recorded by the website. Data were compared to families who participated in a lab-based trial of ImPACT Online (n=27).
Results: 18.71% of parents referred to the program by the diagnostic center enrolled in the program; these children did not differ significantly in age or gender from the referral sample. Parent demographics did not significantly differ between FT and LT groups; the majority of participants in both groups were female (FT: 87%; LT: 96%), married (FT: 81%; LT: 82%), with a college degree or higher (FT: 57%; LT: 56%), were employed outside the home (FT: 58%; LT: 62%), and felt fluent with computer/internet technology (FT: 35.95, SD=3.71; LT: M=35.57, SD=4.25), all *ps*>.05. FT child participants were slightly older (FT: 52.0 months; LT: 43.26 months, t(84.04)=2.24, p<.05) and marginally more likely to be male (FT: 87%; LT: 70%; X^2 (n=89)=3.57, p=.059) and a minority (FT:44%; LT: 22%; X^2(n=89)=3.67, p=.056) than LT children. FT parents had significantly lower program engagement (M=20.51%, SD=28.80) than LT parents (M=81.31%, SD=30.46), t(72)=6.84, p<.001. Program engagement was a significant predictor of post-treatment intervention knowledge, controlling for pre-treatment knowledge and group, β=.41, t=3.37, p=.002.
Conclusions: Families who enrolled in the field trial of ImPACT Online were demographically similar to families who enrolled in the lab-based study. However, parent engagement was much lower, and the reach was limited. Given the relationship between program engagement and gains in intervention knowledge, strategies for increasing engagement with SDT-PMIs in real-world settings are a priority.

95 **108.095** Eye-Tracking of Social Information Processing As an Outcome Measure for Clinical Trials

D. Yurovsky[1], *G. W. Gengoux*[1], *A. Y. Hardan*[1], *T. W. Frazier*[2] *and M. C. Frank*[1], *(1)Stanford University, Stanford, CA, (2)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Social information processing is both a central impairment in autism spectrum disorder (ASD) and also a key target for clinical intervention. Measures of social information processing typically rely either on parent reports or in-person interactions in an unfamiliar laboratory context, neither of which is ideal for providing objective and generalizable measurements. Parent report may be biased (and will likely not be blind to treatment condition for many treatments); clinical interactions, especially with an unfamiliar experimenter, can underestimate social information processing abilities because of the challenging nature of the context. Eye-tracking measures provide one promising alternative approach for measurement: Eye-trackers are inexpensive, but yield substantial amounts of high-reliability data in even a short measurement session. Thus, eye-tracking may be an important tool for assessing the effectiveness of social information processing interventions.
Objectives: Our goal was to develop a fast, reliable, low-demand eye-tracking measure for estimating children's social information processing and word learning abilities, and to use this measure as an exploratory endpoint for an ongoing clinical trial.
Methods: We created a 5-minute video of actors engaging in monologues and dialogues, in which the labels for two novel toys were introduced. While children watched these videos, their eye-gaze was tracked using a 120Hz SMI corneal reflection eye-tracker. To quantify children's ability to follow speakers' social cues, we measured their proportion of time looking to the toy that the actors were talking about. Subsequently, we measured whether children learned the correct label for each toy via their gaze during a two-alternative word recognition test.
Results: We first used our paradigm to measure social information processing in a group of 236 typically developing children aged 1-5. We found that individual differences in following social cues during the monologues and dialogues were highly correlated with individual differences in word learning ($r = .56$). We then tested a group of 40 1-8 year-old children diagnosed with ASD. As expected, these children were less skilled at both following social cues and learning the words for toys than their typically-developing counterparts (Figure), but their social information processing was again highly correlated with their ultimate word learning ($r = .6$). Finally, in on-going work we have used this measure as part of a randomized controlled trial of a Pivotal Response Treatment program (PRT-P). So far, 18 children have been tested 3 times at 6-month intervals. Preliminary analyses show that children in the intervention group performed better on both social information processing and word learning relative to the control group at the second and third time-points.
Conclusions: Individual differences in social information processing can be quantified reliably with short free-viewing eye-tracking measures. These individual differences predict learning in both typically-developing children and those with ASD. Further, preliminary results from our on-going randomized controlled trial show that these measure are sensitive enough to pick up effects of a PRT intervention. Our measure---and measures like it---are thus a promising direction for the rapid assessment of changes in social information processing targeted by clinical interventions.



96 **108.096** Impact of Collaborative Caregiver Training Models on Caregivers, Children, and Early Interventionists

A. Stainbrook[1], *A. Vogel*[1], *A. Spiess*[1], *K. Dorris*[1], *Z. Warren*[2] *and P. Juarez*[3], *(1)Vanderbilt Kennedy Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN*

Background:
Children identified with Autism Spectrum Disorder during toddlerhood often turn to their state Part C early intervention (EI) system for care. Recommended practices in EI emphasize the use of family routines as the intervention context and the role of the EI in teaching parents to embed intervention strategies into daily routines. As a result, there has been an increased emphasis on the value of caregiver-implemented intervention approaches. Therefore, EI providers are charged with a need to not only be knowledgeable in evidence-based treatment strategies for young children with ASD but also how to teach and coach caregivers to use these strategies.
Objectives:
This program evaluation study assesses the impact of a university-driven caregiver training model that includes opportunities for collaboration and consultation with state level EI providers.
Methods:
Approximately 90 families will be provided with services following participation in a psychological evaluation for ASD. All participating families receive 2 home-based evaluation support sessions led by a professional in the field of applied behavior analysis which include focused consultation and training on evidence-based practices for children with ASD. Following completion of this initial service, families are recommended for an additional 2 to 12 caregiver training sessions dependent on location and age at the time of referral. This second round of services includes 2 to 4 live and/or remote collaborative sessions with each family's EI and well as ongoing remote consultation opportunities. Surveys were developed to assess caregiver perceptions of impact on self and child as well as EI perceptions of impact on self and family.
Results:
63 families have completed or are currently engaged in services. Using a Clinician Global Impression rating of improvement (CGI-I) to rate child behavior, caregivers have provided average ratings of 2.9 on a scale of 1 to 7 with 1 equaling "very much improved" and 4 equaling "no change". In addition, caregivers have assigned high ratings to their overall satisfaction with services as well as their own competence in implementing the strategies with overall ratings averaging 3.4 on a scale of 1 to 4. A general satisfaction survey was sent to EI providers to assess perceptions of benefit to the families they work with; ratings averaged 3.3 on a scale of 1 to 4. In addition to the satisfaction survey, surveys were also sent to EIs to assess knowledge gained through participation in collaborative visits and consultation. Results suggest that EIs used recommended strategies 75-100% of the time. When asked to rate how collaboration with the clinician had impacted the interventionists ability to use those recommended strategies, the interventionists responded with an average rating of 3.8 (1 = not at all, 4 = significantly).
Conclusions:
The preliminary results of this project support effectiveness of caregiver training within the community setting. Early intervention providers as well as caregivers reported high levels of satisfaction with services, and early interventionists indicated that they had opportunities to use learned skills with other children creating potential for an impact on greater numbers of children within systems.

97 **108.097** Improving Children's Participation in Everyday Home Routines: Results from an RCT Assessing the Effectiveness of a Web-Based Parenting Tutorial

L. V. Ibanez[1], *W. L. Stone*[1], *L. Wallace*[2], *A. Swanson*[3], *Z. Warren*[3] *and K. A. Kobak*[4], *(1)Department of Psychology, University of Washington, Seattle, WA, (2)Vanderbilt Kennedy Center, Nashville, TN, (3)Vanderbilt University, Nashville, TN, (4)Center for Psychological Consultation, Madison, WI*

Background:
Daily routines such as snack time and bath time provide opportunities for families to engage in rich social interactions. Children with ASD often experience difficulty participating in these family activities. This study examined the effectiveness of an interactive, web-based parenting tutorial for improving both proximal outcomes (parent and child behaviors during routines) and broad outcomes (parenting efficacy and stress and child social-communication).
Objectives:
1. To examine the tutorial's effectiveness in improving child and parent behaviors from baseline (T1) to post-tutorial completion (T2; 4 weeks after T1) and 4-week follow-up (T3; 8 weeks after T1).
2. To examine the extent to which the tutorial's effect on broad outcomes at T3 is mediated by change in proximal outcomes from T1 to T2.
Methods:
Parents of children with ASD (2–6 years old) were randomly assigned to the Tutorial (*n*=52) or Control (*n*=52) condition after they completed T1 surveys. Parents completed surveys about their children's positive and negative behaviors during routines, and about their own use of appropriate verbal (e.g., providing praise) and nonverbal strategies (e.g., using visual supports) during routines. Children's social-communication behavior was assessed using four domains of the Parent Interview for Autism-Clinical Version (PIA-CV): Social Relating, Imitation, Nonverbal Communication, and Language Understanding. Parenting stress was assessed using three subscales from the Parenting Stress Index (PSI-SF): Difficult Child, Parental Distress, and Parent-Child Dysfunction. Parenting efficacy was assessed using the Maternal Efficacy Scale.
Results:
An intent-to-treat approach was applied using Maximum Likelihood in Hierarchical Linear Models (HLM) and Bayesian estimates in mediation analyses.
There were no group differences for any outcomes at T1. Children's negative behaviors were significantly lower in the Tutorial group than the Control group at T2 (β=-.32,*p*=.04) and T3 (β=-.42,*p*<.01); there were no significant differences for positive behaviors. Parents' use of appropriate verbal and nonverbal strategies was significantly higher in the Tutorial group than the Control group at T2 (β_{VERBAL}=.35,*p<.01*=;$\beta_{NONVERB}$=.39,*p*<.01) and T3 (β_{VERBAL}=.24,*p*<.01 ;$\beta_{NONVERB}$=.26,*p=.03*).
Children's Social Relating scores on the PIA-CV were significantly higher in the Tutorial group than the Control group at T2 (β=.29,*p*=.04) and T3 (β=.32,*p*=.04). Parent-Child Dysfunction on the PSI-SF was significantly lower in the Tutorial group than the Control group at T3 only (β=-3.91,*p*=.02). Parenting efficacy tended to be higher in the Tutorial group than the Control group at T2 (β=1.63,*p*=.08) and T3 (β=1.65,*p*=.06). No other significant group differences were found.
Increases in parents' use of appropriate verbal strategies and decreases in children's negative behaviors during routines significantly mediated the tutorial effect on Parent-Child Dysfunction (indirect β_{VERBAL}=-3.75,*95%CI*[-5.70,-1.38];indirect β_{NEGBEH}=-1.59,*95%CI*[-3.11,-.56]) and Parenting Efficacy (indirect β_{VERBAL}=1.94,*95%CI*[.84,3.30];indirect β_{NEGBEH}=.71,*95%CI*[.20,1.44]) at T3. Decreases in child negative behaviors mediated the tutorial effect on Social Relating (indirect β=.10,*95%CI*[.03,.20]) at T3. No other proximal outcomes were significant mediators.
Conclusions:
This tutorial was effective in improving key proximal and broad outcomes immediately and one month after its completion. Changes in parents' verbal strategies and children's negative behaviors during routines are potential mechanisms by which the tutorial impacted broad outcomes. Overall, the tutorial appears to be a promising, accessible way for empowering parents and improving parent-child interactions.

98 **108.098** Influential Factors on Response to Adapted Responsive Teaching Intervention

S. Zheng[1], *L. R. Watson*[2], *E. Crais*[2], *G. T. Baranek*[3] *and A. M. Carroll*[4], *(1)University of North Carolina at Chapel Hill, Carrboro, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)UNC Chapel Hill, Chapel Hill, NC, (4)Occupational Science, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Most early intervention studies focus on efficacy testing by examining main effects on children's developmental outcomes and parental behavior changes. However, with the wide heterogeneity of Autism Spectrum Disorder (ASD), it is important to match interventions with children and families based on their characteristics. There is limited research exploring the influential factors on response to ASD interventions.
Objectives: The objective of the current study is to explore what family, child, and parent factors may function as moderators of the effects of participation in the Adapted Responsive Teaching (ART) intervention.
Methods: ART is a parent-mediated early intervention program designed to facilitate the development of children at risk for ASD by improving parental responsiveness. Eighty-seven infants, screened by the First Year Inventory (FYI) at 12-months of age as at risk for ASD, participated with their families in a RCT efficacy study. They were randomized to either the ART group or the control group (referral to early intervention and monitoring, REIM group). Based on their gains in standard scores on the Communication and Symbolic Behavior Scales Behavior Sample (CSBS-B; Wetherby & Prizant, 2002), two children in each group who had made the most progress were identified as responders (in the ART group) or developers (in the REIM group); two who had the poorest outcomes were identified as non-responders or non-developers. A multiple case study method was employed to explore the similarities and differences in children, parent and family characteristics between responders and non-responders and to generate a profile for responders.
Results: The responders to the ART intervention showed few early markers of ASD (based on the AOSI), low formal language skills but average social-communication skills, and typical sensory processing patterns, while the two non-responders had more uneven profiles of developmental/adaptive skills, somewhat more autism markers, and atypical sensory processing patterns. Both responders received speech-language therapy in addition to ART. Sensory patterns, autism symptoms, and the community service they received may have influenced the children's response to ART. Moreover, both the responders came from families with higher income and fewer children at home compared to non-responders, and mothers (primary caregivers) of responders had higher education levels. Mothers of the ART responders showed high initial responsiveness, higher level of consistency and fidelity in implementing ART at home than mothers of non-responders, and little change in responsiveness but increases in directiveness when interacting with their children over the course of the study. There was no clear pattern for developers or non-developers in the REIM group. Additional cases (n = 26) meeting pre-established criteria of 95% confidence interval for responders (n=9) /non-responders (n=5) and developers(n=9) /non-developers (n=3) will be analyzed to examine the generalizability of the current findings.
Conclusions: The current findings address the potential importance of both child and parent factors in influencing the effectiveness of ART and similar interventions, and thus, suggest that researchers and practitioners need to focus on tailoring intervention strategies to be more family-centered and individualized.

Table 1 Extra Information for the Eight Cases at Pre-test

	ART				REIM			
	Responders		Non-responders		Developers		Non-developers	
Alias	Jack	Jill	Ben	Betty	Matt	Mark	Mike	Mitch

99 **108.099** Jumping the Hurdle: Children with ASD and Symbolic Play

Y. C. Chang[1], *S. Y. Shire*[2], *C. K. McCracken*[3], *W. I. Shih*[4] *and C. Kasari*[2], *(1)Division of Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, El Segundo, CA, (4)UCLA, Monrovia, CA*

Background:
Children with autism spectrum disorder (ASD) demonstrate delays in social communication, play and language, and these abilities are targeted in early interventions. While gains can be made after brief interventions of 3 to 6 months, gaining symbolic play skills are more difficult in children who begin intervention as minimally verbal (Goods et al, 2012; Kasari et al, 2013). Language abilities and social communication skills have both been associated with children's mastery of symbolic play skills, and may travel alongside improvements in play skills.
Objectives:
The current study investigates whether improvement in social communication helps children jump the hurdle from functional play to symbolic play in a sample of preschoolers all receiving the same targeted social communication intervention.
Methods:
Participants included 85 children with autism spectrum disorder (*M*= 46.10 months; *SD*= 7.49 months) who have completed an evidenced-based early social communication intervention program, Joint Attention Symbolic Play Engagement Regulation (JASPER), that ranged from three to six months.
All children were administered the Autism Diagnostic Observation Schedule (ADOS) to confirm their autism diagnosis and to determine their verbal abilities. Children who had less than five spontaneous words on the ADOS were defined as "minimally verbal". Children with more than five words, or children who scored "0" or "1" on Module 1 (using phrase speech and word combinations), or children who scored "0" or "1" on Module 2 and 3, were defined as "verbal".
The *Early Social Communication Scale* (ESCS; Mundy et al., 2003) was used to measure spontaneous initiations of joint attention (IJA) skills. Children's joint attention skills were categorized as "nonverbal IJA", including gestures such as pointing, showing, and giving, or "IJA" which included both gestures and language.
The *Structured Play Assessment* (SPA; Ungerer & Sigman, 1981) was used to assess spontaneous play skills. Children's play behaviors including the number of different spontaneous novel play types and frequency were coded from videotaped SPAs by blind raters. Children who demonstrated at least two types and five times of symbolic play acts were defined as mastered "symbolic play".
Results:
Forty-nine children were defined as "minimally verbal" and 36 were "verbal". Sixty-nine percent of the children who were "verbal" mastered symbolic play at the end of their intervention, and only 38% of children who were "minimally verbal" mastered symbolic play.
Using logistic regression, nonverbal IJA was associated with increased odds of having any symbolic play after adjusting for language, entry symbolic play, and intervention dose (p=0.04).
Conclusions:
These results suggest that it is more difficult for children who are minimally verbal (less than five words) to make that jump from functional play to symbolic than children who are more verbally skilled. This is in line with previous research that shows that language and symbolic play are associated. It is also promising to note that some children who were minimally verbal are making that jump from functional to symbolic. Future research should continue to target social communication and play skills in children who are minimally verbal.

100 **108.100** Mu Suppression to Biological Motion Predicts Pivotal Response Treatment Response in Young Children with Autism Spectrum Disorder

M. J. Crowley[1], *J. Wu*[2], *C. A. Paisley*[3], *M. L. Braconnier*[3], *S. M. Abdullahi*[3], *L. C. Mayes*[4], *K. Pelphrey*[3] *and P. E. Ventola*[3], *(1)Yale School of Medicine, New Haven, CT, (2)Yale Child Study Center, New Haven, CT, (3)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (4)Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Advances in cognitive neuroscience offer promise for personalized treatment to improve outcomes in individuals with ASD. As a treatment with established clinical efficacy, Pivotal Response Treatment (PRT) is a naturalistic behavioral intervention that uses Applied Behavior Analysis (ABA) principles to target social communication deficits in individuals with Autism Spectrum Disorder (ASD) (Koegel et al., 1987). Work from our group (Ventola et al., 2014) has found significant benefit in pragmatic language, social engagement, and adaptive functioning skills for children with ASD and corresponding brain-based normalization (Ventola et al., 2015). Employing electroencephalography (EEG), this study aims to detect pre-existing functioning in the brain circuitry supporting biological motion that predicts which children benefit most from a 16-week course of PRT. Such predictive power could lead to the establishment of a stratification biomarker to help precisely match patients to treatments.
Objectives: We present preliminary findings from an ongoing clinical trial to be completed in the spring of 2016. We investigated the degree to which EEG neurobiomarkers predict treatment response in a sample (*N* = 7) of children (4-7 years; 3 girls, 4 boys) with ASD (Mean IQ=87.13 SD=20.53) who participated in a 16-week trial of PRT.
Methods: Treatment included 6 hours per week of individual work with the child plus parent training. Our Primary clinical outcome was the SRS-2 Total Raw Score (parent report). Participants sat for a high-density EEG session (128-channel Hydrocel Geodesic sensor net), before treatment. During EEG recording, participants were presented with well-validated stimuli depicting point light displays of coherent biological or scrambled biological motion. We evaluated the extent of suppression in the EEG alpha frequency band range (8-12 Hz, mu suppression) in response to viewing biological or scrambled biological motion at baseline and how this measurements predicted the change in the SRS score from baseline to the treatment endpoint. We spectrally analyzed EEG measured over the left and right central regions (corresponding to C3 and C4).

Following standard procedures for data normalization (natural log) and computation of mu suppression. We computed difference between biological motion and rest and the difference between scrambled biological motion and rest considered as a ratio (Bernier, Dawson, Webb, & Murias, 2007).
Results: A 16-week course of PRT resulted in a significant improvement in levels of social impairment as measured via the SRS-2, $t(6) = 3.520$, $p = .013$. Moreover, considering mu suppression to biological motion at EEG site C3, repeated measures indicated a significant time (pre vs. post SRS) by mu suppression interaction, $F(1, 5) = 9.29$, $p = .028$. Scatter plots for the association between C3/C4 and SRS change are presented in Figure 1.
Conclusions: Our preliminary findings suggest functioning in the neural circuitry that supports social perception predicts who will show the most clinical benefit from a 16-week course of PRT. Effects were similar for both lateralized cortical regions, though stronger on the left. These results lead the way to help develop stratification and target engagement biomarkers for ASD clinical trials.

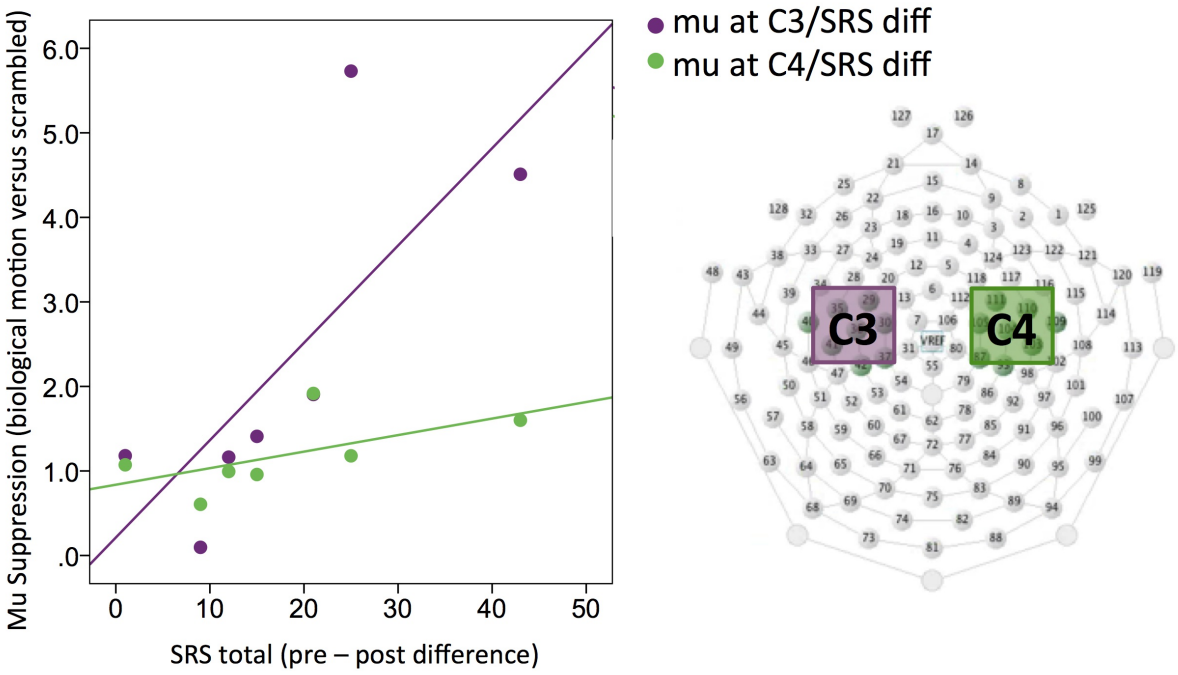

Figure 1. Mu suppression plotted against pre-post change in SRS and EEG scalp location.

101 **108.101** Neuroimaging Predictors of Benefits from Pivotal Response Treatment

A. Y. Hardan[1], *G. W. Gengoux*[1], *J. Hegarty*[1], *J. M. Phillips*[1], *S. Tanaka*[1], *T. W. Frazier*[2] *and A. L. Reiss*[1], *(1)Stanford University, Stanford, CA, (2)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Autism spectrum disorder (ASD) is a heterogeneous disorder and several neurobiologic measures have been examined to identify potential subgroups, with limited success thus far. Applying neuroimaging methodologies to identify prognostic markers or indicators of treatment response may be an alternative approach to address this heterogeneity. To date, no biomarker of treatment response has been identified for any biological or behavioral intervention in autism. Additionally, there is a growing need for innovative, efficient, cost-effective treatment models guided by biological markers of treatment response to optimize results and long-term outcome. This is particularly true for very young children with ASD when the brain is most plastic and time should not be wasted in implementing treatments that might not be beneficial.
Objectives: The goal of this investigation is to use a hypothesis-generating approach and apply multimodal imaging techniques to help identify biomarkers of treatment response. In this investigation, we aim at applying structural magnetic resonance imaging (MRI) and diffusion tensor imaging (DTI) to identify biomarkers of pivotal response training (PRT) treatment response. The development of biosignatures of treatment response is critical and the present study is the first step in providing evidence supporting the possibility of identifying biomarkers to predict response to behaviorally- and biologically-based treatments.
Methods: The PRT intervention consisted of teaching parents behavioral techniques to facilitate language development. PRT training lasted at least 12 consecutive weeks with one session per week. Sessions included in-vivo coaching of parent implementation of PRT techniques with their child, as well as review and feedback on videos of parents practicing PRT at home. Objective and subjective outcome measures were obtained at baseline and at the end of treatment. High-resolution anatomical MRI and DTI scans are being obtained on children with ASD before and after their participation in PRT. Correlations between neuroimaging measures (volume and fractional anisotropy (FA)) in language areas (e.g. superior longitudinal fasciculus(SLF)) and changes in outcome measures were examined.
Results: Eighteen children with ASD have participated in this study to date. Anatomical MRI and DTI scans have been obtained on all individuals at baseline (prior to treatment). Five follow-up scans (post-treatment) have successfully been collected. Neuroimaging and treatment data are available on 8 participants as the additional scans and behavioral information are being processed. Preliminary findings revealed no relationships between the size of any brain regions implicated in language development and response to PRT treatment. However, associations between FA in the SLF and changes in several language measures were observed including the number of utterances during structured laboratory observation and number of words produced out of 396 on the MacArthur-Bates Communicative Development Inventories.
Conclusions: Preliminary findings from this pilot study suggest that neuroimaging measures are potentially useful as predictors of treatment response. Additional analyses will be completed as more data become available. We will discuss these findings and highlight the advantages and challenges of using neuroimaging information in clinic trials to assess treatment response and biologic changes due to the intervention.

102 **108.102** Neuroprediction of Treatment Effectiveness in Young Children with Autism Spectrum Disorder

D. Yang, *K. Pelphrey, C. A. Paisley, M. L. Braconnier, S. M. Abdullahi, D. G. Sukhodolsky, M. J. Crowley and P. E. Ventola, Yale Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Advances in genetics, molecular biology, and cognitive neuroscience offer promise towards personalized treatment to improve outcomes in individuals with ASD. Recent clinical trials have shown favorable results; however, the promise of precision medicine is hindered by a lack of sensitive, objective measures to identify subgroups likely to respond to specific treatments. Instead, our field relies on availability of service, trial-and-error, and clinical judgment to make treatment decisions. Here we built upon our prior research characterizing the neural-systems-level basis of core social communication symptoms in ASD to identify a potential stratification biomarker.
Objectives: We investigated the degree to which fMRI neurobiomarkers predict treatment response in a sample ($N = 17$) of children (4-7 years; 5 girls, 12 boys) with ASD (Mean IQ=102.82, SD=16.72) who participated in a 16-week trial of Pivotal Response Treatment (PRT), a behavioral treatment focused on social communication skill development.
Methods: Treatment included 6 hours per week of individual work with the child plus parent training. Primary clinical outcome was the SRS-2 Total Raw Score. During a 5-minute fMRI scan at 3 Tesla, conducted at baseline, the participants viewed well-validated neuroimaging stimuli depicting point light displays of coherent biological (BIO) or scrambled biological (SCRAM) motion. We evaluated the extent to which activation in response to viewing BIO vs. SCRAM at baseline predicted the change in the SRS score from baseline to the treatment endpoint, while controlling for the baseline SRS score.
Results: Using a whole-brain group analysis (mixed-effects modeling using FSL's FLAME1+2, voxel-level thresholding $Z > 2.33$, cluster-level thresholding $p < .05$, controlling for sex), we estimated the correlation between change in SRS total raw score from baseline to treatment endpoint and magnitude of pre-PRT brain response to BIO vs. SCRAM. This revealed three clusters of neuropredictive activity (Figure 1). Cluster 1 (green) was centered in the right ventrolateral prefrontal cortex, orbitofrontal cortex, anterior insula, and temporal pole. Cluster 2 (blue) was centered in the right fusiform gyrus, inferior and middle temporal gyri, and superior temporal sulcus. Cluster 3 (red) was centered in the left putamen, pallidum, hippocampus, amygdala, and ventral striatum/nucleus accumbens. Figure 2 showed the scatter plot of the improvement in social

communication skills (y-axis) vs. pre-PRT BIO > SCRAM activity (x-axis) for each of the three clusters. Strikingly, none of the demographic (age, IQ, sex) or baseline behavioral (ADOS, ADI-R, SRS, Vineland-II, CELF) variables predicted response to treatment.
Conclusions: We discovered a neuroimaging-based biologically informed stratification biomarker that predicts magnitude of response to an evidence-based behavioral treatment in young children with ASD. Neurosynth results suggest that baseline levels of activity in well-known emotional regulation (cluster 1), social perception and face recognition (cluster 2), and social reward/motivation and emotion (cluster 3) networks predicted the magnitude of clinical response to PRT. Importantly, these biomarkers outperformed pre-treatment behavioral measures of social functioning, language level, and cognitive abilities. Our results provide the first-ever clear evidence of a neuroimaging-derived stratification biomarker in ASD and help the field progress to the goal of targeted, personalized treatment for individuals with ASD.

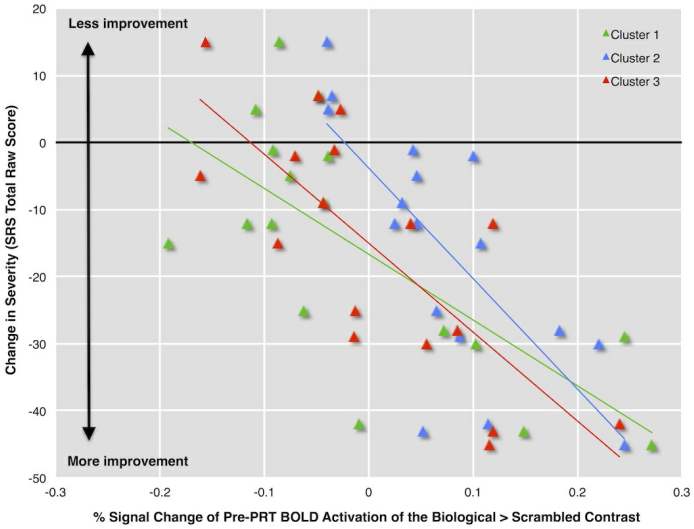

Figure 2. Scatterplot of activation in the pre-treatment neuro-predictors vs. treatment effectiveness

103 **108.103** Outcomes of a 10-Hour per Week Interdisciplinary Early Intervention Program for Young Children with Autism

A. Tanner[1] *and C. Ganam*[2]*, (1)Monarch House, Vancouver, BC, Canada, (2)Monarch House, BUrnaby, BC, Canada*

Background: There are currently no biological markers for diagnosing autism spectrum disorder (ASD) therefore the diagnosis relies solely on behavioral features, and although it is understood that early diagnosis and intervention can maximize the outcomes of children with ASD, children are often not diagnosed until they are between 3 and 6 years of age (Johnson & Myers, 2007). MacDonald, Parry-Cruwys, Dupere & Adhern (2014) found that 90% of children who started intervention prior to 2 years of age made significant gains in their first year of early intensive behavior intervention (EIBI) whereas only 30% of children who began EIBI after 30 months of age made significant gains in their first year of treatment. Monarch House is a multi-disciplinary clinic where children under the age of 6 with a diagnosis of ASD receives a minimum 10 hours of behavior intervention weekly, overseen by an interdisciplinary team consisting of a Behavior Analyst, a Speech and Language Pathologist and an Occupational Therapist.
Objectives: This study reviews the specific clinical model and evaluates the effectiveness of a 10 hour, per week interdisciplinary model using The Autism Diagnostic Observation Schedule (ADOS) and The Verbal Behavior Milestone Assessment and Placement Program (VB-Mapp).
Methods: A single-subject, multiple baseline across participants design was used to evaluate the key outcomes of 30 children with ASD in their first year of intervention. The rate of acquisition (number of milestones achieved per month) for the first year of treatment was evaluated and compared across three intervention groups: those who began intervention prior to age 3, those who began intervention between the 3 and 4 years of age, and those who began intervention after 4 years of age.
Results: Preliminary results suggest that those who began treatment prior to the age of 3 achieved significantly more VB-Mapp Milestones in their first year of intervention than those who began treatment after three years of age.
Conclusions: The effects and benefits of a 10 hour per week interdisciplinary early intervention program will be discussed.

104 **108.104** Peer Versus Teacher Talk in Early Intervention Classrooms: Case Studies Suggest That Inclusion Might be Different

E. F. Ferguson[1]*, A. S. Nahmias*[2]*, L. Bateman*[1]*, K. J. Payton*[1]*, D. S. Mandell*[3]*, R. T. Schultz*[4] *and J. Parish-Morris*[1,5]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania School of Medicine, Philadelphia, PA, (4)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Suite 860, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Children with autism spectrum disorder (ASD) may benefit from being placed in classrooms with their typically developing peers. For example, children who do not floor on language measures in preschool demonstrate steeper rates of cognitive growth in inclusion classrooms than in mixed-disability or autism-specific classrooms (Nahmias et al., 2014). It may be that neurotypical children talk more than children with disabilities, and model and interact with verbal children with ASD to their benefit. Teacher talk may also help; teachers in inclusion classrooms may direct more talk to children with ASD than teachers in autism-only or mixed-disability classrooms. We explore these questions by assessing the language environments of children with ASD in three different classroom types.
Objectives: Measure speech produced by and directed at preschoolers with ASD in three classroom types (inclusion, mixed disabilities, autism-only); measure the association between natural language and standardized assessments.
Methods: Samples have been collected from 25 children; these results concern the first 5 (all others will be transcribed and included before May 2016). Average age was 3.8 years (range=3.7-4.4), Mullen Scales of Early Learning (MSEL) Early Learning Composite scores ranged from very low to below average (mean=60.8, range=49-83), and autism-related symptoms on the ADOS ranged from moderate to high. Participants wore digital language recorders during a normal school day. We transcribed words produced by participants during ~20 minutes of circle time and ~20 minutes of free play (Total Mean=39.2 minutes, SD=2.6, range: 35-42) and language directed toward participants by peers and teachers. Nonparametric correlation analyses assessed associations between natural language production and standardized language tests. Words per minute (WPM) are described in a case-study style for inclusion and autism-only classrooms (N=1 each) and at the mean level for mixed disability classrooms (N=3).
Results: Participants' WPM correlated with expressive language scores, Spearman=.87, p=.05, and teachers' WPM toward participants was positively associated with participants' receptive language scores, Spearman=.89, p=.04. Peers talked more with participants who produced more words themselves, Spearman=.90, p=.04. More peer talk was directed toward participants in the inclusion classroom (8.3 WPM), than in the autism-only classroom (4.1 WPM). The inclusion classroom had the lowest rate of teacher talk directed toward participants (29.8 WPM), while teacher talk in the mixed disability classroom (48.4 WPM) was similar to the autism-only classroom (51.0 WPM).
Conclusions: Short language samples from children with ASD in preschool classrooms correlate significantly with standardized language measures, suggesting that they assess the same underlying construct. Interestingly, the inclusion classroom had both the highest rate of peer talk and the lowest rate of teacher talk directed toward participants. This preliminary finding suggests that inclusion classrooms may feature increased opportunity for peer interaction and modeling, which could benefit some children. Other children with ASD may benefit from higher rates of teacher talk found in the mixed disability and autism-only environments. Future analyses with a much larger sample will include longitudinal moderation analyses to assess the differential effects of classroom language environment on cognitive and social growth over 9 months in children of varying language profiles.

105 **108.105** Preliminary Efficacy of Relationship Development Intervention® and Parent-Implemented Applied Behavior Analysis/Verbal Behavior on Joint Attention and Communication of Preschool Children with Autism

M. Kerwin[1]*, M. E. Soreth*[1]*, C. Gangemi*[2] *and B. Coleman*[1]*, (1)Rowan University, Glassboro, NJ, (2)Family First, LLC, Haddonfield, NJ*

Background: Acquiring joint attention (JA) and functional spoken language by the time a child with autism enters school around the age of 5 years old are critical. Involving parents in treatment maximizes the child's opportunities to learn. Relationship Development Intervention® (RDI) is a relationship-based intervention focusing on recreating developmental milestones through meaningful interactions with parents with a primary goal of increasing JA. However, little research has evaluated the efficacy of this

intervention. In contrast, a model based on Skinner's Analysis of Verbal Behavior (ABA/VB) increases spoken language directly when implemented by therapist and teachers; however, this approach has not been evaluated when implemented by parents. RDI and ABA/VB have different primary targets for intervention; however, both approaches assume that language and JA, respectively, will emerge as a corollary effect of the intervention.
Objectives: The purpose of this pilot study is to compare the efficacy of two parent-implemented adjunctive interventions, RDI and ABA/VB, against Services As Usual (SAU) on JA and language in children 2-6 year old with ASD.
Methods: Participants were 36 children diagnosed with autism spectrum disorder (ASD) by community providers and the Autism Diagnostic Observation Schedule-2™. Participants were randomly assigned to RDI, parent-implemented ABA/VB, or SAU conditions. All parents, regardless of assigned condition, reported weekly on the type and extent of services delivered. The intervention consisted of 16 sessions over 14 weeks delivered in the home. Assessments were conducted pre-treatment and end of treatment (3 months). The primary outcome measure was direct observation of parents and children interacting under different scenarios designed to implement conditions most likely to produce the behavior targeted by the interventions (e.g., joint attention, specific language skills) including prompts that involved having the child ask the parent for preferred items and engaging the child in a conversation about family photographs. The direct observations were coded by research assistants blind to treatment condition and trained to interobserver reliability levels of 80% or above on a coding taxonomy that included an array of parent and child behavior related to joint attention, language, and problem behavior. In addition, two standardized assessments were also administered (Mullen Scales of Early Learning and Communication and Symbolic Behavior Scales).
Results: All participants for the study have been recruited and 29 children have completed the treatment and post-assessment. Preliminary results indicate that both RDI and ABA/VB produced gains in the child's following of bids for joint attention, three-point gazes, and initiating verbalizations while SAU did not result in any gains for any of these behaviors.
Conclusions: This pilot study examines the efficacy of parent-implemented RDI and ABA/VB against SAU on social and emotional communication and language via direct observation and standardized measures. Preliminary results indicate that both interventions are able of producing gains in joint attention and verbal behavior, even though the two interventions differ in primary intervention targets. Furthermore, children in SAU condition did not show evidence of change. These results support that parents can serve as effective agents of change in the implementation of empirically supported early interventions for ASD.

106 **108.106** Project Impact Implementation Fidelity: Researcher, Clinician, and Parent Measures Relative to Child Outcomes

A. B. Barber[1], *H. Noble*[2], *C. H. Cook*[3] *and B. Ingersoll*[4], *(1)University of Alabama, Tuscaloosa, AL, (2)Vanderbilt University, Nashville, TN, (3)Communicative Disorders, University of Alabama, Tuscaloosa, AL, (4)Michigan State University, East Lansing, MI*

Background:
Documented intervention gains resulting from the Project ImPACT intervention model (Ingersoll & Dvortcsak, 2009) include increased spontaneous language (Ingersoll & Wainer, 2013), decreased social impairments (Ingersoll & Wainer, 2011; Stadnick et al., 2015) and increased social engagement (Pierucci, 2013). Further, parents demonstrate adherence to Project ImPACT strategies (Ingersoll & Wainer, 2011, 2013; Pierucci, 2013; & Stadnick, et al., 2015), and report improved parenting efficacy, a critical component to child and parent outcomes (Karst et al., 2012). Little is known about the contributions of implementation fidelity to intervention outcomes (Stahmer et al., 2015), although systematic measurement of treatment fidelity is essential when interpreting intervention efficacy (Zwaigenbaum et al., 2015).
Objectives:
To measure fidelity of Project ImPACT at three levels: researcher, clinician, and parent.
To measure child and parent outcomes and implementation fidelity across two dosage groups: one versus two hours per week of Project ImPACT intervention.
Methods:
Six children with ASD (mean age = 32 months) participated. Group 1 received Project ImPACT for 2 hours per week, for twelve consecutive weeks, group-based parent coaching, an individualized session with a clinician and more dense individual parent coaching. Group 2 received intervention 1 hour per week, group-based parent coaching, an individualized session with a clinician, and less personalized parent coaching. Social engagement, language, and play were assessed using the Social Communication Checklist (SCC; Ingersoll & Dvortcsak, 2009). The Parental Sense of Competency Scale (PSOC) measured parent satisfaction (anxiety, motivation, frustration) and efficacy (competence, problem solving, and capability). Finally, developmental and vocabulary measures were administered. All measures were completed pre-and post-intervention. Fidelity was measured at three levels: group sessions, parent implementation, and clinician implementation.
Results:
An 80% average was considered implementing the strategy with fidelity (Ingersoll & Wainer, 2013). The primary researcher achieved an average of 95% fidelity across both groups. Clinician implementation fidelity during individual sessions averaged 60.7 % and 52.3% in Groups 1 and 2, respectively. Parent implementation fidelity averaged 72% and 54% in Groups 1 and 2, respectively. Fidelity was elevated for both clinicians and parents in the higher dose group. Higher parent fidelity was related to better child outcomes. A Mann-Whitney U test revealed no clinically significant differences in social engagement, (U= 5.50 p=1.0), language (U= 4.00, p=1.0), or social imitation (U=3.50, p=1.0) domains across dosage groups, though all children demonstrated gains. Interestingly, parents with higher fidelity scores reported lower sense of efficacy on the PSOC. Parent sense of satisfaction increased across all parents, though no group differences were found for efficacy or satisfaction. Potential influences of demographic variables will be discussed. Visual analysis of outcomes will be presented.
Conclusions:
Intervention fidelity may be a more accurate predictor of intervention outcomes than dose, at least within this modest comparison. Fidelity outcomes are higher when material is more structured (Stahmer et al., 2015), such as in instructional group settings, and with more experienced clinicians. These findings contribute to growing literature supporting the efficacy of Project ImPACT intervention for young children with ASD and their parents.

107 **108.107** Relations Between Parental Use of Esdm Intervention Techniques and Communication Growth in Toddlers with ASD

M. R. Talbott[1], *K. Moomey*[2], *J. Greenson*[2], *K. S. Davlantis*[3], *C. D. Zierhut*[4], *J. Munson*[2], *N. Lange*[5], *A. M. Estes*[6] *and S. J. Rogers*[7], *(1)University of California, Davis, Sacramento, CA, (2)University of Washington, Seattle, WA, (3)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (4)UC Davis MIND Institute, Sacramento, CA, (5)McLean Hospital, Cambridge, MA, (6)University of Washington Autism Center, Seattle, WA, (7)University of California at Davis, Sacramento, CA*

Background: Communication difficulties are a core domain of impairment for young children with autism spectrum disorders (ASD), and some of the earliest appearing symptoms and most frequently reported parental concerns (Zwaigenbaum et al., 2013). Parent-implemented interventions can be effective in promoting communication skills, but the specific features of parent delivery that underlie developmental change are not well understood.
Objectives: Here, we investigate relations between toddlers' communication skills and two parental variables hypothesized to contribute to treatment-related communication gains: parental use of treatment techniques (fidelity) and the rate of high quality learning opportunities. We hypothesized that parental use of these two delivery features would explain significant variation in toddlers' communication skills. These questions are examined in the context of parent-implemented Early Start Denver Model (P-ESDM), a comprehensive developmental-behavioral intervention for young children with ASD.
Methods: 30 Toddlers with ASD and their parents completed the study. Following baseline assessments, families received 12 weeks of coaching in ESDM followed by a 12 week maintenance phase and a final post-maintenance assessment. Standardized assessments were collected pre-treatment, post-treatment, and post-maintenance. Communication skills were measured monthly using an adapted version of the ESDM Curriculum Checklist (Rogers and Dawson, 2010). Parent treatment delivery was coded from video captured by families in their home at several points over the course of the study. From each video, 3-minute clips of each of three activity types were used for scoring song and game routines, toy-based interactions, and caregiving activities (ex. bath or meal).
Fidelity scores were obtained from ratings of parent techniques used across 13 domains. Learning opportunity scores were calculated for both the rate of successful learning opportunities provided, where success was defined as providing an appropriate response to child behavior (i.e. reinforcing desired behavior and ignoring/correcting unwanted behavior) as well as the percentage of attempted opportunities scored as successful. Successful learning opportunities were further characterized as either parent-initiated or child-initiated to examine effects of parental responsiveness versus elicitation, respectively, in promoting learning.
Results: 30 families contributed data both pre-treatment and post-maintenance. Learning opportunity data pre- and post-maintenance (n=23), and fidelity (n= 30) has been scored. Paired t-tests demonstrate that 1) toddlers made significant gains in standardized measures of language, t(29) = 6.11, $p<.0$, and 2) parents demonstrated significant increases in both ESDM fidelity and percentage of successful, high-quality learning opportunities (Fidelity: t(17) = 2.57, p = .02, Percent successful opportunities: t(10) = 4.68, p = .001). Marginally increases in the frequency of parent-initiated learning opportunities were also observed (t(10) = 2.19, p= .054).
Conclusions: These data demonstrate that a low-intensity parent coaching intervention results in significant increases in parent behaviors hypothesized to support language and communication development and replicate previous reports of child behavior change. Hierarchical models of the relations between parent and child behavior will be discussed.

108 **108.108** Standardized Measures of Improvement in Language Across Two Randomized Clinical Trials of Pivotal Response Treatment

G. W. Gengoux[1], *M. B. Minjarez*[2], *J. M. Phillips*[1], *K. L. Berquist*[1], *C. Ardel*[1], *R. A. Libove*[1], *M. E. Millan*[1], *R. Schuck*[1], *T. W. Frazier*[3] *and A. Y. Hardan*[1], *(1)Stanford University, Stanford, CA, (2)Seattle Children's Hospital, Seattle, WA, (3)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Pivotal Response Treatment (PRT) is an evidence-based naturalistic behavioral intervention. Support for its use in improving language abilities has historically

come from single-case studies using primarily behavioral observation measures. There is a critical need for examination of outcomes from larger samples and from objective measures which can be more easily compared across trials and to normative developmental trajectories.
Objectives: This presentation will review standardized language outcomes from two randomized controlled trials of PRT, including a 12-week trial of PRT Group treatment (PRTG) and a 24-week PRT package treatment (PRT-P) which combines parent training with clinician-delivered in-home treatment. Our aim is to highlight new data demonstrating how standardized measures of language and cognitive abilities can be used to assess treatment response in clinical trials.
Methods: Participants include children with ASD and significant language delay, ages 2-6 years. Participants in the first trial were randomly assigned to either PRTG or a parent psychoeducation control group. Participants in the second trial were randomly assigned to either PRT-P or delayed treatment. Dependent measures include objective tests of language and cognitive abilities as well as Clinical Global Impression Improvement (CGI-I) ratings by raters blinded to treatment condition and standardized parent questionnaires.
Results: The PRTG trial has been completed and the PRT-P trial is ongoing; data are currently available from 47 participants from PRTG and 28 from PRT-P. Findings from the PRTG trial revealed significant improvement on Vineland Adaptive Behavior Scales Communication Scale in the active group compared to control ($F(2,19) = 3.80$, $p = .041$). CGI-I ratings focusing on communication also indicated greater improvement in the PRTG compared to controls ($F(1, 44) = 15.97$, $p < .001$). A non-significant trend was observed for MacArthur-Bates Communicative Development Inventories (CDI) mean length of longest utterance ($F(2, 32) = 3.09$, $p = .059$). Three-month follow-up data revealed that children maintained their improvement on the Vineland Communication Domain Standard Score ($F(2, 12):11.74$, $p=.001$) and cognitive improvement was observed on the Mullen Scales of Early Learning Composite score ($F(1, 20)= 5.43$, $p=.03$). Similarly, preliminary findings from the PRT-P trial revealed children in the active group are acquiring greater vocabulary as evidenced by an average gain of over 150 words on the CDI between baseline ($M=126.6 \pm 111.2$) and post treatment ($M=281.0 \pm 194.3$), which was significantly greater than changes observed in the control ($F(1,20)=5.267$, $p=0.037$). CGI-I ratings indicate that the PRT-P group is showing more overall improvement compared to controls ($X^2= 9.363$; $p=0.025$). Finally, we present data from using the Language ENvironment Analysis (LENA) system to assess generalized language improvements from automated analysis of natural environment audio recordings.
Conclusions: These data provide support for the application of PRT to improve child language and cognitive abilities. At the same time, comparison of standardized language measures across trials reveals clear differences in outcomes which may be attributed to differences in treatment delivery models and to sample characteristics. We will discuss these differences by highlighting the advantages and challenges of specific standardized measures, and provide recommendations for the design of future trials.

109 **108.109** The Differential Relationship Between Competence and Stress Across Parent Groups for Caregivers of Children with Autism Spectrum Disorder

B. Harrison[1], *S. Iadarola*[2], *T. Smith*[3], *K. Bearss*[4], *C. R. Johnson*[5], *L. Lecavalier*[6], *N. Swiezy*[7], *D. G. Sukhodolsky*[8] *and L. Scahill*[9], *(1)University of Rochester, Pittsford, NY, (2)University of Rochester Medical Center, Rochester, NY, (3)Division of Neurodevelopmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (4)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (5)Dept of Clinical and Health Psychology, University of Florida, Gainesville, FL, (6)The Ohio State University, Columbus, OH, (7)University of Indiana, Indianapolis, IN, (8)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (9)Pediatrics, Marcus Autism Center, Atlanta 30329, GA*

Background: Parents of children with autism spectrum disorder (ASD) report exceptionally high levels of stress compared to parents of children with other medical or developmental conditions. Stress patterns relate to core symptomatology as well as externalizing behavior (Davis & Carter, 2008), particularly challenging behavior. Although parent training (PT) seems applicable to these concerns, data on the effects of PT on parenting stress are mixed (Strauss, 2012). Because parent characteristics are likely to influence treatment outcomes, parent variables should be evaluated as potential mediators and moderators. One promising variable is parent competence. In the literature on externalizing disorders and challenging behavior in typically developing children, PT results in increased parent competence (de Graaf et al., 2008; Graf, 2014), which is a mediator of improvement in parent and child behavior (Dekovic, 2010; Graf et al., 2012).
Objectives: Evaluate the extent to which change in parent competence relates to change in parent stress and statistically test if this relationship significantly differs between PT and a control condition (psychoeducation; PE).
Methods: Children with ASD (age 3-7 years) and their families were randomly assigned to parent training (PT; n=89) or to psychoeducation (PE; n=91) for six months. Competence was measured with the Parent Sense of Competence (PSOC), and stress was measured with the Parenting Stress Index (PSI-SF) and Caregiver Strain Questionnaire (CGSQ). The primary child outcome measure was the Aberrant Behavior Checklist – Irritability (ABC-I). Parents completed these rating scales at baseline, week 12, and week 24 (post-treatment). A latent difference score (LDS) approach (McArdle, 2009) was used to examine group differences in initial competence and later stress, as well as whether change in competence predicted change in stress and if this relationship differed across groups.
Results: At Week 24 (post-treatment), parents in PT showed a significant advantage over parents in PE on the PSOC (ES=.34), CGSQ (ES=.50), and Difficult Child subscale of the PSI-SF (ES=.44), although not PSI-SF total (p=.07; ES=.25). Parents in PT and PE began treatment with comparable levels of competence ($p > .05$) and significantly increased competence from baseline to week 12 ($ps<.01$), with parents in PT making greater gains than those in PE ($z=1.99$, $p<.05$). Both groups also reduced stress from Week 12 to Week 24 ($ps<.05$); this amount of change did not significantly differ between PT and PE. Change in competence was not significantly associated with change in stress in either PT or PE. Change in competence predicted favorable change in ABC-I ($p<.05$), but this relationship did not differ across groups.
Conclusions: The differentially greater increase in competence at week 12 in PT (versus PE) did not confer incremental benefit in terms of decreased stress post-treatment. This suggests that while further exploration of competence in this population is warranted, other potential parent variables that may impact treatment outcomes for children with ASD should be explored.

110 **108.110** The Frankfurt Early Intervention Program for Preschool Children with Autism Spectrum Disorder (FFIP) - First Results on the Two Year Development

J. Kitzerow[1], *K. Teufel*[1], *C. Wilker*[1] *and C. M. Freitag*[2], *(1)Autism Research and Intervention Center of Excellence Frankfurt, Goethe University Hospital, Frankfurt, Germany, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Johann Wolfgang Goethe-University Frankfurt/Main, Frankfurt, Germany*

Background: Several studies have shown that early intervention can result in improved development for young children with autism spectrum disorder (ASD). The Frankfurt early intervention program (FFIP) is an individual developmental and behavioral approach with low training intensity (2h/week) and intensive parental involvement which is currently manualized (Teufel et al., in preparation).
Objectives: The aim of this study was to assess the 2-year outcome of FFIP on autism severity (ADOS), adaptive behavior (VABS), mental age (DQ) and additional psychiatric symptoms (SRS, SCQ, ABC, CBCL) in a pre-/post-study. As the present study lacks a control group, the results of FFIP are compared with the results of the RCT ESDM study (Dawson et al., 2010) which showed similar baseline data in most variables.
Methods: N = 27 children with ASD (ADOS severity score = 7.3; SD = 1.4), aged M = 55.5 month (SD = 12.2) took part in the 2-year FFIP study. Difference scores of T2-T1 measures were calculated for the variables of interest and the value was compared to H0: $\mu = 0$, i.e., no change. For mental age, the t-test value μ was set to the expected yearly development (7.9 months/year). To compare the study results with the ESDM groups, μ was set to the relevant change value after 2 years reported in the ESDM study.
Results: The ADOS severity score showed a decline of 0.9 points after 2 years of FFIP which was significantly more than the ESDM control group achieved ($t = -3.44$; $p = .002$) and slightly better than the results of the ESDM treatment group ($t = -1.98$; $p = .059$). No significant change in VABS-II total standard score was observed, but compared with the ESDM groups this result is significant better than the loose of standard scores the control group showed in the total score ($t = 8.3$; $p < .001$) and comparable with the gains of the ESDM treatment group ($t = 1.90$; $p = .070$). After two years of FFIP a cognitive development of 23.5 month was observed. This was significantly more than expected ($t = 3.80$; $p = .001$). The developmental quotient increased by 8.9 points, showing no difference to the ESDM control group ($t = .72$; $p = .478$) and less improvement than the ESDM treatment group ($t = -3.33$; $p = .003$).
Conclusions: This study shows the 2-year development in children who received FFIP. Results on adaptive behavior and autism severity are comparable with the development of children in the ESDM RCT study. This is a conservative comparison, as better therapeutic gains would be expected in the younger ESDM comparison group which received more hours of intervention. Similar to previous reports, variability in outcome was large and the lack of a matched control group is a strong limitation of the study. A randomized-controlled trial needs to be performed to proof its effectivity compared to community-based early intervention programs in Germany.

111 **108.111** The Sequential Oral Sensory Approach Intervention in Treating Children with Autism Spectrum Disorder and Limited Food Repertoire. a Pilot Study

S. Smile[1,2], *M. Pena*[1], *K. Perry*[1], *R. Perlin*[1], *C. Raffaele*[1], *A. Munoz*[2], *M. Lynch*[1] *and A. Dupuis*[3], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Bloorview Research Institute, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada*

Background:
Food selectivity is one of the most common feeding challenges noted within Autism Spectrum Disorder (ASD). This phenomenon is inclusive of food refusal, limited food repertoire (LFR) and high frequency single food intake. Its etiology is thought to be multifactorial, involving sensory, motor and mealtime behavioural idiosyncrasies. Excessive weight gain and nutritional deficiencies have been linked to poor feeding behaviours in ASD. Currently there is a lack of evidence based treatments to address these feeding challenges. Most hospital based interventions used to address this issue are limited to a multidisciplinary team approach which may have economic and human resource limitations. There are a myriad of behavioural interventions targeting feeding challenges; among them, the Sequential Oral Sensory Approach (SOS) is a commonly used approach used within the community. However, SOS is most commonly administered in a dyad (individual and clinician) construct which could be costly to the family. Its application in a group setting to mitigate cost and maximize human resources has not been studied.
Objectives:
This pilot study's aim is to evaluate the feasibility and effectiveness of the SOS approach intervention in increasing the food repertoire in children with ASD and LFR.
Methods:
Children 4 to 8 years with ASD were recruited. LFR was defined as eating less than 20 foods identified in a 3 day food diary. Participants were randomized to receive the 12

SOS intervention sessions (inclusive of a parent education sessions) or to a control group where parents were provided with educational material and three feeding education sessions over a 12 week period.
Results:
Fifteen children completed the study (n=8 in the SOS group and n=7 in the control group). A study participant and a parent attended eighty one percent (81%) of sessions in the SOS group. There is a trend towards an increase in the number of foods eaten over a 12 week period in the SOS group and a decrease in the Brief Autism Mealtime Behaviour Inventory score and reduction of parental stress. All parents met individual goals established at the start of the intervention.
Conclusions:
This study supports the overall feasibility of the SOS intervention in a group based setting to address feeding challenges in ASD based on only 1 participant (12.5%) being unable to complete the 12 week intervention program. This study suggests that participation in the SOS intervention program may help to increase the number of foods eaten by a child with ASD and LFR over time. A larger randomized control trial is needed to further evaluate the effectiveness of the SOS intervention in children with ASD.

112 **108.112** The Use of Mirroring to Improve Social Engagement in Young Children with ASD

K. Radonovich *and K. Reese, University of Florida, Gainesville, FL*

Background: Reduced social engagement in young children with autism spectrum disorder (ASD) can be particularly challenging to treat. If not treated, social deficits could ultimately hinder a child's development, ability to establish meaningful relationships, and engagement in learning opportunities. Interventions that target social skills and social interaction are key in reducing negative outcomes associated with these deficits, and may ultimately improve the quality of life for individuals with ASD. Mirroring is a component of dance-movement therapy (DMT) that is somewhat comparable to imitation. Anecdotal and case study reports suggest the effectiveness of the use of mirroring and DMT to positively engage children with ASD. However, little to no objective data on outcomes of such interventions are available. There is empirical support for imitation interventions in improving play, movement, vocalization, and engagement in children with ASD. Thus, we were interested in objectively determining the effectiveness of mirroring to engage minimally-verbal children with ASD.
Objectives: We sought to measure the effectiveness of a mirroring intervention on the social engagement skills of young, minimally-verbal children with autism.
Methods: A multiple baseline across participants design, with replication was used to measure the effects of the intervention. Thus far, four participants (three boys and one girl) with ASD ages 3-4 years have participated in this study. Prior to intervention, children attended baseline sessions in which no mirroring of the child's behaviors occurred. During baseline the interventionist engaged in non-contingent movement and vocalization. During the intervention phase, the interventionist engaged in mirroring and attunement of the child's movements, vocalizations, and mood throughout the session. Sessions were videotaped and operationalized definitions of dependent measures (e.g., initiations, gaze toward the interventionist, and positive affect) were coded throughout. Data were analyzed using visual inspection and calculation of change in level, trend, immediacy of effect, stability, variability, and degree of overlap. Inter-observer agreement and treatment integrity data were also calculated.
Results: Results indicated that this non-intensive intervention increased all participants' social engagement behaviors almost immediately. A stable and functional relationship between the mirroring intervention and increases in target social engagement skills by all four children was demonstrated. Additionally, results indicate that the intervention was implemented with fidelity.
Conclusions: Overall, findings support the use of mirroring to improve the social engagement skills of young, minimally-verbal children with ASD. This study is one of very few in the literature to quantify and objectively measure the effects of this technique. Additionally, it addresses a gap in research on minimally verbal, young children with ASD using non-intensive implementation. Establishing empirical support for this technique, when implemented by a clinician trained in mirroring is vital. This study has important implications for theoretical basis of mirroring and DMT, as well as clinical and practical implications. Once further empirical support is established, future studies may expand on this technique by training parents, clinicians, and other professionals to utilize mirroring techniques to engage children with ASD.

113 **108.113** Training Caregivers in PRT: Lessons Learned in Private Practice

R. E. Daniels*, Chicago Children's Clinic, Winnetka, IL*

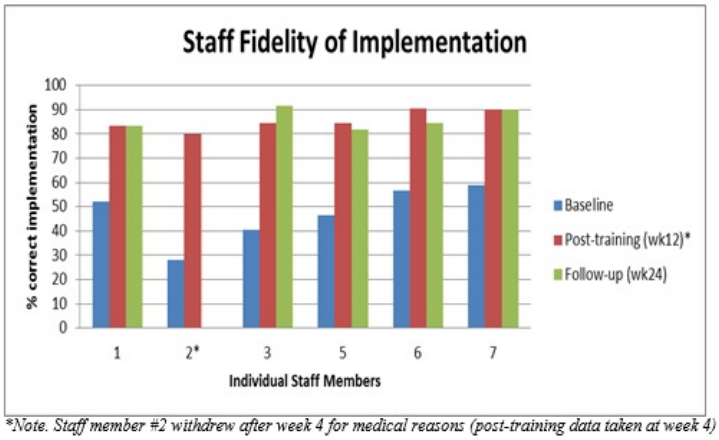
Background: Training parents in evidence-based behavioral intervention techniques can amplify the effect of direct behavioral therapy and improve the developmental trajectory of children with autism spectrum disorder (ASD; Coolican, Smith, & Bryson, 2010; Green et al., 2010; Kasari, Gulsrud, Wong, Kwon, & Locke, 2010; Schreibman et al., 2015). Additionally, parent implemented interventions are associated with reduced costs (Koegel, Bimbela, & Schreibman, 1996; Symon, 2001). Community studies of parent training programs revealed that parents were capable of implementing evidence-based treatments with fidelity and were able to train other caregivers and providers in acquired techniques, thus multiplying the effects of parent training exponentially (Symon, 2005).
Objectives: (1) To identify logistical hurdles encountered in private practice and community settings, (2) To present strategies used at a small, fee-for-service private practice to overcome these hurdles, and (3) To provide recommendations for efficient training of caregivers who possess multiple learning styles, strengths and challenges.
Methods: A review of the caseload at a small, fee-for-service private practice over the past 9 years was conducted to identify characteristics associated with the following outcomes: (1) Clinical outcome; (2) Efficiency of acquisition of treatment procedures with fidelity, and (3) High coordination of care with school and other agencies and providers.
Results: (1) Clinical outcome: When parent training was mandated prior to assignment of an in-home therapist, some parents opted not to work with the practice, but those who did were highly engaged, satisfied, and experienced positive child and family outcomes; (2) Efficient acquisition of treatment procedures occurred when sessions occurred in the home setting; however, the ability to acquire general parenting skills occurred most efficiently in multi-family group settings; (3) Brief, concise treatment plans that included baseline and outcome data, with specific recommendations for how components of PRT could be implemented in additional settings resulted in higher levels of coordinated care. Video examples were very effective at convincing agencies and schools to align their practices with those occurring at home. Parents with multiple children with ASD and/or limited finances required significant support when working with their school district to receive appropriate services.
Conclusions: Although logistical hurdles exist, such as parent compliance and arranging coordinated care with schools, brief parent training in PRT within a private practice setting is feasible for many families and results in positive child and family outcomes. Varying skills (i.e., PRT implementation vs. general parenting skills) may be learned more efficiently in specific settings, and family characteristics may impact the relative ease of coordinating care. This review supports the notion that PRT is a cost-effective intervention that can be adopted widely in community settings, including private practice.

114 **108.114** Training Early Childhood Educators in the Social ABCs Toddler Autism Intervention in a Community Child Care

J. A. Brian[1]*, K. Bernardi*[1]*, E. M. Dowds*[2] *and S. E. Bryson*[3]*, (1)Bloorview Research Institute, Toronto, ON, Canada, (2)The Hospital for Sick Children and Bloorview Kids Rehab, Toronto, ON, Canada, (3)Dalhousie University, Halifax, NS, Canada*

Background: The *Social ABC's* is a parent-mediated intervention shown to increase communication and positive emotion sharing in infants/toddlers with emerging autism. We adapted our program for Early Childhood Educators (ECEs) and Special Needs Resource Consultants (SNRCs) in community childcare settings including the addition of a 3-hour workshop on early detection and intervention in ASD. Training childcare personnel provides unique and valuable opportunities to: (1) increase knowledge in early detection, (2) increase the 'dose' of intervention throughout the day, (3) train highly skilled child development experts, and (4) have a long-term 'return-on-investment' via training individuals who can use the techniques with multiple children over time.
Objectives: To disseminate our *Social ABCs* into the childcare setting, with two research questions: (1) Can a directed workshop increase the knowledge of front-line childcare staff regarding signs of emerging autism? (2) Is it feasible to train staff in the *Social ABCs*in a community childcare?
Methods: (1) Present workshop and test knowledge (n=19); (2) Train frontline staff (n=6): 12 weeks of in-centre, live coaching, followed by 12 weeks' implementation, and follow-up at week 24. Paired samples t-tests evaluated change across time-points.
Results: (1) Workshops provided for 22 attendees; 19 wrote the workshop quiz, with mean improvement of 22.26% from pre- (52.63%, SD = 14.76) to post-workshop (74.89%, SD = 12.51), $t = 7.57$, $p < .001$. (2) Significant improvements in fidelity of implementation from baseline (Mean = 47.08%, SD = 11.51) to post-training (Mean = 85.50%, SD = 4.04), $t = 11.44$, $p < .001$. Gains were maintained at follow-up (Mean = 86.30%, SD = 4.19). All staff achieved fidelity > 80% post-training (see Figure 1).
Conclusions: Significant gains were observed in staff knowledge and skills in response to this training package. The model of training frontline childcare staff is feasible and effective, presenting an opportunity for integration of intensive intervention into daily activities for very young children at risk for ASD in community child care settings. Discussion includes perceived barriers to, and potential solutions for, widespread implementation.

Figure 1. Staff fidelity data from ECE training project (Brian et al)



Note. Staff member #2 withdrew after week 4 for medical reasons (post-training data taken at week 4)

115 **108.115** Understanding and Measuring Change and Impact of Novel Early Intervention Programs

S. Bauman[1], *M. L. Iemolo*[1], *Z. Warren*[2], *C. R. Newsom*[3], *A. Stainbrook*[1], *P. Juarez*[4] *and A. S. Weitlauf*[2], *(1)Vanderbilt Kennedy Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN, (3)Pediatrics, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University Medical Center, Nashville, TN*

Background:
State early intervention systems vary regarding their abilities to offer empirically validated treatments that specifically target ASD symptoms. Randomized controlled trials of manualized interventions have shown promise for some young children but data on their ability to translate into meaningful change in low-resource community settings is lacking. There is a pressing need for (1) enhanced strategies for successful community implementation and (2) better measures of the impact of implemented evidence-based programs for young children with ASD. This work describes one such pilot program that partners a Part C system with behavioral intervention specialists to not only evaluate the impact of the program, but also to understand whether novel metrics for assessing impact may be helpful in program evaluation.
Objectives:

- Assess implementation of evidenced based early intervention program
- Evaluate CGI-I measure as indicator of impact of early intervention program

Methods:
This program evaluation study presents results of use of modified Early Intervention-specific (EI) Clinical Global Impressions of Improvement (CGI-I) scales within the context of a model service delivery program. 58 families were provided with parent education-focused service models through Part C system following a diagnosis of ASD. All 58 families participate in a brief service model that consisted of 2 home-based evaluation support sessions. 19 of these families participate in an extended service that included 12 additional sessions guided by the Early Start Denver Model (ESDM). Clinicians provided CGI-I ratings at the completion of the brief model for each family and again at the completion of the extended model for families that participated in both. Ratings are on a 7-point Likert scale, with higher scores indicating worse functioning and lower scores indicating improved functioning. The CGI-I rating assesses improvement in the following domains: participation in caregiving routines, participation in play routines, verbal and nonverbal communication skills, social skills, engagement in restricted interests and repetitive patterns of behavior, and demonstration of challenging behavior.
Results:
While no significant difference scores were found in pre- and post-service scores on global measures of functioning as indexed by the Vineland Adaptive Behavior Scales-2, both caregivers and clinicians rated children as more improved on the CGI-I for the extended service delivery model, although the clinician reported ($T = 7.56$, $p < .001$) difference was larger than that of the caregiver report ($T = 2.74$, $p < .05$). Follow up comparisons will be presented regarding the main domain drivers of global CGI-I change from pre- to post-intervention within the EI CGI-I .
Conclusions:
The modified CGI scale was able to capture significant changes in total score in an ASD population between pre- and post-intervention. Similar changes were not documented on a common global measure often used as a proxy of change in model programs. Future program implementation and evaluation work may benefit by adopting and validated global and domain relevant CGI rating systems.

116 **108.116** Unity Twelve-Week ABA Parent Training: Weekly Changes in Parent Experiences and Competence

S. Freund[1], *M. N. Gragg*[2], *S. Popovic*[1], *R. Jamil*[1] *and G. Miljevic*[3], *(1)University of Windsor, Windsor, ON, Canada, (2)Psychology, University of Windsor, Windsor, ON, Canada, (3)Summit Centre for Pre-school Children with Autism, Windsor, ON, Canada*

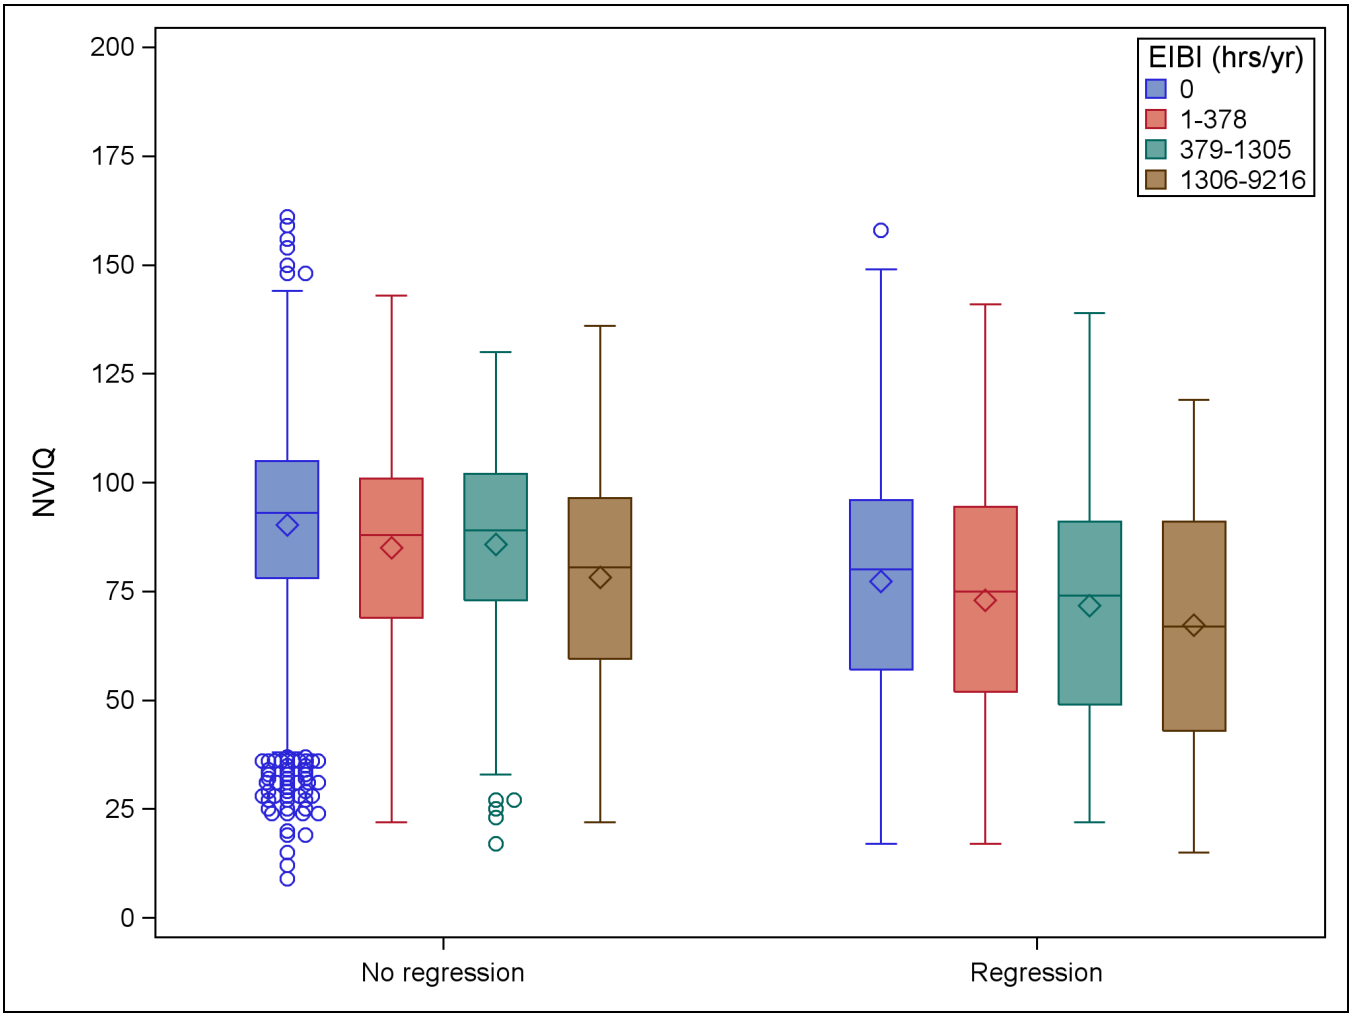
Background: Applied Behavioural Analysis (ABA) has a broad evidence base for improving intellectual and adaptive functioning of children with Autism Spectrum Disorders (ASD). Best outcomes are for children who receive intensive intervention from an early age. Unfortunately, early intervention is often difficult to access due to high demand and scarce resources. Finding alternative ways for parents to access intervention for their children is crucial. Parent training in ABA has gained popularity due to its effectiveness in promoting learned skills, and reducing demands on ABA services through parents serving as co-therapists. Previous findings from the Unity parent training program indicated that parent perceptions of their experiences and competence generally became more positive across the twelve-week program, with temporary dips in ratings during periods of transition.
Objectives: To examine weekly changes in parents' perceptions of their training experiences and competence throughout a twelve-week intensive ABA training program.
Methods: 50 parents/caregivers of preschool children with ASD (90% mothers) who completed the Unity training were participants. Most parents were in the 18-34 year age range (50%), and the 35-44 year range (46%). Only 4% of parents were in the 45-54 year range. 90% of parents had some college education or more, and over 38% reported an annual salary of $75,000+. Their children (80% boys) ranged from 12 to 63 months old; all had a diagnosis of Autism Spectrum Disorder (90%) or PDD-NOS (10%). Participants completed 180 hours of ABA training at an ASD preschool. Each week, participants completed a 17-question survey rating their perceptions of training over the past week (e.g., "How much did you understand the tasks in your child's program?" "How independent were you in carrying out your child's program?")
Results: Overall, parents' belief in the effectiveness of ABA in improving academics, social skills, and difficult behaviours increased significantly from week one to week twelve. Parent perceptions of their own competence increased significantly over the 12-week training program in their understanding of concepts covered and program tasks; independence in carrying out programs, ability to teach ABA concepts to others, confidence, satisfaction in carrying out child's programs, and feeling in control. Other training experiences were rated as more positive over the course of the program, including instructor support, child improvement as result of parent training, and parents'

contribution to their children's programs. Ratings related to training difficulties (challenge in implementation of children's program, stress of the training program, and difficulty in carrying out program tasks) decreased significantly over the twelve weeks.
Conclusions: Parents' perceptions of their experiences and competencies became more positive over the course of the 12-week ABA training program. Ratings in areas of competence (e.g. understanding and implementation of tasks) increased, while ratings in areas of difficulty (e.g., stress, challenge) decreased. Parents consistently reported enjoying their participation in the program. Data collection is ongoing.

117 **108.117** Use of Early Intensive Behavioral Intervention Among Children with ASD: Outcomes for Children with and without a History of Developmental Regression

R. P. Goin-Kochel[1], *S. S. Mire*[2], *L. Berry*[1], *S. M. Kanne*[3], *R. Bernier*[4], *C. G. Minard*[5] *and D. Guffey*[1], *(1)Baylor College of Medicine, Houston, TX, (2)University of Houston, Houston, TX, (3)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (4)University of Washington, Seattle, WA, (5)Dan L. Duncan Institute for Clinical and Translational Research, Baylor College of Medicine, Houston, TX*

Background: Children with autism spectrum disorder (ASD) and lower levels of cognitive functioning generally have less favorable outcomes compared to their counterparts with higher cognitive functioning. However, early intensive behavioral intervention (EIBI) has been empirically validated to underlie improvements in cognitive, language, adaptive, social, and academic test scores for children with ASD. Recent evidence confirms that, by middle childhood, children with ASD who exhibit developmental regression (i.e., lose previously mastered skills) within the first three years have significantly lower cognitive and adaptive-functioning scores than those without regression. It seems possible, then, that EIBI could potentially mitigate the deleterious effects of early skill loss and subsequently enhance their long-term outcomes.
Objectives: To determine whether (a) children with ASD +/- regression differentially access EIBI and (b) those with regression respond differently to EIBI, as no studies have compared EIBI-treatment outcomes between regressed and nonregressed groups.
Methods: Data were collected from 2,695 children with ASD (86.6% male; *M* age = 9 years, *SD* = 3.6, range = 4 to17 years, 11 months) who participated in the Simons Simplex Collection (SSC). All were determined to meet CPEA criteria for ASD based on clinical judgement and cutoff scores on the *Autism Diagnostic Interview—Revised* (ADI-R) and the *Autism Diagnostic Observation Schedule*(ADOS). Regression status was operationalized as a language and/or social-engagement loss at/before 36 months of age, per the ADI-R. Use of EIBI at any time between ages 0 to 4 was determined according to parent report on the SSC Treatment History Form. A continuous measure of EIBI intensity was calculated by multiplying the number of hours of treatment per week by the number of weeks treatment was received each year (hrs/wk*wk/yr). Outcomes of interest included cognitive functioning, adaptive behavior, and ASD severity as measured with the ADOS comparison score.
Results: A total of 737 (28.4%) children reportedly experienced a language and/or social regression at/before 36 months, while 770 (28.6%) had participated in EIBI at some time between ages 0 to 4. Children with skill loss consistently accessed EIBI at higher rates than nonregressed children (45% vs. 23%, respectively). EIBI intensity did not differ between regressed and nonregressed groups from ages 0—3; however, by age 4, children with skill loss were receiving more intensive EIBI (med = 520 hrs/wk*wk/yr) than those without loss (med = 480 hrs/wk*wk/yr, *p*= .04). Regression status did not interact with EIBI intensity to predict functional outcomes; however, within groups (loss or no loss), scoring patterns for cognitive and adaptive-functioning were highly similar, with those who received the most intensive EIBI consistently demonstrating significantly poorer outcomes compared to those who received no EIBI.
Conclusions: While children with ASD and regression demonstrate lower average cognitive and adaptive functioning compared to those without skill loss, these groups have comparable functional *patterns* based on EIBI intensity, suggesting similar responsiveness to EIBI. The most intensive EIBI may be implemented for those with the lowest levels of functioning; however, both pre-treatment baseline measures and longitudinal studies are needed to determine EIBI *efficacy* relative to skill loss.



118 **108.118** Use of Objective Behavioral Observation Measures to Evaluate Outcomes of Pivotal Response Treatment

M. B. Minjarez[1], *G. W. Gengoux*[2], *K. L. Berquist*[2], *C. Ardel*[2], *T. W. Frazier*[3] *and A. Y. Hardan*[2], *(1)Seattle Children's Hospital, Seattle, WA, (2)Stanford University, Stanford, CA, (3)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Behavioral interventions are robustly supported in autism spectrum disorder (ASD) treatment, including those that are parent-administered. There remains a need, however, for objective outcome measures that capture child response to treatment, as well as parent implementation of intervention strategies. Although research in Pivotal Response Treatment (PRT) does often include measures of parent treatment fidelity, detailed information about scoring procedures is sparse in the literature. Other parent training models often do not include information about whether the parents gained the targeted skills and child outcome data are often the sole focus.
Objectives: The goal of this presentation is to review outcomes from an objective behavioral observation measure from two trials of PRT, one randomized controlled trial of the group model of PRT, and one pilot study of a brief model of individual PRT. As there is little description of behavioral observation measures in the literature, especially with regard to parent fidelity of implementation, detailed information will be provided about operational definitions of targeted behaviors, as well as scoring and data analysis procedures.

Methods: In both trials, participants included children, ages 2-6 years, with diagnosis of ASD and significant language delay. In the RCT, 53 participants were randomly assigned to either PRT group or parent psychoeducation control group. In the study of brief individual PRT, child and parent outcomes were evaluated pre- and post-treatment for 13 children. Active treatment included parent training in PRT to target language development across 12 weeks for both studies. Dependent measures included standardized measures and structured lab observation (SLO), which will be the focus of this presentation. The SLO includes several standardized conditions (i.e., standard toys and parent instructions for interaction), designed to evaluate different aspects of parent-child interaction and child language skills. It is video taped and scored by blind raters for several target behaviors, including child language and parent treatment fidelity. This presentation will review administration and scoring procedures in detail, including novel approaches used to score total number as well as types of child utterance and trial-by-trial parent fidelity of implementation.
Results: Outcomes from these studies demonstrate that parent training in PRT was associated with child language improvements, as scored during the SLO, with a significant increase in functional utterances from baseline (34.2 ± 31) to post-treatment (55.9 ± 34; t = -2.922; df =8; p= 0.019) for the brief individual PRT, as well as the RCT of PRT group ($F(2, 43) = 3.53$, $p = .038$). Parents also effectively learned PRT in the RCT, as 84% met fidelity criteria. Fidelity data analyses for the brief PRT trial are ongoing.
Conclusions: Findings from these studies support that parent training programs are effective in teaching parents PRT and children show correlated gains in language. Together with previous studies of PRT, these findings also support the use of SLO procedures to measure parent and child outcomes. Findings will be discussed in light of the structured lab observation's relationship to other standardized measures and its utility as an end point in the study of ASD interventions.

119 **108.119** Using Cluster Analysis to Explore Subgroups in Response to Early Intervention

J. M. Paynter[1] *and A. E. Lane*[2]*, (1)AEIOU for Children with Autism, Moorooka, Australia, (2)University of Newcastle, Callaghan, Australia*

Background: High quality early intervention has been observed to improve outcomes at a group level for children with autism spectrum disorder (ASD) (e.g., Magiati et al., 2012; Warren et al., 2011). However, wide individual variation in response to intervention is also reported (e.g., Kamio et al., 2015). Emerging research suggests subgroups of children with ASD may exist in terms of response to intervention (Szatmari et al., 2015; Stevens et al., 2009). This research is valuable as it may lead to identification of what pre-treatment characteristics predict response to specific interventions, as well as those who may need additional support. The focus of this study is on a Naturalistic Developmental Behavioural Intervention (NDBI; see Schreibman et al., 2015) developed in Queensland, Australia. The program draws from a blend of behavioural and developmental strategies within a centre-based group program and has recently been manualised. Promising outcomes in terms of cognition, language, adaptive behaviour, and ASD symptoms have been found (Paynter et al., 2012; Paynter et al., 2015). However, this included significant variation at the individual level.
Objectives: The aims of this study were to examine (1) subgroups based on response to NDBI intervention; (2) characteristics of subgroups; and (3) intake variables that best predict outcomes.
Methods: Participants included 292 children with ASD aged 2½ to 6 years ($M = 45.19$ months, $SD = 9.61$) who attended the early intervention program between 2010 and 2014. Assessment included adaptive behaviour using the Vineland Adaptive Behaviour Scales-II (VABS-II), cognition using the Mullen Scales of Early Learning (MSEL), and ASD symptoms using the Social Communication Questionnaire completed on intake and exit. Model-based cluster analysis was used to identify potential subgroups based on change scores.
Results: Consistent with previous research, significant improvements in cognitive and adaptive behaviour scores between intake and exit were found for the whole group overall. Model-based cluster analysis identified a four-factor solution based on changes in age-equivalent scores on the VABS-II and MSEL. The majority (96%) of participants fitted into two clusters: a low outcome group ($n = 200$) with significantly lower change scores across all domains; and a high-outcome group ($n = 81$). At baseline, the high outcome group reportedly showed fewer autism symptoms, but were similar in age. Greater differences in groups were seen in verbal and non-verbal cognitive skills, as well as adaptive behaviour. The high outcome group's adaptive behaviour composite was above 70 on average, whereas, the low outcome group was below.
Conclusions: Two distinct clusters were identified with a low-outcome group showing scores on average in line with an intellectual disability, consistent with previous research across a range of interventions grouped together (Szatmari et al., 2015). Different or more intensive interventions may be needed for this group. Intake variables, particularly cognitive and adaptive behaviour skills may provide predictors of response to intervention. There is need for further research to extend this research to explore subgroups on response to intervention across different programs to provide a foundation to inform intervention choice for specific child profiles.

120 **109.120** A Cellular and Molecular Study Investigating the Fetal Androgen Theory of Autism Using a Human Stem Cell Model

D. Adhya[1], *K. Jozwik*[2], *J. Carroll*[3], *J. Price*[4], *D. Srivastava*[5] *and S. Baron-Cohen*[6], *(1)University of Cambridge, Cambridge, England, United Kingdom, (2)Cancer Research UK Cambridge Research Institute, Cambridge, United Kingdom, (3)Cancer Research UK Cambridge Institute, Cambridge, United Kingdom, (4)Institute of Psychiatry, KCL, London, England, United Kingdom of Great Britain and Northern Ireland, (5)Institute of Psychiaty, King's College London, London, United Kingdom, (6)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom*

Background: Autism spectrum conditions (autism) are associated with elevated fetal steroidogenic levels, suggesting a role for fetal steroids such as testosterone in the development of the autism during fetal development. Fetal testosterone is an androgen that 'masculinizes' the brain and reproductive system, reduces apoptosis, and exerts epigenetic influence on gene expression. Fetal testosterone is produced in two-fold quantities in male compared to female fetuses, and may be an important contributor to the early development of autism, given the established male biased sex ratio on the prevalence of autism.
Objectives: To determine the effect of fetal testosterone on cellular and molecular pathways in neurons derived from an individual with autism, and how this differs from its effect in neurons derived from a typically developing individual.
Methods: We used a human induced pluripotent stem cell (hiPSC) model of autism. Keratinocytes from typical individuals, and individuals with autism were reprogrammed into iPSCs, and then differentiated into cortical neurons using the dual SMAD signalling inhibition strategy. Testosterone was administered to these neurons at an early stage of development at the physiological and supra-physiological levels. Quantitative real time PCR was performed to measure gene expression levels. Immunocytochemistry followed by high throughput screening measured cell counts based on neuronal markers expression.
Results: Preliminary data indicates that neurons from individuals with autism develop differentially, while being more responsive to testosterone than neurons from typical individuals. The androgen receptor (AR) and some of its putative downstream genes such as gonadotropin-releasing hormone (GnRH) and p38 (a class of mitogen-activated protein kinases) were differentially expressed in autism neurons compared to typically developing neurons, predicting differential structural and functional outcomes of neurons in the two groups (Fig1a). Genes indicating neuron cell fates such as T-box brain 1 (TBR1) and BRN2 were also differentially expressed in autism neurons, demonstrating altered characteristics (Fig1b). Long term testosterone administration does not seem to regulate TBR1 and BRN2 expression, and cells positive for TBR1 seemed to increase with time especially in autism neurons, while BRN2 positive cells increased in both (Fig2).
Conclusions: These data suggest that the autism phenotype develops in utero at very early stages of brain development, and that neurons of individuals with autism are programmed, at a molecular level, to react differently to sex steroids such as fetal testosterone. The iPSC model has the power to distinguish genetic predisposition to fetal androgen sensitivity, environmental exposure to fetal androgen level, and interactions mediated via epigenetic influences of fetal androgens on the autistic genome. The current experiment casts light on the first two factors, and future work will test the latter hypothesis using RNA-sequencing.

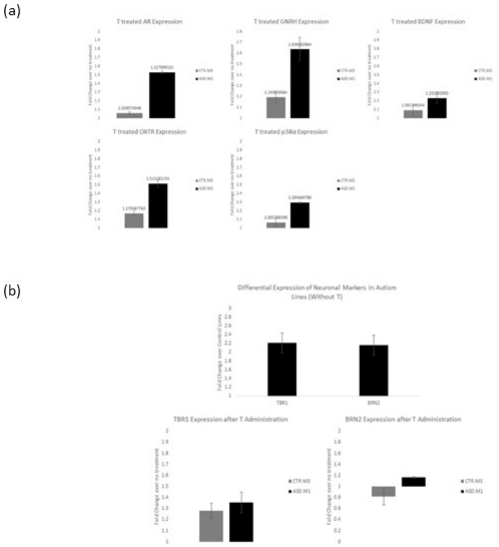

Figure 1: (a) Q-PCR analysis of candidate genes. Autism-derived neurons show significantly more expression of AR, GnRH, BDNF, OXTR and p38α than control-derived neurons at day 35 upon administration of physiological levels of testosterone. **(b)** Q-PCR analysis of neuron development genes. Autism-derived neurons show a higher basal level of TBR1 (early neuron marker) and BRN2 (late neuron marker) than control neurons at D35. Both markers show no significant change in expression levels upon physiological testosterone administration.

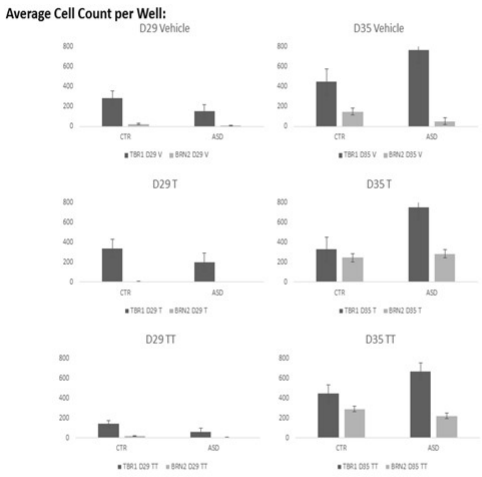

Figure 2: Autism lines have greater TBR1 +ve cells at D35. While TBR1 and BRN2 +ve cells increased from D29 to D35 in autism lines, in the control lines only BRN2 +ve cells significantly increased from D29 to D35. Moreover, there seems to be negligible effect of testosterone (both physiological T and supraphyisological TT) administration on these neuronal markers.

121 **109.121** Alterations in the Autism-Related Gene CEP290 Affects Neurite Formation and Differentiation

M. B. Kilander[1] *and Y. C. Lin*[2], *(1)Suite 301, Hussman Institute for Autism, Baltimore, MD, (2)Laboratory of Neuronal Connectivity, Hussman Institute for Autism, Baltimore, MD*

Background:
While autism is classified as a neurodevelopmental condition, the defined spatiotemporal molecular mechanisms contributing to the establishment of the altered neurophysiology observed in individuals with autism are largely unknown. Large-scale genetic screening implicated several genes, mutations of which may contribute to phenotype found in ASC. CEP290, a protein that is tightly linked to the formation of primary cilium, has been identified among these ASC candidate genes. The primary cilium is a microtubule rich structure protruding out from the cell which has been shown to be crucial for normal cell migration, polarity and division. Moreover, the primary cilium retains a highly specialized nanoenvironment within the cell which serves as the specific compartment for certain types of cell signaling and for cell-environment communication. In particular, Sonic Hedgehog signaling, a cell communication pathway necessary for proper tissue development and maintenance, is preferentially localized to the primary cilium. However, to-date not much is known about the role of the primary cilium in neurodevelopment and in the establishment of mature neural circuits. Mutations in the *CEP290* gene are involved in ciliopathies, i.e. severe multi-organ disorders that are related to dysfunctional primary cilia. Additionally, CEP290 has also been implicated in cancer as well as in intellectual disability syndromes and in individuals with autism. However, how CEP290 plays a role in regulating brain function is still

unclear.
Objectives:
In this study we set out to analyze the impacts of dysfunctions in the *CEP290* gene at a cellular and molecular level in order to dissect the pathways of disrupted neurodevelopment in an autism-related model system.
Methods: Using live cell imaging, immunocytochemistry and molecular techniques we assess the changes in morphological, proliferative and cell signaling mechanisms caused by alterations of CEP290. We employ shRNA techniques to target CEP290 expression and evaluate knockdown efficiencies by Western Blot. Monitoring of cells over 7 days using IncuCyte (Essen Biosciences) allows us to perform detailed analysis on changes in neurite formation and establishment, to make accurate calculations on proliferation rates, and in assessing cell viability and culture quality.
Results:
CEP290 is localized to the primary cilium in Neuro-2a cells. Overexpression as well as knockdown of *CEP290* leads to reduced retinoic acid-induced neurite outgrowth and diminished neurite arborization indicating that disruption in CEP290 expression might be involved in the regulation of proper neuronal differentiation and maturation. Moreover, cells overexpressing CEP290 displayed a higher rate of proliferation resulting in a disrupted balance between proliferation and differentiation within the cell population.
Conclusions: In summary, our present investigation into the cellular functions of CEP290 have the potential to provide novel insight into the role of primary cilium in neurodevelopmental conditions such as autism.

122 **109.122** Autism Patient-Derived Neural Stem Cells Display Neurite Extension and Migration Defects

S. Prem[1], *M. Williams*[1], *C. McDermott*[2], *X. Zhou*[3], *P. G. Matteson*[4], *P. Yeung*[5], *C. W. Lu*[5], *Z. Pang*[5], *L. M. Brzustowicz*[6], *J. H. Millonig*[3] *and E. DiCicco-Bloom*[7], *(1)Neuroscience, Graduate School of Biomedical Sciences, Piscataway, NJ, (2)Queens College, Queens, NY, (3)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (4)Rutgers University, Piscataway, NJ, (5)Child Health Institute of New Jersey, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (6)Genetics, Rutgers University, Piscataway, NJ, (7)Rutgers University - Robert Wood Johnson Medical School, Piscataway, NJ*

Background:
Autism spectrum disorders (ASD) are neurodevelopmental disorders characterized by impaired social interaction and communication and the presence of repetitive restrictive behaviors. Invaluable studies in ASD mouse models have shown changes in neuronal connectivity and migration that replicate findings of human neuropathology and brain-MRI. However, mouse models cannot capture the complexity of human neurodevelopment. Thus, in order to understand a uniquely human disorder like ASD, we need techniques to model human neurodevelopment. Recently, induced pluripotent stem cell (iPSC) technology has allowed the generation of neural stem cells (NSCs) and neurons from individuals with neuropsychiatric disorders thereby allowing study of human neuropathology. Using iPSCs we have generated NSCs from 8 boys with severe idiopathic autism and their unaffected-brothers (Sib) as controls.
Objectives:
Our goals are to study neurite outgrowth and neurosphere migration in our patient-derived NSCs using developmentally relevant extracellular (EC) factors such as PACAP, serotonin (5HT) and nerve-growth-factor (NGF).
Methods:
Neurite Assay: Confluent NSCs were dissociated and plated at low density on fibronectin+ poly-d-lysine coated plates in control media, or media containing EC factors. At 48h, the proportion of cells with neurites >2 cell diameters were counted blind in 1 cm rows. 3 dishes were quantified per condition per experiment. At least 200 cells were counted per dish
Neurosphere Migration: Neurospheres were formed by plating NSCs in absence of substrate. After 48-96h, spheres were plated on Matrigel with control or EC factor media and fixed at 48h. Using phase-contrast images, areas of the inner-cell-mass and total sphere outgrowth were measured. 15-21 spheres were measured blind per condition per experiment. Migration*: total sphere area-inner cell mass area.*
Results:
We have extensively studied neurite outgrowth and migration in NSCs from one family. To ensure that the phenotypes observed were not a consequence of the viral-reprogramming involved in iPSC generation, we have assessed multiple NSCs derived from 2 iPSC clones for Sib and multiple NSCs derived from 3 iPSC clones for ASD.
Neurites:
In control media, Sib NSCs had a significantly higher percent of cells with neurites (15%) than ASD NSCs (8%, $p<0.0001$). Under stimulation of PACAP, there was a 51% increase in cells bearing neurites in the Sib NSCs ($p<0.0004$) but no change in ASD NSCs ($p>0.5$). Similarly, under stimulation of NGF, there was a 58% increase in neurites in Sib NSCs ($P<0.005$) but no change in ASD NSCs ($p>0.7$). Finally, Sib NSCs displayed a dose-dependent increase in neurites with 5HT stimulation while ASD NSCs only responded at the maximal tested dose of 5HT indicating a difference in sensitivity.
Migration:
In control media, Sib neurospheres migrated further than ASD NSCs ($p<0.05$). Under the stimulation of PACAP there was a 50% increase in migration of Sib neurospheres ($P<0.001$) but no change in migration in ASD neurospheres ($p>0.7$).
Conclusions: Our studies of patient-derived NSCs reveal neurobiological abnormalities that may provide insight into impaired brain development and function in ASD. Our studies also illustrate the value of using developmentally-relevant factors to uncover patient-specific abnormalities that may facilitate the development of personalized ASD therapies

123 **109.123** Autism and Immunity: Salivary Cytokines in Children with Autism Spectrum Disorder

L. C. Goodwin[1,2], *H. L. Green*[1] *and K. Froud*[3], *(1)Columbia University, New York, NY, (2)Center for Autism and the Developing Brain, White Plains, NY, (3)Biobehavioral Sciences, Columbia University Teaches College, New York, NY*

Background: Many individuals with ASD demonstrate skewed immune profiles, suggestive of a potential role for immune dysfunction (Noriega & Savelkoul, 2014). Elevated immune mediators such as cytokines have been found in the blood plasma, cerebral spinal fluid, gastrointestinal track, and post-mortem brain tissue of individuals with ASD (Ashwood et al., 2011; DeFelice et al., 2003; Molloy et al., 2006). Genetic studies have uncovered a host of potential immune regulatory related genes altered in ASD, while research on maternal immune activation during fetal development has also been implicated in immune dysregulation in ASD (Patterson, 2011). Other research suggests that volumetric differences, morphological differences, and abnormal neuroinflammation in ASD may be related to neuroimmune factors such as elevated cytokines (Wei, Alberts, & Li, 2013). The study of those with skewed immune panels is crucial for discerning the interaction between the immune system during neurodevelopment and its potential involvement in ASD.
Objectives: This study aims to assess if the inflammatory cytokines interleukin-6 (IL-6) and interleukin 1 beta (IL-1β) are elevated in the saliva of low functioning children with ASD as compared to typically developing control children. This study also aims to explore the relationship between elevated salivary cytokines in autism and the severity of autistic symptoms.
Methods: Twenty-five low-functioning children with ASD and twenty-eight typically developing control children from 6-18 years of age were enrolled in the current study. Salivary samples were collected using the SalivaBio Children's Swab (SCS) Method, which consists of placing a soft swab inside the mouth for 60 – 90 seconds. Salivary IL-6 and Salivary IL-1β levels were flow-rate controlled and measured via enzyme-linked imunnosorbent assays (ELISA) with a 450 nm plate reader. The Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) was administered to children with autism in order to determine severity of ASD.
Results: Salivary IL-6 was significantly elevated in children with ASD (μ= 7.3082 pg/mL) as compared to typically developing control children (μ= 2.691 pg/mL), (t= 2.3444; P=0.0283). There was no significant difference between children with autism (μ=235.28 pg/mL) and typically developing children's salivary IL-1β levels (μ=212.12 pg/mL), (t=.342; p=.735). There was a weak positive correlation between salivary IL-6 levels and ADOS-2 raw scores in ASD children with detectable levels of salivary IL-6 (R= 0.1495). There was also a weak positive correlation between salivary IL-1β levels and ADOS-2 raw scores in ASD children (R=0.1939).
Conclusions: Consistent with related studies, our findings are suggestive of a potential role for immune dysfunction in ASD. To our knowledge there are no published studies that have investigated salivary IL-6 or IL-1 β in individuals with ASD. Previous studies have found relationships between salivary IL-6 and psychosocial factors, immune functioning, stress, and sleep dysfunction (El-Sheikh et al., 2007; Groer et al., 2010; Ris et al., 2015 Sjögren et al., 2006) as well as relationships between salivary IL-1 β and inflammatory conditions (Hernández-Rodríguez et al., 2004; Southerland et al., 2006). Future studies should attempt to correlate blood plasma levels of cytokines to salivary levels of cytokines within same ASD population.

124 **109.124** Behavioral Phenotypes in Mouse Models of Angelman Syndrome

E. Weeber *and S. Ciarlone, University of South Florida, Tampa, FL*

Background: The mouse model for Angelman syndrome was developed over 15 years ago, but represents one of the most useful mouse models for a human cognitive disorder. The AS mouse shows strong phenotypes in the areas of motor coordination, learning and memory, seizure propensity and hippocampal synaptic function.
Objectives: To determine if the strongest phenotypes of the AS mouse model can be reversed in the adult mouse.
Methods: We used Ube3a maternal deficient mice on a background strain of C57BL/6 and 129Svev. The C57BL/6 strain was used for testing learning and memory. The 129Svev strain was used to for testing seizure propensity, duration and EEG abnormalities.
Results: We find that these specific phenotypes can be rescued with multiple strategies. Protein replacement with Adeno-Associated virus, dietary supplementation and

pharmacological intervention have all shown promise as potential therapeutic avenues.
Conclusions: There are multiple molecular sites for therapeutic intervention. It is likely that the AS phenotype can be overcome by multiple strategies due to the global effect of Ube3a deficiency and not a specific singular molecular problem. These associations have implications on future clinical trials and how the AS mouse may be used for further preclinical research.

125 **109.125** Behavioral and Electrophysiological Characterization of Children with 15q11.2-q13.3 Duplications

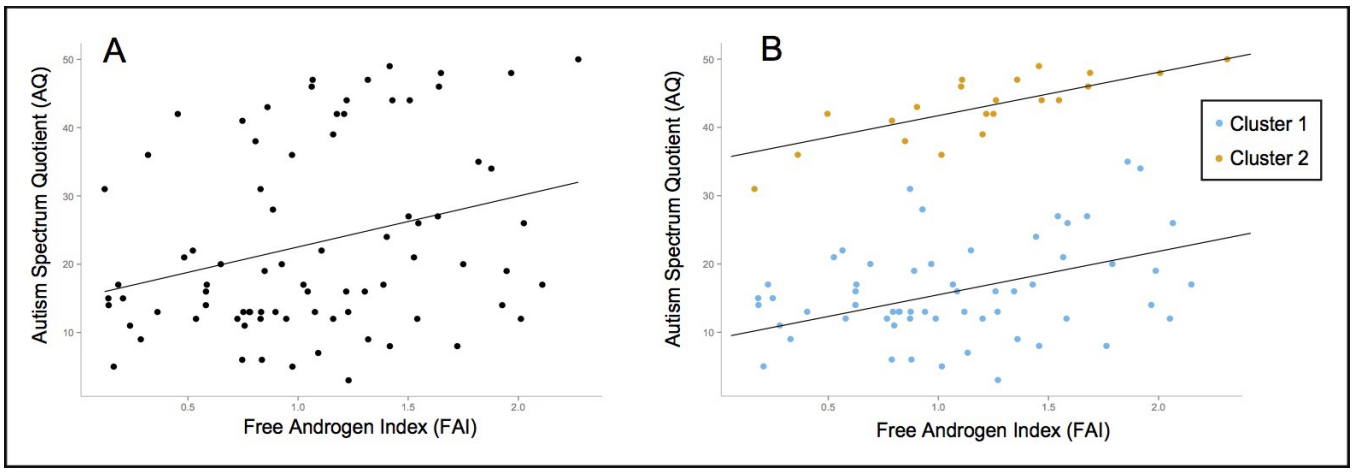
S. S. Jeste[1], *C. DiStefano*[2], *J. Frohlich*[1] *and P. Golshani*[3], *(1)Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (2)Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)Neurology, University of California, Los Angeles, Los Angeles, CA*

Background: The surge in genetic testing for chidlren with Autism Spectrum Disorder (ASD) has facilitated the identification of causative rare genetic variants and, with the ascertainment of subgroups of individuals with shared variants, the identification of clinically meaningful genetic syndromes (Jeste and Geschwind, 2014). Detailed developmental and behavioral characterization has lagged behind the genetic diagnoses, leaving considerable uncertainty regarding prognosis and recommended treatments. Duplication of 15q11.2-q13.3, or Dup15q syndrome, represents one of the most common copy number variants associated with ASD, and its clinical features, particularly in relation to ASD and intellectual disability, are being elucidated through collaborative efforts facilitated by a national Dup15q alliance.
Objectives: The first objective was to identify patterns of social communication, adaptive, and cognitive skills in children with Dup15q syndrome compared to those with nonsyndromic ASD. The second objective was to compare resting state EEG patterns in Dup15q syndrome with nonsyndromic ASD, as case reports have described excessive beta band power in clinical EEGs of these children.
Methods: The Dup15q Alliance has been collecting a registry of patients, with 425 patients in the registry and 212 with complete clinical records. From the registry, 142 children have isodicentric 15q duplications, 30 have interstitial duplications, 14 have mosaic isodicentric duplications, and 26 have “edge” duplications either at q11.2 or q13.3. We recruited 13 children from the UCLA Dup15q clinic and compared them to a 13 IQ and age matched cohort of children with ASD. Participants were assessed for verbal and non-verbal cognition, ASD characteristics [Autism Diagnostic Observation Schedule] and adaptive function [Vineland Adaptive Behavior Scales]. High density EEG was recorded while children watched an abstract video, with an additional TD comparison group also tested. Relative power in delta (1 – 4 Hz), theta (4 – 8 Hz), alpha (8 – 12 Hz), low beta (12 – 20 Hz), high beta (20 – 30 Hz), and gamma (30 – 48 Hz) was calculated. Group comparisons were performed between diagnostic groups: Dup15q and ASD, and within the Dup15q group based on duplication type and epilepsy status.
Results: All children with Dup15q syndrome met criteria for ASD, but severity scores were lower in children with Dup15q syndrome. Children with Dup15q syndrome demonstrated significantly more impairment in motor (Gross motor DQ: Dup15q M=35.38, ASD M=70.21; t=5.9, p<.001; Fine motor DQ: Dup15q M=30.03, ASD M=66.5; t=5.2, p<.001) and daily living skills (Dup15q M=53.18, ASD M=63.82; t=2.41, p=.03). Within the Dup15q group, children with epilpesy demonstrated significantly lower cognitive and adaptive function than those without epilepsy (p<0.01 for all measures). Relative beta power was significantly higher in Dup15q syndrome than in the TD ($p < 1.0 \cdot 10^{-4}$, FDR corrected) and ASD ($p < 1.0 \cdot 10^{-4}$, FDR corrected) groups.
Conclusions: We have identified behavioral and neurophysiological features that distinguish a genetically defined subgroup within the autism spectrum. Ongoing translational studies will link electrophysiological and behavioral phenotypes in mouse models to patients to facilitate the identification of the specific genetic mechanisms underlying the neurodevelopmental symptom profile in children with Dup15q syndrome.

126 **109.126** Bioavailable Testosterone Predicts Autistic Traits in Women with and without Autism

A. L. Pohl[1], *J. R. Lloyd*[2], *L. Ruta*[3], *B. Auyeung*[4] *and S. Baron-Cohen*[1], *(1)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (2)Computational and Biological Learning Lab, University of Cambridge, Cambridge, United Kingdom, (3)Institute of Clinical Physiology, National Research Council (CNR), Taormina, Italy, (4)University of Edinburgh, Edinburgh, United Kingdom*

Background: Individual differences in fetal testosterone levels predict individual differences in autistic traits, specific behaviors (such as eye-contact and language), and performance on specific cognitive tasks (such as those measuring theory of mind or attention to detail) related to autism. It is not yet known if testosterone levels in adults are related to autistic traits.
Objectives: To test whether bioavailable testosterone, estimated by the free androgen index (FAI), predicts autistic traits in adults, measured using the Autism Spectrum Quotient (AQ).
Methods:
We recruited two cohorts of adults with and without autism, and analyzed each cohort separately by sex. Cohort 1 comprised 164 individuals (28 females with an autism spectrum condition (autism), 55 control females, 32 males with autism, and 49 control males). Cohort 2 comprised 103 individuals (19 females with ASC, 26 control females, 44 males with autism, and 14 control males). We measured total testosterone and sex hormone binding globulin (SHBG) levels in serum, and calculated the ratio of total testosterone to SHBG to get the FAI. We tested whether FAI predicted total AQ scores using linear regression, finite mixture modeling, and Bayesian regression. We did not include diagnosis as a grouping variable, as the multifactorial inheritance of autism suggests no difference between diagnostic groups in response to a risk factor in the absence of gene-environment interaction. Instead, we used data-driven approaches to account for the bimodal distribution of AQ scores in our sample caused by including cases and controls.
Results: FAI predicted AQ only in females in a linear regression model (Cohort 1 females, $B_{FAI} = 7.445$, SE=2.780, $t = 2.68$, $p = 0.00903$) (Figure 1). However, we observed a multimodal distribution of error, as expected. To address this problem, we used finite mixture modeling, and found a significant relationship between FAI and AQ in Cohort 1 females, as well as two latent clusters that roughly, but not perfectly, correspond to the distribution of cases and controls in our sample ($B_{FAI} = 6.35$, SE = 1.43, $z = 5.90$, $p = 3.68 * 10^{-9}$) (Figure 1). To confirm this finding, we used probabilistic programming to encode a model that could account for possible latent clusters in our data without determining the number of clusters *a priori*. We performed Bayesian inference in our generative model using data from Cohorts 1 and 2. In females, data from Cohort 1 were consistent with frequentist results, and data from Cohort 2 confirmed a positive relationship between FAI and AQ, and the existence of latent structure not accurately accounted for by diagnostic labels in our data.
Conclusions:
Autistic traits in adults are predicted by bioavailable testosterone in females only. This result is consistent with the finding that testosterone administration lowers mind-reading ability in women (van Honk et al, 2011, *PNAS*). Furthermore, this study demonstrates the importance of choosing appropriate statistical models for regression when the data do not meet the assumption of being normally jointly distributed. This study further supports a role for testosterone in sex-differential autism risk.



127 **109.127** Compromised Neurite Morphology of Induced Pluripotent Stem Cell-Derived Neurons: Similar Patterns from Independent Non-Syndromic Autism Cases

V. Roman[1], *J. Kobolák*[2], *H. Avci*[2], *Z. Ábrahám*[3], *B. Hodoscsek*[3], *S. Berzsenyi*[3], *B. Koványi*[3], *P. Dezsõ*[3], *J. Nagy*[3], *A. Chandrasekaran*[2], *A. Ochalek*[4], *E. Varga*[2], *C. Nemes*[2], *I. Bock*[2], *K. Pentelényi*[5], *K. Németh*[6], *A. Balázs*[7], *J. Molnár*[5], *A. Dinnyés*[2], *G. Lévay*[8] *and B. Lendvai*[9], *(1)Neurodevelopmental Biology, Gedeon Richter Plc., Budapest, Hungary, (2)BioTalentum Ltd., Gödöllõ, Hungary, (3)Molecular Cell Biology, Gedeon Richter Plc., Budapest, Hungary, (4)Molecular Animal Biotechnology, Szent István University, Gödöllõ, Hungary, (5)Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary, (6)Autism Foundation, Budapest, Hungary,*

(7)Outpatient Clinic, Autism Foundation, Budapest, Hungary, (8)Cognitive Pharmacology, Gedeon Richter Plc., Budapest, Hungary, (9)Division of Pharmacology and Drug Safety, Gedeon Richter Plc., Budapest, Hungary

Background: Autism spectrum disorder (ASD) is a highly prevalent neurodevelopmental condition, yet without approved pharmacological treatment options for the core symptoms. This significant need for effective treatments has resulted in great efforts to find reliable preclinical models of the disorder. Human behavioral aspects of ASD seem to be overwhelmingly difficult to recapitulate in in vivo models, therefore the want for in vitro disease models with high translational value is huge.
Objectives: The aim of the present study was to establish a human-derived in vitro disease model of ASD using the induced pluripotent stem cell (iPSC) technology.
Methods: Blood samples of three subjects on the autism spectrum and two controls were taken after ethical approval and obtaining written informed consent. The diagnosis of subjects was confirmed with the Autism Diagnostic Observation Schedule and Autism Diagnostic Interview Revised. To exclude syndromic ASD forms, next generation sequencing was performed with TruSight Autism Rapid Capture Kit (Illumina) to analyse 103 ASD associated gene variations. Mononuclear cells were isolated from the blood samples and a non-integrating delivery system was used to overexpress the genes of reprogramming factors in the cells. Two to three clones per subject were selected for further differentiation among the reprogrammed clones. The iPSCs showed embryonic stem cell morphology, normal karyotype, expressed pluripotency markers, and were able to spontaneously differentiate into cells of the three germ layers. Then, iPSCs were differentiated into neuronal precursor cells and neurons by a dual-SMAD inhibition protocol. Neuronal differentiation was demonstrated by neuron specific immunolabelling for MAP2, detection of tetrodotoxin-sensitive sodium currents and bicuculline-sensitive chloride currents by using patch clamp, as well as live cell calcium imaging.
Results: iPSC-derived neuronal cell cultures were investigated in order to detect substantial phenotypical differences between neurons originated from autistic and neurotypical subjects. As ASD is widely accepted as a neurodevelopmental connectivity disorder, first neurite morphology of the cells was explored. According to the morphological parameters (measured by using an Operetta® High Content Imaging System; PerkinElmer), neuronal maturation was found significantly less pronounced in autistic samples. Investigation of further cell biological parameters is in progress.
Conclusions: Our findings support the approach that iPSC-derived neuronal cultures may serve as relevant in vitro models that can shed light on the pathophysiology of autism, help to identify novel biomarkers and/or therapeutic targets for the treatment of ASD as well as provide a platform for screening novel drug candidates.

128 **109.128** Disrupted Short- and Long-Range Neural Connectivity in a Mouse Model of Autism

N. Cheng[1], *F. Alshammari*[1], *M. Khanbabaei*[1], *E. Hughes*[1], *R. Tobias*[1], *K. Murari*[2] *and J. M. Rho*[1], *(1)Alberta Children's Hospital Research Institute, University of Calgary, Calgary, AB, Canada, (2)Electrical and Computer Engineering, University of Calgary, Calgary, AB, Canada*

Background:
Autism spectrum disorder (ASD) is characterized by deficits in socio-emotional functions and language development, as well as repetitive and/or restrictive behaviours. The behavioural domains that define ASD together with the vast heterogeneity of the clinical symptoms suggest that these deficits likely involve widely distributed neural systems. Accordingly, it has been proposed that ASD may represent a condition of disrupted connectivity. Neuroimaging studies have shown diffuse impairment in brain networks of ASD patients, including both focal deficits in specific brain regions and aberrant long-range connections. However, their cellular substrates and molecular underpinnings remain poorly understood.
Objectives:
We investigated the development of neural circuitry in the BTBR mouse model of autism, which displays all of the three defining behavioural features of ASD. First, we examined eye-specific segregation in the lateral geniculate nucleus (LGN), which is a model system to study how precise patterning of synaptic connections form and refine during development. Second, we investigated the development of dendritic arbors and neuronal densities of hippocampal pyramidal neurons, which integrate spatial, contextual, and emotional information and transmit it to various regions throughout the brain.
Methods:
We labelled retinal afferents from both eyes with an anterograde tracer conjugated with different fluorophores, and compared eye-specific segregation in the LGN between the BTBR and B6 animals, a strain commonly used as a control for the BTBR mice in ASD studies. Next, we used Golgi staining to reveal dendritic structure, and Nissl staining to measure neuronal density of hippocampal CA1 pyramidal neurons. Western blots were used to quantify relative expression levels of proteins known to regulate dendritic structure.
Results:
We found that in neonatal animals, the total area of dorsal LGN occupied by retinal afferents was more rounded in shape, and significantly smaller in size in the BTBR compared to B6 mice. Notably, the degree of overlap between the ipsi- and contralateral afferents was significantly greater in the BTBR mice. Moreover, these abnormalities continued into adulthood in the BTBR animals, suggesting persistent deficits rather than delayed maturation of axonal refinement. Further, we found that both total length and branching of the dendritic arbor were significantly greater in neonatal BTBR compared to B6 animals, while no differences were found in the density of CA1 pyramidal neurons or the thickness of the neuronal layer. A significant difference in the protein levels of ERK pathway, but not BDNF or S6 kinase signaling, was found between the two strains, indicating that altered ERK signaling may be involved in the dendritic changes observed in the BTBR model.
Conclusions:
Circuit formation and refinement were disrupted in the BTBR model of ASD, including both precise patterning of synaptic connections by long-range axonal projections and the development of dendritic arbor. Together, these results indicate disrupted connectivity at both local and long-distance levels in the BTBR model of autism, suggesting that such abnormalities could contribute to the overall impaired connectivity observed in ASD, and may ultimately contribute to the behavioural symptoms.

129 **109.129** Elucidating the Antigenic Epitopes in Maternal Autoantibody Related Autism Spectrum Disorder (ASD)

E. Edmiston[1], *J. Van de Water*[2] *and K. L. Jones*[3], *(1)Internal Medicine, UC Davis, Sacramento, CA, (2)University of California at Davis MIND Institute, Davis, CA, (3)University of California at Davis, Sacramento, CA*

Background:
Numerous researchers have described the presence of maternal autoantibodies reactive to fetal brain proteins in a subset of mothers of children with autism spectrum disorder (ASD). Our laboratory recently determined the identity of the autoantigens targeted by autoantibodies in maternal autoantibody related (MAR) ASD; we identified seven autoantigens: lactate dehydrogenase A and B (LDH-A, LDH-B), stress-induced phosphoprotein 1 (STIP1), collapsin response mediator proteins 1 and 2 (CRMP1, CRMP2), cypin, and Y-box binding protein 1(YBX1). A detailed understanding of the targeted epitopes on each autoantigen will be critical in dissecting the pathology associated with maternal autoantibodies.
Objectives:
The specific objective of this study was to elucidate and verify the immunodominant epitope sequences targeted by maternal autoantibodies for each of the MAR ASD autoantigens.
Methods:
The amino acid sequences of the candidate autoantigens were obtained from the NCBI protein database. Working in conjunction with PEPperPRINT© microarray solutions, each protein was translated into a peptide array composed of duplicate, overlapping peptide sequences, which were 15 amino acids long with a 14 amino acid peptide-peptide overlap. Two microarray schemes were synthesized: one microarray containing LDH-A, STIP1, and CRMP1 sequences, and the other comprising LDH-B, CRMP2, Cypin, and YBX1 sequences. Each array was incubated with maternal plasma samples obtained from the Childhood Autism Risk from Genetics and Environment (CHARGE) Study at UC-Davis, which were predetermined via western blot and ELISA to be highly reactive to the target proteins. Immunodominant epitopes were consequently verified using microarrays, which contained peptide sequences identified in the previous arrays. We ran 24 plasma samples from mothers of children with severe ASD status, 12 plasma samples from mothers of children with mild ASD, and 12 samples from mothers of TD controls. Diagnosis of all enrolled children was confirmed at the UC Davis M.I.N.D. Institute.
Results:
We successfully determined that the MAR ASD autoantibodies recognized unique, discrete peptide sequences on each target autoantigen. We further determined that there are 3 epitopes for LDH-A, 3 epitopes for LDH-B, 3 epitopes for STIP1, 1 epitope for cypin, 3 epitopes of YBX1, 4 epitopes for CRMP1, and 9 epitopes for CRMP 2. Overall, we have determined that autoantibodies from mothers of children with ASD reacted to more autoantigens and more epitopes per autoantigen than autoantibodies from mothers of typically developing children.
Conclusions:
The results of this project will enable the development of robust biomarkers for ASD risk assessment and subphenotype stratification. Additionally, we have used these peptide epitopes to break tolerance in a mouse model, which will help us to better understand how the maternal autoantibodies are interacting with the candidate autoantigens, thus providing insight into the pathologic mechanisms through which these antibodies alter developmental trajectory, and the critical pathways that may serve as a template for therapeutic intervention. Future experiments using a larger sample population will be performed to determine if maternal autoantibody reactivity to individual or combinations of peptides correlate with increased aberrant behaviors and/or increased cognitive and social deficits.

130 **109.130** Hyperexcitability in Stem Cell-Derived Neurons from Dup15q Autism and Angelman Syndrome Patients

J. Fink[1], *T. Robinson*[1], *S. Chamberlain*[2] *and E. Levine*[1], *(1)Dept Neuroscience, University of Connecticut Health Center, Farmington, CT, (2)Genetics and Genome Sciences, University of Connecticut Health Center, Farmington, CT*

Background: Individuals with a duplication of the 15q11-q13 chromosomal region suffer from a neurodevelopmental disorder known as Dup15q syndrome, which represents the most common copy number variant associated with autism. In addition to the autistic-like symptoms such as intellectual disability and language delay, >50% of Dup15q patients suffer from some form of seizure disorder. Similarly, patients with maternal deletion of the same chromosomal region present with Angelman syndrome (AS), a related neurodevelopmental disorder in which a majority of the patients also develop seizures at some point in their life. Although the genetic cause of Angelman syndrome has been identified as the UBE3A gene, the specific gene or set of genes directly responsible for the Dup15q phenotype remains less clear, though UBE3A is thought to play an important role in Dup15q pathophysiology. Even less clear are the downstream UBE3A targets that might mediate these disease phenotypes, though several synaptic targets have been reported.
Objectives: Given the seizure phenotype associated Dup15q and AS, we examined the excitability of neurons derived from these patients using induced pluripotent stem cell (iPSC) lines. Hyperexcitability can result from a variety of network and cell-intrinsic properties. For this reason we investigated resting membrane potential (RMP), spontaneous excitatory and inhibitory synaptic currents, and action potential (AP) firing in these cells.
Methods: *Cell Culture Preparation*: Induced pluripotent stem cells (iPSCs) were derived from fibroblasts obtained from two AS subjects (1M/1F), 3 control subjects (2M/1F), and 2 Dup15q patients (2F) and differentiated into neurons and plated onto coverslips as previously described (Germain et al. 2014). *Electrophysiology:* Coverslips were individually transferred to a recording chamber and continuously perfused with carboxygenated artificial cerebrospinal fluid. Whole-cell patch recordings were obtained from morphologically-identified neurons. Cells were noted for RMP by injection with zero current, AP firing by holding at -40 mV or applying 10mV current injection steps from -70mV, and spontaneous synaptic activity via a holding potential of -70 mV. *Calcium Imaging*: Coverslips of neurons were incubated in Fluo-4 AM (10 µM) calcium dye for 45 minutes. Cells were then placed in a recording chamber and imaged for 40 minutes at a frequency of 10 Hz.
Results: We have observed disruptions in the electrophysiological maturation of neurons derived from AS and Dup15q patients. Specifically, these neurons show depolarized RMPs, immature AP firing, and a reduction in spontaneous synaptic activity. Additionally, neurons derived from Dup15q patients displayed significant increases in spontaneous AP firing at -40 mV as well as increased network synchrony.
Conclusions: Overall, data collected from both AS and Dup15q patients show significant differences compared to control subjects in a variety of electrophysiological properties throughout their development. These specific differences may contribute to hyperexcitability of these cells, a phenotype that could relate to the seizures associated with both AS and Dup15q syndrome. Therefore, these approaches may prove useful for identifying novel targets for drug discovery and for screening potential therapeutics aimed at reversing the seizures, movement disorders, and language and cognitive impairments in these patients.

131 **109.131** Identification of Serum Protein Biomarkers for Autism Spectrum Disorder

L. Hewitson[1], *S. Singh*[2], *U. Yazdani*[2], *B. Gadad*[2], *S. Zaman*[2], *N. Roatch*[1], *C. Schutte*[1], *L. S. Hynan*[3], *C. N. Marti*[4] *and D. C. German*[2], *(1)The Johnson Center for Child Health and Development, Austin, TX, (2)UT Southwestern Medical Center, Dallas, TX, (3)Clinical Sciences (Biostatistics) and Psychiatry, UT Southwestern Medical Center, Dallas, TX, (4)Abacist Analytics, Austin, TX*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication and social interaction, and restricted, repetitive patterns of behavior, interests or activities. Given the lack of specific pharmacological therapy for ASD and the clinical heterogeneity of the disease, current biomarker research efforts are geared mainly toward identification of markers for determining ASD risk or for assisting with earlier diagnosis. A wide range of putative biological markers for ASD are currently being investigated, including biomarkers pertaining to the genetic, epigenetic, transcriptomic, proteomic, and metabolomic levels. Proteomic analyses have indicated that the levels of many proteins in blood are altered in ASD suggesting that a panel of serum proteins may provide a possible biomarker for ASD.
Objectives: The aim of this study was to compare the levels of proteins in serum samples from 2-8 year old boys with and without ASD in order to identify possible early biological markers for ASD.
Methods: Subjects included 30 boys with ASD (mean age 5.47, SD 1.73 years) and 30 age-matched, typically developing (TD) controls (mean age 5.37, SD 1.75 years). ASD subjects underwent a diagnostic assessment using the ADOS and ADI-R. Clinical diagnosis was made based on these assessments and overall clinical impression using DSM-IV criteria. Only subjects with a diagnosis of Autistic Disorder were included. Controls were screened with the ABAS-II. To identify blood biomarkers of ASD we used the Myriad Rules Based Medicine (RBM) DiscoveryMAP to simultaneously measure a large number of proteins by multi-analyte profiling. Validation of two proteins identified from the Myriad RBM platform were subsequently performed on the MesoScales Discovery platform. Protein levels were subsequently regressed on each of the ADOS subdomain scores to determine whether they were related to a clinical measure of ASD.
Results: There were 11 proteins, 7 of which were significantly different between the two groups (p<0.05), which collectively predicted ASD vs. TD samples. Cross-validation of two proteins, thyroid stimulating hormone (TSH) and interleukin-8 (IL-8), was performed on 43 ASD boys (mean age 5.08, SD 1.77 years) and 37 TD boys (mean age 5.09, SD 1.86 years) for TSH, and 36 ASD boys (mean age 5.46, SD 1.61 years) and 35 TD boys (mean age 5.69, SD 1.94 years) for IL-8. TSH levels were 30% lower in ASD boys whereas IL-8 levels were 16% higher in ASD boys. When combining the levels of TSH and IL-8 to predict ASD, the predictive accuracy was 82%. Three ADOS subdomains exhibited a significant negative effect whereby higher scores in the subdomains (i.e. more ASD symptoms) were associated with lower levels of TSH: social interaction (z=-2.61, p=0.009), communication + social interaction (z =-2.12, p=0.034), and stereotyped behavior and restrictive interests (SBRI) (z=-2.28, p= 0.023). There was not a significant relationship between TSH and the ADOS communication subdomain, or IL-8 and any of the ADOS subdomain scores.
Conclusions: These data suggest that a panel of serum proteins can be useful as a blood biomarker for ASD in boys.

132 **109.132** Innate Versus Adaptive Immune Response Pathways in Peripheral Blood from ASD Children with Ileocolonic Inflammation

S. J. Walker[1] *and A. Krigsman*[2], *(1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Far Rockaway, NY*

Background:
Gastrointestinal symptoms are a common co-occurring medical issue in ASD children. GI mucosal inflammatory infiltrates of both the small and large intestine have been noted in the setting of GI-symptomatic ASD and represent a potential etiology for many of the observed GI symptoms. Anecdotal and published reports of behavioral and cognitive improvement upon treatment of ASD-associated GI inflammatory disease supports the plausibility of a GI association for at least some of ASD behavioral and cognitive symptoms. We have previously described unique GI mucosal biomarkers specific for ASD-associated ileocolitis. It is not yet known whether these unique biomarkers are also present in the blood of these children. Identification of a validated blood-based biomarker of ASD-associated ileocolitis would allow for earlier identification of co-morbid GI disease and earlier GI intervention in affected patients. Moreover, it would provide insight into the relevant genes and biologic pathways in ASD-ileocolitis.
Objectives:
The goal of these studies is to evaluate blood-based gene expression In GI-symptomatic ASD children with demonstrated histologic ileocolitis to identify the genes and biological pathways most affected.
Methods:
The study cohort was comprised of whole blood from 22 ASD children undergoing clinically-indicated ileocolonoscopy for chronic GI symptoms, and 24 non-ASD (typically developing, TD) children undergoing ileocolonoscopy for a variety of GI symptoms. All ASD children had histologic inflammation of the ileum, colon, or both. The TD “controls” used for this study were selected based on absence of histologic inflammation anywhere in the GI tract and absence of a neurodevelopmental disorder. Differential gene expression in peripheral blood from ASD children (with ileocolitis) compared to TD children (without ileocolitis) was examined to identify differentially expressed transcripts that may serve as a proxy for GI inflammation.
Results:
We reported in an earlier study (Walker *et al*., PlosOne, 2013) that inflamed ileocolonic biopsy tissue from GI-symptomatic ASD children has a gene expression profile that overlaps with known inflammatory bowel disease. These earlier findings were apparent in inflamed ileocolonic mucosal tissue in this second cohort as well. In addition, we found that there is significant differential gene expression in peripheral blood of children with ASD and ileocolitis compared to TD children without GI inflammation. Two key immune-related pathways that were up-regulated in the blood of ASD cases are B cell receptor signaling and the Wnt signaling pathway, both important components of the *adaptive* immune response. In contrast, some of the key biological pathways that are coordinately down-regulated in the blood of the ASD (with inflammation) group are NOD-like receptor signaling, hematopoietic cell lineage, and Toll-like receptor signaling. Each of these pathways is important for pathogen recognition and for generating the host *innate* immune response.
Conclusions:
Gene expression in peripheral blood from ASD children with ileocolitis reveals a down-regulation of the host defense mechanism (innate immune response) together with an up-regulation of pathways that constitute the adaptive immune response, a pattern seen in other inflammatory bowel diseases. Studies are ongoing to validate these findings in additional samples.

133 **109.133** Non-Coding RNAs in Autism

ABSTRACT WITHDRAWN

Background: The human genome mostly consists of DNA that does not encode for protein. Although originally thought to represent evolutionary ‘junk,’ it has been shown

that much of the non-coding DNA in the human genome is actively transcribed to RNA in a highly regulated, tissue-specific manner.
Objectives: Following this insight, non-coding RNAs (ncRNAs) were demonstrated to be fundamental to many intracellular processes, such as targeting transcription factors to their binding sites, initiating chromatin remodeling, blocking transcription or translation of other genes both in cis and trans, and a variety of other functions that are still being uncovered. Perhaps not surprisingly, studies quickly followed showing that disruption of ncRNA biogenesis can lead to molecular and cellular defects.
Methods: Recently, ncRNAs have been demonstrated to be abnormal in the brains of patients with common neurodevelopmental disorders and their animal models, such as autism, schizophrenia, and bipolar disorder. These diseases were previously known to have a significant hereditary component, but their genomic etiology is complex and has remained poorly understood.
Results: Emerging research into underlying ncRNA problems in these disorders has the potential to reconcile their known heritability with their genomic and phenotypic heterogeneity, and hopefully unveil novel genomic pathologic mechanisms that can ultimately lead to new molecular therapeutics. In this presentation, we will present a broad overview of previous findings from our laboratory and others that have implicated long non-coding RNAs and short non-coding RNAs (such as microRNAs) in idiopathic autism.
Conclusions:
We will also present new work investigating non-coding RNAs expressed from the mitochondrial genome that appear altered in autistic brain.
Note: MNZ is an 'early career investigator' as defined by IMFAR

134 **109.134** Noncoding RNAs and Autism: The Impact of Employing Integrated Approaches

***Z. Talebizadeh**, Children's Mercy Hospital, Kansas City, MO*

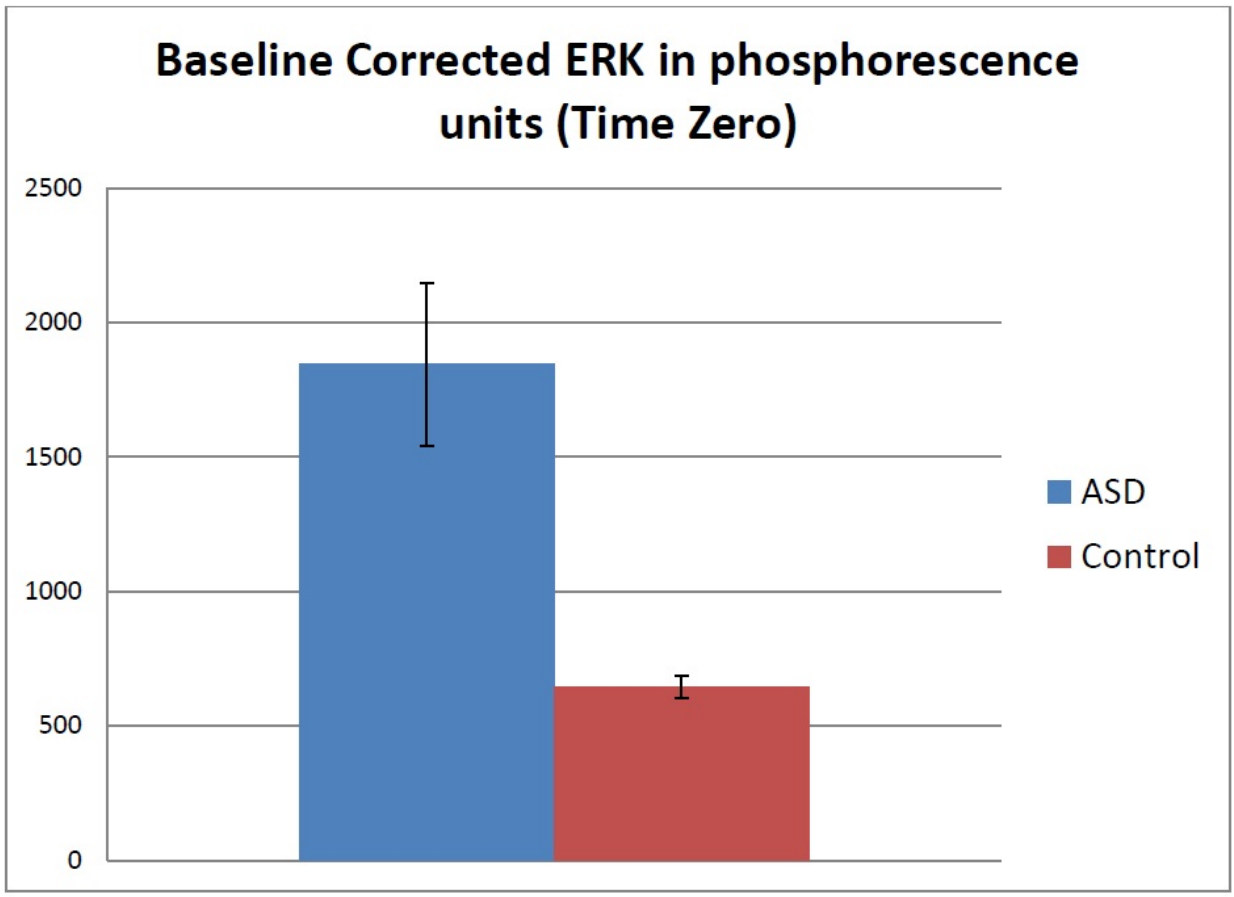
Background:
The field of noncoding RNAs (ncRNAs) is perhaps still in its infancy. However, because of the fascinating concept that they represent, regulation of gene expression, ncRNAs have become a topic of intense interest in understanding the underlying mechanism of human diseases. ncRNAs do not code for protein, but because of their influence on gene expression they may provide the key to uncover missing links in understanding the etiology of complex human diseases. Despite growing line of evidence indicating the essential role of ncRNAs in the brain function, they have been understudied in autism spectrum disorders (ASD).
Objectives: Among the main challenges in identifying causative genes for ASD are the extensive heterogeneity in the presentation of ASD and gene-environment interactions. Some of the undetected disease-causing mutations may alter gene regulation, whereas the candidate gene's genomic sequence remains intact. To address this critical gap, the existing and ongoing large-scale autism genetic sequencing and expression data need to be also analyzed with respect to assessing the gene regulatory factors.
Methods: Integrated approaches (i.e., utilizing two or more phenotypic and genetic/epigenetic factors as well as bioinformatics and data mining pipelines) would be beneficial in detecting biologically relevant and replicated findings that move the autism field forward.
Results: We highlight findings derived from a few integrative approaches, which had resulted in promising discoveries and provided practical examples of how uncovering genetic causes of autism may be accelerated.
Conclusions: The selected examples describe integrating different layers of genetic factors, including ncRNAs, thereby connecting the dots, which is expected to lead to the construction of autism-specific system biology networks (i.e., autism interactomes).

135 **109.135** Peripheral Lymphocytic Extracellular Signal Related Kinase Activation in Young Children with Autism Spectrum Disorder

***K. C. Dominick**[1], R. Shaffer[2], A. Duncan[1], C. L. Thomas[1], K. O'Brien[1], H. Meyer[1], L. K. Wink[3], E. Pedapati[4], C. R. Tessier[5] and C. Erickson[1], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Harrison, OH, (3)Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)INSAR Cincinnati Children's Hospital Medical Center, cincinnati, OH, (5)Indiana University School of Medicine - South Bend, South Bend, IN*

Background: Given the phenotypic variability within autism spectrum disorder (ASD), peripheral blood biomarker development offers the potential to objectively predict and measure treatment response. Additionally, peripheral biomarkers may aid early diagnosis and potentially predict disease severity. Biomarker development in ASD has been met with limited success to date. Recently, biomarker development has focused on looking at central points of cellular signaling and activity such as the extracellular signal-related kinase (ERK) signaling cascade. The ERK cascade plays critical roles in brain development, learning, and memory and has been linked with many neurogenetic disorders associated with ASD, including FXS, TS and neurofibromatosis.
Objectives: The purpose of this study was to examine ERK activation in peripheral lymphocytes in young children with ASD, aged 3 to 5 years old compared to age- and gender-matched neurotypical controls.
Methods: ASD diagnosis was based upon clinical interview with the Autism Diagnostic Observation Schedule completed by a research reliable examiner along with a score greater than or equal to 15 on the Social Communication Questionnaire (SCQ). Additional ASD subject characterization was done using the Aberrant Behavior Checklist (ABC), Social Responsiveness Scale (SRS) and Vineland Adaptive Behavior Scales. Participants with ASD had stable psychotropic drug dosing. Diagnosis of schizophrenia, another psychotic disorder, bipolar disorder, or alcohol or other substance abuse based on DSM-V criteria was exclusionary. Participants completed an extracellular signal-regulated kinase (ERK) activation assay administered at baseline and 8-12 weeks later to provide test-retest data. Neurotypical control subjects participated in baseline blood testing only to limit subject burden. ERK lymphocyte activation assays were completed by flow cytometry blind to participant diagnosis. Comparisons include baseline ERK activation (phosphorylation) and time to half maximum ERK phosphorylation following phorbol myristate acetate stimulation.
Results: There were 15 children in each group (4 female). Groups were matched for age with a mean ages of 4.5 and 4.2 in the ASD and control groups respectively ($p=0.26$). Groups were not matched on IQ with the children with ASD having a significantly lower IQ. Children with ASD had a significantly higher baseline ERK activation as compared to the control group ($p=0.037$). The time to half-maximum phosphorylation did not differ between groups (ASD M=5.67 minutes *s.d.*=0.84, Control M=5.87 *s.d.*=0.84 minutes, $p=0.662$).
Conclusions: ERK is a promising potential biomarker for ASD in young children. Further work is needed to fully understand how it may serve to aid in monitoring of treatment response or early identification.

Table 1: Group characteristics, ERK activation levels and time to half maximum ERK activation.			
	ASD	**Control**	**Paired t test**
Age	4.51 +/- 0.81 years	4.20 +/- 0.78 years	P=0.26
SCQ Score	21.53 +/- 5.94	4.64 +/- 4.43	P < 0.0001
IQ	58.88 +/- 23.48	102.09 +/- 9.19	P<0.0001
Corrected ERK in phosphorescence units at baseline (Time Zero)	**1844.87 +/- 1166.07**	**645.23 +/- 166.60**	**P=0.037**
Time to half maximum ERK activation following phorbol myristate acetate stimulation	5.67 +/- 1.23 minutes	5.87 +/- 0.84 minutes	P=0.662



136 **109.136** Reversing the Behavioral Phenotypes in fmr1 KO By the Reduction of Potassium Channel, Kv4.2

H. Y. Lee *and L. Jan, UCSF, SF, CA*

Background: Fragile X syndrome (FXS) is a common form of mental disability and one of the known causes of autism. The mutation responsible for FXS is a large expansion of the trinucleotide CGG repeats that leads to DNA methylation of the fragile X mental retardation gene 1 (FMR1) and transcriptional silencing, resulting in the absence of fragile X mental retardation protein (FMRP), an mRNA binding protein. Although it is widely known that FMRP is critical for metabotropic glutamate receptor (mGluR)-dependent long-term depression (LTD), which has provided a general theme for developing pharmacological drugs for FXS, specific downstream targets of FMRP may also be of therapeutic value. We reported dendritic localization of mRNA of Kv4.2 voltage- gated potassium channel, which regulates synaptic plasticity, and its local translational regulation by FMRP. FMRP suppression of Kv4.2 is revealed by elevation of Kv4.2 in neurons from fmr1 KO mice. Moreover, treating hippocampal slices from fmr1 KO mice with Kv4 channel blocker restores long-term potentiation (LTP) induced by moderate stimuli.
Objectives: We reported dendritic localization of mRNA of Kv4.2 voltage- gated potassium channel, which regulates synaptic plasticity, and its local translational regulation by FMRP. FMRP suppression of Kv4.2 is revealed by elevation of Kv4.2 in neurons from fmr1 KO mice. Moreover, treating hippocampal slices from fmr1 KO mice with Kv4 channel blocker restores long-term potentiation (LTP) induced by moderate stimuli.
Methods: To test the effect of Kv4.2 levels in FXS, we generated fmr1 mutant mice with a 50 % reduction in Kv4.2 expression and studied a range of phenotypes with relevance to the human disorders.
Results: We found that Kv4.2 reduction in fmr1 KO mice reverses the altered repetitive and perseverative phenotype of fmr1 KO mice. We also found Kv4.2 reduction rescues the deficit in social behaviors.
Conclusions: Our results demonstrate that Kv4.2 contributes significantly to the pathogenesis of the disease, a finding that has significant therapeutic implications for FXS.

137 **109.137** Sexual Dimorphism of Regulatory Small Non-Coding RNA in the Superior Temporal Gyrus Brain Region of Autism Spectrum Disorders: A Pilot Study

B. Stamova[1], *B. P. Ander*[2], *F. R. Sharp*[3] *and C. M. Schumann*[1], *(1)UC Davis MIND Institute, Sacramento, CA, (2)Department of Neurology, UC Davis MIND Institute, Sacramento, CA, (3)University of California at Davis, Sacramento, CA*

Background: Autism spectrum disorders (ASD) are more common in boys than girls. The bases for sex differences in ASD are poorly understood. It is theorized that higher etiologic load, including genetic and/or environmental load, is needed for females to develop ASD. Though sex differences in ASD neuropathology have been reported, sex differences in ASD brain transcriptomes remain largely unexplored. Male and female ASD subjects could have different molecular mechanisms for normal regional patterning in the brain which could contribute to sex differences in ASD. Thus, we investigated differential expression of small non-coding RNAs (sncRNA, including microRNA) in the superior temporal gyrus (STG) of male and female brains of ASD compared to typically developing (TD) controls. We investigated the superior temporal sulcus (STS) and primary auditory cortex (PAC) within the STG. STS is an association cortex involved in social perception, joint attention, face perception and speech perception and is implicated in ASD. PAC is a primary sensory cortex modulating auditory processing.
Objectives: To assess sncRNA expression in STS and PAC in postmortem male and female human brains of ASD compared to TD controls.
Methods: Affymetrix miRNA 3.0 arrays were run on 34 samples (5 ASD Female, 5 ASD Male, 2 TD Female, 6 TD Male; two brain regions – STS, PAC; 4-58 years of age; two of the 18 subjects had only one brain region available). ANOVA was used to identify sexually dimorphic differentially expressed sncRNA ($p<0.005$, $|\text{fold-change}|>1.2$). REML variance estimate suitable for unbalanced designs was used. To account for normal sexual dimorphism, we compared ASD female to TD female and ASD male to TD male, and overlapped the differentially expressed sncRNA to identify sexually dimorphic sncRNA expression specifically in ASD (Fig.1).
Results: We found sexually dimorphic sncRNA expression in the ASD postmortem brain, with a higher number of sncRNA being dysregulated in females compared to males (Fig.1). There were 27 sexually dimorphic sncRNA in ASD STS (7 in male and 20 in female), 9 in ASD PAC (2 in male, 7 in female), and 71 regionally dysregulated (between STS and PAC) (31 in male, 39 in female, and 2 common) (Fig. 2). The predicted mRNA targets of the mature miRNAs are over-represented in different pathways in male and female in STS and PAC. Axonal Guidance Signaling was the most over-represented canonical pathway in the regionally dysregulated (STS vs PAC) mature miRNAs both in male (FDR-corrected p=3.1E-12) and female (FDR-corrected p=2.4E-09). However, most of the predicted dysregulated target mRNAs were different in males compared to females. A number of predicted targets have been implicated in ASD, such as MET (in female), NTRK3 (in male), and SHANK2 (in both).
Conclusions: The sexually dimorphic sncRNAs in male and female ASD brains likely contribute to aberrant development and function of STS and PAC and likely contribute to some of the sexually dimorphic features of ASD. Future studies will need to confirm these findings.

138 **109.138** Syntaxin Binding Protein 5 Regulates Neurite Differentiation in an Autism-Related Model

W. Shen*, J. A. Frei and Y. C. Lin, Laboratory of Neuronal Connectivity, Hussman Institute for Autism, Baltimore, MD*

Background:
Autism is a neurological condition that features marked qualitative differences in communication and social interaction. It has been estimated that as many as 1/3 of individuals with autism spectrum condition also have epilepsy. Consistent with the extremely heterogeneous presentation of autism, genetic studies have implicated numerous genes that may contribute to the autism phenotype. Deletion and mutations of syntaxin binding protein 5 (*STXBP5*, also known as tomosyn) are identified in association with autism and epilepsy. *STXBP5* contains three distinct domains: C-terminal region containing an R-SNARE, synaptobrevin-like coiled-coil domain, and an N-terminal region enriched with WD40 repeats. *STXBP5* has a presynaptic role that negatively regulates neurotransmitter release by forming syntaxin-SNAP25-tomosyn complex. *STXBP5* is also detected in the postsynaptic domain in cerebellum. However, the postsynaptic role of *STXBP5* has not been well elucidated. Interestingly, WD40 as scaffolding domains, interact with diverse proteins, peptides or nucleic acids using multiple surfaces. It has been found that *STXBP5* is homologous to the L(2)gl, which is instrumental in establishing cell polarity. Therefore, we hypothesize that *STXBP5* may be involved in regulating cell growth and differentiation.
Objectives:
To knock down *STXBP5* and generate mutations of *STXBP5* in cell lines and primary mouse neurons to reveal the postsynaptic function of *STXBP5* and determine how mutations of *STXBP5* found in autism may contribute to the phenotype.
Methods:
Several shRNAs were created to knock down murine *STXBP5*. Knockdown efficiency is determined by Western blot analysis and the most efficient one is selected to knock down *STXBP5* in Neuro-2A cells. We use retinoic acid (RA) to induce Neuro-2A differentiation and determine whether *STXBP5* plays a role in this process. Neurite outgrowth is measured by live cell imaging with IncuCyte. We also use a mutagenesis method to generate several *STXBP5* mutations that are found in individuals with autism. Ongoing experiments are using primary neuron cultures as a model system to investigate the function of *STXBP5* for synapse and dendrite stability.
Results:
RA-induced Neuro-2A cells exhibit a characteristic bipolar-like shape, suggesting retinoic acid stimulates neurite outgrowth. shRNA of *STXBP5* shows 57% knockdown efficiency in Neuro-2A cells. Suppression of *STXBP5* by shRNA remarkably inhibits neurite outgrowth induced by retinoic acid.
Conclusions:
STXBP5 plays a role in regulating neurite outgrowth. Mutations of *STXBP5* found in individuals with autism may play a key role in altering neuronal differentiation including neurite outgrowth potentially disrupting normal developmental processes.

139 **109.139** Transcriptional Profiling of Human Neural Differentiation Implicates Noncoding RNA and ASD-Associated Genes

P. Hecht[1], *D. B. Campbell*[1], *N. A. Grepo*[2] *and J. A. Knowles*[1], *(1)University of Southern California, Los Angeles, CA, (2)USC, LOS ANGELES, CA*

Background: Increasing evidence suggests that noncoding RNAs hold diverse functions in various cellular processes and alterations in their expression may contribute to the etiology of several neuropsychiatric conditions, including autism spectrum disorder. Despite being abundantly expressed in the brain, the functional properties of these non-protein coding RNAs in human neuronal cells remains largely unknown. Exploring the complete transcriptional profile of human neurons may uncover gene networks underlying complex human disorders and may identify the noncoding RNAs possibly regulating these networks.
Objectives: The present study aimed to identify the transcriptional landscape of two human neural progenitor cell lines as they differentiate into human cortical projection neurons.
Methods: The human neural progenitor cell lines, SK-N-SH and ReNcell CX, were used to measure gene expression as they undergo differentiation. Cells were harvested at two stages of differentiation and RNA sequencing was performed to explore the transcriptional landscape of these cells. Differential expression analysis and weighted gene co-expression network analysis (WGCNA) was performed to identify genes showing altered expression and to infer the functional properties of noncoding RNAs through their co-expressed genes.
Results: Protein coding genes were found to account for 54.8% and 57.0% of expressed genes in SK-N-SH and ReNcell CX cells, respectively, and alignment of RNA sequencing reads revealed that only 25.5-28.1% mapped to exonic regions of the genome. Differential expression analysis in the two cell lines identified altered gene expression in both protein coding and noncoding RNAs as they undergo neural differentiation with 222 differentially expressed genes observed in SK-N-SH cells and 19 differentially expressed genes in ReNcell CX. Interestingly, genes showing differential expression in SK-N-SH cells are enriched in genes implicated in autism spectrum disorder, but not in gene sets related to cancer or Alzheimer's disease. Weighted gene co-expression network analysis (WGCNA) was used to detect modules of co-expressed protein coding and noncoding RNAs in SK-N-SH cells and found four modules to be associated with neural differentiation. These modules contain varying levels of noncoding RNAs ranging from 10.7% to 49.7% with gene ontology suggesting roles in numerous cellular processes important for differentiation.
Conclusions: These results indicate that noncoding RNAs are highly expressed in human neural progenitor cells and likely hold key regulatory roles in gene networks underlying neural differentiation and neurodevelopmental disorders, such as autism spectrum disorder.

140 **109.140** Urinary Metabolomics of Young Italian Autistic Children Supports Abnormal Tryptophan and Purine Metabolism

F. Gevi[1], ***S. Gabriele***[2], *L. Zolla*[1] *and A. M. M. Persico*[3,4], *(1)Department of Ecological and Biological Sciences, University of Tuscia, Viterbo, Italy, (2)Child & Adolescent Neuropsychiatry Unit, Lab of Molecular Psychiatry and Neurogenetics, University Campus Bio-Medico of Rome, Rome, Italy, (3)Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy, (4)Child and Adolescent Neuropsychiatry Unit, Lab of Molecular Psychiatry and Neurogenics, University Campus Bio-Medico, Rome, Italy*

Background: Autism Spectrum Disorder (ASD) is still diagnosed through behavioral observation, due to a lack of biomarkers, which could instead greatly aid clinicians in providing earlier diagnoses, more timely referrals to behavioral intervention programs and evidence-based prognostic predictions. Metabolomic technologies offer a sensitive means to search human biofluids for metabolite profiles potentially usable as biomarkers for ASD. Initial metabolomic studies, analyzing urines and plasma of ASD and control individuals, suggested that autistic patients may share some metabolic abnormalities, despite several inconsistencies stemming from differences in technology, ethnicity, age range, and definition of "control" status.
Objectives: Our study aims to detect differences in urinary metabolic patterns between tightly matched young autistic and typically developing children previously shown to differ in urinary *p*-cresol levels (Altieri et al., 2011) by applying a highly sensitive, accurate and unbiased approach suitable to ensure broad metabolite detection coverage on human urine.
Methods: ASD-specific urinary metabolomic patterns were explored at an early age in 30 ASD children and 30 controls tightly matched by age, sex, Italian ancestry and city of origin within the country (age range 2-7, M:F=22:8) using hydrophilic interaction chromatography (HILIC)-UHPLC-MS. Metabolites were then subjected to multivariate statistical analysis (MetaboAnalyst 3.0 software) and grouped by metabolic pathway.

Results: Urinary metabolites displaying the largest differences between young ASD and control children belong to the tryptophan and purine metabolic pathways. Also vitamin B6, riboflavin, phenylalanine-tyrosine-tryptophan biosynthesis, pantothenate and CoA, and pyrimidine metabolism differ significantly. ASD children preferentially transform tryptophan into xanthurenic acid and quinolinic acid (two catabolites of the kynurenine pathway), at the expense of kynurenic acid and especially of melatonin. Also the gut microbiome contributes to altered tryptophan metabolism, yielding increased levels of indolyl 3-acetic acid and indolyl lactate.
Conclusions: The metabolic pathways most distinctive of young Italian autistic children largely overlap with those found in rodent models of ASD following maternal immune activation or genetic manipulations. These results are consistent with the proposal of a purine-driven Cell Danger Response, accompanied by overproduction of epileptogenic and excitotoxic quinolinic acid, large reductions in melatonin synthesis, and gut dysbiosis. These metabolic abnormalities could conceivably underlie some comorbidities frequently associated with ASD, such as seizures, sleep disorders, and gastrointestinal symptoms, and could contribute to autism severity. Their diagnostic sensitivity, disease-specificity and interethnic variability merit further investigation.

141 **109.141** Using iPSCs to Study Pathobiology and Drug Targets for Phelan-Mcdermid Syndrome

A. Browne[1], *E. Drapeau*[2] *and J. D. Buxbaum*[3], *(1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Icahn School of Medicine at Mount Sinai, Long Island City, NY, (3)Psychiatry, Seaver Autism Center at Mount Sinai, New York, NY*

Background:
Autism spectrum disorder (ASD) has high heritability and a prevalence of ca. 1% worldwide, but heterogeneity has made identifying the underlying pathobiology difficult. By focusing on genetic disorders with high penetrance for causing ASD, common pathobiological pathways might be identified. Phelan-McDermid syndrome (PMS) is one such genetic ASD-associated syndrome, where the neurobehavioral changes are caused by haploinsufficiency of the gene *SHANK3*, which encodes for a scaffolding protein of the post-synaptic density of glutamatergic synapses. While animal models provide great insight into the pathways involved in PMS, some features of the disease may not be captured because of neuronal variation across species. One approach to deal with this shortcoming is to generate induced pluripotent stem cells (iPSCs) from patients that can then be differentiated into neural progenitor cells (NPCs) and neurons.
Objectives:
Results from a recent study indicate that iPSC-derived neurons from PMS patients show excitatory synaptic deficits similar to those seen in animal models. This provides further support for our hypothesis that expression analysis from such cells can provide valuable insight into the underlying pathobiology and can be mapped to the expression profiles of FDA-approved drugs to identify candidates for repositioning as novel PMS therapeutics. Therefore, we aim to 1) generate high-quality iPSC clones from PMS patients and siblings; 2) differentiate them into neurons that capture the neurobiological phenotype of PMS in patients; 3) identify PMS-associated differential gene expression in iPSC-derived neurons by RNA sequencing; and, 4) identify candidate drugs by comparing gene expression patterns for FDA-approved drugs with PMS-associated expression.
Methods:
Blood samples from patients with PMS and unaffected siblings have been collected for 14 patient/sibling pairs and are being reprogrammed using a non-integrating virus to express reprogramming factors. Three clones are selected for each patient after quality control (QC). Clones are then transfected with lentiviruses carrying vectors to induce expression of NGN2 under the control of doxycycline, followed by puromycin selection. Astrocytes are added at day 2 to support synapse formation, and after 3 weeks, cells are harvested and processed for RNA isolation, followed by RNA sequencing. The PMS-associated changes in gene expression are then analyzed to understand the underlying neurobiology, and compared to known gene expression profiles of FDA-approved drugs and used to identify candidate PMS therapeutics based on anti-correlation between disease and drug gene expression.
Results:
Ten patient/sibling pairs have been reprogrammed and high quality clones have been obtained after QC, while the remaining 4 patient/sibling pairs are currently being reprogrammed. NPC generation and neuronal induction has been performed on clones as they finish QC testing. Studies making use of Axion high-throughput Microelectrode arrays are being piloted as a means of high throughput electrophysiological analyses.
Conclusions:
iPSCs from PMS patients offer a powerful tool for disease characterization, drug identification, and screening. Generating an expression profile for these patient-derived neurons will provide a unique perspective on the transcriptional signature of PMS that can be used to understand neurobiology and, in conjunction with other models of the disease and known drug expression profiles, to identify new therapeutics.Background: Autism spectrum disorder (ASD) has high heritability and a prevalence of ca. 1% worldwide, but heterogeneity has made identifying the underlying pathobiology difficult. By focusing on genetic disorders with high penetrance for causing ASD, common pathobiological pathways might be identified. 11:30 AM - 1:30 PM - Hall A

142 **110.142** A Dynamic Systems Approach to Emotion Coregulation in Families of Children with Autism Spectrum Disorders and Families of Typically Developing Children

Y. Guo[1], *W. A. Goldberg*[1], *D. R. Garfin*[1] *and A. R. Ly*[2], *(1)University of California Irvine, Irvine, CA, (2)University of Delaware, Newark, DE*

Background: Parent-child coregulation lays the foundation for the development of adaptive skills and future self-regulation in child. Emotional dysregulation is one of core symptoms in children with autism. Previous research on Autism Spectrum Disorders (ASD) has focused primarily on children's ability to recognize and describe emotional experiences. Little is known about role of the dynamic interplay between parents and their young children with ASD in emotion regulation. Impaired emotional regulation may hallmark behavioral rigidity in ASD. However, there is no study examining dyadic flexibility which indicates dyad's ability to shift emotional states.
Objectives: To compare moment-to-moment processes of emotion coregulation between dyads of mother-child with ASD and dyads of mother-typically developing (TD) child in terms of dyadic flexibility and emotional content using a dynamic systems method.
Methods: Seventy-four dyads of mothers and children (47 ASD dyads and 27 TD dyads) participated in a 10-minute Three Boxes procedure at home. An original coding scheme was developed to evaluate positive engagement, negative engagement, and disengagement in dyadic mother-child interaction every five-second intervals using Mangold International's INTERACT 9.47 software. Inter-coder reliability for child and mother engagement was 91.07% (k = .82) and 91.76% (k = .81). The observation data were imported into the State Space Grid (SSG) software to operationalize dyadic *flexibility* indicated by *dispersion* (higher values indicating more flexibility or wider range of dyadic engagement states), *transition* (higher values indicating more flexibility or frequent changes in dyadic engagement states) and *average mean duration* (AMD: lower values indicating more flexibility or spending short times in a particular dyadic engagement state), and *emotional content of coregulation* indicated by five regions marked in the SSG: (1) *mutual positive* (both mother and child showed positive engagement), (2) *mutual negative* (both mother and child showed negative engagement), (3) *child negative/mother positive*, (4) *child positive/mother negative*, and (5) *child object*(child engaged only with toy/objects). T-tests and OLS regressions controlling for maternal

education and child age were used to analyze the data.
Results: As expected, in comparison to TD dyads, ASD mother-child dyads had more frequent engagements that were mutually negative, child negative/mother positive and child object-focused; also, ASD child negative/mother positive engagements were of longer duration. Mutual positive engagements were shorter in duration, but more frequent. Surprisingly, ASD dyads exhibited greater flexibility compared to TD dyads, indicating by higher dispersion and higher transition and lower AMD (see Table 1).
Conclusions: To our knowledge, this study is the first to examine emotion coregulation process in mothers and children with ASD using the State Space Grid method. The findings suggest that flexibility and emotional content of coregulation are congruent. Constant change between positive and negative dyadic engagement support the idea that unstable structures of dyadic interactions may be observed in ASD dyads. The dynamic systems approach to assessing emotional coregulation in families with a child with ASD has both research and therapeutic implications.

A Dynamic Systems Approach to Emotion Coregulation in Families of Children with Autism Spectrum and Families of Typically Developing Children

†<.10; *p<.05; **p<.01; ***p<.001 [a]AMD=Mean duration per visit
Note: Analyses were conducted using the standardized values for region-level variables; the pattern of results was identical. For ease of interpretation, unstandardized estimates with the raw data are presented. Ordinary Least Squares Regression analyses were used to confirm bivariate models: significance remained in three grid-level variables (dispersion, transition and AMD), four region-visits variables (mutual positive, child object, child negative/mother positive, and mutual negative), and three region-duration variables (mutual positive, child object, child negative/mother positive).

110.143 A Longitudinal Study of the Social-Cognitive Phenotype of ASD and Reading Comprehension Development

N. S. McIntyre[1], *P. C. Mundy*[2], *M. Solomon*[3], *T. Oswald*[4], *L. E. Swain-Lerro*[1], *M. C. Zajic*[1], *J. B. McCauley*[4] *and H. K. Schiltz*[5], *(1)University of California at Davis MIND Institute, Davis, CA, (2)Education and Psychiatry, University of California at Davis, Sacramento, CA, (3)MIND Institute, Sacramento, CA, (4)University of California at Davis MIND Institute, Sacramento, CA, (5)Human Development, University of California at Davis, Davis, CA*

Background:
Observations suggest that reading comprehension (RC) impairment is part of the social communication phenotype of higher-functioning school-aged children with ASD (HFASD), showing significant negative associations between ASD symptom intensity, oral language skills, text reading fluency, and RC (e.g. McIntyre et al., 2015; Norbury & Nation, 2011). This includes observations that social cognition, as operationalized by Theory of Mind (ToM) tasks, was a unique predictor of RC even after controlling for oral language and word reading for adolescents with ASD (Ricketts et al., 2013).
Objectives:
1) To compare changes in RC over a 15-month development period across children with HFASD, ADHD, or Typical Development. 2) To test the hypothesis that social cognition is a specific predictor of RC development among children with HFASD.
Methods:
Participants included 8- to 17-year-old children with HFASD (N=70), ADHD (N=30), and typical development (TD, N=40). The groups were matched on age but varied on FIQ (99, 100, 115, respectively). Analyses control for FIQ where appropriate. ASD symptoms were confirmed with the ADOS-2 and presence of ADHD symptoms were confirmed with Conners-3 parent reports. Reading fluency and comprehension were measured with the Gray Oral Reading Test-5 (GORT-5), and a latent ToM score was comprised of scores from the Strange Stories (Happe, 1994) and the Silent Films (Devine & Hughes, 2012) tasks.
Results:
A repeated measures ANCOVA revealed little change in RC for any of the diagnostic groups in GORT-5 across 15 months, $\lambda = .99$, $F(2,139)=0.28$, $p=.76$ $\eta^2_p = .004$. The HFASD group, however, was significantly lower than both the ADHD and TD groups at Time Points 1 & 2, $F(2,143)=7.10,6.10$, $p's<.01$, $\eta^2_p=.09$ & .08, respectively. MANCOVA results indicated the HFASD group performed significantly lower than both the ADHD and TD groups on both ToM measures, $\lambda = .88$, $F(2,139)=0.28$, $p=.76$ $\eta^2_p = .06$. A regression predicting Time Point 2 RC with Diagnostic Group, Time Point 1 RC, FIQ, language measures, the latent ToM Score, and the Diagnostic Group by latent ToM score interaction term revealed that the latter was significant after considering all other variables in the equation, change in $R^2=.07$, $F(1,62)=6.21$, $p<.02$. Follow-up regressions within each of the three diagnostic groups indicated that latent ToM measure explained unique significant portion of the variance in TP2 RC for HFASD Group, but not for ADHD or TD groups (Table 1). Separate regressions revealed the association between the ToM and TP 2 RC in HFASD was significant when both the more verbal (Strange Stories) or less verbal (Silent Films) measures were used the analyses.
Conclusions:
Results indicated that while children with HFASD did not lose reading comprehension skills, neither did they make any progress toward closing the previously-reported gap, placing them at risk for falling further behind as reading materials become increasingly more complex and integral to academic achievement. Furthermore, mental state understanding (ToM) in the HFASD group was impaired relative to the other diagnostic groups and explained unique variance in TP2 RC providing evidence that the social cognitive phenotype of ASD is important to consider when designing reading interventions for children with ASD.

144 **110.144** A Meta-Analysis of Friendships in School-Age Youth with ASD

J. Mendelson[1], *J. A. Gates*[2] *and M. D. Lerner*[3], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Greensboro, NC, (2)Stony Brook University, Smithtown, NY, (3)Stony Brook University, Stony Brook, NY*

Background: As a result of the core social deficits of autism spectrum disorder (ASD), some have questioned whether meaningful social relationships, including friendship, are even possible in this population (e.g., Hobson, 1993; Calder, Hill, & Pellicano, 2013; Mitchell & Locke, 2014). Friendship serves a range of crucial functions across the lifespan (Baumeister & Leary, 1995), with friendlessness yielding serious, negative implications for children (Bagwell, 2004; Berndt & Keefe, 1995). [JG1] Crucially, recent studies indicate that at least some youth with ASD *do* make friends according to their parents, peers, and themselves (e.g., Kasari et al., 2011; Bauminger et al., 2008), and that these friendships may vary as a function of age and cognitive ability (Mendelson & Lerner, 2014). However, to date no systematic meta-analysis of friendship presence and patterns in youth with ASD has been conducted.

Objectives: We aimed to meta-analyze the empirical literature on friendships of children with ASD.

Methods: We conducted a systematic review of the literature (via PsycINFO and PubMed) on friendships (sociometric, self-report, parent-report) among school-age youth with ASD. 659 candidate articles were identified, and a pair of blinded coders examined them according to these inclusion criteria: a) empirical studies presenting quantitative data not previously published; b) published in peer-reviewed journals; c) claimed to include individuals with ASD; d) included some confirmation of ASD diagnostic status; e) included at least one participant in the 8-12 age range; f) not intervention studies; g) presented quantitative data on friendship. This yielded 18 articles. All 18 articles were double-coded by two blinded raters on demographic variables and all component scales. Coders achieved excellent agreement (ICC(1,2) > .97). Three articles were excluded due to overlapping participant samples and 14 were included in the final analysis. Meta-analyses were run for sociometric, self-report, and parent-report measures of friendship. If significant variation was found across the studies, fixed effects moderator analyses were conducted for age and IQ.

Results: Results from 1,768 participants with ASD were analyzed $M_{\%male}$ =85.46, M_{age}=114.92; M_{IQ}=91.85). We found that youth with ASD *do* make friends according to peers and parents (Figure 1; Hedges's g > 2.84). However, self-reported friendship quality (Hedges's g = -1.09) and parent- and peer-reported quantity (Hedges's g < -0.63)

were poorer than TD peers (Figure 2). For sociometric and self-report quality of friendship measures, the differences between ASD and TD peers were smaller with both age and higher IQ Older youth with ASD made more friends than younger youth according to sociometrics. Parents reported youth with higher IQ to have fewer/less active friendships.
Conclusions: Despite the widespread assumption that youth with ASD do not make friends, this meta-analysis reveals that they do so, and that they are of reasonable quality. Indeed, the difference from zero friendships was *larger* than the differences between youth with ASD and TD. Nonetheless, these friendships were lower in number and quality than those of their TD peers. These friendship patterns appear dynamic across time and IQ. This meta-analysis provides a foundation for future friendship studies in ASD.

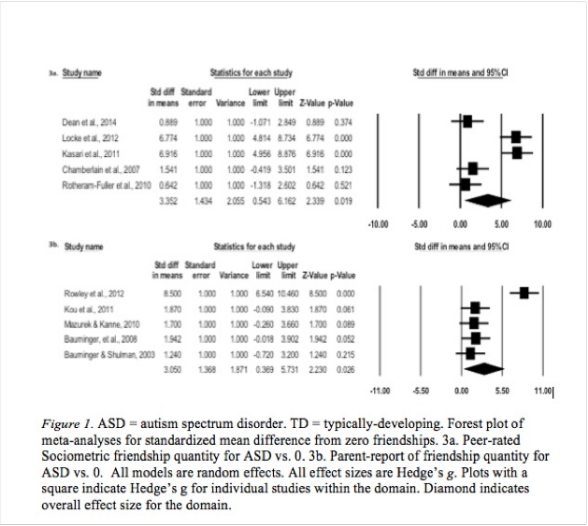

Figure 1. ASD = autism spectrum disorder. TD = typically-developing. Forest plot of meta-analyses for standardized mean difference from zero friendships. 3a. 145 **110.145** Abnormal Joint Attention Network in Children and Adolescents with Autism: An Interactive Eye-Tracking Paradigm

E. Oberwelland[1,2], *L. Schilbach*[3,4], *I. Barisic*[3,5], *S. C. Krall*[2,6], *K. Vogeley*[2], *G. R. Fink*[2,7], *B. Herpertz-Dahlmann*[1], *K. Konrad*[1,2] *and M. Schulte-Rüther*[1,2], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (2)Cognitive Neuroscience, Institute of Neuroscience and Medicine (INM-3), Jülich Research Center, Jülich, Germany, (3)Department of Psychiatry, University Hospital Cologne, Cologne, Germany, (4)Max Planck Institute of Psychiatry, Munich, Germany, (5)Department of Humanities, Social and Political Science, ETH Zurich, Zurich, Switzerland, (6)Department of Child and Adolescent Psychiatry, Psychosomatics, and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (7)Department of Neurology, University Hospital Cologne, Cologne, Germany*

Background: Social interactions form a substantial part of human daily living and develop from fundamental processes during infancy, such as joint attention (JA), to highly sophisticated processes in adolescence and adulthood. In the case of autism spectrum disorder (ASD), social interactions are typically affected with deficits in JA as one of the earliest sign to be at risk for ASD. Numerous behavioral studies have consistently demonstrated the compelling link between JA and ASD. However, to fully understand the deficits in JA and the link to ASD, it is crucial to examine the underlying neural processes during development, which are until now poorly understood.
Objectives: We compared the neural correlates of JA and its modulation by a familiar and unfamiliar interaction partner and by self- and other-initiation in children and adolescents with and without ASD.
Methods: We used an interactive eye-tracking setup (Wilms et al., 2010), in which participants were looking at a face surrounded by three targets (left, right and top). In the *Self-Initiated* conditions, participants shifted their gaze towards a target. The interaction partner followed the participant's gaze (*JA-Self)* or the interaction partner shifted her gaze downwards (*Control_Self*). In the *JA-Other* condition, participants were followed the interaction partner's gaze. In the *Control-Other* condition, participants shifted the gaze towards the target that changed color while the interaction partner shifted her gaze downwards. Importantly, the gaze-contingent setup allowed for comparison of neurofunctional differences for successfully established JA irrespective of behavioral differences. We analyzed 14 participants with ASD (8-18 years) and 14 age-, gender-, and IQ-matched TD participants. Brain imaging data were analyzed with SPM8, using a flexible factorial ANOVA model (random effects analysis, threshold: $p<0.05$ cluster-level FWE corrected, voxel level $p<0.001$).
Results: TD participants elicited greater activation in the right STS during JA than control conditions compared to participants with ASD who even showed deactivation during JA. Similarly, TD participants elicited left TPJ and left inferior parietal lobe activation specifically for JA, whereas participants with ASD elicited the left TPJ over all conditions with no differentiation between JA and control conditions. TD participants also deactivated the right temporal pole during control conditions and showed nearly no activation during JA. Participants with ASD though, deactivated the same region during JA. Furthermore, we found an overall effect of familiarity in the ASD group, i.e. increased activation when interacting with their mother in bilateral fusiform gyrus, left precuneus, left STS, ventral striatum and amygdala.
Conclusions: The STS, TPJ and temporal pole have all been discussed as critical brain regions for social processing with documented abnormalities in ASD (Allison, Puce, & McCarthy, 2000; Olson, Plotzker, & Ezzyat, 2007; Zilbovicius et al., 2006). Specific neurofunctional differences even during successfully established JA in children and adolescents with ASD suggest persistent developmental differences in JA capabilities, contributing to social processing difficulties. Thus, for basic processes such as JA abnormalities in neural functioning appear to persist despite seemingly successful behavioral maturation. Additionally, our data supports previous studies demonstrating

enhanced activation in participants with ASD when processing familiar faces.

146 **110.146** Adolescents' Ability to Differentiate Interest Levels of Their Conversational Partners on the Contextual Assessment of Social Skills (CASS)

C. O. Leonczyk, *S. Mrug, R. Murray, L. N. Perry, J. W. Blackston and S. E. O'Kelley, Psychology, University of Alabama at Birmingham, Birmingham, AL*

Background:
The Contextual Assessment of Social Skills (CASS) is a new observational measure that uses semi-structured role-plays to assess conversational abilities, ability to perceive conversational partners' interest, and ability to adapt to changes in social context (Ratto, Turner-Brown, Rupp, Mesibov, & Penn, 2011). The initial validation study compared adolescents with high-functioning ASD to college-aged healthy controls. Compared to college-aged healthy controls, individuals with ASD perceived less of a difference in bored and interested conversational partners. Studies have not compared the CASS in adolescents with ASD and adolescents with other developmental or social difficulties.
Objectives:
To compare adolescents with ASD and adolescents with other developmental or social difficulties' ability to differentiate the interest level of their conversational partners on the CASS.
Methods:
We administered the CASS to 23 high school students referred for a school-based social skills intervention. All students were referred because they displayed difficulty making friends and some level of social difficulty. Some students had diagnoses of ASD (n = 7) and the remainder (n = 16) had other developmental disabilities or social difficulties (e.g., language disorders, learning disorders, shyness, social anxiety). Each student participated in two consecutive semi-structured role-play conversations. During the first role-play, the confederate acted interested in the conversation. During the second role-play, a different confederate acted bored in the conversation. After each role-play the participant filled out the Conversation Rating Scale (CRS), which consists of 5 items rating the confederate's perceived interested on a Likert-scale. We calculated a CRS Difference Score (CRS Interested condition score – Bored condition score), which reflects the adolescent's ability to distinguish between the two conditions. Higher difference scores indicate better ability to perceive differences in the confederate's interest level. We compared CRS Difference Scores between students with and without ASD using an independent samples t-test. We also examined the correlation between students' CRS Difference Scores and autism symptoms, as measured by the SRS-2 teacher report.
Results:
We found a significant difference in CRS Difference Score between students with and without ASD, $t(21) = -.61$, $p < .05$. Students with ASD had lower CRS Difference Scores (M = 5.83, SD = 12.12) than their peers without ASD (M = 8.18, SD = 6.27), indicating less ability to perceive the change in partner's interest level. Interestingly, three students with ASD and two students without ASD perceived no difference between the two conditions (i.e., had CRS Difference scores of 0 or negative CRS Difference Scores). Higher autism symptoms on the SRS-2 were associated with lower CRS Difference scores, $r(19) = -.48$, $p < .05$, indicating less ability to perceive differences in conversational partner's interest level.
Conclusions:
Compared to peers with other developmental disorders or social difficulties, students with ASD were less able to perceive a difference in their conversational partners' interest level. More than 1/5 of students (including some without ASD) did not perceive any difference in their conversational partners' interest levels, which is a critical social skill. Future studies should evaluate the CASS' potential as a treatment outcome measure for social skills interventions.

147 **110.147** Affective Flexibility during the Self-Referenced Memory Task: A Novel Analytic Approach

C. A. Burrows[1], *S. Sun*[2], *L. V. Usher*[1], *J. C. Britton*[2] *and H. A. Henderson*[3], *(1)University of Miami, Coral Gables, FL, (2)Psychology, University of Miami, Coral Gables, FL, (3)University of Waterloo, Waterloo, ON, Canada*

Background: Individuals with high-functioning autism (HFA) demonstrate difficulties in several domains, including cognitive flexibility, emotion understanding and self-referenced processing, which have been linked to maladaptive outcomes. However, little research has examined affective flexibility, or the ability to switch between information of emotional content, in HFA. The valence of information (positive versus negative) and processing condition (thinking about oneself or another person) are two factors that may influence affective flexibility in individuals with HFA.
Objectives: The goals of this study were to examine the effect of switching between adjective valence and condition on behavioral measures of affective flexibility in children and adolescents with HFA and a matched comparison sample (COM) on a self-referenced memory task.
Methods: Children and adolescents with HFA (N=76, 65 males, Mage=12.51, SD=2.58) and a comparison sample (N=72, 52 males, Mage=13.28, SD=2.15) completed a self-referenced memory paradigm, where they judged both positive and negative traits with reference to themselves or a familiar other person (e.g., Harry Potter). Switch cost was computed as the reaction time (ms) difference between switch-trials (trials that differed in valence from previous trials) and non-switch trials (trials that had the same valence as previous trials). The difference score was computed for positive-negative (P-N) and negative-positive (N-P) switches in the self and other conditions.
Results: Mean switch cost values for each group and condition are presented in Table 1. A Group (HFA, TD) x Condition (Self, Other) x Switch type (P-N, N-P) repeated-measures ANCOVA was conducted on the switch cost data, controlling for verbal IQ and gender. Overall, there was a main effect of switch, $F(1,146)=8.55$, $p=.004$, with a greater slowing in reaction times in the positive-negative switches than in negative-positive switches. A three-way interaction also emerged, $F(1,146)=4.01$, $p=.047$, indicating that the differential switch-cost by condition and type differed by group. Follow-up analyses revealed that the group effect was specific to the difference between self and other P-N switches, $F(1,147)=4.46$, $p=.036$. Reaction times of participants with HFA were particularly affected by switching from positive- to negatively-valenced adjectives in self relative to other condition.
Conclusions: This study is the first to examine elements of affective flexibility using a self-referenced processing task. All participants found it easier to process positive information. However, the reaction time cost was accentuated when children with HFA were required to think of switch between positive and negative self-referenced information, relative to thinking of another person. It may be more effortful for them to evaluate negative self-referential information, indexing affective inflexibility. These impairments could account for different patterns of comorbidity in children with HFA.

Table 1. Switch cost (difference in reaction times between switch trials and non-switch trials) values for each group in milliseconds. Estimated marginal means and standard errors are presented, controlling for verbal intelligence and gender. Positive values indicate greater slowing between switch and non-switch trials. Note: HFA = high-functioning autism; COM = comparison, *=group difference.

	HFA Group			COM Group		
	Self	Other	Self-Other Difference	Self	Other	Self-Other Difference
Positive to Negative Switch Cost	127 (42)	4 (46)	126 (61)*	66 (43)	112 (48)	-65 (63)*
Negative to Positive Switch Cost	-179 (47)	-130 (42)	-49 (60)	-80 (49)	-117 (44)	37 (63)

148 **110.148** Alexithymia, Executive Function and Mind-Reading in Children with and without Autism Spectrum Disorders

B. Auyeung[1,2], *C. Griffin*[3] *and M. V. Lombardo*[4], *(1)Department of Psychology, School of Philosophy, Psychology and Language Sciences, University of Edinburgh, Edinburgh, United Kingdom, (2)Department of Psychiatry, Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (3)Psychology, University of Edinburgh, Edinburgh, United Kingdom, (4)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom*

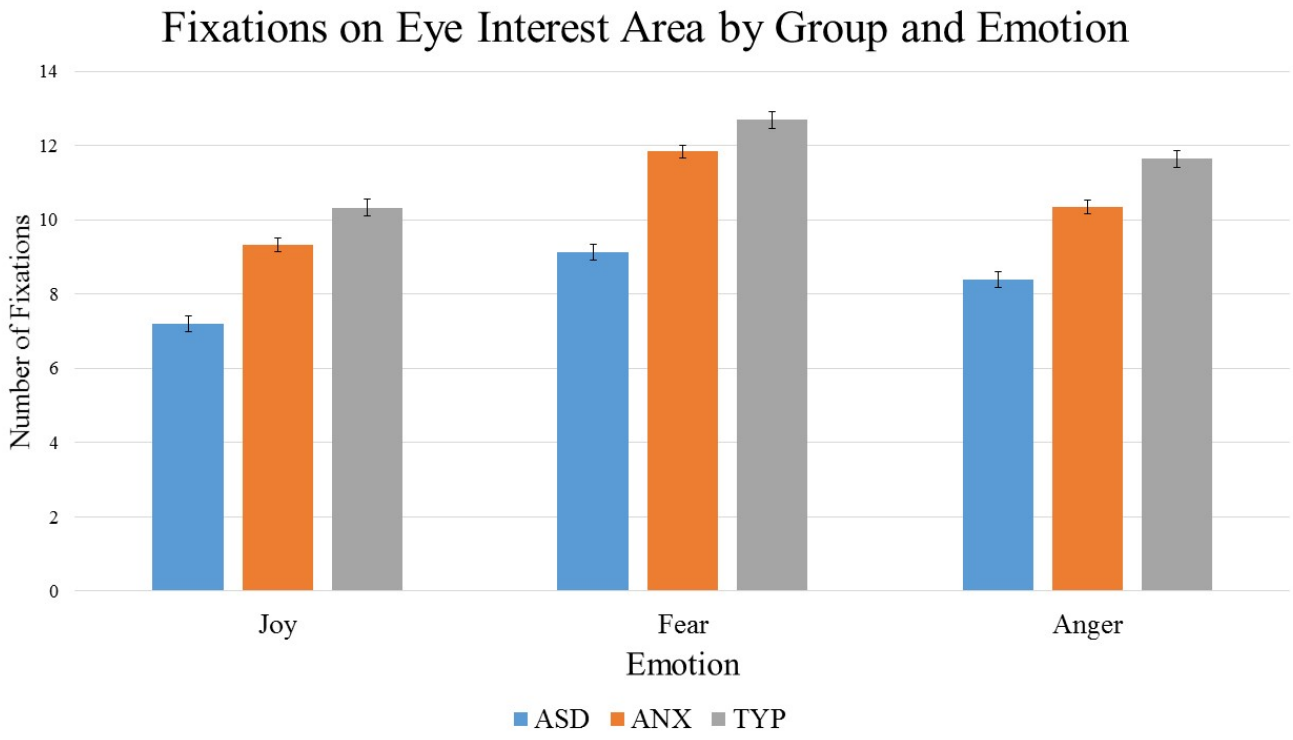
Background: Alexithymia refers to a pronounced difficulty in identifying and describing one's own emotions, and is associated with an externally oriented focus of thinking. Alexithymia is known to be much more common in adults with autism spectrum disorders (ASD) compared to the typically-developing adult population. However, we know very little about alexithymia in young children with ASD and advancing our understanding of this topic may be of critical clinical and translation importance.
Objectives: To investigate alexithymia and it's relationship with autistic traits, executive functioning (EF) and mind-reading in children with and without ASD.
Methods: The sample consisted of 57 school- aged children (7-12 years) both with (n= 25) and without (n=32) Autism Spectrum disorder (ASD). Both self and parent- report questionnaires were chosen to assess alexithymia. Autistic traits and communication difficulties were measured using parent-report measures. EF was measured using the Delis- Kaplan Executive Function System and mind-reading was measured using the children's Reading the Mind in the Eyes test.

Results: We found that alexithymia is substantially elevated in ASD on both self- (ASD mean=21.667, SD=5.87; TD mean=16.5, SD=5.38; t=2.40, p=0.009, Cohen's d=0.94) and parent-report (ASD mean=19.70, SD=10.20; TD mean=5.71, SD=6.24; t=4.74, p<0.0001, Cohen's d=1.74) measures. Despite both measures being sensitive to on-average group differentiation, we found no evidence of correlation between such measures, indicating that children and their parents may be using different sources of information. Parent-rated alexithymia was also associated with increasing levels of autistic traits when corrected for multiple comparisons (i.e. p<0.0025). A discrepancy between self and other alexithymia ratings were also associated with autistic traits, but only in ASD (SRS r=-0.54, p=0.01; AQ r=-0.42, p=0.06). Mind-reading significantly predicted higher scores on both self (F (3,43) = 6.16, p < .001) and parent-report alexithymia measures (F (4,44) = 16.19 p < .001). No relationship between EF and alexithymia were observed.
Conclusions: These results suggest that assessing alexithymia in ASD at younger ages may be important in identifying subgroups that have particular difficulties in the domain of emotion processing. This may aid our ability to deconstruct some of the heterogeneity in ASD and may be useful in developing tailored interventions for children with ASD.

149 **110.149** Alexithymia, Not Autism or Anxiety Symptoms, Predicts Reduced Eye Fixation in a Transdiagnostic Adult Sample

K. G. Stephenson[1], *N. Top*[1], *S. Luke*[1], *T. Shuman*[1], *L. Peacock*[1], *A. Ward*[1] *and M. South*[1,2], *(1)Brigham Young University, Provo, UT, (2)Psychology and Neuroscience, Brigham Young University, Provo, UT*

Background: Beyond the core clinical symptoms of autism spectrum disorder (ASD) are common comorbid symptoms such as anxiety and alexithymia (i.e., difficulty identifying, expressing, and feeling emotional states). These associated features are related to increased distress and avoidance in ASD and may also underlie social deficits. There is considerable research suggesting reduced eye fixation in ASD, even from an early age. One study has found that comorbid alexithymia, more than autism symptoms, predicts reduced eye fixation in ASD.
Objectives: The goal of this study was to add to existing literature by assessing the role of alexithymia, compared to symptoms of autism and anxiety, in both reduced eye fixation and emotional labeling accuracy, in ASD, anxious, and neurotypical control groups.
Methods: Participants were 25 adults diagnosed with ASD as well as 27 anxious controls (ANX) recruited from a university counseling center, and 25 neurotypical university students (TYP). All participants completed a battery of questionnaires including the Toronto Alexithymia Scale (TAS-20), the Autism Spectrum Quotient (AQ), and the Penn State Worry Questionnaire (PSWQ). Participants viewed filmed emotional expressions selected from the Amsterdam Dynamic Facial Expression Set (ADFES) and indicated whether they portrayed *joy*, *fear*, or *anger* while we tracked their eye movements.
Results: Overall emotion identification accuracy was high (~98%) and did not differ significantly between groups. Repeated-measures ANOVA indicated a significant main effect for group [$F(2, 61) = 5.05$, $p < .001$, $\eta^2 = .13$] in the number of fixations on the eyes during while watching the emotional expressions (ASD < ANX < TYP). Average eye fixation across all emotions was significantly correlated with alexithymia levels (TAS-20, $r = .26$) and autism symptoms (AQ, $r = .18$), but not with trait worry (PSWQ, $r = .01$). Hierarchical regression indicated that only TAS-20 was a significant predictor of eye fixation ($\beta = -.28$).
Conclusions: Our results replicate and extend previous findings of the role of alexithymia in reduced eye fixation in ASD. A similar pattern in an anxious control group provides added evidence of the transdiagnostic importance of alexithymia in processing emotional faces. While additional research is needed to better understand the directionality of these effects, these preliminary findings suggest that treating alexithymia may be a promising therapeutic intervention for social difficulties in clinical populations.



150 **110.150** An Examination of Prosocial Behaviors in Children with and without Autism Spectrum Disorders

H. Van Etten *and L. J. J. Carver, University of California San Diego, La Jolla, CA*

Background: Past research has provided insight into the development of prosocial behaviors in typically developing children, but surprisingly little research has been done examining this behavior in children with ASD. To engage in prosocial acts, one must be aware of subtle social cues that indicate prosocial behaviors are warranted, as well as be motivated and have the necessary means to accomplish these behaviors (Dunfield, Kuhlmeir, O'Connell, & Kelley 2011). As children with ASD display social communication deficits – specifically impairments in social motivation and difficulty interpreting social cues – engaging in prosocial behavior may prove difficult. Surprisingly little research has been done examining this social behavior, though a few studies have found decreased levels of helping and sharing in children with ASD measured in experimental tasks (Travis, Sigman, & Ruskin, 2001; Dunfield, O'Connel, Kuhlmeier, & Kelley, 2012), and caregiver report (Iizuka et al. 2010; Jones and Fredrickson, 2010; Russel et al. 2012). Previous differences in prosociality between typically developing children and those with ASD may be attributed to differences in the ability to recognize and interpret social cues.
Objectives: The aim of this study is to examine how and if children with ASD respond to social cues indicting an opportunity to engage in prosocial behaviors, and whether this response differs from typically developing children. Additionally, as no previous studies combined parent-report measures of prosocial behaviors with experimental data, this study is the first of its kind to do so.
Methods: Caregivers filled out questionnaires to assess for Autism symptomology (AQ) and difficulties in prosocial behaviors (SDQ). Typically developing children and children with ASD, aged four-and-a-half to six-years old, engaged in a variety of naturalistic tasks that were designed to elicit prosocial behaviors, specifically helping and sharing. In each task, children were exposed to progressively explicit cues (ranging from eye gaze shifts to verbal prompts) indicating that prosocial behaviors were warranted. Additionally, children engaged in a structured sticker-sharing task to further examine sharing behaviors.
Results: 75% of children helped the experimenter and 38% shared with the experimenter during naturalistic prosocial tasks. During the sticker-sharing task, typically developing children shared on average 49% of their stickers with another child. Results of the caregiver questionnaire indicated that all children displayed typical levels of prosocial behaviors and no children were reported as displaying significant Autistic traits. We predict that the children with ASD will show lower levels of helping and sharing behavior in the prosocial scenarios, will require more explicit cues, and will be less likely to engage in sharing on the sticker task.
Conclusions: Understanding if the inability to respond appropriately to social cues impacts children with ASD can have important implications for future prosocial therapies.

Therapies may be able to target prosocial skills through slowly decreasing the reliance on explicit cues. Additionally, as engaging in these behaviors are an important aspect of peer relationships, improving prosocial behaviors in children with ASD can help in the formation of these relationships.

151 **110.151** Are “Strange Stories” Strange to a Non-Clinical Population? Relationships Between AQ and Physical and Mental State Reasoning

*T. Loucas[1], P. Beaman[1], **M. Younas**[2] and L. E. Martin[2], (1)Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)University of Reading, Reading, United Kingdom*

Background: Performance associated with autism spectrum disorders has been demonstrated in individuals with high levels of autistic traits but without a diagnosis of ASD. These include lexical effects (Stewart & Ota, 2008) and compensation for co-articulation (Yu, 2010) in speech perception; cognitive flexibility in set-shifting (Goken et al., 2014); and social cognition (Goken et al., 2014; Sasson et al., 2012). One of many lines of evidence indicating that individuals with ASD have a specific deficit in reasoning about the mental states of others comes from the “strange stories” test (Happé, 1994) which reveal that children and adolescents with ASD diagnoses score particularly poorly on stories that require reference to mental states compared with stories which require causal reasoning about physical states only. It is not known whether this pattern of results extends to those members of the general population who score highly on autistic traits as measured by instruments such as the Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001).
Objectives: We hypothesized that participants without an ASD diagnosis who nevertheless scored highly on the AQ would perform less well on the mental-state stories than participants with low AQ scores, and that there would little or no relationship between AQ and performance on the mental state stories.
Methods: The AQ was completed online by a sample of 177 adult participants, all of whom reported no previous or current ASD diagnosis. Participants also completed both physical and mental-state strange stories), in which individuals with ASD typically perform poorly on the mental-state stories.
Results: Pearson’s correlation coefficients revealed that AQ was negatively associated to a significant extent with performance on both mental and physical state stories. A stepwise multiple regression analysis showed that – once educational level and verbal ability were accounted for – ability to answer mental-state stories accounted for significant variance in AQ scores once variance associated with ability to answer physical state stories was accounted for, but the converse was not the case: Once variation associated with ability to answer mental-state stories was accounted for, performance on physical state stories no longer accounted for significant variance in AQ scores.
Conclusions: These results show the utility of running behavioral studies in a general population with the advantages this gives of easy access to large numbers of participants, and with AQ scores as a proxy for ASD-like traits. The results also indicate that – contrary to initial suppositions – ASD-like traits in a general, non-clinical, population (as measured by the AQ) are associated not only with difficulties in reasoning about mental states but also with difficulties in reasoning about physical states when these are presented in a verbal, “strange story” format. Mental-state story scores did, however, account for a unique proportion of the variance in AQ suggesting that individuals who score highly both have a general difficulty with verbally-presented reasoning tasks and a specific difficulty with such tasks when they require explicit reference to the mental states of others.

152 **110.152** Assessing and Training Emotion Recognition: A Comprehensive Facial Expression Training Program for Children with ASD

S. Matsuda[1,2] *and J. Yamamoto[3], (1)University of Tsukuba, Ibaraki, Japan, (2)Japan Society for the Promotion of Science, Tokyo, Japan, (3)Dept. of Psychology, Keio University, Tokyo, Japan*

Background: Deficits in emotion recognition have been well documented in children with autism spectrum disorders (ASD); therefore, previous studies have focused on improving emotion recognition in intervention programs (e.g., Bölte et al., 2002; Golan & Baron-Cohen, 2006; Silver & Oakes, 2001). However, these programs have been developed only in Western countries even though there are cultural differences in emotion recognition (Elfenbein & Ambady, 2002). We have developed the comprehensive facial expression training program called Face-Expression Expert Program (FEEP) over a period of several years in Japan, which is based on the Sidman’s stimulus equivalence analysis (Sidman, 1994). The program consisted of 10 stimulus-response relations. In the current series of studies, we assessed and trained emotion recognition in the children with ASD using FEEP.
Objectives: This presentation review preliminary outcomes from the studies of the comparison between children with and without ASD, as well as effects of training.
Methods: The current FEEP assessment consisted of five stimulus-response relations; (1) “facial expressions – facial expressions (identical),” (2) “facial expressions – facial expressions (categorical),” (3) “words – facial expressions,” (4) “affective prosodies – facial expressions,” (5) “descriptive images – facial expressions.” 13 children with ASD and 43 typically developing (TD) children, aged 3 to 10 years, participated in the series of group comparison studies. 7 children with ASD also participated in the series of intervention studies used single-subject designs on (3) “words – facial expressions,” (4) “affective prosodies – facial expressions,” and (5) “descriptive images – facial expressions.”
Results: Preliminary findings from assessments suggest there were no difference between children with ASD and TD in four stimulus-response relations (1) “facial expressions – facial expressions (identical),” (2) “facial expressions– facial expressions (categorical),” (3) “words – facial expressions,” (5) “descriptive images – facial expressions.” On the other hand, there was a difference between two groups in (4) “affective prosodies – facial expressions.” Results of the interventions showed that trained stimulus-response relations were established. The results of intervention for (3) “words – facial expressions” indicated symmetrical relation “facial expressions – words” emerged. The results of intervention for (4) “affective prosodies – facial expressions,” and (5) “descriptive images – facial expressions showed generalizability to untrained stimuli.
Conclusions: The current series of studies indicated the utility of the training program, FEEP, for both assessments and training emotion recognition in children with ASD. Although data collection is still ongoing, these findings extend past work by showing that children with ASD in Japan can be taught emotion recognition. Updates will be provided from the results of the ongoing iPad software use and a multi-site study.

153 **110.153** Associations Between Emotional Problems and Cognition in Autism Spectrum Disorders

*C. Cantio[1] and **N. Bilenberg**[2], (1)Child and Adolescent Psychiatry, Odense C, Denmark, (2)Research Unit, Child and Adolescent Psychiatry, Odense, Odense C, Denmark*

Background:
Depression and anxiety disorders are seen far more in individuals with autism spectrum disorders (ASD) than in the background population, and the estimated prevalence of these co-morbid diagnoses in ASD sums up to 80%. It is unknown why individuals with ASD have a higher prevalence of these disorders, but both depression and anxiety have been associated with ASD symptomatology, and it is possible that this increased risk derive from underlying causes, such as cognitive dysfunctions.
Objectives:
We aimed to study these co-morbid problems in a prospective design, where we examined the associations between depression and anxiety, and the three most prominent cognitive theories of ASD; Theory of Mind (ToM), Executive Functions (EF) and a Local processing Bias (LB). Additionally, we investigated the correlations to ASD symptomatology.
Methods:
We examined these objectives in a group of high-functioning children (IQ>70) with ASD (N=22) and a matched group with neurotypical development (NTD, N=30) at baseline and three years later. At both time points, a comprehensive battery of cognitive tasks were applied and co-morbid problems as well as ASD symptomatology were assessed with questionnaires. Additionally, the ASD group was examined with ADOS and ADI at baseline.
Results:
We found strong correlations between the parent-rated co-morbidity and the parent-rated ASD symptomatology although very few of these correlations held in the groups individually. Clinically observed symptoms (ADOS) and parental interviews (ADI) of ASD symptomatology was barely correlated to depressive or anxious symptoms.
A general relationship between Theory of Mind (ToM) and symptoms of depression and anxiety was found at Time 1 and across time, but not at Time 2. Interestingly those individuals in the ASD group who showed persistently high levels of anxiety had a different trajectory of ToM performance; their ToM performance decreased, while the individuals with persistent low levels of anxiety improved their ToM performance.
Conclusions:
The results suggest that the level of anxiety is important in the development of ToM.

154 **110.154** Attention Orienting to Direct Gaze in Young Children with Autism Spectrum Disorder - a Heart Rate Study

T. M. Helminen[1], *J. K. Hietanen[1], J. M. Leppänen[2], K. Eriksson[2] and A. Kylliainen[1], (1)School of Social Sciences and Humanities / Psychology, University of Tampere, Tampere, Finland, (2)School of Medicine, University of Tampere, Tampere, Finland*

Background:
Reduced use of eye contact is a prominent characteristic of individuals with autism spectrum disorder (ASD). It has been disputed whether this reflects 1) *active avoidance* due to negatively valenced heightened arousal to eye contact or 2) *passive avoidance* due to diminished attention towards eyes.
Objectives:
The objective was to investigate whether young children with ASD show a normative physiological index of attentional orienting to direct vs. averted gaze. To this end, we measured heart rate deceleration (orientation) responses. It was hypothesized that the direct gaze would elicit stronger orientation response than averted gaze in children without ASD, whereas this would not be observed in children with ASD.
Methods:

20 children with ASD (2.5 – 5.3 years, developmental age 1.2 – 4.2 years), 20 typically developing control children matched by chronological age, and 18 children with developmental delay matched with developmental age were presented pictures of faces with direct and averted gaze directions. During the stimulus presentation, their heart rate and eye movements were recorded and evaluated. The experiment was repeated after 4-5 months with the same participants, to see whether the results of the initial experiment could be replicated.
Results:
The results of the initial experiment showed that, in the control children (both typically developing and with developmental delay), the heart rate deceleration response was more prominent to direct than to averted gaze. No heart rate deceleration was observed in children with ASD in either gaze condition. Based on eye tracker data, the lack of heart rate deceleration was not explained by reduced looking at the eye region. In the follow-up visit, the control children responded to both gaze directions with more prominent heart rate deceleration than the ASD children. Again, no heart rate deceleration was observer in children with ASD.
Conclusions:
The results indicated that, in contrast to children without ASD, children with ASD do not show heart rate deceleration to direct or averted gaze. These findings support the assumption that direct gaze, or perhaps faces in overall, do not attract the attention of the children with ASD and this leads to reduced initiation of eye contact.

155 **110.155** Autism Subgroups Defined By Heterogeneity in Performance on an Advanced Mentalizing Test

M. V. Lombardo[1], *M. C. Lai*[2], *B. Auyeung*[3], *R. Holt*[4], *C. Allison*[4], *P. Smith*[4], *B. Chakrabarti*[5], *A. N. Ruigrok*[4], *C. MRC AIMS*[6], *C. Ecker*[7], *M. Craig*[7], *D. G. Murphy*[7] *and S. Baron-Cohen*[4], *(1)University of Cyprus, Nicosia, Cyprus, (2)Centre for Addiction and Mental Health, The Hospital for Sick Children, and Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (3)University of Edinburgh, Edinburgh, United Kingdom, (4)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (5)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (6)Autism Research Centre, University of Cambridge; the Institute of Psychiatry (IoP) at King's College, London; Autism Research Group, University of Oxford, Cambridge, United Kingdom, (7)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background: Difficulty in the domain of mentalizing is a key cognitive explanation behind the social-communication difficulties that are hallmarks of autism. However, heterogeneity is also present, and individuals differ in their degree of competency in mentalizing, particularly in adulthood. Understanding how such heterogeneity manifests may be clinically important, particularly with regards to personalizing intervention and may also present opportunities for stratification that may help increase sensitivity for detecting underlying neurobiological mechanisms of importance in autism.
Objectives: Here we use unsupervised hierarchical clustering to stratify adults on the autism spectrum into discrete subgroups, based on their performance on an advanced mentalizing test.
Methods: Two datasets (discovery and replication) were used to test whether discrete autism mentalizing subgroups emerge in a replicable fashion. The discovery dataset consisted of 190 adults with autism (96 males, 94 females) and 251 typically-developing controls (TD; 130 males, 121 females) who completed the Reading the Mind in the Eyes test (RMET) online as part of the Cambridge Autism Research Database (CARD). The replication dataset consisted of participants from the MRC AIMS Consortium dataset (n=123 autism; 85 male, 38 female; n=128 TD; 87 male, 41 female). For both datasets, we used unsupervised two-way hierarchical clustering to cluster the data along both dimensions of RMET items and autism subjects. We tested the hypothesis that similar discrete subgroups would emerge across both discovery and replication datasets. We then compared autism subgroups to TD using RMET total scores and estimate replication Bayes Factors (repBF) to quantify evidence for replicability (repBF ~ 1 indicates no evidence supporting replication; repBF>100 indicates extremely strong evidence supporting replication).
Results: Across both discovery and replication datasets there was evidence for 2 discrete autism subgroups that can generally be characterized as 'Impaired' or 'Good'. The 'Good' subgroup showed no consistent difference in RMET total scores compared to the TD group (Discovery: t = 1.82, p = 0.06, Cohen's d = 0.21; Replication: t = -3.72, p = 0.0002, Cohen's d = 0.52; repBF = 0.22). However, the 'Impaired' subgroup had RMET total scores that were massively reduced in a replicable manner compared to the TD group (Discovery: t = -16.96, p = 4.10e-47, Cohen's d = 2.10; Replication: t = -13.04, p = 3.13e-27, Cohen's d = 2.36; repBF = 1.63e+25).
Conclusions: The RMET can be a valuable tool for parsing heterogeneity in mentalizing in adults with autism. After stratification, there is a useful distinction between autism individuals with intact versus impaired mentalizing ability. Stratification by these mentalizing subgroups may be useful in future work with clinical and translation aims. For example, in direct extensions of this work, we will directly test these subgroups for differentiation within mentalizing circuitry with existing task and resting state fMRI data from the MRC AIMS dataset.

156 **110.156** Autism Symptom Severity and Social-Emotional Cognition Among Children with High Functioning Autism Spectrum Disorder

C. S. Albaum[1], ***P. Burnham Riosa***[2] *and J. A. Weiss*[2], *(1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, Canada*

Background: Autism spectrum disorder (ASD) is characterized in part by social communication difficulties, such as deficits in recognizing and understanding body language and facial expression during social interaction (American Psychological Association, 2013). A large body of research in this area has focused on how emotion recognition differs between children with ASD and typically developing peers (Harms, Martin, & Wallace, 2010), but relatively few studies have focused on how symptom severity in particular relates to difficulties with social cognition. Understanding the relation between ASD severity and social cognition challenges may be useful in informing interventions focusing on social-emotional cognition targets.
Objectives: To identify the relation between autism symptom severity and social-emotional cognition in school-aged children with high functioning ASD.
Methods: Data were collected from 47 children with high functioning ASD (87.2% male) and their parents as part of a larger trial to improve child emotion regulation. Children were 8 to 12 years of age (*M* = 9.74, *SD* = 1.36) with at least average IQ (*M* = 103.40, *SD* = 13.87, Range: 79-140). Measures of interest were collected at baseline, before children received the intervention. We collected parent-reported autism symptom severity ratings using the *Social Responsiveness Scale, Second Edition* (*SRS-2*; Constantino & Gruber, 2012) and data on social-emotion cognition performance using the following two child administered tasks: 1) *Reading the Mind in Films* (RTMF; Golan, Baron-Cohen, & Golan, 2008), in which children watched a scene from a film and identified how a character was feeling; and 2) *CogState-Research Tasks Social Emotional Cognition* task (SEC; Collie et al., 2003), in which children identified the character whose emotional expression was different from the other three characters.
Results: When controlling for age and IQ, total ASD symptom severity scores were not significantly correlated with performance on the social-emotional cognition tasks ($p > .05$). Upon further examination of SRS-2 subscales, we found that when controlling for age and IQ, there was a significant partial correlation between parent-reported social cognition and SEC task performance ($r(42) = -.36$, $p = .015$). No other SRS-2 subscale scores were correlated with social-emotion cognition task performance nor was ASD severity correlated with performance on the RTMF task ($p > .05$).
Conclusions: Contrary to expected, overall ASD severity scores did not correlate with social-emotion cognition task performance when controlling for age and IQ; however, greater parent-reported social cognition difficulties was correlated with poorer performance on an emotion discrimination task. Global ASD symptomatology was not related to social cognition task performance in our sample. The implications of these findings will be discussed.

157 **110.157** Automated Measurement of Head Movement in Children with and without ASD

K. B. Martin[1], *Z. Hammal*[2], *J. Cohn*[3], *J. Cassell*[4] *and D. S. Messinger*[1], *(1)Psychology, University of Miami, Coral Gables, FL, (2)The Robotics Institute, Carnegie Mellon University, Pittsburgh, PA, (3)Psychology, University of Pittsburgh, Pittsburgh, PA, (4)School of Computer Science, Carnegie Mellon University, Pittsburgh, PA*

Background:
Motor and social deficits are associated in children with Autism Spectrum Disorders (ASD). Successful social interactions require typical coordination and motor movement initiations (Piek & Dyck, 2004). Motor abnormalities, such as head motion atypicalities, in development may contribute to the perceptual and social impairments that characterize individuals with ASD. To date, deficits in motor movement in children with ASD have been characterized descriptively by human observers. In lieu of laborious human coding, automated measurement provides objective, continuous measurement to quantify head position and head movement.
Objectives:
To objectively quantify differences in head movement in children with and without ASD.
Methods:
Participants were 48-to-68- month old children with a diagnosis of ASD (*n*=20) or no evidence of ASD (n=20). A diagnosis of ASD or no ASD was confirmed for all children with the Autism Diagnostic Observation Schedule (Lord et al., 2000), which yielded severity scores for social affect and restricted, repetitive behaviors (Hus, Gotham, & Lord, 2014). Children were video recorded while watching a 16 minute video of six stimuli blocks, 3 social and 3 nonsocial stimuli. Three degrees of rigid head movement—pitch (nodding), yaw (head turns), and roll (lateral head inclinations) were tracked from the video recordings using an automatic person-independent tracker (Zface; Jeni, Cohn, & Kanade, 2015) (**Figure 1**). To measure the dynamics of head movement, head angles were converted into angular displacement and angular velocity. The root mean square was then used to measure the magnitude of variation of the angular displacement and the angular velocity for yaw, pitch, and roll for each stimulus block and for each infant separately.
Results:
Repeated measures ANOVA revealed differences in yaw angular displacement and roll angular velocity by stimulus block, *p*s<.05. There were no interaction effects of stimulus block and ASD status in angular displacement or velocity of yaw, pitch, and roll. Children with ASD exhibited larger angular displacement of yaw and roll than children without ASD, $F(1, 36)=5.29$, $p=.027$, *partial* $\eta_p^2=.13$ and $F(1, 36)=4.10$, $p=.05$, $\eta_p^2=.10$, respectively, indicating greater variability in head position. They also

exhibited greater angular velocity of yaw, $F(1, 36)=4.09$, $p=.050$, $\eta_p^2=.10$, and roll, $F(1, 36)=7.69$, $p<.01$, $\eta_p^2=.18$, than children without ASD (**Figure 2**), indicating greater variability in head motion. There were no ASD status effects in angular displacement or velocity of pitch, $ps>.10$. Over both groups, children with greater angular displacement in yaw showed higher levels of repetitive behaviors ($r=.37$, $p<.01$) and social affect deficits ($r=.30$, $p=.036$).

Conclusions:

To our knowledge, this is the first study to use objective measurements to quantify head movement differences in children with and without ASD. The findings suggest that children with ASD nod (pitch) and turn their heads (yaw) with greater variability than children without ASD. Moreover, greater variability in head turns (yaw displacement) was associated with higher ASD symptomatology in both the social affect and repetitive behavior domains. These head movement differences may create sensory experiences for children with ASD that involve greater accommodation to changes in head position and movement than those experienced by children without ASD.

158 **110.158** Biological Motion Preference and Autism Symptomatology in Adolescents with Fragile X Syndrome

K. E. Caravella[1], *F. Shic*[2], *Q. Wang*[2] *and J. E. Roberts*[3], *(1)University of South Carolina, Columbia, SC, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Psychology, University of South Carolina, Columbia, SC*

Background: Fragile X syndrome (FXS) has the highest known penetrance of autism spectrum disorder (ASD) of any single gene disorder, with up to 60% of individuals

meeting criteria for ASD, and up to 90% showing at least 1 symptom of the disorder. While symptomatology overlaps significantly between the two disorders, controversy continues to exist over a shared underlying mechanism driving the similar behavioral presentation.
Objectives: This study aims to examine preliminary data on a biological motion eye-tracking paradigm collected on individuals with FXS. Preference for biological motion is a foundational social cognitive skill known to be present in typically developing infants from the first days of life, and has been shown to be deficient in individuals with idiopathic autism (Annaz, Campbell, Coleman, Milne & Swettenham, 2011). It is unknown whether this preference for biological motion is intact in individuals with FXS, and whether the presence or absence of a co-morbid diagnosis of ASD is related to this particular social cognitive skill.
Methods: Participants included 14 adolescent males with FXS who are part of a larger study on language development (5 FXS, 9 FXS+ASD). Data were collected on an SR Eyelink 1000 plus eye tracker. Stimuli consisted of a split screen video of biological motion point light displays horizontally juxtaposed to random point light displays with the same motion, presented at16° visual angle, for 30 trials, 4-5seconds each. A central fixation point was displayed before each trial that triggered the start of the next trial after a 250ms fixation. Percentage of looking time at biological motion was the time spent looking at biological motion divided by the total looking time at either region of interest (biological motion or random motion control), aggregated across all trials to create a single outcome measure of each participant. Trials with total looking times in both interest areas (i.e. biological motion and random motion) less than 1000ms were removed from the analysis. Participants also completed the ADOS-2. Severity scores from the ADOS-2 were used in the analysis as a measure of autism symptomatology. Analysis included Pearson-product moment correlations and a one-way ANOVA.
Results: No significant correlations were observed between percentage of time looking at biological motion and severity scores on the ADOS-2 (r = -.12, p = .7). An ANOVA to compare mean looking times between the individuals with FXS with and without autism indicated no differences in mean looking time to biological motion, FXS (M = 52.2%, SD =3.56) and FXS+ASD (M = 52.11%, SD=6.38).
Conclusions: Findings suggest that severity of autism symptomatology is not related to preferential attention to biological motion in individuals with FXS, and preferential attention to biological motion does not differ between individuals with FXS and FXS+ASD. Given variability in the data, we will examine these data with a larger sample, add a group with idiopathic (non-FXS) autism and examine the effect of other variables (e.g., genetics) to document preferential looking to biological motion in FXS.

159 **110.159** Cardiac Vagal Tone Predicts Eye Gaze Fixation in the Broad Autism Phenotype

J. Klusek[1], *J. Schmidt*[2], *A. Porter*[1] *and J. E. Roberts*[1], *(1)Psychology, University of South Carolina, Columbia, SC, (2)University of Central Florida, Orlando, FL*

Background: Diminished gaze fixation is a primary feature of autism spectrum disorder (ASD) that is associated with abnormal neural activation patterns (Dalton et al., 2005; Senju et al., 2005). Diminished gaze fixation has also been documented as part of the broad autism phenotype (BAP), both in infant siblings of children with ASD (Dalton et al., 2005), as well as among parents of children with ASD (Adolphs et al., 2008). The expression of the BAP among unaffected relatives is believed to reflect genetic liability for ASD, and studies aimed at defining mechanisms underlying these features may hold important clues into causal pathways in ASD. Autonomic nervous system dysfunction is present among some individuals with ASD and is thought to underlie aberrant social behavior (Klusek et al., 2015). The present study examined cardiac vagal tone, an index of the parasympathetic “rest and restore” response, as a potential mechanism for diminished gaze fixation in the broad autism phenotype.
Objectives: To investigate the relationship between cardiac vagal tone and gaze fixation patterns in response to direct and averted eye gaze among mothers of children with ASD and control mothers of children with typical development.
Methods: Eye movements of 16 mothers of children with ASD (mean age=48.39 years) and 21 control mothers of children with typical development (mean age=43.15) were recorded while watching an animated female face displaying either direct or averted gaze for 6.3 seconds (stimuli from Weiser et al., 2009). Trials began with participants fixating within the eye region and the percent of time dwelling within the eye region was quantified. Prior to completing the eyetracking paradigm, baseline cardiac activity was measured during a 3 minute baseline where participants viewed a calming ocean scene. CardioEdit/Batch software (Brain-Body Center, University of Illinois) was used to extract mean estimates for respiratory sinus arrhythmia, an index of vagal tone. Higher vagal tone reflects increased parasympathetic control and thus improved autonomic flexibility.
Results: Repeated measures ANOVA tested the effect of vagal tone, group, their interaction, and condition (averted vs. direct gaze) on the percent of time spent dwelling within the eye region of the face. A significant group-by-vagal tone interaction was detected, where higher vagal tone was associated with a greater percent of time dwelling within the eye region among the mothers of children with ASD, whereas these variables were unrelated in the control mothers (F[1,33] = 4.70, p = .038). The effect of condition was not significant (p = .449).
Conclusions: Poorer autonomic nervous system flexibility among mothers of children with ASD, indexed by dampened parasympathetic vagal tone, was associated with decreased gaze fixation. This finding highlights autonomic nervous system dysfunction as a potential mechanism that may underlie atypical gaze fixation patterns seen in ASD and its broader phenotypes.

160 **110.160** Children with Autism Are Hypo-Responsive to Human Eyes Presented without Sound, but Hyper-Responsive to Eyes Presented after Social Sounds

J. L. Kleberg[1], *E. Thorup*[2] *and T. Falck-Ytter*[3], *(1)Box 1225, Uppsala University, Uppsala, Sweden, (2)Uppsala universitet, Hägersten, Sweden, (3)Uppsala University, Uppsala, Sweden*

Background: Children with this autism spectrum disorder (ASD) often fail to make use of human gaze to learn about the social world. A subcortical network involving the superior colliculus, amygdala and putamen underlies rapid orientation to human faces. Influential theories have suggested that altered functioning of this network is an important part of the ASD phenotype. Recent studies have questioned these theories by demonstrating intact orienting to face-like configurations in people with ASD.
Objectives: We hypothesized that children with ASD would be slower than typically developing (TD) children to orient to isolated eyes. Our study was based on the prediction that visual orienting to human eyes rather than to faces as a whole is reduced in ASD. This prediction was based on single-cell recordings in monkeys and electrophysiological data from humans demonstrating that the neural mechanisms underlying responses to eyes and whole faces are partly dissociable. In addition, we examined the effect of spatially nonpredictive social and nonsocial sounds on visual orienting in children with and without ASD.
Methods: Seventeen children with ASD (mean age: 6.5 years) participated in the experiment along with a typically developing (TD) control group matched for age and nonverbal IQ. We presented images of human eyes with direct gaze along with three nonsocial objects. Trials could be preceded by a social sound (a single phoneme spoken by a human voice), by a common nonsocial sound or by no sound. The eye regions of fearful faces were used as stimuli. We used eyes displaying fear to maximize the likelihood of quick orienting of attention (based on previous research). The latency of the saccades was measured with corneal reflection eye tracker at a sample rate of 60 hz.
Results: We found a strong interaction effect between group and sound type (p <.001), indicating that the presence of sound had a different impact on saccadic latency in the two groups. As expected, the ASD group was slower to orient to the eyes than the TD group on silent trials (p = .01). In contrast, children with ASD were faster to orient to the eyes than the TD group after social sound (p <.001). No group difference was found after nonsocial sounds. Higher degrees of ASD symptoms as measured with the ADOS-2 predicted faster orienting to the eyes after social sounds (r = .61; p <.05).
Conclusions: Our results provide clear evidence of reduced social orienting in ASD, but suggest that brain mechanism underlying responses to eyes rather than to whole faces are the source of this effect. The strong modulation by non-visual information provides support for the view that ASD is characterized by network-wide atypicalities in information integration. Our results show that the multisensory environment is highly important for early social attention in children with ASD. These results have implications for our understanding of early attentional impairments in ASD.

161 **110.161** Common Genetic Variation in Neuropeptide Receptors and Social Processing Across Neurodevelopmental Disorders

D. A. Baribeau[1], *A. Dupuis*[2], *T. A. Paton*[3], *S. W. Scherer*[4], *R. Schachar*[5], *P. D. Arnold*[6], *P. Szatmari*[7], *R. Nicolson*[8], *S. Georgiades*[9], *N. Soreni*[9], *J. Crosbie*[2], *J. A. Brian*[10], *A. Iaboni*[11] *and E. Anagnostou*[1], *(1)University of Toronto, Toronto, ON, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)the Centre for Applied Genomics at the Hospital for Sick Children, Toronto, ON, Canada, (4)Centre for Applied Genomics (TCAG), Hospital for Sick Children, Toronto, ON, Canada, (5)Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (6)University of Calgary, Calgary, AB, Canada, (7)Centre for Addiction and Mental Health, Toronto, ON, Canada, (8)University of Western Ontario, London, ON, Canada, (9)McMaster University, Hamilton, ON, Canada, (10)Bloorview Research Institute, Toronto, ON, Canada, (11)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Common genetic variation in the oxytocin receptor (OXTR) and vasopressin receptor (AVPR1a) genes has been associated with differences in social abilities in typically developing individuals and in those with autism spectrum disorder (ASD). Whether common genetic variation in OXTR or AVPR1a also affects social abilities to the same degree in other neurodevelopmental disorders is unknown.
Objectives: To examine the effects of common genetic variation in the oxytocin receptor (OXTR) and vasopressin receptor (AVPR1a) genes, on social communication and perception abilities across different childhood onset neurodevelopmental disorders.
Methods: Children with autism spectrum disorder (ASD), attention deficit hyperactivity disorder (ADHD), or obsessive-compulsive disorder (OCD) (n=253), completed a standardized social perception task (Reading the Mind in the Eyes Test-RMET) and their parents/caregivers completed the Social Communication Questionnaire (SCQ). DNA from blood/saliva was analyzed to determine individual genotypes for 5 OXTR single nucleotide polymorphisms (SNPs) and AVPR1a RS3 microsatellite length. Social communication, as measured by the SCQ, and social perception abilities, as measured by the RMET, were compared by genotype using regression models, while controlling for differences in age, sex, ancestry and IQ. Significant findings were examined for interactions with diagnosis.
Results: Social communication abilities varied significantly by genotype for one OXTR SNP (OXTR rs53576) and showed a trend towards an association for another (OXTR rs237887) (p = 0.007, and p = 0.05 respectively). For OXTR rs237887, secondary pairwise comparisons of RMET scores by genotype revealed a pattern congruent with SCQ scores. Length of AVPR1a RS3 did not impact social communication or perception abilities. For analyses involving OXTR rs53576, genotype effects on SCQ scores were

highly significant in the group with ASD only ($p \leq 0.0001$), with no significant effects detected in the other diagnostic groups. Specific allele pairs in combination [OXTR rs53576 (GG) and OXTR rs237887 (AA)] were associated with greater social communication deficits.
Conclusions: Common genetic variation in OXTR, but not AVPR1a, was associated with variable social communication abilities across neurodevelopmental disorders in this sample, suggesting that common variation may play a role in modifying severity of social impairment. Children with ASD may be more sensitive to this effect.

162 **110.162** Developing an Eye-Tracking Biomarker to Measure Social Motivation in Minimally Verbal Children with ASD

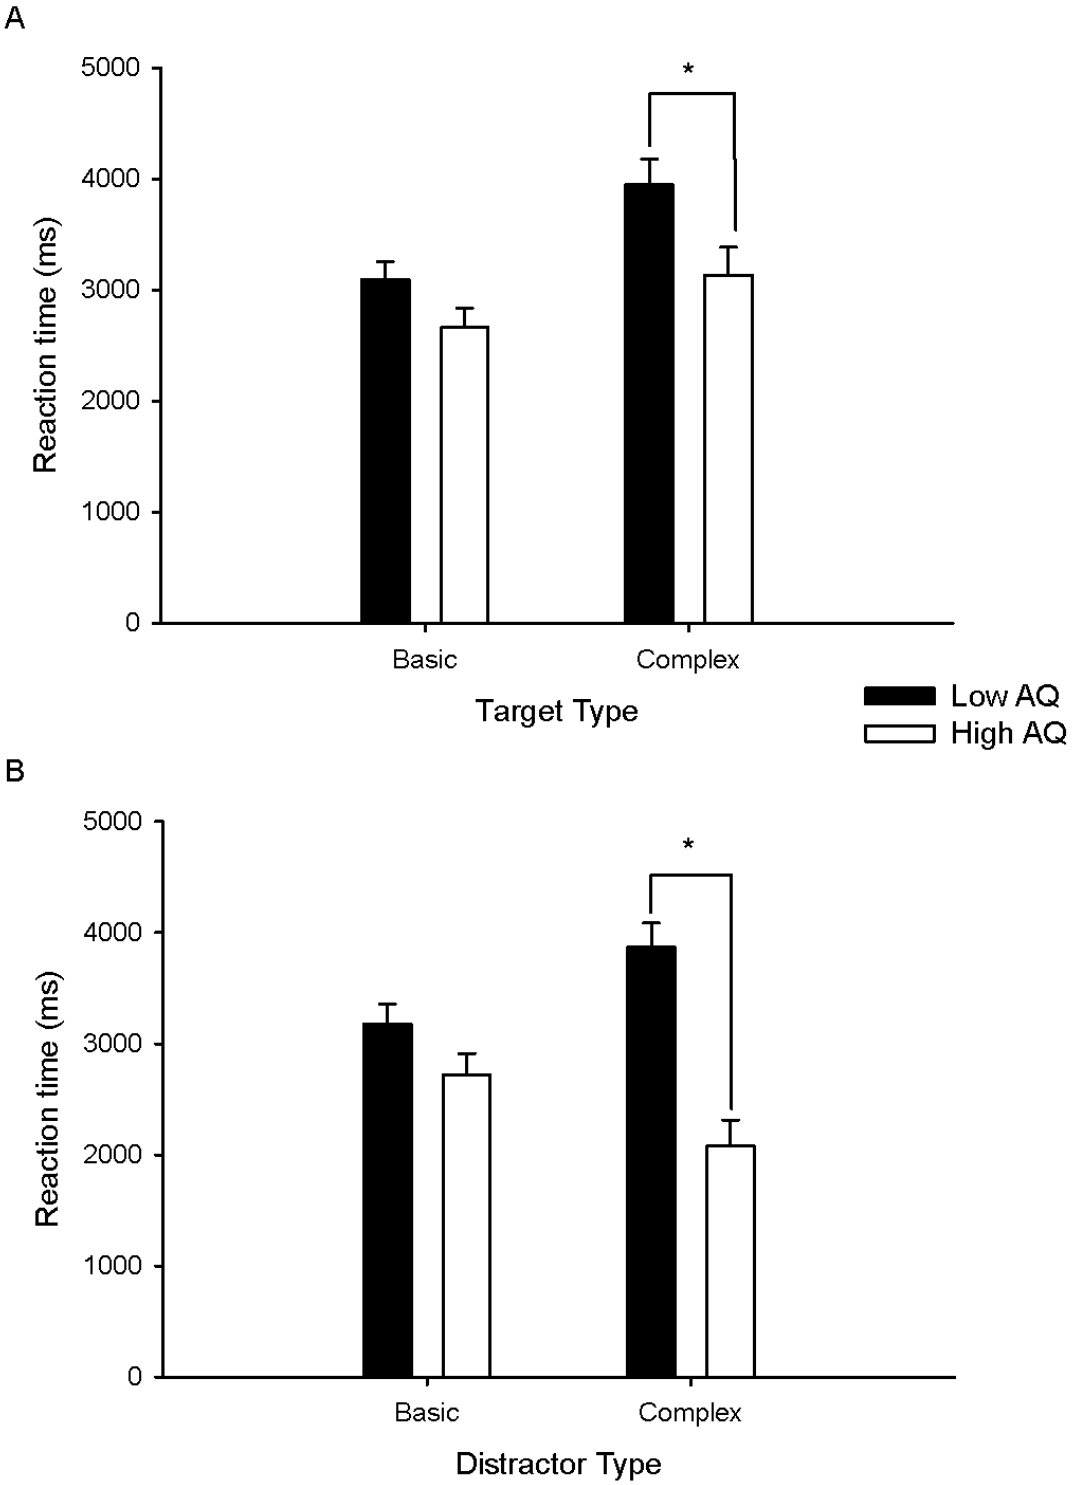
K. Unruh[1,2], *J. W. Bodfish*[1,2,3] *and E. Morrow*[1,3], *(1)Vanderbilt University, Nashville, TN, (2)Vanderbilt Brain Institute, Nashville, TN, (3)Vanderbilt Bill Wilkerson Center, Nashville, TN*

Background: Approximately 30% of persons with autism have minimal verbal ability (MVA). This subgroup of cases often experiences significantly greater morbidity and poorer outcomes relative to their ASD peers with average verbal ability (AVA). This subgroup is frequently excluded from research studies, as most ASD-related measures are not applicable to persons with cognitive / language deficits. Eye-tracking technology can be used to quantify ASD-relevant features such as social attention and motivation, can be configured to require minimal task demands of the participant. For these reasons, this method is a reasonable platform for the development of measures applicable to cases with cognitive / language deficits.
Objectives: To compare subgroups of minimal verbal ability (MVA) and average verbal ability (AVA) children with ASD on gaze measures from a passive social versus nonsocial image paired preference task.
Methods: Our preferential viewing (eye-tracking) task measures patterns of visual attention to social and nonsocial content. Social images (SOC) are paired with one of two types of objects: images of high interest to children with ASD (HAI images; e.g. trains, electronics) and images of low interest to children with ASD (LAI images; e.g. clothing, furniture). Stimuli were presented in a passive manner (no instructions) for 5 seconds each, with a variable 2-6 second interstimulus interval. Participants with ASD were classified as either MVA (Verbal IQ < 70; N = 15; mean age = 11.9 years) or AVA (Verbal IQ > 90; N = 48; mean age = 13.9 years); our sample also included typically developing peers (TYP; N = 31, mean age = 13.8 years).
Results: Task completion rate was similar across ASD groups (67% of MVA, 69% of AVA). Both MVA and AVA subgroups were slower than the TYP group to orient to faces (latency), only when paired with HAI images ($F(2,71) = 6.59$, $p = .002$) but not LAI images ($F(2, 71) = .457$, $p = .635$). Latency to face did not differ between ASD subgroups for either array type ($t = -1.6$, $p = .22$). MVA participants made more fixations to faces than both TYP and AVA participants ($F(2,59) = 11.2$, $p < .001$); however, these fixations were shorter in their average duration ($F(2,59) = 17.18$, $p < .001$).
Conclusions: Here we demonstrate that minimally verbal children with ASD can successfully complete a passive eye-tracking task at rates that are comparable to those of verbal ASD peers. Both MVA and AVA children were significantly slower to look to faces when paired with an HAI image, relative to TYP, providing evidence that social motivation deficits may manifest similarly in both ASD subgroups. Domain general attentional parameters (e.g., fixation duration) were similar in AVA and TYP but altered in MVA suggesting that MVA children may have a unique attentional impairment relative to their verbal peers with ASD.

163 **110.163** Differences in Reaction Time to Detect Emotion Faces Varies Based on Autistic Social Skills and Communication Abilities in Young Adults

J. Burk[1], *C. Dickter*[1], *J. Zeman*[2] *and K. M. Fleckenstein*[3], *(1)College of William & Mary, Williamsburg, VA, (2)Psychology, College of William and Mary, Williamsburg, VA, (3)College of William and Mary, Williamsburg, VA*

Background: Individuals with autism spectrum disorders (ASD) show challenges with tasks that involve rule switching or ignoring distracting stimuli, but better performance in visual search tasks that require identification of specific features in the target stimulus.
Objectives: The goal of the present study was twofold. We wanted to test a group of participants who were along the broader autism phenotype (BAP) in a visual search task. We modified the task to include emotion faces to test whether advantages in visual search performance would be stronger with these stimuli, rather than neutral stimuli.
Methods: Participants were 136 non-ASD undergraduate students (44.4% men; M_{age} =19.1 years; 76.3% Caucasian). Participants completed the Autism Quotient (AQ, Baron-Cohen et al., 2001).), a measure that assesses self-report of autistic-like behaviors. The AQ has five sub-scales assessing autistic behaviors including social skills, attention switching, communication, imagination, and attention to detail. Participants completed a modified visual search task, a procedure that typically measures attention by assessing response speed whenthere is a discrepant stimulus among other stimuli displaying the same properties (Plaisted et al., 2010). The visual search task was modified by using faces that displayed either basic emotions (i.e., happiness,anger) or complex emotions (i.e., surprise, fear). Participants indicated whether a group of 8 or 16 faces on the screen depicted the same emotion or different emotion by pressing a certain key on a keyboard.
Results: For the total AQ and each subscale, the top and bottom third of participants were compared. Reaction time data were analyzed using a 2 (Target: basic, complex) x 2 (Distractor: basic, complex) x 2 (Number of Stimuli: 8, 16) x 2 (AQ scale: bottom third [low AQ], top third [high AQ]) mixed model ANOVA. Only significant effects involving AQ are reported below. For total AQ, there was a between-subjects main effect, with low AQ participants responding more slowly ($M = 3905.99$, $SE = 263.01$) than high AQ participants ($M = 3105.19$, $SE = 241.93$), $F(1, 70) = 5.02$, $p = .03$. For the Social Skills subscale, there was a Target x AQ interaction, $F(1, 81) = 5.04$, $p = .03$. For complex targets, low AQ participants were significantly slower than high AQ participants, $F(1, 82) = 5.69$, $p = .02$ (Figure 1A). There was also a Distractor x AQ interaction, $F(1, 81) = 4.19$, $p = .04$. For complex distractors, low AQ participants were significantly slower than high AQ participants, $F(1, 82) = 6.20$, $p = .02$ (Figure 1B). For the Communication subscale, there was a Distractor x AQ interaction, $F(1, 70) = 4.71$, $p = .03$. For basic emotions, $F(1, 70) = 5.63$, $p = .02$ and complex emotion, $F(1, 70) = 8.39$, $p = .01$, distractors, low AQ participants were slower than high AQ participants.
Conclusions: Individuals who scored high on the total AQ and the socioemotional AQ subscales, and may be along the BAP, show faster identification on a visual search task compared to those who score low on these measures, even when the target stimuli are emotion faces.



164 **110.164** Dissociating Social Functioning in ASD and Schizophrenia Using Clinical Assessment and Neural Response to Gaze Cues

J. H. Foss-Feig[1], *A. Naples*[2], *K. Deckert*[3], *E. J. Levy*[3], *K. K. Stavropoulos*[2], *M. Rolison*[2], *N. Santamauro*[4], *U. Kosir*[5], *C. Schleifer*[5], *V. Srihari*[4], *A. Anticevic*[4] *and J. McPartland*[2], *(1)Yale School of Medicine, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT, (3)Yale Child Study Center, New Haven, CT, (4)Yale University School of Medicine, New Haven, CT, (5)Yale University, New Haven, CT*

Background:
Social difficulties, including deficits in maintaining and interpreting social gaze and in face and emotion processing, are hallmark features of autism spectrum disorder (ASD). Atypical social functioning and gaze processing are not, however, unique to ASD. Both are also impaired in schizophrenia (SCZ), a disorder with genetic, neurobiological, and phenotypic commonalities with ASD. This study utilized novel methods, integrating eye-tracking and electrophysiology (EEG), to study social behavior and brain function during simulated face-to-face interactions in individuals with ASD and SCZ. Specifically, we evaluated P100 and N170 response to direct and averted gaze in adults with ASD, SCZ, and typical development to determine between-group differences in neural processes associated with face decoding. In parallel, we evaluated social functioning on a battery of diagnostic, clinical, and neurocognitive assessments. In this way, we evaluate whether specific abnormalities in gaze processing differ by diagnostic category or are general indicators of social dysfunction across neurodevelopmental disorders.
Objectives:

To evaluate neural markers of gaze processing during simulated face-to-face interactions in individuals with ASD, in comparison to those with SCZ and controls.
Methods:
Participants included 13 adults with ASD, 14 with SCZ, and 15 controls. EEG data was recorded using a 128-channel sensor net, and eye-tracking data was collected using an Eyelink-1000 remote camera system. Participants were presented with 80 distinct photorealistic, animated faces matched for low-level visual features. Contingent upon participants' fixating on the face, stimuli responded by shifting eye gaze (either from direct to averted or averted to direct). EEG data was preprocessed off-line, and the P100 and N170 was extracted from electrodes over right occipitotemporal scalp. Participants completed the Social Responsiveness Scale, the Benton Face Recognition task, and the Reading the Mind in the Eyes Test. All were administered gold-standard diagnostic measures of both ASD and SCZ (Autism Diagnostic Observation Schedule; Positive and Negative Symptom Scale). Between-group differences were examined with repeated measures ANOVAs; transdiagnostic associations between neural response to gaze shift and clinical assessment scores were explored with bivariate correlations.
Results:
Between-group analyses revealed amplified P1 response in SCZ, but not ASD, and altered N170 response in ASD, but not SCZ (Fig.1). In contrast to ERP markers, self-report measures of ASD and SCZ symptomatology did not differentiate between diagnostic categories. Across groups, greater P1 response was associated with more positive symptoms of SCZ and with fewer social communication deficits associated with ASD (Fig.2).
Conclusions:
Results revealed that neural efficiency of visual processing and face-decoding during simulated face-to-face interactions differentiates ASD from SCZ. In contrast, signal strength relates to symptom severity transdiagnostically, rather than varying by diagnostic category. These findings support a dimensional approach to understanding gaze processing differences in ASD and related disorders.

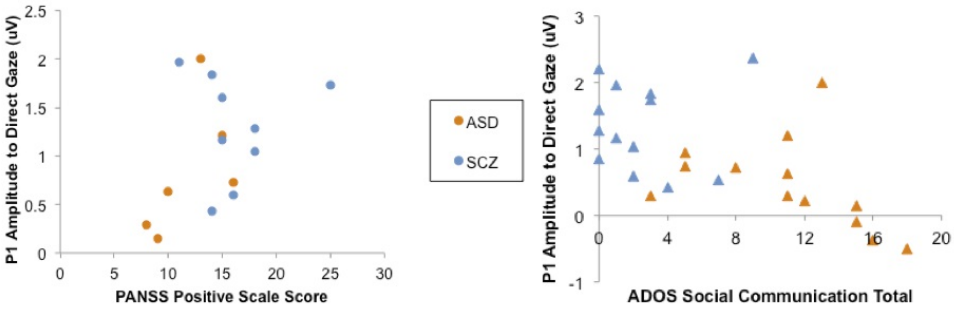

Fig.2. Neural response to gaze associate with symptoms of SCZ and ASD transdiagnostically

165 **110.165** Distinctive Abnormalities in Imitative Response to Socially Engaging Versus Neutral Partners Are Specific to ASD and Predict Treatment Outcomes

G. Vivanti, *Olga Tennison Autism Research Centre, Melbourne, Australia*

Background: While imitation difficulties are often documented in preschoolers with ASD, it is not yet clear whether such abnormalities reflect differences of a social, attentional, cognitive and/or motor nature. As early educational intervention programs often require children to imitate actions and behaviors that are demonstrated to them during social routines, it is plausible that differences in imitation will impact on response to educational programs in this population. Therefore, a fine-grained understanding of the social, attentional, motor and cognitive processes underlying imitation abnormalities in ASD has the potential to advance knowledge on both the mechanisms of impairment and the mechanisms of treatment response in this population.

Objectives: We investigated multiple processes underlying imitation in 35 preschoolers with ASD and 20 peers with Williams syndrome (WS), matched for age, cognitive, verbal and motor functioning, with the aim to identify whether putative imitation differences between the groups were (1) specifically linked to differences in sociability observed in these two disorders, or associated with motor and cognitive difficulties shared by ASD and WS, and (2) linked to learning outcomes in response to early intervention in ASD.

Methods: We tested participants' spontaneous propensity to imitate others and the accuracy of imitation performance in response to a series of novel eye-tracking-based imitation tasks, in which the following factors were manipulated 1) motor demands, 2) social engagement of the model demonstrating the action, 3) presence/absence of clear mean-goals structure, and 4) attentional demands. In the ASD group, we also examined the extent to which individual differences in imitative learning were correlated to intensive early intervention gains occurring in the 12 months following the test.

Results: We found that children with WS increased their attention to the model and their propensity to imitate the demonstrated action in response to a socially engaging versus a neutral partner. In contrast, preschoolers with ASD showed a similarly reduced propensity to look at the model and to imitate her actions regardless to whether the model was socially engaging or neutral (Group by Condition Interaction F (2, 52)=5.5; p<0.05, η2= 0.95). We also found that children with WS imitated actions that were not relevant to the actions' outcomes (overimitation) while this was not the case in children with ASD (Mann Whitney U = 290, p<.05). In contrast, the two groups showed similar strengths in the instrumental aspects of imitation (e.g. understanding of the mean-goals articulation of the demonstrated actions) and a similar decrease in imitation accuracy as the motor complexity of the demonstrated actions increased. Imitative response to a socially engaging but not to a neutral model in ASD was a robust predictor to early intervention outcomes (r=.7, p<.005).
Conclusions: Social motivational factors underlying imitation appear to be distinctively impaired in young children with ASD and to be linked to early intervention outcomes.

166 **110.166** Does Early Response to Joint Attention Predict Executive Functioning Among Infant Siblings at School-Age?

M. del Rosario[1], *K. Gillespie-Lynch*[2], *N. Pham*[3], *T. A. De los Santos*[3] *and T. Hutman*[4], *(1)Medicine, University of California, Los Angeles, Los Angeles, CA, (2)City University of New York, College of Staten Island, Staten Island, NY, (3)University of California, Los Angeles, Los Angeles, CA, (4)University of California Los Angeles, Los Angeles, CA*

Background: Response to joint attention (RJA) (Mundy et al., 1986) and executive functioning (EF) (Dawson et al., 1998) are impaired in children with ASD. Difficulty regulating attention may contribute to JA and EF challenges in ASD (Dawson et al., 2002; Van Hecke et al., 2011). RJA deficits among children with ASD are evident by 12 months (Osterling and Dawson, 1994) while impairments in EF are not apparent until approximately school age (Dawson et al., 1998; 2002). Concurrent relations between RJA and EF have been found in young children with ASD (Dawson et al., 2002). Among typically-developing children, early RJA has been associated with EF at preschool age (Van Hecke et al., 2011; Morales et al., 2005). Longitudinal relations between RJA in toddlerhood and later EF have not been evaluated in ASD.
Objectives: The current study examines associations between RJA at 18 months and EF at school age among children with and without ASD.
Methods: Participants were at high- (n=48) and low-risk (n=17) for ASD. High-risk participants had an older sibling diagnosed with ASD. Diagnostic assessments at or after 36 months yielded three "outcome" groups: ASD (n=11), non-ASD developmental concerns (Concerns; n=10), and typically developing (TD; n=44). RJA, evaluated at 18 months using the Early Social and Communication Scales (Seibert et al., 1982), was calculated as the percentage of trials on which participants followed the examiner's points to pictures in a book (RJA proximal) and posters on the wall (RJA distal). Parents completed the Behavior Rating Inventory of Executive Functioning (BRIEF; Gioia et al., 2000) when participants reached school age (5-9 years old). Higher BRIEF scores correspond to poorer EF.
Results: MANOVAs indicated no differences in EF subscales between risk groups, but ASD > TD and Concerns groups on inhibitory control, attention shifting, working memory, planning, and the ability to monitor effect on others; ASD > TD only on emotional control, p's < .05. Kendall's tau correlation analyses with the full sample indicated negative associations between RJA proximal and inhibitory control, attention shifting, working memory, and planning, and associations between RJA distal and inhibitory control (tau's ranged -.25 to -.32, p's ≤ .05). When correlations were tested separately in ASD and non-ASD groups, associations between RJA and EF were specific to the ASD group: inhibitory control was associated with both RJA proximal (tau = -.741, p=.014) and RJA distal (tau = -.684, p=.042).
Conclusions: Findings extend upon prior research demonstrating that RJA is a core difficulty in ASD (e.g., Sigman & Ruskin, 1999) by documenting longitudinal associations between RJA and EF in ASD. Early difficulties regulating shared attention (RJA) may contribute to later difficulties inhibiting ineffective behaviors. Although associations between RJA and EF were not observed in the non-ASD group, both RJA proximal and RJA distal were negatively correlated with inhibitory control in the ASD group. Inhibitory control is positively associated with math and literacy skills (Blair & Razza, 2007). Thus, early intervention targeting RJA among infants at risk for ASD may support the development of self-regulation and academic achievement.

167 **110.167** Effects of Reciprocal Imitation Training on Brain and Behaviour: A Pilot Randomized Controlled Trial

S. Malik[1], *C. Oliver*[1], *J. Moss*[2], *B. Ingersoll*[3], *C. Stefanidou*[4], *A. Wainer*[5], *L. Kossyvaki*[6] *and J. McCleery*[7], *(1)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (2)University of Birmingham, Birmingham, England, United Kingdom of Great Britain and Northern Ireland, (3)Michigan State University, East Lansing, MI, (4)University of Birmingham, Birmingham, United Kingdom, (5)Autism Assessment, Research, Treatment and Services Center, Rush University Medical Center, Chicago, IL, (6)School of Education, University of Birmingham, Birmingham, United Kingdom, (7)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

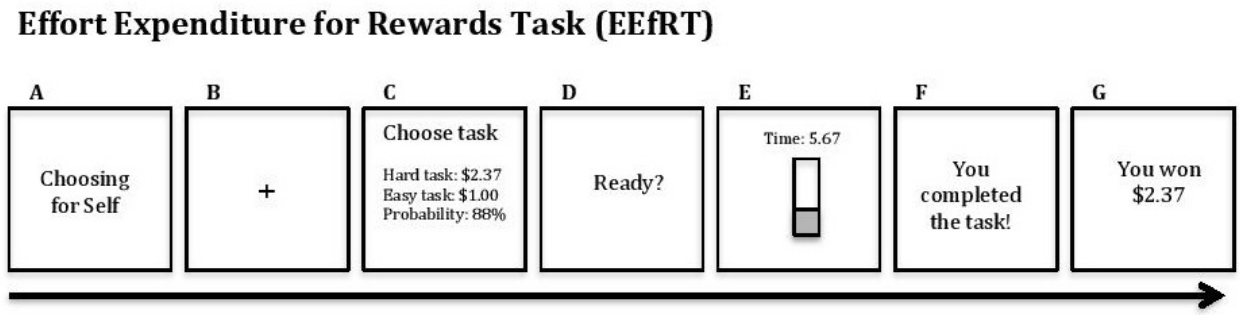
Background:
Reciprocal Imitation Training (RIT) is a play-based developmental-behavioural intervention focused on increasing imitation skills and gesture use, developed to address social imitation deficits in individuals with autism. Previous research has demonstrated RIT to be effective for increasing spontaneous object and gesture-based imitation.
Objectives:
The current study is an examination of electroencephalographic (EEG) measures of brain activity as potential biomarkers for these intervention effects, in the context of an external-laboratory replication trial.
Methods:
Participants in this completed Randomized Controlled Trial were 24 children with autism aged 2- to 6-years. An intervention group received 20 sessions of RIT over a period of 12 weeks, relative to a Wait-List control group. Stratified randomization was conducted utilizing pre-defined chronological age and verbal ability criteria at intake. Pre- and post-intervention assessments included the verbal portion of the Mullen Scales of Early Learning, the Autism Diagnostic Observation Schedule, and two experimental-behavioural change measures: Unstructured Imitation Assessment (UIA) and Structured Imitation Assessment (SIA), administered by experimenters who were blinded to intervention status. Event-related potentials were recorded at post-training utilizing a Rapid Auditory Mismatch paradigm for Human versus Non-Human Action Sound Processing previously utilized in our laboratory to study children with and without Autism Spectrum Disorder.
Results:
Behavioral effects of RIT were evaluated using a repeated-measures ANOVA, with post-hoc t-tests further comparing baseline scores with scores after 12 weeks. Children in the intervention group (N = 12; M = 11.08, S.D. = 10.4) made significantly more gains in spontaneous imitation measured via the UIA as compared to children in the wait-list group (N = 12; M = 6.3, S.D. = 9.3), F (1,22) = 8.09, p < .01, η_p^2 = .27. Follow-up t-tests on the intervention group data further supported this finding, exhibiting a significant difference between pre-intervention and post-intervention imitation scores, t (11) = -3.1, p = .01. Repeated measures ANOVAs conducted on event-related potentials data recorded over medial central and medial parietal cortex produced interactions of Participant Group (Intervention, Wait-List) by Stimulus (Human, Non-Human) by Congruency (Match, Mismatch) which indicated that children in the Intervention group (N = 8) exhibited larger amplitude responses for human stimuli which were preceded by a non-human stimulus (mismatch) whereas Wait-List participants (N = 7) exhibited larger amplitude responses for human stimuli which were preceded by a human stimulus (match), F (1,13) = 11.45, p < .01, η_p^2 = .47 and F(1,13) = 5.59, p=0.02, η_p^2= 0.3 for central and parietal components respectively.
Conclusions:
The current findings produced an external-laboratory replication of previous behavioural intervention effects driven by RIT, providing further experimental evidence for the effectiveness of RIT for improving socially interactive imitation during unstructured play. The results of the event-related potentials assessment provide further experimental evidence to suggest that these behavioural effects are associated with increased attentional orienting responses to social stimuli, reflected in increased central and parietal brain activity in response to human sounds which are not predicted from the preceding context.

168 **110.168** Effort-Based Decision-Making in Adolescents with Autism Spectrum Disorders

M. G. Mosner[1], *J. Kinard*[2], *S. McWeeny*[3], *C. R. Damiano*[4], *M. R. Burchinal*[5], *H. J. V. Rutherford*[6], *M. T. Treadway*[7] *and G. S. Dichter*[8], *(1)University of North Carolina, Carrboro, NC, (2)Carolina Institute for Developmental Disabilities, University of North Carolina School of Medicine, Chapel Hill, NC, (3)Psychology, University of Chapel Hill, Carrboro, NC, (4)University of North Carolina, Durham, NC, (5)Data Management and Analysis Core, Frank Porter Graham Child Development Institute, University of North Carolina, Chapel Hill, NC, (6)Yale Child Study Center, Yale University, New Haven, CT, (7)Department of Psychology, Emory University, Atlanta, GA, (8)University of North Carolina, Chapel Hill, NC*

Background: The purpose of this investigation is to examine effort-based decision-making in adolescents with autism spectrum disorder (ASD). It is well established that ASD is characterized by deficits in social cognition, social perception, and social communication. However, there has been recent emphasis on addressing motivational aspects of social deficits in ASD (Chevallier, Kohls, Troiani, Brodkin, & Schultz, 2012). Although current conceptualizations of reward processing deficits in ASD have focused specifically on processing of social rewards, evidence suggests that processing of non-social rewards is impaired in ASD as well (Dichter & Adolphs, 2012). Recently, our research group reported that adults with ASD are characterized by impaired effort-based decision-making in the context of monetary rewards (Damiano, Aloi, Treadway, Bodfish, & Dichter, 2012).
Objectives: The present study is a downward extension of our previous findings and explores effort-based decision-making in adolescents with ASD. Additionally, effort-based decision-making in the context of rewards for self versus others will be investigated.
Methods: To date, we have collected data from 15 typically developing controls (TDCs; age *M*= 14.79, IQ *M* =109) and 24 high-functioning adolescents with ASD (age *M*=14.96, IQ *M* =97). ASD diagnoses were confirmed with the ADOS-2 and groups were matched on age and gender distribution (*p*'s>.05). By the date of the IMFAR conference, we anticipate that we will have collected data from an additional 10 TDCs and 10 participants with ASD. A modified version of the Effort Expenditure for Rewards Task (EEfRT) was used as a behavioral measure of effort-based decision-making. In this task, participants were provided with the probability of receiving monetary rewards on a given trial and asked to choose between an "easy task" for a small, stable reward or a "hard task" for a variable but consistently larger reward (Damiano et al., 2012; Treadway, Buckholtz, Schwartzman, Lambert, & Zald, 2009). In addition, participants were told they were either playing to win money for themselves ("self" condition) or for a

hypothetical person on a particular trial ("other" condition).
Results: Analyses examined the proportion of hard task choices in the "self" and "other" conditions. Results revealed a main effect of group such that the ASD group made fewer hard task choices across both self (p=.014) and other (p=.057) conditions compared to the TDC group. There was no main effect of condition (self vs. other) nor was there a significant group x self vs. other interaction.
Conclusions: Findings suggest that adolescents with ASD are biased towards less effort expenditure for rewards for themselves and for others. These results stand in contrast to our previous findings, in which we found that adults with ASD were biased towards more effort expenditure for rewards. Adolescence in particular may be a period during which reward-based decision-making differs compared to adults (Blakemore, 2008; Rilling & Sanfey, 2011), and these results further highlight that ASD research should be framed in the context of longitudinal change (Karmiloff-Smith, 1998). Future research in this area will consider younger children with ASD as well as effort expenditure for more personally relevant rewards in ASD.



Vicarious version: Schematic diagram of a single trial of the Effort Expenditure for Rewards Task ('EEfRT'). A) Subjects begin by seeing a 1s fixation cue. B) Subjects are told whether they are "Choosing for Self" or "Choosing for Other." C) Unlimited choice period in which subjects are presented with information regarding the reward magnitude of the hard task for that trial, and the probability of receiving any reward for that trial. D) One-second "ready" screen. E) Subjects make rapid button presses to complete the chosen task for 7s (easy task) or 21s (hard task). F) Subjects receive feedback on whether they have completed the task. G) Subjects receive reward feedback as to whether they received any money for that trial.

169 **110.169** Elementary School Impact of Early ABA Intervention

E. Rotheram-Fuller[1], *K. S. Turner*[1], *H. Park*[1], *D. Martinez*[1], *N. L. Matthews*[2] *and C. J. Smith*[2], *(1)Arizona State University, Tempe, AZ, (2)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Applied Behavior Analysis has been shown to be the most effective intervention methodology for children with ASD (Wong et al., 2015). Although there are some initial studies that support the long-term effects of early intervention using ABA for this population (Virués-Ortega, 2010), there remain some questions about all of the ways that intensive early intervention can support children with ASD later in school.
Objectives: This pilot study specifically compared elementary teacher reports of students with ASD who had received early intensive ABA services, relative to students with ASD who did not receive early intervention.
Methods: This study included 14 students with ASD at various functional levels, who completed diagnostic (ADOS-2), intelligence (KBIT-2), and adaptive skills measures (Vineland-II), as well as parent report of previous educational supports and interventions. Nine (64.3%) of these children had previously received intensive early intervention ABA services. Participants were predominantly Caucasian (57.1%), with 28.6% who identified as Latino, 7.1% African American, and 7.1% Asian. The group had IQ scores that ranged from 40 to 87, with a mean score of 63.11 (SD=19.70). All children attended one diagnostic visit at a clinical site, and then the teachers of each child were asked to complete a rating scale on students social and classroom behavior.
Results: There were no significant differences in parent age or education, although this was likely due to sample size. Parents of children receiving ABA services had an average education level of a Bachelors degree, while parents of children not receiving ABA services had an average level of a high school diploma. Of the nine students who received early intervention services, 7 (77.8%) were in inclusive regular education classrooms, while all (n=5) students who did not receive early ABA intervention were in Special Education classrooms. Teacher ratings of students' social behavior did not differ significantly by group, however, their ratings of children's classroom behavior was significantly worse for children who had not received ABA services (M=26.20, SD=3.96), relative to those who had (M=19.88, SD=4.02; t(12)=-2.78, p=0.018).
Conclusions: These preliminary results show that while later social behavior may not be as impacted by early ABA services, classroom behavior is significantly improved for those with early behavioral intervention. Behavior functioning in classrooms is a key to educational success, and may be an essential factor to allow students to remain in less restrictive settings.

170 **110.170** Emotion Recognition Patterns from Facial Expressions in Children with ASD: Results from a Cross-Modal Matching Paradigm

O. Golan[1], *I. Gordon*[1,2], *K. Fichman*[3] *and G. Keinan*[3], *(1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Yale Child Study Center, Yale University, New-Haven, CT, (3)School of Psychological Sciences, Tel-Aviv University, Tel-Aviv, Israel*

Background:
Emotion Recognition (ER) deficits are considered a core characteristic in Autism Spectrum Disorder (ASD). These deficits have been described in specific modalities (e.g., facial expressions, voices) as well as in cross modal settings. Although the clinical definitions and experimental evidence point to a global ER deficit in ASD, several studies also argue for emotion-specific deficits. These conflicting findings raise the question of the specificity of ER deficits in ASD and point to the need for further comparisons of distinct emotions. In addition, inconsistent findings regarding ER in ASD could be related to paradigm requirements as well as to sample characteristics, such as age or levels of functioning.
Objectives:
The current study aimed to (1) Assess ER patterns of four distinct emotions: *happy, angry, sad* and *surprised* in children with ASD, compared to typically-developing (TD) children; and (2) to examine the relative contribution of cues from several perceptual modalities to ER by utilizing a matching paradigm in which cues from 3 different modalities (verbal, vocal or facial) were presented alongside three options of facial expressions.
Methods:
Twenty nine children with medium to high functioning level ASD (5 girls), aged 8-12, were matched on verbal mental age (PPVT) and gender to a group of 34 TD children (7 girls), aged 3-6. In the ER assessment, participants were presented with stimuli in three modalities: facial expressions (NimStim database), non-verbal emotional vocal cues (Montreal Affective Voices), or emotional verbal labels. Each target was presented alongside 3 photos of different facial emotional expressions. Participants were asked to select the facial expression that matches the emotion presented as target. Each of the four emotions tested was represented by four items, comprising three 16 item conditions: face-face, voice-face, and word-face.
Results:
Compared to the TD group, the ASD group had lower scores across all modalities, but group differences were most pronounced in the face-face condition, followed by the word-face and voice-face conditions.
For each of the 4 emotions tested, the ASD group had lower scores than the TD group. Within group comparisons revealed that, whereas in the TD group recognition of *surprise* was significantly lower compared to recognition of all other emotions, that were not different from each other, in the ASD group recognition of *anger* and *surprise* was significantly poorer than recognition of *sadness* and *happiness*.

Verbal mental age had an effect on ER, but had no significant interaction with group.
Conclusions:
Our findings demonstrate a developmental delay in the acquisition of ER skills in children with ASD. Deficits were found not only in emotions requiring mentalization, such as surprise, but also in more basic, situational emotions, such as anger. Our findings regarding the role of modalities in ER, namely that the ASD group seemed to have succeeded the most in the cross-modal (voice-face) condition, and struggled the most in the within modality (face-face) condition, challenge previous findings on cross-modal integration difficulties in ASD, and on visual compensatory mechanisms characteristic of ASD.

171 **110.171** Emotional Effects of Ostracism in ASD: A Physiological Approach

E. Trimmer[1], *S. McDonald*[2], *D. Mathersul*[3] *and J. A. Rushby*[4], *(1)University of New South Wales, Potts Point, NSW, Australia, (2)Psychology, University of New South Wales, Sydney, Australia, (3)University of Pennsylvania, Philadelphia, PA, (4)University of New South Wales, UNSW, Sydney, NSW, Australia*

Background: Social exclusion or ostracism is experienced by most people at some point in their lives. This is even greater for individuals with Autism Spectrum Disorder (ASD). Individuals with ASD experience difficulties making and maintaining friendships as well as difficulties with social communication, often leading to feelings of isolation and social exclusion. Very little research has examined the perceptions and emotional experience of individuals with ASD when they are being ostracized.
Objectives: This study aims to explore the emotional and psychophysiological responses to ostracism in individuals with ASD.
Methods: Twenty-five individuals aged 16 or older (21 males; mean age 27 years) with a diagnosis of ASD and twenty-six matched controls (21 males, mean age 26) participated in an online game of ball tossing, Cyberball. Each participant played two games, both against fictional players: one game in which they were excluded from the game and another in which they were included and the ball was shared equally between players. Whilst playing, participants' arousal level was monitored via skin conductance. Participants were also required to complete a self-report questionnaire about their experience and mood after both games.
Results: Individuals with ASD showed increased arousal compared with controls when playing the game ($p < .001$), both when excluded and included. Furthermore, individuals with ASD demonstrated higher levels of arousal when excluded from the game compared with when they were included. Individuals with ASD did not demonstrate habituation of arousal over the course of the game, as controls did. Psychological responses indicated that individuals with ASD showed similar patterns of responses to controls and shared the same social needs and mood.
Conclusions: The present findings suggest that, when excluded, individuals with ASD exhibited greater emotional response to the game compared to controls. This would suggest that they are more sensitive to ostracism and these effects do not dissipate as quickly as controls. However, these elevated physiological effects of ostracism are not recognised and interpreted as emotionally salient by individuals with ASD.

172 **110.172** Evaluating the Role of Social Approach Behaviors in Language Development

J. Weber[1], *A. Gutierrez*[2] *and M. Alessandri*[2], *(1)Els for Autism Foundation, Jupiter, FL, (2)University of Miami, Coral Gables, FL*

Background:
According to social motivation and social orienting models of autism, decreased social interest leads to less social input and fewer social learning opportunities (Chevallier et al., 2012; Mundy & Neal, 2001). These models suggest that the ability to initiate and participate in social interactions are important factors in language development. Research in this area has focused on the role of joint attention in language development however; the current study takes a broad view of social interest and posits that not only joint attention, but all socially mediated behaviors are important in language development
Objectives:
To evaluate a novel behavioral-coding scheme of social approach behaviors and determine the relationship between social approach behaviors and language development.
Methods:
Thirty-nine children, 3-5 years of age, with ASD who particpated in a completed multisite study comparing pre-school programs were included in the study. The current study utilized ADOS, PLS4 and MSEL assessments, administered at both the beginning and end of the academic year.
A social approach (SA) coding scheme was devised that used frequency counts of seven social behaviors (gaze to a person, smiling, showing, pointing, giving, vocalizations and laughing) emitted during an ADOS. These behaviors were coded as being either initiated by the child or occurring in response to the parent or examiner. No distinction was made on the basis of the function of the behavior. Composite scores of social initiations and responses were used to evaluate the role of these behaviors in both concurrent language abilities as well as language development over the course of an academic year
Results:
SA rates were correlated with existing measures of social motivation suggesting that SA coding is capturing a similar construct as those of existing measures.

Multiple regression was used to determine the relative contribution of ADOS social affect scores, social initiation rates and social response rates. The model significantly predicted concurrent receptive language abilities, however, only social responses significantly contributed to this relationship (Table 1). Hierarchical regression was used to evaluate the role of social initiations and social responses in receptive language development. Both social initiations ($\Delta R^2 = .054$) and social responses ($\Delta R^2 = .076$) were found to significantly contribute to receptive language development.
Equivalent analyses were run for expressive language. Again, only social responses significantly contributed to concurrent expressive language using the multiple regression model (Table 2). Similarly both social initiations ($\Delta R^2 = .043; .05$) and social responses (($\Delta R^2 = .034; .053$) were found to contribute to expressive language development as assessed by the PLS4 and MSEL, respectively.
Conclusions:
The SA coding scheme provides an alternative way to quantify behaviors on the ADOS that may be used in treatment development and assessment. Given the relationship between SA rates and language development, using this coding scheme may provide a way to determine those individual behaviors that lead children to differentially respond to various interventions. Continuing with this line of research will help parents/professionals determine which types of intervention are most beneficial to children based on various pretreatment behavioral profiles.

173 **110.173** Event-Related Potential and Induced Gamma Study of Facial Expression Processing Deficits in Autism

*E. M. Sokhadze[1], **Y. WANG**[2], A. S. El-Baz[3], G. E. Sokhadze[4] and M. F. Casanova[5], (1)Outpatient Clinic, University of South Carolina School of Medicine, Greenville, SC, (2)State Key Laboratory of Cognitive Neuroscience and Learning,BeiJing Normal University, Beijng, China, (3)University of Louisville, Louisville, KY, (4)Anatomical Sciences & Neurobiology, University of Louisville, Louisville, KY, (5)Pediatrics and Biomedical Sciences, University of South Carolina School of Medicine, Greenville, SC*

Background:
Autism spectrum disorder (ASD) is one of neurodevelopment disorders, which presents with impairments in communication and social skills, and stereotyped, repetitive patterns of behavior. Disturbances of affective reactivity and innate inability to perceive and respond to the social cues including facial emotional expressions in a typical and appropriate manner are the hallmark deficits of ASD. There are several theories describing the neurobiology of underlying deficits. The study used event-related potentials (ERP) and single-trial induced EEG gamma oscillations recording in a modification of a "Theory-of-mind" (ToM) test using facial emotional expression recognition to test emotional responsiveness in children with autism and typical age-matched children.
Objectives:
Autism is featured by difficulty in decoding affective facial cues. The goal of the study was to find the differences between ASD group (N=19, mean age 16.3, SD= 4.9 yrs) and typically developing children (CNT group, N=21,14.9 yrs, SD= 4.5 yrs) in behavioral (reaction time and accuracy), induced gamma and ERP correlates of processing emotional information from facial expressions. Children with ADHD (N=14, 14.4 yrs, SD=3.9 yrs) served as a contrast group in induced gamma analysis.

Methods:
Task had 4 different conditions: either to identify the gender or the emotion of the face. Dense-array EEG was recorded using 128 channel EGI system. The ERP components analyzed in the study were parieto-occipital N170, frontal P3a, and parietal P3b, while induced gamma oscillations were recorded at 8 frontal and parietal sites.
Results:
ERP measures yielded following group differences: N170 showed a more negative amplitude in the ASD group than controls when identifying emotional faces (F= 5.66, p=0.023). The latency of N170 was prolonged in the ASD group (F= 7.54, p=0.01). The ASD group had a larger frontal P3a amplitude as compared to controls when differentiating emotions (F= 5.15, p=0.03). In the emotion recognition conditions, P3b had larger amplitude in autism (F= 4.17, p=0.049). Induced gamma (35-45 Hz) oscillations in ASD showed significant differences from controls at all 8 sites of recording in facial emotion discrimination condition (p<0.05).
Conclusions:
The results of the study indicate that more effort is required for an individual with autism to recognize emotion rather than gender from viewing a face. Abnormal processing of emotional stimuli may provide an explanation for some of the social and communicative deficits observed in autism. The results of the study contributes to better understanding of possible neurobiological mechanisms resulting in abnormal processing of facial information resulting in deficient social communication and mentalizing abnormalities in autism spectrum disorders. Analysis revealed larger difference waves in ASD subjects in the N170 component from the occipital cortex and in the P3a component from the frontal cortex. The parietal P3b measurements also showed a larger amplitude and shorter latency when viewing emotion in autism, representing more evaluation of one's performance after a task. The measurement of single trial induced gamma oscillations with advanced alignment technique provides confirmation that differences exist between how children with autism, and those with typical development process emotional stimuli.

174 **110.174** Examining Ecological Validity in the Use of Eye-Tracking for Toddlers with Autism Spectrum Disorders

A. Navab[1], *T. Vernon*[1], *J. Bradshaw*[2], *E. J. Horowitz*[1], *A. Barrett*[3], *J. Ko*[3], *S. Offman*[1], *J. Gong*[1], *A. C. Voos*[1], *T. German*[1] *and R. L. Koegel*[1], *(1)University of California, Santa Barbara, Santa Barbara, CA, (2)Marcus Autism Center, Emory University, Atlanta, GA, (3)Koegel Autism Center, University of California Santa Barbara, Santa Barbara, CA*

Background:
A growing body of eye-tracking literature demonstrates that when compared to TD controls, toddlers with ASD exhibit decreased attention towards socially salient stimuli and increased fixation on non-social stimuli (Pierce et al., 2015; Shic et al., 2011). The degree of deviation away from a typical gaze pattern appears to be a reliable measure of autism severity and holds promise as a potential diagnostic tool (Jones et al, 2008; Rice et al, 2012). However, there is currently little known regarding how eye-tracking task performance relates to preferential gaze during naturalistic interactions with caregivers. Such lines of inquiry may elucidate the ecological validity of eye-tracking data as a social engagement predictor in the real world—especially within the context of crucial interactions with caregivers that may serve as fundamental agents of change during early intervention efforts.
Objectives:
The current study presents data from an intervention study using eye-tracking as an indicator of social motivation prior to treatment onset among toddlers with ASD. Baseline levels of preferential looking were compared to TD toddler performance. Eye-tracking preferential looking was also compared to behavioral performance on measures of autism symptomology (ADOS) and gaze during parent-child interactions in a structured laboratory observation (SLO).
Methods:
Participants included toddlers with ASD (18-54 months) and TD controls. Children viewed a social versus non-social preference paradigm modeled after the social preference task adapted from Pierce et al. (2011). Six 5s videos depicted clips of social interactions presented side-by-side with clips of non-social geometric patterns. Differential looking scores (DLS) for preference across videos were calculated and compared within and between groups. Analyses included associations between DLS and ADOS social affective scores and gaze toward caregiver during the SLO.
Results:
An independent samples t-test revealed that ASD toddlers preferentially gazed at non-social stimuli significantly more than TD controls (T=2.6, p<0.05). This lower mean social preference ratio found in the ASD group was moderately associated with ADOS severity of social impairment. No relationships were found between non-social preferential eye-tracking looking behavior and gaze to caregiver during the SLO.
Conclusions:
The data suggest that compared to TD controls, toddlers with ASD displayed a preference for non-social eye-tracking stimuli that predicted severity of social affect symptoms. Findings also revealed that participants' preference for non-social eye-tracking stimuli did not predict decreased gazing to caregivers during the SLO. Different eye-tracking paradigms may be better suited for unique functions. The task used in this study appears to be a strong indicator of symptom severity, but alternative paradigms may be better suited as a metric of real world social performance. In the future, naturalistic social paradigms may need to be explored as a method for predicting ecologically valid social behaviors in the real world (e.g. looking behaviors, joint attention). Social looking behaviors appear to be influenced by motivational interactions with a caregiver and may be a responsive target to early intervention efforts. Additional post-intervention data may enhance these findings and reveal how social motivation may be a prognostic indicator for treatment outcome for toddlers with ASD.

175 **110.175** Examining the Relationship Between Social Engagement, Self-Esteem, and Self-Perceived Popularity in Adolescents with Autism Spectrum Disorder

E. Kutasevich[1], *J. W. Yang*[2], *E. Veytsman*[3] *and E. A. Laugeson*[3], *(1)Psychiatry, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)The Help Group-UCLA Autism Research Alliance, Sherman Oaks, CA, (3)Psychiatry and Biobehavioral Sciences, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background:
Popularity is often thought to be an important assessment of self-esteem, as well as social standing for adolescents (Boutot 2007). Social acceptance seems to be a predictor of future social functioning throughout adolescence, and later into adulthood (McElhany, Antonishak, Allen 2008). Perhaps due to lack of social skills, adolescents with autism spectrum disorder (ASD) are rarely perceived as popular by their peers (Boutot 2007). Research suggests that adolescents with ASD experience greater peer rejection and poorer friendship quality (Reichow & Volkmar 2010), resulting in less social engagement, which is a key necessity for adolescents with ASD (Conn 2014). With increased expectations to include youth with ASD into mainstream classrooms, there has been an increased need for social inclusion (Owen-DeSchryver et al. 2008); however, research suggests that youth with ASD integrated into general education settings often demonstrate poor quality of social interactions with peers (Owen-DeSchryver et al. 2008). Studies also suggest that when integrated into general education settings, adolescents with ASD are at an increased risk for peer rejection as well as social isolation (White, Koenig, & Scahill 2006). Although poor self-esteem and social standing might easily influence social interactions with others, the relationship between self-perceived popularity, and self-esteem more broadly, has yet to be examined in relation to social engagement in adolescents on the autism spectrum.
Objectives: The purpose of this study was to investigate the relationship between self-esteem, self-perceived popularity, and social engagement among adolescents with ASD without intellectual disabilities.
Methods: Participants included 322 males and 87 females ranging from 11-18 years of age (*M*=13.75, S*D*=1.86) who presented for social skills treatment through the UCLA PEERS® Clinic. To understand the relationship between self-esteem, popularity, and social engagement, teens completed the Piers-Harris Self-Concept Scale-Second Edition (PHS-2; Piers, & Herzberg 2002), which measures perceived self-esteem, including self-perceived popularity, and the Quality of Socialization Questionnaire (QSQ; Frankel & Mintz 2008), which assesses frequency of hosted and invited get-togethers with peers. Pearson correlation coefficients were calculated to examine the relationship between self-reports on the PHS-2 and the QSQ.
Results: Results indicate that greater number of hosted get-togethers on the QSQ are associated with higher levels of self-perceived physical attractiveness on the PHS-2 (p<.001). Moreover, frequency of invited get-togethers on the QSQ is associated with higher levels of self-perceived popularity (p<.001) and physical attractiveness on the PHS-2 (p<.001).
Conclusions: These findings reveal a relationship between self-esteem and social engagement among adolescents with ASD. Results suggest that greater self-perceived popularity and physical attractiveness is associated with greater social engagement with peers. Future research targeting increased self-esteem in youth with ASD might focus on interventions to increase social engagement as another mechanism to improve overall self-concept. With the trend to include adolescents with ASD in general education classrooms, interventions aimed at increasing social engagement in natural social settings, where youth with ASD are often socially isolated (White, Koenig, & Scahill 2006), may not only provide a means for improved social interaction, but may in turn increase self-esteem.

Piers-Harris 2

Quality of Socialization Questionnaire	Perceived Physical Attractiveness
Number of hosted get-togethers	.209

176 **110.176** Exploring Levels of Self-Reported Sympathy and Distress in Individuals with Autism

R. Holt[1], *J. Upadhyay*[2], *P. Smith*[3], *C. Allison*[3], *R. Newman*[2], *T. Boardman*[2], *B. Chakrabarti*[4] *and S. Baron-Cohen*[3], *(1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (4)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background: Difficulties with aspects of social interaction, including empathy, comprise a core symptom of autism spectrum conditions (autism). Sympathy is considered an aspect of empathy involving both cognitive and affective empathy components.
Objectives: Here we present data from a new task of self-reported sympathy and personal distress. Aims: 1) To examine group differences between those with and without autism; 2) To examine sex differences within the autism and control groups; 3) To test for any association between the sympathy task, measures of personal distress, with the Empathy Quotient (EQ).
Methods: Participants with autism (93 males; 161 females) and controls (40 males, 93 females) took part in an online survey via the Autism Research Centre or Cambridge Psychology websites. Participants completed a task where they were asked rate 80 images according to the amount of sympathy they had for the individual and the personal distress they felt. The images consisted of emotionally distressing and non-distressing control images. Participants also completed the EQ and Autism Spectrum Quotient (AQ) questionnaires.
Results: Significant differences ($p < 0.001$) were found between the autism and control groups for both self-reported sympathy and distress, with participants with autism giving lower ratings than controls. When analysing the data from males and females independently the difference between females with autism and control females ($p<.001$) was more pronounced. Males with autism gave significantly lower sympathy ratings compared to controls ($p=.039$) but there was no significant difference for distress ratings. Typical females scored significantly higher than typical males in both sympathy ($p=.001$) and distress ($p=.011$). However sympathy and distress ratings did not differ significantly by sex in the autism group. EQ showed positive correlations with sympathy ($r=.332$) and distress scores ($r=.403$).
Conclusions: Using a new measure to assess levels of self-reported sympathy, this study showed that both males and females with autism gave lower ratings of sympathy when viewing people in distressing scenarios, compared to controls. Females with autism also reported lower levels of distress. Task ratings were correlated with self-reported scores of empathy, providing some validation for this task. The absence of the typical sex difference in autism confirms a pattern seen on other measures of sex differences in empathy. The findings provide further evidence of empathy performance in autism. This task could be useful tool in assessing sympathy as it is less dependent on language ability compared to some other measures. Future research could analyse performance in different subgroups and test physiological arousal to distressing scenarios as another index of how people with autism are different in their experience of sympathy. These results should not be taken to indicate that people with autism are uncaring, as there is considerable evidence that they do care; only that their processing of emotional cues in distressing scenes does not elicit the same level of self-reported sympathy or distress.

177 **110.177** Exploring the Mechanisms Underlying Reduced Emotion Contagion in Autism Spectrum Disorders

D. M. Berry[1] *and A. H. Osborn*[2], *(1)School of Psychology, Keele University, Staffordshire, United Kingdom, (2)School of Life Sciences, Keele University, Staffordshire, United Kingdom*

Background: Why is laughter 'contagious' and why might it be less contagious for people with autism spectrum disorders (ASD)? Typical adults often find certain emotional expressions contagious, particularly laughter. Observing someone laughing frequently results in the observer reciprocating laughter, even if the reason for the original laughter is unknown (Dimberg, 1982). This emotion contagion is suggested to have developed to serve a social function, bonding individuals involved in an interaction (Provine, 2005). Emotion contagion is thought to involve three processes: 1) a physiological response via the sympathetic nervous system 2) internalisation of the observed emotion in the form of a perceived change in subjective mood 3) mirroring the observed emotion by imitating the expression (laughing back).
Objectives: Recent research and numerous case reports suggest that people with ASD are less likely to demonstrate emotion contagion than typical people (Helt, Eigsti, Synder & Fein, 2010) but the reason for this reduced emotion contagion is unknown. The objective of the present research was to identify which of the three processes involved in emotion contagion is impaired in ASD by measuring physiological responses, changes in subjective mood, and time spent mirroring emotions, in adult participants with ASD compared to matched controls.
Methods: Twenty-two participants with ASD (20 males; Mean age = 22.2 years) were matched with 22 controls (20 males; Mean age = 21.1 years) on gender, age and National Adult Reading Test score. Participants viewed three naturalistic video montages of strangers laughing, yawning and crying. Physiological responses to the videos were measured using galvanic skin conductance recording throughout viewing. Internalisation of emotions was measured by comparing pre-and post-video questionnaire responses, in which participants rated their subjective moods. Mirroring was measured by video recording and subsequently coding the amount of time participants spent reciprocating the observed emotion using their facial expressions.
Results: The three processes were analysed separately using 2 (ASD, controls) x 3 (observing laughter, yawning, crying) mixed ANOVAs. Participants in the ASD group showed comparable skin conductance responses to controls while observing emotional expressions ($p>.05$). However, they were significantly less likely to perceive changes in their own emotions as a result of viewing emotional expressions ($p<.01$) and they also spent significantly less time than controls mirroring the observed emotions through their facial expressions ($p<.001$). This was particularly true for laughter, where the largest discrepancies between the ASD and control groups were found ($p<.001$).
Conclusions: Participants with ASD showed the same physiological reactions as controls to observing emotional expressions, which suggests a typically functioning sympathetic nervous system. However, they were significantly less likely to internalise or mirror these expressions, particularly laughter. Emotion contagion is thought to foster social cohesion, and sharing positive emotions may promote strong positive bonds between individuals. Consequently, this reduced emotion contagion in people with ASD, particularly noticeable for laughter, is likely to further impede social relationships, which may already be difficult.

178 **110.178** Exposure to Elements in Fetal and Early Postnatal Periods and Autistic Traits

M. Arora[1], *K. Tammimies*[2], *C. Gennings*[1], *C. M. Willfors*[3], *A. Reichenberg*[4] *and S. Bolte*[3], *(1)Preventive Medicine, Mount Sinai School of Medicine, New York, NY, (2)Karolinska Institutet, Stockholm, Sweden, (3)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden, (4)Mount Sinai School of Medicine, New York, NY*

Background: Environmental factors likely play an important role in the etiology of autism, but are understudied. Of the many possible environmental risks, fetal and early childhood exposure to toxic metals as well as deficiencies of nutritional elements are interesting candidates for investigation as they have been associated with several adverse developmental outcomes.
Objectives: Using a novel tooth matrix biomarker this study examined exposure to multiple elements in relation to autistic traits.
Methods: Participants are members of the Roots of Autism and ADHD Twin Study in Sweden, a population based case-control twin sample recruited from nation-wide registries in Sweden. We used newly developed tooth matrix biomarkers to establish detailed temporal profiles of multiple metal toxicants and essential elements over the prenatal and early postnatal periods. Autistic- traits were assessed using the Social Responsiveness Scale-2 (SRS-2).
Results: From the Roots of Autism and ADHD Twin Study Sweden 51 members contributed teeth samples. Manganese was inversely associated with SRS-2 ($r = -0.3$ to -0.5), with this association being significant over the pre- and postnatal periods, suggesting that deficiencies are associated with increasing autistic symptomatology. A significant inverse association of zinc with SRS-2 was also observed in the third trimester. The relationship of other elements, including lead and copper, and SRS-2 severity, is currently undergoing and will also be presented.
Conclusions: Prenatal and early postnatal uptake of multiple metal toxicants and essential elements contributes to individual differences in autistic traits. Prenatal and early

life excess or deficiency of elements may contribute to autism risk.

179 **110.179** Gaze Following Atypicalities in Children with Autism: The Role of Motivation

***E. Thorup**, J. L. Kleberg and T. Falck-Ytter, Uppsala University, Uppsala, Sweden*

Background: Although impairments in joint attention are common in ASD, several studies have found intact gaze following accuracy. In a recent study (Falck-Ytter et al, 2014), we found that typically developing (TD) children displayed a first fixation duration (FFD) bias towards an object being attended to by another person, as compared to an unattended object. In an ASD-sample, no such FFD bias was found. This suggests that the FFD measure might detect subtle gaze following atypicalities that are not reflected by the more common accuracy measure. Given the explorative nature of the previous study, independent replication is required. More knowledge about the mechanisms underlying the altered response in ASD is also needed.
Objectives: The aim of the present study was twofold. First, we wanted to replicate the previous finding of a weaker processing bias for attended vs. unattended objects in ASD as compared to TD-children. Second, we aimed to explore the potential role of motivational factors.
Methods: The study included a group of high functioning children with ASD (n = 16, mean age = 81.6 months) and a group of typically developing children (n = 18, mean age = 73.6 months). Using eye tracking technology, the children's gaze patterns were recorded as they watched videos of a model looking at one of multiple objects. In the Circumscribed Interest (CI) condition, the objects were model trains and toy cars (common circumscribed interests, expected to be particularly motivating for children with ASD). The objects in the non-CI condition were plants. Two measures were used: (1) Gaze following accuracy was measured as a difference score (DS) with the number of incongruent gaze shifts subtracted from the number of congruent gaze shifts; (2) FFD bias was measured as a DS with the mean FFD at the unattended objects subtracted from the mean FFD at the attended object.
Results: The groups did not differ in terms of gaze following accuracy in neither condition, and no interaction effect was found (p:s > 0.05). More importantly, the previous finding of a reduced FFD bias for attended objects in ASD was replicated in the non-CI condition ($p < 0.05$). However, in the CI condition, no group difference was found. A 2x2 ANOVA confirmed that the manipulation modulated the responses differently in the two groups ($p < 0.05$).
Conclusions: The previously found greater FFD bias for attended objects in a TD- as compared to ASD-sample was replicated in the non-CI condition, suggesting that the FFD measure reliably tracks gaze following atypicalities in children with ASD. However, no group difference was found in the CI-condition, showing that the altered FFD response in ASD does not generalize across all object types. Rather, this demonstrates that when objects known to be particularly interesting for children with ASD are included, the performance of these children does not differ from that of their typically developing peers. This finding speaks to the importance of motivational factors in joint attention behaviors in ASD.

180 **110.180** Gender As a Moderator of the Association Between Social Responsiveness and Cognitive Ability for Children with Autism

***J. L. Irwin** and M. Beeghly, Psychology, Wayne State University, Detroit, MI*

Background: The male-female ratio for autism is 4-5:1 (Fombonne, 2011). Consequently, most autism research has focused on males, and the female autism phenotype is poorly understood. Also understudied is whether social responsiveness contributes to cognitive performance among children with autism, and whether gender moderates these associations.
Objectives: The aims of the current study were to evaluate whether male and female children with autism vary in cognitive profiles, whether social responsiveness contributes to cognitive functioning, and whether gender moderates these associations.
Methods: A sample of individuals with ASD (N=217, 53% male) was derived from the National Database for Autism Research. Cognitive profiles were evaluated using the DAS-II School Age (standard scores), and social functioning with the Social Responsiveness Scale (t-scores). Gender moderation was analyzed using the PROCESS macro for SPSS. Expectation maximization was used to address missing data.
Results: In separate analyses for each outcome/predictor pair (see Table 1), gender significantly moderated the association between 1) social motivation and general conceptual ability (adjusting for age); 2) social cognition, social communication, social motivation, autistic mannerisms and verbal IQ (adjusting for nonverbal IQ); and 3) social motivation and nonverbal IQ (adjusting for verbal IQ). For 1) and 2), the slope of each interaction was significant only for females, and for 3), the slopes for males and females were significant and in opposing directions (see Table 2).
Conclusions: Results show that the cognitive and social phenotype for females differs from that of males, underscoring the need for greater attention to females in autism research. Findings also demonstrate the utility of evaluating social as well as cognitive functioning in this population, and suggest that interventions for children with autism should consider gender differences in cognitive and social ability.
Acknowledgments: Data used in the preparation of this abstract reside in the NIH-supported NIMH Data Repositories, specifically in the National Database for Autism Research. Collection IDs and submitters are available upon request.

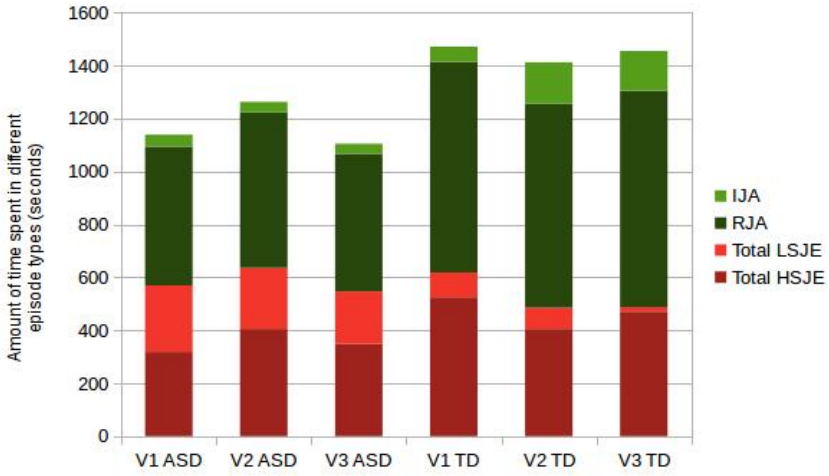
181 **110.181** High and Lower Order Supported Joint Attention in Autism and Typical Development

***A. M. Abdelaziz**[1], M. Wagner[2], D. A. Fein[3] and L. Naigles[4], (1)University of Connecticut, Mansfield Center, CT, (2)Literatures, Cultures, and Languages, University of Connecticut, Storrs, CT, (3)Psychology, University of Connecticut, Storrs, CT, (4)University of Connecticut, Storrs, CT*

Background:

Joint attention (JA) (i.e. the child and caregiver alternate between each other and an object) has been found to play a role in the language development of typically developing (TD) children, as well as children with ASD (e.g. 6). JA behaviors are generally impaired in children with ASD (e.g. 3, 4, 5, 7). However, more recent analyses of caregiver-child interactions have revealed that children with ASD participate in Supported Joint Engagement (SJE), in which the caregiver influences the child's object play, but the child engages with the caregiver without visually referencing him/her (1). Bottema-Beutel et al., (2014) also reported that by dividing SJE into Higher order (HSJE; the child responds by reciprocating and collaborating with the caregiver) and Lower order (LSJE; the child responds without reciprocal or collaborative exchange with the caregiver) types, HSJE predicted later social communication and expressive language in children with ASD. However, less is known about the relative proportions of time in which children with ASD participate in different types of social interactions and the nature of SJE activities in TD children.
Objectives:
We extend the paradigm of Bottema-Beutel et al. (2014) to a new sample of children with ASD, compare them to TD children, and investigate the amount of time TD children and children with ASD engage in episodes of SJE and JA.
Methods:
The sample includes 15 children with ASD ($ASD_{MA\ ge}$ = 34.93 months, 12 males), and 15 TD children (TD_{MAage} = 19.82 months, 13 males), who were recorded at 3 visits, 4 months apart, and matched on language level (raw scores) ($M\ ASD_{MullenEL}$ = 16.44(6.22), $M\ TD_{MullenEL}$ = 20.35(5.70)) at visit 1. Children and their parents engaged in 30-minute play sessions, which were coded for amount of time spent in HSJE, LSJE and JA episodes.
Results:
Figure 1 presents the mean episode durations of all TD children and children with ASD across the 3 visits. The TD children were engaged with their caregivers for approximately 77% of the play session whereas the children with ASD were engaged for 67% (p = .15). TD children spent more time in JA episodes than children with ASD (p = .006), whereas children with ASD spent more time in LSJE episodes than the TD children (p = .005). Interestingly, children with ASD spent approximately one-third of the play session engaged within JA episodes.
Conclusions:
Contrary to earlier findings, children with ASD participated in several different types of social interactions with their caregivers for about two-thirds of the play session, with considerable amounts of time spent in JA, LSJE, and HSJE. All three types of interactions were also observed in the TD group, although as expected the duration of JA episodes was longer, and LSJE episodes, shorter. These findings warrant further investigation into the predictive value of each interaction type for later development, as well as the more detailed examinations of the nature of the children's and caregivers' activities.



182 **110.182** How Do People with Autism Spectrum Disorder (ASD) Perform on the Ultimatum Game? Using Game Theory to Study Social Decision Making in ASD

*C. Cheung[1], K. Woodcock[2], D. H. H. Skuse[3] and **W. Mandy**[4], (1)Clinical Psychology, UCL, London, United Kingdom, (2)Psychology, Queens University, Belfast, Belfast, United Kingdom, (3)Institute of Child Health, London, United Kingdom of Great Britain and Northern Ireland, (4)University College London, London, United Kingdom*

Background: This research seeks to elucidate how people with ASD behave in real-world social situations, by studying social decision making, herein defined as the capacity to attend to, process, interpret and act upon information to inform spontaneous, effective interpersonal behaviour. Game theory researchers working in behavioural economics have developed psychometrically sound, ecologically valid tools for measuring social decision making, but these have rarely been used to study the strengths and difficulties of people with ASD. This study investigated social decision-making in ASD using a game theory task called the Ultimatum Game (UG), which is an interactive bargaining task measuring reciprocal responses to social norm violations and unfairness. In the UG, a sum of money, for example £10, is to be divided between two players – William and Mary. William chooses how to share the money, for example making a fair offer (£5) or an unfair offer (e.g. £2) to Mary. Mary can then decide whether to accept or reject William's offer. If she accepts, both parties will each receive the agreed share of the money. If she rejects, neither will receive anything. The "ultimatum" refers to the take-it-or-leave-it offer in the game.
Objectives: We sought to discover whether young people with high-functioning ASD showed atypical performance on the UG, compared to controls, both in terms of the proposals they made, and their decisions about whether to accept unfair offers. We also investigated whether elements of cognition associated with ASD (namely, difficulties with theory of mind, emotion regulation and executive function) predicted suboptimal performance on the UG.
Methods: Twenty young people (aged 11 to 17 years) with ASD and an IQ in the normal range participated in the UG, which was delivered as a computerized task. Their behaviours as proposers of offers, and their responses to offers (including unfair offers) were measured. Participants also completed measures of theory of mind, emotion regulation and executive function, and parents completed a questionnaire on EF. Two typically developing comparison groups were used, one matched on chronological age (n=20) and the other matched on developmental age (n=20).
Results: Young people with ASD proposed significantly fewer fair offers to their opponents in the UG, but did not differ from controls in their responses to unfair offers. In the ASD group, participants with better theory of mind were more likely to propose fair offers. Participants with better executive function – especially those with better emotional control and behavioural regulation – accepted more unfair offers.
Conclusions: Young people with ASD demonstrated preserved aspects of SDM in a 'reactive' social context, which appeared to recruit executive functioning, especially emotional control and behavioural regulation. They differed to their TD peers when behaving in a 'proactive' social situation, which seemed to depend partly on theory of mind abilities.

183 **110.183** How Social Others Form First Impressions of Adults with Autism Spectrum Disorder

***D. J. Faso**[1], K. E. Morrison[2] and N. J. Sasson[3], (1)University of Texas at Dallas, Allen, TX, (2)The University of Texas at Dallas, Dallas, TX, (3)University of Texas at Dallas, Richardson, TX*

Background: First impressions are rapidly formed and assert long-term influences on social preferences and behavior. Whether first impressions of adults with autism spectrum disorder (ASD) differ from those made of typically-developing (TD) adults, and the factors underlying their formation, is not well understood. Highlighting aspects of social presentation in ASD that affect evaluation by potential social partners may ultimately be used to mitigate social interaction impairments in ASD by educating social others about behavioral differences in ASD and inform ASD adults about these perceived differences.
Objectives: The ongoing project obtained first impressions from TD adults observing real-world behavior of adults with ASD, as well as TD comparison participants. We examined how specific information channels (i.e., visual cues, audio cues, and speech content) drove impression formation of adults with ASD across a range of personality traits and whether these impressions were associated with intentions to socially engage with the observed individual.
Methods: 147 TD observers, blind to the diagnostic status, rated twenty ASD adults and twenty TD comparison adults matched on gender, age, ethnicity and IQ engaging in a social presentation task. The first 10s of dialogue produced by participants was extracted to produce stimuli depicting five different presentation modalities: (a)audio content only, (b)video content only, (c)a written transcript of speech content, (d)a static frame, and (e)the full 10s clip with audio-visual. Observers gave first impressions across six character traits (attractiveness, intelligence, trustworthiness, likability, awkwardness, dominance) and indicated their intent to socially engage with the participant.
Results: A 6(traits) X 5(modality) X 2(group) mixed-model ANOVA revealed the ASD group was rated as more awkward, less attractive, less dominant, and less likeable than the TD group (all p's<.01), with no difference on trustworthiness or intelligence. A three-way interaction between group, modality, and trait ($F(20,760)=3.06$, $p<.001$) showed

that group differences largely persisted across the audio, video, static frame, and audio-visual modalities, with no group differences found for the transcript condition except for on awkwardness. Likeability was the strongest correlate with intent to socially engage for both groups (r=.88, ASD; r=.89, TD); however, awkwardness more strongly related to observers intent to socially engage with the ASD group (r=.560) compared to the TD group (r=.242), a significant difference using an r-to-z transformation (p=.004). Future factor analytic approaches (i.e., Correspondence Analysis) will examine how first impression ratings of each trait is distributed across the specific presentation modalities, and whether patterned profiles distinguish the ASD and TD groups.
Conclusions: Adults with ASD are generally perceived less favorably compared to TD matched comparison adults, except for ratings of intelligence and trustworthiness. These patterns were consistent across audio, video, static image, and audio-visual conditions, but not for the transcript of the speech content. This failure to find differences in the transcript conditions suggests that the content ASD adults choose to discuss does not seem to drive initial impression formation, rather all audio/visual social presentation cues appear to be similarly influential. Findings are pertinent for exploring situations where ASD adults are interacting with a novel social partner (e.g., job interview).

184 **110.184** Humor on the Autism Continuum

M. Brosnan[1] *and P. Welsh*[2]*, (1)University of Bath, Bath, United Kingdom, (2)Bathspa University, Bath, United Kingdom*

Background:
Autism Spectrum Disorder (ASD) is defined in part as a deficit in social communication and interaction. Humor can be key to developing and maintaining social relationships, referred to as a 'social lubricant' or a 'social glue'. Asperger drew attention to a 'humorlessness' in ASD, although also noting competence in wordplays. Subsequent research has suggested a preference in people with ASD for humor such as wordplay or slapstick, which do not necessitate taking the perspective of others. Additionally, recent theories of humour have proposed different styles of humour, namely socially-adaptive positive humour styles and socially-maladaptive negative humour styles.
Objectives:
To identify if those with higher levels of autistic traits from a general population and those with a diagnosis of ASD demonstrate a deficit in the appreciation of positive humour specifically (contrasted with negative humor). To explore differences in the preferences for different types of humor in ASD.
Methods:
Three studies were conducted. 1) Autistic traits were assessed in a general population (n=163) and contrasted with positive and negative: a) humor styles, b) humor experiences, and c) humor preferences. 2) A group diagnosed with ASD (n=16) were compared with a Typically Developing (TD, n=16) group to explore differences in positive and negative: a) humor experiences, and b) humor preferences. 3) A group diagnosed with ASD (n=26) were compared with a Typically Developing (TD, n=75) group to explore differences in a) humor preferences, and b) the perceived humor of five comedic principles (Concept-based; Character-based; Slapstick; Exaggeration & Escalation; Wordplay).
Participants completed the Autism Quotient and the Humor Styles Questionnaire (Study 1), the Humour Experiences Questionnaire and rated comedy clips for perceived humor (all studies).
Results:
In Study 1, higher AQ scores significantly and negatively correlated with positive humour style and positive humor experiences (controlling for gender). There were no correlations between AQ and negative humor style and negative humor experience. There was a trend for higher AQ to correlate with finding both positive and negative humor less funny.
In Study 2, there were no significant group differences in positive or negative humor experiences. The ASD group reported that the positive humor was significantly less funny than the control group. There were no group differences in the perceived funniness of negative humor.
In Study 3, the ASD group reported significantly less positive humour experiences than the control group with no differences in negative humor experiences (no gender differences). The ASD group reported that the clips demonstrating 1) Wordplay and 2) Character-based comedic principles were less funny than the control group, with no differences in the ratings of the other comedic principles.
Conclusions:
Taken together, the results suggest a diminished preference for, and experience with, positive humor associated with higher levels of autistic traits (including those with a diagnosis of ASD) which does not extend to negative humor. This is pertinent as positive humor if argued to be socially adaptive and facilitate social relationships. There is also evidence that humor is often rated as less funny by those with high autism traits and ASD.

185 **110.185** Imitation Impairments in Autism Spectrum Disorder: A Social Motivation or Motor-Execution Problem?

L. Chetcuti[1]*, K. Hudry*[1]*, M. Grant*[1] *and G. Vivanti*[1,2]*, (1)Olga Tennison Autism Research Centre, Melbourne, Australia, (2)Victorian ASELCC, Melbourne, Australia*

Background: Imitation is an important early developmental skill; it provides a means to acquire practical knowledge and to practice and develop interpersonal skills (e.g., Munson, Meltzoff, & Dawson, 2006). Imitation deficits are a characteristic feature of autism spectrum disorder (ASD) and, while several explanatory theories have been proposed, the mechanisms underlying these difficulties remain unclear (Edwards, 2014).
Objectives: Within a mixed quasi-experimental and individual differences design, this study examined the contribution of reduced social motivation and motor-execution difficulties for propensity to imitate among children with ASD.
Methods: Among 55 child participants – 35 with ASD, 20 typically developing (TD) – a novel imitation task was delivered via . This included four experimental conditions arising from manipulations of social and motor domains; to-be-imitated actions were presented by a *social* and an *asocial* model, and under conditions of *low-* (single action) and *high motor-demand* (multiple actions in sequence). Imitative performance in each condition was coded such that higher total score indicated more accurate imitation. Several standardized assessments were also conducted; fine motor coordination was assessed using the Vineland Adaptive Behavior Scales (VABS-II; Sparrow, Cicchetti, & Balla, 2005) and Mullen Scales of Early Learning (MSEL; Mullen, 1995), and social motivation was assessed among children with ASD using the Autism Diagnostic Observation Schedule, Social Affect domain (ADOS-2 SA; Lord et al., 2012).
Results: There was a nonsignificant trend towards overall reduced imitation by children with ASD vs. TD children. Imitative performance was significantly better in the low- relative to high motor-demand condition, for each group with no between-group differences in performance in either motor demand condition. There were no between-group imitation differences in response to the social vs. asocial model. However, a significant three-way interaction term revealed that children with ASD imitated more poorly during the high- relative to low motor-demand condition, when demonstration was by a social model. Among children with ASD, propensity to imitate was not associated with ADOS-2 SA score, and showed a conflicting pattern of correlations with fine motor skills as assessed via the MSEL (significant positive association) and VABS-II (no significant association).
Conclusions: While there was a trend for poorer imitation by children with ASD, the lack of clear group differences on this novel task of spontaneous imitation did not provide robust replication of previously-reported imitation deficits in this population. Moreover, findings of a) a lack of between-group differences in imitation in response to a social vs. asocial model, and under conditions of low- vs. high motor-demand, and b) nonsignificant correlations between imitation performance and standardized measures of sociability and fine motor skill suggest that neither social motivation nor motor-execution capacities decisively underpin the propensity to imitate by children with ASD. Interestingly, these data suggest that imitative performance in ASD may arise from a complex interplay between these factors, as imitation was poorer for children with ASD as both the social-processing and motoric task demands increased. Further research is warranted to understand precisely how social motivation and motor execution capacities combine to influence spontaneous imitation in ASD.

186 **110.186** Increased Eye Contact during Conversation Versus Play in Children and Adolescents with ASD

R. M. Jones[1]*, A. Hamo*[1]*, C. Carberry*[1]*, E. Komarow*[1]*, A. Southerland*[2]*, C. A. Bridges*[2]*, S. Nay*[2]*, E. Stubbs*[2]*, J. M. Rehg*[2]*, A. Rozga*[2] *and C. Lord*[1]*, (1)Weill Cornell Medical College, White Plains, NY, (2)Georgia Institute of Technology, Atlanta, GA*

Background: Atypical eye contact is a diagnostic hallmark of Autism Spectrum Disorder (ASD). Individuals with ASD typically make less eye contact overall than those who are typically developing (TD). Research on TD children suggests eye contact is limited during free-play interactions highlighting the importance of context for eliciting eye contact (Arnold et al., 2000). To date, there is limited research comparing the amount of eye contact across different contexts in ASD, which may be important for interpreting social communication behavior in a clinical setting.
Objectives: To determine if the amount of eye contact differs during distinct aspects of social interactions, specifically interactive play compared to conversations. We hypothesized that the amount of eye contact with an examiner would be less during play than during conversation segments in ASD.
Methods: 26 children and adolescents with ASD (M = 8.5 years, 5-17 years) completed the Brief Observation of Social Communication Change (BOSCC) assessment. The BOSCC is a 12-minute clinician-subject interaction that consists of two 5-minute play segments with a standardized set of toys, separated by a 2-minute conversation segment. The BOSCC was recorded via Pivothead Kudo glasses that are worn by an examiner. They contain an outward facing camera and readily capture the child's face and shifts in eye gaze to the examiner. The duration of eye contact was manually coded using ELAN, a video annotation software, to capture eye contact duration by the millisecond in both play and conversation. Proportions of eye contact with the examiner were calculated by dividing the duration of eye contact with the examiner by the total time for the play segment versus the conversation. A subset of 8 individuals had a second BOSCC session four weeks after the first session. Repeated Measures ANOVAs determined 1) differences in the duration of eye contact during play versus conversation; 2) stability across time in the duration of eye contact in participants who had two time points and 3) the impact of age, cognitive abilities (VIQ, NVIQ) and autism symptom severity (ADOS CSS) on eye contact duration in the two segments.
Results: The duration of eye contact was significantly greater during conversation as compared to play (p < 0.001, Mean Play = .05, Mean Conversation = .28). There was no significant interaction with age, severity of autism symptoms, NVIQ, or VIQ. Similarly, children made more eye contact during conversation versus play across two time points

($p < 0.001$) with no significant difference between the two time points, highlighting the stability of the findings.
Conclusions: School-aged children with ASD make less eye contact during play with an examiner than during conversation, independent of age, autism symptom severity, or cognitive abilities. In the absence of any distracting toys or materials, children made more eye contact, highlighting the importance of considering context and the environment when measuring different forms of social communication. The finding that the amount of eye contact was contingent upon environmental demands that are commonly used in clinical settings has important implications for studies that examine behavior changes during intervention.

187 **110.187** Increased Synchronous and Sustained Social Interactions Following a Social Skills Intervention for Adolescents with ASD

M. Murray[1], *A. Pearl*[2], *Z. Soulliard*[1], *K. C. Durica*[1], *A. Heintzelman*[3] *and S. Brown*[1], *(1)Penn State Hershey, Hershey, PA, (2)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hummesltown, PA, (3)Penn State College of Medicine, Hershey, PA*

Background: Despite increases in research examining the efficacy of social skills interventions for individuals with Autism Spectrum Disorder (ASD), few studies have targeted adolescents. This is problematic as peer relationships during adolescence demand interactions that display complex social behaviors (i.e. behaviors occurring at the same time as each other) for optimal impact and efficiency.
Objectives: This study examined the effectiveness of a social skills intervention for adolescents with ASD as evidenced by an increase of synchronized behaviors (i.e., eye contact, affect, and verbalization) at post-intervention of the social skills project compared to pre-intervention.
Methods: Twenty-one adolescents between the ages of 13- and 18-years-old ($M = 14.57$, SD = 1.40) completed a 5-minute unstructured conversation with a same-age peer confederate pre- and post-intervention. The adolescents (71% male, 90% Caucasian) were diagnosed with ASD, confirmed by parent reports on the Checklist for Autism Spectrum Disorders (CASD; $M = 23.29$, SD = 3.80). Additionally, verbal IQ was estimated using the Kaufman Brief Intelligence Scale, Second Edition (KBIT-2; $M = 97.38$, SD = 17.72). The target participants' behaviors were coded using Noldus Information Technology software. The 5-minute dyad conversations were coded for seconds of eye contact and positive affect. Verbal activity was also coded, including the number of questions, validating statements, commenting statements, topic changes, run-on statements, and social niceties. Finally, the number of four-part conversations were coded between the participant and same-age peer confederate.
Results: *T*-tests were conducted to compare the participants' use of synchronized behaviors at pre- and post-intervention. The duration of synchronized behaviors increased greatly at post-intervention, including the integration of affect, verbalizations, and eye contact during conversations ($t = -4.31$, $p < 0.001$). Additionally, participants increased the length of use of affect paired with eye contact ($t = -4.31$, $p < 0.001$), affect paired with verbalizations ($t = -5.33$, $p < 0.001$), and verbalizations paired with eye contact ($t = -5.77$, $p < 0.001$). Participants also engaged in significantly more four-part conversations ($t = -3.32$, $p < 0.001$) with same-aged peers.
Conclusions: Presently, there is little research regarding the efficacy of social skills interventions for adolescents with ASD. Results of the current study show an overall increase in adolescents' use of complex social behaviors, as well as an increase in reciprocal conversation with peers. These skills can be an indicator of quality conversations, though the skills often need to be explicitly taught to individuals with ASD to increase social functioning. The study shows preliminary evidence that an intervention targeted specifically to adolescents is successful in increasing these complex social behaviors.

188 **110.188** Individual Differences in Cooperation and Equality: Data from ASD

I. M. Eigsti*, University of Connecticut, Storrs, CT*

Background: Society must balance the demand of *community*, associated with interdependence and empathy, with those of *autonomy*, associated with free will, independence, and self-fulfillment. To meet these demands, both individuals and societies (Fukuyama, 1995) requirse cooperation and trust (Balliet & Van Lange, 2013) as well as the ability to predict others' behaviors (McAllister, 1995). Empathy and mentalizing play a critical role in the development of a shared system of values and principles of conduct (Smetana et al., 2012). This study evaluated individual differences in mentalizing (Baron-Cohen, Leslie, & Frith, 1985) and empathy (e.g., Sigman et al., 1992) by including individuals with autism spectrum disorder (ASD), who may show differences in both.
Objectives: We measured social values orientation (SVO), the degree to which an individual prioritizes community over autonomy, and its association with empathy and mentalizing, in 1) adults with a verified ASD diagnosis, recruited through the Interactive Autism Network (IAN); and 2) adults recruited via M-Turk. Mentalizing abilities were assumed to fall along a broad continuum. We evaluated the degree to which mentalizing (associated with ASD symptomatology) and empathy mapped onto SVO.
Methods: SVO research has often relied upon complex narratives (e.g., Barnes et al., 2009) and verbally-demanding questions such as *did the victim suffer* or *is the agent responsible* (e.g., Buon et al., 2013), which typically excludes individuals with lower verbal skills. The current study made use of an experimental SVO game, which has been shown to reveal three primary patterns: (1) a *prosocial* orientation, in which cooperation and interdependence is a goal; (2) an *individualist* orientation that maximizes one's own outcomes with no regard for others' outcomes; and (3) a *competitor* orientation that maximizes one's own outcomes relative to others, seeking a relative advantage (Van Lange, Otten, De Bruin, & Joireman, 1997). This game requires participants to imagine another person, with whom they are playing, and then to assign points to themselves and the other person on successive trials. We measured ASD symptomatology via the Autism Spectrum Quotient self-report questionnaire (Baron-Cohen et al., 2001) and empathy via the Empathy Quotient self-report questionnaire (Wheelwright et al., 2006). Our measures were programmed in Qualtrix and collected on-line.
Results: Participants included adults with (n=114) or without (n=45) ASD. Results showed that adults with ASD were significantly less likely to adopt a competitive SVO, p<.001. In the M-Turk group but not the ASD group, AQ score was correlated with prosocial SVO. SVO patterns were not associated with empathy.
Conclusions: ASD characteristics in the general population were associated with a preference that all participants in a game experience equal outcomes, compared to individuals low in ASD symptomatology. Individuals who met the full diagnostic criteria were less likely to maximize their outcomes and penalize their competitors. Social values of equity or fairness may depend more on an interest in rules and incentives (Balliet, Mulder, & Van Lange, 2011) than on mentalizing. Future research will evaluate the relationship of SVO to biological measures of perceived fairness (Aoki, Yomogida, & Matsumoto, 2015).

189 **110.189** Inference or Integration? Mechanisms of Mental State Understanding in High-Functioning Autism

J. Korman[1], *B. F. Malle*[1], *M. Leboyer*[2,3], *A. Gaman*[2,3] *and T. Zalla*[4], *(1)Cognitive, Linguistic, & Psychological Sciences, Brown University, Providence, RI, (2)Department of Psychiatry, INSERM U 955, IMRB & University Paris Est Créteil, AP-HP, Henri Mondor-Albert Chenevier Hospitals, Créteil, France, (3)Fondation FondaMental, French National Science Foundation, Créteil, France, (4)Institut Jean Nicod, CNRS, Ecole Normale Supérieure, PSL Research University, Paris, France*

Background:
By the time many high-functioning individuals on the autism spectrum (henceforth HFA individuals) reach adulthood, they have acquired partial competence in dealing with other people's mental states—a partial "Theory of Mind" (ToM). Nevertheless, HFA adults do not make full use of mental state information for moral judgment (Moran et al., 2011; Zalla and Leboyer, 2011; Zalla et al., 2011), and in faux pas tasks (e.g., Baron-Cohen et al., 1999; Zalla et al., 2009). In particular, they detect unintentional offenses (or "faux pas") but struggle to understand that such offenses stem from the offenders' false beliefs.
Objectives:
In this project we probe the specific mechanisms underlying continued ToM deficits in adulthood. We address two possible accounts of HFA adults' struggle to understand the offender's false belief in the faux-pas task. First, HFA adults may lack the ability to infer novel mental state information from behavior. Second, even if HFA adults might glean such mental state information, they may lack the ability to integrate the information into a coherent understanding of behavior. We seek to distinguish between these two accounts by manipulating the participants' task to either infer mental state information or integrate provided mental state information.
Methods:
15 HFA adults (diagnoses confirmed with the ADOS and ADI-R, Lord et al., 2000), and 34 typically developing, age, gender, and IQ-matched controls completed the study online. Each participant saw a total of 8 "faux pas" stories, in which a character committed an unintentional offense because he or she had a false belief. The stories represented a three-level within-subject factor. In the "no information" condition, the stories contained no explicit references to the character's mental states. In the "belief" condition, the false belief underlying the character's behavior was made explicit; in the "desire" condition, the character's desire was made explicit. For each story, participants (1) answered a question about whether the character possessed a false belief, and (2) provided open-ended explanations for the faux pas.
Results:
Control participants scored barely higher on the belief question ($M = 1.65$ correct, $SD = .49$) in the no-information condition than did HFA participants ($M = 1.47$ correct, $SD = .52$), $t(47) = 1.18$, ns. While both control and HFA participants benefited from receiving explicit belief information $F(1, 47) = 17.69$, $p < .001$, only HFA participants benefited from explicit desire information, $t(14) = 3.06$, $p < .01$. Overall HFA and control participants gave comparable numbers of mental states in their behavior explanations, $F(1, 26) = .09$, ns; but in the "no-information" condition, HFA participants provided even more mental state explanations than control participants, $F(1, 29) = 3.62$, $p = .06$.
Conclusions:
We showed some evidence for the integration hypothesis, as HFA adults improved on the belief question when being given either belief information or desire information. Interestingly, when explaining no-information stories, HFA individuals offered more mental states than controls (even though they had marginally poorer performance on the belief question), suggesting that merely mentioning mental state information does not constitute genuine faux-pas understanding.

190 **110.190** Information-Theoretic Approaches to Optimizing Early Detection of ASD in Toddlers Based on Preferential Attention to Audiovisual Synchrony

G. Ramsay[1], *A. Abraham*[2], *J. B. Northrup*[3], *D. Lin*[4], *A. Klin*[5] *and W. Jones*[5], *(1)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (2)Vanderbilt University, Nashville, TN, (3)University of Pittsburgh, Pittsburgh, PA, (4)Department of Neurology, Massachusetts General Hospital, Boston, MA, (5)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: Children with ASD exhibit atypical patterns of visual attention to the social world, responding differently to physical and social contingencies relative to non-autistic peers. In previous studies examining preferential attention to audiovisual synchrony, we showed that ASD infants are relatively insensitive to social contingencies afforded by talking faces, focusing instead on physical contingencies between light and sound. By manipulating audiovisual stimuli comprising faces and shapes synchronized with speech and tones, we found that TD controls exhibited a preference for synchronous faces and speech, lacking in ASD participants, even though groups did not differ in baseline sensitivity to audiovisual synchrony. In those studies, significant differences were found based on simple measures of visual attention derived from mean relative fixation durations. Although these measures are traditional in eye-tracking research, inspection of our data clearly revealed complex statistical patterns that were predictive of autism, but were not captured by simple tests of differences in mean fixation on any one region of interest alone. Accordingly, we applied techniques from information theory to quantify differences between full probability distributions of eye-tracking trajectories across groups.
Objectives: Our goal was to test whether information-theoretic measures of differences in visual attention between TD and ASD toddlers outperform traditional statistics, to determine whether current approaches to detection of autism may be significantly under-exploiting the discriminative power of behavioral probes.
Methods: Toddlers with autism (N=34) and typically developing controls (N=20) participated in a simple preferential-looking paradigm based on split-screen presentation of video stimuli (faces and shapes) paired with audio stimuli (speech and tones). Using different combinations of video and audio stimuli, and manipulating audiovisual synchrony between the two, we tested for differences in attention to social and physical contingencies. Eye-tracking was used to quantify response. Using machine learning techniques, we derived optimal measures of overall attention and attention to social target across all stimulus combinations, focusing on responses to speech and non-speech. We used a permutation test to determine significant differences between the entire joint distribution of our measures across groups, based on the information divergence calculated from kernel density estimates. We contrasted these results with traditional measures calculated from relative percentage of total fixation time on the social target, testing for differences in means using ANOVA. Receiver operating characteristics were further used to quantify classification performance.
Results: We found highly significant differences in the full probability distributions ($P<0.00001$), which were not reflected in tests of differences in centroids alone ($P<0.01$). Sensitivity and specificity improved from 78.5%/83.3% for single mean fixation measures to 79.5%/97.4% using our information-theoretic approach.
Conclusions: Significant differences in visual scanning exist between ASD and TD children that cannot be fully quantified without characterizing the mutual information between entire probability distributions of responses. Current approaches to screening of children at risk of autism based on group means significantly underexploit information present in behavioral measures of the syndrome.

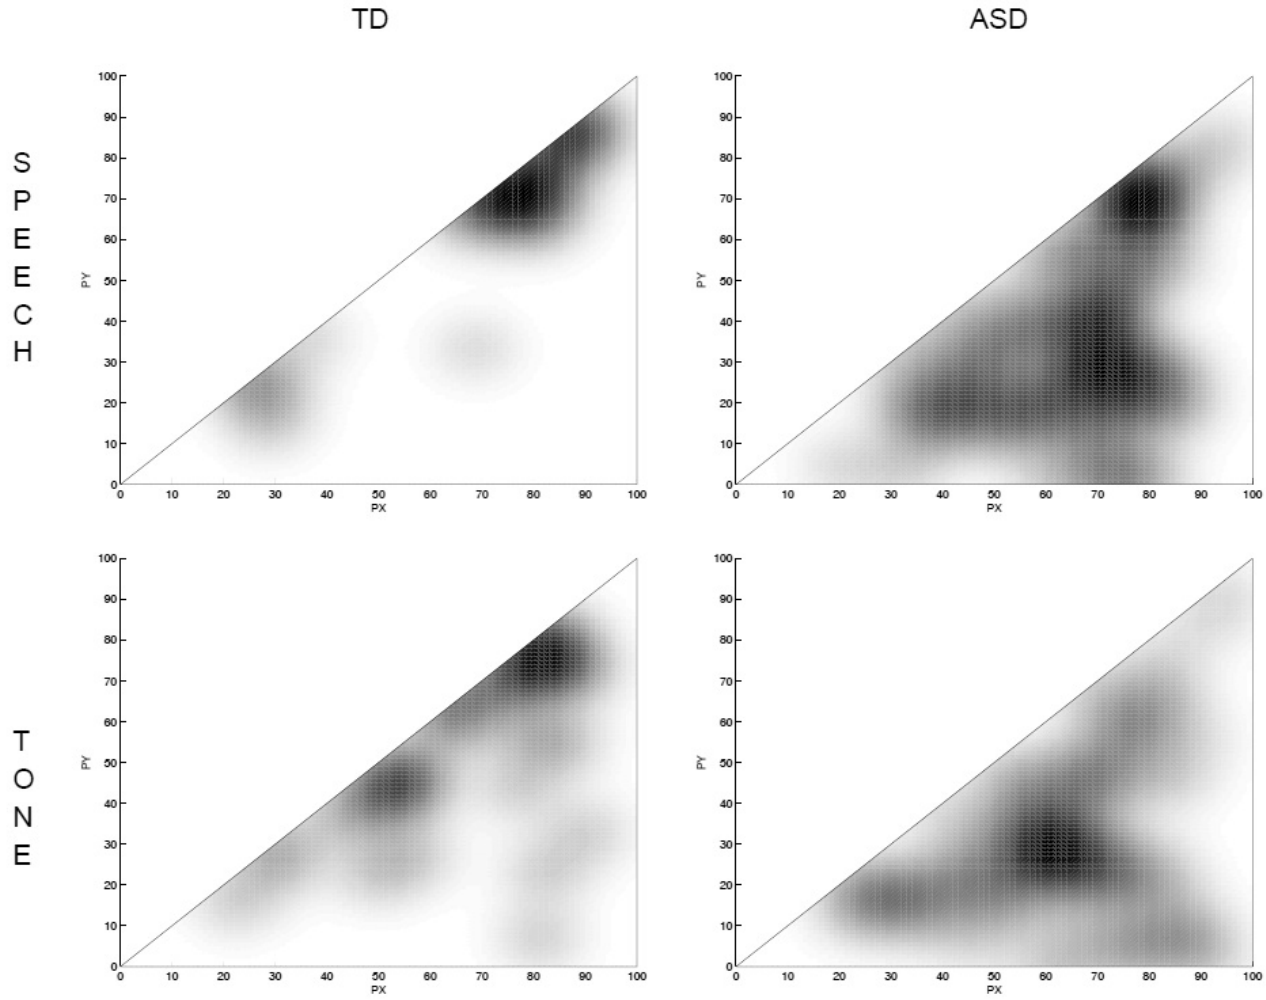


Figure 1. Joint probability density functions for two composite measures of visual attention using results from our preferential-looking paradigm. Results were combined across all video conditions with either speech or tone as the audio soundtrack, for TD and ASD participant groups. PY is a measure of visual fixation on the synchronous target, whereas PX is a measure of overall attention to the screen; both are derived via machine learning techniques from the eye-tracking trajectories. Group differences in the full 2D distributions are not captured by differences in 1D means alone.

191 **110.191** Interactions Between Children with Autism Spectrum Disorder and Their Younger Sibling

***C. Bontinck**, P. Warreyn, S. Van der Paelt, E. Demurie and H. Roeyers, Ghent University, Ghent, Belgium*

Background: Due to the complementary and reciprocal nature of sibling interactions, siblings play a unique socialization function in the early development. Research however suggests that interactions between young infants and their older sibling with autism spectrum disorder (ASD) differ from those in which no child with ASD is involved. Given that siblings of children with ASD have an increased risk of developing ASD or subclinical features of ASD (Broader Autism Phenotype), early sibling interactions may be especially important for them.
Objectives: The aim was to explore differences in early sibling interactions between high-risk infants and a low-risk control group. Additionally, social-communicative characteristics of both children were taken into account.
Methods: Sibling interactions between 18-month-old infants and their older sibling (21 high-risk dyads and 29 low-risk dyads) were observed and videotaped during a play observation at home. Frequencies and/or durations of interactive behaviour (initiation-response, interaction with each other/experimenter/parent) and non-interactive behaviour (orientation toward sibling, doing nothing, solitary play, repetitive/stereotyped behaviour, distress) were coded. Social-communicative skills were examined using the ADOS2 and the Social Responsiveness Scale.

Results: Preliminary analyses in a subsample show that children with ASD tended to use more negative initiations than older typically developing children (U=65; p=.071). Second, in the control group, older children took a more dominant role (more positive (Z=-3.30, p<.001) and negative (Z=-4.51, p<.001) initiations than their younger sibling) while younger children followed their lead (more positive (Z=-4.50, p<.001) and negative (Z=-2.38, p=.016) responses). In the high-risk group, only the negative initiations were significantly more prevalent in older siblings with ASD (Z=-2.12, p=.047).
In both groups, we found positive correlations between the number of initiations of the youngest/oldest child and the number of responses of the oldest/youngest child (range r: .53 to .83). These higher levels of initiations and responses were positively correlated with mutual shared attention (range r: .43 to .94). In the high-risk group, social difficulties of the child with ASD were positively correlated with the youngest child's positive initiations (r=.58). Furthermore, we found that interactive behaviour of the youngest child at 18 months (positive initiations, responses) was negatively associated with social difficulties (ADOS) at 24 months (range r: -.53 to -.63). More elaborate analyses on the whole sample will be presented at the conference.
Conclusions: The current study confirms that interactions between young infants and their older sibling with ASD differ significantly from interactions between young infants and their older typically developing sibling. While in typical development roles are more asymmetric and reciprocal (e.g., teacher and learner), younger siblings of children with ASD seem to compensate more for the social difficulties of their older brother/sister. In addition, younger siblings of children with ASD who were more interactive with their brother/sister at 18 months showed better social-communicative abilities at 24 months.

192 **110.192** Is Social Categorization the Missing Link Between Weak Central Coherence and Theory of Mind Abilities in Autism?

***D. Skorich**, T. Gash, K. Stalker, A. May, L. Talipski, M. Hall, A. Dolstra and B. Gunningham, Australian National University, Canberra, Australia*

Background: Autism Spectrum Disorder (ASD) is currently understood as a 'fractionated' disorder, composed of separate but co-occurring clusters of features. At present, no common causative mechanism has been identified to explain why these different clusters of features co-occur in the disorder. In the current research, we present evidence that the cognitive process of social categorization could explain the co-occurrence of at least two of these clusters: those related to Theory of Mind (ToM) dysfunction and to Weak Central Coherence (WCC).
Objectives: To determine whether social categorization might be the missing link between WCC and ToM dysfunction in ASD.
Methods: Participants from the general population were asked to complete a category confusion task, in which hierarchically-embedded categories and social information were made to co-vary at the local level, the global level, both levels simultaneously, or at neither level. Participants were then asked to infer the mental states of novel category members, and to complete the Autism-Spectrum Quotient (AQ).
Results: Results revealed a positive relationship between AQ and categorization at the local level, and a positive relationship between AQ and mental state inference at the local level, when there was competing covariation at both the local and global levels. The pattern of social categorization was also found to predict the pattern of mental state inferences, thus demonstrating a causal relationship between central coherence and ToM abilities.
Conclusions: These results provide preliminary evidence that WCC and ToM abilities in ASD might be related via a social categorization mechanism, and suggest the possibility of a more unified cognitive account of the disorder.

193 **110.193** Joint Attention Behaviors Across Contexts in Young Children with ASD

***K. M. Walton** and R. Kirchner, The Ohio State University, Columbus, OH*

Background: Young children with autism spectrum disorders (ASD) show early-emerging impairments in joint attention. During both naturalistic observations and structured assessments, they show fewer joint attention behaviors, such as pointing, showing, and following another person's gaze or pointing gesture. Joint attention is a particularly important skill, as it is thought to underlie the development of more sophisticated language and social skills later in development. Despite the importance of joint attention in development, quantifying joint attention in young children still remains challenging. Two of the most frequent strategies for measuring joint attention include the use of the Early Social Communication Scales (ESCS) and coding of specific joint attention behaviors from videotaped interaction in more naturalistic settings (e.g., free play or a parent-child interaction). Children with ASD appear to use fewer joint attention behaviors than typical children in both structured and unstructured play contexts. However, is unclear how children's joint attention behaviors compare across these contexts, or how patterns of visual attention to people and objects during these interactions relates to children's use of higher-level joint attention behaviors, such as pointing and showing.
Objectives: This study will compare children's joint-attention related gaze behaviors across two contexts—a parent-child interaction and the Early Social Communication Scales. In addition, we will examine how visual attention (i.e., gaze at people at objects) in each context relates to children's scores on measures of higher- and lower-level joint attention behaviors during the ESCS.
Methods: Young children with ASD (N=12) and typical development (N=17) participated in two videotaped assessments: the ESCS and a 10-minute parent-child interaction. Gaze behaviors (gaze at objects and gaze at people) were then coded from videotape to determine the frequency and duration of different gaze types, and the frequency of gaze switches between objects and people. In addition, higher-level (e.g., pointing, showing) and lower-level (e.g., gaze alternation) joint attention behaviors were scored from the ESCS.
Results: Preliminary analyses suggest that there are marked differences in gaze patterns between the ESCS and the parent-child interaction context, with both typically developing children and children with ASD engaging in many fewer object-person gaze shifts during the parent-child interaction compared to the ESCS. Additional analyses with the full sample will examine the relationships between gaze behaviors in each context and joint attention scores on the ESCS to examine to what extent these measures tap the same constructs.
Conclusions: These results highlight the importance of considering context when assessing joint attention in young children, as observations in different types of play contexts are likely to yield different numbers of joint attention behaviors. Future research should focus on understanding what types of assessment contexst yield the most useful information in relationship to diagnostic status and relationships with other key developmental skills (e.g., language, social engagement patterns).

194 **110.194** Learning about Objects from Referential Gaze Versus Arrows in Children with and without ASD

***J. Bang** and A. Nadig, McGill University, Montreal, QC, Canada*

Background: Children with autism spectrum disorders (ASD) often struggle with understanding another's subtle communication cues, such as referential gaze (looking at an object). This is important in different contexts: when a person labels a new object and looks at it (*word learning*, **WL**), or when a person looks at an object they will act on next (*action understanding*, **AU**). Successful learning from gaze is often attributed to understanding another's communicative intentions, and poorer learning in ASD has been attributed to a lack of understanding intent. Yet gaze may simply direct attention -- successful learning may not require understanding intent. Prior work has not explored how children with ASD learn from referential gaze across contexts, or versus an attentional control.
Objectives: We investigate how 6- to 10-year-old children with ASD and typically-developing (TD) children learn in both **WL** and **AU** contexts. Specifically, we examine how children attend to and learn from referential gaze versus a moving arrow (attentional control).
Methods: Participants were children with ASD (n = 18) or TD (n = 18) matched on age, gender, and nonverbal IQ. Children watched videos that taught the name of a new word (**WL**) and how to build a tower (**AU**). In both contexts a cue (referential gaze vs. an arrow) directed attention to one of two objects. An eye-tracker recorded children's on-line attention during baseline, teaching, and test phases. Children were also asked to point to the learned object during test.
Results: 2 (group) x 2 (cue condition) x 2 (context) mixed ANVOAs were conducted (alpha = .05). During teaching, there was no main effect or interaction with group. All children looked significantly longer at gaze (M = .212, SD = .178) versus the arrow (M = .127, SD = .122). Children also looked significantly longer at the cues in **AU** (M = .200, SD = .181) versus **WL** (M = .142, SD= .128). No main effects or interactions were found for looking at the target during teaching.
During test, results differed by context and group. In **WL** many children successfully pointed to the target regardless of cue (10 ASD, 14 TD); for successful pointers, there were no main effects or interactions for latency of first look to or proportion of time looking at the target. Remaining children included: inconsistent pointers with either cue (5 ASD, 3 TD), selective pointers with arrow (1 ASD, 1 TD), and unsuccessful pointers (2 ASD). In contrast, few children successfully pointed in **AU** (1 ASD, 5 TD), and many were consistently unsuccessful (12 ASD, 5 TD). Remaining children included: inconsistent pointers (1 ASD, 3 TD), selective pointers with gaze (2 ASD, 4 TD), and selective pointers with arrow (2 ASD, 1 TD).
Conclusions: When learning about an object, children with and without ASD treat referential gaze differently from an arrow, both in *word learning* and *action understanding*. Despite similar attention to the targets during teaching, TD and ASD groups differed at test. Future analyses will address relationships between teaching and test and the quality of learning over time.

Figure 1. Example action understanding (top) and word learning context (bottom) video phases, with arrow (top) and referential gaze cues (bottom) illustrated

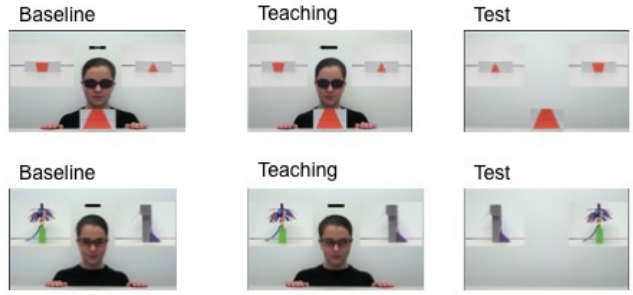

Figure 2. Proportion of time looking at the gaze vs. arrow region in action understanding (left) and word learning (right) contexts

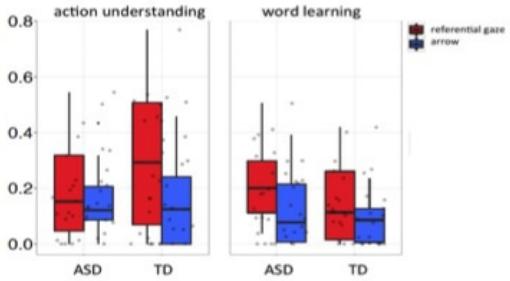


195 **110.195** Let Us Face It! a Meta-Analysis of Atypical Viewing Patterns in Individuals with ASD

K. Evers[1,2,3,4], *J. Prinsen*[4,5], *R. Van der Hallen*[1,4] *and J. Wagemans*[1,4], *(1)Laboratory of Experimental Psychology, KU Leuven, Leuven, Belgium, (2)Parenting and Special Education Research Unit, KU Leuven, Leuven, Belgium, (3)Department of Child Psychiatry, UPC-KU Leuven, Leuven, Belgium, (4)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium, (5)Research Group for Neuromotor Rehabilitation, KU Leuven, Leuven, Belgium*

Background: Reduced eye-contact is one of the core symptoms of ASD, sometimes already present early in infancy. Some studies have indeed found that individuals with ASD made fewer fixations at faces, more specifically at eyes, and that they fixated mouths or the background more often than a control sample. Other studies, however, obtained no evidence for atypical viewing patterns in individuals with ASD. Differences are sometimes very subtle and the exact pattern of results appears strongly dependent on task and stimulus factors.
Objectives: Instead of yet another empirical study evaluating the fixation patterns of individuals with ASD, the field is in need of a systematical and quantitative overview of all the evidence. We therefore wanted to examine and combine all available empirical data on this topic, by means of a meta-analysis, in which the effect size across different studies was calculated, evaluating the overall evidence for differences in social attention between individuals with and without ASD.
Methods: Our literature search yielded over 2,500 articles, of which all abstracts were further reviewed, applying a set of strict inclusion and exclusion criteria. The remaining set of 57 articles was included in our quantitative meta-analysis. Several moderator variables, such as participants' age, gender, stimulus and task characteristics, and region of interest, were incorporated as moderator variables in our analysis. Hedges' *g*effect sizes were examined.
Results: Overall, results provided evidence for a reduced saliency of faces in individuals with ASD (Hedges' *g* effect size = -0.52, $p < .0001$), which was stronger for upper ($g = -0.79$, $p < .0001$) compared to lower ($g = -0.32$, $p = .0341$) face regions. These viewing pattern differences were partially overcome by using task instructions, compared with free-viewing tasks ($F(1,208) = 5.96$, $p = .0154$). Group differences appeared strongest in age groups between 12 and 25 years old, and for individuals with average IQ scores between 85 and 115.
Conclusions: This meta-analysis provided evidence for atypical viewing patterns in individuals with ASD, characterized by a reduced saliency of faces and – more specifically – all internal facial features, with moderate to strong effect sizes. The impact of several moderator variables will be discussed.

196 **110.196** Linkage Between Autism-Spectrum Quotient (AQ) of Parents and Autism Severity of Their Children with Autism: An Italian Experience in the Field of the Broader Autism Phenotype

A. Narzisi[1], *M. Pinzino*[2], *S. Calderoni*[3], *G. Scarselli*[4], *J. Barsotti*[4], *R. Tancredi*[5] *and F. Muratori*[6], *(1)IRCCS Stella Maris Institute, Pisa, PI, Italy, (2)University of Pisa, Calambrone, Italy, (3)Magnetic Resonance Laboratory, Division of Child Neurology and Psychiatry University of Pisa; Stella Maris Scientific Institute, Pisa, Italy, (4)IRCCS Stella Maris, Calambrone, Italy, (5)University of Pisa – Stella Maris Scientific Institute, Pisa, Italy, (6)IRCCS Stella Maris Institute, Pisa, Italy*

Background: Features of the Broad Autism Phenotype (BAP) are disproportionately prevalent in parents of a child with autism, highlighting familial patterns indicative of heritability.
Objectives: The main aim of this research was to identify phenotypes in mothers and fathers that are specifically associated with disturbances in social affect and repetitive behaviours in their young children (age range 4-11 yrs) with autism spectrum disorder (ASD) in an Italian sample.
Methods: Autistic traits in parents were evaluated using the italian version of the Autism-spectrum Quotient (AQ), in 42 parents (21 mothers and corresponding fathers) of children with ASD and in a sample of parents (mothers and fathers) of typically developing (TD) children. For the measurement of autistim severity in children we employed the ADOS-2, for autism quotient we used AQ-Child. For the measurement of IQ, in children, we employed the Wechsler scales. With typically developing (TD) children we used also AQ-Child.
Results: In the five AQ subscales the parents (mother and father) of ASD children scored significantly higher than did the parents of TD children. In addition, in mothers of ASD children, there were significant positive correlations between the five AQ subscales and AQ-Child subscales and ADOS-2-calibrated severity score in their children. In ASD children IQ was not correlated with AQ-Child and with AQ of parents.
Conclusions: This study demonstrate that some autistic traits in parents (above all mothers) are specifically associated with disturbances in the social impairments of their young children with ASD, as measured by the AQ-Child and ados-2 calibrated severity score. Further study are necessary to confirm these preliminary results .

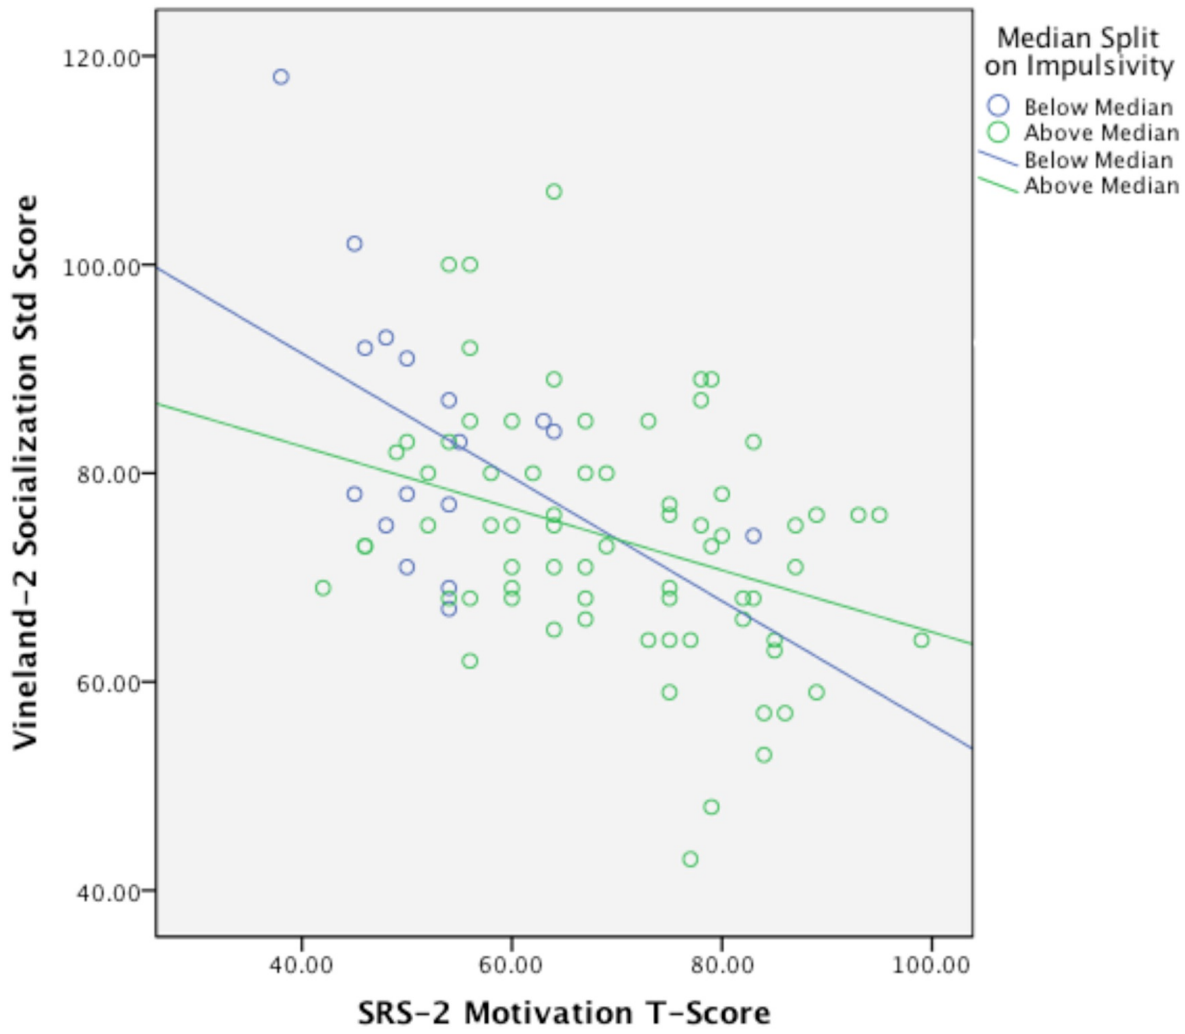
197 **110.197** Linking Social Motivation to Social Skill: Contributions of Anxiety & Impulsivity

E. E. Neuhaus[1], *A. Kresse*[2], *E. J. Libsack*[2], *S. J. J. Webb*[3], *R. Bernier*[3] *and K. Pelphrey*[4], *(1)PO Box 5371, Seattle Children's Hospital, Seattle, WA, (2)Seattle Children's Research Institute, Seattle, WA, (3)University of Washington, Seattle, WA, (4)Yale Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Several recent models propose that social motivation deficits underlie social dysfunction in ASD. Such models assume that social motivation is fundamental to social skill. Although likely, this assumption is not well established empirically. Moreover, additional traits likely contribute to social functioning among children. Both anxiety and impulsivity are plausible candidate traits that may blunt the facilitative effects of social motivation – high levels of anxiety and impulsivity may inhibit appropriate social behavior and exacerbate inappropriate social behavior, respectively. Indeed, impaired social skills are commonly observed among children with heightened anxiety, as well as those with heightened impulsivity.
Objectives: We aim to explore the contributions of social motivation, anxiety, and impulsivity to determine whether individual differences in these traits promote or inhibit social success among children with and without ASD.
Methods: Data were obtained from two related studies spanning four research sites across the US, for a total sample of 160 children and adolescents (66 female; mean age=11.9 yrs, SD=2.7, range=8 to 18) with ASD (n=87) or typical development (TD; n=73). All children were verbally fluent, at or above average IQ levels, and all ASD children met clinical cut-offs on ADOS-2, ADI-R, and DSM-5 criteria. Social motivation was assessed via parent report on the SRS Social Motivation subscale. Social skill was measured via the Vineland Socialization domain. CBCL subscale T-scores were used as measures of parent-reported impulsivity and anxiety.
Results: For the full sample, social motivation accounted for 49.7% of the variance in social skill ($F(1, 159)=158.36$, $p<.000$). Stronger motivation was associated with better

skills. The addition of impulsivity and the Motivation x Interaction accounted for an additional 10% of variance in skill ($F(3, 159)=79.58$, $p<.001$). The inclusion of anxiety did not account for additional variance, however ($p=.853$). Next, relationships were examined within the ASD and TD groups separately. For TD children, social motivation was associated with social skill and accounted for 15.3% of the variance ($F(1, 72)=13.99$, $p<.001$), with no evidence of influence by either anxiety or impulsivity ($ps>.16$). In contrast, for the ASD group, a model containing social motivation, impulsivity, and their interaction accounted for 24.8% of the variance in social skill ($F(3, 86)=10.45$, $p<.001$), with significant contributions from motivation and impulsivity ($ps<.03$). Better skills were associated with stronger motivation and lower impulsivity. The interaction between these traits was marginal ($F(3, 86)=10.45$, $p=.069$); the association between social motivation and skill was weaker for children with higher levels of impulsivity (Figure 1).
Conclusions: Our results suggest that social motivation facilitates social skills, but also indicate a role for behavioral impulsivity. This relationship was most apparent for children with ASD, highlighting an additional target for interventions aiming to improve social functioning. Notably, anxiety did not appear to contribute to social skills for children with ASD. Neither anxiety nor impulsivity contributed to social skill for typically developing children, suggesting that additional factors not included in our analyses may be important for understanding social functioning more broadly. Findings underscore the complexity of behavioral factors promoting social success and engagement during childhood.

Figure 1: Interaction of social motivation and impulsivity in predicting social skills among children with ASD



198 **110.198** Loneliness and Friendship Quality in School-Aged Children with ASD

A. Dominguez[1], *M. Mladenovic*[2], *W. I. Shih*[3], *R. Landa*[4], *C. Lord*[5], *B. King*[6] *and C. Kasari*[7], *(1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)UCLA, Monrovia, CA, (4)The Kennedy Krieger Institute, Baltimore, MD, (5)Weill Cornell Medical College, White Plains, NY, (6)University of Washington and Seattle Children's Hospital, Seattle, WA, (7)University of California Los Angeles, Los Angeles, CA*

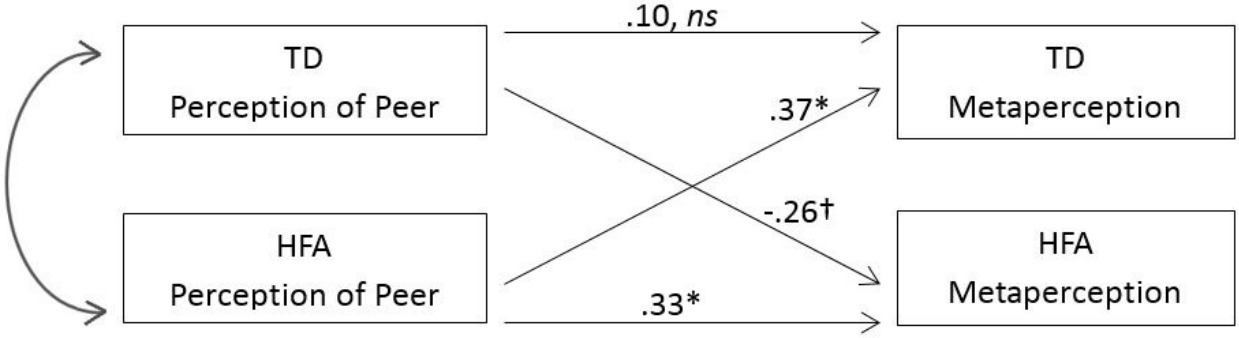
Background: Deficits in social skills and poor peer relationships are characteristic of individuals with autism spectrum disorder (ASD) (Chamberlain, Kasari, & Rotheram-Fuller, 2006). Adolescents with ASD often report more loneliness at school than their typically developing classmates (Bauminger, Shulman, & Agam, 2003). Loneliness tends to be higher in older children than younger children (Burner, Orlich, Dean et al., submitted). Previous studies have suggested that greater child-reported feelings of loneliness may be tied to poorer quality friendships or peer relationships at school (Bauminger & Kasari, 1999). Further, children who are isolated or peripheral in their social network relative to classmates may exhibit more loneliness. However, few studies have investigated the connection between loneliness in elementary-aged children with ASD and friendship quality or social connectivity to peers.
Objectives: This study aimed to 1) explore how quality of friendships and social connection with classmates are related to loneliness in children with ASD, and 2) compare self-reported ratings of loneliness in school-aged children with ASD to those of their typically developing peers.
Methods: Participants were 135 children with ASD (mean age = 8.13) and 239 typically developing classmates enrolled in mainstream classrooms. The data were collected at four sites across the U.S. as part of a larger study conducted by the Autism Intervention Research Network on Behavioral Health (AIR-B). Children with ASD completed three questionnaires: a) Loneliness Questionnaire (Asher, Hymel, & Renshaw, 1984) measured feelings of loneliness, b) Friendship Survey (Cairns & Cairns, 1994) analyzed social connectivity within the classroom using child nomination of classmates as friends, and c) Friendship Qualities Scale (FQS; Bukowski, Hoza, & Boivin, 1994) assessed aspects of companionship, conflict, help, security, and closeness within each child's relationship to his or her best friend. Typically developing peers from the same classrooms as the children with ASD also completed the Loneliness Questionnaire.
Results: Comparing children with higher ($n = 43$) versus lower scores ($n = 45$) on the Loneliness Questionnaire, children with ASD who reported less loneliness also reported more companionship ($p \leq .05$) and more closeness ($p \leq .05$) in friendship quality with their best friend. However, loneliness scores were not related to social network connectivity within the classroom. No differences were found between loneliness scores of children with ASD and their typically developing peers.
Conclusions: While previous research indicates that adolescents with ASD report greater feelings of loneliness than their typically developing peers, our results suggest that this distinction may not be as salient among younger children with ASD. Nevertheless, the child's relationship quality with his or her best friend was found to be an early indicator of emerging feelings of loneliness. This finding stresses the importance of targeting peer relationships at a young age in social interventions that aim to increase feelings of companionship and closeness in relationships between children with ASD and their peers. Given the association between higher quality friendships and lower levels of loneliness, these interventions should begin at early ages in hopes of decreasing loneliness of children with ASD before they reach adolescence.

199 **110.199** Metaperception in Adolescents with High Functioning Autism: Accuracy and Associations with Perceptions of Others

L. V. Usher[1], *C. A. Burrows*[1] *and H. A. Henderson*[2], *(1)University of Miami, Coral Gables, FL, (2)University of Waterloo, Waterloo, ON, Canada*

Background: During everyday social interactions with peers, individuals formulate both perceptions of their peers and impressions of what peers think about them, or metaperceptions (Laing, Phillipson, & Lee, 1966). The ability to accurately perceive others' impressions is crucial for interpersonal success (Carlson & Kenny, 2012). The association between perception and metaperception has not been examined in adolescents or in those with high functioning autism (HFA), but may offer insight into mechanisms underlying deficits in social reciprocity observed in adolescents with HFA.
Objectives: We aimed to quantify both adolescents' perceptions of an unfamiliar peer and their metaperceptions using a novel self-report measure. We also examined the associations between dyadic perception and metaperception.
Methods: This study included 24 dyads composed of gender-, age-, and verbal IQ-matched adolescents with HFA paired with unfamiliar typically developing adolescents (M_{age}=14.40, *SD*=1.41). Immediately following a five-minute unstructured social interaction, each participant completed the Perceptions and Metaperceptions Questionnaire (PAMQ) indexing *perception* of the peer (e.g., "How cool is ___?") and *metaperception*, or predictions of peer's impressions (e.g., "How cool does ___ think you are?").
Results: Multilevel modeling was used to estimate the effect of an adolescent's own perceptions of the peer on his or her own metaperception, and the effect of the peer's perception on the adolescent's metaperception (see Figure 1). For adolescents with HFA, their perception of the peer was positively associated with their metaperception, β=.33, *t*(28)=2.27, *p*=.03, indicating that the higher they rated their peers, the higher they believed their peers would rate them. However, for TD adolescents, their perception of the peer was independent of their metaperception, β=.10, *t*(28)=.71, *p*=.49.
Agreement between an individual's metaperception and the peer's perception of them differed by diagnostic group, β=.31, *t*(35)=2.25, *p*=.03. Specifically, for typically developing adolescents, metaperception was positively associated with partner's perception, β=.37, *t*(24)=2.27, *p*=.03, indicating accuracy of metaperception. The higher the partner rated the typically developing adolescent, the higher the adolescent predicted the partner rated him/her. In contrast, for adolescents with HFA, metaperception was marginally and negatively associated with the partner's perception , β=.-.26, *t*(34)=-1.93, *p*=.06. The higher the partner rated the adolescent with HFA, the lower the adolescent predicted the partner would rate him/her, indicating poor accuracy of metaperception.
Conclusions: Results indicate that while TD adolescents display relatively accurate metaperceptions, adolescents with HFA experience difficulty distinguishing between perspectives of the self and other. HFA participants' lack of ability to accurately interpret social partners' impressions may be a factor that impedes social functioning in adolescents with HFA, and presents interesting implications for targeted social skill treatment. These novel findings will be discussed in terms of ecological validity.

Figure 1. Actor-partner interdependence model (APIM) for examining dyadic perception and metaperception in unfamiliar dyad members.



Note. * $p < .05$, † $p < .07$. HFA = high functioning autism, TD = typically developing

200 **110.200** Morality in Autism: As Understood through the Empathizing-Systemizing (E-S) Theory

D. M. Greenberg[1,2], *R. Holt*[3], *C. Allison*[3], *P. J. Rentfrow*[4], *D. J. Stillwell*[4], *M. Kosinski*[5], *J. Haidt*[6] *and S. Baron-Cohen*[3], *(1)Departments of Psychology and Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)Department of Clinical Psychology, City University of New York, New York, NY, (3)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (4)University of Cambridge, Cambridge, United Kingdom, (5)Stanford University, Stanford, CA, (6)New York University, New York, NY*

Background: What is the nature of morality in autism? Children and adults with autism are able to distinguish and judge moral transgressions, but little is known about their moral profile. The present research addresses this gap using Moral Foundations Theory (MFT), which postulates that all of our moral judgments can be explained by five universal 'moral foundations': Care, Fairness, Loyalty, Authority, and Sanctity.
Objectives: The aim of this research is to use several large datasets to (a) investigate the moral profile in autism; (b) understand how individual differences in moral foundations are underpinned by empathizing-systemizing 'brain types'; and (c) examine which components of empathy (cognitive vs affective) drive moral foundations the most.
Methods: In Study 1, 193 adults with autism completed the Moral Foundations Questionnaire (MFQ) via the Autism Research Centre's database. In Study 2, 7,595 adults without autism completed the MFQ and short versions of the Empathizing Quotient (SQ) and Systemizing Quotient (SQ) at YourMorals.org. In Study 3, 1,676 adults without autism completed the full 60-item version of the EQ via the MyPersonality Facebook Application, which allowed for examination of the different components of empathy to be made.
Results: In Study 1, adults with autism rated Fairness significantly greater than Care and the other moral foundations. In Study 2, on average, people with empathizing 'brain types' (Extreme Type E and Type E) had a moral profile that placed the highest value on Care, and people with systemizing 'brain types' (Type S and Extreme Type S) had a moral profile that placed the highest value on Fairness/reciprocity. In Study 3, affective empathy was a stronger predictor than cognitive empathy for Care, Fairness, and Sanctity morals. Strikingly affective empathy was a stronger predictor than demographic factors, political ideology and the Big 5 personality traits, where previous associations with moral foundations have been reported.
Conclusions: The findings show that individuals with autism rate Fairness over Care and that this profile may be due to their heightened systemizing tendencies. This moral profile resembles findings from previous research which has shown that libertarians also rate Fairness over Care. Future research needs to explore the extent to which the moral profile of autism resembles a hybrid of that shown previously by liberals and libertarians. Importantly, this work also provides evidence that individual differences in moral foundations are rooted in part by empathizing-systemizing 'brain types' in the general population.

201 **110.201** National Service and University Studies in Young Adults with ASD in Israel

C. Shulman[1], *S. Hanan*[2] *and J. Koller*[3], *(1)The School of Social Work, Hebrew University of Jerusalem, Jerusalem, Israel, (2)The Hebrew University of Jerusalem, Jerusalem, Israel, (3)School of Education, Hebrew University of Jerusalem, Jerusalem, Israel*

Background:
After high school most 18-year olds in Israel choose some form of national service. Individuals choose to volunteer in the civil sector or, if they meet criteria, to do military service. Until three years ago, individuals with ASD were automatically exempt from military service and could only volunteer to do civil service. High-functioning individuals with ASD are now inducted in the Israeli army, although many still choose other forms of national service or not to serve at all. After their service, many high functioning individuals with ASD begin university. The interface between national service and academic studies has not been examined in young adults with ASD, although the social demands in both may be challenging for individuals with ASD.
Objectives:
The present study examines choices made by young adults with ASD regarding national service and university study and their relationship to utilization of social support, reports of loneliness and social affiliation.
Methods:
Twenty-seven young adults with ASD (5 females), ranging from 22-27 years of age, presently enrolled in a university in the center of the country which has a support system

for students with ASD, participated in this research. Each participant completed an online, anonymous questionnaire which surveyed demographics, utilization of social support and feelings of loneliness and social competence.
Results:
Significant differences in social competence between participants who chose some form of national service (n=16) and those who did not (n=11). Those who did not serve reported more loneliness ($t(1, 25) = 1.37$, $p < 0.05$) and less social affiliation ($t(1,26) = 5.23$, $p = < 0.01$). These differences in social affiliation and loneliness were also reflected in reports of their social experience in university, with the group who did national service reporting significantly more ($t(1,26) = 0.45$, $p < 0.02$) social satisfaction. When reporting about their social support systems in university, all but five reported that they made use of the support provided by the university for students with ASD, which included mentors, activities and academic help. The five who did not take advantage of the supports within the university reported that they felt unaffiliated and that they found social support was outside the university.
Conclusions:
Findings suggest that young adults with ASD can successfully serve in some form of national service, which is correlated with higher social affiliation scores and lower loneliness scores. Those who served report that at university, they use social supports and feel more socially involved than young adults who did not experience any form of national service. Understanding choices that young adults with ASD make and their implications for social competence may help professionals support young adults with ASD as they begin to navigate adulthood.

202 **110.202** Not Knowing What I Feel: Emotional Empathy in ASD

E. Trimmer[1], *S. McDonald*[2] *and J. A. Rushby*[3], *(1)University of New South Wales, Sydney, NSW, Australia, (2)Psychology, University of New South Wales, Sydney, Australia, (3)University of New South Wales, UNSW, Sydney, NSW, Australia*

Background: Empathy can be defined as "natural tendency to share and understand the emotions and feelings of others in relation to oneself" (Jean Decety & Meyer, 2008, p. 1053). Empathy involves both a cognitive (understanding other's intentions and meaning) and an emotional (feeling what another person is feeling) component. Individuals with Autism Spectrum Disorder (ASD) have been shown to have difficulties with cognitive empathy and perspective taking. Less is known about emotional empathy in these individual and the present literature is inconsistent.
Objectives: This study examines the emotional empathy of individuals with ASD whilst watching emotionally-driven stimuli.
Methods: Twenty-four individuals aged 16 or older (22 males; mean age 28 years) with a diagnosis of ASD and 25 matched controls (21 males, mean age 27) watched a series of five emotionally distressing film clips and five non-emotional clips. Participants then rated their mood and level of arousal on a 9-point Likert scale. Skin conductance was recorded as a measure of arousal along with corrugator EMG as a measure of emotion expression.
Results: No significant differences were found between groups for either of the psychophysiological measures indicating comparable physiological responding. Participants with ASD rated less negative mood to the emotional clips than control participants indicating a flattening of self-report affect, whereas self-reported arousal was similar between groups.
Conclusions: Whilst individuals with ASD appear to experience similar levels of physiological responding to emotionally-driven stimuli, they appear to interpret this response as having less emotional salience than controls. This has significant implications for understanding empathy impairments in the ASD population.

203 **110.203** Patterns of Visual Engagement Differ As a Function of Cognitive Profile in School-Aged Children with ASD

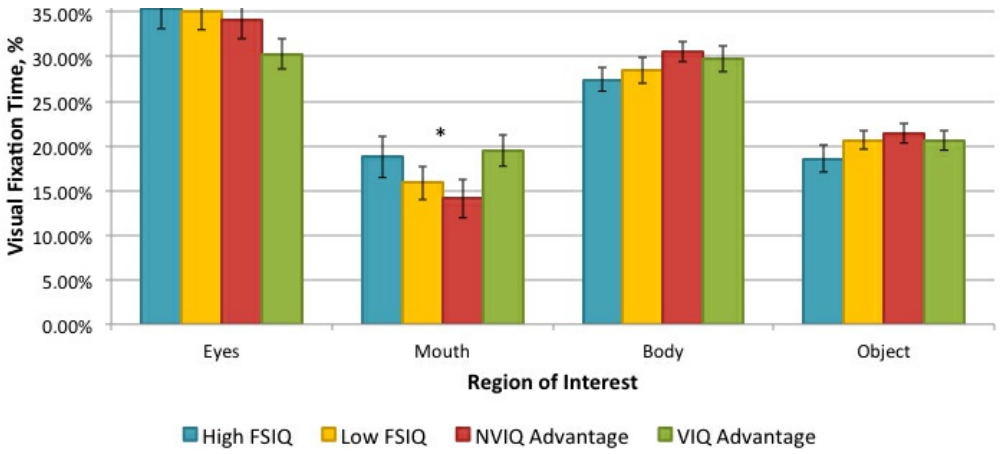
J. R. Yurkovic, *I. Stallworthy, E. Coben, W. Jones, A. Klin and S. Shultz, Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: Heterogeneity in autism spectrum disorder (ASD) is an obstacle to advancements in identifying and treating causes of the disorder. Measures capturing the core underlying features of ASD, such as reduced interest in socially adaptive stimuli, may provide a means for parsing phenotypic heterogeneity in ASD. For example, previous research has revealed that the social adaptive value of *where* children looked when viewing social scenes differed significantly based on IQ profile (Rice et al., 2012). To further investigate how different patterns of visual engagement are related to cognitive functioning, the present study uses a novel approach for quantifying not only *where* a child is looking but also their *level of engagement* with scene content.
Objectives: Examine whether visual *engagement* with scene content differs between subgroups of ASD characterized by different cognitive profiles.
Methods: School-age children with ASD (n=174) watched age-appropriate, socially relevant videos while eye-tracking data were collected. The ASD sample was divided into four subgroups as in Rice et al. (2012): Participants with a verbal IQ (VIQ) advantage (VIQ-NVIQ>12), a non-verbal IQ (NVIQ) advantage (NVIQ-VIQ>12), an even IQ profile and higher full-scale IQ (FSIQ), and an even IQ profile and lower FSIQ (see Table 1). Viewer engagement was quantified by measuring patterns of eye-blink inhibition, a method that capitalizes on the finding that people unconsciously adjust the timing of eye-blinks to minimize the likelihood of missing critical information (Shultz et al. 2011). Probabilistically, people are *least likely* to blink when *highly engaged* with what they are viewing and *most likely* to blink when *less engaged*. Permutation testing identified periods of statistically significant blink inhibition (indicating moments when children were highly engaged) and statistically significant increased blinking (moments when children were less engaged) for each subgroup separately. Percentage of visual fixation time on eyes, mouth, body, and object regions were calculated for each child.
Results: Comparisons of visual fixation over the entire viewing session revealed that VIQ and high FSIQ subgroups looked more at mouths compared with the NVIQ subgroup ($p<.01$) (Figure 1A). No other differences were found. In contrast to the relatively similar patterns of visual fixation between subgroups, patterns of eye-blinking revealed striking differences in *when* subgroups were highly engaged with scene content. Only 1.24% of highly engaging movie frames were perceived as engaging to all 4 subgroups. By contrast, 75.76% of highly engaging movie frames were perceived as engaging by only one subgroup (Figure 1B). These data suggest that subgroups likely engage with and experience these movies in very different ways. Ongoing analyses are aimed at further investigating the type of content that is perceived as engaging to each ASD subgroup.
Conclusions: This study identified patterns of visual engagement in one of the largest eye-tracking samples of school-age children with ASD. Our findings demonstrate that patterns of engagement with social content are influenced by the cognitive profile of children with ASD. These measures provide a promising means for parsing heterogeneity in ASD and represent an important step towards developing interventions tailored to an individual's specific learning style.

Table 1: Comparison of Characterization Measures across Four Distinct Cognitive Profile Subgroups of Children with ASD.

	High Even FSIQ Subgroup (n = 38)	Low Even FSIQ Subgroup (n = 49)	NVIQ Advantage Subgroup (n = 48)	VIQ Advantage Subgroup (n = 39)	Full Sample (n = 174)	P Value
Gender male/female	30 / 8	40 / 9	40 / 8	28 / 11	138 / 36	0.58
Age	10.04 (2.92)	10.76 (3.41)	10.47 (3.07)	10.92 (3.03)	10.56 (3.12)	0.62
ADOS Calibrated Severity Scores	6.71 (2.49)	7.41 (2.17)	7.90 (1.96)	6.80 (2.25)	7.23 (2.24)	0.13
ADOS Restricted and Repetitive Behavior Score	2.28 (1.28)	2.97 (1.73)	3.72 (2.19)	2.90 (1.95)	2.98 (1.87)	0.03
ADOS Social Affect Score	9.31 (4.16)	10.66 (4.46)	11.97 (4.41)	8.73 (3.82)	10.23 (4.37)	0.02

Note: Data are mean (SD). Higher Autism Diagnostic Schedule (ADOS) severity scores denote higher levels of social disability. FSIQ = full scale IQ; NVIQ = nonverbal IQ; VIQ = verbal IQ.



b

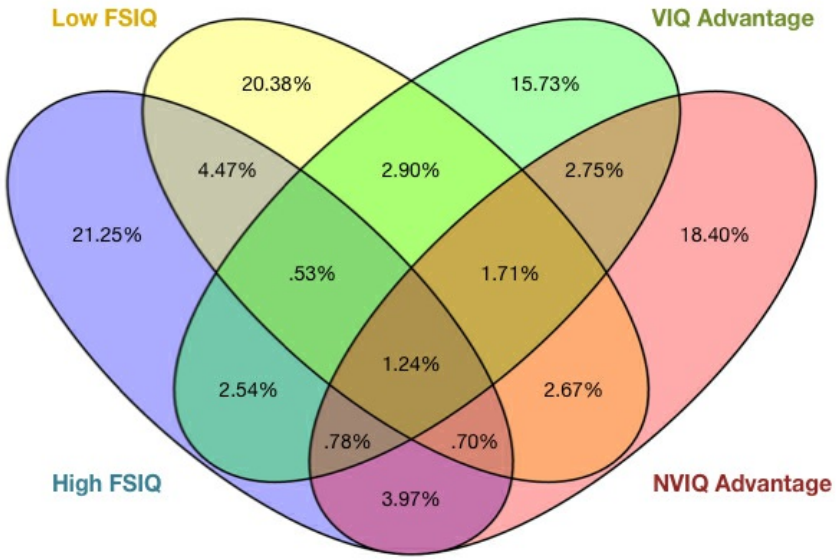


Figure 1: Patterns of Visual Fixation and Visual Engagement across Four Subgroups of Children with ASD. **(a)** Percent fixation time on regions of interest in subgroups of children with ASD. *p<0.05. The VIQ advantage and high FSIQ subgroups looked more at mouths than the NVIQ advantage subgroup. **(b)** Venn diagram showing percent overlap in frames perceived as engaging by children with ASD. Only 1.24% of highly engaging movie frames were perceived as engaging by all 4 subgroups. 3.71% of highly engaging frames were engaging to three subgroups, and 19.30% were engaging to two subgroups. 75.76% of highly engaging frames were perceived as engaging by only one subgroup. Values presented in all elements of the Venn diagram sum to 100%. In contrast to the relatively similar patterns of visual fixation (a), patterns of eye-blinking (b) reveal differences in *when* subgroups were highly engaged with scene content.

204 **110.204** Patterns of Visual Fixation during Moments of High Engagement in School-Age Children with and without Autism Spectrum Disorder

I. Stallworthy, *E. Coben, J. R. Yurkovic, W. Jones, A. Klin and S. Shultz, Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: Atypical perceptions of the social world are a hallmark feature of Autism Spectrum Disorder (ASD). When viewing social scenes, individuals with ASD spend less time looking at the eyes of others and more time looking at less socially relevant features, such as objects (Rice et al., 2012). This atypical pattern of visual attention suggests that individuals with ASD experience the world in profoundly different ways compared to their typically developing (TD) peers. For greater insight into the subjective experience of individuals with ASD, this study examines not only *where* children with ASD look when viewing social scenes, but also how *engaged* they are with what they are looking at. Viewer engagement is quantified by measuring patterns of eye-blink inhibition, a novel method that capitalizes on the fact that blinking temporarily interrupts incoming visual information. Because blinking interrupts visual information, people unconsciously adjust the timing of their blinks to minimize the likelihood of missing critical information. Probabilistically, people are *least likely* to blink when looking at what they *perceive to be most important* and *most likely* to blink during moments *perceived to be least important*. Thus, by measuring patterns of visual fixation and blinking we can examine *where* children with ASD look when they are *highly engaged*.
Objectives: To investigate: (1) where children with and without ASD look when viewing naturalistic social scenes; and (2) whether looking patterns are modulated by engagement with scene content.
Methods: Eye-tracking data were collected while 92 children with ASD (mean age=10.32(3.2) years; 28 female) and 44 age- and IQ-matched TD children (mean age=10(2.9) years; 15 female) watched age-appropriate movies. Permutation testing was used to identify periods of statistically significant blink inhibition (indicating moments when children were *highly engaged*) and statistically significant increased blinking (indicating moments when children were less engaged) for each group separately (Figure 1). Percentage of visual fixation time on eyes, mouth, body, and object regions were calculated for each child over: (1) the entire viewing session; (2) periods of high engagement; and (3) periods of less engagement.
Results: Multivariate ANOVAs showed that, over the entire viewing session, TD viewers fixated more on eyes and mouths compared to children with ASD, who instead looked more at objects and bodies (all *p's*<0.0001). These group differences were also observed during periods of high engagement (all *p's*< 0.05; Figure 2a). Finally, there was a significant interaction between diagnosis and level of engagement, with TD viewers looking more at mouths when highly engaged compared to when they were less engaged (p<0.05; Figure 2c).
Conclusions: Results show that children with ASD and their TD peers perceive social stimuli in markedly different ways. TD viewers attend more to faces, while viewers with ASD attend more to objects. Critically, these differences become even more pronounced during periods when viewers were *highly engaged* with the stimuli. Ongoing analyses, examining between-group differences in the timing of *when* children are engaged and with *what* type of content, will further elucidate the subjective experience of individuals with ASD.

205 **110.205** Perceiving Pain in Others: Altered Physiological and Cognitive Regulation of Distress in ASD

M. Hoogenhout *and S. Malcolm-Smith, Department of Psychology, University of Cape Town, Cape Town, South Africa*

Background: Perceiving the pain of others normally activates the affective brain areas responsible for perceiving self-pain. These responses are thought to be required for feeling empathic concern for others, but need to be down-regulated in order to minimise personal distress and facilitate prosocial behaviour. Evidence from neuro-imaging studies suggest that vicarious responses are poorly regulated in autism spectrum disorder (ASD), but corresponding electrophysiological evidence is scant. Furthermore, there is evidence that poor self-regulation may stem in part from deficits in perspective-taking and own-emotion understanding (alexithymia).
Objectives: We investigated affective and sensory-motor empathy in individuals with varying levels of autism traits in response to viewing sensory pain displays. We also investigated the relationship of perspective-taking ability and alexithymia to self-reported personal distress and empathic concern. We hypothesised that participants with higher autism traits would show (1) poorer perspective-taking and higher levels of alexithymia, and (2) greater muscle activation, distress and sympathetic arousal when observing pain.
Methods: 105 individuals (27 ASD; ages 14 – 46) completed the Toronto Alexithymia Scale (TAS-20), the Interpersonal Reactivity Index (distress and empathic concern indices) and the Emotional Contagion Scale. Autism trait scores were calculated using participants' Autism Diagnostic Observation Schedule 2 algorithm and Autism Spectrum Quotient scores. Participants were shown videos of painful stimuli (a hand being stabbed), during which muscle activity in the participant's hand was measured at 100ms intervals using surface electromyography. Skin conductance responses were sampled as a measure of sympathetic activity. Using multilevel modelling, autism traits were correlated with (1) self-reported trait empathic concern, personal distress, emotional contagion and alexithymia, and (2) muscle activation and skin conductance when observing pain.
Results: High levels of alexithymia ($p = .0006$) and emotional contagion ($p < .0001$), and higher autism traits ($p = .038$), predicted higher personal distress. In contrast, good perspective-taking ($p < .0001$), low alexithymia ($p = .0002$) and high emotional contagion scores ($p < .0001$) predicted higher levels of empathic concern. Autism trait scores did not predict empathic concern ($p = .550$). Participants with high levels of autism traits had significantly higher muscle activity; with the highest activity occurring at the time of highest pain intensity in the video ($p = .0043$). Skin conductance was significantly higher in participants with high autism traits and those with high trait levels of distress ($p = .0064$).
Conclusions: The study replicates and extends previous findings showing that people with ASD experience increased levels of distress and physiological arousal when witnessing painful stimuli. Alexithymia and poor perspective-taking in this group may contribute to the distress experienced. Physiologically, participants with high autism traits had significantly greater sympathetic arousal and muscle activation than those with low autism traits and low trait levels of distress. Autism trait levels were not correlated with empathic concern. These findings suggest intact empathic concern in ASD, but poorer self-regulation of vicarious emotion at the cognitive and physiological levels. Our data speak to the potential value of incorporating self-regulation strategies into ASD interventions to reduce distress and promote prosocial behaviour.

206 **110.206** Perceptions of Self and Other: Gaze Patterns and Social Perception of Children with and without ASD

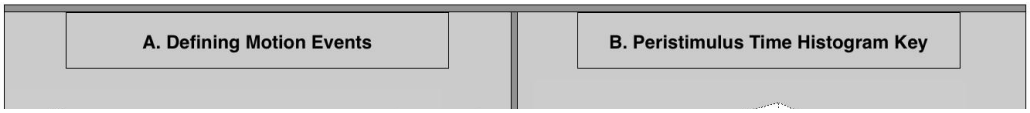
R. B. Grossman*, E. Zane, J. Mertens and A. Nikolaidis, Emerson College, Boston, MA*

Background:
First impressions are formed quickly and have lasting effects. Previous research shows that – without knowing the diagnosis of a child in a video clip - typical adults perceive children with ASD as social awkward after as little as one second (Grossman 2014). Typical adults also assume within a few seconds that children with ASD have fewer friends, are less socially engaged, and get along less well with others (Grossman at al. 2015). However, no evidence is available yet on how children with and without ASD perceive themselves and each other.
Objectives:
To understand the experience of a first encounter with an unfamiliar age-peer who may or may not have ASD, we analyzed gaze patterns to faces, as well as responses to questions probing the willingness of participants to engage with potential social partners.
Methods:
We showed brief (1.4 to 4.1 seconds) video clips of children (ages 10-17) with and without ASD retelling fragments of stories without revealing diagnoses. Participants were 9 children with ASD and 32 TD controls matched on age (mean 13:5, range 10:8-17:2), sex, IQ, and language ability. After conclusion of each video clip, participants were asked to rate (by moving a cursor on a continuous scale) how likely the person in the video would be to engage with others and whether the rater would be willing to engage with the person in the video. We used an SMI remote eyetracker to capture gaze patterns to the face, eyes, and mouth of children in the videos.
Results:
Behavioral responses and eye gaze patterns were significantly affected by the diagnosis of the child in the video but not by the diagnosis of the raters.
Both participant groups rated children with ASD significantly less likely to get along with others ($p < .001$), more likely to spend time alone ($p = 0.03$), and more likely to be socially awkward (($p < .001$) than their TD peers. Similarly, raters indicated they were significantly more likely to start a conversation ($p < .001$) and sit at lunch ($p < .001$) with TD children than children with ASD. There was no main effect for participant group, indicating that both cohorts rated videos of children with ASD more negatively than those of TD children.
Eye gaze analysis shows that both participant groups gazed significantly longer at TD children than children with ASD across all areas of interest ($p = 0.01$ for eyes, $p < 0.001$ for mouth, and $p < .001$ for face). There were no significant between-group differences in fixation durations to face, eyes, and mouth of the children in the videos.
Conclusions:
Children with and without ASD prefer to interact with and gaze at TD peers rather than peers with ASD. These data suggest that first impressions of children with ASD evoke a reduced willingness in their peers to visually and socially engage with them, even if those peers also have an ASD diagnosis. This may significantly contribute to the difficulties in social integration experienced by individuals with ASD.

207 **110.207** Physical Properties of Social Scenes Modulate Visual Engagement in School-Age Children with Autism Spectrum Disorder

E. Coben*, J. R. Yurkovic, I. Stallworthy, W. Jones, A. Klin and S. Shultz, Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: While reduced engagement with the social world is a defining feature of Autism Spectrum Disorder (ASD), less is known about what *is* perceived as important to individuals with ASD. Building on previous research demonstrating that individuals with ASD show increased attention to physical cues, including inanimate objects (Rice et al., 2012), objects in motion (Shultz et al. 2011), and audiovisual synchrony (Klin et al. 2009), the present study examines the extent to which viewers with ASD are *engaged* by physical cues within naturalistic social scenes. Viewer engagement is quantified by measuring patterns of eye-blink inhibition, a method that capitalizes on the fact that blinking temporarily interrupts visual information (Shultz et al., 2011). To accommodate this interruption, viewers unconsciously adjust the timing of their eye-blinks to minimize the likelihood of missing critical information. Probabilistically, people are *least likely* to blink when looking at what they *perceive to be most important*. Thus, by measuring change in rate of eye-blinking relative to ongoing scene content we can index *engagement* in viewers with ASD.
Objectives: Determine whether physical properties within social scenes, such as motion, luminance, and loudness, are engaging to children with ASD.
Methods: Eye-tracking data were collected from 92 children with ASD (mean age=10.3(3.2) years; 28 female) and 44 age- and IQ-matched typically-developing (TD) children (mean age=10.0(2.9) years; 15 female) during viewing of movies depicting age-appropriate social scenes. Motion, luminance, and loudness were quantified at each movie frame. Peristimulus time histograms were created to quantify percent change in blink rate relative to movie frames with physical property values exceeding a percentile threshold. A range of percentile thresholds were used to examine how engagement varies as a function of onscreen physical properties (Figure 1).
Results: Preliminary analyses revealed that both TD and ASD viewers are highly engaged when viewing motion, with engagement increasing as onscreen motion increases (Figure 2A). However, level of engagement was highest amongst ASD viewers, even at lower motion thresholds, with absolute change in blink rate peaking at 21.4% relative to movie frames with motion values above the 70th percentile. By contrast, absolute change in TD blink rate peaked at 15.1% relative to frames with motion values above the 80th percentile (Figure 2B). Both groups showed greater engagement immediately before and after motion events, with ASD engagement peaking approximately 350ms before and 330ms after motion events and TD engagement peaking approximately 650ms before and 950ms after motion events (Figure 2C).
Conclusions: While motion modulates engagement for both groups, viewers with ASD showed a more pronounced increase in engagement that was also more closely time-locked with motion events compared to TD viewers. These findings suggest that viewers with ASD show greater sensitivity towards motion and perceive motion to be more salient compared to TD viewers. Future analyses will ascertain the influence of luminance and loudness on visual engagement in viewers with ASD. These efforts will shed light on cues that engage individuals with ASD and may identify alternate viewing strategies used by these individuals to make sense of complex scenes.



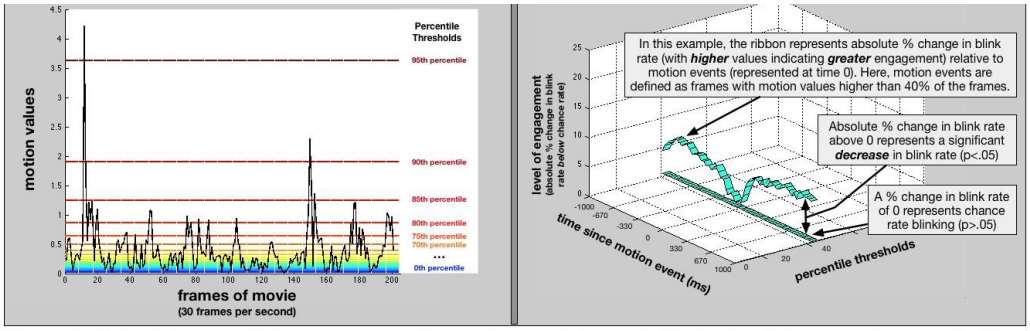


Figure 1. Methods for quantifying onscreen motion and percent change in blink rate relative to motion events. (A) Motion values, calculated as the absolute change in grayscale pixel values between frames, at each movie frame. Colored dashed lines mark percentile thresholds used to define motion events. Twenty sets of motion events were defined using 20 evenly spaced percentile thresholds, ranging from the 0th to the 95th percentile. A 200-frame excerpt from video data is shown. **(B)** A key for interpreting the peristimulus time histograms presented in Figure 2. Y-axis shows absolute percent change in blink rate *below* chance levels (p<.05, with greater percent change in blink rate indexing *increased* engagement) relative to motion events (represented at time 0 on the X-axis). The Z-axis shows the percentile thresholds used to define motion events.

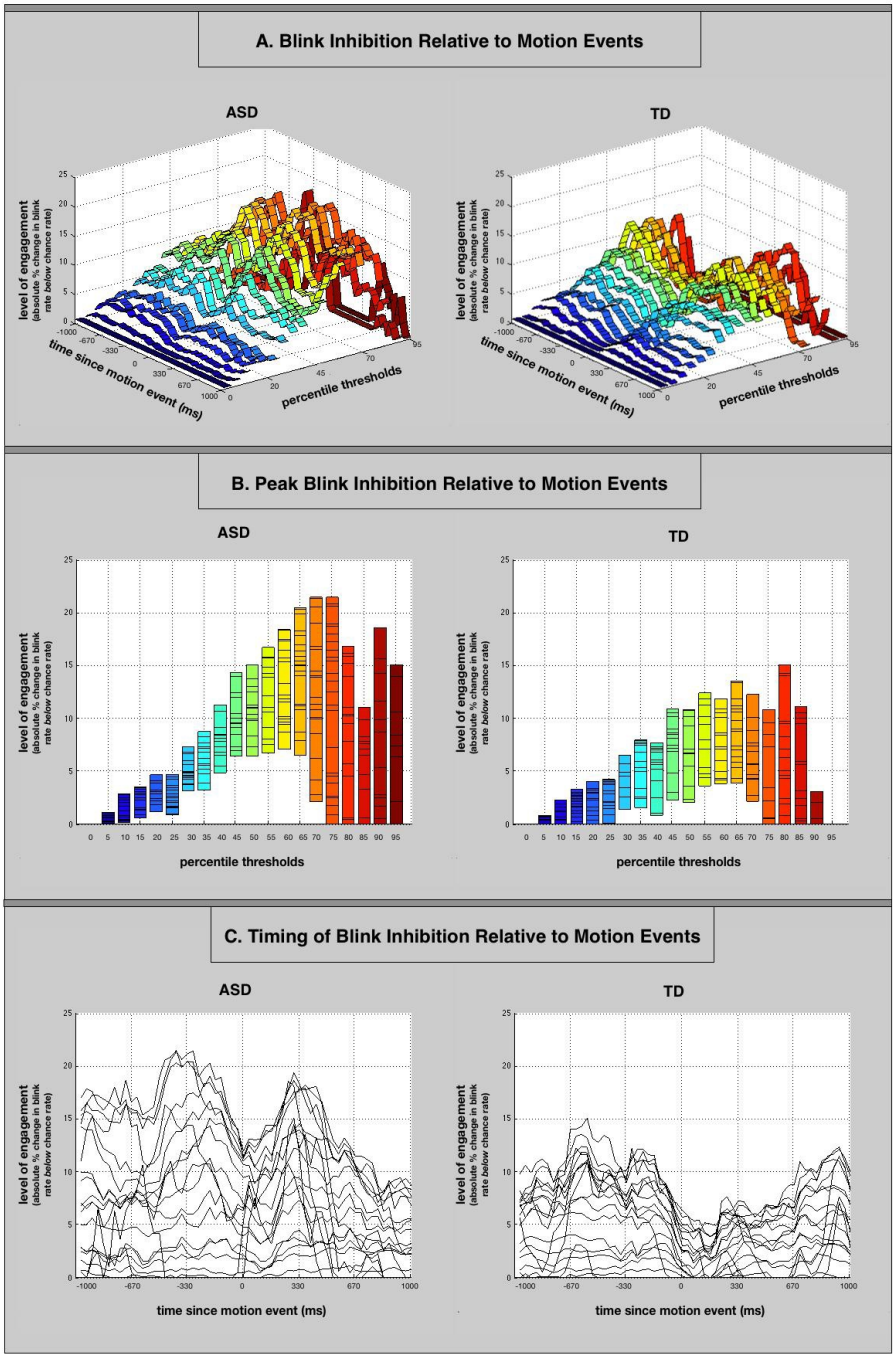

Figure 2. Absolute percent change in blink rate relative to motion events. (A) Peristimulus time histograms (PSTHs) show absolute percent change in blink rate *below* chance rates relative to motion events. One PSTH is plotted for each percentile threshold used to define motion events. **(B)** Peak absolute percent change in blink rate for each percentile threshold used to define motion events. **(C)** PSTHs (plotted for each percentile threshold) showing the timing of change in blink rate relative to motion events (represented at time 0).

208 **110.208** Promoting Reciprocal Social Interaction through Comprehensive Imitation Training for Nonverbal and Minimally Verbal Children with Autism in Japan

Y. Ishizuka[1], *N. Naoi*[2], *A. Matsuzaki*[2], *S. Matsuda*[3], *Y. Minagawa*[4] *and J. Yamamoto*[4], *(1)Japan Society for the Promotion of Science, Tokyo, Japan, (2)CREST, Japan Science and Technology Agency, Tokyo, Japan, (3)University of Tsukuba, Ibaraki, Japan, (4)Dept. of Psychology, Keio University, Tokyo, Japan*

Background:
Imitation skills are one of the most pivotal behaviors emphasized within teaching programs for children with autism. In particular, previous studies have shown effects of imitation training on social communication abilities such as language, joint attention and play skills (Ingersoll, 2012; Ingersoll & Schreibman, 2006). However, few studies have examined the effect of low intensity imitation training for children with autism and shown effects on imitation skills (Warreyn and Roeyers, 2014). In addition, more studies are needed to understand the effects of imitation training on reciprocal social interaction. Finally, little is known about how visual fixation patterns may change during imitation tasks following imitation training.
Objectives:
The purpose of this study is to examine whether a low intensity comprehensive imitation training program promotes reciprocal social interaction and changes socially relevant eye gaze behavior in children with autism.
Methods:
Six children with autism participated in this study, in a multiple baseline design. The range of chronological ages was 4 years to 6 years, and developmental age ranged from 1 year to 3 years. Children came to the laboratory once or twice per week and received 60-minute imitation training sessions, for approximately 12 weeks. During the training, children were taught motor imitation, object imitation, and vocal imitation skills and were trained to imitate actions sequentially for as long as they could. Imitation training was conducted primarily in a structured setting. To demonstrate the process of acquiring imitation skills, we utilized a multiple baseline across target behaviors experimental design. We also utilized six dependent variables in pre and post assessments to evaluate the effect of imitation training, as follows: (1) Imitation skills: Motor Imitation Scale (MIS); (2) Reciprocal social interaction: Proportion of social engaged imitation, frequency of spontaneous language, and the duration of chained mutual imitation through 5-minute video observations between child and mother and child and therapist; (3) Gaze behavior: Change of visual fixation pattern during imitation tasks using eye tracker Tobii; (4) Motor development : Scores on the Developmental Voluntary Movement Test. Pre to Post assessment changes were evaluated using Wilcoxon signed-rank tests.
Results:
All children improved in their imitation skills sequentially through multiple baseline design. Preliminary results suggest that low intensity comprehensive imitation training produced significant increases in imitation skills which were not used in the training in pre and post assessment (Wilcoxon signed-rank test: Z =-2.14, p=0.032, two-sided). The results also showed that imitation training increased the proportion of socially engaged imitation and spontaneous language production in the post assessment. Children also changed their visual fixation patterns during imitation tasks after training, looking at an adult's face more than during the pre-training assessment. Finally, motor development also improved from the pre to post assessment.
Conclusions:
The current findings suggest that a low intensity comprehensive imitation training program promoted reciprocal social interaction between mother and child. The finding of increased looking time at the adult's face following imitation training provides further information and support for the observed behavioral effects on reciprocal social interaction.

209 **110.209** Relationship Interest, Knowledge and Experiences Among Young Adults with Autism Spectrum Disorder

N. C. Cheak-Zamora[1], *M. Teti*[2], *C. Regan*[3] *and A. Maurer-Batjer*[3], *(1)University of Missouri, University of Missouri, Columbia, MO, (2)University of Missouri- Columbia, Columbia, MO, (3)University of Missouri, Columbia, MO*

Background:
Sexuality and intimacy are important parts of all adolescent development and influence health and quality of life. Recent research has debunked the notion that young adults with ASD (YA-ASD) lack sexual experiences and desires. However, developing and maintaining sexual and romantic relationships are difficult for YA-ASD due to communication barriers and lack of social awareness. Further, a dearth of research exists about YA-ASD 's sexual and romantic relationship experiences and desires from the perspectives of YA-ASD themselves.
Objectives:
The objective was to explore the perspectives and experiences of YA-ASD regarding their sexual and romantic relationships using qualitative methods.
Methods:
Subjects were recruited from three major ASD treatment and support sites in different cities within the Midwest United States. We conducted 45 minute semi-structured interviews with 27 YA-ASD to explore sexuality and intimacy. Interviews were transcribed verbatim totaling over 1,000 pages of session transcripts and 150 pages of observational notes. The data was analyzed using theme analysis, which included initial and axial coding, analytical memos, and organizational matrices and reports. An iterative process was used and three separate investigators coded all data to ensure coder agreement.
Results:
The 27 young adult participants ranged in age from 16-25 years old (= 19.19). The majority of participants in the study were non-Hispanic white (96%) and male (74%). Most participants described themselves as having Asperger's Syndrome (41%) or Autism/ Autistic Disorder (33%) and having mild ASD symptomology (74%).
Four thematic categories were uncovered that defined YA-ASD's sexual and romantic relationship experiences and perspectives including: 1) Interest in relationships, 2) Imagined ideal partners, 3) Reality of relationships, and 4) Seeking advice. Although many YA-ASD expressed wanting to be in a relationship, few reported having partners. Among those that had present or past relationships, the actual relationships rarely met their ideals. YA-ASD talked to their parents and friends but rarely health care providers about relationships and sexuality. The few reported conversations with providers were usually vague and about future planning (ex. Marriage). Most young adults, even those uninterested in having a relationship, expressed the desire for more and clearer information about sex and relationship building.
Conclusions:
This study was the first to talk to young adults about sexuality and romantic relationships and provides greater insight into how young adults perceive romantic relationships, their experiences and desires for the future. We found that YA-ASD are interested in romantic and sexual relationships but are relatively unprepared to develop or sustain them. Very few young adults had conversations about sexual safety with health care providers or formal sexual health education.
These findings are important because they not only improve our understanding of sexuality of YA-ASD, but also demonstrate a sound methodological procedure (individual interviews) to facilitate input from YA-ASD.
We recommend that sexual education is introduced early and includes social/relationship skills-building and courtship modeling. Caregivers, educators and health care providers must initiate discussions about sexual health with YA-ASD including concepts of sexual self-hood and risk. Future research should examine issues of sexuality from the young adult's perspective.

210 **110.210** Self-Referential Processing in Autism: Does Valence Matter?

C. A. Burrows[1], *L. V. Usher*[1] *and H. A. Henderson*[2], *(1)University of Miami, Coral Gables, FL, (2)University of Waterloo, Waterloo, ON, Canada*

Background: A strong sense of self incorporates both affective self-attributions, and social-cognitive processes. Individuals with high-functioning autism (HFA) endorse a less positive view of themselves than typically-developing individuals, and do not preferentially remember self-relevant over other-relevant information. These differences represent atypical organization of both affective and cognitive components of the self in individuals with autism. However, the associations between the affective encoding and later memory for personally-relevant information, and dissociable correlates of each have not been examined on the self-referenced memory task.
Objectives: The goals of the current study were to examine 1) group differences in endorsement of positively- versus negatively-valenced information about self and others on the self-referenced memory task, 2) associations between endorsement and memory for self- and other-referenced information and 3) affective and socio-cognitive correlates of the endorsement and memory phase of the task in children with HFA and a matched comparison sample (COM).
Methods: Children and adolescents with HFA (N=76, 65 males, Mage=12.51, SD=2.58) and a comparison sample (N=72, 52 males, Mage=13.28, SD=2.15) completed a self-referenced memory paradigm, where they judged positive and negative trait adjectives with reference to themselves, and a familiar other person (i.e., Harry Potter). After a delay, participants were asked whether they recognized the adjectives from a list among distractor adjectives. An index of Self-Positivity Bias (SPB) was calculated as the difference in endorsement between self-referenced adjectives of positive and negative valence. In the recognition phase, self- and other-referenced memory, as well as the difference between the two (i.e., Preferential Self-referenced Memory) were computed. Self-reported Internalizing problems were evaluated by the Behavior Assessment Scale for Children (BASC). A Theory of Mind (ToM) composite was created by standardizing and averaging performance on two tasks: Reading the Mind in the Eyes and Strange Stories.
Results: Controlling for gender and VCI, HFA participants displayed a lower Self-Positivity Biases and reduced Preferential Self-referenced Memory, than COM participants, $F(1, 145) = 6.98$, $p=.009$, $\eta^2_{partial}=.05$, and $F(1, 145) = 21.27$, $p<.001$, $\eta^2_{partial}=.13$, respectively. The Self-Positivity Bias was predictive of Preferential Self-referenced Memory in the COM group, $r(71)=.23$, $p=.049$, but not the HFA group, $r(75)=-.06$, $p>.05$ (Figure 1). Self-reported internalizing problems were inversely related to Self-Positivity Bias (p's<.05; Figure 2), but not preferential self-referenced memory in both groups. In contrast, the ToM composite was associated with memory performance in the self- and other-referential conditions, but not the difference score in the HFA (p's<.001), but not COM group (p's>.05).
Conclusions: Typically-developing children demonstrated a coherent sense of self, where positive affective self-understanding supported enhanced socio-cognitive

processing. However, the same was not true in children with HFA. Children with HFA may demonstrate a more dissociated sense of self, with positive self-perceptions linked to lower levels of internalizing problems, while recognition of self- and other-referenced adjectives supports social cognition. Two avenues of intervention could target the dissociated sense of self for children with HFA. Certain individuals may benefit from interventions that target negative self to reduce internalizing problems, while others need training of socio-cognitive skills to improve awareness of themselves and others.

Figure 1. Self-positivity bias was associated with preferential self-referenced memory in the comparison sample (COM) but not in the participants with HFA.

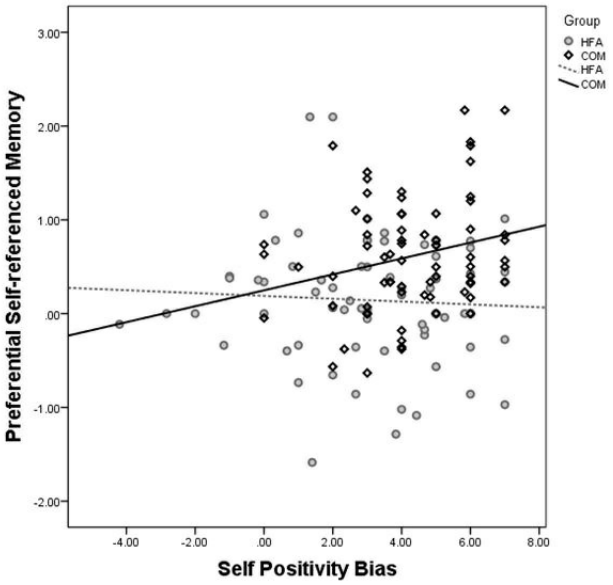

Figure 2. Self-positivity bias was associated with levels of internalizing problems in both groups.

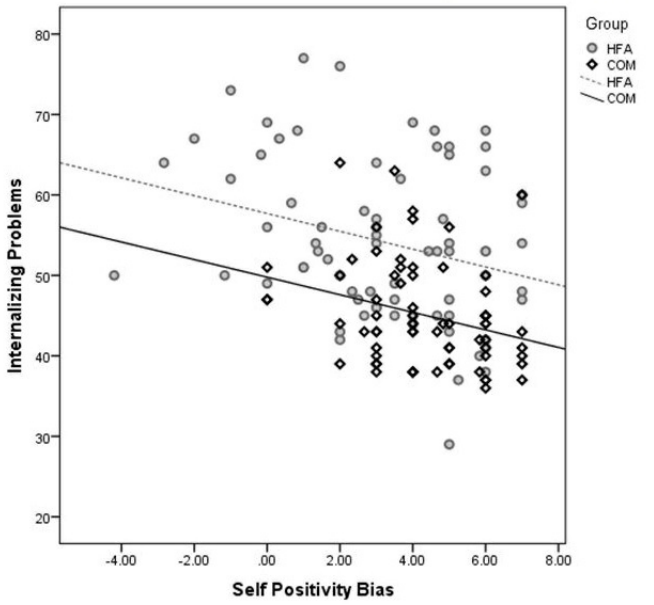

211 **110.211** Sex Differences Across Parent, Clinician, and Performance-Based Measures of Social Behavior in Autism Spectrum Disorder

J. M. Moriuchi[1], *A. Klin*[2] *and W. Jones*[2], *(1)Emory University, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background:
Previous results on sex differences in Autism Spectrum Disorder (ASD) have been ambivalent. Although there have been limited differences in the clinical phenotype of social disability in ASD in past studies, as measured by standardized instruments, underlying genetics and brain function do seem to differ across sexes. Females with ASD tend to carry more genetic mutations, have distinct structural brain differences, and show differential activation patterns in social brain regions when compared to males with the disorder. Based on these identified biological differences, it is possible that measures utilized in past studies may not have been sensitive or detailed enough to detect potential sex differences in social behavior. Because information source has been cited repeatedly as a factor impacting equivalence across measures, the current study sought to clarify the effect of sex on the manifestation of social disability in children with ASD by leveraging multiple levels of behavioral metrics.
Objectives:
The current study aimed to examine differences both within and across methods of ascertainment, including parent report of social behavior, clinician rating of social behavior, and performance-based measures of social visual engagement.
Methods:
Participants included 161 children with ASD (114 male, 47 female) representing a broad range of ages (mean=10.1(2.8), range=5 to 17 years) and cognitive functioning (DAS-II GCA: mean=94.5(22.8), range=32 to 149). Males and females did not differ based on chronological age or level of cognitive functioning. Social behavior was measured by parent report using the Social Responsiveness Scale (SRS); by clinician rating using the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2); and by performance-based measures of social visual engagement collected via eye-tracking. Eye-tracking data were recorded while children viewed social scenes of children and adults engaged in naturalistic, age-appropriate social interaction within everyday settings.
Results:
Across methods of ascertainment, males and females with ASD did not exhibit between-group differences on summary measures of social disability (SRS: p=0.91; ADOS-2 Social Affect: p=0.12; Eyes fixation: p=0.20). However, sex significantly moderated the relationship between parent rating and clinician rating of social behavior (B=-0.18, p=0.03) as well as the relationship between clinician rating and performance-based measurement of social behavior (B=15.95, p=0.04). Parent and clinician ratings were more strongly correlated in females with ASD than in males. In contrast, clinician ratings and performance-based measurement of social behavior were more strongly correlated in males with ASD than in females. Parent ratings and performance-based measurement of social behavior were not significantly correlated in either males or females with ASD.
Conclusions:
In the absence of mean differences in social behavior between males and females with ASD across parent ratings, clinician ratings, and performance-based measurement, there were significant sex differences in the relationships between measures of social behavior. These differences suggest that the underlying structure of social disability may differ across sexes in ASD and have implications for the clinical assessment of ASD in males and females.

212 **110.212** Sex Differences in Social Cognition, Executive Functioning and Repetitive Behaviours in Children and Adolescents with ASD

R. Leung[1,2], *V. M. Vogan*[1,3], *V. Yuk*[1,2] *and M. J. Taylor*[1], *(1)Diagnostic Imaging, The Hospital for Sick Children, Toronto, ON, Canada, (2)Psychology, University of Toronto, Toronto, ON, Canada, (3)School and Clinical Child Psychology, Ontario Institute for Studies in Education, Toronto, ON, Canada*

Background: One of the most replicated findings in the field of Autism Spectrum Disorder (ASD) research is a male preponderance. Recent studies suggest that the frequently stated 4:1 male to female ratio is influenced by many biases including differences in symptom presentation, IQ, and diagnostic criteria. Females with ASD have been observed to show increased social behaviour, higher language ability and less repetitive behaviours, relative to their male counterparts. These findings collectively suggest that the skewed sex ratio may be due to males exhibiting more disruptive and stereotypical symptoms of ASD that warrant clinical attention, relative to females. Females who have ASD and higher IQs may thus 'mask' their ASD symptomology, and diagnosis may be missed altogether, which in turn contributes to the skewed sex ratio in this population. Investigating sex differences in ASD symptomology contributes to better understanding and characterization of the female ASD phenotype, which in turn has implications for diagnosis and the treatment of ASD.
Objectives: To investigate sex differences in executive functioning, social skills and repetitive behaviours in children and adolescents with and without ASD.
Methods: We collected data in 187 children and adolescents: with ASD (N=96, M=10.54+2.32 years, IQ=100.89+15.46; females only: N=14, M=11.07+2.22 years, IQ=99.33+15.47) and typically developing controls (N=91, M=11.02+2.55 years, IQ=113.36+12.19; females only: N=23, M=10.39+2.25 years, IQ=114.05+14.67). For all participants, parents filled out the parent form of the Behavior Rating Inventory of Executive Function (BRIEF), Social Responsiveness Scale (SRS), and Repetitive Behaviour Scale – Revised (RBS-R). It should be noted that all participants, including the clinical sample, were high-functioning as they were recruited as part of a larger neuroimaging study.
Results: A two-way ANOVA with IQ as a covariate showed a main effect of group for all SRS, BRIEF and RBS-R variables ($p<0.001$) as well as a significant group by sex interaction on the Social Awareness subscale of the SRS ($F(1, 156) = 6.38$, $p=0.01$). Females with ASD were more impaired in social awareness relative to males with ASD, whereas in the control group scores reflected a greater social awareness in females relative to males. Sex effects were also found in the Restrictive and Repetitive Behaviour subscale of the SRS ($F(1, 156) = 5.12$, $p= 0.03$), with males showing consistently greater restricted and repetitive behaviours relative to females.
Conclusions: These preliminary results suggest that impairment in social awareness is particularly heightened in female children and adolescents with ASD. Reduced social awareness in child and adolescent females with ASD reflect difficulties in picking up social cues during social interactions. Our finding highlights that impaired social awareness may be a defining trait in the female ASD phenotype.

213 **110.213** Shortcutting Reciprocity: Using Similar, Low-Recursion Learning Styles to Predict Humans and Machines Behavior Underpins Strengths and Weaknesses in ASD. a Computational Psychiatry Study

*M. Devaine[1], J. Daunizeau[2], A. Duquette[3] and **B. Forgeot d'Arc**[4], (1)Brain and Spine Institute, Paris, France, (2)Brain and Spine Institute, INSERM, Paris, France, (3)Psychology, Université de Montréal, Montréal, QC, Canada, (4)Psychiatry, Université de Montréal, Montreal, QC, Canada*

Background: Beyond the common notion that Theory of Mind (ToM) might be altered in the autism spectrum, the alternative cognitive strategy used by individuals with autism spectrum conditions in reciprocal social interactions remains poorly understood. It is known that typically developed adults (TDA) use ToM to anticipate others' decisions. Such strategic anticipation may even culminate in recursive ToM when competitors also use ToM to anticipate one's own decision. In the context of repeated interactions, this yields (recursive) learning styles that differ from simpler alternative strategies such as imitation or (anti)-perseveration.
Objectives: Here, we ask whether, similarly to TDA, adults with autism spectrum disorder (AwASD) switch to a recursive learning style when engaged in a social interaction. In particular, we hypothesize that (1) AwASD would use similar learning styles when interacting with humans or machines, (2) they would use low-recursion learning styles, eventually impairing performance when interacting with ToM agents.
Methods: AwASD and TDA matched for age, IQ and gender took part to the study (n=48). AwASD had been assessed with ADOS-G and met DSM-IV criteria for an ASD. All participants had FSIQ>85. Participants with self-reported depression (Beck depression Inventory score>20) were excluded. We used a previously validated computerized game (Devaine et al. 2014) to access participants' learning styles by varying the ToM sophistication of their virtual opponents. This sophistication ranged from a random sequence with a bias to artificial ToM with two steps of recursion. Critically, the task was either framed as an on-line competitive game played against another participant or as a slot machine game. We captured participants' learning style in terms of the trial-by-trial impact of previous choices onto their current decision (as quantified by logistic regressions). We then analyzed both participants' performance and learning style patterns, across opponents and framing conditions.
Results: Contrary to TDA, AwASD had strikingly similar performance patterns in both framings (AwASD:r^2=.60, p=.003/TDA:r^2=-.20, p=.57) and did not appear to modulate their learning style. Moreover, learning style and performance of AwASD were different from TDA's in both framings. More precisely, AwASD performed better than TDA (p=2e-6) against opponents with low sophistication and worse than controls (p=7e-6) against sophisticated opponents in the social framing. Only TDA varied their learning style in response to the framing manipulation, eventually engaging in recursive ToM inference in the social framing.
Conclusions: Our results are consistent with the idea that learning style involves both imitation of the other player's previous moves and strategic (adaptive) choice alternation. Contrary to TDA, knowing that they interact with other humans does not change the learning style of AwASD, which leads to performance losses when playing against agents with recursive ToM. Critically however, the learning style of AwASD is more efficient than TDA's against artificial agents that do not possess recursive ToM (even when these agents are capable of learning).
Overall, this study constitutes an important input from computational psychiatry to understand ToM reasoning and its alternatives in autism, and to resolving the apparent paradox of co-occurring strengths and weaknesses of autistic cognitive style.

214 **110.214** Sniff Check! Adults with Greater Autism Symptoms Report Odors As Being More Positive

***E. N. Keenan**, T. Rosen, E. Kang and M. D. Lerner, Stony Brook University, Stony Brook, NY*

Background:
Many have speculated that hypoactivation of the amygdala is a key feature of autism spectrum disorder (ASD) (Baron-Cohen et al., 2000). While evidence for amygdala hypoactivation is mixed, there is some support for the notion that abnormal connectivity of the amygdala and orbitofrontal cortex may be implicated in the social deficits seen in ASD (Zalla and Sperduti, 2013). Evidence indicates that the amygdala and the orbitofrontal cortex are also involved with the attribution of emotional valence to olfactory stimuli (Zald and Pardo, 1997).
A growing literature suggests the presence of aberrant olfactory processing in ASD. For example, evidence suggests that odor identification, though not detection, is impaired in ASD (Suzuki et al., 2003). Likewise, children with ASD do not adjust their sniff response time to unpleasant versus pleasant odors, an atypical pattern which correlates with social impairment (Rosenkrantz et al., 2015). Similarly, it has been speculated that children with ASD are less likely to report emotional attributions to odors (Legiša et al., 2013). However, to date, no study has assessed odor valence rating as a function of ASD symptomatology.
Objectives:
This study examined relationship between ASD symptomatology and bias in emotional valence to olfactory stimuli. It was hypothesized that adults with greater subclinical ASD symptoms would show a less negative response to typically aversive scents.
Methods:
Thirty-one typically developing adults (21 female, 10 male; ages 18 - 47, M_{age} = 22.2, SD_{age} = 6.0) completed a self-report measure of autism symptomology, the Social Responsiveness Scale-2 (SRS-2; Constantino & Gruber, 2012), as well as an olfaction task (Jin et al., 2015). The task featured 9 scents that varied by positive, negative, and neutral valence. Participants rated the valence and familiarity of each scent on a continuous scale.
Results:
There was a correlation between greater autism symptoms and rating negatively-valenced odors more positively (r = .355, p =.007), an effect which remained significant after controlling for familiarity (r = .412, p = .002). The correlation was also significant for both subscales of the SRS-2, but moreso for social communication (r = .468, p < .001) than for restricted and repetitive behavior (r = .331, p = .013).
Conclusions:
Adults with greater levels of sub-clinical ASD symptoms subjectively reported negatively-valenced odors as more pleasant. This could explain the aberrant sniff response found by Rosenkrantz et al., as perhaps individuals with ASD do not perceive negatively-valenced scents as negatively as TD controls. Taken together, these findings converge with past studies suggesting a potential relationship between ASD symptoms, particularly in the social communication domain, and atypical olfactory processing. Given that intact amygdala and orbitofrontal cortex functioning is needed to identify the pleasantness of an odor, these findings may provide a behavioral index of abnormal amygdala and orbitofrontal cortex connectivity in ASD (Zalla and Sperduti, 2013). When presented, these results will be augmented via the inclusion of 30 adults with ASD as well.

215 **110.215** Social Anxiety in Young People with Autism: Cognitive and Behavioural Models

*H. Wood[1], S. Rusbridge[1] and **A. J. Russell**[2], (1)psychology, university of bath, bath, United Kingdom, (2)University of Bath, Bath, United Kingdom*

Background:
Social anxiety is more prevalent in adolescents with autism spectrum disorder (ASD) than typically-developing adolescents (Bellini, 2004), and is one of the most common anxiety disorders in adolescents with ASD (White et al., 2009). Whilst the cognitive model of social anxiety has a well-established evidence-base for typically-developing individuals (Clark & Wells, 1995), its applicability for individuals with ASD is unclear. The cognitive model outlines how appraisals about one's own social performance and self-focused attention are central factors in the development and maintenance of social anxiety and are important focii for any intervention. Historically interventions for social anxiety in ASD have adopted a deficit model with improvements in social skills considered essential. Adolescents and young adults with ASD (n=52) took part in a paradigm designed to elicit social anxiety (adapted from Cartwright-Hatton et al., (2003)).
Objectives: to explore the role of cognitive factors in social anxiety in Autism.
Methods: An adapted paradigm provoking social anxiety was employed, and individual ratings of social performance were compared with objective observer ratings. Self focused attention was measured using an adapted autonomic perceptions questionnaire.
Results: Approximately 50% of the group scored above clinical threshold on a measure of social anxiety. Group differences in the discrepancy between self-and observer ratings of social performance skills were recorded, with the socially anxious group rating social performance as significantly poorer than observer ratings. An adapted version of the Autonomic Perceptions Questionnaire also revealed between-group differences in the extent of self-focused attention.
Conclusions: These findings suggest that cognitive factors may be as relevant in our understanding of social anxiety in young people with ASD as typically developing youth and have implications for psychological treatments.

216 **110.216** Social Attention and Empathy in High Functioning Women with Autism Spectrum Disorders

***M. P. Ketelaars**[1], A. In't Velt[2], A. Mol[3], H. Swaab[1], F. Bodrij[4] and S. Van Rijn[1], (1)Department of Clinical Child and Adolescent Studies, Leiden University, Leiden, Netherlands, (2)Centrum Autisme Rivierduinen, Leiden, Netherlands, (3)Altrecht, Nieuwegein, Netherlands, (4)Centre for Child and Family Studies, Leiden University, Leiden, Netherlands*

Background : Females with autism spectrum disorders (ASD) have become the focus of research only recently after clinical reports of an altered phenotype. This altered phenotype may be responsible for delays in diagnosing females on the spectrum. There is, however, limited research into the female phenotype and its possible underlying mechanisms. A promising avenue in ASD research is social attention. Social attention has been shown to relate strongly to ASD symptoms, and information on this mechanism in the female population may provide us with valuable information for diagnostic assessment and treatment of this specific group.
Objectives : The present study investigates social attention using sensitive and ecologically valid measures by assessing gaze fixation patterns. In addition, social attention

is related to the behavioral level by examining its relation to informant ratings of empathic abilities.
Methods : Participants consisted of 31 adult women with ASD and 29 non-clinical controls. Social attention was assessed by measuring eye fixation patterns using eye tracking while participants watched four real-life movie clips in which children displayed differing emotions. Empathic abilities were assessed using the informant reported Interpersonal Reactivity Index (IRI).
Results : Results show decreased fixation duration on the face and mouth in women with ASD compared to non-clinical controls. No differences were found in fixation duration on the eyes, objects and outside the areas of interest. Women with ASD showed reduced cognitive empathy, and more personal distress in stressful situations compared to non-clinical controls. Additionally, there was a negative correlation between personal distress and total fixation duration to the face for this group.
Conclusions : The current findings suggest subtle impairments in social attention in women with ASD, though fixation on the eyes was normal. Since lack of eye contact is the hallmark of ASD, this may put women with ASD at risk of underdiagnosis. As the pattern of impairment is contrary to the current research findings on the male population, it warrants caution in assuming that current research findings regarding social attention in individuals with ASD automatically apply to the female ASD population. In addition, the negative relationship between face fixation and feelings of personal distress is suggestive of the involvement of the arousal system, with a possibility that women with ASD have problems downregulating their arousal in social situations.

217 **110.217** Social Functioning in Children with Autism: Which Processes to Measure?

***A. P. F. Key**, D. Jones and B. A. Corbett, Vanderbilt University, Nashville, TN*

Background: Social functioning depends on optimal brain mechanisms, cognitive processes, and behavioral skills. Examining social deficits in children with ASD using a multidimensional approach should yield more detailed information about their strengths and weaknesses associated with social interactions.
Objectives: The purpose of this study was to investigate which neural mechanisms supporting social cognition (perception of vs. memory for faces) are associated with social behavior during peer interactions in children with autism.
Methods: Brian mechanisms supporting face perception and memory were evaluated using visual event-related potentials (ERPs) in 74 children with autism (age 7-16 years) during passive viewing of color photographs depicting unfamiliar smiling young adults or front views of houses, a subset of which were randomly selected and repeated throughout the test session while the rest were shown only once. Social cognition was assessed using NEPSY Memory for Faces test. Social behavior was documented using caregiver reports (Social Communication Questionnaire, Social Responsiveness Scale, Adaptive Behavior Assessment System, Child Behavior Checklist) and coded observations of playground behaviors with peers.
Results: All participants demonstrated perceptual discrimination of faces vs. houses as reflected in the larger N170 responses to the former, suggesting social perception mechanisms comparable to those of typical individuals, but only the youngest group (7-9 years) evidenced increased N170 amplitudes following stimulus repetition regardless of stimulus category. These effects on the N170 amplitude decreased with age (face vs. house: r=.526, p<.001; repeated vs. single: r=.416, p<.001). N170 latency varied with IQ, with shorter responses to houses vs. faces observed only in the high-IQ (>115) group. Examination of the social memory processes indexed by the frontal and parietal “old/new” responses in the 300-500ms interval revealed familiarity with (FN400) but not recall (parietal) of the repeated houses in the youngest (7-9 years) and oldest (13-16 years) groups, while no significant differences were observed for faces due to high inter-individual variability. Social brain-behavior correlations demonstrated that larger N170 amplitudes to faces and to repeated stimuli were associated with fewer parent-reported social problems (CBCL). Conversely, larger FN400 responses to repeated faces were associated with fewer autism symptoms (ADOS communication and total scores), higher verbal IQ, better performance on NEPSY memory for faces (immediate), fewer social problems (CBCL), as well as more cooperative play, gestures, and verbal communication during a playground interaction with peers. Perceptual and memory responses to houses correlated with age and IQ, but not social behavior.
Conclusions: Examination of social functioning in children with autism using neural, cognitive, and behavioral assessments suggests that neural measures of more complex social cognition processes, such as face memory reflected in the “old/new” ERP responses, may be more informative about social functioning in children with autism than early perceptual brain responses due to more extensive connections with social cognition and behavior.
Social functioning depends on optimal brain mechanisms, cognitive processes, and behavioral skills. Examining social deficits in children with ASD using a multidemensional approach should yield more detailed information about their strengths and weaknesses associated with social interactions.

218 **110.218** Student-Teacher Closeness Impacts School Engagement

***B. Hedges**[1], C. Kasari[2], W. I. Shih[3], C. Lord[4], R. Landa[5] and B. King[6], (1)Semel Institute for Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA, Monrovia, CA, (4)Weill Cornell Medical College, White Plains, NY, (5)The Kennedy Krieger Institute, Baltimore, MD, (6)University of Washington and Seattle Children's Hospital, Seattle, WA*

Background:
Mainstream education incurs both benefits and risks for children with autism spectrum disorders. Despite typical peer models, these children are often socially isolated in the mainstream classroom (Chamberlain 2007). A recent study examined the efficacy of different social skills interventions for children with ASD in mainstream classrooms (Kasari 2015), finding that teacher reports of closeness to the target children moderated the children’s responsiveness to intervention. Previous research indicates that the student-teacher relationship has an impact on the social functioning of typically developing preschoolers (Howes 2008), as well as academic success (Hamre and Pianta, 2001). A study of intellectually disabled children found that the student-teacher relationship was less close and less stable than typically developing peers. Child behavior problems in ID youth predicted greater student-teacher conflict whereas social skills predicted greater closeness (Blacher 2009). We have yet to examine how the student-teacher relationship affects peer to peer relationships of children with ASD.
Objectives:
To understand the relationship between student-teacher closeness and peer engagement at school for children with ASD.
Methods:
Participants included 134 children, 110 males. The average age was 8 years. All children were in general education classrooms for at least 80% of the day and had ADOS-confirmed diagnosis of ASD. Data was collected using the Student Teacher Relationship Scale (Pianta 2001), the Behavioral Assessment System for Children (Reynolds, 2004), and a classroom friendship survey which included the number of classmates the target child nominated as a friend (out-degrees) and the number of times the target child was nominated as a friend by classmates (in-degrees). Peer engagement was measured using the Playground Observation of Peer Engagement (Kasari et al 2005).
Results:
Correlational analyses were used to examine teacher-child closeness with adaptive functioning, in-degree and out-degree nominations, peer engagement on the playground, and student-teacher conflict. Teacher –child closeness was positively linked to higher scores of observed peer engagement on the playground (r=.214, p=.0198). Additionally, higher closeness was associated with in-degrees (r=.346,p<.001). Children with higher teacher closeness tended to be rated higher on measures of adaptive functioning by both teacher and parent (r=.484, p<.001 and r=.218, p=.0257, respectively). High teacher closeness was negatively correlated with teacher reports of conflict within the teacher-child relationship (r=-.323, p<.001). Finally, no significant relationship between child’s IQ and teacher-child closeness was found.
Conclusions:
Children with ASD who are rated as having a closer relationship with their teachers tend to have higher engagement with peers on the playground and more positive peer nominations. Classroom interventions focused on improving social engagement in children with autism rarely target the teacher-child relationship directly; further research may be warranted to investigate whether teacher-child closeness has an effect on social engagement in young children with autism spectrum disorders.

219 **110.219** Subtle Differences in Explicit Facial Identity and Facial Expression Recognition in Young Adults with ASD

***S. Vettori**[1,2], C. Dillen[1,2], H. Op de Beeck[3], J. Steyaert[1,2] and B. Boets[1,2], (1)Child and Adolescent Psychiatry, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research consortium (LAuRes), KU Leuven, Leuven, Belgium, (3)Laboratory of Biological Psychology, KU Leuven, Leuven, Belgium*

Background:
Fluently recognizing faces and facial expressions is highly important for our social interactions. Impaired and atypical face processing have often been postulated as a key deficit in autism spectrum disorders (ASD). Despite the great amount of research on face identity and facial expression recognition in ASD, the results are mixed. This is partly because many studies included a relatively small sample of participants and administered only a single face processing task.
Objectives:
Therefore, our goal is to examine face identity and facial expression recognition in a substantial sample of young adults with ASD and matched typical control subjects, assessed with a battery of explicit face processing tests targeting identity and emotion recognition via matching and memory tasks. In addition, we will investigate mutual associations between face processing performance, and associations with self-reported autism characteristics and symptoms of depression and anxiety.
Methods: 26 high-functioning young men with ASD and 26 male healthy control subjects without any psychiatric disorder completed computerized versions of the Benton Facial Recognition Test (BFRT), the Cambridge Face Memory Test (CFMT), the Emotion Recognition Index (ERI) and the Emotion Recognition Task (ERT). In addition to verbal, performal and total IQ, clinical assessments included ADOS and self-report questionnaires assessing quantitative autism characteristics (Social Responsiveness Scale, SRS), symptoms of depression (Beck Depression Inventory) and symptoms of anxiety (State-Trait Anxiety Inventory).
Results:
Results on both face identity recognition tasks (CFMT and BFRT) showed that there were no main group differences in performance between ASD and control subjects. However, on the CFMT, adults with ASD were more hindered by increasing task difficulty through increasing noise and tended to perform worse than controls. Further, we

found no group differences on average accuracy on both facial expression recognition tasks (ERI and ERT). Yet, individuals with ASD needed more time to provide correct answers on the ERI. In the presentation we will further expand these results by showing correlations between face processing performance and symptom severity and IQ scores.
Conclusions:
We examined a series of face processing abilities with widely used standardized tests. Overall, we found no obvious group differences in face identity recognition and facial expression recognition performance in this sample of adults with ASD versus controls. None of the tests showed an overall group difference, but results on the ERI and the CFMT suggest that subjects with ASD memorize facial identity slightly less accurately and process facial expressions slightly more slowly. In sum, this study indicates that explicit face processing abilities are fairly intact in men with ASD. However, this finding does not rule out that altered face processing is still a key deficit in ASD. If the nature of this deficit is implicit, than the widely used task tapping explicit face processing may give an incomplete estimate of face processing abilities in ASD.

220 **110.220** Successfully Directing Eye Gaze Does Not Improve Face Recognition Ability in Children with ASD

S. J. Thompson, *S. R. Leekam, G. Powell and C. Jones, School of Psychology, Cardiff University, Cardiff, United Kingdom*

Background: Individuals with ASD show unusual patterns of eye gaze to the face and perform poorly on face processing measures. However, whether prompting individuals with ASD to look at optimal face regions will improve accuracy is unknown. In previous research we found that when told to look at the mouth, neurotypical adults showed difficulty inhibiting an unconscious preference for first looking to the eye region. In addition, prompting instructions improved accuracy. What remains unknown is: (i) whether individuals with ASD show a first look eye preference (ii) whether directing eye gaze can improve their accuracy.
Objectives: (1) To establish whether typically developing (TD) and ASD children have a preferred first look location that is difficult to inhibit. (2) To establish whether directing eye gaze improves accuracy.
Methods: Fourteen children with ASD (8–13 years) and 24 matched TD children participated. Using a forced-choice face recognition paradigm, participants had to distinguish the previously seen target face from an alternative image, where the eyes or mouth were digitally altered. This was first conducted with no looking instructions (unprompted condition) and then with instructions to look to the changed region (prompted condition). Eye movements and task performance were measured. A control task using houses was also included.
Results: Both child groups showed the same eye tracking patterns found in neurotypical adults. With respect to objective 1, first looks were significantly more often made to the eyes than mouth in the unprompted condition by both groups. With respect to objective 2, when prompted to look to the mouth, the first look for both groups was as often to the mouth as to the eyes, whereas when directed to the eyes, first looks reflected task instruction. Analysis of dwell time indicated no group differences, with both groups spending more time looking at the prompted region. However, the groups differed on task performance. Unlike the TD group, the ASD group did not show better face recognition ability when prompted where to look than in the unprompted condition, and did not show better performance when the eyes were the changed region compared to the mouth. Performance on the control task was comparable between groups.
Conclusions: Children with ASD showed similar looking patterns to TD children; they had a bias for first looking to the eye region. Further, this bias was difficult to inhibit even when it was an optimal strategy for task performance. Both groups overcame this initial bias and spent most time looking at the prompted region. The data indicate that it is possible for children with ASD to show typical patterns of looking to the face, albeit in a controlled laboratory environment. However, unlike the TD group, children with ASD could not benefit from the prompts and their behavioural performance did not improve.

221 **110.221** Support Needed for Japanese Adolescent Girls with ASD: The Gap Between Girls with and without ASD

Y. Nishio[1] *and M. Torii*[2]*, (1)Kobe University, Osaka, Japan, (2)Kobe University, Kobe, Japan*

Background:
Only a few studies have been conducted on females with Autism Spectrum Disorder (ASD). Females often have different difficulties than males. If we focus on the sex differences, we should direct our attention to adolescence. It's a period in which not only physical changes but mental ones appear in the development of secondary sex characteristics. Accordingly, their social relationships change and the child-parent relationship often becomes strained. When we consider those with autistic characteristics, adolescents with ASD have higher risks of maladjustment than others. Especially in Japan, more for girls than boys, changes in social behavior tend to be expected after puberty. Since the status of women is still lower in Japanese culture, "femininity" is required of them.
Objectives:
The purpose of our study is to clarify support needed for adolescent girls with ASD from the both sides of autistic traits and sex differences.
Methods:
Participants: The typical development (TD) group consisted of 330 adolescents, comprising 174 boys and 156 girls. The ASD group consisted of 43 adolescents, comprising 23 boys and 20 girls. The two groups were matched in age (Mean±SD, TD group: 12y6m±1y2m, ASD group: 11y5m±1y2m).
Materials: We created a questionnaire about attachment to parents (e.g. "Even if I don't tell anything, parents understand my feeling."). There're also sections about distressing experiences of 7 items. Then participants ranked their advisers.
Results:
With regard to attachment to parents, A factorial ANOVA revealed a significant main effect for group ($F_{(1)}$=20.99, p<.001). The ASD group (M=2.79, SD=.77) scored higher than the TD group (M=2.22, SD=.76).
Chi square test and residual analysis compared distressing experiences . Regardless of group, girls had significantly more troubled experiences with health ($\chi^2_{(6)}$=33.08, p<.01) and friendship ($\chi^2_{(6)}$=61.07, p<.01). Only the TD group had significantly sex differences, and TD girls had troubled experience with personality than TD boys ($\chi^2_{(6)}$=33.57, p<.01).
As shown in Table, a similar ANOVA was conducted to compare advisers in group and sex. There was a significant main effect for sex ($F_{(1)}$=6.88, p<.01), girls reporting less consulted with their father than boys. There was a significant main effect for group ($F_{(1)}$=18.22, p<.001), with the ASD group regarding their teacher as an adviser than the TD group. With respect to friends, there were significant main effects of both group ($F_{(1)}$=28.80, p<.001) and sex ($F_{(1)}$=9.18, p<.01).
Conclusions:
These results suggest the ASD group was further behind when it comes to psychological separation from their parents than the TD group. Because it is difficult for the ASD group to promote friendship, their relationship seems to be hard to shift. Consequently, they ask teachers for advice next to parents. Especially TD girls rely on their friends, which was markedly different from girls with ASD. This gap poses a large problem because learning various things from friendship is very important part of growing up socially. A further direction of this study will be to create the support program for adolescent girls with ASD considering not only autistic traits but also sex differences.

Table Comparison of advisers by group and sex

Adviser	ASD		TD		*F*-test
	Boy *M* (*SD*)	Girl *M* (*SD*)	Boy *M* (*SD*)	Girl *M* (*SD*)	
Mother	1.86(1.09)	1.78(.85)	1.71(1.01)	1.92(.93)	Group: $F_{(1)}=.000$, $p=.99$ Sex: $F_{(1)}=.19$, $p=.67$ Interaction: $F_{(1)}=.86$, $p=.36$
Father	0.94(.83)	.66(.55)	1.06(.83)	.69(.71)	Group: $F_{(1)}=.331$, $p=.57$ Sex: $F_{(1)}=6.88$, $p<.01$ Interaction: $F_{(1)}=.15$, $p=.70$
Brother/ Sister	.35(.55)	.41(.64)	.49(.66)	.70(.75)	Group: $F_{(1)}=3.48$, $p=.06$ Sex: $F_{(1)}=1.47$, $p=.23$ Interaction: $F_{(1)}=.45$, $p=.50$
Friend	.33(.45)	.71(.63)	1.01(.83)	1.41(.80)	Group: $F_{(1)}=28.80$, $p<.001$ Sex: $F_{(1)}=9.18$, $p<.01$ Interaction: $F_{(1)}=.01$, $p=.93$
Teacher	.70(.57)	.93(.71)	.47(.56)	.38(.54)	Group: $F_{(1)}=18.22$, $p<.001$ Sex: $F_{(1)}=.59$, $p=.44$ Interaction: $F_{(1)}=3.12$, $p=.08$

Score: First place→3 points, Second place→2 points, Third place→1 point

222 **110.222** Surfing Safely: An Examination of Online Dating Skills in Young Adults with Autism Spectrum Disorder

M. E. Roth[1,2] *and J. Gillis*[3]*, (1)Department of Child and Adolescent Psychiatry, The Child Study Center at New York University Langone Medical Center, New York, NY, (2)Department of Psychology, Auburn University, Auburn University, AL, (3)Department of Psychology, Binghamton University, Binghamton, NY*

Background: Adults with Autism Spectrum Disorder (ASD) have difficulty forming romantic relationships, despite having motivation to establish them. The lack of success through traditional, face-to-face dating may lead adults with ASD to pursue relationships through other modalities, such as online dating. There are a number of advantages offered by online dating for adults with ASD; however, there are also a number of disadvantages to online dating for the population, including potential victimization. Although it has been thought that adults with ASD are at a higher risk for victimization, compared to other clinical populations, only one study to date has examined victimization risk in a sample of adults with ASD (Brown-Lavoie et al., 2014). In addition, it is thought that the core deficits of ASD put adults with ASD at risk for inappropriate courting, also known as "stalking," which was demonstrated by Stokes and colleagues (2007). With regards to online dating, one survey study (Roth & Gillis, 2014) revealed that adults with ASD use online dating, however safety was a primary concern. The victimization risk of adults with ASD, and risk of inappropriate courtship, in online settings has yet to be examined empirically.
Objectives: To date there has not been an empirical examination of online safety skills or online dating skills in adults with ASD, which was the aim of the current study.
Methods: Participants included 30 adults with ASD and 57 typically developing adults, whom were compared on a number of variables including ASD symptoms, dating history, online dating history, sources of learning about dating, online victimization history, inappropriate courtship behaviors, online dating safety knowledge, online dating safety skills, and motivation to remain safe while online dating. Participants completed measures online.
Results: The results revealed that adults with ASD had fewer previous relationships, sources to learn about relationships, and behavioral skills in online dating. Conversely, the ASD group had more online dating experience, previous online victimization, and inappropriate methods of courting. The two groups had equal knowledge of online dating and motivation to remain safe.
Conclusions: Although adults with ASD are interested in, and are using, online dating services, they are less successful in dating compared to same aged peers. In addition, safety concerns may be interfering with adults' ability to enjoy the benefits of online dating. Given that the current study indicates that adults with ASD have poor knowledge regarding online dating safety, fewer sources to learn about dating safety, more online victimization history, more history engaging in inappropriate courting, and less behavior safety skills, it is important for the field to capitalize on the population's motivation to remain safe while online and help adults with ASD lead safe and productive social and romantic lives.

223 **110.223** Systematic Evaluation of Self-Esteem, Internalizing Symptoms, and Theory of Mind in Youth with ASD, ADHD, and Typical Development

J. B. McCauley[1,2]*, M. A. Harris*[2]*, M. C. Zajic*[3]*, H. K. Schiltz*[2]*, L. E. Swain-Lerro*[3]*, T. Oswald*[1]*, N. S. McIntyre*[3]*, K. Trzesniewski*[2]*, P. C. Mundy*[4] *and M. Solomon*[5]*, (1)University of California at Davis MIND Institute, Sacramento, CA, (2)Human Development, University of California at Davis, Davis, CA, (3)University of California at Davis MIND Institute, Davis, CA, (4)Education and Psychiatry, University of California at Davis, Sacramento, CA, (5)MIND Institute, Sacramento, CA*

Background: Although self-esteem is a robust indicator of a wide range of clinically significant mental health outcomes in youth with typical development (TYP) and with Attention Deficit Hyperactivity Disorder (ADHD), little is known about these relations in youth with autism spectrum disorder (ASD). Self-esteem reports from youth with ASD may provide a new barometer of mental health within the population. Although, impairments in social-cognitive skills thought to be requisite for self-assessment, such as theory of mind (ToM), may compromise the validity of these reports.
Objectives: The objectives of the current study were to: (1) describe how individuals with ASD rate their self-esteem compared to age-matched individuals with ADHD, and TYP; (2) test how self-esteem relates to anxiety and depression in all three groups; and (3) examine if ToM performance moderated these associations.
Methods: 98 children and adolescents, aged 9 to 17 (See Table 1), were administered a battery of questionnaires and assessments as part of a longitudinal study of academic functioning. Participants completed two measures of self-esteem -- the Marsh SDQ (Marsh, 1992), and the Lifespan Self-esteem questionnaire (LSE; Harris, 2015) -- along with measures of depressive symptoms (Center for Epidemiological Studies-Depression Scale [CES-D; Radloff 1977]), and anxiety symptoms (Multidimensional Anxiety Scale for Children, 2nd edition [MASC-2; March 1997]). Furthermore, participants were administered two tasks of ToM capabilities, the Strange Stories (Happe, 1994), and the Silent Films (Devine & Hughes, 2013) tasks. ANOVAs, correlations, and multiple regressions were performed using SPSS 22.
Results: There were no significant differences between the ASD, ADHD, and TYP group ratings of self-esteem assessed on both the Marsh SDQ, $F(2, 94) = 2.25$, $p=.11$, and the LSE, $F(2, 94)=2.10$, $p=.13$. As predicted, self-esteem ratings were negatively correlated with depressive symptoms across all three groups (Pearson's r's ranged from -.62 to -.47). Self-esteem was negatively associated with anxiety symptoms in the ADHD ($r(23)=-.56$) and TYP groups ($r(32)=-.60$), but had a positive association in the ASD group ($r(37)=.31$) that was driven by the Obsessions and Compulsions and Harm Avoidance subscales of the MASC-2, suggesting that endorsing items on these scales, emphasizing following rules and insistence on sameness, may be closely related to self-worth for individuals with ASD. Furthermore, there was no evidence that ToM moderated the relations between self-esteem and both depressive symptoms and anxiety symptoms in the ASD and ADHD groups.
Conclusions: All three groups demonstrated comparable self-esteem ratings that were negatively associated with depression. There were inconsistencies between the groups' reports of the relations between self-esteem and anxiety symptoms. The ASD group reported that self-esteem was positively associated with anxiety symptoms involving following rules and compulsive behaviors, suggesting they may be interpreting some anxiety symptoms idiosyncratically. Finally, there was no evidence that ToM moderated the relations between self-esteem and internalizing symptoms in the ASD and ADHD groups, indicating that ToM abilities are not impacting the validity of these reports. Consequently, these results indicate that children and adolescents with ASD can report self-esteem relatively accurately and may provide insights to mental health functioning across groups.

Table 1
Sample Characteristics

	ASD (n=39)	TYP (n=34)	ADHD (n=25)
Males (%)	33 (85%)	22 (65%)	18 (72%)
Females (%)	6 (15%)	12 (35%)	7 (28%)
Chronological Age (SD)	12.75 (2.22)	12.82 (2.26)	13.01 (2.20)
Verbal IQ (SD)	96.97 (15.62)	110.56 (14.44)	100.96 (14.75)
Nonverbal IQ (SD)	104.41 (15.57)	117.06 (15.04)	100.68 (15.10)
Full-Scale IQ (SD)	100.48 (13.91)	115.59 (13.83)	100.96 (15.04)
ADOS-2 Total	10.46 (2.87)	NA	3.48 (3.88)
ADHD Comorbidity	8 (21%)	NA	NA

224 **110.224** The Extent and Nature of Conflict within the Peer Relationships of Adolescents on the Autism Spectrum

F. R. Sedgewick[1], *V. Hill*[2] *and E. Pellicano*[1], *(1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)Psychology and Human Development, UCL Institute of Education, London, United Kingdom*

Background: Friendships are a crucial part of our development as social individuals, from childhood through to adulthood. Conflict within these relationships is a ubiquitous phenomenon and can offer insight into the extent and nature of social relationships, particularly the maintenance of friendships. While there has been a great deal of research on autistic children and adolescents' friendships and on the conflict that occurs outside of friendships (in the form of bullying), to our knowledge there is no research on the conflict experienced by autistic adolescents *within* their friendships and peer relationships.
Objectives: This study sought to understand the extent and nature of the conflict experienced within the relationships of adolescents on the autism spectrum, using interview and questionnaire-based methods. We also investigated the relationship between adolescents' social awareness and the degree of conflict within their friendships.
Methods: Data collection is ongoing. Nine adolescents with autism, aged 11–16 years, have taken part. Participants completed an in-depth semi-structured interview about their friendships, in addition to the Friendship Qualities Scale (FQS), a test of perceived best-friendship quality (which included a Conflict subscale), the Revised Peer Experiences Questionnaire (RPEQ), a measure of aggressor/victim status in peer interactions, and The Awareness of Social Inference Test (TASIT), a test of social awareness.
Results: Adolescents on the autism spectrum reported many conflicts with their friends, although these were often unresolved due to the adolescents' focus on their friends' actions rather than underlying motivations. Furthermore, we found that adolescents with greater social awareness had a lower level of conflict within their best-friendship ($r = -.68$, $p < .05$). The effect was similar in direction and strength for two aspects of social awareness (as measured by the TASIT), including sarcasm-awareness ($r = -.55$, $p < .05$) and lie-awareness ($r = -.35$, $p < .05$). Finally, higher conflict levels were associated with a greater likelihood of aggressor-status in peer interactions ($r=.50$, $p < .05$).
Conclusions: These results suggest that conflicts within the friendships of adolescents on the autism spectrum often go unresolved because they fail to focus on the underlying cause of the conflict. These qualitative data were supported by the data from questionnaires, which showed that those who are more aware of others' motivations were more able to negotiate their interactions with peers (i.e. without conflict) and, as a result, more likely to maintain their friendships. These findings highlight the importance of managing conflict within friendships with peers, which might be a limiting factor in autistic adolescents' ability to both obtain and sustain social relationships and should be an important target for intervention.

225 **110.225** The First Step of Reciprocity: Bidirectional Social Influence Intact in ASD. a Computational Psychiatry Study

M. Devaine[1], ***B. Forgeot d'Arc***[2], *A. Duquette*[3] *and J. Daunizeau*[4], *(1)Brain and Spine Institute, Paris, France, (2)Psychiatry, Université de Montréal, Montreal, QC, Canada, (3)Psychology, Université de Montréal, Montréal, QC, Canada, (4)Brain and Spine Institute, INSERM, Paris, France*

Background: Autism originally means « egocentrism ». Despite recent examples of preserved social influence in ASD, the hypothesis that individuals with ASD might be less influenced by others (reduced social influence) and be more influenced by their own ideas when understanding others (strong projection bias) remains appealing
Objectives: In this study, we ask whether adults with ASD (AwASD) learn about and from others' pseudo-personality traits (impatience and prudence) similarly to typically developed adults (TDA). In particular, we want to investigate: (1)whether AwASD's projection bias is stronger than TDA's, (2)whether learning others' pseudo- traits is preserved in AwASD, (3)whether AwASD are immune to social influence for such pseudo- traits.
Methods: AwASD and TDA matched for age, IQ and gender took part to the study (n=48). AwASD had been assessed with ADOS-G and met DSM-IV criteria for an ASD. All participants had FSIQ>85. Participants with self-reported depression (Beck depression Inventory score>20) were excluded. In a series of trials, participants were presented with binary choices involving a trade-off between a cost (in terms of delay or risk) and a reward (high vs low). Participants had to successively make their decisions (block 1,3,5) and predict the choices of another (virtual) participants (block 2,4). Note that, in blocks 2 and 4, participants were given feedback to enable them to learn the virtual participant's pseudo-trait. Based on their choices, we could estimate participants' personality traits (impatience and prudence) in each decision block. In turn, we could manipulate the similarity of the virtual participant, which was endowed with similar (*Same* condition) or different (*Different* condition) pseudo-traits. We measured participants' projection bias by comparing their prediction performance in the Same vs Different conditions (prior to learning), and their sensitivity to social influence by estimating the drift in their trait after having tried to predict the choices of a *Different* other.
Results: Prediction accuracy at the beginning of the prediction blocks was higher in the Same condition than in the Different condition for both groups (AwASD:p=.003,TDA:p= 1e-4), indicating a significant projection bias that was otherwise not different between groups (p=.6). Second, at the end of the prediction phase, accuracy was good in both conditions and did not differed between groups (AwASD:85%,TDA:89%,p=.2).
Moreover, we found that both participants in both groups increase (resp., decrease) the frequency of prudent or impatient choices they make if they previously tried to predict somebody who was more (resp., less) prudent or impatient than themselves (p=.005). This resulted in an alignment of pseudo-traits that was not different between groups (p=.3).
Conclusions: This study is in line with recent results suggesting that social influence is not affected in ASD. For the first time, it also demonstrates that AwASD and TDA differ neither in terms of their underlying projection bias nor in their ability to learn others' pseudo-traits. Altogether, our results suggest that the first step of reciprocity (i.e. observational Theory of Mind) is intact in ASD. Further work remains to be done to understand how AwASD cope with reciprocal social interactions.

226 **110.226** The Impact of Social Skills Development on Fear of Negative Evaluation and the Prediction of Positive Mental Health Outcomes Among Adolescents with ASD

A. McVey[1], *B. Dolan*[1], *A. M. Carson*[2], *J. S. Karst*[3], *S. Stevens*[4], *K. S. Willar*[1], *C. Caiozzo*[1], *E. Vogt*[1], *S. Potts*[1] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Autism Center & Psychology Service, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (3)Children's Hospital of Wisconsin, Wauwatosa, WI, (4)University of Minnesota, Minneapolis, MN*

Background: Fear of negative evaluation (FNE) is defined as a fearfulness of being viewed poorly by others (Winton, Clark, & Edelmann, 1995). FNE often results in hypervigilance during and avoidance of social situations (Mogg, Bradley, De Bono, & Painter, 1997; Wieser, Pauli, Weyers, Alpers, & Mühlberger, 2009). Although this pattern is most common among individuals with social anxiety, research suggests that social anxiety and autism spectrum disorder (ASD) often co-occur, and therefore vigilance-avoidance merits examination in ASD (Bellini, 2004, 2006; Kuusikko et al., 2008). Specifically, research demonstrates that social skills deficits in ASD may significantly influence the development of a fearful response in social situations for these individuals (Bellini, 2003).
Objectives: The primary objectives of this study were to examine if self-report of FNE symptoms significantly decreased over the course of an empirically validated social skills intervention and whether such changes were predictive of improved mental health.
Methods: Seventy-two adolescents ($N = 72$; 10 female) between the ages of 11 and 16 with high-functioning ASD participated in this study. Participants included in this

analysis represent those in the experimental treatment group from a randomized controlled trial. Adolescents received the *Program for the Education and Enrichment of Relational Skills* (PEERS®), a 14-week social skills intervention demonstrated to be effective at improving social competence among teens with ASD (Laugeson, Frankel, Mogil, & Dillon, 2009). Adolescents completed the Social Anxiety Scale (SAS; La Greca, Dandes, Wick, Shaw, & Stone, 1988), the Social Interaction Anxiety Scale (SIAS; Mattick & Clarke, 1998), and the Short Mood and Feelings Questionnaire (SMFQ; Sharp, Goodyer, & Croudace, 2006) at pre-test, post-test, and six months following post-test.
Results: Participants demonstrated a significant decrease in their self-report of FNE (SAS-FNE) from pre-test to six-month follow up ($F(2, 78) = 7.83$, $p = .001$, partial $\eta^2 = .167$). Furthermore, scores on the SAS-FNE were significantly correlated with lower scores on the SIAS ($r(38) = .36$, $p = .022$) and SMFQ ($r(20) = -.538$, $p = .010$) at six-months follow up.
Conclusions: Results suggest that, with the improvement of social skills, adolescents with ASD demonstrate significant declines in symptoms of FNE. These declines are demonstrated, not only from pre- to post-intervention, but also six-months after the treatment period ends. In addition, these improvements predicted lower levels of overall social anxiety and decreased depressive symptoms at six-month follow up. This is consistent with existing literature on social anxiety and ASD that describes a cycle of fear and avoidance that results in a lack of development of social skills which only perpetuates fear and avoidance of social stimuli (Bellini, 2006). This is the first study, to our knowledge, to provide empirical support for the development and maintenance of social skills as functioning to break this cycle and promote lower social anxiety and depressive symptoms among adolescents with ASD.

227 **110.227** The Impact of Transition from Primary to Secondary School on the Psychosocial Adjustment, Sense of School Membership and Academic Progress of Children with Autism Spectrum Disorders

J. S. Hebron, *Oxford Road, University of Manchester, Manchester, England, United Kingdom*

Background: The experience of education has a profound influence on the lives of children, from academic progress through to social understanding, ultimately informing the way in which adult life is negotiated. Secondary school requires a high degree of self-organisation among pupils as they move from the top of the social hierarchy at primary school to the bottom of a more complex one. Despite this, research indicates that deleterious effects are transitory for most children. However, for children with autism spectrum disorders (ASD) the challenge of transition can be significant, and the residual difficulties can be profound and long-lasting. The child-centred environment of a primary school can be difficult to replicate in a secondary school where children have multiple subject staff, whose awareness and understanding of ASD may be limited. In adjusting to secondary school, children are expected to form new social relationships in unfamiliar settings and adapt to changes in routine, both of which are major challenges for pupils with ASD. Despite this apparent vulnerability, there are very few quantitative studies in this area, none of which explore the post-transition trajectory using multiple timepoints. Developing knowledge and understanding of such issues is a crucial step towards designing effective interventions.
Objectives: To explore the effects of the primary to secondary school transition for young people with ASD compared to their typically developing peers (TD), with particular reference to psychosocial adjustment, sense of school membership and academic progress.
Methods: This is a longitudinal study approaching completion. There are four points of data collection (T1-4):

- T1 = June/July 2014 (Year 6, final term of primary school*).
- T2 = November/December 2014 (Year 7 term 1, first year of secondary school)
- T3 = June/July 2015 (Year 7 term 3, first year of secondary school)
- T4 = November/December 2015 (Year 8 term 1, second year of secondary school)

*In England the school year contains three terms and starts on September 1st.
Students were aged between 10 years 9 months and 11 years 9 months at T1. At each time point, students in the ASD ($N = 38$) and TD ($N = 22$) groups, their parents and teachers complete a quality of life questionnaire, with an additional questionnaire for the students on school membership. Attainment in Mathematics/English and attendance are also recorded at each time point. Parents of pupils with ASD completed the Social Responsiveness Scale (2nd ed.) at T1 to permit exploration of within group differences according to severity of autistic symptoms. Background data were collected on each student including gender, support provided in school and educational placement.
Analysis will include descriptive statistics and inferential statistics to assess change over time within and between groups and according to respondent.
Results: Longitudinal findings exploring within and between group differences from T1 to T4 will be presented for the first time at the conference, following the final wave of data collection in November/December 2015.
Conclusions: Findings will be discussed in relation to the existing broader literature, along with a consideration of the implications for policy and practice.

228 **110.228** The Level of Intelligence Modulates the Recognition of Emotional Point-Light Displays in Children with Autism Spectrum Disorder (ASD): A Comparison Between High Functioning and Low Functioning ASD

N. Mazzoni[1], *T. Del Bianco*[1], *I. Landi*[2], *P. Ricciardelli*[3,4], *R. Actis-Grosso*[3,4] *and P. Venuti*[1], *(1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, TN, Italy, (2)MPBA/Center for Information and Communication Technology, Fondazione Bruno Kessler, Trento, TN, Italy, (3)Dept. of Psychology, University of Milano - Bicocca, Milano, MI, Italy, (4)Milan Centre for Neuroscience, Milan, Italy*

Background:
The moving human body is a nuance-rich cue of others' attitude: patients with Autism Spectrum Disorder (ASD) often fail to figure out its meaning and show anomalous pattern of brain activation during motion perception. Besides, their ability to recognize emotion is generally impaired, especially when conveyed by biological elements – motion included. Point Light displays (PLD) are reliable tools to assess the ability to identify the emotion shown through a moving human body. Evidence in the literature mostly involves high-functioning (HF) ASD samples and there is a lack of information on low-functioning (LF) ASD population's abilities. It is still debated if the ASD's impairment in social interaction is related to the processing of biological motion (BM), besides it is unclear the relation between emotion recognition and IQ level.
Objectives:
We explored the ability to understand BM with different emotional valence in children with ASD. We enquired if their impairment was specific for the recognition of emotions or widespread to BM in general. Moreover, we explored the role played by the IQ level in this ability.
Methods:
24 typically-developing (TD) children, 23 children with HF ASD and 17 with LF ASD took part in our study. Respectively, the mean age and IQ of each group were 9.05, 111; 9.5,100; 12.2,49. After each PLD clip, we asked the children to categorize the emotion (fear, happiness, neutral) by pressing the corresponding key. Emotional categories were presented coupled in three separated blocks. The dichotomous choice allowed also LF ASD children to perform the task. Accuracy and response times (RTs) were measured.
Results:
Total accuracy was significantly different according with the functioning: TD children outperformed children with ASD, children with HF ASD showed higher levels of accuracy than children with LF ASD. A positive correlation between accuracy and IQ was found in all the groups, though the generalized linear model which takes IQ into account explained accuracy only in the two ASD groups.
Considering RTs relative to recognized stimuli, TD were significantly faster than ASD; no differences emerged between HF and LF ASD groups. IQ resulted negatively correlated with rapidity and significantly predicted it in the generalized linear model for all the three groups.
Comparing performances between the three emotional categories: TD were significantly more accurate and faster in recognizing of all the three classes of stimuli, while no differences between ASD groups emerged.
Conclusions:
Our findings suggests that the ability to recognize the emotional meaning of BM is impaired in ASD children, independently of its emotional content.
Cognitive level seems pivotal for recognizing affective biological motion in children with ASD. Although IQ doesn't seems to impact the accuracy of this mechanism when it works properly, it is important when the mechanism is impaired. A more efficient cognitive substrate might mediate the acquisition of compensatory mechanisms, which help ASD children to better understand the human gestures. Besides, for all participants IQ is important for promptly recognize the stimuli. Therefore, the IQ level seems to mediate the efficiency of the biological motion processing, boosting its rapidity.

229 **110.229** The Preschool Imitation and Praxis Scale (PIPS): Measure Standardization and Autism Spectrum Disorder (ASD)-Specific Imitation Profiles in High-Functioning Preschoolers

M. Vanvuchelen[1] *and H. Roeyers*[2], *(1)Faculty of Medicine and Life Sciences- Rehabilitation Research Centre (REVAL), Hasselt University, Diepenbeek, Belgium, (2)Ghent University, Ghent, Belgium*

Background:
Although imitation impairments are often reported in children with ASD, previous work has not yet determined whether there is a profile of preserved and impaired imitative abilities that is specific to ASD. Insight into this profile has the potential to make a significant difference in our ability to facilitate social learning in this population.
Different ways of copying others' actions often serve different functions and reflect distinct underlying processes; for instance copying to learn about objects (i.e., procedural imitation) versus copying to be social (i.e., bodily imitation). Studies of imitation have also compared meaningful and meaningless actions. The factor of meaning is almost inevitably confounded with familiarity because such actions are likely to have been performed before. Meaningless actions are often novel. Another dimension explored in a

number of studies concerns the temporal complexity of the demonstrated actions (i.e., singular versus sequential actions) (Vivanti & Hamilton, 2014).
The general pattern emerging from the available literature is that children with ASD imitate actions on objects better than actions that do not involve objects, have more difficulties in the imitation of meaningless than meaningful gestures, and find it more difficult to imitate sequences of actions than singular actions (Vivanti & Hamilton, 2014). However, major drawbacks of former studies are that different types of actions are not investigated at once in a single study and that they have looked at the accuracy of imitation performance without controlling for age and developmental level. Given these gaps it is impossible to come to a firm conclusion about an ASD-specific imitation profile.
Objectives:
The present study aims to report the standardization of the Preschool Imitation and Praxis Scale (PIPS) and to apply this measure to examine the imitation profile of high-functioning preschoolers with an ASD.
Methods:
To construct the PIPS action types with different effects (salient environmental in procedural, internal in bodily imitation), representational levels (meaningful, meaningless), temporal complexities (singular, sequential) and visual monitoring possibilities (transparent, opaque) were chosen to tap the full range of possible imitation mechanisms. Performances on the 30 imitation tasks are scored on a 3 to 5 point scale, which evaluates the spatiotemporal resemblance between the modelled and copied actions. 654 typically developing children (TDC) and 33 children with ASD between 23 and 53 months of age (performance IQ 85-113) participated in the standardization study.
Results:
PIPS scale has produced high internal consistency and demonstrates acceptable intra- and interrater and test-retest reliability. Bodily and procedural imitation age-equivalents were derived from PIPS scores of 654 TDC between 12 and 59 months of age (Vanvuchelen, et al., 2011a,b,c). Further details on the results will be presented at the meeting.
Conclusions:
The PIPS is a much-needed and comprehensive measure of imitation skills and abilities, which has been standardized on a population of TDC. The application of this measure to young, high-functioning children with ASD in the current study is a critical first step towards a detailed understanding the unique profile of imitation skills in this population, which has been elusive to date.

230 **110.230** The Recognition of Self-Conscious Emotions from Situational Contexts in Children with and without Autism Spectrum Disorders

D. Davidson[1] *and E. Hilvert*[2]*, (1)Loyola University Chicago, Chicago, IL, (2)Loyola University, Chicago, IL*

Background: The ability to understand and reflect upon one's own emotions and the emotions of others is central to emotional competence. Self-conscious emotions, in particular, are thought to facilitate our social interactions and relationships by motivating us to adhere to social norms (guilt) as well as personal standards (pride).
Objectives: Despite the importance of self-conscious emotions, almost all studies have explored basic emotion processing in children with ASD (see Uljarevic & Hamiliton, 2013). Moreover, recognition of emotions is often assessed through facial recognition tasks, with emotions presented at full intensity. The purpose of this research was to assess the recognition of basic and self-conscious emotions from situational contexts that varied in intensity. Relations between emotion recognition, ASD symptomatology, and Theory of Mind (ToM) were also explored.
Methods: Twenty-three children with ASD and 25 neurotypical (NT) children were tested. No significant differences between groups were found for age, male:female ratio, or non-verbal reasoning (Table 1). Children were given a situational emotional test that provided 12 emotional situations for basic (happy, fear, sad) and self-conscious (pride, embarrassment, guilt) emotions. An intense and a less intense version of each emotion were presented. Children were asked to label the emotions (free, cued) and rate the intensity and duration of the emotions (1-5 scale).
Results: Mixed-model ANOVAs and follow-up tests with Bonferroni correction were conducted. In the *cued response* condition, NT children were significantly better than children with ASD at recognizing intense examples of pride, embarrassment and guilt, and non-intense examples of pride and embarrassment (Table 2). NT children were better at recognizing fear from intense and non-intense situations. In the *free response*condition, NT children were better at recognizing intense examples of embarrassment and guilt, and non-intense examples of embarrassment. All children were good at labeling fear in the intense condition (Table 2). No significant group differences were seen in the recognition of happy and sad emotions. All children rated the intensity and duration of "intense" emotions as greater than that for "less intense" emotions. Children with ASD rated situations eliciting pride and embarrassment as being more intense and longer lasting than NT children (Table 2). Significant relations were found between ToM scores and the recognition of emotions in children with ASD, but not in NT children. No other significant relations were found.
Conclusions: The present study shows that children with ASD are generally less accurate than NT children in their recognition of self-conscious emotions from situational contexts. This is important given the significance of self-conscious emotions in terms of emotional competence. These results conflict with a study (Tracy et al., 2011) showing that children with ASD are as accurate as NT children at recognizing pride from facial expressions—suggesting that the measurement of emotions (facial vs. situational) is important. Consistent with facial recognition studies (Tell et al., 2014), some evidence was found that children with ASD were generally less accurate than NT children at recognizing fear. ToM abilities appear to underlie emotion recognition in children with ASD, but not in NT children.

Table 1 ***Comparison of Matching Variables and Participant Characteristics***

	Diagnostic Group	
	ASD (N=23)	***NT (N=25)***
Age	11;09 (2.0)	11;06 (2.1)

Table 2 ***Mean Proportion Correct in Recognizing Basic and Self-Conscious Emotions from Situational Contexts in Children with Autism Spectrum Disorders (ASD) and Neurotypical (NT) Children***

			CUED RESPONSE CONDITION			
	Basic Emotions			Self-Conscious Emotions		
	Happy	**Sad**	**Fear**	**Pride**	**Embarrassed**	**Guilt**
Intense						
ASD	.61 (.49)	.89 (.34)	.70 (.47)[a]	.78 (.42)[a]	.74 (.45)[a]	.43 (.51)[a]
NT	.60 (.50)	.83 (.38)	.92 (.28)	.92 (.28)	.92 (.28)	.76 (.44)
Non-Intense						
ASD	.78 (.45)	.83 (.39)	.65 (.49)[a]	.61 (.49)	.52 (.51)	.34 (.49)
NT	.83 (.38)	.80 (.41)	.80 (.41)	.68 (.48)	.64 (.49)	.36 (.49)
			FREE RESPONSE CONDITION			
	Basic Emotions				Self-Conscious Emotions	
	Happy	**Sad**	**Fear**	**Pride**	**Embarrassed**	**Guilt**
Intense						
ASD	.56 (.51)	.91 (.27)	.91 (.28)	.61 (.50)	.69 (.47)[a]	.43 (.51)[a]
NT	.60 (.50)	.92 (.28)	.92 (.28)	.56 (.51)	.92 (.28)	.64 (.49)
Non-Intense						
ASD	.78 (.42)	.73 (.45)	.65 (.43)[a]	.61 (.49)	.43 (.51)[a]	.13 (.34)
NT	.72 (.46)	.76 (.44)	.88 (.33)	.56 (.51)	.68 (.48)	.20 (.41)

Note. [a] Denotes significant group differences. Situations were approximately three to four sentences in length, and had been validated for each emotion and intensity level by adults ($N = 45$) prior to the start of the experiment. Children were asked to identify the emotion of a child protagonist in each situation, and using rating scales, to rate how intensely the protagonist experienced the emotion as well as estimate the duration of the emotion. Children with ASD rated the intensity (M_{ASD} 4.3/5.0; M_{NT} 3.9/5.0) and duration (M_{ASD} 4.2/5.0; M_{NT} 3.3/5.0) of pride situations, as being greater than NT children. A similar pattern was found for the intensity (M_{ASD} 3.78/5.0; M_{NT} 3.40/5.0) and duration ratings (M_{ASD} 2.74/5.0; M_{NT} 2.6/5.0) for embarrassment. For all children, the free response condition was administered before the cued response condition. Standard deviations are in parentheses.

231 **110.231** The Relationship Between Interpersonal Synchrony and Social Attention during Rhythmic Inter-Limb Coordination Tasks in Children with Autism Spectrum Disorder

S. Izadi-Najafabadi[1], *I. Park*[2], *S. Srinivasan*[1], *M. Kaur*[1], *T. Gifford*[2], *K. L. Marsh*[3] *and A. N. Bhat*[1], *(1)University of Delaware, Newark, DE, (2)University of Connecticut, Storrs, CT, (3)Psychology, University of Connecticut, Storrs, CT*

Background:
Children with Autism Spectrum Disorder (ASD) have significant social impairments such as reduced social attention/monitoring and eye contact (American Psychiatric Association, 2013). This will affect their ability to learn everyday activities through observational learning. In addition, motor coordination impairments observed in children with ASD will affect their ability to synchronize and keep up with others subsequently contributing to their social disconnect (Bhat, Landa, Galloway, 2011). To date, no study has examined the relationship between the direction of social gaze and interpersonal synchrony (IPS) in children with ASD.
Objectives:
In this study, we aimed to compare the direction of social gaze and IPS between children with ASD and typically developing (TD) children during various simple (dual-limb, clap, march, alternate drumming) and complex (multilimb, march-clap and asymmetrical drumming) coordinated rhythmic actions performed with a social partner.
Methods:
11 children with ASD and 12 age- and gender-matched TD children between 4 and 12 years of age were observed in a dyadic context during simple and complex rhythmic actions of clapping, marching, and drumming. Children were asked to perform these activities while synchronizing their movements with an adult social partner and a metronome beat. During these activities we recorded the visual field of the child by placing a wide-angle camera on the forehead to record gaze direction. Gaze direction was coded as looking at the upper or lower body of the social partner or away within the central visual field of the child. IPS was coded as the proportion of total time the child was in, opposite, or out of synchrony with the social partner.
Results:
We found that children with ASD spent more time looking away (14.43±15.37) compared to TD children (3.22±6.31) indicating deficits in sustained social monitoring. Moreover, children with ASD (drum: 61.16 ± 38.64, march: 87.83 ± 13.84, clap: 63.95 ± 28.28) were less synchronous in their movements with the social partner compared to the TD children (drum: 97.12 ± 14.5, march: 98.32 ± 5.92, clap: 95.52 ± 6.90). In both groups, leg motions (Complex march: 91.66 ± 13.63, Simple march: 94.62 ± 9.12) were more synchronous than arm motions (Complex clap: 79.65 ± 23.73, Simple clap: 80.33 ± 27.26). Lastly, during the simple actions both groups attended to the task-relevant limbs i.e.; lower-limb during marching or upper limb during clapping. However, during complex multilimb actions, both groups appear to simplify their perceptual information by primarily focusing on the clapping hands than the marching feet.
Conclusions:
Our results show how social monitoring impairments may contribute to the lack of interpersonal synchrony in children with ASD. Movement clinicians such as OTs/PTs must encourage focused social attention as well as socially embedded motor activities in children with ASD to further enhance their interpersonal synchrony with others.

232 **110.232** The Relationship Between Socialization Skills and Externalizing Problems in Autism Spectrum Disorder

N. Shea[1], *J. Kopec*[2], *E. Payne*[1], *E. McKernan*[1] *and N. Russo*[1], *(1)Syracuse University, Syracuse, NY, (2)Psychology, Syracuse University, Syracuse, NY*

Background: Although not a core symptom of Autism Spectrum Disorders (ASD), externalizing symptoms such as aggression and behavior problems are common and have the potential to negatively impact daily functioning and academic achievement (Klin & Volkmar, 2000; Volker et al., 2010). Klin & Volkmar (2010) suggested that externalizing behaviors associated with ASD may be a function of social difficulties (Klin & Volkmar, 2000). Specifically, it has been suggested that individuals with ASD engage in problem behaviors to achieve desired social responses as a result of difficulties adjusting to social demands in socially appropriate ways (Macintosh & Disssanayake, 2006). Despite this suggestion, there has been no empirical assessment of this postulated relationship.
Objectives: The goals of this study were to (a) provide empirical evidence to support the relationship between socialization and behavior problems, (b) and to investigate whether this relationship is unique to individuals with ASD.
Methods: Participants in this study included 20 children with ASD and 34 typically developing (TD) children. Participants with ASD met diagnostic criteria for ASD as determined by the Autism Diagnostic Observation Schedule, Second Edition, Autism Diagnostic Interview-Revised, and clinical judgment based on DSM-5 criteria. All participants were administered the Wechsler Abbreviated Scale of Intelligence, Second Edition (WASI-II; Wechsler, 2011). Parents of participants completed the Vineland Adaptive Behavior Scales, Second Edition (Vineland-II; Sparrow, Cicchetti, & Balla, 2005) and the Behavioral Assessment System for Children, Second Edition (BASC-2; Reynolds & Kamphaus, 2004). Of interest to the present study were the Externalizing Problems Domain on the BASC-2 and the Socialization domain on the Vineland-II. Participant's ages and IQ scores are presented in Table 1. There was a significant difference in Full Scale and Verbal IQ (but not in the Perceptual Reasoning Index) between the typically developing and ASD groups, however IQ was not significantly correlated with the relevant Vineland or BASC-2 scales for either of the two groups.

Results: Linear regressions were run separately for the ASD group and the TD group to predict Socialization scores on the Vineland-II from the Externalizing Problems scores on the BASC-2. Externalizing problems predicted social functioning in the expected direction for the individuals with an ASD $F(1,18) = 9.96$, $p = .005$, with an R^2 of .356, but not for the TD participants $F(1,32) = 1.745$, $p = .196$, with an $R^2 = .052$.
Conclusions: These findings support the relationship between socialization and behavior problems in ASD, specifically that children with more socialization difficulties have more behavior problems. Further, this relationship might be unique to individuals with an ASD, though this specification requires further study.
(Table 1 is uploaded as an image)

Table 1

	N	Age	FSIQ*	PRI	VCI*
ASD M (SD)	20 (6 female)	11, 10 (2)	102.95 (10.63)	103.45 (11.16)	101.80 (12.91)
TD M (SD)	34 (17 female)	10, 5 (3)	112.29 (11.76)	106.09 (14.26)	115.29 (10.50)

Notes. M = mean, SD = standard deviation, FSIQ = Full Scale Intelligence Quotient, PRI = Perceptual Reasoning Index, VCI = Verbal Comprehension index. Age is represented in years, months. * Indicates significant differences at the p<.05 level.

233 **110.233** The Role of Theory of Mind in the Daily Living Skills of Children with ASD

T. Estrada[1], *R. Bowler*[1], *E. A. Lovell*[1], *K. Duskin*[1] *and B. Wilson*[2], *(1)Seattle Pacific University, Seattle, WA, (2)Clinical Psychology, Seattle Pacific University, Seattle, WA*

Background: Children with autism spectrum disorder (ASD) commonly exhibit deficits in activities of daily living (ADL) skills when compared to typically developing (TD) peers (Bal et al., 2015). Additionally, social deficits are defining characteristics of children with ASD (APA, 2013) and have been shown to predict decreased ADL abilities (Bal et al., 2015). The present study hypothesized that that the ADL deficits seen in children with ASD are related to Theory of Mind (ToM), an indicator of social perception (Kimhi et al., 2014). ToM skills are often impaired in children with ASD (Baron-Cohen, Tager-Flusberg, & Cohen, 1985; Kimhi et al., 2014).
Objectives: This study aimed to develop a greater understanding of how social factors may contribute to decreased ADL skills in children with ASD. Therefore, the purpose of this study was to test our hypothesis that ToM abilities would moderate the association between children's status and their ADL skills.
Methods: Participants included seventy-two children, ages 3:0 to 6:11. Twenty-two children were previously diagnosed with ASD and 50 children were TD. Children completed a ToM battery in a laboratory setting. Parents' ratings from the *BASC-2* (Reynolds & Kamphaus, 2004) were used to evaluate children's ADL skills. Additionally, the *DAS-II* (Elliott, 2007) was used to assess children's language abilities.
Results: A moderation analysis using the SPSS macro PROCESS (Hayes, 2013) tested whether the association between developmental status and ADL skills was moderated by ToM abilities. Controlled variables included children's language abilities and age. The main effect of status on ADL skills was significant ($B = -45.93$, $SE = 14.96$, $p < .001$) but the main effect of ToM skills on ADL skills was not significant ($B = .09$, $SE = .88$, $p = .14$). The contribution of the interaction between status and ToM was significant, $\Delta R^2 = .04$, $F(21, 66) = 4.64$, $p < .05$. Specifically, children with ASD who had low (-1 SD; $B = -20.26$, $SE = 4$, $p < .001$) and mean ($B = -13.82$, $SE = .2.91$, $p < .001$) levels of ToM abilities had lower ADL skills when compared to TD children. However, when children with ASD had greater ToM abilities (+1 SD; $B = -7.38$, $SE = 4.34$, $p = .09$), their ADL scores were not significantly different from TD children. This suggests children with ASD may have comparable ADL skills when they also display higher ToM abilities.
Conclusions: These results supported our hypothesis that the association between status and ADL skills would be moderated by ToM abilities. Specifically, when children with ASD had low or mean levels of ToM abilities, they had greater deficits in ADL skills than TD children. However, this relation was not significant for children with ASD who had ToM abilities above the mean, which suggests that their high ToM skills may buffer them against potential deficits in their daily living skills which are characteristic of ASD. The findings suggest that targeting interventions to increase ToM abilities may play a role in improving ADL skills for children with ASD and, therefore, improve independence.

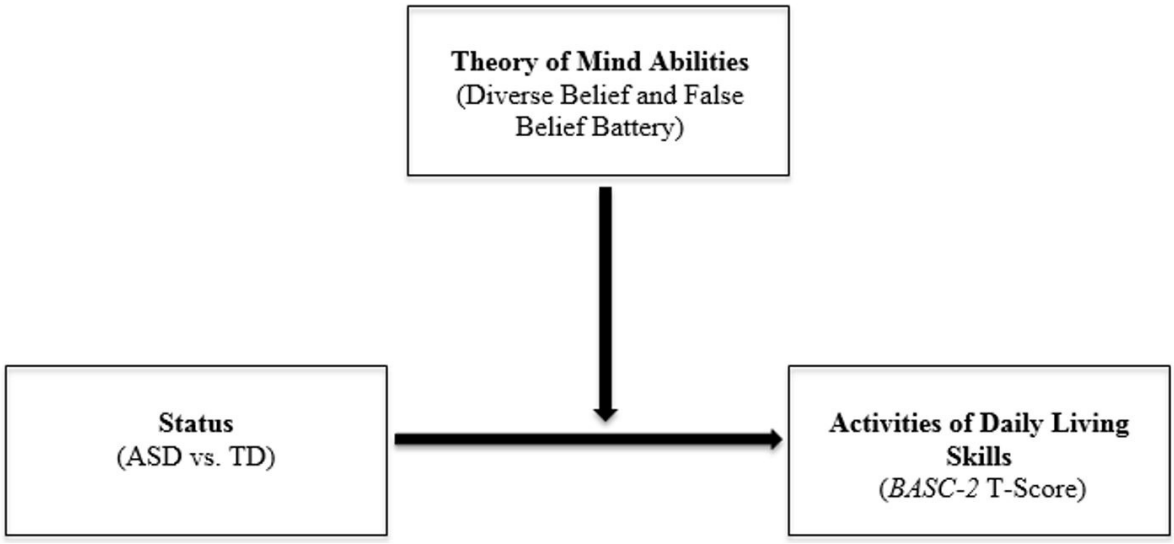

Figure 1. Moderation model

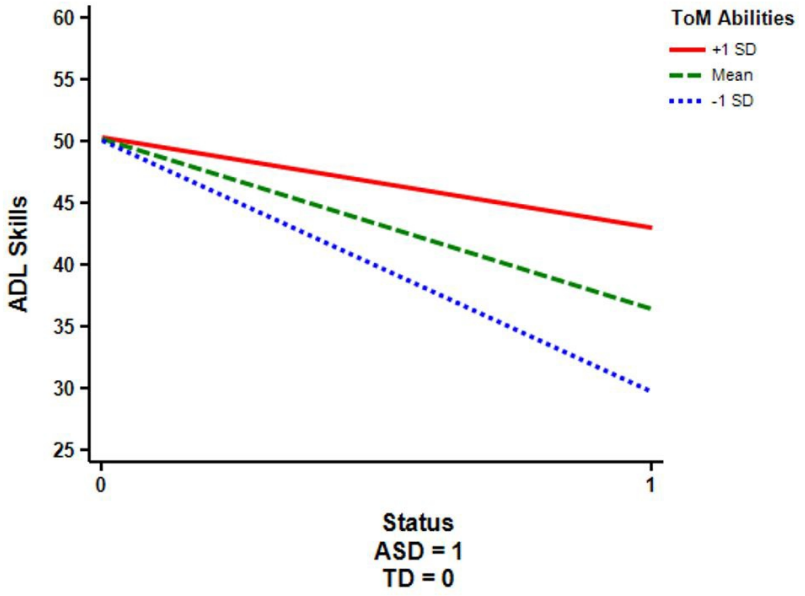

Figure 2. The interaction between status and ADL skills at high, mean, and low levels of ToM abilities

234 **110.234** The Stare-in-the-Crowd Effect: How We Notice When Others Look at Us and How This Is Affected By Psychopathology

E. T. Crehan[1,2], *H. E. Frering*[1], *N. Durand*[1], *C. Pirro*[1], *K. Reeves*[1] *and R. R. Althoff*[3], *(1)Psychology, University of Vermont, Burlington, VT, (2)Psychology, University of Alabama, Birmingham, AL, (3)Psychiatry, Psychology, and Pediatrics, University of Vermont, Burlington, VT*

Background:
Humans are particularly adept at detecting if someone is looking at them in a crowd of other faces. This “stare-in-the-crowd effect” is implicated in numerous moment-to-moment interactions yet relatively little is known about its characteristics. Properly detecting and reacting to gaze informs social interactions; deficits in this perceptual system cause an individual to miss out on large amounts of social information and is a core deficit observed in ASD. A newly validated paradigm was used to study stable gaze detection as well as dynamic (e.g. catching another person staring and getting caught staring) to capture these deficits.
Objectives:
-To determine if different gaze conditions elicit differential eye movements and physiological arousal
-To determine how the stare-in-the-crowd effect presents relative to ASD and related traits
Methods:
A total of 36 young adults (ages 18-35) completed an eye tracking task, heart rate monitoring, a brief cognitive assessment, and three self-report questionnaires, including the Social Responsiveness Scale (SRS), the Theory of Mind Inventory (ToMI), and the Liebowitz Social Anxiety Scale (LSAS). Four eye tracking outcomes (interest area (IA) dwell time, IA fixation count, and IA second fixation duration, and pupil size) and one heart rate outcome (RMSSD) were analyzed in four eye tracking conditions.
Results:
The overall sample included 36 adults (M = 20.53, SD = 2.22; 41.7% female). Of these, 15 were diagnosed with ASD or PDD and 21 were not. There were no significant differences between the two groups by age, sex, or IQ. Two by four ANOVAs yielded a significant interaction of diagnosis and condition on IA dwell time ($F(3,139)=5.67$, $p<.005$); a significant interaction of diagnosis and condition on IA second fixation duration ($F(3,139)= 4.77$, $p<.005$); a non-significant interaction of diagnosis and condition on IA second fixation duration ($F(3,139)=2.18$, $p=.094$); and no significant main effects or interaction of diagnosis and condition on pupil size ($F(3,139)=1.5$, $p=.33$).
Change scores for IA Dwell time, IA Fixation count, IA Second Fixation Duration, Pupil Size, and RMSSD were calculated relative to stable and dynamic conditions (e.g. How many more IA fixations did a person make in the Catching another staring and getting caught staring conditions versus the Stable Averted and stable Mutual conditions?) and relative to amount of self-directed gaze conditions (e.g. What was the difference in RMSSD between the Stable Averted and Catching another staring conditions versus Stable Mutual and Getting caught staring conditions?). Regressions using the SRS and LSAS to predict psychophysiological outcomes were not significant. Advanced theory of mind as measured on the ToMI significantly predicted IA Fixation Count, IA Dwell Time, and RMSSD.
Conclusions:
The pattern of differences in eye tracking outcomes confirms that individuals with ASD are impacted by the stare-in-the-crowd effect but to a lesser extent than typically-developing individuals. Advanced theory of mind is significantly associated with gaze behavior. Both group comparisons and dimensional analyses highlight targets for intervention.

235 **110.235** The Use of Ipads to Enhance Joint Attention Skills in Children with Autism Spectrum Disorder (ASD)

C. Mangafa, *L. Moody, A. Woodcock and A. Woolner, School of Art and Design, Coventry University, Coventry, United Kingdom*

Background: iPads™ are increasingly used in primary schools with reported benefits in communication, independent learning and creativity. Children with autism spectrum disorder have an affinity with mobile technology, which is recognised by the autism research community with many studies emerging in this field. Joint attention (JA) is an essential life skill which can indicate the later development of social communication and language acquisition. It is usually absent or impaired in children with autism, which means that they often find it difficult to share attention with an adult or peer about a toy or activity by keeping eye contact and pointing, but also showing interest to the other person. Research on the use of iPads™ to develop JA skills in autism is still in infancy.
Objectives: This qualitative study aims to explore primary school teachers' and parents' perspectives and experiences of developing JA skills in children with autism using iPads™.
Methods: Semi structured interviews with 16 school staff members and non-obtrusive observations of 12 pupils interacting with their teacher using iPads™ were held in three UK schools. Also, parents of children with autism aged 4-11 years old are currently being interviewed to investigate parents' practice of developing JA beyond school hours and exploring the iPad™'s benefits in promoting JA in different contexts.
Results: All teachers used teaching strategies to promote JA on a daily basis but a few used iPads™ in their classroom. Participants expressed different opinions about the effectiveness of teaching strategies and iPad™ use in developing JA.The observations showed that teachers used a variety of evidence-based strategies to engage their pupils with autism in JA opportunities but that there was little use of iPads™. The iPad™ was mainly used as a reward, a motivator to direct and sustain pupils' attention, to practice turn-taking and waiting skills and to teach the curriculum. Preliminary findings derived from the semi structured interviews with parents have shown that parents use a variety of social activities to boost their child's joint attention skills. Their views though were contradictory regarding the iPad™'s contribution in developing JA skills, with a few parents mentioning that the iPad™ can be a solitary device that can further isolate their child from daily human interactions while other parents have mentioned that the iPad™ is a motivating tool used to grasp their child's attention and teach them JA. Parents have also mentioned that they wish to have stronger links with their child's school.
Conclusions: The research concludes that schools would benefit from teacher training and dissemination of good practice on how to use iPads™ for JA purposes. Parents are also interested in discovering how they can best address their children's needs in cooperation with the schools. To that end, the future steps of this research include creating guidelines about the way to develop JA opportunities at home and school with the use of the iPad™ as an engaging educational device.

236 **110.236** Understanding Social Versus Private Intention: Exploring the Neural Correlates of Intention Understanding Based on Intentional Content

N. I. Berger, *Michigan State University, East Lansing, MI*

Background: Given that children with ASD demonstrate impairment in social-cognition, developing a comprehensive understanding of intention understanding in ASD is important as it is believed to be a foundational skill upon which higher level social-cognition is built. Recent behavioral work in young children with significant ASD symptomatology suggests that while deficits are not present on tasks requiring intent to be inferred from an actor's action on an object (private intention), impairment is evident on tasks in which intent must be inferred from the actor's social-communicative behavior such as eye gaze, vocalizations, or facial expressions (social intention). However, it is unclear whether the neural correlates supporting each type of intention are distinct.
Objectives: The purpose of this study was to validate a novel ERP paradigm to assess the neural correlates of private and social intention understanding that could be used to examine these constructs in children with ASD. As part of this validation process, we examined the relationship between the neural correlates of each type of intention understanding and autistic traits.
Methods: We examined neural indices of attention to social and non-social intention understanding in 35 typically developing young adults, exploring modulation of each type of intention understanding by level of autistic traits. Participants viewed a sequence of pictures depicting either social or private intention with the final picture of the sequence varying such that sometimes the actor completed the intended action and sometimes he performed an unintended action. Participants made a response only if the actor did what he intended to do; no responses were made to unintended actions. Autistic traits in this non-clinical sample were quantified using the Broader Autism Phenotype Questionnaire.
Results: Across participants, there was a main effect of trial type, such that unintended actions resulted in greater allocation of attention — as indexed by larger P3 amplitude — compared to intended actions, and a main effect of intentional content, such that private intention stimuli resulted in greater allocation of attention — as indexed by larger P3 amplitude — compared to social intention stimuli. An interaction between trial type and intentional content was also observed, which indicated that the difference in P3 amplitude between intended and unintended actions was greater for private than for social stimuli. Higher expression of autistic traits, specifically aloofness, was correlated with an attenuated allocation of attention — as indexed by smaller P3 amplitude — for social intention understanding, but was unrelated to private intention understanding.
Conclusions: Neuroelectric indices of attention concord with behavioral findings of a dissociation between social and private intention understanding, and highlight that it is the processing of social intention in particular that is related to ASD traits. Notably, the attenuated allocation of attention for social intention understanding observed at higher levels of autistic traits seems to suggest that social intention stimulus cues (i.e., eye gaze and head turn) fail to induce a strong sense of expectancy for these individuals. This finding demonstrates that attenuated responsiveness to social-communicative cues extends to autistic characteristics within the range of typical functioning.

237 **110.237** Using Facial Expression Analysis Software to Examine the Relationship Between Abnormal Facial Expressions and Alexithymia in Children with and

without Autism

D. A. Trevisan[1], *M. Bowering*[2] *and E. Birmingham*[1], *(1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Linguistics, Simon Fraser University, Burnaby, BC, Canada*

Background: Buck and Powers (2013) argue that the ability to nonverbally express one's emotions is an important developmental skill, because the ways in which caregivers respond to those emotions can help children understand *what* emotion they are experiencing, *why* they are experiencing it, and may subsequently offer strategies on how to regulate that specific emotion. If children are non-expressive or express their emotions in confusing ways, learning opportunities are lost and *alexithymia* (i.e., difficulties identifying and describing one's feelings) could develop over time. Buck and Powers' hypothesis may be especially relevant for children with Autism Spectrum Disorder (ASD), as approximately 50% of this population has high rates of alexithymia compared to 10% in the neurotypical population (Berthoz & Hill, 2005), and because ASD is characterized in part by blunted and/or confusing nonverbal emotional expression (APA, 2013). While Buck and Powers' hypothesis has been supported by several studies using neurotypical adults, to date, no studies have examined the relationship between nonverbal emotional expression and alexithymia in child participants or in the ASD population.
Objectives: The objective of this study was to examine associations between nonverbal expression and alexithymia in children with and without ASD.
Methods: Participants (see Table 1) viewed images and videos extracted from YouTube and Google Images designed to evoke various emotional responses, while being covertly recorded with a webcam. The stimuli were collated into a 15-minute .mp4 video file. Participants were instructed to sit still and watch carefully for the entire video. Subsequently, webcam recordings were analyzed using iMotion's Emotient software (ImotionsGlobal, 2015), which estimates which emotions are being expressed based on Ekman et al.'s (2002) facial action coding system (FACS). In cases where the entire 15-minute recording was not usable (e.g., due to participant distraction), "inattention time" was partialed out. Concurrently, parents completed the parent-report Children's Alexithymia Measure (CAM; Way et al., 2010), with higher scores on the CAM reflecting stronger alexithymic traits.
Results: A significant negative correlation was observed between CAM scores and expression of contempt, $r(32) = -.351$, $p = .021$, as well as an aggregate of all negative emotions (including sadness, contempt, disgust, anger and fear), $r(31) = -.336$, $p = .028$). In addition, higher CAM scores were associated with higher rates of neutral expression $r(32), = .341$, $p = .024$. Thus, children with stronger alexithymic traits produced weaker negative expressions and were more expressively neutral than children with weaker alexithymic traits.
Conclusions: This study is the first to show that less salient facial expressions are associated with higher levels of alexithymia in children with and without ASD, consistent with Buck and Power's (2013) hypothesis. These results support the possibility that blunted or confusing emotional expression may contribute to the high rates of alexithymia in the ASD population, although causation cannot be inferred from this study's design. Future research should use more ecologically valid stimuli, longitudinal designs, and examine facial expressions during interactions between children and caregivers to gain a clearer understanding of how abnormal facial expressions may contribute to the development of alexithymia.

Table 1. *Participant Demographics*

Gender Distribution	14M:3F	12M:5F

238 **110.238** Using Qualitative Methods to Explore the Subjective Experience of Eye Contact in Autistic Teens and Adults

D. A. Trevisan[1], *C. Lin*[2], *N. K. Roberts*[1] *and E. Birmingham*[1], *(1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background:
Several theories attempt to explain why individuals with Autism Spectrum Disorder (ASD) are reluctant to engage in eye contact during social interaction. *Social motivation* accounts suggest that social information is less intrinsically rewarding to individuals with ASD (Chevallier et al., 2012). *Aversion theories* suggest that mutual gaze elicits a hyperarousal response in ASD, possibly mediated by amygdala dysfunction, leading to an aversion to eye contact (e.g., Dalton et al., 2005). Finally, *Sensory processing* accounts suggest individuals with ASD have difficulties coordinating multiple sensory systems (Crane et al., 2009) and therefore avoid eye contact during conversation to avoid sensory overload. Remarkably, no published research to date has utilized qualitative methods to explore the subjective experience of eye contact in individuals with ASD, which could have significant theoretical implications. Objectives:
Objectives:
The purpose of this study was to understand how high-functioning adults and teenagers with ASD experience eye contact in their daily lives. Our research question was "How do people with ASD experience eye contact?"
Methods:
Using keywords "Eye Contact" and "Autism," we searched the Internet for high quality autobiographical accounts of teenagers and adults with ASD describing their lived experiences with eye contact. We accepted videos for analysis when the person in the video spoke in English, reported a diagnosis of ASD, and discussed their *own*experience with eye contact (as opposed to discussing the ASD population generally). Although data collection is still in progress, nine YouTube videos have met the inclusion criteria thus far. Videos were transcribed and entered into NVivo. Using a phenomenological approach (Groenewald, 2004), we coded the transcripts, identified trends and generated themes.
Results: (Preliminary Themes)
1) *Sensory overload*. Two participants described a need to concentrate on the mouth during conversation to aid comprehension. Four described maintaining eye contact as being exhausting, in part due to the overwhelming amount of information provided by the eyes and face. Similarly, three described an inability to simultaneously make eye contact and comprehend words of their conversation partner.
2) *Aversion*. Seven participants described one or more negative feelings including embarrassment, discomfort or anxiety while making eye contact. Three said eye contact feels "unnatural," and four expressed feelings of *invasion* or *violation* from being looked at in the eye.
3) *Cultural norms*. Three participants described a failure to understand the importance of eye contact and why it is an expected social convention. Two participants expressed a desire for society to accept their differences, and to not assume they are being disrespectful for neglecting eye contact. Two recognized the importance of eye contact for the purpose of "fitting in" or appearing "normal."
Conclusions:
In general, data support theories that suggest sensory processing abnormalities and aversion contribute to lack of eye contact in the ASD population, but little evidence for social motivation accounts were observed. Interventions should evaluate the individual with ASD's views on cultural norms surrounding eye contact in designing appropriate solutions for eye contact difficulties. Results of this study should be interpreted with caution due to sampling bias.

239 **110.239** Using the Social Responsiveness Scale to Characterize Social Deficits in Children Referred for Aggressive Behavior

M. Tudor, *K. Ibrahim, E. Bertschinger, A. Sedlack and D. G. Sukhodolsky, Yale Child Study Center, Yale School of Medicine, New Haven, CT*

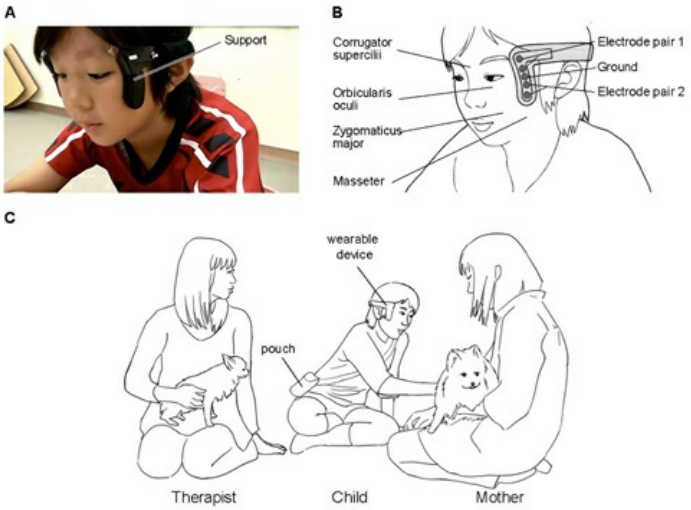
Background: The Social Responsiveness Scale (SRS; Constantino & Gruber, 2003) is a measure of social deficits that has been mostly used in children with autism spectrum disorder (ASD). While the measure reflects social deficits (e.g., awareness, motivation, communication), commonly seen in ASD, there is evidence that it may also reflect dimensions that relate to social behavior in children with other psychiatric diagnoses, such as anxiety (Cholemkery et al., 2014, Settipani et al., 2012). Aggressive behavior and irritability is another phenotypic presentation that may be associated with social deficits (Sukhodolsky and Scahill 2012). However, the associations between social deficits as reflected by the SRS and aggressive or disruptive behavior in children without ASD has yet to be examined.

Objectives: The goal of the current study was to examine the relationships between scores on measures related to aggression and SRS scores in typically developing children referred for aggressive behavior relative to matched typically controls without any psychiatric or developmental psychopathology.
Methods: A total of 87 parents completed a battery of measures of disruptive behavior and social function as part of ongoing research study of anger and aggression in children. Fifty-seven children were referred for disruptive behavior (19 female; age *M*=11.54, *SD*=2.32) and the remaining 30 were recruited as healthy controls (6 female; *M*=12.95, *SD*=2.10). Thus, the sample reflected a wide range of aggression and social behavior profiles. Parents reported on their child's aggression using the Child Behavior Checklist (CBCL), Inventory of Callous Unemotional Traits (ICU), The Home Situations Questionnaire (HSQ), and the Disruptive Behavior Rating Scale (DBRS). Social abilities were reported using the SRS.
Results: As expected, the TD clinic sample demonstrated higher scores on all aggression-related measures. SRS Total scores (*M*=66.47/"Mild" range for corresponding T-score), *SD*=28.40) were also significantly higher within the TD clinic sample than the healthy control subsample (*M*=22.76/"Normal" range for corresponding T-score, SD=15.43; *t*[84]=7.72, p<.00).
When examining the full sample, SRS Total scores were positively correlated with several indicators of aggression and disruptive behavior ($p<.01$): CBCL Aggressive Behavior subscale, $r(84)=.62$, HSQ Total $r(84)=.56$, DBRS Total, $r(85)=.55$, and ICU Total, $r(85)=.48$. Additionally, via hierarchical regression, age ($\beta=.01$, $t=-2.54$, $p=.01$) and Total SRS scores ($\beta=.60$, $t=7.03$, $p<.01$) were shown to significantly predict CBCL Aggressive Behavior; this was not true for gender or SRS subscales.
Conclusions: The results of the current study suggest that typically developing children with aggressive behavior surpass clinical cutoffs on the SRS and that, more generally, SRS scores are correlated with various types of aggression, irritability and noncompliance. This finding indicates that Total SRS scores can be added to clinical evaluation of children who are not on the ASD spectrum in order to characterize social deficits associated with other behavioral problems; as examined in this report, aggression and irritability. SRS subscales may be less useful for such characterization. Past studies have shown some similar relationships in samples of siblings of youth with ASD (Hus et al., 2013) but not ASD samples (Kanne & Mazurek, 2011), further suggesting the utility of differential use of this instrument across populations.

240 **110.240** Wearable Devices for Reading Facial Expression and Detecting Face-to-Face Behavior of Children with ASD

***K. Suzuki**, Center for Cybernics Research, University of Tsukuba, Tsukuba, Japan*

Background:
The social imaging technologies to identify and represent social behaviors is introduced. We reported several wearable devices to measure interactions among people, e.g. physical touch (Iida et al., 2011) and group dynamics (Miura et al. 2013). In this study, a wearable device for detecting smile based on biosignals, and the feasibility study with children with ASD is introduced. Monitoring signals from facial muscles can be a way to measure emotional information (Niedenthal et al. 2009) but children with ASD might show limited observable expression when they are enjoying an activity (Welch 2012). A preliminary study with a child demonstrated that our wearable device effectively correlated positive social behaviors of the child with ASD increased when the smiles increased, and that negative social behaviors decreased when the smiles increased during an AAA (Animal-Assisted Activities) session (Funahashi et al., JADD 2013).
Objectives:
We proposed a wearable device (Gruebler et al. 2014) to detect the smiles of children with ASD using electromyographic signals from the side of the face. We conducted a two-year study to analyze the facial expressions of children and compare data by our device with the evaluation of interventions by a specialized medical examiner while the children experienced AAA with small dogs.
Methods:
The device we designed is compact so the children can wear it during long periods of time, it allows complete mobility of the child in their environment. Independent Component Analysis (ICA) and Artificial Neural Network (ANN) is used to classify the signals from different muscles groups in the face. Thirteen children with ASD (10 boys and 3 girls, mean age = 12.8) and 8 normal healthy children (3 boys and 5 girls, mean age =12.3) were recruited to participate in, which they did voluntarily. Four children with ASD did not want to put on the wearable device during the session, but 9 children with ASD and all 8 control children had no difficulty doing so. Using the typical smiles and the baseline, suitable EMG segments were selected for the training set to perform ICA and to train the ANN. The change in the total duration of each child's smiles in both groups are analyzed.
Results:
The training set was prepared for each participant, and the accuracy of smiling and non-smiling detection was on average 99.84% SD=0.22 and 99.21% SD=0.96, respectively. We found positive correlation between ME and device for threshold levels between 0.65 and 0.95 in all participants through 4 successive sessions and the average number of smiles of each group
Conclusions:
Our findings were consistent with our previous finding using a child with ASD under the same experimental condition. The wearable device can be used to code facial expressions during any other interactions such as face-to-face interactions and quantifying people's facial expressions while on-the-go regardless of context. We have also developed a wearable device using IR sensor for detecting face-to-face time and duration based on head orientations of children. Further investigations include the analysis spontaneous smile and behavior such as with touch, reaching, and face-to-face.



Poster Session
111 - Miscellaneous
11:30 AM - 1:30 PM - Hall A

241 **111.241** Home-Based Parent-Implemented Early Intervention for Young Children with Autism Spectrum Disorders: A Systematic Review and Meta-Analysis

***D. A. Prykanowski**, B. Reichow, J. R. Martinez and K. Marsh, University of Florida, Gainesville, FL*

Background: Family-centered practices are part of a developing literature base in early intervention to help parents/caregivers to support the positive development of their young children with autism spectrum disorders (ASD). One way in which these practices are being implemented is through parent training of early intervention strategies so they will be able to implement interventions with their children in the natural home setting. While there are a variety of parent training programs, many are conducted in clinical or group settings with the expectation the parent will generalize those strategies to the home setting. It is important to investigate the research that examines training a parent within a natural setting and determine the effect on child outcomes, as well as overall parent/family outcomes.
Objectives: The objective of this systematic review is to explore the effects of parent-implemented interventions on communication and behavioral outcomes of young children with ASD, as well as parent skills to conduct the intervention following training and implementation based primarily in the home. A secondary objective is to examine additional outcomes related to the child (i.e. ASD symptomology) and those related to parent/family well being due to the home-based training.
Methods: Studies included in this review were conducted using a randomized control trial design comparing the home-based parent implemented intervention to community

services, and/or waitlist interventions. Studies were located through an extensive search of multiple electronic databases, as well as utilizing a snowball method identifying other possible inclusions. All studies were by two authors independently and discrepancies were resolved. After data extraction, the components of these studies, as well as the effects on child and family outcomes were synthesized using descriptive narratives; visual displays using harvest plots, and other meta-analytic techniques.
Results: The search yielded an initial result of 17,528 articles and following initial screening, 135 full-text articles were assessed for eligibility resulting in the inclusion of 15 studies. Table 1 provides a descriptive summary of the included studies. The studies included 448 child participants in treatment, and 430 in control groups. Overall, the primary outcome assessed most often across these studies was responsive interactions between parent and child, followed by child communication. Eight different types of interventions were used across studies with focused play being the most used intervention. Results were limited in reporting of implementation fidelity and maintenance data.
Conclusions: While effects on the interaction between parent and child were positive, demonstrating that parents can act as primary interventionists in this setting, this poster will discuss the limitations of the studies including the study quality, use of fidelity measures, as well as the varied, inconsistent training strategies that have been used across these interventions. Intervention packages often consistent of multiple training strategies which make it difficult to parcel out the most effective way to teach parent to implement interventions. Additionally, measures used in these studies were not sensitive enough to capture the change over time needed. These results will be used to suggest areas for future research involving parent training and young children with ASD.

Study	Type of Manuscript	Participants Child age in months, N	Intervention	Comparison	Outcomes
Drew et al. 2002	Journal article	Mean (SD) age of Treatment= 21.4(2.7), n=12; Mean (SD) of Control= 23.6(3.8), n=12	Training parents to increase their child's joint attention and joint action skills	Community Services	Primary: Communication Secondary: Parent Stress

Oral Session - 1A

112 - Gene-Environment Interactions that Contribute to ASD

1:45 PM - 2:35 PM - Hall B

1:45 **112.001** Gene-Environment Interactions in ASD: PBDE Exposures and DNA Methylation in the Early Autism Risk Longitudinal Investigation

K. M. Bakulski[1], *A. P. Feinberg*[2], *J. Feinberg*[2], *E. Schriver*[3], *S. C. Brown*[4], *L. A. Croen*[5], *I. Hertz-Picciotto*[6], *C. J. Newschaffer*[3] *and M. D. Fallin*[7], *(1)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Johns Hopkins University, Baltimore, MD, (3)A.J. Drexel Autism Institute, Philadelphia, PA, (4)Mental Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (5)Division of Research, Kaiser Permanente, Oakland, CA, (6)Dept of Public Health Sciences, School of Medicine, UC Davis MIND Institute, Davis, CA, (7)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD*

Background: The environment and genetics both contribute to the etiology of autism spectrum disorder (ASD), but few studies have investigated risks from both sources jointly. *In utero* exposure to polybrominated diphenyl ethers (PBDEs) has known neurodevelopmental effects and is suggested to be an ASD risk factor. DNA methylation plays a complex role in ASD etiology, and we tested whether epigenetic state at birth may be associated with exposure to PBDEs during pregnancy.
Objectives: The goal of this analysis is to determine whether DNA methylation measured in cord blood mediates the association, if any, between prenatal exposure to PBDEs and risk of ASD.
Methods: In the Early Autism Risk Longitudinal Investigation (EARLI) enriched-risk ASD pregnancy cohort, 11 PBDE congeners were measured in maternal blood samples during pregnancy. Genome-wide DNA methylation was assessed in cord blood samples using the Illumina Infinium Humanmethylation 450k array. ASD risk was estimated at 12-months using the clinician administered Autism Observation Scale for Infants (AOSI) scale. We tested pairwise associations between PBDE concentration and DNA methylation as well as DNA methylation and AOSI score. We will use causal inference testing to assess mediation of the potential PBDE-ASD relationship via DNA methylation.
Results: Paired maternal PBDE, cord DNAm, and offspring AOSI were available for 201 families. AOSI scores ranged from 0-20 (mean(SD) 5.4(4.8)). PBDE-28 concentration ranged from 0-69.1 pg/g (mean(SD): 7.6(10.2)) and PBDE-99 concentration ranged from 0-365.1 pg/g (mean(SD): 29.9(52.0)). DNA methylation was modestly associated with specific PBDE congener concentrations and DNA methylation was also associated with AOSI score at specific locations. Results of the mediation analysis will be presented.
Conclusions: This is a proof-of-concept study using PBDEs as an example for testing mediation of an exposure-ASD relationship via DNA methylation. DNA methylation represents an intersection of environmental exposures and underlying genetic architecture, and may be an effective tool for estimating gene-environment interaction in ASD risk.

1:57 **112.002** Polygene – By – Prenatal Environment Interaction in Autism Spectrum Disorder Using Copy Number Variant Burden

B. Sheppard[1], *K. Benke*[2], *A. B. Singer*[3], *L. A. Croen*[4], *J. L. Daniels*[3], *C. J. Newschaffer*[5], *A. M. Reynolds*[6], *D. E. Schendel*[7], *L. A. Schieve*[8], *C. Ladd-Acosta*[9] *and M. D.*

Fallin[10,11], (1)Epidemiology, Johns Hopkins School of Public Health, Baltimore, MD, (2)Mental Health, Johns Hopkins School of Public Health, Baltimore, MD, (3)University of North Carolina, Chapel Hill, NC, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)A.J. Drexel Autism Institute, Philadelphia, PA, (6)University of Colorado - Denver, Aurora, CO, (7)Aarhus University, Aarhus, Denmark, (8)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, (9)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (10)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (11)Johns Hopkins Bloomberg School of Public Health (JHBSPH), Baltimore, MD

Background: Autism Spectrum Disorder (ASD) is a complex disease with both genetic and environmental risk factors. Increased copy number variation (CNV) burden has previously been associated with (ASD). The prenatal period is also of increasing importance towards understanding the environmental risk factors contributing to ASD etiology. However, evidence for specific environmental risk factors has been inconclusive. A joint approach allowing for the possibility that environmental effect may be modified by polygenic risk, as measured by CNV burden, may increase the ability to detect environmental effects.
Objectives: The purpose of this work is to evaluate the association between four prenatal self-reported environmental exposures – smoking, alcohol, beta-2 adrenergic receptor (B2AR) agonists, and selective serotonin reuptake inhibitors (SSRI) – and ASD, while allowing for potential effect modification by CNV burden in the Study to Explore Early Development (SEED).
Methods: SEED is a multi-site case-control study of children aged 3-5 years with ASD and a control group drawn from the general population. All children were born between September 2003 and August 2006. Prenatal exposure to environmental risk factors was ascertained through a detailed maternal interview that occurred 3-5 years after pregnancy. A Hidden Markov Model approach (PennCNV) was used to call CNVs from Illumina genotype array data. Measures of CNV burden were assessed on both a genome-wide scale and restricted to ASD candidate regions determined by the SFARI gene online database. Associations with environmental exposures were first assessed by likelihood ratio test (LRT) comparing the likelihood of a full model with environmental exposure plus covariate terms to a null model constraining environmental exposure term to zero (H_0: $\beta_E = 0$). Interactions were then tested by a 2-degree-of-freedom LRT comparison of a full model with CNV burden, environmental exposure, and interaction terms to a null model where environment and interaction terms are jointly constrained to zero (H_0: $\beta_{CNVxE} = \beta_E = 0$). All models contained sex and the first five ancestral principal components derived from principal component analysis on measured single nucleotide polymorphisms (SNPs) as covariates.
Results: Allowing for effect modification by copy number burden revealed a significant association between prenatal SSRI use and ASD in the presence of large (>400kb) CNVs (LRT p = 0.033), where the CNV-free SSRI association was not statistically significant. Additionally, a negative association between prenatal alcohol exposure and ASD was revealed among those with high CNV kb burden in SFARI candidate genes (LRT p = 0.011). Prenatal smoking exposure was associated with ASD risk with and without consideration of CNV burden, although adjustment for potential SES confounders was not yet considered.
Conclusions: To our knowledge, this is the first effort to evaluate genome-wide CNV burden by environment interaction in an ASD case and population-derived control sample. Allowing for the presence of effect modification by CNV burden permitted us to detect associations of ASD with self-reported prenatal alcohol and SSRI exposure where the marginal testing failed to do so. Accounting for genetic risk may potentially elucidate mechanisms of environmental risk for ASD.

2:09 **112.003** Dysregulation of RORA, a Risk Gene for ASD, By "Low-Dose" Exposure to the Herbicide Atrazine, an Endocrine Disrupting Compound

***K. Kocher**, K. Janczura and V. Hu, Dept. of Biochemistry and Molecular Medicine, The George Washington University, Washington, DC*

Background: We have previously shown that retinoic acid-related orphan receptor alpha (*RORA*) is deficient in a subgroup of individuals with ASD and that it potentially regulates the transcription of hundreds of ASD-associated genes. Because *RORA* is in turn regulated in opposite directions by male and female sex hormones, we hypothesize that *RORA* may be dysregulated by endocrine disrupting compounds (EDCs), like the herbicide atrazine, which may result in downstream or genome-wide changes in the expression of genes relevant to the pathobiology of ASD.
Objectives: The goals of this study were to: 1) investigate changes in *RORA* expression induced by low-dose exposure to atrazine; 2) investigate the potential for genome-wide alterations of biochemical pathways relevant to ASD; and 3) develop a high-throughput assay for screening other EDCs that may elevate risk for ASD based on dysregulation of *RORA* expression.
Methods:
Treatment of neuronal cells with low-dose atrazine. The human neuronal cell model (SH-SY5Y) was exposed to 10-fold dilutions of atrazine solubilized in DMSO (range 0.1nM-1000nM) for 2 hours.
RORA expression and transcriptome analyses. *RORA* expression as a function of atrazine concentration was determined by RT-qPCR analyses. Transcriptome analyses of atrazine-treated SH-SY5Y samples at selected doses were also performed using the Affymetrix GeneChip Human Transcriptome Array 2.0. Genome-wide expression changes were analyzed using Transcriptome Array Console (TAC) and Expression Console software, as well as Partek Genomics Suite. Functional and network prediction analyses were performed using QIAGEN Ingenuity Pathway Analysis (IPA).
Development of a high-throughput screening assay. SH-SY5Y cells were co-transfected with a construct containing the *RORA* promoter-driven Firefly luciferase reporter gene and a separate construct containing the *Renilla reniformis* luciferase gene under the control of a constitutive promoter. Following transfection, the cells were exposed to varying levels of atrazine for 2 hours. Firefly luciferase activity was normalized to that of *Renilla* luciferase in each well to determine the relative levels of *RORA* promoter activity in each sample.
Results: Preliminary results show that *RORA* is dysregulated biphasically in a neuronal cell model by low-dose exposure to atrazine. Additionally, using microarrays for expression profiling, we were able to observe that exposure to subnanomolar and nanomolar concentrations of atrazine induce differential gene expression at the whole genome level, notably affecting genes with ASD-associated neurological functions. Furthermore, a number of genes impacted by atrazine exposure are among the annotated genes within the SFARI database of ASD risk genes. The high-throughput dual-luciferase reporter assay replicates in part the atrazine-induced changes in *RORA* expression seen by RT-qPCR analyses.
Conclusions: Low, subtoxic doses of EDCs, such as atrazine, may increase risk for ASD by dysregulating *RORA*, a gene that we have validated as a transcriptional regulator of multiple genes associated with the pathobiology of autism. We anticipate that our high-throughput screen will provide additional insight into gene-environment interactions that impact neurodevelopment as well as increased awareness of the biological consequences of low-dose levels of EDCs that are below current EPA-approved limits.

2:21 **112.004** Maternal Immune Activation Dysregulation of the Fetal Brain Transcriptome and Relevance to the Pathophysiology of Autism

*M. V. Lombardo[1,2], E. Courchesne[3] and **T. Pramparo**[4], (1)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (2)Department of Psychology and Center for Applied Neuroscience, University of Cyprus, Nikosia, Cyprus, (3)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA, (4)Autism Center of Excellence, UCSD, La Jolla, CA*

Background: Maternal immune activation (MIA) has emerged as a useful model to study how maternal infections during pregnancy might confer prenatal environmental risk for atypical neurodevelopmental phenotypes such as autism spectrum disorders (ASD). However, the molecular cascade of events due to MIA that lead to transcriptome dysregulation that is shared with ASD is less well understood.
Objectives: We tested the hypothesis that MIA-induced gene expression dysregulation would hit ASD-associated genes. These genes have been prioritized based on highly penetrant and recurrent "likely gene-disrupting" variants as well as missense mutations found in large genomic ASD studies. We also aimed to identify the transcriptional changes, both at the single gene level and at the network level, characteristic of the ASD postmortem brain that are shared in the MIA rat fetal brain.
Methods: We employed differential expression (DE) analyses to identify genes and networks dysregulation in ASD and MIA cortical transcriptomes. We used two publicly available datasets, Voineagu and colleagues (2011; GEO: GSE28521) and Oskvig and colleagues (2012; GEO: GSE34058). DE analyses were performed using the sva and limma packages. Network analyses were performed using the WGCNA package. Functional enrichment analyses were performed using the MetaCore GeneGO software.
Results: We show that MIA-dysregulated midgestational fetal brain gene expression is substantially enriched in highly penetrant ASD-associated genetic mechanisms. MIA downregulates pathways involved in synaptic processes, but upregulates translation initiation processes and both sets of processes are similarly dysregulated in the postnatal ASD cortical transcriptome. Upregulated translation initiation co-expression modules are highly preserved across MIA and ASD. The cap-dependent translation initiation gene *EIF4E* is the most affected ASD-associated gene (Cohen's d = 8.27) and targeted analyses demonstrate prominent MIA-dysregulation of *EIF4E*-dependent networks and mechanisms.
Conclusions: This work identifies several routes through which MIA can dysregulate fetal brain gene expression that are highly relevant to ASD.

Oral Session - 1B

113 - Mouse Models of Environmental and Genetic Risk Factors in Autism Spectrum Disorder

2:40 PM - 3:30 PM - Hall B

2:40 **113.001** Autism-Relevant Behaviors in the Antigen-Driven Mouse Model of Maternal Autoantibody Related Autism

***K. L. Jones**[1], J. L. Silverman[2], M. Yang[3], E. Edmiston[2], J. N. Crawley[4] and J. Van de Water[5], (1)University of California at Davis, Sacramento, CA, (2)UC Davis, Sacramento, CA, (3)UC Davis School of Medicine, Sacramento, CA, (4)Psychiatry and Behavioral Sciences, MIND Institute, Sacramento, CA, (5)University of California at Davis MIND Institute, Davis, CA*

Background: Maternal autoantibodies reactive to fetal brain proteins have been described in a subset of mothers of children with autism spectrum disorder (ASD), but not in mothers of typically developing children, by numerous researchers. Additionally, several animal models have demonstrated the pathological significance of these autoantibodies using passive transfer of human IgG, further supporting their role in the development of ASD. Our lab identified the seven protein antigens for maternal autoantibody related (MAR) ASD, finding antibody reactivity to these proteins in 23% of mothers of children with ASD versus less than 1% in women with typically developing children. Most recently, we have mapped the antigenic epitope sequences recognized by these ASD-specific maternal autoantibodies. Previous animal models have all utilized passive transfer of human IgG yielding promising results but did not reflect a constant exposure to the salient autoantibodies throughout gestation, as would be the case in the clinical setting.
Objectives: This study aimed to generate the first biologically relevant animal model of MAR ASD in order to directly assess the pathologic significance of prenatal exposure to epitope-specific autoantibodies in generating autism-relevant behaviors in offspring.
Methods: Prior to breeding, female C57BL/6J dams were randomly assigned to either MAR-ASD or control treatment. In order to generate epitope-specific autoantibodies that mimic those found in the mothers of children with ASD, the MAR-ASD females received a series of immunizations containing peptide epitope sequences of the four primary target proteins of MAR ASD (lactate dehydrogenase A and B, collapsin response mediator protein 1, and stress-induced phosphoprotein 1) conjugated via Multiple Antigenetic Peptide (MAP) system technologies in addition to adjuvant. Control females were injected with saline only. Following confirmation of autoantibody production in immunized animals by ELISA, females were then paired with male breeders to produce the experimental offspring of interest. Subsequent male and female offspring were tested for a variety of autism-relevant behaviors and developmental milestones (MAR-ASD offspring = 24; Control offspring = 22).
Results: MAR-ASD offspring had significant alterations in development, with significant increases in body weight on postnatal days (PD) 4-14 and head width on PD 12 relative to control offspring ($p<0.01$). During juvenile reciprocal social interactions on PD 25, MAR-ASD offspring displayed robust deficits in social interactions as compared to control offspring, with significant decreases in the number of front approach, nose-to-nose sniffing, nose-to-anogenital sniffing, push/crawl, and following bouts ($p<0.045$). Furthermore, significantly more rearing and self-grooming ($p<0.0001$) bouts were observed in MAR-ASD offspring compared to controls ($p<0.0001$).
Conclusions: Our results suggest that the presence of autism-specific maternal autoantibodies to fetal brain protein during gestation produce alterations in development and behaviors that are highly relevant to ASD. By generating the MAR ASD-specific epitope antibodies in female mice prior to breeding, our antigen-driven model demonstrates for the first time that these ASD-specific maternal autoantibodies are directly responsible for alterations in behaviors. These findings contribute to the ongoing efforts toward identification of biological markers specific to sub-phenotypes of autism, and the establishment of a highly translatable animal model of ASD.

2:52 **113.002** Prenatal Immune Activation Alters the Adult Neural Epigenome but Can be Partly Stabilized By a n-3 Polyunsaturated Fatty Acid Diet

ABSTRACT WITHDRAWN

Background:
Prenatal exposure to Maternal Immune Activation (MIA) increases the risk of autism. The MIA rodent model permits direct experimental evaluation of the biological mechanisms driving this vulnerability. It also provides an opportunity to screen novel prevention strategies.
Objectives:
In this study we tested the hypotheses that MIA in the mouse model has wide-spread effects on the epigenome; and that these can be prevented by a post-weaning diet enriched with *n-3* polyunsaturated fatty acids (PUFA).
Methods:
Pregnant mice were exposed to intravenous Polyl:C (a viral analogue) or saline (control) on gestation day 9. Half the offspring were weaned using a conventional lab diet (*n-6* PUFA); half had a *n-3* PUFA enriched diet. Genome-wide DNA methylation in hypothalamic brain tissue was examined using Next Generation Sequencing techniques.
Results:
Adult offspring exposed to MIA prenatally had significant global DNA hypomethylation. Pathway analyses revealed that genes regulating synaptic plasticity were differentially methylated following MIA. Moreover, DNA methylation differences were concentrated at risk loci linked to neurodevelopmental disorders. More than 80% of genes affected by MIA were 'stabilized' by the n-3 PUFA intervention.
Conclusions:
Thus, MIA during prenatal life causes persistent widespread epigenetic changes in the postnatal brain that can be limited by early dietary intervention with n-3 PUFA. These effects on the epigenome may have functional consequences. For example, we have previously reported that the brain biochemical and behavioural consequences of MIA can also be prevented by n-3 PUFA diet. That the developmental impact of early life immune activation can be modified - especially by a relatively simple and low cost intervention – is a critical observation and deserves further study.

3:04 **113.003** Maternal Stress Causes Behavioral Changes in C57BL/6J Mice

K. K. Chadman[1] *and L. Leone*[2]*, (1)Developmental Neurobiology, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (2)Developmental Neuroscience, College of Staten Island, City University of New York, Staten Island, NY*

Background: The etiology for most cases of autism spectrum disorder (ASD) is unknown at this time. There is strong evidence for the genetic role in ASD but environmental factors also have a modifying role. One potential environmental factor is maternal stress during pregnancy. Stress during prenatal development increases the vulnerability of affective disorders including schizophrenia and ASD. Prenatal stress has been shown to lead to postnatal behaviors that resemble the defining symptoms of ASD as well as other behaviors that occur frequently in ASD (Kinney et al., 2008).
Objectives: The objective of these experiments was to determine if restraint stress during pregnancy results in autistic-like behavioral alterations in the offspring. A commonly used inbred mouse strain, C57BL/6J was used because these mice to not typically have behaviors resembling the ASD phenotype.
Methods: Timed pregnant C57BL/6J mice were subject to restraint stress three times a day for 30 minutes, at least 2 hours apart for 9 days starting on GD11. The control pregnant mice were left undisturbed during gestation. Both male and female offspring from both stressed and control dams were behaviorally phenotyped as adults. One female and male per litter were used in up to four tests, each test at least 2 days apart. The tests included the social approach test, elevated plus maze, light <--> dark box, marble burying, rotarod, open field and cued and contextual fear conditioning.
Results: In general there were few differences between the male and female offspring. There were no significant effects of maternal stress in the offspring on tests of anxiety such as the elevated plus maze and light <--> dark box, obsessive-compulsive like behavior in the marble burying and spontaneous grooming tests, motor ability and learning on the accelerating rotarod, or learning and memory assessed by the cued and contextual fear conditioning test. However, there were differences in social behavior and acute exploratory activity between the stressed and control mice. The offspring from the stressed dams were less social, spending less time sniffing the stranger mouse in the social approach test compared to the novel object. The stressed mice were also less active at the beginning of the open field exploration test, as shown by travelling a significantly smaller distance, having a reduced speed and spending more time immobile than the control mice.
Conclusions: Prenatal restraint stress affected the behavior of these mice in ways that resemble one of the defining symptoms of ASD, decreased social behavior. Future testing with other inbred strains, including ones that are already considered mouse models of ASD will hopefully shed light on the contribution of prenatal stress to the etiology of ASD. This will provide information on a potentially preventable environmental factor associated with ASD.

3:16 **113.004** Aberrant Sensory Processing in Mice Lacking Autism Associated Met Receptor Function: A Role for Insulin?

F. S. Lo, R. Erzurumlu and ***E. M. Powell****, Anatomy & Neurobiology, University of Maryland - Medicine, Baltimore, MD*

Background: *MET*, the gene encoding the tyrosine kinase receptor for hepatocyte growth factor/scatter factor (HGF/SF), has been identified as a common susceptibility allele for autism spectrum disorders (ASD). Both Met and HGF are expressed in the cerebral cortex during development, and HGF-Met signaling has been implicated in a number of cellular processes, including proliferation, migration, survival, and process formation. Alterations in HGF-Met signaling may therefore affect cortical development, potentially leading to neuroanatomical changes such as those thought to play a role in neurodevelopmental disorders such as ASD. We have previously found an expansion of the cerebral cortex at rostral levels in transgenic mice expressing a kinase-dead Met in the *Emx1* lineage. Earlier studies imply defects in cortical connectivity after loss of Met signaling in the *Met-Emx1* mice. Behavioral observations indicate potential altered sensory processing in *Met-Emx1* mice.
Objectives: We investigated sensory processing in mice lacking functional Met receptor in the cerebral cortex (*Met-Emx1*). The study focused on the rodent whisker system and the inhibitory response in the barrel cortex to reveal underlying cellular mechanisms of decreased or absent Met signaling.
Methods: We used in vitro recordings from thalamocortical slices to test our hypotheses that loss of Met altered the balance of excitation to inhibition (AMPA/GABA ratio). We also measured the multiple input index and paired pulse ratios of EPSCs and IPSCs. Immunohistochemistry and immunoblots were used to confirm expression levels and anatomical alterations.
Results: Our data show altered excitation/inhibition (E/I) balance at the thalamocortical synapse. In addition, treatment with insulin, which recruits GABA-A receptors to restore inhibition in control slices, failed to change the E/I balance in slices lacking a single copy of functional *Met*.
Conclusions: Our results suggest that the sensory circuitry in the *Met-Emx1* cortex exhibits impaired E/I balance and is resistant to insulin. These data suggest the approved therapies for diabetes may be helpful in the prevention or amelioration of the symptoms associated with ASD, especially in the individuals who have the common autism associated *MET* alleles.

Oral Session - 2A

114 - Sensory and Motor Phenotypes Useful for Biomarkers and Parsing Heterogeneity

1:45 PM - 2:35 PM - Room 307

1:45 **114.001** Common Sensory Endophenotypes Spanning Sensory Processing Disorder and the Autism Spectrum

J. J. Foxe[1,2] *and S. Molholm*[3]*, (1)Albert Einstein College of Medicine, Bronx, NY, (2)Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY, (3)Neuroscience and Pediatrics, Albert Einstein College of Medicine, Bronx, NY*

Background:
Sensory-processing anomalies constitute a hallmark symptom domain of the ASDs, but similar sensory symptoms are often observed in other neurodevelopmental disorders (e.g. Obsessive Compulsive Disorder, Attention Deficit Hyperactivity Disorder), suggesting some shared genetic liability and the possibility of common endophenotypes. There is also emerging recognition amongst clinicians and researchers that there exists a substantial cohort of children who do not meet diagnostic criteria for a categorical neurodevelopmental disorder, but nonetheless manifest clinical levels of hypo- or hyper-sensitivity to sensory inputs. These otherwise typical children with sensory processing disorder (SPD) are of specific interest to the research community in that the restriction of their pathology to the sensory processing domain allows for study of a relatively "purified" phenotype.
Objectives:
To assess both basic unisensory and multisensory processing in SPD with the use of psychophysics and high-density electrophysiological recordings of brain activity, and compare with unisensory and multisensory processing in neurotypical controls and individuals with ASD.
Methods: N/A
Results:
Study 1: Somatosensory evoked potentials (SEPs) to trains of stimuli delivered at varying presentation rates (ISIs ranging from 150ms to 1050ms) were examined to determine whether differences in the initial registration and processing of tactile inputs might account, in part, for aberrant reactions to the sensory environment. Thirteen children with SPD (5.3 - 15.2 years) and 13 matched neurotypicals produced SEPs that were similar in their temporal and spatial properties. Clear between-group differences in SEP amplitude as a function of stimulation rate were observed, and these were most apparent in later phases of sensory processing (130-195ms). Response slopes as a function of ISI suggested a steeper slope for the SPD group, due to greater increase in response amplitude as ISI increased. These findings suggest a potential neural mechanism for the increased reactivity to tactile inputs observed in SPD.
Study 2: High-density ERPs interrogated multisensory integration (MSI) in three groups of fourteen age- and IQ-matched children: those with ASD, those with SPD, and neurotypical individuals. Participants responded as quickly as possible to unisensory-visual, unisensory-auditory or bisensory-audiovisual stimuli. Probing the behavioral data for evidence of MSI (i.e., race model violation) indicated clear separation between the two clinical groups and the TD children, and analysis of the electrophysiological data subtly distinguished children in the ASD group from their peers in the TD and SPD groups.
Study 3: It is now well-established that children with an ASD show severe deficits in their ability to integrate seen and heard speech. Children with SPD do not show the social communication deficits that are part of the diagnostic criteria for an ASD. Here we asked whether they would also show deficits in multisensory speech integration under noisy environmental conditions. Monosyllabic words were presented in different levels of noise, which were sometimes accompanied by videos of the person articulating the word. Comparing performance measures of 12 SPD children to 12 matched neurotypical controls, we find a clear deficit in multisensory speech integration.
Conclusions:
Collectively, these studies point to clear anomalies in sensory processing across three modalities in SPD children.

1:57 **114.002** Reduced GABA Levels Predict Altered Sensory Function in Children with Autism Spectrum Disorder

N. A. Puts[1,2]*, E. L. Wodka*[3]*, A. D. Harris*[4]*, D. Crocetti*[3]*, M. Tommerdahl*[5]*, R. A. Edden*[6] *and S. H. Mostofsky*[7]*, (1)Radiology and Radiological Science, Johns Hopkins University, Baltimore, MD, (2)FM Kirby Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, (3)Kennedy Krieger Institute, Baltimore, MD, (4)Department of Radiology, University of Calgary, Calgary, AB, Canada, (5)University of North Carolina, Chapel Hill, NC, (6)Johns Hopkins University School of Medicine, Baltimore, MD, (7)Johns Hopkins School of Medicine, Baltimore, MD*

Background: Difficulties with sensory stimuli have been increasingly recognized and are now included as a diagnostic feature of ASD. Multiple lines of evidence suggest that GABA, the main inhibitory neurotransmitter in the brain, plays a role in the pathophysiology of ASD. It is well known that GABA plays a key role in regulating tactile processing. However, the link between GABA and autism-associated impairments in vibrotactile processing remains unclear.
Objectives: GABA can be measured using edited Magnetic Resonance Spectroscopy (MRS) and we developed a technique to measure tactile sensitivity in children objectively, in tasks linked to inhibition[6]. In this study, in a large cohort, we aimed to investigate whether 1) children with ASD have reduced GABA levels, 2) children with ASD show altered vibrotactile processing, and 3) whether altered GABA levels are associated with abnormal tactile processing in ASD.
Methods: Subject and parental consent were obtained under local IRB approval. Data were acquired in 37 children with ASD (10.69 ± 1.4 years, 6F) and 35 TDC (10.09 ± 1.25 years; 8F). Children had normal IQ. GABA-edited MR spectra were acquired from $(3\ cm)^3$ voxels over right primary sensorimotor (Fig 1A&B) and occipital cortices. GABA levels were calculated against the unsuppressed water signal from the same voxel and tissue corrected. *Behavioral*: Children performed: 1) Static and Dynamic detection tasks (DT; where the increasing (dynamic) sub-threshold stimulus is thought to act through feed-forward inhibition); 2) Amplitude discrimination with- and without an adapting stimulus (AD; linked to lateral inhibition); and 3) Frequency discrimination (FD; encoded through GABAergic inhibition).
Results:
Sensorimotor GABA levels were significantly reduced in children with ASD compared to TDC (2.20 ± 0.44 i.u. and 2.40 ± 0.25 i.u. respectively, $p = 0.016$). There were no group differences in occipital GABA levels. For children with ASD, sensorimotor GABA levels correlated positively with dynamic DT, with higher GABA levels indicating a higher DT (Fig 1C). The difference between a static and dynamic DT (Figure 1D) were significantly correlated with GABA levels within the entire cohort; this finding was driven by children with ASD, such that those with lower GABA levels showed a reduced effect of sub-threshold stimulation. AD performance after single-site adaptation correlated with GABA levels in TDC but not in ASD (Fig 1E) adaptation was absent in ASD. Tactile FD is correlated with GABA in TDC, which has been previously reported (Fig 1F); this association was not observed in ASD.
Conclusions: Sensorimotor GABA levels were reduced in children with ASD compared to TDC, while occipital levels are normal, consistent with previous work. Tactile abnormalities in ASD were consistent with previous work, and consistent with reduced GABA-mediated inhibition. Our correlative results are consistent with the prediction for children with ASD; reduced GABA level was associated with stronger effect of modulating stimuli. Children with ASD show reduced GABA levels, and are associated with abnormalities in tactile performance. Altered in vivo GABA levels might explain abnormal tactile information processing in ASD. The GABA system may be a future and novel target for therapies in ASD.

2:09 **114.003** The Variability of Restricted Repetitive Behavior in Neurodevelopmental and Neuropsychiatric Disorders

D. W. Evans, *Geisinger Health System, Lewisburg, PA*

Background:
Restricted, repetitive behavior (RRB) appears in a wide variety of neurodevelopmental and neuropsychiatric disorders including intellectual disability (ID), autism spectrum disorders (ASD), obsessive-compulsive disorder (OCD), Tourette syndrome (TS) and schizophrenia (Sz), among others. Within each diagnosis there is substantial individual variability in the severity of RRB; the source of this variability has been the subject of considerable debate. Our recent work on genetic copy number variation syndromes (CNVs) indicates that probands' phenotypic variability on a range of quantitative traits is influenced by family background factors. Thus the degree of impairment exhibited by patients/probands may be influenced by the performance of non-carrier/non-patient family relatives.
Objectives: This study aims to explore sources of variability of RRBs across neurodevelopmental and neuropsychiatric disorders. We examine parental RRB as a contributing factor explaining the variability of children's RRB in a range of disorders.
Methods: Three thousand twenty-nine families with at least one child ranging in age from 1 to 18 years of age participated in an online assessment of RRB. These families were recruited through Scientific Sampling International, and were demographically representative of the general U.S. population in terms of race/ethnicity, geographic region, income, and mental health status. Seven hundred forty seven of these children had been diagnosed with at least one neurodevelopmental/neuropsychiatric disorder, including developmental delay, developmental coordination disorder, intellectual disability, ASD, specific language impairment, OCD, TS, depression, anxiety, bi-polar disorder, and schizophrenia. Parents completed the Childhood Routines Inventory-Revised (CRI-R) a 63-item parent report measure of repetitive behavior and restricted interests. Parents also self-reported on the newly developed Adult Routines Inventory (ARI).
Results:
Factor analysis revealed a two-factor solution for both the CRI-R and the ARI: Motor Behavior and Compulsions (MBC) and Restricted Interests/Insistence on Sameness (RIS). Next we created "clusters" based on children's diagnoses. These included: ADHD, depression/anxiety, developmental delay/intellectual disability, ASD, conduct disorder/oppositional defiant disorder, obsessive-compulsive disorder/Tourette syndrome, bi-polar/schizophrenia. Analysis of Variance compared the total CRI-R, MBC and RIS t-scores between the diagnostic cluster groups. The groups differed significantly for total CRI-R ($F(8,2852)= 59.24$); MBC ($F(8,2852)=41.20$) and RIS ($F(8,2852)=59.86$ (all $p< 0.00001$). Post hoc tests revealed that the ASD and OCD/TS groups had higher total CRI-R scores and for MBC than all other diagnostic groups. For the RIS factor, bi-polar/schizophrenia and OCD/TS were higher than all other groups, with ASD similar to all other diagnostic groups (and greater than children with no diagnosis). Further analyses revealed that a) parent- child intraclass correlations on all scales of the ARI and CRI-R were significant; b) the parents of children with a diagnosis had elevated ARI scores – even when the parents themselves had no history of a clinical diagnosis.
Conclusions:
The findings reported here provide further clarification of the nature of RRB across a variety of neurodevelopmental and neuropsychiatric disorders. We discuss the relevance of these findings for quantitative approaches to clinical assessment and diagnosis. We also discuss the importance of considering family background when determining clinical morbidity, particularly in studies of genomic copy number variation syndromes.

2:21 **114.004** Sensorimotor Abnormalities in Biological Mothers and Fathers of Individuals with ASD

L. M. Schmitt[1,2], *S. P. White*[2,3], *K. C. Conroy*[2], *J. A. Sweeney*[2,3] *and M. W. Mosconi*[4], *(1)UT Southwestern Medical Center, Dallas, TX, (2)Center for Autism and Developmental Disabilities, Dallas, TX, (3)Center for Autism and Developmental Disabilities, University of Texas Southwestern, Dallas, TX, (4)Dole Human Development Center, University of Kansas, Lawrence, KS*

Background: Eye movement studies provide a precisely quantifiable and translational method for examining sensorimotor impairments in autism spectrum disorder (ASD). Individuals with ASD show reduced accuracy and increased accuracy variability of saccadic eye movements. We have demonstrated that unaffected first-degree relatives of individuals with ASD also show reduced saccade accuracy and increased saccade variability suggesting that eye movement abnormalities may be familial. Here, we used a family trio design to determine the extent to which eye movement abnormalities are familial, and to examine whether they are differentially expressed in mothers versus fathers.
Objectives: To assess the familiality of eye movement abnormalities in individuals with ASD and their unaffected parents.

Methods: Thirty-five family trios (proband with ASD, biological mother, biological father) and 70 age-, IQ- and gender-matched healthy controls (42 proband controls, 28 parent controls) completed eye movement testing. Participants with ASD were between ages 6-20 years, 89% male, and had a Performance IQ >70. Parents of probands were <55 years old and completed the Broad Autism Phenotype-Questionnaire (BAP-Q). Participants completed 60 trials of a visually-guided saccade task during which they made saccades to peripheral targets that appeared with equal probability at 12 or 24 deg to the left or right of center**.** Saccade accuracy, accuracy variability, peak velocity, and peak acceleration were measured for each trial.
Results: During the visually-guided saccade task, individuals with ASD demonstrated reduced saccade accuracy and increased accuracy variability compared to age-matched controls**.** Mothers of individuals with ASD also demonstrated reduced saccade accuracy compared to adult female controls. Fathers of individuals with ASD did not show any differences in the accuracy or variability of their saccades relative to male controls. Deficits in saccade accuracy, peak velocity, and peak acceleration were found to be highly familial, co-varying more strongly in mother-child versus father-child dyads. However, their saccade accuracy and accuracy variability were associated with BAP-Q rated social aloofness, pragmatic language deficits, and behavioral rigidity for fathers of individuals with ASD. This was not observed for mothers, and no other cognitive or demographic characteristics related to their oculomotor deficits.
Conclusions:
Our findings provide further support that sensorimotor impairments in ASD are familial, with novel evidence suggesting primarily maternal influences. Fathers did not show sensorimotor deficits compared to controls, but their ability to make accurate saccades was related to broader autism phenotypic characteristics suggesting that sensorimotor processes among unaffected fathers may be one component of a broader constellation of sub-clinical features that confer risk onto their offspring. In contrast, mothers in our sample appear to have relatively isolated sensorimotor deficits that may be directly related to the deficits observed in their offspring, yet have factors protecting them from exhibiting broader phenotypic characteristics. Future studies should be aimed at better understanding maternal versus paternal contributions to risk susceptibility in ASD, identifying potential protective factors in mothers, and determining how maternal and paternal influences affect sensorimotor functioning in female probands.

115 - Early Dysmaturation of Sensory and Motor Systems as Critical Predictors of Symptom Severity

2:40 PM - 3:30 PM - Room 307

2:40 **115.001** Cataloguing and Characterizing Interests in Typically Developing Toddlers and Toddlers Who Develop ASD

*J. T. Elison[1], J. J. Wolff[2], **E. P. Teska**[1], K. Botteron[3], A. M. Estes[4], H. C. Hazlett[5], J. Pandey[6], R. T. Schultz[7], L. Zwaigenbaum[8], J. Piven[9] and .. The IBIS Network[9], (1)Institute of Child Development, University of Minnesota, Minneapolis, MN, (2)University of Minnesota, Minneapolis, MN, (3)Psychiatry and Radiology, Washington University School of Medicine, St. Louis, MO, (4)University of Washington Autism Center, Seattle, WA, (5)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Children's Hospital of Philadelphia, Philadelphia, PA, (7)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (8)University of Alberta, Edmonton, AB, Canada, (9)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Little is known about the prospective emergence of restricted interests in autism spectrum disorder (ASD).
Objectives: Our aims were three-fold: 1) attempt a replication and extension of DeLoache et al. (2007) findings that indicate a greater proportion of typically developing toddler/preschool-aged males show extremely intense interests as compared to similar aged females; 2) examine whether the intensity and/or peculiarity of interests reported at 18 or 24 months differentiated children at high-familial-risk who later met diagnostic criteria for ASD at 24 months as compared to high and low risk children who did not meet diagnostic criteria at 24 months; and 3) test a feature of the "extreme male brain theory" by examining whether females at high-familial risk for developing ASD show a greater proportion of male sex-typed interests as compared to low-risk females.
Methods: The *Intense Interests Inventory* (Elison & Bodfish, 2009) was conducted in a semi-structured interview format. Parents reported their child's primary interests at 18 and 24 months of age in the context of the IBIS study. Interests were rated by clinical examiners on a 5-point scale with respect to the intensity and peculiarity of each interest listed. The sample consisted of 95 low-risk infants (53 males), 157 high-risk infants who did not meet diagnostic criteria for ASD at 24 months (86 males), and 38 high-risk infants who met diagnostic criteria for ASD at 24 months (33 males).
Results: 1) Among children not meeting diagnostic criteria for ASD at 24 months, a Mann-Whitney U test revealed that the distribution of intensity ratings varied across sex ($p = 0.029$) at 18 months of age, with a greater proportion of males showing moderate or intense interests as compared to females. The effect of sex was not significant at 24 months. 2) Interests of high-risk infants who met diagnostic criteria for ASD at 24 months were rated as more peculiar at 18 months (Mann-Whitney U test, $p = 0.006$) and 24 months (Mann-Whitney U test, $p = 0.030$) as compared to those children not meeting diagnostic criteria. The intensity of interests did not differentiate these two groups. 3) The proportion of females, who do not meet diagnostic criteria for ASD at 24 months and whose primary interest was classified as masculine, feminine, or indeterminate did not depend on familial risk status (18 months, $p = 0.325$; 24 months, $p = 0.572$).
Conclusions: We report evidence partially consistent with DeLoache et al. (2007) that a greater proportion of males show intense interests at 18 months as compared to females, but this finding may be transient or specific to this age. We also report evidence consistent with ADI-R conventions that peculiarity of interests and not the intensity of interests differentiate children who meet diagnostic criteria at 24 months of age. Finally, our finding that females at high-risk for ASD do not show a greater proportion of male sex-typed interests as compared to low-risk females does not support the extreme male brain theory.

2:52 **115.002** Infant Motor Skill and ASD

***E. S. LeBarton**[1] and R. Landa[2], (1)Kennedy Krieger Institute & Johns Hopkins School of Medicine, Baltimore, MD, (2)The Kennedy Krieger Institute, Baltimore, MD*

Background: Emerging theoretical and empirical work suggests that infant motor skill is a characteristic of a prodromal period for autism spectrum disorder (ASD) and developmental vulnerability in infants with an older sibling with ASD (High-risk, HR infants). However, few studies have focused on the first year of life—when delays are proposed to be first evident. Further, little research has addressed this question for HR infants for whom developmental delays have been observed.
Objectives: (1) Examine the presence of motor delays in HR infants relative to infants with no family history of ASD (Low-risk, LR infants). (2) Examine the presence of motor delays in infants later identified with ASD. (3) Examine the relation between infant motor skill and concurrent ASD symptomatology.
Methods: Our sample included 104 HR infants and 55 LR infants assessed at 6 months of age as part of an ongoing longitudinal study. Older sibling's ASD was confirmed using the Autism Diagnostic Observation Schedule (ADOS) and clinical judgment. We assessed infant motor skill using the standardized Peabody Developmental Motor Scales (PDMS). Motivated by previous work, we used the Stationary gross motor subscale and two fine motor subscales (Grasping and Visual-motor Integration, VMI). To assess autism symptomatology at 6 months, we administered the Autism Observation Scale for infants (AOSI). To date, a subset of 74 infants (49 HR, 25 LR) have reached a 24-month follow-up session and these infants were divided into one of two groups based on whether they met our ASD criteria (ADOS score for ASD and clinical judgment). This resulted in 11 infants with ASD (all from HR group) and 63 infants without ASD (No Diagnosis, ND group). Due to unequal sample sizes, we performed non-parametric tests for all analyses (the pattern of results is unchanged using parametric alternatives).
Results: We found that the HR infants scored lower than LR infants on the Stationary scale (z=2.76, p=.006) and both fine motor scales (Grasping: z=2.52, p=.012; VMI: z=2.03, p=.043) (Figure 1). A subset of infants had AOSI scores available (HR: n=74, HR: n=45) to test relations between infant motor skill and concurrent autism symptomatology. Overall, the HR group had higher AOSI scores (mean = 7.80, SD = 3.76) than the LR group (mean = 5.67, SD = 3.02), indicating greater ASD symptomatology in the HR group (z=3.13, p=.002). Within the HR group, AOSI scores significantly related to PDMS stationary (rho=-.333, p=.004) and grasping scores (rho=-.284, p=.014). Finally, we found motor delays in infants later identified with ASD relative to those without ASD. The ASD group scored lower than the ND group on the PDMS stationary scale (z=2.62, p=.009) and both fine motor scales (Grasping: z=2.97, p=.003; VMI: z=2.42, p=.016)(Figure 2).
Conclusions: Our findings provide evidence supporting infant motor skill as an area of developmental vulnerability in HR infants and an early indicator of ASD. In combination this points to the importance of considering motor skill when characterizing a putative prodromal period for ASD and developmental monitoring of HR infants.

3:04 **115.003** Posture Development from 6 to 14 Months in Infants with Vs. without Risk for ASD

N. B. Leezenbaum *and J. M. Iverson, University of Pittsburgh, Pittsburgh, PA*

Background: During the first 14 months, TD infants progress from postures in which the body is supported by a surface (lying) to postures that require greater strength, muscle coordination, and balance (unsupported sitting, all fours, standing). Although it is well established that individuals with ASD demonstrate difficulties with postural control (Fournier et al., 2010), relatively little is known about the emergence and course of posture development in infants eventually diagnosed with ASD.
Objectives: 1) Describe trajectories of posture development in infants at heightened ASD risk (later-born siblings of children with ASD; HR) and infants with low ASD risk (infants with a negative family history of ASD; LR); and 2) Evaluate the extent to which delays or impairments predict a later ASD diagnosis at 36 months.
Methods: Twenty-five LR and 59 HR infants were observed at home for 25 minutes at 6, 8, 10, 12, and 14 months. Durations of lying, supported sitting, unsupported sitting, all-4, supported standing, and unsupported standing were coded from 6 to 14 months. At 36 months, HR infants received language and ASD diagnostic evaluations using the ADOS-G (Lord et al., 2000) and Mullen Scales of Early Learning (Mullen, 1995). Fourteen HR infants were diagnosed with ASD (HR-ASD), 17 HR infants were classified as language delayed (HR-LD), and 28 HR infants received no diagnosis (HR-ND).
Results: Hierarchical Linear Modeling was used to compare posture development across groups. All groups declined in Lying, but the HR-ASD group spent more time than the LR, HR-ND, and HR-LD groups in Lying at 10 (p=.005; .011; .022) and 12 months (p=.011; .030; .045). With regard to Sitting, HR-ASD and HR-LD groups spent more time than the LR group in Supported Sitting (p=.016; .035) and less time in Unsupported Sitting (p=.002; .042) at 6 months. In terms of All-4, the HR-ASD group did not exhibit the decelerating pattern of growth characteristic of the LR, HR-ND, and HR-LD groups (p < .001). The HR-ASD group spent less time in All-4 than LR, HR-ND, and HR-LD groups at 8 (p=.002; .006; 025) and 10 months (p = .009; .038; 017), however, they caught up the other groups by 12 months, and at 14 months spent more time in All-4 than the other three groups (p = .001; .023; 010). For Supported Sitting, the HR-ASD and HR-LD groups exhibited slower growth than the LR group (p=.002; .024), diverging from the LR group by 8 months (p=.001; .009). The HR-ASD group also exhibited slower acceleration than the LR group in Unsupported Standing (p=.005) and spent less time in this posture by 14 months (p=.006).
Conclusions: Relative to LR infants, HR-LD and HR-ASD infants exhibited delays in Unsupported Sitting and Supported Standing. Delays in All-4 were specific to ASD, and from 10 months on, the HR-ASD infants spent more time than all three groups in less developmentally advanced postures (i.e., Lying: 10-12 months and All-4: 14 months). Taken together, these findings indicate that posture delays are likely among the earliest identifiable disruptions in the unfolding of ASD.

3:16 **115.004** Do Restricted and Repetitive Behaviors during Early Childhood Predict School-Age Executive Functioning Among Children with Autism Spectrum Disorders?

E. Troyb[1], *K. Knoch*[2], *L. Herlihy*[3] *and D. A. Fein*[4], *(1)Brown University, Providence, RI, (2)University of Connecticut, Storrs, CT, (3)Hospital For Special Care, New Britain, CT, (4)Psychology, University of Connecticut, Storrs, CT*

Background: Restricted and Repetitive Behaviors (RRBs) are core features of Autism Spectrum Disorders (ASDs) and include motor stereotypies, preoccupation with parts of objects, restricted interests, insistence on sameness, and sensory interests. One theory proposed to explain the purpose of RRBs points to executive dysfunction and argues that RRBs result from a tendency to perseverate, as well as from deficits in planning, self-monitoring, inhibition of ongoing behaviors, and initiation of new behavior (Russell, 1997). However, because RRBs emerge earlier in development than functions usually grouped under executive functioning (EF), it is important to consider the alternate causation, namely, the effect that RRBs may have on the development of EF. Studies examining the relationship between EF and RRBs are limited and have not examined the impact that early RRBs have on the development of EF (see Leekham et al., 2011).
Objectives: The current study used a longitudinal design to examine the extent to which RRBs at two points in early childhood predict school-aged executive functioning.
Methods: Participants included 40 children diagnosed with ASD at age 1-2 years and again at age 3-5 years. Participants were recruited from a study examining the effectiveness of the Modified Checklist for Autism in Toddler (M-CHAT), a screening instrument designed to identify children at risk for developing ASDs. RRBs were examined at age 1-2 years (M=2.2, SD=0.3; M(Mullen ELC)=58.7, SD=8.5) and 3-5 years (M=4.3 years, SD=0.4; M(Mullen ELC)=63.1, SD=19.5), and were assessed using both direct observation and parent report. RRBs were used to predict EF at age 8-10 years (M=9.9, SD=0.8; M(VIQ)=70.8, SD=31.5; M(NVIQ)=81.4, SD=27.4). EF was examined using the Behavior Rating Inventory of Executive Function (BRIEF), a parent report questionnaire designed to assess EF in daily settings.
Results: Linear regression indicated that RRBs observed at age 1-2 are significant predictors of school-age EF as measured by the Global Executive Composite (GEC) of the BRIEF (F(6, 25)=2.52, p<.05, *Adjusted* R^2=.23). Specifically, RRBs at age 1-2 significantly predicted difficulties with cognitive flexibility and initiation of new behaviors (Shift: F(6, 25)=2.51, p<.05, *Adjusted* R^2=.23; Initiation: F(6, 25)=2.75, p<.05, *Adjusted* R^2=.25). According to these models, increased self injurious behaviors predicted

greater difficulty with cognitive flexibility (*beta*=0.47, *p*<.05). In contrast, reduced repetitive motor mannerisms predicted more difficulty with initiation of new behaviors (*beta*=–0.36, *p*<.05). When RRBs were assessed at age 3-5 years, they did not predict the GEC ($F(6, 25)=1.59$, $p=.19$, *Adjusted* $R^2=.11$), but RRBs were significant in predicting reduced cognitive flexibility ($F(6, 24)=3.01$, $p<.05$, *Adjusted* $R^2=.29$). At age 3-5, more severe adherence to rituals or routines (*beta*=0.42, *p*<.05*)* and greater preoccupations with parts of objects (*beta*=0.41, *p*<.05) predicted increased difficulty with cognitive flexibility.
Conclusions: This study found a predictive relationship between RRBs in early childhood and school-aged EF. Because RRBs emerge earlier in development than classically defined EF, these findings raise two possibilities: first, that RRBs may impact neurocognitive development and the development of EF, and second, that precursors of EF, such as early manifesting inflexibility and perseveration, impact the development of both RRB's and later developing EF.

Oral Session - 3A
116 - Variation in Early Trajectories of ASD
1:45 PM - 2:35 PM - Room 308

1:45 **116.001** Different Developmental Trajectories of ASD: Slow and Rapid Onset of Symptoms in Toddlers from the General Population

E. C. Bacon[1], *L. Schreibman*[2], *A. C. Stahmer*[3], *C. Carter*[1], *E. Courchesne*[1] *and K. Pierce*[1], *(1)Neuroscience, UCSD Autism Center of Excellence, La Jolla, CA, (2)University of California San Diego, La Jolla, CA, (3)University of California at Davis MIND Institute, Sacramento, CA*

Background:
The heterogeneity of ASD is widely documented, however there is little documentation regarding variability in *onset* of ASD symptoms. This question is particularly difficult to answer as it requires the prospective study of ASD. A recent study by Ozonoff et al. (2015) examined the onset of ASD in a baby-sibling population, and found over half the sample that eventually received an ASD diagnosis at age three, did not initially meet criteria for ASD between 1-2 years.
Objectives:
This study aimed to analyze differential developmental trajectories of toddlers with ASD, and specifically compare toddlers initially identified as ASD that retained a diagnosis (*Rapid-Onset*) versus children initially identified as non-ASD who were identified as ASD at a later evaluation (*Slow-Onset*) in the general population.
Methods:
ASD and contrast toddlers were primarily identified using the One-Year Well-Baby Check-Up Approach (Pierce et al., 2011). Children were evaluated using the Mullen, Vineland, ADOS, and the Geometric Preference Test, a preferential looking eye-tracking test designed to quantify a toddlers' preference for geometric or social stimuli (Pierce et al. 2011; 2015). Toddlers were included if initially evaluated ≤24 months (M=17.1) and diagnosis was confirmed at three. Children were reassessed every 9-12 months (M= 3.14 evaluations). Seventy-four language delayed (LD) and 132 typically developing (TD) toddlers were included for comparison. Growth curve analysis was used to examine longitudinal trajectories. Visual preference patterns based on eye-tracking were also compared at intake.
Results:
Within our sample 86 toddlers were considered Rapid-Onset ASD (RO-ASD; i.e., initially identified as ASD and retained that diagnosis over time) and 41 toddlers were identified as Slow-Onset ASD (SO-ASD; i.e., were initially identified as non-spectrum or having a delay such as language delay, but were identified as ASD at a subsequent evaluation). See figure 1 for trajectories of ADOS scores. An ANOVA showed a significant difference in looking times for geometric stimuli across groups ($F_{(3, 127)}=11.406$, $p < .001$). The RO-ASD group showed the highest preference for geometric images (M=42.1 sec), followed by SO-ASD (M=30.3), LD (M=24.9), and TD group (M=18.2; see figure 2). Eleven RO-ASD and 2 SO-ASD cases looked at geometric images at very elevated levels (≥69%) which has been demonstrated to be highly associated with diagnosis of ASD (Pierce et al., 2011).
Conclusions:
Our study showed strikingly different symptom onset patterns within ASD toddlers from the general population. For language and ADOS scores, the RO-ASD group initially showed more impairment than the SO-ASD group, but both groups showed similar performance at age three. Importantly, the SO-ASD group was not initially identified as ASD based on their behavioral presentation, and instead were often identified as having some other delay (i.e. LD). Interestingly, a small subset of SO-ASD children showed elevated preference for geometric images at intake. This finding highlights the need for robust biological markers of autism as they may be able to identify children before behavioral symptoms become clear. These results also emphasize the necessity of repeated screening and follow-up for children showing any delay, as ASD symptoms emerge differently across children.

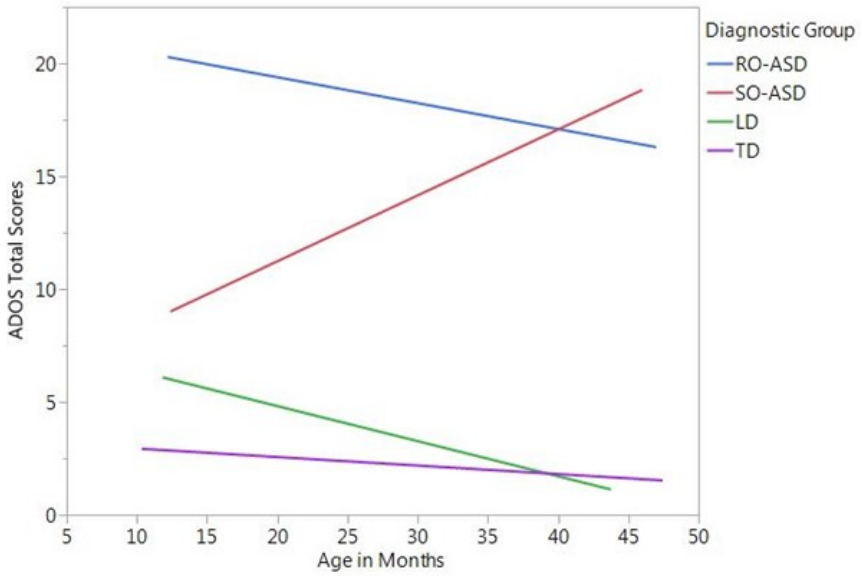

Figure 1. ADOS total scores across time across diagnostic groups.

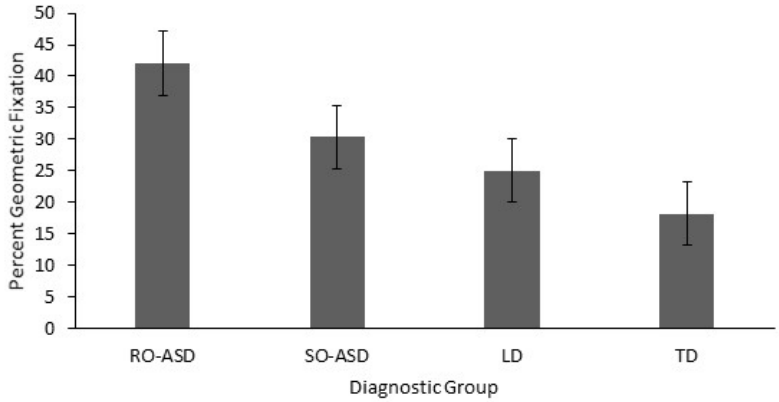

Figure 2. Percent fixation on geometric stimuli across diagnostic groups. Even though the SO-ASD group were not identified as ASD at this early age, percent geometric fixation were already elevated relative to the TD and LD groups.

1:57 **116.002** Characterizing Early Developmental Trajectories in Tuberous Sclerosis Complex

K. J. Varcin[1], *D. Senturk*[2], *M. Sahin*[3], *J. Y. Wu*[4] *and C. A. Nelson*[5], *(1)Harvard Medical School, Boston Children's Hospital, Cambridge, MA, (2)Biostatistics, University of California, Los Angeles, Los Angeles, CA, (3)Department of Neurology, Boston Children's Hospital, Boston, MA, (4)UCLA, Los Angeles, CA, (5)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Tuberous Sclerosis Complex (TSC) is one of the most commonly occurring genetic disorders associated with autism spectrum disorder (ASD). Up to 60% of children with TSC will meet criteria for ASD and up to 80% will experience cognitive delay. Importantly, cognitive delays and ASD often co-occur in this population, posing challenges for diagnosis, intervention targets and treatment selection. Despite hypotheses about the role of epilepsy, cortical pathology, and co-occurring genetic mutations in predicting neurodevelopmental outcomes in TSC, no single clinical factor has been identified as a consistent predictor of atypical neurodevelopment. As TSC is often diagnosed very early in life, often prenatally, allows for prospective investigation of developmental trajectories and early markers of ASD in this population.
Objectives: Modeling the approach taken in our work with infant siblings at high-risk for ASD, we conducted the first, prospective, longitudinal study of infants with TSC, mapping development from 3-6 months through to 36 months of age. Within the context of this prospective study design, we aimed to characterize early delays in cognitive development that precede, and possibly predict, the development of ASD in this high-risk population.
Methods: Infants with TSC (n = 40) and typically developing infants (n = 34) were recruited as early as 3-6 months of age and followed longitudinally until 36 months of age. For all infants, we assessed developmental functioning using the Mullen Scales of Early Learning. Social communication was assessed using the Autism Observation Scale for Infants (AOSI). At 18, 24 and 36 months a diagnostic evaluation of ASD was performed using the Autism Diagnostic Observation Schedule (ADOS). For TSC infants, detailed clinical and seizure history information was obtained at each time point.
Results: Infants with TSC show delays in cognitive development (especially in fine motor [p = .01] and visual receptions skills [p = .03]) and social communication skills (especially in visual tracking [p < .01], disengagement of attention [p < .01] and anticipatory responses [p = .02]) as early as 6 months of age, with more global delays from 9 months (all ps < .05). Infants with TSC who develop ASD (n = 22 of 40 infants with TSC) show more cognitive impairment from 12 months of age (ps < .05) and a slowing of non-verbal skills development between 12 to 36 months of age compared to infants with TSC without ASD, even after controlling for seizure severity (slope estimate -0.80, p = .01).
Conclusions: This research has unveiled a developmental profile in TSC that is marked by prominent and early delays in non-verbal skills, regardless of ASD outcome. Declines in non-verbal skills development between 12 and 36 months in infants with TSC and ASD suggest a domain-specific pathway to ASD in this population. These findings have contributed to the development of a targeted, early intervention trial for this high-risk population.

2:09 **116.003** Longitudinal Development of Social Visual Engagement in Infants Later Diagnosed with ASD

L. A. Olson[1], *A. Klin*[2], *S. Shultz*[2] *and W. Jones*[2], *(1)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Decatur, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: From birth, typically-developing infants preferentially attend to the social signals, such as eye gaze, of their caregivers (Haith et al., 1977). Recent findings from

our laboratory revealed that infants later diagnosed with autism spectrum disorder (ASD) exhibit decline in eye fixation from 2 until 24 months of age and that the decline is already underway within the first 6 months after birth. In contrast, typically-developing infants show an increase in eye fixation from 2 to 6 months (Jones & Klin, 2013). These findings represent the earliest known indicators of social disability in infancy. If confirmed in larger samples, these findings have the potential to inform efforts at early identification and intervention prior to the emergence of overt symptoms of social disability in ASD.

Objectives: Measure growth charts of social visual engagement from 2-24 months in TD infants and infants later diagnosed with ASD.

Methods: 106 infants were enrolled as risk-based cohorts: N = 40 at low risk (22 males) and N = 66 at high risk for ASD (41 males). Risk status was based on having either a full biological sibling with ASD (high) or on not having ASD among 1st, 2nd, or 3rd degree relatives (low). Diagnostic status was ascertained at 36 months. Of the HR sample, at outcome 13 received a diagnosis of ASD (9 male); 13 showed symptoms of the Broader Autism Phenotype (BAP, 11 male), and 40 (20 male) were confirmed non-ASD. Infants were shown scenes of naturalistic caregiver interaction as in Jones & Klin (2013). Eye-tracking data were collected at 10 time points (months 2, 3, 4, 5, 6, 9, 12, 15, 18, and 24). Longitudinal looking profiles for this cohort were compared with those of the earlier sample (2013) for eyes, mouth, body, and object regions within and between diagnostic group categories. Cohorts 1 and 2 were also combined for larger sample analyses.

Results: Analyses of the ASD replication cohort by functional ANOVA are consistent with earlier results: longitudinal looking profiles for eyes, mouth, body, and object were not significantly different between cohorts 1 and 2 (all $F < 2.4$, $P > 0.14$) (Fig.1). Analyses of the TD replication cohort showed no significant differences from cohort 1 in eye or object fixation (all $P > 0.5$), but did differ from cohort 1 in mouth ($F = 4.95$ $P = 0.032$) and body ($F = 5.55$, $P = 0.024$) fixation. Across outcome groups, typically-developing children show increasing eye fixation; non-ASD siblings show increasing eye fixation; siblings with subthreshold (BAP) symptoms show neither increasing nor decreasing eye fixation, and infants later diagnosed with ASD show declining eye fixation. Similar spectrum effects are observed for body fixation (Fig. 2).

Conclusions: Our results replicate earlier findings showing that infants later diagnosed with ASD show decline in eye fixation from 2-to-24 months. Spectrum effects emerging in the first 6 months give early indication of social disability in infants later diagnosed ASD. Future analyses will include longitudinal looking profiles for female infants with TD (35) and ASD (7) outcomes.

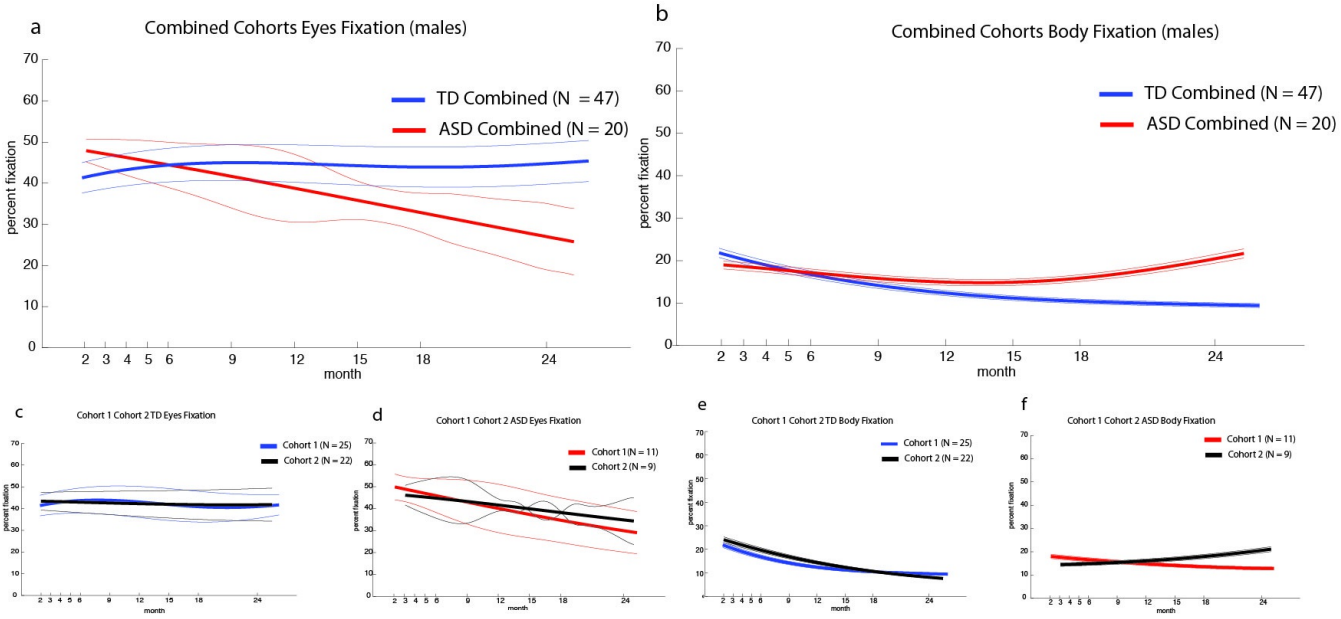

Figure 1 | Growth charts of social visual engagement for typically developing children and children diagnosed with ASD. a, b, Percent visual fixation to eyes (a) and body (b) regions from 2-24 months for TD (blue) and infants later diagnosed with ASD (red). c-f, Comparisons to cohort 1 (Jones & Klin 2013) for visual fixation to eyes (c, d) and body (e, f) regions from 2-to-24 months for TD infants (cohort 1: blue; cohort 2: black) and infants later diagnosed with ASD (cohort 1: red; cohort 2: black). Thick lines indicate mean growth curves, thin lines indicate 95% conficence intervals.

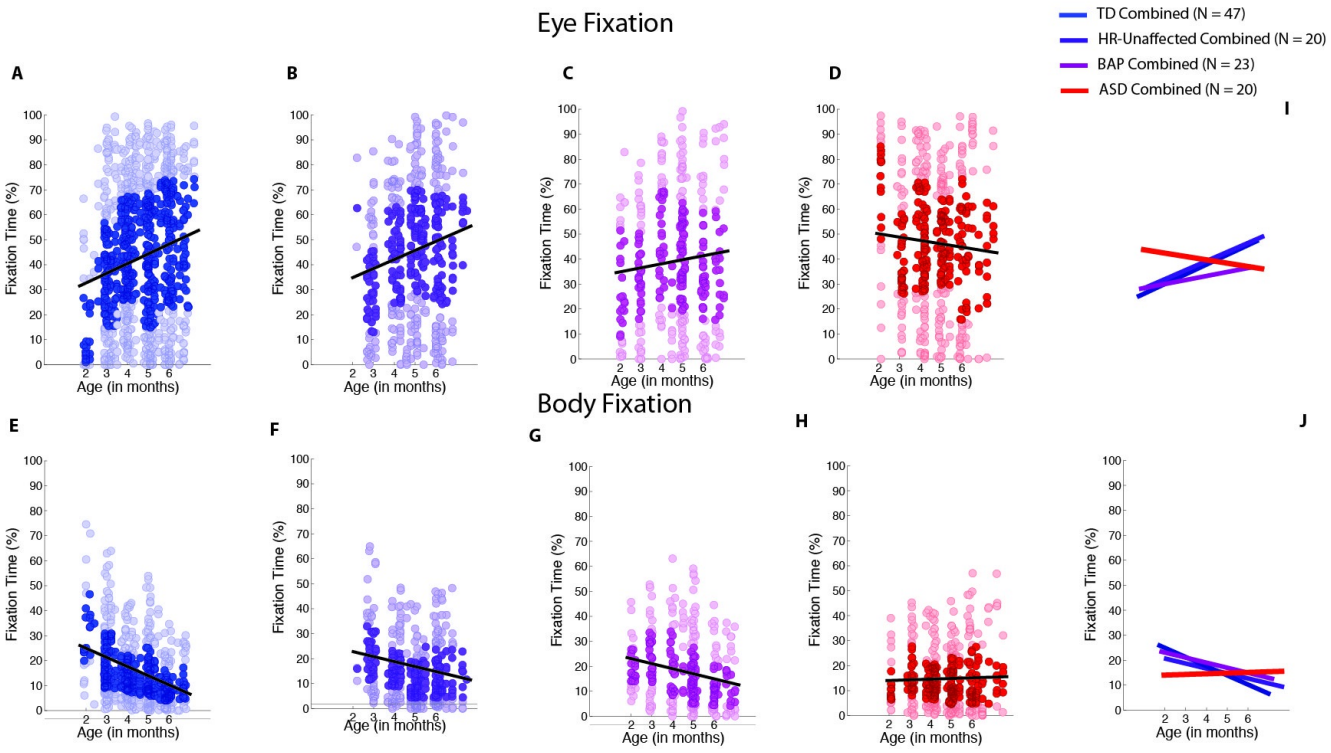

Visual Fixation between 2 and 6 months of age for combined cohorts 1 and 2. A-D: Plots show raw data for percent eyes fixation (interquartile range in bold). E-H: Raw data for body fixation. Plots in J and I show mean trend lines for eyes and body fixation by outcome.

2:21 **116.004** Longitudinal Stability of Quantitative Autistic Traits in Toddler Twins

N. Marrus[1], *Y. Zhang*[2], *A. Glowinski*[3], *T. Jacob*[4], *S. Kennon-McGill*[3], *S. Sant*[5], *T. Gray*[5], *A. Haider*[2] *and J. N. Constantino*[2], *(1)Washington University School of Medicine, Webster Groves, MO, (2)Washington University School of Medicine, Saint Louis, MO, (3)Washington University in St. Louis, St. Louis, MO, (4)Family Research Center, VA Palo Alto Health Care System, Menlo Park, CA, (5)Washington University School of Medicine, St. Louis, MO*

Background:
The ability to measure the early trajectory of core autistic traits has significant implications for elucidating developmental mechanisms of heterogeneity in ASD and tracking incremental responses to early interventions. Previously (Marrus et al., *J Child Psychol Psychiatry* 2015), we demonstrated that a video-referenced rating of Reciprocal Social Behavior (vr-RSB), a novel toddler measure in which caregivers rate their child's level of RSB compared to a typically developing video anchor, shows strong psychometric properties including a continuous, unimodal distribution of autistic trait severity (as indexed through levels of RSB), high heritability, excellent test-retest reliability, and marked impairments in RSB in toddlers with ASD.
Objectives:
To investigate in a general population sample whether quantitative autistic traits (QAT) measured using the vr-RSB at age 18 months predict variation in QAT at age 36 months, the latter measured using the preschool version of the Social Responsiveness Scale (SRS), which has been extensively validated in prior autism research (Baranek et al., *Autism 2013*; Duku et al., *J Autism Dev Disord* 2013).
Methods:
Parents of 252 epidemiologically representative toddler twins [monozygotic (MZ)=31 pairs, dizygotic (DZ)=95 pairs] participated in the Early Reciprocal Social Behavior Study (ERSB), a longitudinal study of early social development. Parents rated their 18-month-old twins on the vr-RSB, and subsequently completed the preschool SRS on their children at age 36 months. Pearson's correlations were performed for total RSB scores at 18 and 36 month time points, as well as sub scale scores for social communication

(SC) and restricted, repetitive behavior (RRB). Comparisons of intraclass correlations (ICCs) for MZ vs. DZ twins provided estimates of heritability at each developmental juncture. An exploratory principal components analysis (PCA) using a varimax rotation was conducted at each time point, based on common items across the vr-RSB and SRS-2.

Results:

Total RSB scores were strongly correlated between 18 and 36 months, r=.666, p<.01 (Fig. 1). Similarly high correlations were observed for SCI and RRB scores across the two time points as well. ICCs for MZ twins were greater than DZ twins for total RSB scores, SC, and RRB scores at 36 months (Table 2). PCA of 18 month data demonstrated a first principal factor accounting for 19% of the variance which mapped well to the principal factor derived from PCA of 36 month data.

Conclusions:

Levels of RSB, and by extension autistic traits, demonstrated strong longitudinal stability in a general population sample over the critical period from 18 to 36 months, when interventions typically begin for children affected by ASD. The ability to serially implement reliable quantitative trait measurements during this period offers the opportunity to track nuanced changes in core features of the autistic syndrome over time and in response to intervention.

Figure 1. Pearson Correlations for Reciprocal Social Behavior, Social Communication, and Restricted, Repetitive Behavior Scores Between 18 and 36 months

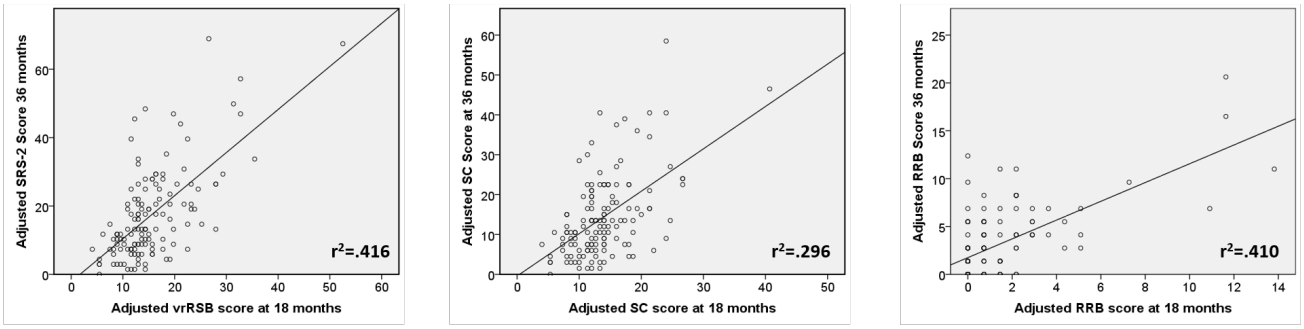

Fig. 1 Quantitative autistic trait scores at 18 months strongly predict those at 36 months for total RSB score as well as SC and RRB scores.

Table. 2 Twin-Twin Intraclass Correlations for Early RSB and Related Traits at 36 months

Twin type (pairs)	Age in Months (Mean, SD)	RSB Total Score	Social Communication Items	Restrictive Repetitive Behavior Items
MZ (n=18)	36.1 (.59)	.944 (p<.01)	.930 (p<.01)	.843 (p<.01)
DZ (n=51)	36.2 (.58)	.280 (p<.05)	.300 (p<.05)	.225 (p>.05)

117 - Early Markers of ASD: Laboratory and Community Studies

2:40 PM - 3:30 PM - Room 308

2:40 **117.001** Combining Multiple Eye Tracking Measures at 6 Months in Infant Siblings: Associations with Outcomes

***F. Shic**, Q. Wang, S. Macari and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Atypical scanning patterns towards social information are evident by 6-7 months in infant siblings of children with ASD who later develop ASD themselves (Chawarska, Macari, & Shic, 2013; Elison et al., 2013; Jones & Klin, 2013; Shic, Macari, & Chawarska, 2014). However, it is not yet clear how different variables uncovered by eye tracking can be related to one another and to developmental outcomes.

Objectives: To use data reduction techniques to develop more compact representations of the latent structure associated with visual scanning strategies evidenced by high risk infant siblings of children with ASD at 6 months of age. To associate this structure with later outcomes, both directly and via clustering.

Methods: Eye-tracking data were collected from 6-month-old high-risk infant siblings (*N*=85). Primary eye tracking tasks included the Dyadic Bid (DB) Probe (Chawarska, Macari, & Shic, 2012) and the Speaking Face (SF) Task (Shic, Macari, & Chawarska, 2014). Region of interest variables reflecting time looking towards the Scene, Faces, and Eye-Mouth ratio were dependent measures. Missing dependent measures caused by movement or inattention were imputed with bootstrap methods using augmented data from up to 6 other experimental conditions. This reconstructed dataset was subject to principal component analysis (PCA) using parallel analysis to identify number of components followed by hierarchical clustering with the number of clusters determined via majority vote via NbClust (Charrad & Ghazzali, 2014). Outcomes included diagnoses of ASD (*N*=12), atypical development (ATYP, *N*=34, e.g. language delay), or typical development (TYP, *N*=39) at 24 or 36 months of age. Pearson's correlation analysis was used to explore phenotypic relationships between 6-month eye tracking variables and clinical outcomes at 24 months.

Results: Two principal components (PCs) were identified, with the first PC reflecting decreased looking at the scene and at faces in both the DB and SF tasks and decreased looking at the eyes in SF task and increased looking at eyes in the DB task. This PC correlated with ADOS 1 composite and total scores (*r*=.32 to .36, *p*<.01). Hierarchical clustering on the two PCs revealed 3 clusters. One cluster showed poor overall attention (non-lookers, NON, *N*=35), another showed greater looking at eyes (EYE, *N*=20), and the last more looking at mouths (MOU, *N*=30). The MOU group was predominantly female (62% female) and showed the fewest autism symptoms (ADOS 1 TOT = 5.1), whereas the NON and EYE groups were more male (80% and 75% male) and showed more symptoms (TOT=7.2, 9.2). Children with outcomes of ASD were primarily in the NON cluster (58.3%); children with TYP outcomes were more often in the MOU cluster (46.2%).

Conclusions:

6-month old eye tracking phenotypic data combined using data reduction techniques and augmented with clustering can provide insight into the developmental relationships between visual scanning strategies early in development and the heterogeneous outcomes associated with ASD. Results suggest that gender as well specific looking patterns to the mouth or eyes in differing contexts may provide clues regarding developmental trajectories.

2:52 **117.002** Computer Vision Detects Delayed Social Orienting in Toddlers with Autism

***K. Campbell**[1], K. L. Carpenter[1], J. Hashemi[2], S. Espinosa[2], S. Marsan[1], J. Schaich Borg[3], A. Harris[1], Z. Chang[2], Q. Qiu[2], M. Tepper[2], R. Calderbank[2], J. P. Baker[4], G. Sapiro[2], H. Egger[3] and G. Dawson[1], (1)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (2)Duke University Pratt School of Engineering, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC, (4)Duke University School of Medicine, Department of Pediatrics, Durham, NC*

Background: A failure to orient when a child's name is called has been identified as a potential risk marker for autism spectrum disorder (ASD) in young children.[1,2] Although screening and diagnostic measures use failure to orient to name as a sign of risk for ASD, delayed orienting is not generally noted on clinical assessment. However, Dawson et al. found that, when young children with ASD do orient to their name, they are more likely to exhibit delayed responses, as compared to children with typical development.[2]Such delayed responses might be difficult to detect during a clinical observation, and require frame-by-frame rating of videos. Novel and scalable approaches that can automatically detect relevant autism risk behaviors, such as delayed orienting, are needed.

Objectives: To apply computer vision technology to precisely characterize presence and timing of orienting to name in 16-30 month olds with and without risk for ASD.

Methods: Interim analyses were conducted on 14 toddlers who met criteria for ASD on the ADOS-T and 14 age and gender-matched children with typical development who participated in an experimental assessment. Children watched videos on an iPad while an examiner standing behind the child administered 3 opportunities for the child to orient to their name. The front-facing camera within the iPad recorded video. Orienting to name was assessed using algorithms to detect movement of facial landmarks toward the examiner. Automated scoring was compared to rating by a human coder. Precise measurement of initiation of head movement (sampling rate: 30 frames/sec) allowed for analysis of latency to response. Frequencies of orienting and Kaplan-Meier curves were derived to compare the two groups of toddlers.

Results: Computer vision analysis of orienting showed moderate reliability with human rating and excellent agreement on timing of head turn (kappa= 0.52, ICC=.80). On the first name call, 71% of the typically-developing toddlers oriented to name, whereas only 36% of toddlers with ASD oriented. In the typical group, mean latency to orienting on the first name call was 0.83 seconds (sd 0.68), whereas mean latency in the ASD group was 1.53 seconds (sd 1.17). Kaplan-Meier curves were found to be statistically

different on log-rank test (p=0.04; hazard ratio 3.03; 95% CI [1.02,9.02]) (Figure 1).
Conclusions: We demonstrated that typically-developing toddlers tend to orient to their name within 1 second, whereas toddlers with ASD orient inconsistently and with longer latency. Computer vision analysis allowed for automated and precise characterization of the social orienting response in toddlers. Development of computerized behavioral assessments of autism risk behaviors may aid in developing automated, scalable methods of early detection of ASD. Future analyses will be conducted with a larger sample in this ongoing study.

3:04 **117.003** Attention Capture By Faces within a Naturalistic Scene in Toddlers with ASD

***L. DiNicola**, F. Shic, S. F. Fontenelle, K. K. Powell, S. Macari and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Eye-tracking studies have documented atypical attention toward facial stimuli in children with autism spectrum disorder (ASD), including both diminished attentional bias (Chawarska, Macari & Shic, 2013) and atypical scanning patterns (Chawarska, Volkmar & Klin, 2010; Chawarska & Shic, 2009). Such results raise the question of whether or not faces capture the attention of individuals with ASD to the same extent as typically developing (TD) peers. Although adolescents with ASD have been shown to take longer than those with TD to fixate faces in naturalistic images (Freeth et al., 2010), the degree to which faces within naturalistic scenes capture the attention of toddlers with ASD has yet to be investigated.
Objectives: To investigate the attentional capture of faces within naturalistic scenes for TD toddlers and those with ASD.
Methods: 135 toddlers (ASD, *n*=80; TD, *n*=55) between 15 and 40 months of age (M_{ASD}=25.76 months, M_{TD}=23.16 months) viewed an eye-tracking task testing spontaneous attention toward eight static images. Each image appeared for five seconds and contained a different woman smiling and facing forward within a naturalistic scene (e.g., sitting at an office desk or preparing food in a kitchen). Faces appeared in locations equidistant from a central fixation point that preceded each trial. Primary outcome variables were the average time it took for a child to orient toward the face within a scene (Latency_Face), the average number of discrete gaze shifts toward a face (Shift_Face), and the average percentage of valid scene-viewing time spent attending to a face (%Face). All participants received the Mullen Scales of Early Learning (MSEL; Mullen, 1995), and all toddlers diagnosed with ASD received the Autism Diagnostic Observation Schedule (ADOS-G; Lord et al., 2000).
Results: ANOVA analysis revealed no significant differences between diagnostic groups concerning the total time spent attending to the scenes (*p*=0.2). Linear mixed effects modeling was employed to examine the effect of diagnostic group on Latency_Face, Shift_Face and %Face, controlling for age and Mullen nonverbal developmental quotient (DQ). No significant differences were observed between toddlers with TD and ASD on Latency_Face, %Face, or Shift_Face. Effect sizes were small for all variables (Cohen's *d*s<0.3). Within the ASD group, Pearson's *r* correlations revealed no significant relationships between any of the three variables of interest and Mullen verbal or non-verbal DQs or ADOS total scores.
Conclusions: Toddlers with ASD exhibited no differences from TD peers in attention capture by faces within complex naturalistic scenes. The number of gaze shifts toward faces and percent of viewing time spent attending to faces during the eye-tracking session also did not differ between groups. These results add to a growing body of work indicating that social stimuli capture the attention of young children with ASD (e.g., Johnson, 2013; Elsabbagh et al., 2012). The ability to detect and orient toward faces, even within complex visual environments, appears unimpaired in toddlers with ASD. Mechanisms contributing to the documented attentional atypicalities in these toddlers, as well as relationships to attentional differences later in life, merit further exploration.

3:16 **117.004** Social Communication Screening and Parent Concern at 9-21 Months of Age: Comparison of a Large Primary Care Sample and Children Later Diagnosed with ASD

***A. M. Wetherby**[1], D. Dow[2], E. A. Allgood[3], E. Slate[3], A. Delehanty[4], T. N. Day[2] and C. E. Rice[5], (1)Florida State University Autism Institute, Tallahassee, FL, (2)Psychology, Florida State University, Tallahassee, FL, (3)Statistics, Florida State University, Tallahassee, FL, (4)Communication Science & Disorders, Florida State University, Tallahassee, FL, (5)Emory Autism Center, Decatur, GA*

Background: The American Academy of Pediatrics recommends screening all children for ASD at 18 and 24 months. However, there is limited evidence of well-validated autism-specific screening tools in primary care settings. Unlike families referred for suspected ASD or high-risk siblings who may have heightened concern, families in the primary-care population may receive positive screening results before raising concerns about their child. In a review of current evidence for ASD screening, examining how broadband and autism-specific screening tools can be used together to improve accuracy was a priority for future research (Zwaigenbaum et al., 2015).
Objectives: To compare the results of a broadband screen for social communication (SC) delay and parent concern from a large sample screened in primary care by the FIRST WORDS®Project with a subgroup of children later diagnosed with ASD.
Methods: Children were first screened for SC delay based on parent-report with the *Infant-Toddler Checklist* (ITC; Wetherby & Prizant, 2002) through primary care providers at 9-21 months of age and negative screens were invited for re-screening. Two autism-specific screening tools were used for children with a positive SC screen— the *Early Screening for Autism and Communication Disorders* (ESAC) based on parent-report and the *Systematic Observation of Red Flags of ASD*(SORF) based on video-recorded observation. Children with a positive autism screen were invited for a diagnostic evaluation to confirm or rule out ASD between 24-36 months of age. Parent concern reported on the ITC was coded into 16 types of concern. This sample represented the region with 57.6% white, 30.6% black, 8.4% multiracial; 7.6% Hispanic; 47.2% first-born, 32.1% second-born, 20.5% later-born; 15.4% bilingual. The results were grouped into 3-month age intervals from 9-21 months and analyzed.
Results: Based on screening of 8,161 children, the percent of positive SC screen ranged from 15-20%, indicating selection bias of the sample based on the tenth-percentile screening cutoff. There were 194 children diagnosed with ASD by 3 years. The percent of parents with concern in the full sample increased from 6% at 9-11 months to 15% at 18-21 months. For the ASD subgroup, the percent of positive screen ranged from 53% at 9-11 months to 78% at 18-21 months. The percent of parent concern in the ASD

subgroup was 22% at 9-11 months, 33% at 12-14 months, 50% at 15-17 months, and 67% at 18-21 months. Most concerns were initially expressive language and motor skills, and predominantly expressive language by 18-21 months. Patterns of screening outcome and parent concern will be examined by age and race/ethnicity.
Conclusions: These findings document the effectiveness of a developmental surveillance system to screen for ASD in a general population sample of toddlers using a broadband SC screener followed by two autism-specific screeners. There was an increase in parent concern from 9-21 months, but the broadband SC screening outcome was more sensitive than parent concern across this age range. These findings illustrate that parents are fairly accurate at reporting social communication milestones but less accurate at knowing whether to be concerned about delays in these milestones.

Oral Session - 4A
118 - Sociodemographic Diversity and Screening, Diagnosis, and Clinical Presentation
1:45 PM - 2:35 PM - Room 309

1:45 **118.001** Parental Satisfaction with Diagnostic Evaluations: The Effects of Diagnosis, Race, and Education

M. Khowaja[1], *R. K. Ramsey*[2] *and D. L. Robins*[3], *(1)Georgia State University, Atlanta, GA, (2)Psychology, Georgia State University, Atlanta, GA, (3)Drexel University, Philadelphia, PA*

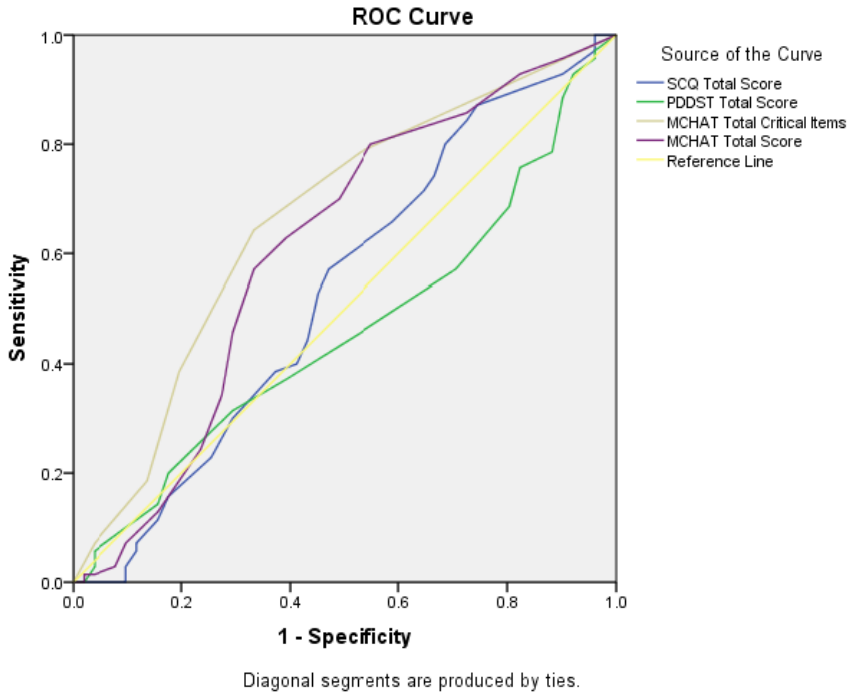
Background: Parents receiving a diagnosis of developmental disability for their child have noted a substantial amount of dissatisfaction or negative appraisals with the diagnostic evaluation process (Goin-Kechel et al., 2006; Stuart & McGrew, 2009). Criticisms relate to timeliness, professionalism, clarity of results, and thoroughness of recommendations (Keenan et al., 2010). Moreover, health-related disparities for minorities and low-income families have been identified across a range of childhood disorders, including autism, regarding early identification, access to intervention, and prognosis (Fountain et al., 2012; Kuo et al., 2012; Tregnago & Cheak-Zamora, 2012). However, research on sociodemographic disparities regarding parents' perception of screening and evaluation is limited.
Objectives: The goal of this study is to identify factors that affect parental satisfaction with the autism screening and evaluation process, to pinpoint strengths and areas of improvement in clinical practice. Given disparities in healthcare utilization and access, this study specifically explores sociodemographic factors.
Methods: Toddlers demonstrating risk on autism screening during routine pediatric visits were referred for diagnostic evaluation. Families received comprehensive assessment and oral and written feedback, which included test results, diagnosis, and specific recommendations. Parents completed and mailed back Post Evaluation Satisfaction Questionnaires after receiving the written report. Using MANOVA and independent samples *t*-tests, the effects of parental race, education, income, and diagnostic outcome were measured on satisfaction outcomes.
Results: The sample of parents (n=68) was 32.4% racial/ethnic minorities, 41.7% with bachelor's degree, and 92.6% mothers; mean age of toddlers was 25.9 months, with 55.9% diagnosed with ASD. Racial/ethnic minorities identified screening and evaluation services as more helpful than Whites, $t(52)=-2.230$, $p=.030$. Parents who earned less than a bachelor's degree demonstrated greater agreement with evaluation results compared to bachelor's degree holders, $F(2, 56)=3.227$, $p=.047$. Additionally, parents of children diagnosed with ASD reported lower clarity of information and quality of staff interactions compared to those who had a non-ASD delay (ps <.05). However, when accounting for parental race, income, and education this effect of diagnosis was no longer apparent.
Conclusions: Results suggest that minority status and lower education were associated with higher agreement with findings and ratings of helpfulness. One might hypothesize that minorities and/or parents with lower education experienced power differentials in the evaluation process, which contributed to social desirability bias, or that increased helpfulness may have been due to reduced baseline knowledge regarding child development. Also, receiving a diagnosis of ASD is related to lower perceived clarity of information and quality of interaction compared to other developmental delays. This may be due to the complex nature of autism symptomatology. However, sociodemographic variables also seem to differentiate parent satisfaction outcomes. Because parental education, race, and income are interrelated, further examination of these factors may be of value in understanding gaps in service provision. One study limitation was the use of a convenience sample, which may yield sampling bias. Researchers and practitioners are encouraged to seek parental feedback to help inform the shift in healthcare for individuals with developmental disabilities to a more comprehensive, family-centered care model.

1:57 **118.002** Examining the Cross-Cultural Accuracy of Three Early Autism Screening Instruments

J. McDonough[1], ***J. M. Campbell***[2], *L. Gardner*[3] *and L. Murphy*[3], *(1)Irving Independent School District, Irving, TX, (2)University of Kentucky, Lexington, KY, (3)Boling Center for Developmental Disabilities and Department of Psychiatry - University of Tennessee Health Science Center, Memphis, TN*

Background: Autism Spectrum Disorder (ASD) is often diagnosed later than the time at which it can be reliably identified. Differences exist between minority racial and SES groups with regard to age at first diagnosis of ASD. Population-wide screening for ASD has been recommended to aid in early identification as well as to reduce disparities in timing of diagnosis, particularly for underserved groups. Although findings related to the psychometric properties of ASD assessment instruments are fairly well established, little information is available regarding use of ASD assessment instruments with culturally diverse populations.
Objectives: Investigators documented accuracy of three commonly used screening instruments to detect ASD within a referred sample. Investigators compared scores across three screeners as well as compared their accuracy in correctly detecting ASD. The overall goal of the investigation was to compare the validity of three early ASD screening instruments across cultural groups to inform clinical use of the instruments with diverse populations.
Methods: *Social Communication Questionnaire* (SCQ), *Modified Checklist for Autism in Toddler* (M-CHAT; Total Score and Critical Item Score), and *Pervasive Developmental Disorders Screening Test-II* (PDDST-II) parent ratings were collected for 121 children (M age = 3.74 years, SD = 1.14) completing a comprehensive diagnostic evaluation between 2010 and 2012. Comprehensive diagnostic evaluation included use of the *Autism Diagnostic Observation Schedule (ADOS) and ADOS-Second Edition* (ADOS-2) and *Childhood Autism Rating Scale-Second Edition* (CARS-2); final clinical diagnosis was established via team consensus. A total of 70 children met criteria for ASD (57.9%); 51 children met criteria for another disorder (42.1%). Screeners were completed in counterbalanced order and clinicians were blind to the results of the screeners. Correlations between test scores were calculated and test accuracy was calculated via area under the curves (AUCs) derived from receiver operating characteristic analysis. AUCs were compared for the entire sample and across race groups (i.e., Caucasian, African-American, Other) and maternal education (i.e., No High School Graduate, High School Graduate, Some College or Higher) or each screener via z tests.
Results: All screeners were positively correlated at the $p < .01$ level with Pearson correlations ranging from .42 to .85. For the entire sample, AUCs ranged from .46 (PDDST-II) to .66 (M-CHAT-Critical Items; see Figure 1). M-CHAT-Total and M-CHAT-Critical Item AUCs were significantly greater than the SCQ AUC ($z = 2.29$, $p = .02$ and $z = 3.08$, $p = .002$). The M-CHAT-Critical Item AUC was significantly greater than the PDDST-II AUC ($z = 2.14$, $p = .03$). For African-American children, the M-CHAT-Total was more accurate when compared to children of Other races ($z = 2.14$, $p = .03$). No differences in accuracy were found across maternal education groups.
Conclusions: In general, screeners showed poor accuracy (i.e., AUCs = .46 - .66) for discriminating between children with and without ASD in a referred sample. The M-CHAT performed significantly better than the SCQ and PDDST-II screeners. Few differences were noted across race and SES groups. The findings should be extended to population-based screening as the present sample consisted of a referred group of children.

Figure 1. *ROC Curves for M-CHAT, M-CHAT Critical Items, SCQ, and PDDST-II Total Scores, Total Sample*



2:09 **118.003** Disparities in the Clinical Characterization Profiles of African American Vs Caucasian Individuals with Autism

C. A. Saulnier[1], *J. M. Moriuchi*[2], *J. Berman*[3], *M. Reid*[4] *and A. Klin*[5], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Psychology, Emory University, Atlanta, GA, (3)Children's Healthcare of Atlanta, Atlanta, GA, (4)Pediatrics, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (5)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background:
Studies examining differences between African-American and Caucasian individuals with autism have yielded equivocal findings. African-American individuals are more likely to have developmental delays (e.g., Cuccaro et al., 2007), but are less impaired on measures of adaptive behavior and executive functioning and exhibit less externalizing and stereotypical behavior compared to Caucasian peers (Ratto et al., 2015; Sell et al., 2012). Factors underlying this discrepancy remain unclear, but likely contribute to previous findings of delays in diagnosis, misdiagnosis of disruptive behavior disorders, and less access to care for African-American individuals with autism (e.g., Mandell et al., 2009).
Objectives:
This study compares phenotypic profiles of African-American and Caucasian school-age individuals with ASD on measures of cognition, adaptive functioning, and diagnostic symptomatology.
Methods:
Participants included 184 individuals (93 African-American, 91 Caucasian) with Autism Spectrum Disorder ranging in age from 3 to 18 years (mean=99.62 months; SD=46.81) who received a clinical evaluation through research studies at the Marcus Autism Center. Measures included the *Differential Ability Scales, 2nd Edition* (DAS-II);

the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2)*; the Autism Diagnostic Interview, Revised* (ADI-R)*, and the Vineland Adaptive Behavior Scales, 2nd Edition, Survey Form* (Vineland-II).
Results:
ANOVA analyses on a preliminary sample (93 African-American, 21 Caucasian) revealed significant racial differences; African-American individuals scored significantly lower than Caucasian individuals across measures of verbal, nonverbal, and overall cognitive ability [DAS-II GCA: F(1,63)=24.56, p<.001], and adaptive communication [Vineland-II Communication: F(1,106)=5.25, p<.05], and exhibited significantly greater restricted and repetitive behavior [ADOS-2 RRB: F(1,99)=12.49, p<.01]. Adaptive communication differences disappeared when controlling for cognition.
Given the significant difference in cognitive ability, analyses were repeated in a subset of participants without cognitive impairment (i.e., DAS-II GCA>70; 21 African-American, 19 Caucasian). Within this sample, significant differences remained across measures of cognitive ability. Differences in ADOS RRB were no longer significant. However, African-American individuals without cognitive impairment had significantly lower adaptive socialization scores, even after controlling for cognitive ability [Vineland-II Socialization: F(1,31)=13.12, p<.01]. Across analyses, no differences were found on Vineland Internalizing or Externalizing scales or on ADI-R scores.
Conclusions:
In summary, we found that African-American individuals exhibited significantly lower levels of cognition and higher levels of restricted and repetitive behaviors than Caucasian individuals. Only 5% of the Caucasian sample had cognitive scores below 70 compared to 47% of the African-American sample. When limiting the sample to the "cognitively-able" range, African-American individuals still exhibited lower cognition in addition to adaptive socialization deficits, but no differences in stereotypical behaviors, suggesting that the higher RRB levels noted in the total sample were likely influenced more by cognitive impairment than autism symptomatology. In contrast, African-American individuals' adaptive socialization deficits remained even after controlling for cognitive functioning and even in the absence of differences in autism symptomatology. These findings help clarify the discrepancy in clinical profiles of African-American and Caucasian individuals with autism, highlight areas for targeted intervention, and raise questions about how to most appropriately conceptualize "level of functioning."

2:21 **118.004** Do Domains of Developmental Risk Identified By Parents during ASD Screening and Areas of Risk Identified during ASD Diagnostic Assessment Differ: Findings from a Case Series of Ethnically Diverse, Low-Income Toddlers

S. J. Jerome[1]*, J. Sandler*[1]*, S. broder-Fingert*[2]*, K. Devlin*[1] *and E. Feinberg*[1]*, (1)Community Health Sciences, Boston University School of Public Health, Boston, MA, (2)Division of General Pediatrics, Boston University School of Medicine, Boston, MA*

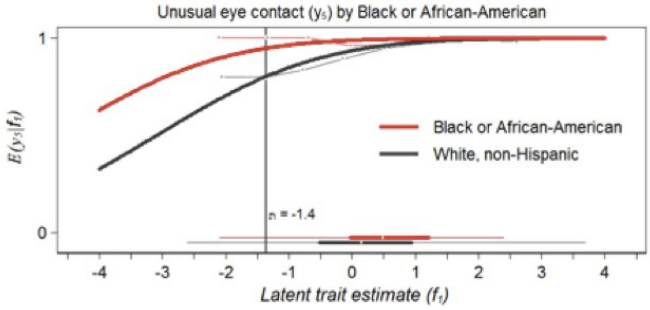
Background: Universal screening for Autism Spectrum Disorder (ASD) is a recommended strategy to address disparities in age of ASD diagnosis. The M-CHAT is the most widely used instrument to screen children primary care settings. Recent studies suggest that M-CHAT performs differently based on family demographic characteristics. However, few studies have explored how such differences correspond to performance on ASD diagnostic assessments.
Objectives: To explore the relationship between domains of developmental risk identified by low-income families during ASD screening and areas of risk identified during ASD diagnostic assessment.
Methods: Screening (MCHAT-R/F) and diagnostic (ADOS-2) data were collected from 44 children who were referred for an ASD diagnostic evaluation and were participants in randomized control trials studying methods to improve early identification of ASD. All met ASD risk criteria based on the MCHAT-R/F initial screen and follow-up interview. MCHAT-R/F items were categorized based on the four ADOS-2 domains: communication, reciprocal social interaction, play, and restricted and repetitive behaviors. For each domain, we assessed whether areas of risk identified in the MCHAT-R/F and ADOS-2 were concordant or discordant. For discordant results, we assessed patterns of risk identified by parents compared to the child's performance on the ADOS-2.
Results: Twenty-four of 44 children meet ASD diagnostic criteria, yielding a PPV of 55%, consistent with published MCHAT-R/F performance characteristics. Twenty children were not diagnosed with ASD. In this low-income (91%), majority minority sample (84%), children who were not diagnosed with ASD were significantly more likely to come from larger, single- parent households. Based on responses to items on the MCHAT-R/F, 80% of parents endorsed risks in the domain of communication; 79% in reciprocal social interaction; 15% in play, and 20% in restricted and repetitive behaviors. Based on performance on the ADOS-2, 75% of children met diagnostic criteria related to communication; 35% of children related to reciprocal social interaction; 21% of children related to play, and 39% related to restricted and repetitive behaviors. The most common discordant pattern was related to reciprocal social interaction, which was identified as an area of risk by 80% of parents and was confirmed during diagnostic assessment in only 35% of children. The most discriminatory item on the MCHAT-R/F for ASD was item one, "If you point at something across the room, does your child look at it?"; 80% of children who failed this item were diagnosed with ASD. The most discordant item was item eighteen, "Does your child understand when you tell him or her to do something?"; 79% of children who failed this item did not receive an ASD diagnosis.
Conclusions: This study identified two areas that may play a role in classifying low-income, largely minority children who do not meet diagnostic criteria for ASD as having elevated risk. The first is parental appraisal of children's social interaction skills and the second is parental expectation of children's response to parent-initiated communication. Further research that explores parental understanding of developmental norms is needed and could lead to more accurate assessment of ASD risk in this population.

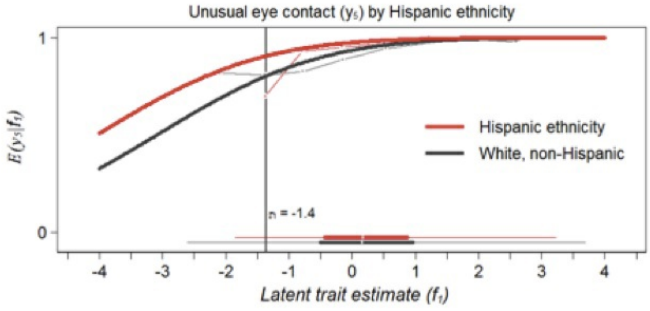
Oral Session - 4B
119 - International and Cross-cultural Perspectives on Screening and Diagnosis
2:40 PM - 3:30 PM - Room 309

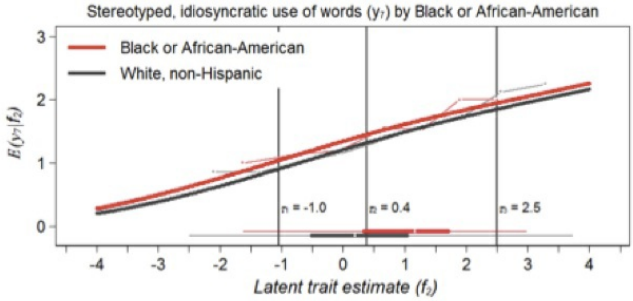
2:40 **119.001** Examining Potential Measurement Biases in the Autism Diagnostic Observation Schedule for Race, Ethnicity and Gender

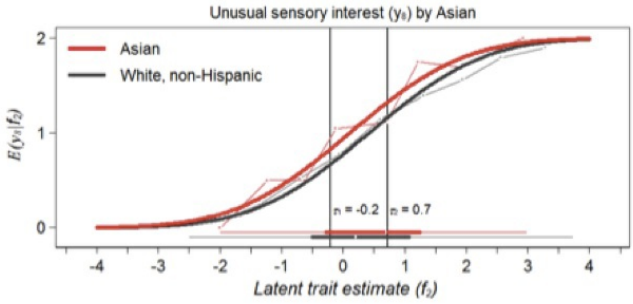
A. J. Harrison[1]*, M. R. Naughton*[1] *and R. N. Jones*[2]*, (1)University of Georgia, Athens, GA, (2)Warren Alpert Medical School, Brown University, Providence, RI*

Background:
The Autism Diagnostic Observation Schedule (ADOS) is widely used across cultural contexts to assess symptoms of autism spectrum disorders (ASD; Blacher et al, 2014). Little research has examined whether demographic characteristics such as race, ethnicity, and gender contribute to differential variability on ADOS score profiles, in spite of known cultural differences in social norms and variability in ASD symptom presentation across demographic groups (Bernier, Mao, & Yen, 2010). For example, cross-cultural variability exists regarding amount and type of social eye contact (e.g., Fugita, 1973; McCarthy, Lee, Itakura, & Mur, 2006) and facial expression (Vrana & Rollock, 2002), which may directly result in symptom variability in an assessment context depending on the diagnostic tests used. In potential support of this point, research shows variability exists with regard to ASD symptom presentation (Tek & Landa, 2012) and identified symptom profiles (Kharod, Giarelli, Blum, Hanlon, & Levy, 2012) across different demographic groups.
Objectives:
The objective of this study is to examine the ADOS to determine if item-level biases exist among distinct sociodemographic groups including race (Caucasian, African American, or Asian), ethnicity (Hispanic or non-Hispanic), and gender.
Methods:
Participants included in this study (n = 2459) were part of the Simons Simplex Collection (SSC), had complete data and fell within one of the racial categories identified as sufficiently powered for analysis: White (n = 2245), Black/African American (n = 103), or Asian (n = 111). The majority participants classified their ethnicity as not Hispanic or Latino (n = 2165) rather than Hispanic or Latino (n = 294) and were male (n = 2129). We examined a subset of ten items from the ADOS that were included in at least three of the four ADOS modules and were worded the same in both the item description and the coding categories across all modules.
Results:
A measurement noninvariance analysis was used, and approached using a Multiple Causes analytic framework. The focus was limited to differences in item location. All analyses controlled for age and IQ. Holding level of overall ADOS score constant, we found significant item level bias for three items. We observed Black children we more likely have higher ratings on the ADOS items assessing levels of usual eye contact and stereotyped or idiosyncratic word use. Asian children were more likely to have elevated ratings on the unusual sensory interests ADOS item. In terms of ethnicity, Hispanic children were also more likely to have higher ratings on the ADOS item assessing levels of usual eye contact. No item level biases were observed for gender.
Conclusions: This study revealed that of the ten ADOS items examined, item level biases existed for race among three specific items. In a diagnostic assessment context, this variability within ADOS items may result in overestimation of impairment for specific racial groups. These findings speak to the need for more research assessing the need for specific norms for different racial and ethnic groups to aid in more accurate diagnosis.









2:52 **119.002** The Diagnosis of Autism Spectrum Disorder in Low and Middle Income Countries: Concordance of Assessment Instruments in Jamaica

M. E. Samms-Vaughan[1], *M. H. Rahbar*[2], *A. S. Dickerson*[3], *K. A. Loveland*[4], *D. A. Pearson*[4], *J. Bressler*[2], *S. Shakespeare-Pellington*[1], *M. L. Grove*[5], *C. Coore-Desai*[1], *J. A. T. Reece*[1], *E. Boerwinkle*[2] and *M. Hessabi*[3], *(1)Department of Child and Adolescent Health, The University of the West Indies, Mona Campus, Kingston 7, Jamaica, (2)Division of Epidemiology, Human Genetics, and Environmental Sciences (EHGES), University of Texas School of Public Health at Houston, Houston, TX, (3)Biostatistics/Epidemiology/Research Design (BERD) Component, Center for Clinical and Translational Sciences (CCTS), University of Texas Health Science Center at Houston, Houston, TX, (4)Psychiatry & Behavioral Sciences, University of Texas Medical School at Houston, Houston, TX, (5)University of Texas School of Public Health at Houston, Houston, TX*

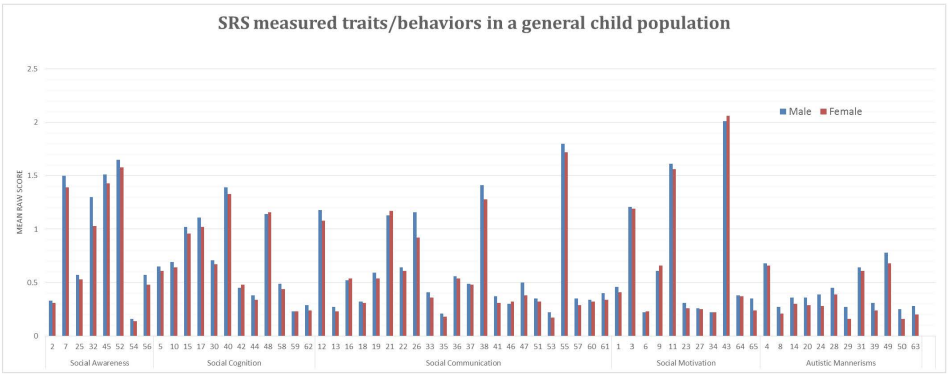
Background:
The high prevalence of ASD has encouraged development of new valid and reliable diagnostic tools. While the ADOS and ADI-R are widely used in diagnosis in High Income Countries (HIC), their administration requirements, including costly in person training, expensive test booklets and lengthy administration time, make them less suitable for Low and Middle Income Countries (LMIC). Yet, it is important that ASD be diagnosed accurately so that children with and without ASD receive appropriate interventions. The cost-efficiency and flexible administration requirements of the Childhood Autism Rating Scale (CARS) has made it an instrument of choice for ASD assessment in HIC, as well as LMIC countries, like Jamaica. There has been limited assessment of its diagnostic accuracy in LMIC.
Objectives:
The objective of this paper is to determine the concordance of the CARS, ADOS and ADI-R in Jamaica, a LMIC, to identify the most feasible instrument for use in this setting.

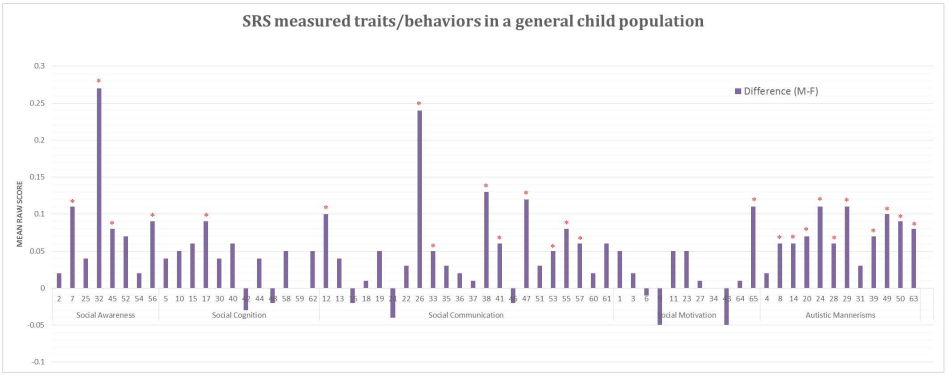
Methods:
149 children, aged 2-8 years, previously diagnosed with ASD by an experienced clinician using the CARS were re-evaluated using the ADOS and ADI-R. The proportion of children confirmed as having ASD by ADOS, ADOS-2 and ADI-R was determined and mean CARS, ADI-R and ADOS scores compared using ANOVA, with significance at a 5% level.
Results:
The mean age of the sample was 64.4 (SD=21.6) months; the male female ratio was 6:1. All children (100%) were confirmed as having ASD using the ADOS, 98.7% (147/149) using ADOS 2 and 94.6% (141/149) using the ADI-R. Of the ten children whose ASD status was not confirmed by ADI-R or ADOS-2, seven did not reach the threshold in at least two domains of the ADI-R, two did not reach the threshold for the ADOS-2, and only one did not reach the threshold scores for either the ADOS-2 or ADI-R. Concordance between the ADI-R and ADOS and ADOS2 was 94.6% and 93.3% respectively. Total ADI-R ADOS and ADOS-2 domain scores were significantly higher for children classified with autism than for those classified autism spectrum ($P<0.01$, $P<0.05$).
Conclusions:
The CARS, used by an experienced clinician, was shown to have high concordance in Jamaica. Use of this easily administered, economical and time efficient instrument by a clinician experienced in ASD, may be appropriate in other LMIC settings. The use of the CARS by clinicians of varying levels of experience with ASD should be evaluated before general recommendations for its use in these settings are made.

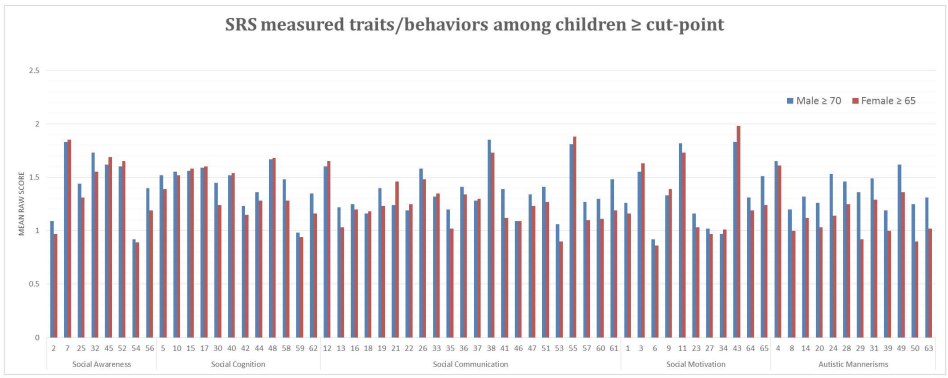
3:04 **119.003** Distributions of SRS-Measured Autistic Traits in a Taiwanese Population of Children Aged 6-8 Years

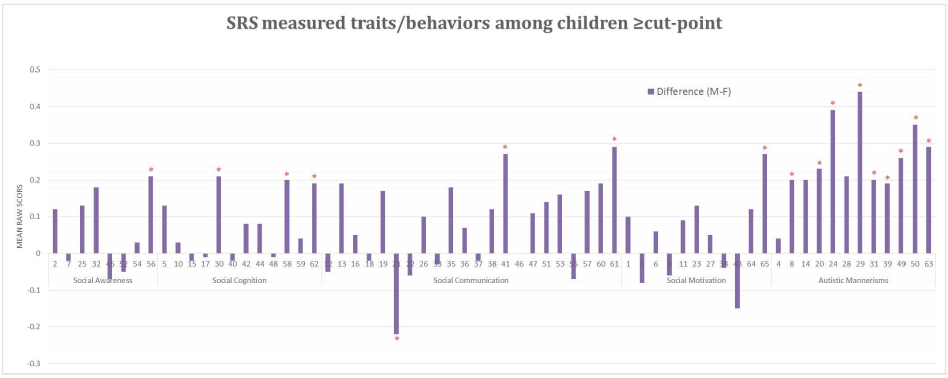
P. C. Tsai[1], *L. C. Lee*[2], *R. A. Harrington*[3] *and F. W. Lung*[4], *(1)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Johns Hopkins University, Baltimore, MD, (4)Calo Psychiatric Center, Pingtung, Taiwan*

Background: It is well accepted that Autism Spectrum Disorder (ASD) represents one end of a larger spectrum of quantitative impairment that is continuously distributed in the general population. The Social Responsiveness Scale (SRS) is an instrument that characterizes quantitative impairments in social awareness, cognition, communication, motivation, and repetitive behavior/restricted interests that define ASD, and provides a subtler characterization of individual symptoms than using traditional classification systems. This tool is particularly feasible for assessing autistic traits in large, population-based studies because it can quantify the spectrum of dimensional impairments of ASD. Implementing the SRS in a large population will allow it to be utilized across different settings and against different norms and subgroups such as gender, age, or racial/ethnical background.
Objectives: To examine the distributions and sex difference of SRS item scores by its five dimensions in a Taiwanese population of children aged 6-8 years.
Methods: Caregiver-reported SRS data were collected by an epidemiologic autism study conducted in Pingtung Taiwan. A total of 2891 primary caregivers completed the SRS for 1428 males and 1546 females. Children whose sex was not reported were excluded from this analysis. Distributions of mean item raw scores were examined by SRS domains and by child sex to describe the population-baseline, and those whose total raw scores were above the cut-point. As recommended in the literature, a raw score of >=70 in males and >=65 in females is a cut-point that provides evidence for the presence of an ASD in Western countries. Of all the included participants, 172 males and 185 females met these recommended cut-points. T-tests were conducted to compare the mean item raw scores between males and females.
Results: As expected, males were rated with higher raw scores on the majority of SRS items (55 out of 65) compared to females in the general population. Significant sex differences were observed for the majority of items in the domains of Social Awareness, Social Communication, and Autistic Mannerisms (AM). Similar score distribution patterns were shown among children who met the recommended cut-points. Notably, the magnitude of item score differences between males and females who met the cut-point is particularly paramount in the AM domain, being between 3 to 4 times that of sex differences in the general population.
Conclusions: Our findings indicate male children in this Taiwanese population have higher item SRS scores than female children, in the general population and in those at high risk of ASD. Higher SRS scores in males have been reported in clinical-based studies, our findings are the first to confirm such a distribution in the general population. We found that sex differences particularly stand out in the AM domain, in both the general population and in children at high risk of ASD. AM may play a key role in interpreting the sex disparity of ASD diagnoses. As there are no autism epidemiologic studies of this kind, our study provides first insights on how autistic traits are distributed in general populations (population baseline) and in those at high risk of ASD.









3:16 **119.004** Counting without the Numbers: Venezuelan Attempts at Prevalence Studies

C. Montiel-Nava[1,2]*, Z. Gonzalez*[1] *and J. A. Chacin*[3]*, (1)Psychology, La Universidad del Zulia, Maracaibo, Venezuela, (2)Center for Graduate Studies, Universidad Latina, Panama, Panama, (3)La Universidad del Zulia, Maracaibo, Venezuela*

B**ackground:** Diagnostic studies involving the Spanish-speaking population are scarce. Although there is no evidence that the clinical presentation of ASD varies across cultures, ethnicities, or races, there are disparities in prevalence and age of diagnosis for the different countries and ethnic groups. Globally, ASD prevalence has increased and the age of diagnosis has decreased, but not for the Latino population. Prevalence studies in LAMI countries serve many purposes: They offer data for health and educational planning, allow international comparisons for the study of risk factors, protective factors, and cultural influences, and, finally, permit the cultural adaptation of assessment tools.

Objectives: The aim of this manuscript is: (1) to discuss the results of epidemiological research in Venezuela in light of methodological features and (2) to offer conclusions about the best up-to-date methods for data collection.

Methods: We present the results of three different studies that focused on ASD prevalence in Venezuelan children. We considered and analyzed sampling processes, screening and diagnostic procedures, and response rates. Then we reviewed and compared adjustments from standard prevalence estimation approaches used in other countries.

Results: The first report was designed as a population study However, birth records, visits to pediatricians, and vaccinations among others were not always registered. Other

logistic difficulties included the absence of public services (electricity, sewage, telephone) for many houses, which made them nonexistent in public records. In addition, some urban areas were dangerous, which prevented researchers from going into the houses to assess children. Obstacles to implementing this method hindered data collection, the determination of research findings, and, hence, the proper calculation of prevalence rates for ASD. The second study aimed to establish prevalence through the review of records in public and private institutions for special education and in specialized clinics. The overall prevalence of ASD was 1.7 per 1,000 (95% CI: 1.3-2.0). For this approach, we found that some of the children's records were missing. Moreover, despite legal requirements, not every child with disability was included in the school system or the health system. The third study used school records. Thus, it was possible to assess the children in their schools and, consequently, to avoid security issues. For this study, the estimated prevalence was 7.18 per 1,000 (95% CI: 5.3-9.6). We faced the same difficulties with records because not all children were attending school at the time of the study. The last approach was the best one we identified for the development of data in a culturally appropriate way.
Conclusions: In Venezuela, as in most Latin American countries, the difficulties experienced while conducting prevalence studies were not related to translation and the adaptation of diagnostic instruments. The main problems were related to sampling procedures and the quality of public records. As we develop a stronger, valid, cross-cultural process for the identification of ASD, our findings could be compared to those of other countries and larger databases.

120 - Social Cognition and Social Behavior
1:45 PM - 2:35 PM - Room 310

1:45 **120.001** Social Reinforcement Learning and Its Neural Modulation By Oxytocin in Healthy Young Adults

J. A. Kruppa[1,2], *A. Gossen*[1,2], *N. Großheinrich*[1], *H. Schopf*[1], *G. Kohls*[1], *G. R. Fink*[2], *B. Herpertz-Dahlmann*[1], *K. Konrad*[1,2] *and M. Schulte-Rüther*[1,2], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (2)Cognitive Neuroscience, Institute of Neuroscience and Medicine (INM-3), Jülich Research Center, Jülich, Germany*

Background: Currently, no pharmacological treatment of the social symptoms of Autism Spectrum Disorder (ASD) is available and behavioral interventions only show modest effects. Recently, oxytocin (OXT) has been shown to enhance motivation and attention to social stimuli, by modulating the brain reward circuitry in social situations. Likely, these effects have the potential to enhance social reinforcement learning, the core mechanism of behavioral interventions. However, it is unclear whether these effects are mediated by an OXT-induced increase in saliency towards social stimuli per se or whether they are due to a modulation of the brains' reward circuitry, which is specific for social feedback. This question plays an important role for the design of future interventions aiming to combine OXT and behavioral treatments in ASD.
Objectives: We investigated the influence of OXT on socially reinforced learning and its underlying neural mechanisms in a social learning task, which allowed for the differentiation of social feedback stimuli and social stimuli as the target of learning.
Methods: Using functional Magnetic Resonance Imaging we assessed brain activation during performance of a probabilistic reinforcement learning task in 24 typically developing controls (18-25 years). We used a double-blind placebo-controlled cross-over design. Participants indicated whether social or non-social stimuli belong to category A or B. After a jittered delay, social or non-social feedback (either rewarding or neutral) with non-100% contingencies was provided. Data were analyzed using computational modeling of reinforcement learning, according to the Q-learning model. From the behavioral choice data, individual model parameters were estimated and used to calculate trial-by-trial reward-prediction error values. We assessed the correlation of brain activation with reward-prediction error values during feedback as well as brain activation related to the anticipation of reward during choice. Results were significant at $p<.05$ (cluster-level corrected, $p<.001$ voxel level).
Results: Analyses revealed a significant correlation of brain activation in the striatum with the reward prediction error across conditions, confirming that overall learning was mediated by striatal circuitry. During feedback anticipation, OXT selectively enhanced brain activation in the striatum and insular cortex for social *feedback* conditions despite the learning target being non-social. The learning *target* being social, however, did not show a modulation by OXT during feedback anticipation. Behaviorally, subjects demonstrated significant learning during the task independent of task or treatment condition. More extensive analyses including data of patients with ASD will follow.
Conclusions: Our results demonstrate that in healthy controls, OXT selectively enhances brain activation related to the acquired anticipation of social feedback, but no selectivity was evident for social stimuli as a learning target. This pattern suggests that the modulatory role of OXT during reward processing is tied to the feedback phase being social. Our investigation therefore provides deeper insights into the neural mechanisms of OXT-induced modulation of the reward system and its potential enhancement of socially reinforced learning. Combinations of behavioral interventions with OXT might be particularly effective, if emphasis is put on positive, socially mediated feedback. Further investigations are needed to study this mechanism and its implications for interventions with OXT in ASD.

1:57 **120.002** Influences of Others' Gaze Behaviors on Attentional Allocation during Activity Monitoring in Adults with and without ASD

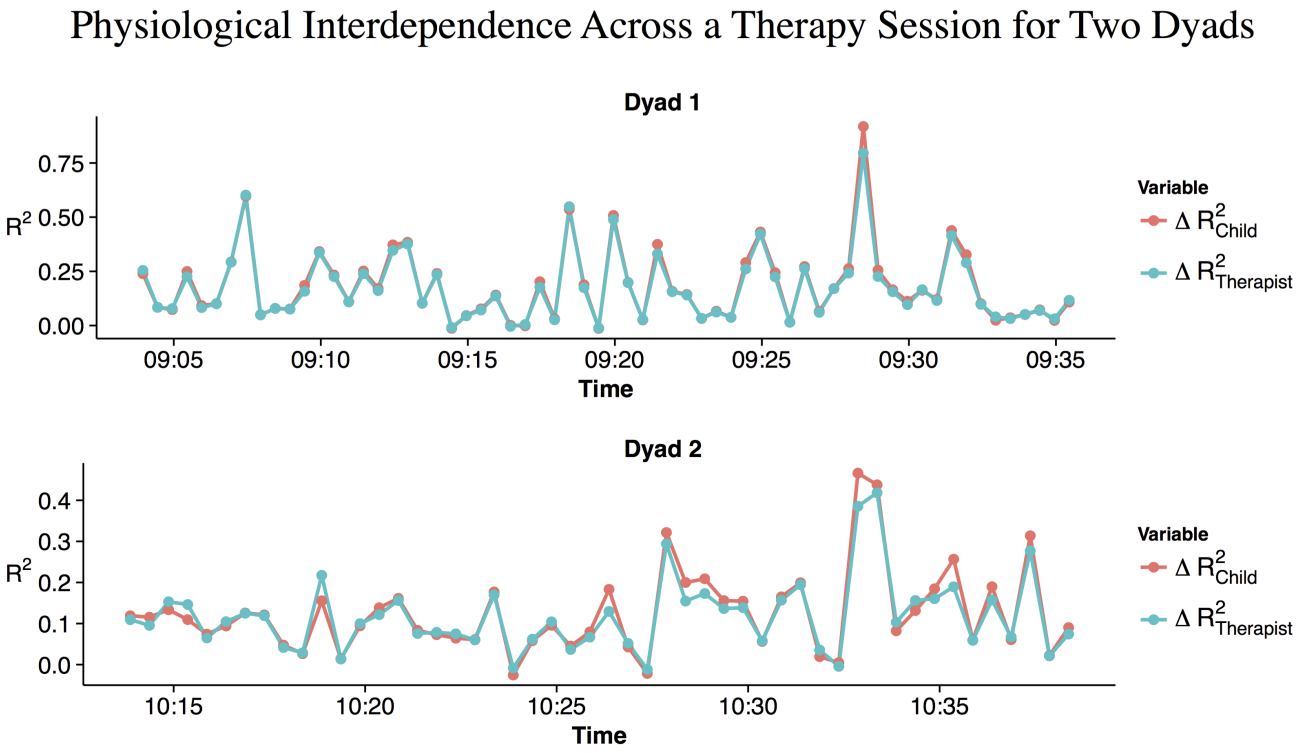
Background: Previous work implementing an activity monitoring eye-tracking task in 20-month-old toddlers suggested diminished attention towards people and their activities in toddlers with autism spectrum disorder (ASD) when compared to developmentally delayed and typically developing (TD) comparison groups (Shic et al., 2014). However, no significant differences in attentional allocation between ASD and comparison groups were found in response to varying gaze cues from actresses in the task. It is unknown if this lack of differential response to others' gaze behaviors in ASD and TD toddlers remains stable across development.
Objectives: To explore the effects of others' gaze behaviors on attentional allocation during activity monitoring in adults with and without autism.
Methods: Participants included high-functioning adult males with autism (n=18; M_{age}=24.89±6.45; M_{FSIQ}=102.26 SD=14.31) and TD adult males (n=19; M_{age}=26.68±4.33; M_{FSIQ}=117.68 SD=9.70). One participant with ASD was lost due to missing data, and an additional 2 ASD and 2 TD participants were excluded due to high numbers of trials with invalid calibration (n=15 ASD, n=17 TD remaining). Participants were seen over two days to complete clinical and experimental assessments, including an eye-tracking battery. One eye-tracking task was an activity monitoring task, in which participants viewed 12 video clips, each 20s in duration, of 2 actresses interacting in naturalistic scenes, engaging in a shared activity. This task was parsed into two gaze conditions: (1) the actresses fixated on the shared activity (activity gaze condition), (2) the actresses fixated on each other (mutual gaze condition). Analyses were conducted to examine the effect of gaze condition on the proportion of time participants spent looking at the actresses' heads (%Head).
Results: Linear mixed model analyses revealed a significant effect of gaze condition on %Head ($p<.001$, d= 0.67), with both TD and ASD participants directing their gaze more to actresses' heads during mutual gaze trials. However, there was a significant group x gaze condition interaction ($p<.05$), with differences in %Head in response to gaze condition significantly larger in the TD group.
Conclusions: Comparisons suggest that high-functioning individuals with ASD exhibit sensitivity to gaze behaviors of others during activity monitoring, but to a lesser degree when compared to TD participants. Unlike toddlers, adults with and without ASD appear to attend to actresses' gaze information. The significant group x gaze condition interaction may be attributed to the fact that the mutual gaze condition deviates more notably from typical gaze patterns, which may drive increased fixation to heads in TD participants. It is possible that the high-functioning adults with ASD were not recognizing the deviations from typical gaze patterns to the same degree as TD participants. These findings differ from those previously observed in toddlers, suggesting that sensitivity to gaze information in ASD and TD individuals presents differently across development, with once similar responses in childhood diverging in adulthood. Examination of response patterns in school-aged children and adolescents, and across greater variability in social and cognitive functioning, is still necessary in order to understand the complete developmental trajectory of sensitivity to gaze information during activity monitoring in ASD.

2:09 **120.003** Quantitative Assessment of Socio-Affective Dynamics in Autism Using Interpersonal Physiology

O. O. Wilder-Smith[1], *J. C. Sullivan*[1], *R. V. Palumbo*[1], *C. DiStefano*[2], *A. Gulsrud*[3], *C. K. McCracken*[4], *C. Kasari*[5] *and M. S. Goodwin*[1], *(1)Northeastern University, Boston, MA, (2)Psychiatry and Biobehavioral Sciences, University of California Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)University of California, Los Angeles, El Segundo, CA, (5)University of California Los Angeles, Los Angeles, CA*

Background: Children with Autism Spectrum Disorder (ASD) often have great difficulty interpreting and using nonverbal communication, understanding and navigating social relationships, and making sense of their own and others' emotions. Many of these impairments relate to deficits in *social reciprocity* (SR), the ability to recognize and understand the mental states of others and respond appropriately. In addition, deficits in emotion regulation (ER), the ability to modulate emotional response to a situation to achieve a goal, are implicated in several core features of ASD, including socioemotional problems and challenging behaviors (Cohen, et al., 2011; Gross, 2013; Gulsrud, Jahromi, & Kasari, 2010; Mazefsky et al., 2013). One possible explanation for these findings is that early SR deficits interfere with effective infant-caregiver *co-regulation*, caregiver-driven regulation crucial for developing effective self-driven ER and an important target for early intervention (Gulsrud, Jahromi, & Kasari, 2010). SR and ER are under-studied in ASD, and existing methods for assessing co-regulation mainly rely on labor-intensive and potentially subjective behavioral observation. Physiological measures offer a complimentary means for objectively evaluating SR and ER simultaneously in dyads that include an individual with ASD and a partner (e.g., peer, caregiver,

teacher), shedding light on biological processes that may underlie observable behavior. However, dyadic physiological data is complex to analyze and interpret, and to-date only two published studies have examined such data in children with ASD (Baker et. al., 2015; Chaspari et. al., 2014).
Objectives: Develop a novel analytic procedure for modeling interpersonal physiological dynamics and evaluate that model on pilot data collected from minimally-verbal (MV) children with ASD and their therapists during an empirically validated intervention focused on joint engagement and co-regulation (Kasari, Freeman, & Paparella, 2006). Using dynamical systems models, our analytical method provides clear effect sizes for levels of physiological interdependence (i.e., synchrony) and shows consistency with existing behavioral coding data.
Methods: Electrodermal activity (EDA) data was wirelessly recorded from six MV children with ASD and their therapists during intervention sessions. Using a windowed time-series approach, we applied a dynamical systems model of self- and co-regulation. For each child-therapist dyad we extracted the percentage of variance explained by their partner's physiology via hierarchical regression. Subsequently, we assessed correspondence of these interpersonal physiological parameters with expert-coded behavioral measures of SR using a mixed-effects model to account for the nested structure of the data.
Results: Our dynamical systems model explained significant variance attributable to interpersonal influence (R^2 range: 0.0 – 0.67), and showed correspondence with behavioral coding of SR-relevant behaviors ($F(2,61)=4.21$, $p<.05$, $R^2=0.10$).
Conclusions: These data confirm the co-regulatory nature of the child and therapist physiology, and correspond to behavioral ratings, while providing greater temporal specificity on co-regulatory dynamics. To our knowledge, this is the first time interpersonal physiological measures using dynamical systems models have been applied to dyadic interactions in children with ASD. The utility of physiological measures for evaluating interpersonal functioning, and our new analytic technique, shows promise for allowing more efficient, objective, reproducible, and sensitive indices of SR and ER to study developmental underpinnings of socio-affective dynamics in ASD.

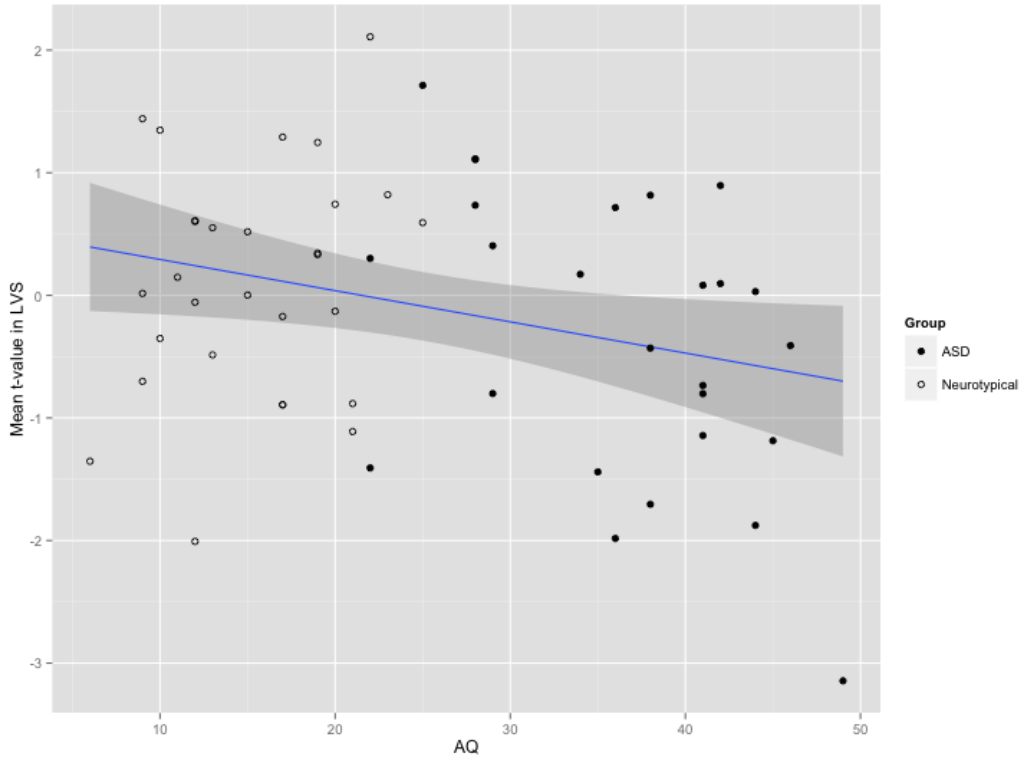


*R^2 = Percentage of variance explained in one person's physiology by her or his partner's physiology

2:21 **120.004** Reduced Reward Related Response to Imitation in Autism Spectrum Conditions

B. Chakrabarti[1], *J. Neufeld*[1,2] *and C. T. Hsu*[1], *(1)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)Center of Neurodevelopmental Disorders, Karolinska Institutet, Stockholm, Sweden*

Background:
Imitation facilitates the formation of social bonds in humans, from an early age. Parents routinely imitate their babies to build rapport. Neurotypical humans find others who imitate them to be more rewarding, and imitate those who are more rewarding to them. These phenomena suggest a link between imitation and reward. In separate EMG and fMRI studies in individuals with and without Autism Spectrum Disorders (ASD), we have previously demonstrated that autistic traits modulate imitative responses to rewarding social stimuli. These results suggest that autistic traits modulate the link from reward to imitation. However, the link from imitation to reward has not been studied in ASD. Investigating this link is vital in light of the crucial role of imitation as an instrument of social bonding. On the basis of our previous results showing an atypical reward-imitation link in individuals with high autistic traits and a clinical diagnosis of ASD, we hypothesised that being imitated may not be equally rewarding for individuals with ASD.
Objectives:
To test if individuals with ASD show a reduced reward-related neural response to being imitated.
Methods:
26 ASD and 30 neurotypical (NT) adults, matched for age, gender, and IQ, performed a 2-part task. The first part was a conditioning task outside the scanner, where participants were mimicked by one face and 'anti-mimicked' by another. The participants were instructed to make a facial expression (happy/sad) while watching faces on screen that would either make a congruent or an incongruent expression, 700ms after the participant initiated the instructed expression. This created the subjective impression of being mimicked/ anti-mimicked. The second part was done in a 3T fMRI scanner, where participants passively viewed neutral expressions of the conditioned faces one at a time, using an event-related design. We hypothesised that the NT group would show greater reward-related ventral striatal (VS) response to the mimicking compared to the anti-mimicking faces, when compared to the ASD group. The VS cluster was defined using an independent meta-analysis of reward processing studies (Liu et al, 2010).
Results:
Data were analysed using SPM8, using a standard processing pipeline. Contrast statistics for [mimicking>anti-mimicking faces] were extracted from the VS cluster, and analysed using multiple regression. This analyses showed a main effect of group in the left VS (beta [group] = -0.662, p = 0.0265). Specifically, the left VS response to [mimicking>antimimicking faces] was found to be significantly lower in the ASD group compared to the NT group (t = -1.69, p = 0.0486). The left VS response negatively correlated with self-reported autistic traits (as measured using the Autism Spectrum Quotient, AQ) across the whole sample (r = -0.29, p = 0.0307). No significant differences were observed in the right VS.
Conclusions:
The results support our hypothesis that in individuals with high autistic traits and those with a clinical diagnosis of ASD, being imitated is associated with lower reward-related striatal response when compared to controls. This result offers a potential explanation for why individuals with ASD find it difficult to form social bonds.

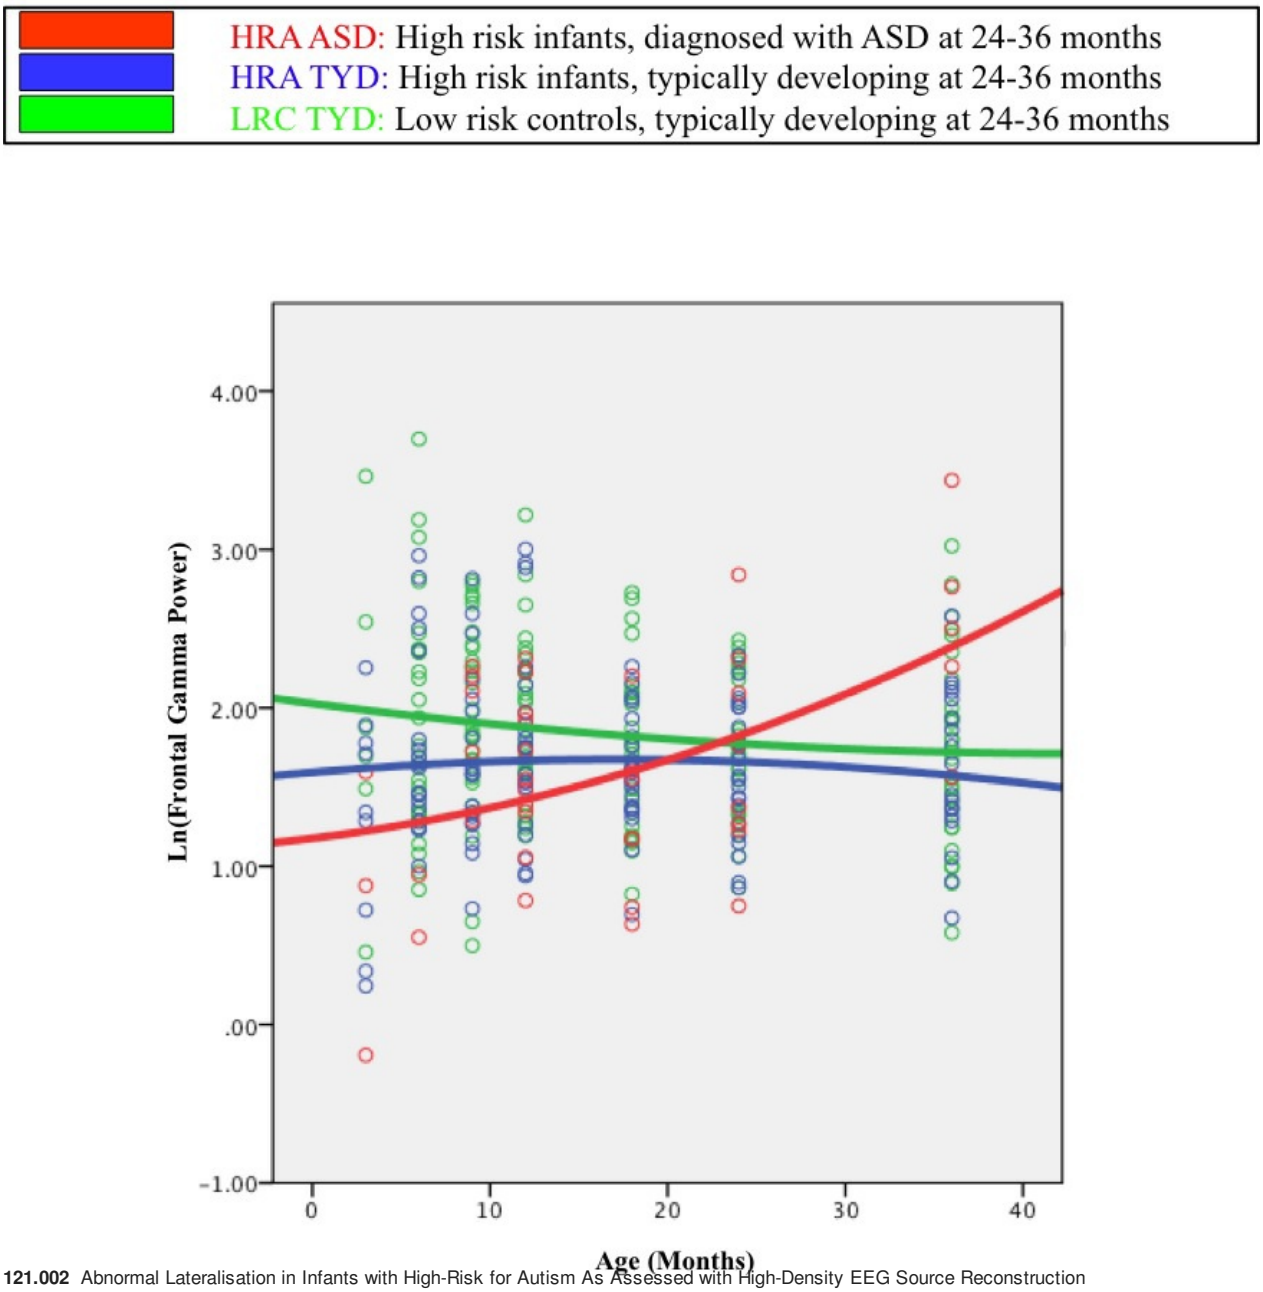


Oral Session - 5B
121 - New Frontiers in Infant Brain Functional Imaging
2:40 PM - 3:30 PM - Room 310

2:40 **121.001** Trajectories of Frontal Gamma Power from 3 to 36 Months in Infants Later Diagnosed with Autism Spectrum Disorder

A. R. Levin[1], *H. M. O'Leary*[2], *K. J. Varcin*[3], *M. K. Crossman*[4], *H. Tager-Flusberg*[5] *and C. A. Nelson*[6], *(1)Boston Children's Hospital, Brookline, MA, (2)Neurology, Boston Children's Hospital, Boston, MA, (3)Harvard Medical School, Boston Children's Hospital, Cambridge, MA, (4)Boston Children's Hospital, Watertown, MA, (5)Boston University, Boston, MA, (6)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Baseline gamma band activity is altered in people with autism spectrum disorder (ASD) at a variety of ages, and may represent abnormalities in local processing or feedback between excitatory and inhibitory neurons. Infants with an older sibling with autism have a high risk of developing ASD (HRA), whereas infants with a typically developing older sibling act as low risk controls (LRC). Tierney et al. (2012) previously demonstrated that from 6-24 months, the trajectory of EEG gamma power differed in HRA compared to LRC infants.
Objectives: We aimed to evaluate the extent to which the developmental trajectory of EEG gamma power in infants who go on to meet criteria for ASD differs from the trajectory of those that do not.
Methods: We collected serial high-density baseline EEGs on infants 3-36 months of age. At 36 months, diagnosis of ASD was determined via ADOS and confirmed by clinical impression. We calculated frontal gamma power in EEGs from 3 groups of subjects: Low risk controls who do not develop ASD ((LRC-, n=80); high risk subjects who do not develop ASD (HRA-, n=64); and high risk subjects who do develop ASD (HRA+, n=23). We used multilevel modeling to assess change over time in frontal gamma power for subjects in each of the 3 groups. We then calculated the sensitivity and specificity of an upgoing trajectory of gamma power in predicting ASD.
Results: High risk infants who subsequently developed ASD (HRA+) showed an altered trajectory of frontal gamma power during the first 36 months of life, compared to HRA- ($p<.05$) and LRC- ($p<.05$) infants. An upgoing trajectory of gamma power between 3 and 36 months is 70% sensitive and 72% specific for a diagnosis of ASD.
Conclusions: The developmental trajectory of frontal gamma power tends to be more positive in infants who later develop ASD. Further research is necessary to better understand the mechanism underlying this finding, and to develop clinically applicable tests and treatments that offer utility prior to the onset of definitive behavioral manifestations of ASD.



2:52 **121.002** Abnormal Lateralisation in Infants with High-Risk for Autism As Assessed with High-Density EEG Source Reconstruction

C. O'Reilly[1], *M. Elsabbagh*[2] *and T. B. Team*[3], *(1)École Polytechnique Fédérale de Lausanne, Geneva, GE, Switzerland, (2)McGill University, Montreal, PQ, Canada, (3)Birkbeck, University of London, London, United Kingdom*

Background: Aberrant lateralisation of functional connectivity has been reported in many EEG and MEG studies of autism. For example, using MEG recordings, Keehn et al. (2015) [Autism Res, 8(2), 187-198] reported autism to be associated with leftward (instead of the normal rightward) lateralisation of face processing emerging around one year of life. No such spatially-resolved analyses have yet been proposed using EEG source reconstruction.

Objectives: To investigate abnormal lateralisation in EEG functional connectivity.

Methods: Our sample contains recordings from 14-months-old infants at-risk for autism who were later diagnosed with ASD (ASD; N=11) or not (noASD; n=24), as well as controls (Control; N=40). Infant EEG was recorded in response to gaze shift directed toward or away from the infants [Elsabbagh et al., (2012), Cur Biol, 22, 338-342]. After basic preprocessing (reformatting to average reference, notch filtering, within-condition time-locked averaging), sources were estimated from high-density EEG recordings using a newly developed MRI template. The first principal component was then computed from dipoles included within every region of the Tzourio-Mazoyer atlas. Finally, between-regions connectivity was computed using phase-locking values.

Results: Following a preliminary exploratory investigation, we concentrated our analysis on delta activity (1-4 Hz) during direct gazes because this condition yielded the strongest between-group differences. Three regions showed significant effects (Bonferroni corrected at $p<0.05$ corresponding to uncorrected $p<0.00056$) for ASD vs. Control comparison and four regions for the noASD vs. Control comparisons. All significant effects were showing overconnectivity for the noASD group and underconnectivity for the ASD group. The table accompanying this abstract gives the mean (± standard deviation) of the phase-locking value as well as p-values and t-values for the 7 most significant regions, for both group comparisons. Further, the three regions (see the accompanying figure for violin plots showing the distribution of the connectivity for these regions) giving the most significant differences for noASD group (right thalamus; left middle temporal gyrus; right inferior frontal gyrus, triangular part; all overconnected) were all showing clear underconnectivity in the homologous regions (i.e., same regions, opposite hemisphere) for the ASD group. These homologous regions were among the first seven most significantly affected regions for the ASD group, all with $p < 0.0065$ (uncorrected). Had these two sets of 3 and 7 regions been picked randomly, the odds of observing at least three such correspondences would only have been of only 0.03%.

Conclusions: Spatially-resolved connectivity obtained through source reconstruction distinguishes both noASD and ASD from controls, with strikingly opposed patterns of abnormal lateralisation. Our results also showed clear underconnectivity in the ASD group and clear overconnectivity in the noASD group, showing a possible compensatory mechanism in infants at-risk who do not develop ASD. These effects were clearly seen in the delta band, when showing pictures of direct gazes.

region	noASD	control	p-values	t-values
Left Middle temporal gyrus	0.91 (±0.03)	0.85 (±0.05)	9.0E-06	-5.00
Right Thalamus	0.83 (±0.07)	0.70 (±0.14)	1.2E-04	-4.10

Background: Autism spectrum disorder (ASD) is a common neurodevelopmental disorder defined by impaired social communication and interaction, and restricted and repetitive behaviors. The relationships between restricted and repetitive behaviors and underlying brain function, especially during the first years of life, have yet to be elucidated.

Objectives: This work investigates whether particular patterns of correlations between brain regions, as measured with resting state functional connectivity MRI (fcMRI), relate to restricted behaviors, as assessed with the Repetitive Behavior Scale – Revised (RBS-R).

Methods: This work focuses on fcMRI and RBS-R data collected from N=95 24 month old (mo) children across four sites within IBIS, an NIH ACE Network.

Cohorts: Children were classified as high risk (HR) if they had a sibling with ASD, or low risk (LR) if they had at least one sibling without ASD and no 1st or 2nddegree relatives with ASD. Groups were assigned by research clinical best estimate using the DSM-IV-TR checklist at 24mo (HR+/HR-/LR-: n=22/59/13).

fcMRI data: For each child, fcMRI data were processed using state-of-the-art protocols, including motion scrubbing at a conservative FD level of 0.2 mm. Analyses utilized 150 frames of clean fcMRI data from each subject. Time traces from 230 functionally-defined regions of interest (ROI) throughout the cerebrum and cerebellum were correlated to yield fc values, and grouped into each of 17 putative functional networks, identified using the Infomap community detection algorithm (**Figure 1a**).

Restricted behavior data: The RBS-R is a behavioral assessment composed of 43 parent/caregiver-rated items that rates the level of stereotypical, self-injurious, compulsive, sameness, ritualistic and restricted behavior of the subject (**Figure 1b**). These analyses focus on the restricted subscale.

Brain-behavior analysis: Enrichment analyses were used to determine which functional brain networks are most associated with restricted behaviors. Each ROI-pair fc value was correlated (Spearman) across subjects with the RBS-R restricted subscale scores. These correlation values were then thresholded at an uncorrected p-value of 0.05. Two complementary metrics (a $\chi^2$and a hypergeometric test) were used to determine if the number of strong brain-behavior correlations within each network-pair of the matrix was greater than the number expected by chance. Empirical significance levels were determined using randomization. An experiment-wide false-positive rejection rate of 5% was used.

Results: Specific groupings of significant correlations of fc with restricted behaviors (**Figure 1c-f**) occurred for either an attention, a control, or the default mode network (i.e. the parietal dorsal attention network (pDAN), the default mode network (DMN), the posterior DMN (pDMN), the anterior frontoparietal task control network (aFPC), the posterior FPC (pFPC), the dorsal-anterior DMN (daDMN), the medial visual (mVis) network and the pPFC (**Figure 1g**)). The pPFC is also significantly enriched within its intra-network connections.

Conclusions: Restricted behavior and brain functional connectivity in 24mo children are strongly associated with a small set of specific functional brain networks. These involve infant-toddler manifestations of the default mode, dorsal attention, and fronto-parietal task control networks.

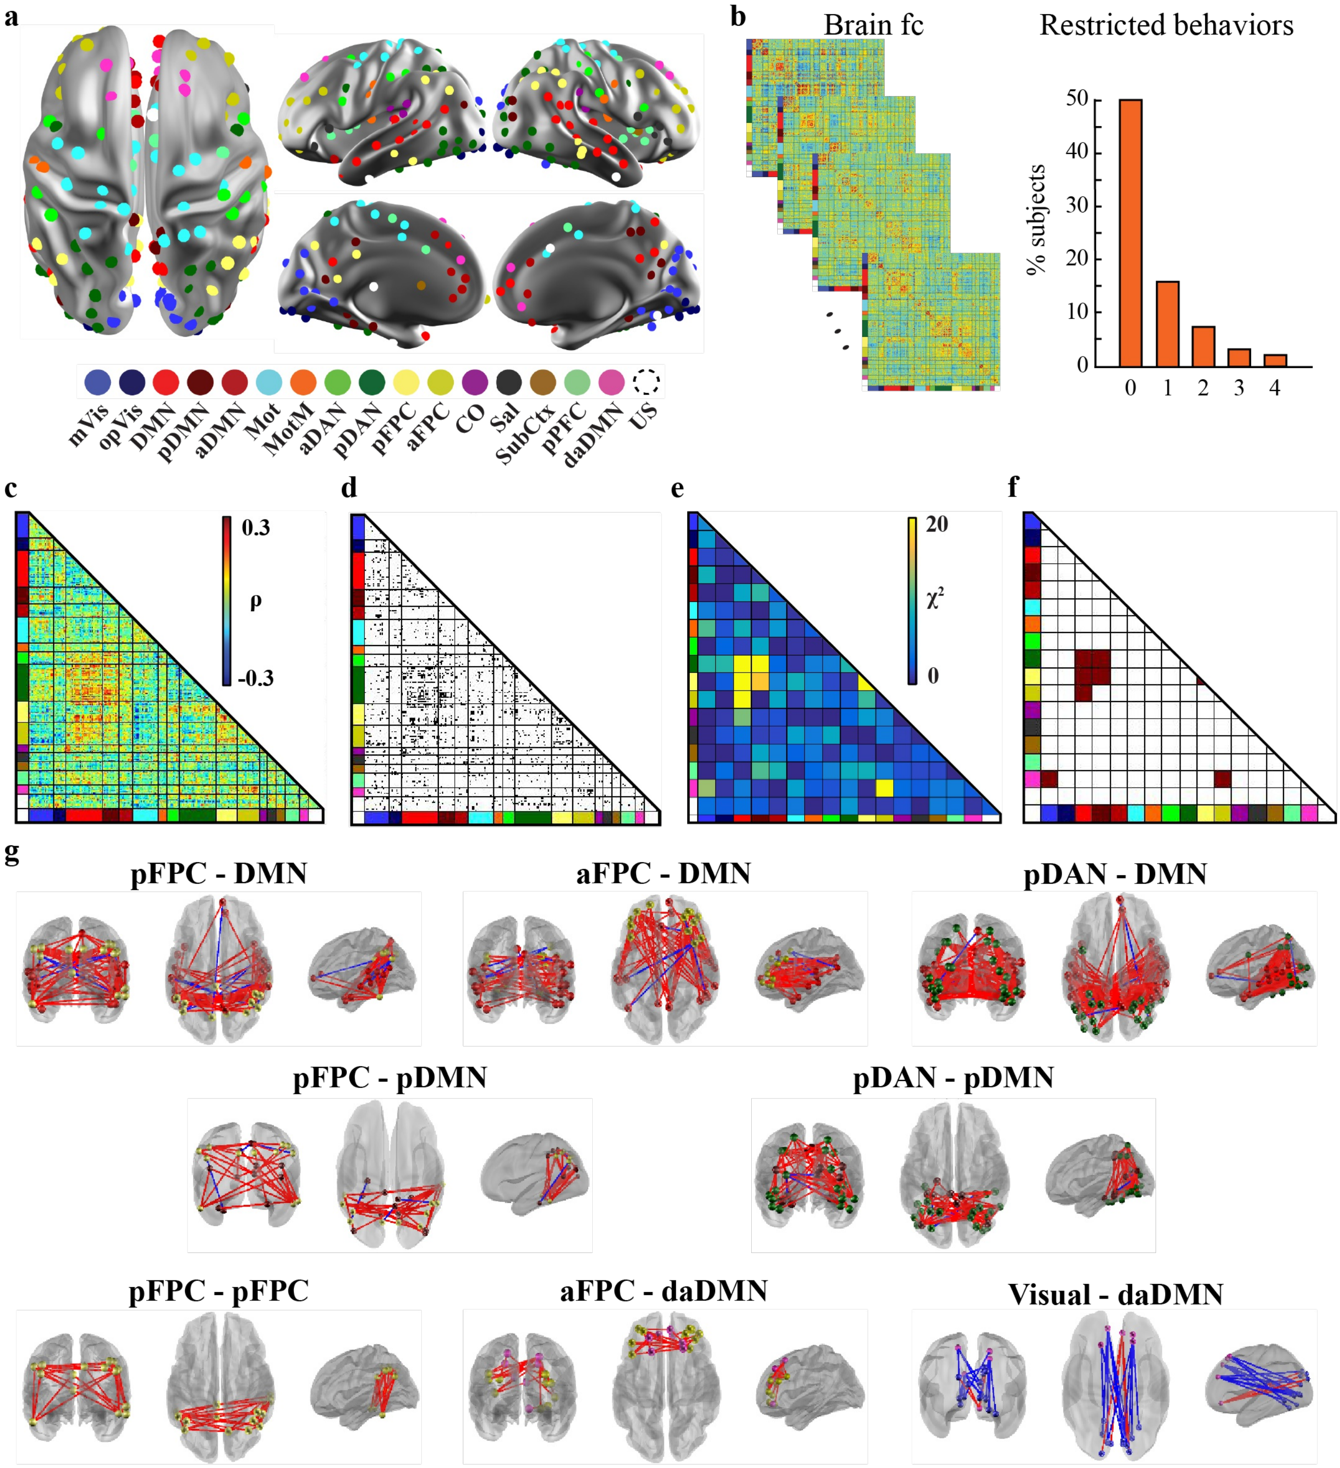

Figure 1 | Brain-behavior analyses of restricted behaviors in 24-mo toddlers. a The functional organization of the toddler brain throughout 230 regions of interest (ROIs) was derived using the Infomap algorithm on the mean fcMRI matrix from 37 subjects with longitudinal data. The color of ROIs represents their putative functional network. **b** Brain fc between 26,335 ROI pairs was correlated across subjects against the RBS-R restricted behavior score, yielding a matrix of Spearman - ρ correlation values (**c**) and a matrix of uncorrected p-values less than 0.05 (**d,** black). **e** The χ^2 statistic calculates the enrichment level of strong brain-behavior correlations within network pairs. **f** Significant enrichment (red squares) was determined through randomization. **g** Significantly enriched network pairs tend to exhibit primarily positive (red lines) or negative (blue lines) brain-behavior correlations.

Background: Gross motor deficits in infancy are one of the earliest findings linked to ASD, highlighting the potential interrelationship between motor delay and ASD-specific symptom emergence. Characterizing brain-behavior relationships for specific aspects of motor function may, therefore, elucidate neurobiology underlying the development of

ASD.

Objectives: To test whether correlations between gross motor behavior and ROI-ROI functional connectivity (fc) 1) are enriched for specific brain networks, and 2) change between 12 and 24 months.

Methods:

Participants:The Infant Brain Imaging Study includes high-risk (HR: has sibling with ASD) and low-risk (LR: has sibling(s) without ASD) infants. A clinical best estimate ASD diagnosis was assigned at 24 months. Included participants had fcMRI and behavioral data at 12 (n=129; HR+/HR-/LR-=12/76/38) and/or 24 months (n=108; HR+/HR-/LR-=19/63/25).

***Imaging*:** Resting state fcMRI data were acquired on identical 3T Tim Trio scanners at 4 sites with up to 3 BOLD runs (130 frames each run with TR=2.5 seconds). Data processing included motion scrubbing at a FD level of 0.2 mm. One-hundred-fifty frames of clean data were used per subject. Time traces were correlated between 230 functionally-defined regions of interest (ROI) to yield fc values (**Fig.1b**). ROIs were sorted into 17 putative functional networks using the Infomap community detection algorithm run on the mean connectivity matrix for longitudinal fcMRI data from 37 subjects (**Fig.1a**).

Measures: Gross motor function was indexed by raw gross motor scores on the Mullen Scales of Early Learning (**Fig.1c**). Five items were summed to create a "walking scale" at 12 months.

Brain-behavior analysis* (Fig.1d):* We identified network-network pairs significantly enriched for ROI-ROI fc values that strongly correlated with behavior. fc values for all ROI pairs were correlated against behavioral scores and thresholded at p<.05 (uncorrected). 2x1 X^2 tests and hypergeometric tests established whether enrichment within network pairs exceeded that expected by chance. A 5% false-positive rejection rate was determined by permutation**.** McNemar tests assessed whether enrichment differed between 12 and 24 months.

Results:

Brain-behavior correlations frequently involved the motor network, especially at 12 months (**Fig.1d-f**). Largely interhemispheric ROI pairs within the motor network markedly overlapped for gross motor and walking scores, mapped predominantly to the presumed lower limb region of motor cortex, and negatively correlated with behavior at 12 months (**Fig.1g-h**). Conversely, several motor-frontoparietal and motor-dorsal attention network pairs positively correlated with behavior. There were greater involvements of frontoparietal and dorsal attention network pairs at 24 months. Significant age-dependent differences in brain-behavior relationships were observed (**Fig.2a,b).**

Conclusions:

Motor network involvement at 12 and 24 months supports the face validity of this analytic approach. Brain-behavior correlations enriched within the motor network suggest that decreased fc between interhemispheric (potentially lower limb) motor ROIs correlates with greater walking ability in early development. At 24 months, enriched positive brain-behavior correlations involving task-control and dorsal attention networks implicate these networks in motor skill development. Future directions include comparisons of brain-behavior relationships for motor functioning in children with and without ASD, and investigating whether similar observed brain-behavior relationships correlate with the differential development of social communication in ASD.

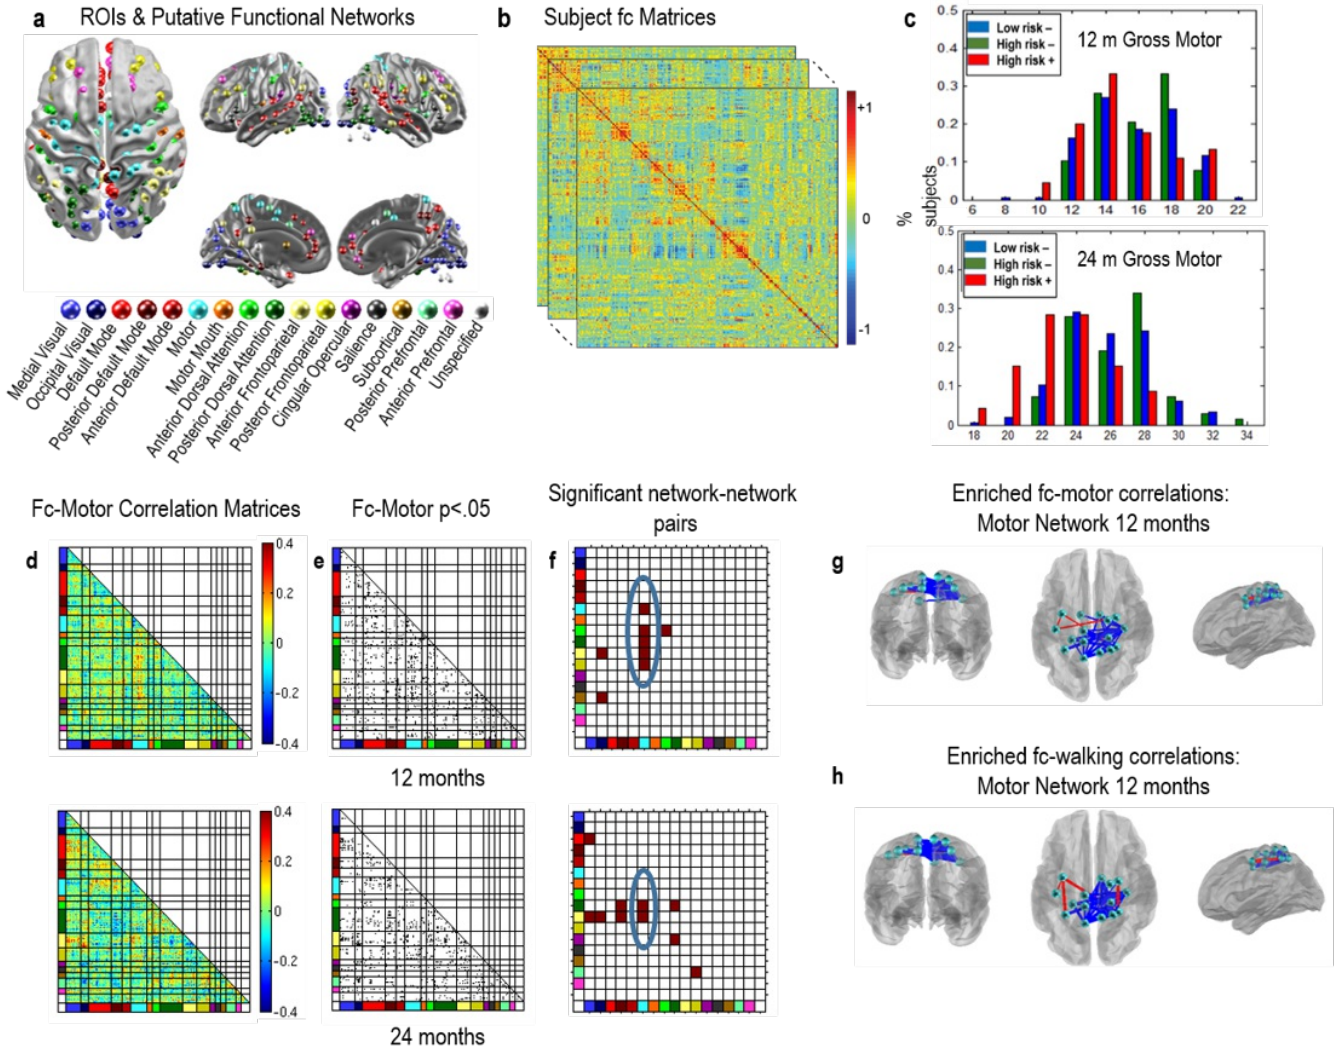

Figure 1. Brain Behavior Analysis (a) Balls represent functionally defined ROIs. Colors indicate network associations as listed. (b) Each child contributes a 230 ROI x ROI fc-matrix. (c) Raw gross motor score distributions at 12 and 24 months, divided by diagnostic subgroup. Children across all diagnostic subgroups were pooled for brain-behavior analyses. (d-g) Parallel analyses for 12 and 24 months to identify network-network blocks enriched for brain-behavior relationships in which functional connectivity (fc) for given connections (ROI-ROI pairs) is significantly associated with motor score. (d) ROI-ROI Pearson correlation of fc with behavior. Side bar indicates correspondence between colors and strength of brain-behavior correlation values, which range between 0.4 and -0.4. (e) ROI-ROI pairs with fc-motor correlation of p<0.05 (uncorrected). (f) Network pairs passing significance testing as determined by permutation analysis are shown in red. Blue circles indicate blocks involving the motor network. (g) ROI pairs in motor-motor subnetwork block whose fc significantly correlates with gross score at 12 months. Blue indicates a negative brain-behavior relationship between ROI pairs, which are mostly interhemispheric. (h) ROI pairs in the motor-motor network block whose fc correlates with a derived walking score at 12 months. Note the close similarity in the ROIs for walking and gross motor scores, as well as the location near regions of motor cortex associated with control of lower limbs.

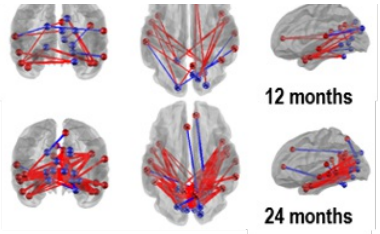
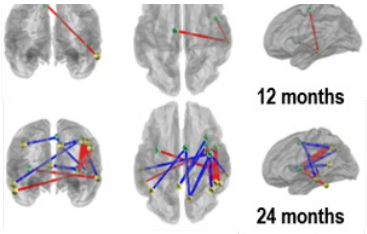
Figure 2. Changes in Patterns of Enriched fc-Motor Correlations in Network Pairs at 12 and 24 months: 2a & b



Default Mode-Medial Visual



Posterior Fronto-parietal-
Poster Prefrontal Cortical

Correlations in Network Pairs at 12 and 24 months: 2a & b show the 2 network pairs with a significant change in the pattern of enrichment based on the McNemar test. Red and blue lines indicate positive and negative brain-behavior relationships, respectively. At 24 months, both 2a and 2b show more ROI pairs whose fc significantly correlates with motor function. 2c-e display the 3 significant network pairs at 12 and 24 months *which did not significantly change in amount of enrichment*. In 2c, the direction of the fc-motor correlations switched from negative to positive, while in 2d, a profile of mixed positive and negative fc-motor correlations became predominantly positive, showing the potential for marked variability in brain-behavior relationships over time.

1 **122.001** . Altered Pupil Responsivity to a Gaze Following Task in Children with an Autism Spectrum Disorder

M. A. Braeken, *L. Van Schuerbeeck and M. Vanvuchelen, Faculty of Medicine and Life Sciences - Rehabilitation Research Center (REVAL), Hasselt University, Diepenbeek, Belgium*

Background: Previous research has shown that changes in pupil size reflect cognitive resource allocation. Moreover, pupillary response is often used as a physiological measure for emotional arousal. Therefore, pupillary responses potentially can provide more insight in cognitive deficits and stress regulation as an underlying mechanism in deficits characteristic for Autism Spectrum Disorders (ASD).
Objectives: The aim of this study is to investigate which aspect primarily affects the physiological response (i.e., pupillary response) to a gaze following task in children with ASD and age-matched typically developing children, i.e. an object presence or an adult's eyes state.
Methods: Twenty children were divided into three groups: 7 children with an ASD (mean chronological age 64 months, SD 7.6 months and mean mental age 35.8 months, SD 19.9 months), 7 mental-age-matched typically developing children (mean chronological age 36.7 months, SD 19.4 months) and 6 chronological-age-matched typically developing children (mean chronological age 63.1 months, SD 9.2 months). All children were observed when seeing a video clip in which a female adult model, wearing a black shirt, sat behind a table against a neutral background. The clip had two open-eyes state conditions and two closed-eyes state conditions. Each condition was once performed towards an object (object-present) and once towards an empty space (object-absent), resulting in four conditions in total.
Results: Multilevel regression analyses revealed a statistically significant negative association between the object presence and pupillary response (b=-0.1, SE=0.04, p= .03). No association was found between the eyes state and pupillary response. Furthermore, both the mental-age-matched c and chronological-age-matched typically developing children had a significant larger pupil dilatation (b=0.15, SE=0.07, p= .04; b=0.29, SE=0.08, p< .001) than children with an ASD. No significant interaction was found between group (i.e., ASD vs. mental-age-matched and chronological-age-matched children) and object presence.
Conclusions: The results of this study confirm earlier studies showing altered physiological reactivity to a gaze following task in children with an ASD. More specifically, we found that children with an ASD show less pupil dilatation over all conditions compared to typically developing children. Additionally, the present study suggests that children's pupillary responses are not influenced by the adult's eyes, but rather by the presence of objects. Children showed less pupil dilatation when the adult looked at an object compared to an empty space, but this response did not differ between children with ASD and mental-, respectively chronological-age-matched peers.

2 **122.002** A Profile of Visual Illusion Susceptibility in ASD

O. Landry[1], *I. Sperandio*[2], *S. Crewther*[3] *and P. Chouinard*[1], *(1)La Trobe University, Bendigo, Australia, (2)University of East Anglia, Norwich, United Kingdom, (3)La Trobe University, Melbourne, Australia*

Background: Visual illusions provide a means to understand how contextual visual information is used to perceptually rescale how people see objects in the world. Previous research examining illusion susceptibility in ASD has yielded inconsistent conclusions as to whether or not people with an ASD perceive illusions differently. One possible explanation is that previous research has tended to treat global processing, which underlies illusory susceptibility, as a singular cognitive construct. We hypothesize that one cannot treat visual illusions this way. Illusions come in different classes, each class reflecting distinct cognitive operations, which may or may not be affected in ASD.
Objectives: Our objectives were to test a battery of visual illusions in participants with ASD and examine susceptibility across different classes of illusions. These classes of illusions were derived in a separate study of 131 typically developing adults using factor analysis (Chouinard et al., under review).
Methods:
24 participants, including 12 with ASD were included. Comparison participants were selected to best match the participants with ASD one-to-one on age and Raven's Progressive Matrices raw scores (mean age: 13 yrs, range: 7 to 23 yrs; mean RPM score 36, range 24-50). We measured susceptibility to 13 of some of the most frequently tested visual illusions using the Methods of Adjustment approach. The illusion battery consisted of the Ponzo, Sander's Parallelogram, Ehenstein, Jastrow (Component 1), Helmholtz-Square, Horizontal-Vertical line, Muller-Lyer, (Component 2), Delboeuf, Ebbinghaus (Component 3), Shepard's tabletops, Square-Diamond (Component 4), Oppel-Kundt and Poggendorf (Component 5) illusions. To allow meaningful comparisons between illusions, we computed normalised indices of susceptibility for each illusion as: ((Perceived Size of Stimulus B - Perceived Size of Stimulus A) / (Perceived Size in Stimulus A + Perceived Size of Stimulus B)); B denoting the stimulus one would expect to see greater judgements in perceived size. Participants also completed control tasks to measure basic abilities in visual acuity and discrimination.
Results:
We found significantly reduced susceptibility on Component 4 ($t(22) = 2.10$, $p=.048$) but not on any of the other four Components (largest $t(22)=1.71$, $p=.10$). Examination of the illusions that made up this Component revealed that the reduced susceptibility was specific to the Shepard's tabletop illusion ($t(22)=2.28$, $p=.032$) and not found for the Square-Diamond illusion ($t(22)=0.20$, $p=.844$).
Conclusions: In ASD, we found reduced susceptibility to one specific illusion, the Shepard's tabletop illusion. This is consistent with a previous report by Mitchell, Mottron, Soulières, and Ropar, (2010). Furthermore, in adults, this specific illusion elicits a strong illusory percept, which is correlated with autistic traits as measured by the AQ (Chouinard et al., under review). Within our sample, the Shepard's tabletop is also the only illusion for which children's susceptibility scores are lower than those of adults (as reported in Chouinard et al., under review), however susceptibility was not correlated with age within our sample. These findings will contribute to our more general understanding of altered visual perception in ASD, shedding light into the nature of global processing. Particularly, what types may or may not be affected in ASD.

Table 1: Susceptibility index scores for participants on five classes of visual illusion for participants with and without ASD, matched on age and Ravens Progressive Matrices raw scores. The classes were derived using factor analysis (reported in Chouinard et al., under review). The illusions are: Ponzo, Sander's Parallelogram, Ehenstein, Jastrow (Component 1), Helmholtz-Square, Horizontal-Vertical line, Muller-Lyer, (Component 2), Delboeuf, Ebbinghaus (Component 3), Shepard's tabletops, Square-Diamond (Component 4), Oppel-Kundt and Poggendorf (Component 5).

3 **122.003** Accessing Meaning of Ambigous Homographs Embedded within Sentences in Children with ASD

R. E. Beabout, *Psychology, Marietta College, Marietta, OH*

Background: Considerable research focus concerning the theories of Weak Central Coherence (WCC) and Executive Functioning (EF) have been directed towards the cognitive atypicalities that may account for verbal comprehension impairments in individuals with ASD. The cause of language comprehension deficits in individuals with ASD is still not fully understood. To date evidence pertaining to individuals with ASD to process information in context remains mixed and has mainly focused on pronunciation tasks
Objectives: My thesis study investigated how children with ASD can use meaning activation of word primes to disambiguate target homographs inserted in the context of a sentence at automatic (300ms) and controlled (1000ms) stimulus onset asynchronies (SOAs).
Methods: Ten children with ASD and ten typically developing controls were first matched on chronological age and mental by utilizing the Kauffman Brief Intelligence Test, Second Edition. ASD symptomatology was verified using the Adolescent Autism Quotient and Vineland II Adaptive Behavior Scales. A semantic priming keystroke task was created using Inquisit Priming software. Participants were given 120 prime-homograph word target pairs split into four different conditions. Each trial consisted of the priming task consisted of a word prime(related or unrelated to the homograph), a 300ms or 1000ms delay, followed by a homograph word target embedded within the context of a sentence. Participants judged if the sentence made sense or not by either pressing X(Does not make sense) M(Makes sense) on the keyboard. Reaction time and accuracy of each trial were recorded.
Results: Children with ASD were as accurate as typically developing children in disambiguating the target homograph in each sentence. Incorrect responses between related and unrelated meaning trials did not differ. The second major finding of this study is that children with ASD were as fast as typically developing children in making a determination as to whether a sentence made sense in both related and unrelated conditions. Additionally, no differences in reaction time were observed between the ASD and typically developing group in conditions involving short or long SOAs.
Conclusions: The most fitting explanation concerning the results of this study is that children with ASD may have a specific language-processing deficit that prevents them from using semantic knowledge in spoken language. The patterns of results from this study show no deficit in verbal comprehension on a priming task that did not require pronunciation. Results run contrary to other studies concerning the accounts of WCC and EF and that may be because the research examining these theories put too much emphasis on pronunciation of a word rather than actual comprehension of the meaning of a word. Overall, children with ASD were able to use contextual information provided by the word primes in order to disambiguate target homographs embedded within the context of a sentence.

4 **122.004** Adults with Autism Spectrum Disorders Imitate Means to an End: The Effects of Sensorimotor Integration and Interference

M. Andrew[1], *S. J. Bennett*[2], *D. Elliott*[2] *and S. J. Hayes*[2], *(1)Liverpool John Moores University, Rossendale, England, United Kingdom, (2)Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom*

Background:
When imitating a novel action, the sensorimotor system is configured by representing and executing observed biological motion kinematics. Although this process is functional in early development, individuals with autism spectrum disorders (*autism*) show significant difficulties imitating biological kinematics. Rather than this deficit being underpinned by a core dysfunction in the sensorimotor system, it could be a function of how the lower-level sensorimotor processes are engaged to integrate information during imitation. Here we present three experiments that used a novel 'true' imitation protocol designed to facilitate (Exp. 1), and disrupt (Exp. 2 and 3) sensorimotor integration during the imitation of biological motion kinematics in individuals with autism.
Objectives:
Examine whether the imitation of biological kinematics is influenced by sensorimotor integration and interference.
Methods:
Fifteen (*neurotypical*) adults, and fifteen adults with *autism*, diagnosed by a clinical assessment and ADOS, participated in each experiment of this study. The study was approved by an ethics committee. Participants imitated *atypical* and *typical* biological motion. A control stimulus displayed *typical* biological motion where peak velocity occurred at 44% of the movement. This is typical of most "bell-shaped" velocity profiles exhibited during goal-directed aiming. An experimental model displayed *atypical* biological motion where peak velocity occurred at 18% of the movement. Although this peak occurred earlier, it was still achievable, and thus allowed the direct examination of imitation of biological kinematics. In Experiment 1, the stimuli were presented in a fixed predictable trial order (e.g., 30 trials of *atypical* motion, followed by 30 trials of *typical* motion). This order facilitates integration across trials because afferent and efferent sensorimotor information from trial *n* can be processed and integrated during the inter-trial delay, and used to plan trial *n+1*. In Experiments 2 and 3, we disrupted sensorimotor integration using a secondary interference task that was placed in the inter-trial delay (Exp. 2), or by presenting the stimuli in a random unpredictable (Exp. 3) trial order (i.e., 60 trials of *atypical* and *typical* motion randomised).
Results:
Individuals with autism imitated *atypical* biological motion to a similar level of accuracy as matched neurotypical controls ($p > 0.05$), and significantly ($p < 0.01$) different to the *typical* control stimulus. Following the secondary task (Exp. 2), and random trial order (Exp. 3), the autism groups became significantly less accurate than the neurotypical control groups at imitating *atypical* biological motion ($ps < 0.05$). The interference effects resulted in the autism groups exhibiting comparable timing of peak velocity in the *atypical* and *typical* models ($p > 0.05$).
Conclusions:
Poor voluntary imitation in autism, and its underlying sensorimotor aetiology, has received a great deal of attention and is still a matter of controversy. Experiment 1 established robust imitation effects when adults had opportunity to integrate, consolidate and represent atypical biological kinematics in a predictable environment. Experiments 2 and 3 disrupted sensorimotor integration and consequently attenuated imitation fidelity. Rather than there being a core deficit in imitation, the findings indicate intact sensorimotor processing of biological motion in autism when the system has opportunity to repeatedly integrate information.

5 **122.005** Age-Related Differences in Local and Global Processes for Social and Non-Social Information in Autism: How Do Children and Adolescents Differ?

J. Guy[1,2], *J. Mettler*[2,3], *D. Tullo*[2,3], *L. Mottron, M.D.*[4] *and A. Bertone*[2,3,5], *(1)Integrated Program in Neuroscience, McGill University, Montreal, QC, Canada, (2)Perceptual Neuroscience Laboratory for Autism & Development, Montreal, QC, Canada, (3)Educational and Counselling Psychology, McGill University, Montreal, QC, Canada,*

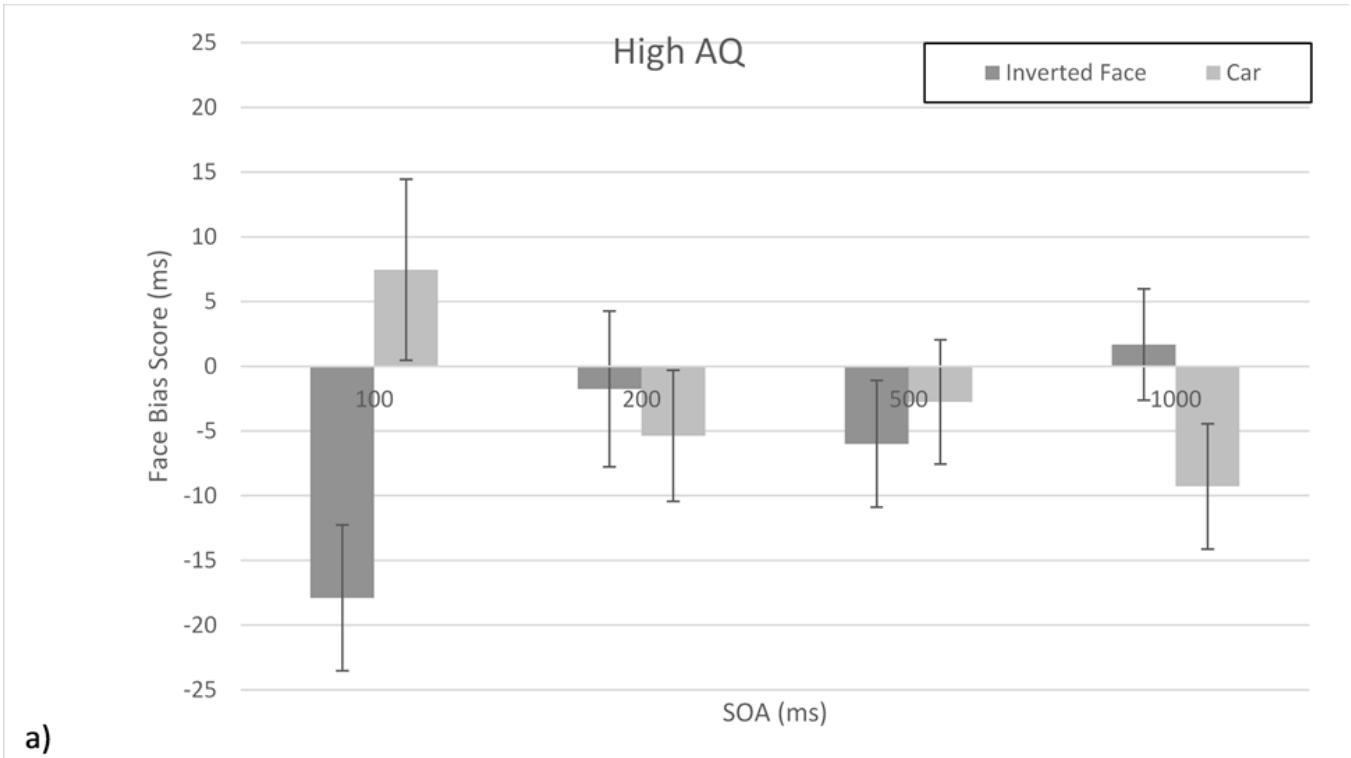
(4)Centre d'Excellence en Troubles Envahissants du Développement, Montréal, QC, Canada, (5)Centre d'excellence en Troubles envahissants du développement, Montréal, QC, Canada

Background: Individuals with autism present both an atypical and distinctive visuo-perceptual profile (Mottron et al., 2006; Bertone et al., 2010). Despite marked social and behavioural impairments, individuals with autism often excel at tasks requiring a local analysis of detailed information and preferentially attend to the constituent parts of a stimulus rather than its whole form. It remains unknown, however, whether a bias for such local analysis is at the origin of other aspects of the social cognitive phenotype in autism, such as facial information processing. Age-related changes in local and global processes are also poorly understood.
Objectives: The goal of this study was to assess age-related differences in local and global visual processing strategies used in social (face identity discrimination task) and non-social (Block Design task) visuo-perceptual tasks in children and adolescents with and without ASD.
Methods: Twenty-eight participants with autism and twenty typically-developing participants were split into child and adolescent age groups (5-11; 12-17 years). All participants performed social and non-social visual perceptual tasks under conditions favouring either a local or global analysis. Both tasks incorporated a simultaneous presentation of a central target and four surrounding choice probes on a touchscreen monitor. In the social task, participants completed a face identity discrimination task wherein they matched identities across varied viewpoints (i.e. front, inverted and view-change). The presentation of faces in the same-view (front or inverted) biased a local analysis, whereas in different views (view-change) biased a global analysis. In the non-social task, participants completed a block design task incorporating puzzle-like designs wherein they identified the correct match to a target design. The puzzles were manipulated in terms of perceptual coherence (PC), with high PC patterns favouring a global analysis and low PC patterns a local analysis. All responses were made with a simple press on the display. Measures of accuracy and reaction time were recorded.
Results: In the social task, children and adolescents with autism were significantly less accurate than typically-developing participants only when matching faces across different views. Interestingly, adolescents with autism responded significantly slower than children with autism in the view-change condition, when access to local information was minimized and a more global analysis was required. In the non-social task, all participants achieved higher accuracy on the high than low PC patterns, and adolescents made significantly more correct responses than children. All participants responded significantly faster to the high than to the low PC patterns.
Conclusions: Our findings illustrate subtle, yet significant differences in social information processing in children and adolescents with autism, specifically when a global analysis is required. However, we found no differences between groups in the local and global processing of non-social information. Strengths in local and/or weaknesses in global processing in ASD may be more apparent in adolescence than in childhood, consistent with other age-related findings (Guy et. al, in press).

6 **122.006** Assessing Temporal and Contextual Factors Affecting Preferential Attention to Faces in Individuals with High and Low Levels of Autistic Traits

***C. I. Mitchell**, C. Dickter and J. Burk, College of William & Mary, Williamsburg, VA*

Background:
Past research on attentional preferential attention to faces (face-bias) in individuals with and without autism spectrum disorder (ASD) shows conflicting results, depending on how long stimuli are presented (the stimulus onset asynchrony (SOA)), and what types of distractor stimuli are used (Bar-Heim et al., 2006; Moore et al., 2012). Inverted faces and face-like objects such as cars are often used as "control" distractor images but there are important perceptual differences between these stimuli that might account for discrepancies in study results (Hadjikhani et al., 2009; Haxby et al., 1999). Finally, as ASD individuals process social stimuli more slowly than individuals without ASD (Dawson et al., 2005), examining face-bias at different SOAs could reveal temporal factors influencing attention to faces in this group.
Objectives:
This study examined preferential attention to faces in a sub-clinical sample of students with different levels of autistic traits using a dot-probe paradigm with four distinct SOAs and two types of distractor stimuli.
Methods:
Participants consisted of 105 undergraduate students (36 males; M_{age}= 19.10), who completed the Autism Quotient (AQ; Baron-Cohen et al., 2001), a self-report measure of autistic behaviors. Each participant completed a dot-probe task to measure attentional bias to probes following a target or distractor stimulus. Faces were target stimuli; cars and inverted faces were distractor stimuli. SOAs of 100ms, 200ms, 500ms, and 1000ms were used. A median split on AQ scores (M=20.26, SD=8.34, Median=21) divided participants into High AQ and Low AQ groups for
Results:
Face-bias scores were created by subtracting the mean reaction time (RT) on distractor-cued trials from the RT on face-cued trials. A 2(Distractor type) x 4(SOA) x 2(AQ group) mixed ANOVA indicated a three-way interaction, $F(3,309)=3.10$, $p=.03$. This interaction was examined separately for the High (Figure 1a) and Low (Figure 1b) AQ groups. There was a significant Distractor type x SOA interaction only for the High AQ group, $F(3,165)=4.29$, $p<.01$. Pairwise comparisons indicated that High AQ participants had significantly lower face bias scores at 100ms in the inverted face condition than in the car condition, $t(55)=2.90$, $p<.01$, but marginally higher face bias scores in the inverted face than the car condition at 1000ms, $t(55)=1.671$, $p=.10$ (see Table 1 for means). Additionally, one-sample t-tests were run for High AQ and Low AQ participants for each Distractor/SOA to identify face-bias scores significantly different from zero. Low AQ participants exhibited marginally positive face-bias scores at 200ms for both car, $t(48)=1.70$, $p=.10$, and inverted face, $t(48)=1.01$, $p=.11$, distractor trials. Conversely, High AQ participants exhibited significantly negative face-bias scores in the car distractor condition at 1000ms, $t(55)=1.97$, $p=.05$, and in the inverted face condition at 100ms,$t(55)=2.85$, $p<.01$.
Conclusions:
These results suggest that individuals who are high in autistic traits show a different temporal pattern of attention to faces depending on what kind of competing stimulus is present, with a trend over time of increasing face-bias for inverted face distractors and decreasing face-bias for car distractors. These results highlight the importance of examining temporal and contextual factors in face-bias studies when drawing conclusions.



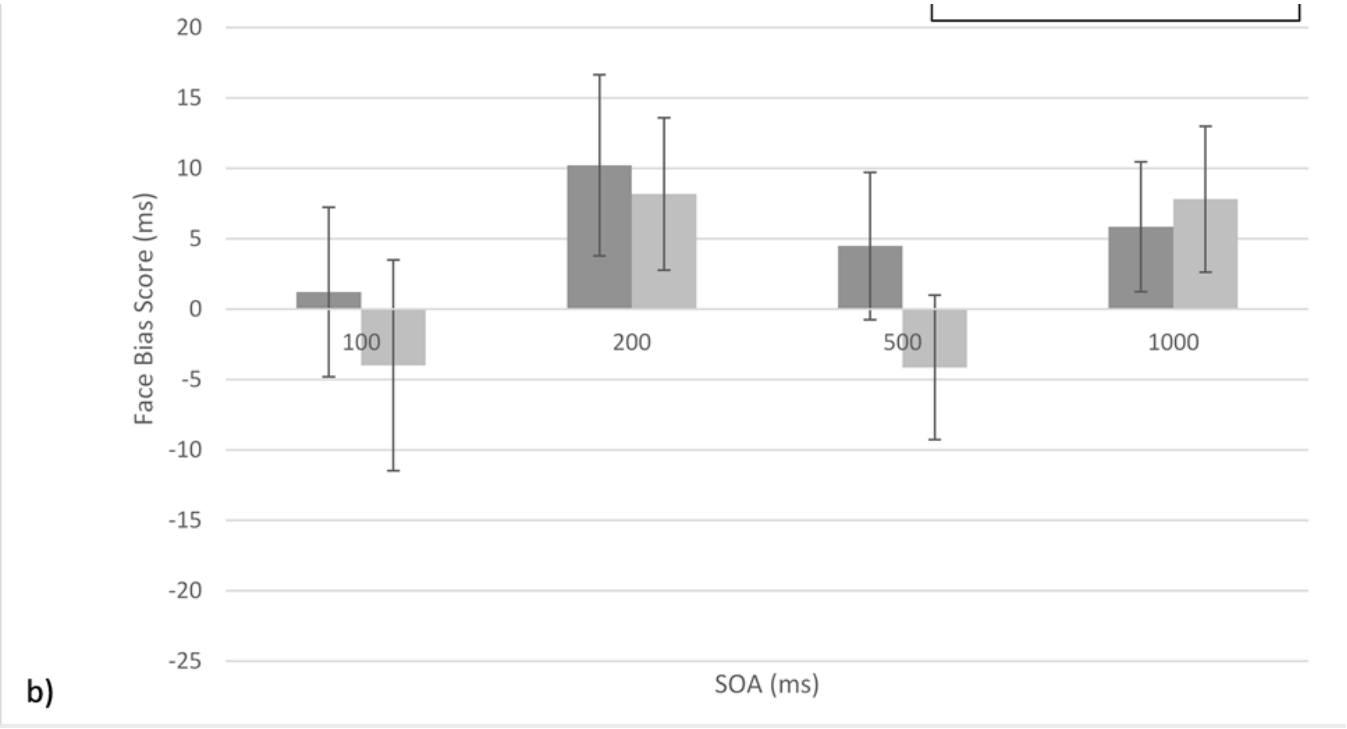


Figure 1. Face-bias scores at each Distractor/SOA condition for a) High AQ participants and b) Low AQ participants. Positive face-bias scores indicate an attentional preference toward faces, face-bias scores of zero indicate no attentional preference to face or distractor stimuli, and negative face-bias scores indicate an attentional preference for the distractor stimulus.

Table 1. Face-bias scores for each AQ Group/Distractor/SOA condition.

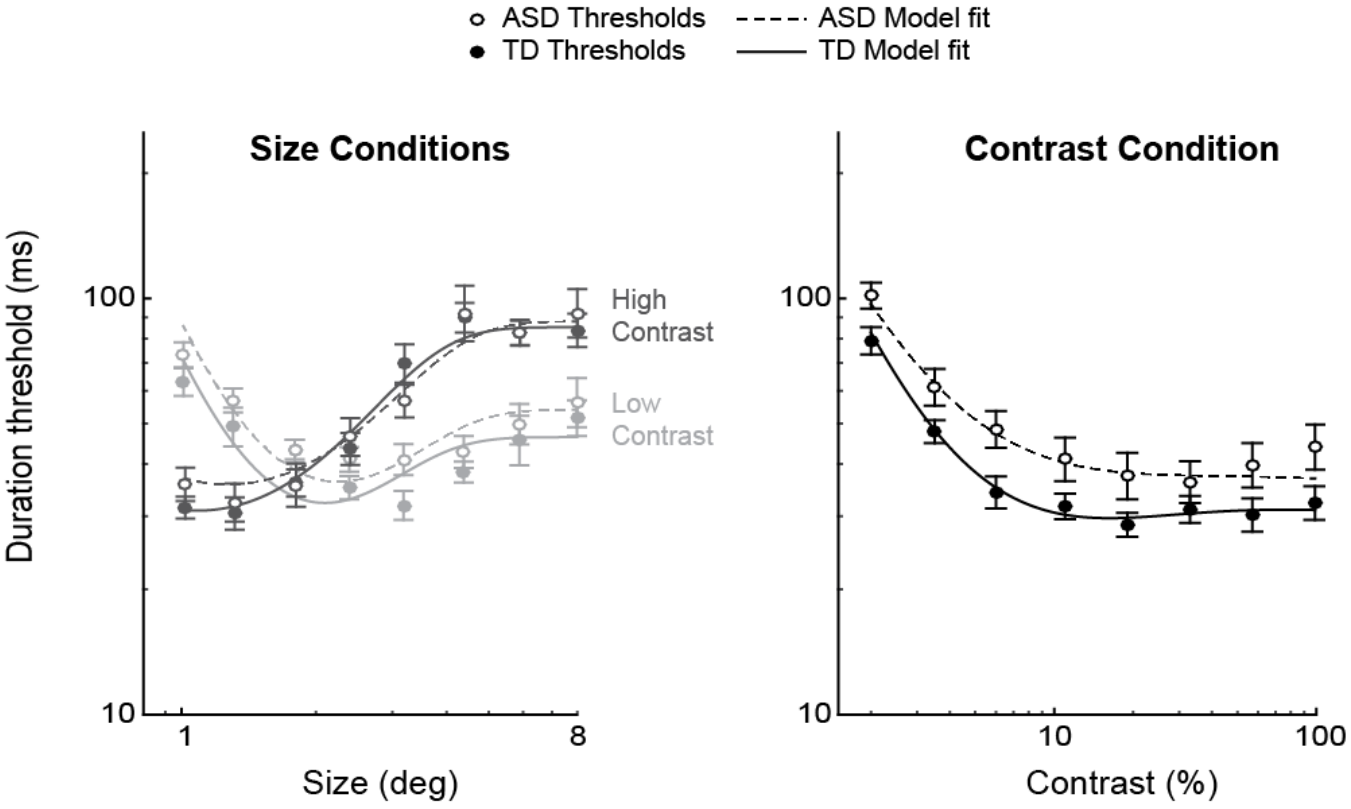
Condition			Face-Bias Scores	
Group	Distractor	SOA (ms)	M	SD
High AQ	Inverted Face	100	-17.90	42.15
		200	-1.74	45.03
		500	-5.99	36.67
		1000	1.68	32.22
	Car	100	7.45	52.35
		200	-5.37	37.89
		500	-2.76	35.94
		1000	-9.28	36.24
Low AQ	Inverted Face	100	1.21	42.15
		200	10.21	45.03
		500	4.48	36.67
		1000	5.85	32.23
	Car	100	-4.00	52.35
		200	8.17	37.88
		500	-4.15	35.94
		1000	7.81	36.25

7 **122.007** Atypical Motion Sensitivity Characterized By Larger Receptive Fields in Autism Spectrum Disorder

W. J. Park[1], *K. B. Schauder*[2], *L. Bennetto*[2] *and D. Tadin*[1], *(1)Brain and Cognitive Sciences, University of Rochester, Rochester, NY, (2)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY*

Background: Individuals with autism spectrum disorder (ASD) demonstrate atypical visual processing abilities across a wide range of tasks. However, we still have a limited understanding of mechanisms contributing to such perceptual abnormalities. Recent studies have identified two possible mechanistic explanations: differences in 1) contrast gain control, a mechanism responsible for regulating the amplitude of neural responses in relation to stimulus contrast, and 2) visual receptive field (RF) sizes, which can affect how the brain responds to stimuli of different sizes. Notably, both of these mechanisms are important for maintaining the balance between excitatory and inhibitory (E/I) neural responses. This is of specific interest given growing evidence for E/I imbalance in ASD.
Objectives: To investigate the integrity of contrast gain control and RF size, and their effects on visual motion perception in ASD.
Methods: Participants were 20 children and adolescents with ASD and 20 age- and IQ- matched typically developing (TD) controls. A visual motion discrimination task was employed, where participants judged the motion directions (left or right) of briefly presented moving gratings. Contrast and size of stimuli were manipulated in three

conditions. In two Size conditions, stimulus size varied (1-8 deg in radius) while the contrast was fixed at either low (2.3%) or high (99%) contrast. In the Contrast condition, contrast varied (2-99%) with a fixed stimulus size (1 deg). Duration thresholds (i.e., minimum stimulus duration required to reliably judge motion direction) were estimated to evaluate motion perception. A computational model, based on divisive normalization of E/I responses with parameters representing gain control and RF sizes, was fitted to the thresholds, thus assessing the underlying mechanisms contributing to differences in performance. Group differences in thresholds were assessed using a Mixed Model ANOVA, and a non-parametric bootstrap analysis was used to compare the model parameters between groups.
Results: Individuals with ASD had higher thresholds (worse performance) across all contrast levels in the Contrast condition ($F(1,38) = 5.49$, $p < 0.05$). No significant group differences in thresholds were observed in either of the Size conditions (p's > 0.05), but there was a trend for higher thresholds overall in the Low-contrast Size condition, and for the smallest size in the High-contrast Size condition in ASD. The model analysis revealed this pattern of results can be explained by a significantly larger excitatory RFs in ASD compared to TD ($p< 0.05$).
Conclusions: Our threshold results reveal decreased perceptual sensitivity to motion directions in ASD for small stimuli across all contrast levels. This motion perception difference was best explained by larger size of excitatory RF in ASD, consistent with a previous fMRI study showing larger population RFs in ASD (Schwarzkopf et al., 2014). Our findings suggest that differences in RF sizes may disrupt the E/I balance in ASD; reduction in excitatory responses to stimuli smaller than the RF size may lead to changes in the E/I response ratio and perceptual sensitivities to stimuli with different sizes. Future studies can further investigate the association between RF size differences and other behavioral and sensory symptoms of ASD.



8 **122.008** Auditory Spatial Attention and Symptom Severity in Children with Autism Spectrum Disorder

L. N. Soskey[1], *P. D. Allen*[2] *and L. Bennetto*[1], *(1)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (2)Department of Otolaryngology, University of Rochester Medical Center, Rochester, NY*

Background: One of the earliest observable impairments in autism spectrum disorder (ASD) is a failure to orient to speech and other social stimuli. Auditory spatial attention, a key component of orienting to sounds in the environment, is likely to play a critical role in the early development of social communication skills and social functioning throughout the lifespan. In fact, auditory spatial attention has already been shown to be impaired in adults with ASD, but has not yet been characterized in children with ASD or linked to core ASD symptoms.
Objectives: We aimed to characterize auditory spatial attention in children with ASD and neurotypical peers. Our secondary goal was to explore the relationship between auditory spatial attention abilities and core behavioral symptoms of ASD.
Methods: Sixteen rigorously diagnosed (ADOS, ADI-R) children and adolescents (ages 10-17) with ASD and 18 neurotypical age- and IQ-matched peers participated in this study. In the spatial attention task, target and distractor sounds were played randomly in rapid succession from six speakers in a free-field array. Subjects attended to a speaker directly in front of them, and were instructed to respond to target sounds at the attended location while ignoring sounds from adjacent speaker locations. The spatial attention gradient was characterized using the proportion of subjects' responses to target sounds at attended vs. adjacent speakers, using *d'* as a measure of spatial attention. Well validated parent report measures provided information regarding current ASD symptom severity, as well as a characterization of attention deficit hyperactivity disorder (ADHD) symptoms.
Results: Children with ASD had significantly more diffuse auditory spatial attention compared to neurotypical children (F=8.94, p=.005, partial eta-squared =.22). While both groups had equal accuracy in detecting the target sound, children in the ASD group had significantly increased responding to sounds at adjacent non-target locations. Due to the magnitude of the group difference in spatial attention, correlational analyses were conducted separately by group. Within the ASD group, more diffuse auditory spatial attention was significantly associated with greater ASD symptom severity (r=.675, p=.01). In contrast, diffusion of auditory spatial attention was not related to ADHD attention symptom severity (r=.310, p=.33) or age (r=.311, p=.24). Spatial attention was not significantly associated with ASD symptoms, ADHD symptoms, or age in the neurotypical group.
Conclusions: Auditory spatial attention was significantly more diffuse in children with ASD than their neurotypical peers, primarily due to difficulty ignoring nearby competing sounds. In the children with ASD, those with more diffuse auditory spatial attention had greater ASD symptom severity. Importantly, spatial attention abilities were not significantly related to ADHD attention symptoms in this population, providing further evidence that auditory spatial attention abilities may be uniquely associated with the development of ASD symptoms. It will be crucial for future research to examine the early development of auditory spatial attention and its role in the development of social communication differences in ASD.

9 **122.009** Childhood Profiles of Cognitively Gifted Individuals with Autism Spectrum Disorder

J. Gilger[1], *J. Kaboski*[2] *and M. Cain*[3], *(1)School of Social Sciences, Humanities & Arts, University of California - Merced, Merced, CA, (2)University of Notre Dame, Notre Dame, IN, (3)Psychology, University of Notre Dame, South Bend, IN*

Background: Historically, cognitive giftedness and autism spectrum disorder (ASD) were considered mutually exclusive. As a result, there is only a dearth of knowledge regarding those who display this unlikely combination of giftedness and ASD. Previous studies on cognitive giftedness and ASD relied mostly on case studies with small nonrandom samples. A number of prominent researchers in the field have noted this serious lack in the literature and recommended longitudinal research with larger samples (e.g., Foley-Nicpon et al., 2011).
Objectives: This study was designed to accurately describe the children who are identified as having both giftedness and ASD in terms of their prevalence, demographics, characteristics of schools attended, and patterns of school services utilized. In order to understand how their academic performance may fluctuate over time, we also plotted academic trajectories as they moved from preschool through adolescence. The results were juxtaposed against the rest of the ASD sample.
Methods: Secondary data analysis was conducted on PEELS (Pre-Elementary Education Longitudinal Study) and SEELS (Special Education Elementary Longitudinal

Study). When combined, these datasets comprise nationally representative samples of children ages 3 through 16 who received special education services. The sample for this study was reduced to those with the primary diagnosis of ASD (n=1642). In this study, an individual was categorized as "gifted" if he/she: (1) scored above 90th percentile on any of the subtests on the Woodcock Johnson III achievement test; or (2) qualified for gifted/talented programs offered by the students' school[1]. Single proportion results were compared using an independent samples proportion test comparing gifted to non-gifted participants. Childhood trajectories were obtained by fitting children's achievement test results over five waves of PEELS and SEELS to a multilevel model using linear and quadratic trends of age as random effects, and giftedness as a level-2 predictor for all random effects.

---

[1] These criteria are consistent with the conceptualization of giftedness often found in other studies.

Results: 263 (16%) of individuals with ASD could be categorized as gifted in at least one academic subject. When gifted children were compared to their non-gifted counterparts, statistically significant differences emerged in many dimensions: the gifted subsample had more females, more racially white, higher maternal education, and higher family income. Speech therapy was the most utilized school services for both groups. In general, the gifted group tended to use more school services compared to those who are not gifted. In terms of academic trajectories, there was a significant initial difference between the two groups and there was no significant change in academic performance over time in either group.

Conclusions: The results suggest that gifted students come from a more privileged background than their non-gifted counterparts. They also used more school services than the rest of the ASD population. This may be a reflection of their parents' more effective advocacy and influence rather than the actual need for more services. Further inferential analysis is needed in order to establish causality.

Table 1. Comparison of Sample Characteristics: ASD Gifted vs. ASD Not-Gifted

	Gifted N=204	Not-Gifted N=996	*Z, t or* X^2
Gender: Female	21%	16%	1.73**
Race: White	79%	56%	41.78**
Black	6%	19%	
Hispanic	9%	19%	
Other/Multi	6%	6%	
Mother has B.A./B.S.	66%	37%	7.61**
Income Less than $50,000	25%	49%	-6.30**
Mental Functioning (Range 4-16, higher better)	13.5	11.0	
Living Skills (Range 1-4, lower better)	2.0	2.0	
Classroom Behavior (Range 1-4, higher better)	2.5	2.5	
Adequate Insurance	77%	81%	
Social work services used	20%	14%	
Mental health services used	33%	28%	
Speech therapy used	80%	85%	
Occupational therapy used	68%	58%	
Physical therapy used	15%	18%	
Personal assistant in classroom	55%	45%	
Assistive technology used	36%	45%	
Tutoring or learning strategy services	66%	62%	

Note: *$p < .05$, **$p < .01$.

10 **122.010** Cognitive Remediation Therapy in Autism Spectrum Disorder: Effects on Working Memory

***M. Hajri**, Z. Abbes, H. Ben Yahia, S. Ouenness, S. Halayem and A. Bouden, psychiatric hospital Razi, Tunis, Tunisia*

Background: Cognitive impairment, especially executive dysfunction has been linked to a number of developmental disorders, including Autism Spectrum Disorder (ASD). Cognitive Remediation Therapy (CRT) is a novel rehabilitation method that aims to produce improvement in cognitive processes. CRT has been used in patients with schizophrenia.

Objectives:

we aimed in this study to examine the effectiveness of CRT for improving working memory and clinical symptoms in children with ASD.

Methods: Children meeting the Diagnostic and Statistical Manual for Mental Disorders (DSM-5) criteria for ASD were recruited from clinical population at the Child and Adolescent Psychiatry Department in Razi University Hospital – Manouba - Tunisia. The CRT program was conducted at the rate of one session per week of 45 minutes each. The main outcomes measures are working memory, assessed by forward and backward digit span, and clinical symptoms assessed by Childhood Autism Rating Scale (CARS). These outcomes were measured at baseline and one week after completion of the treatment.

Results:

Of the 25 patients included, 16 achieved assessments tests after CRT, thus constituting our final sample. Their average age was 10.87 years. The mean number of sessions performed was 22.38. After completion of CRT, patients showed significant improvement (p=0.001) on forward digit span which score was 3.38 before CRT and 4 after

completion of the program. Concerning backward digit-span, the mean score increased from 2.21 before CRT to 3.09 after it. This improvement was significant (p=0.006). As for clinical symptoms, lower scores (26.81) were found after CRT in comparison with baseline mean scores (27.87). This improvement was also significant (p=0.001).
Conclusions:
Our study showed evidence that CRT can yield positive effects in cognitive performance and clinical symptoms, but it is not known whether these effects are sustainable. The durability of cognitive and clinical benefits obtained from neurocognitive treatment should be investigated in further studies.

11 **122.011** Comparison and Structural Alignment Processes of Learning New Relational Concepts in Children with ASD

O. E. Hetzroni *and M. Hessler, Special Education, University of Haifa, Haifa, Israel*

Background:
Structural Mapping Theory (SMT) uses multiple comparisons for creating a map of structural similarities between different structures of knowledge, with low (perceptual) and high (conceptual) levels to enable efficient learning and reasoning processes. In terms of SMT, individuals with ASD often find it difficult to deal with tasks that require the creation of structural similarity based on deep internal connections.
Objectives:
This study used SMT to examine learning patterns of individuals with high functioning ASD (HFASD) to investigate structural mapping processes that occur during acquisition of new relational concepts (using comparisons and familiarity) among children with HFASD, compared to children with typical development (TD) and children with intellectual and developmental disabilities (IDD).
Methods:
Participants included 24 children with IDD (ages 8-16), 24 children with HFASD (ages 5-8), and 24 children with TD (ages 5-6), all matched in receptive mental language age. A computerized task included 13 sets of graphic illustrations of familiar, partly familiar and unknown items that were presented in novel spatial configurations with and without comparison to the standards; first with a presentation of one standard (no comparison), followed by a presentation of two standards (with comparison). The children heard a label for a standard followed by a request to extend this label to one of two alternatives: one that shared an item with the standard and another that shared relational configuration.
Results:
When one standard was available (no comparison), participants from all three groups demonstrated a preference style for extending concepts by matching to items (perceptual categorization) rather than to relational structures (conceptual categorization). However, when presented with two standards (with comparison), children with TD and IDD demonstrated significant increase in their tendency for matching based on relational concepts, while participants with HFASD did not change their preference and continued selection based on item matching. When presented with familiar and partially familiar stimuli, there was a significant increase in selection of relational concepts for children with TD and IDD in the comparison condition, with no difference for children with HFASD.
Conclusions:
Results demonstrate that children IDD and TD were able to benefit from comparisons in learning new relational concepts presented to them as graphic illustrations and used structural mapping processes to highlight common features for creating new relational concepts. However, children with HFASD did not benefit from the opportunity to compare between the graphic representations. Thus, children with HFASD continued to base their preferences on perceptual characteristics even in the comparison conditions. Moreover, in contrast to children with TD and IDD, who benefited from the opportunity given to them to apply existing knowledge for creating conceptual categories, children with HFASD demonstrated a similar trend regardless of the level of familiarity.
In this, individuals with HFASD were characterized by atypical activity of the structural mapping processing, demonstrating a tendency to perceptual categorization in the process of concept acquisition, without producing significant benefits from the opportunity to compare different knowledge structures and / or use existing knowledge structures, for a comprehensive analysis of the connections between structures.

12 **122.012** Concept Identification and Formation in High-Functioning Adolescents with ASD

J. Beck[1]*, J. Shapleton*[2]*, M. South*[1] *and M. Solomon*[3]*, (1)Brigham Young University, Provo, UT, (2)Duke University, Durham, NC, (3)MIND Institute, Sacramento, CA*

Background: Abstraction refers to the ability to find common features across different stimuli. *Concept identification* involves recognizing patterns of features created by an external agent. *Concept formation* is more difficult, requiring independent creation of schemata to organize information. Impairments in concept identification and formation are theorized to underlie a variety of practical difficulties of individuals with ASD (e.g., failure to generalize learning in one context to a similar, but new context). However, past research has yielded mixed results, with some finding significant impairment and others finding intact concept identification and formation. Contradictory findings may be due to differences in assessment methodology. For example, studies utilizing strictly perceptual tasks likely minimized impairment in ASD, while studies using strictly verbal tasks likely exaggerated impairment.
Objectives: We sought to use a single task that would allow the evaluation of (1) concept *formation* relative to concept *identification*, and (2) *verbal* concept formation and identification relative to *perceptual* concept formation and identification. Also, we sought to explore (3) the relationship between concept identification and formation and autism symptomatology. We hypothesized that (1) we would replicate previous findings of intact concept identification but impaired concept formation in ASD (Minshew et al., 2002); (2) impaired concept formation would be more notable on verbal tasks; and (3) worse impairments would be associated with more severe autism symptoms.
Methods: The sample consisted of 27 high-functioning (FIQ > 80) adolescents with ASD and 27 age (*M* 14.8 years)- and FIQ (*M* 102.8)-matched typically-developing controls. Concept formation and identification abilities were assessed using the Delis-Kaplan Executive Function System (D-KEFS) Card Sorting task. One-way ANOVAs explored group differences on task performance variables. Partial correlations explored the relationship between task performance and autism symptomatology measured using the Social Responsiveness Scale (SRS-2). Given the significant correlation between FIQ and every measure of task performance, FIQ was entered as a covariate in all analyses.
Results: Controlling for FIQ, (1) there was no group difference on tasks requiring concept identification (Sort Recognition; assessor sorts cards); however, there was a small significant effect of group on concept formation tasks (Free Sort; participant sorts carts) ($F(1,51) = 4.218$, $p = .045$, $\eta^2 = .02$), with the ASD group exhibiting worse performance; (2) there was no group difference on verbal or perceptual tasks of concept identification and formation; and (3) SRS-2 Total scores (higher scores indicate more severe autism symptoms) were associated with concept formation ($r(54) = -.31$, $p < .05$), but not concept identification ($r(54) = -.20$, $p = .15$).
Conclusions: Our findings add to a growing body of research showing a dissociation between concept identification and concept formation in ASD. This dissociation, which existed after covarying FIQ, suggests that concept formation deficits may underlie impairments across levels of cognitive functioning in ASD. While previous research demonstrated that a combined measure of concept identification and formation was correlated with autism symptom severity (McLean et al., 2014), our finding that autism symptoms are significantly associated with *only* concept formation further strengthens the theoretical significance of concept formation deficits in ASD.

13 **122.013** Differentiating Old from New-but-Similar: Tracking Episodic Memory Profiles in Children with Autism

H. N. Wakeman[1]*, M. Rosenberg-Lee*[1]*, M. South*[2]*, B. Kirwan*[2] *and V. Menon*[1]*, (1)Stanford University School of Medicine, Stanford, CA, (2)Brigham Young University, Provo, UT*

Background:
Autism spectrum disorders (ASD) are marked by an uneven profile of memory performance; with reports of selective deficits in episodic memory, yet intact semantic memory (Shalom, 2003). A key feature of successful episodic memory is distinguishing old experiences from similar but distinct new ones, a task thought to require hippocampal pattern separation (Kirwan et al., 2012). Previous research finds that adults with ASD struggle to correctly differentiate previously seen stimuli from similar yet distinct distractors (i.e. lures), instead tending to label lures as new (South et al., 2015). Little is known about this crucial memory capacity in children with autism.
Objectives:
In this study, we sought to characterize the ability of children with ASD to distinguish old from new-but-similar items, in multiple contexts.
Methods:
16 children with autism ages 8-11 and 13 age-, IQ-, and gender- matched TD peers completed the Behavioral Pattern Separation Object (BPS-O) and NEPSY-II Memory for Designs Delayed (MDD) tasks. The BPS-O is a modified visual object recognition task where items are identified as “old” (i.e. previously seen stimuli), “new” (i.e. stimuli not previously seen in the context of the experiment) or “similar” (i.e. lures that are similar but not identical to previously presented stimuli). MDD is a standardized spatial memory task, where participants distinguish between target and distractor designs to recreate a layout of 10 abstract designs after a delay.
Results:
On the BPS-O, children with ASD were less likely to correctly identify lures than TDs (p=0.019), and more likely to call lures “new” (p=.007). While children with ASD demonstrated unimpaired spatial location performance (p=0.251), they were more likely to incorrectly select distractors on the MDD task than TDs (p=0.039). Among children with ASD, the number of distractors selected in MDD correlated with performance on BPS-O lure identification, with increased selection of distractors related to lower performance identifying lures (r=-.57, p=.021). This same correlation was not observed in TD children (r=-.23, p=.449).
Conclusions:
Consistent with studies of adults on the spectrum, our results suggest that difficulty differentiating between old and new-but-similar items may be a hallmark of memory impairments in children with ASD. Crucially, spatial memory was intact in children with ASD, indicating that not all forms of episodic memory are impaired in this group. Further, the unique relationship between two distinct measures of lure detection suggests a common origin for this capacity among children with autism, potentially relating to

hippocampal functioning.

14 **122.014** Do Individuals Diagnosed with Autism Spectrum Disorders Have an Advantage in Real-World Visual Search Tasks?

***N. C. Russell**, K. G. Stephenson, T. Shuman, A. Ward, L. Peacock, M. South and S. Luke, Brigham Young University, Provo, UT*

Background: People diagnosed with Autism Spectrum Disorders (ASD) often perform better than typically developing (TD) individuals in lab-based visual search tasks. This ability is often attributed to superior bottom-up processing (an ability to discriminate between a target and distractors, related to weak central coherence). However, research has also suggested that individuals with ASD show difficulties with top-down processing (integrating contextually relevant information to aid search), which may cause problems in real-world situations. Little is known about whether these differences in the performance of individuals with ASD are also represented in more ecologically valid visual searches and how this might influence their everyday functioning.
Objectives: We report findings from a real-world scene search study to compare ASD, TD, and Anxious control (ANX) participants. We used eye tracking data to the record the task performance and search strategy for contextual and non-contextual targets.
Methods: Twenty-five individuals with ASD, 27 TD individuals, and 28 ANX individuals completed two simple visual search tasks. For both tasks, participants had to find a named object within a real-world scene. In one task, objects were located in contextually-relevant locations; in the other task, the objects were superimposed upon the picture in a non-relevant position. Each participant completed 41 trials in each condition, each with a unique scene. Eye movements were recorded using an SR Research EyeLink 1000 eyetracker.
Results: All groups performed better in the contextual target condition than the non-contextual condition. In the non-contextual search, the ASD group were less accurate than the other two groups. However, preliminary analyses indicate that this difference was not significant. For the contextual search, the ASD group were also less accurate. Group means were significantly different with the ASD group being lower than the other two groups. Reaction time (RT) data suggest that the ASD group were also significantly slower than the TD and ANX groups in both conditions.
Conclusions: Our preliminary results suggest that a previously proposed advantage for ASD in locating targets without contextual information may be lost when these targets are contained within real-world scenes. Our ASD group appears to benefit less than both typical and anxious comparison groups, when targets are contextually relevant to these scenes. Previous research has also suggested that ASD groups may perform faster in some visual search tasks. However, these RT data suggest that, even though their accuracy was comparable to TD and ANX individuals when finding the non-contextual targets, they took longer to do so. This suggests that the presence of complex real-world information, whether related to the target they are searching for or not, may interfere with simple visual search and increase difficulty in navigating daily physical and social interactions.

15 **122.015** Examining the Complex Experiences of Parents of Gifted Students with Autism Spectrum Disorder

***L. D. Rubenstein**[1] and S. M. Wilczynski[2], (1)Educational Psychology, Ball State University, Muncie, IN, (2)Ball State University, Muncie, IN*

Background: Parents of students on the autism spectrum often experience higher levels of stress than both parents of typically developing children and parents of students with other disabilities. This stress can lead to fatigue, strained relationships, and increased levels of anxiety and depression. Understanding and promoting parents' psychological well-being is essential not only for the parents themselves, but also because they significantly affect their children's ability to be successful in school and form stable relationships. While several studies have examined parents of students on the spectrum, little is known about parents of intellectually gifted students on the spectrum.
Objectives: This study aimed to address this gap, guided by the research question, "What are the lived experiences of parents of gifted students on the spectrum?" The research team used a phenomenological, qualitative design to capture both the nuances of each parent's experiences and the common themes across experiences.
Methods: The research team recruited participants through a twice-exceptional website, and interested parents contacted the researchers. Thirteen parents participated from across the United States and Australia. All parents had students who were both identified as gifted and diagnosed on the spectrum. Researchers used an interview protocol to guide interview sessions. Interviews were recorded, transcribed, and analyzed using an iterative coding approach with two researchers. Following the first analysis, the parents were provided copies of the findings and given the opportunity to review and comment, thereby adding trustworthiness to the data through the use of a member checks/respondent validation.
Results: Parents' experiences illustrated the complexity of raising gifted students on the spectrum. First, parents wrestled with the identification/diagnosis process. Receiving the labels caused many emotions, ranging from relief to devastation. Because of the extreme asynchronous development within many of these students, some parent's spouses or family members did not accept the label, causing social conflicts. Beyond the label, parents also struggled to find appropriate educational opportunities for their children. Either schools would meet students' social needs with specialized autism support, or schools would address students' cognitive needs with enrichment opportunities. Rarely, however, were schools equipped to address both, so parents worked tirelessly to advocate for their children. Additionally, many parents discussed alienation and judgment from peers, teachers, family, or even strangers. Their children were asked to leave playgroups or schools, and the parents worried their children's behavior reflected the parents. Finally, the parents also recognized the joy that accompanies raising such unique children. They enjoyed their children's interests, sense of humor, and often, logical view of the world.
Conclusions: This study provides unique insight into the lived experiences of parents of gifted students on the spectrum. While they share some experiences with other parents of students with exceptionalities, they also face additional challenges, including advocating for services, explaining their child's asynchronous development to others, and finding a support system for themselves. The results of this study have the potential to promote empathy from outside individuals and to encourage other parents with gifted students on the spectrum that they are not alone.

16 **122.016** Examining the Executive Function Profile of Children with Autism, Autism Plus Significant Symptoms of Attention Deficit Disorder, and Typical Development

***S. Faja**[1], G. Greco[2] and T. Clarkson[3], (1)Boston Children's Hospital/Harvard Medical School, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Boston Children's Hospital: Harvard Med School, Boston, MA*

Background: Attention deficit/hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) are very common early onset neurodevelopmental disabilities. ADHD co-occurs in 28-53% of children with ASD (Sinzig et al., 2009, Simonoff et al., 2008; Leyfer et al., 2006). Executive function (EF), or the ability to manage complex or conflicting information in the service of a goal, is significantly impaired in both ASD and ADHD. EF encompasses inhibition, shifting and working memory by mid childhood. Executive function impairments are particularly problematic because poor EF is related to: (1) lower academic performance, and (2) higher rates of aggression and disruptive behavior. In 2013, the DSM-5 first permitted the dual diagnosis of ASD and ADHD. As a result, there is relatively little information about the behavioral profiles of children with both disorders in contrast to ASD alone.
Objectives: To examine the executive function profile of 7 to 11-year-old children with ASD, ASD+ADHD and typical development.
Methods: To date, participants include 20 children with ASD, 8 children with ASD+ADHD and 33 children with typical development (TD) all between 7-11 years of age. Enrollment of children with ASD is ongoing. ASD was confirmed via the ADOS-2 and ADI-R. Symptoms of ADHD were measured via the Child Behavior Checklist (CBCL). The three groups did not differ on age, sex, verbal IQ, or performance IQ. Executive function was measured by four separate tasks, each completed using a laptop computer: The Color-Word Stroop and the Child ANT Flanker Task measured inhibition of interfering information, the Change Task assessed inhibition of responses and set-shifting, and the Backward Digit Span Task examined verbal working memory skills.
Results: For the two measures of inhibition that involved suppressing interfering information (Stroop and Flanker), the overall effect of group approached significance (ps=.06). The groups significantly differed on the inhibitory measure that required suppression of a dominant response (Change Task), $F(2,53)=7.96$, p=.001 (ASD+ADHD < ASD, TD). Shifting (Change Task) also differed by group, $F(2,54)=5.23$, p=.008 (ASD < ASD+ADHD, TD). Finally, groups differed in verbal working memory skills, $F(2,58)=5.57$, p=.006 (ASD+ADHD < ASD, TD).
Conclusions: We found that children with ASD+ADHD were distinguished from children with TD and ASD alone using a behavioral battery of EF tasks by measures of inhibition of dominant responses and working memory. Children with ASD were distinguished by a measure of shifting. Results suggest that the type of inhibitory task demands may be particularly informative in distinguishing children with ASD from children who have both ASD and ADHD. Additionally, results suggest that other EF domains such as working memory and shifting contribute to the unique profile of ASD versus ASD+ADHD.

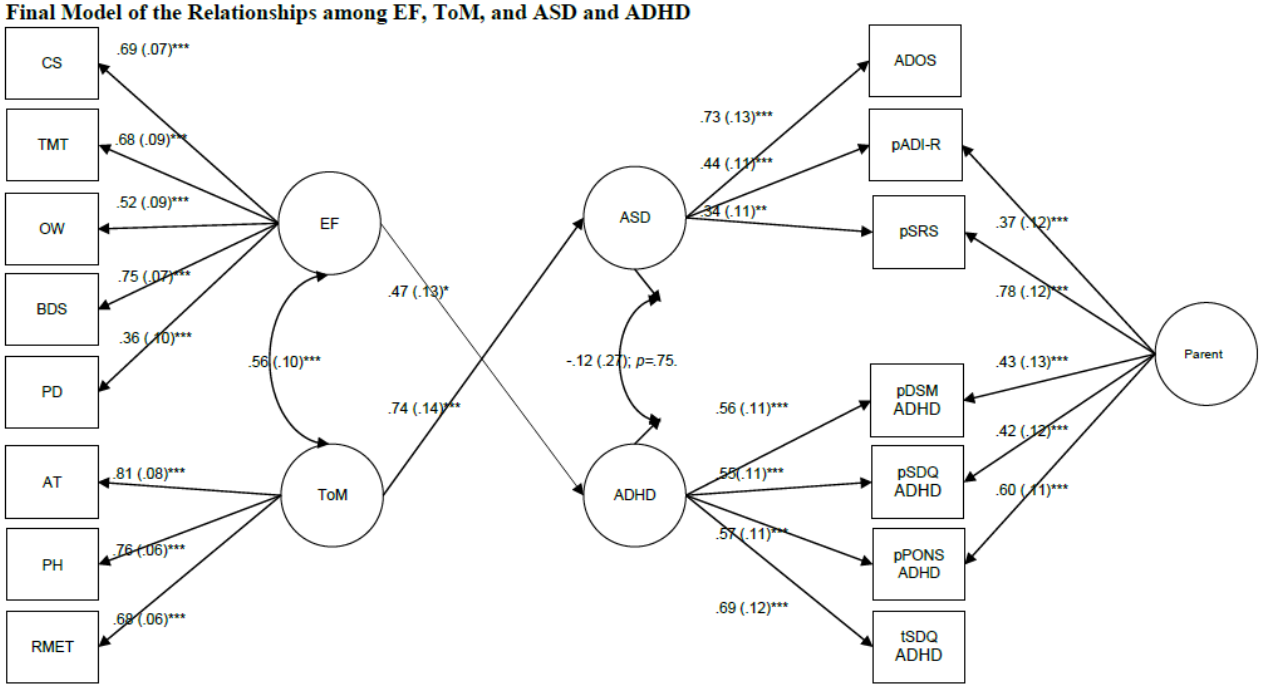
17 **122.017** Executive Function Deficits Are Associated with ADHD Symptoms Whilst Theory of Mind Is Associated with ASD Symptoms in Adolescents with ASD

***S. Lukito**[1], C. Jones[2], A. Pickles[3], G. Baird[4], F. Happé[5], T. Charman[6] and E. Simonoff[6], (1)Child & Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)School of Psychology, Cardiff University, Cardiff, United Kingdom, (3)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (4)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (5)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Individuals with autism spectrum disorder (ASD) have high levels of attention-deficits/ hyperactivity disorder (ADHD) symptoms, although the reasons for this are unknown. ASD is often linked to deficits of theory of mind (ToM), i.e., the ability to mentalise or understand others' mind; and of executive functions (EF), i.e., the capacity for self-control. In contrast, ADHD has been associated with impairments of EF, and to a lesser extent, ToM. The relationships among these factors in the ASD population are the focus of this study.

Objectives: We build a working model of the associations among EF, ToM and symptoms of ASD and ADHD in adolescents with ASD.
Methods: We investigated a population-based cohort of 100 adolescents with ASD (the Special Needs and Autism Project – SNAP), aged 14-16 years and full scale IQ≥50. Structural equation modelling was used to model the relationships between EF, ToM and ASD or ADHD symptom levels. Measures of inhibition (TEA-Ch Opposite Worlds), planning (drawing task), switching (Trail Making Test and card sorting task), and working memory (Backward Digit Span) indexed EF; while measures of mentalising (the Frith-Happe Animated Triangles, Strange Stories, Reading the Mind in the Eyes) indexed ToM. All neurocognitive assessments took place at 14-16 years. ADHD symptoms were indexed by the parent-rated Strengths and Difficulties Questionnaire (SDQ) hyperactivity subscale (14-16 years) and teacher-ratings of SDQ (10-12 years), parent-rated Profile of Neuropsychiatric Symptoms (PONS) ADHD (14-16 years), and DSM-IV ADHD symptom counts from structured diagnostic interviews with parents (10-14 years). ASD symptoms were indexed by the algorithm scores of Autism Diagnostic Interview-Revised (ADI-R) and Autism Diagnostic Observation Schedule (ADOS), both from 10-12 years, and the parent-reported Social Responsiveness Scale (SRS) from 14-16 years. To account for shared sources of information, a parental-rating latent factor was constructed using a subset of the ASD and ADHD symptom measures (ADI-R, SRS, parent-rated SDQ, PONS, and ADHD symptom counts).
Results: The final model reached acceptable fit ($\chi^2[81] = 101.7$, $p = .06$; CFI = .94; TLI = .92; RMSEA = .051). EF deficits were associated with ADHD symptoms (standardized coefficient = .47), and not with ASD symptoms, while ToM deficits were associated only with ASD symptoms (standardized coefficient = .74). The EF and ToM latent factors were significantly correlated (standardized coefficient = .56). Prior to including a parent rating factor, a significant correlation was found between ASD and ADHD symptoms (standardized coefficient = .63). However, this model had an overall poorer fit than the present and the correlation between the ADHD and ASD factors became non-significant after including the parent rating factor, which suggests that the association between the two symptom domains was due to a shared parental rating effect.
Conclusions: ADHD symptoms in individuals with ASD are specifically associated with EF deficits. This is consistent with the finding of EF deficits in those with ADHD alone. Our findings would benefit from replication in samples of individuals with pure ASD, ADHD and combined ASD-ADHD profiles to better understand whether this represents a shared underlying factor for observed co-occurrence.

Final Model of the Relationships among EF, ToM, and ASD and ADHD



Note: Abbreviations of neurocognitive measures: CS = Cardsort, TMT = Trail-making, OW = Opposite worlds, BDS = Backward Digit Span, PD = Planning/drawing task, AT = animated triangle, PH= Penny Hiding, RMET=Reading the Mind in the Eye Tasks, EF=Executive Function, ToM=Theory of Mind. Abbreviations for ASD or ADHD measures: ADOS =Autism Diagnostic Observation Schedule Total Score, ADI-R=Autism Diagnostic Interview-Revised, SRS=Social Responsiveness Scale, DSM = Diagnostic and Statistical Manual of Mental Disorders symptom numbers, SDQ ADHD=Strengths and Difficulties Questionnaire ADHD domain, PONS ADHD=Profile of Neuropsychiatric Symptoms ADHD domain. The prefix p on these behavioural measures indicates parent-based reports whereas the prefix t on the SDQ indicates a teacher-based report. Adding the latent factor Parent isolates the parental-reporting effect resulting in increased loadings of ADOS on the ASD factor and tSDQ ADHD on the ADHD factor. Significant levels * $p < .05$, ** $p < .01$, and *** $p < .001$

18 **122.018** Executive Function in Autism: A Systematic Review and Meta-Analysis

A. M. Nader[1], *V. D. Therien*[2], *M. E. Leclerc*[3], *Z. Khalladi*[4], *S. Grot*[5], *D. Luck*[6] *and I. Soulières*[7], *(1)Psychology, University of Quebec at Montreal, Montreal, QC, Canada, (2)Psychology, University du Québec à Montréal (UQAM), Terrebonne, QC, Canada, (3)Centre de recherche de l'Institut universitaire en santé mentale de Montréal, Montréal, QC, Canada, (4)Bishop University, Montreal, QC, Canada, (5)Centre de recherche de l'Institut universitaire en santé mentale de Montréal, 7331, rue Hochelaga, QC, Canada, (6)Psychiatry, University of Montreal, Montréal, QC, Canada, (7)University of Quebec in Montreal, Montreal, QC, Canada*

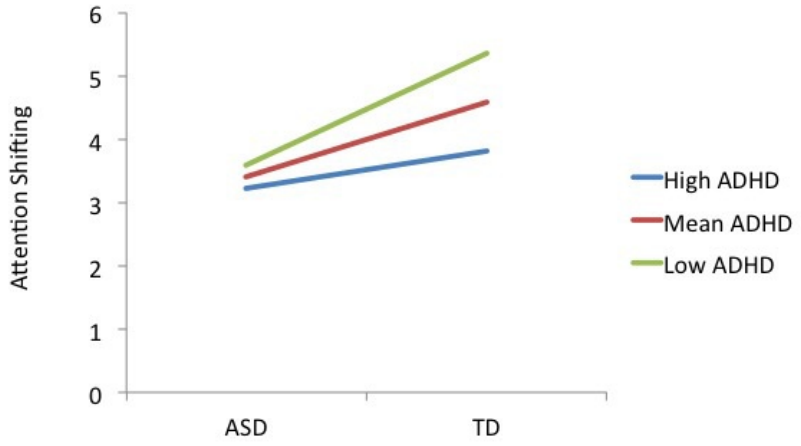
Background: Executive function (EF) is an umbrella term for functions such as working memory, impulse control, planning, mental flexibility and fluency. Deficits in EF are common in autism but not present in all individuals. Numerous studies investigated EF among the spectrum but have yielded varying findings according to the age of the participants and the type of task used (Hill, 2004). Some studies revealed global deficits in overall functions, some more specifically in planning and flexibility (Ozonoff et al., 1999) while some indicated no difference with typically developing (TD) individuals (Russell, 1999). Furthermore, greater deficits seem present in children compared to adults (Happé, 2006). The nature of EF difficulties in autism remains unclear due to an important heterogeneity among previous results and the lack of systematic review.
Objectives: The main goal of this meta-analysis was to determine the pattern and magnitude of executive deficits in autism spectrum disorder.
Methods: A systematic literature search was performed (PubMed, PsycINFO; 1970-2015) using key word such as “autism”, “ASD”, “PDD”, “Asperger”, “working memory” and “executive function”. A total of 1770 studies were identified. 100 cognitive behavioural studies met the inclusion criteria (presence of an age and IQ-matched control group; FSIQ≥70; use of standardized test), involving 2706 ASD and 2778 typically developed (TD) individuals. Results were analyzed with comprehensive meta-analysis software according to the different executive functions (inhibition, flexibility, planning / organization, fluency and working memory) for ASD and TD individuals. Effect sizes were calculated (Cohen’s *d*, standardized mean difference) for each executive function and supplementary analysis were computed for each type of measure and more recurrent test used.
Results: Analyzes showed inferior results for autistic individuals, relative to TD individuals, in all areas of executive functions ($d = 0.25$ to 0.54; all $p \leq .001$). ASD individuals showed the strongest and most consistent difficulties in set-shifting and planning (d = respectively 0.54, 0.49, both $p \leq .001$). Significantly lower performances in working memory are found exclusively in visuospatial tasks (d=0.25, p=.001), not in verbal working memory tasks. Lastly, moderate group differences were found on measures of inhibition ($d = 0.45$, $p \leq .001$) and fluency (d= .46, $p \leq .001$) relative to controls. Data analysis is still undergoing for the effect of intellectual level and the developmental aspect.
Conclusions: This systematic review reveals that while autism is associated with global executive difficulties, executive function difficulties are most consistent for measures of planning and mental flexibility. A better understanding of the executive functions profile of autistic individuals will support 1) a better understanding of the nature of some symptoms seen in autism and 2) development of appropriate intervention and educational strategies, especially since the development of executive functions in autism seems to follow a different pathway. However, detailed research is needed to define the role of some comorbidities in the autism spectrum executive profile, especially the role of ADHD.

19 **122.019** Externalizing Behaviors, Attention Shifting, and ADHD Symptoms in Young Children with ASD

E. F. Geib[1], *H. Dauterman*[2], *W. Mason*[1], *R. Bowler*[3] *and B. Wilson*[1], *(1)Clinical Psychology, Seattle Pacific University, Seattle, WA, (2)Seattle Pacific University Department of*

Clinical Psychology, Seattle, CA, (3)Seattle Pacific University, Seattle, WA

Background:
Children with autism spectrum disorder (ASD) often present with comorbid and clinically significant attention deficit/hyperactivity disorder (ADHD) symptoms, which result in higher rates of externalizing problems (Simonoff et al., 2008; Yerys et al., 2009). Research is attempting to outline the deficit profiles of children with ASD and ADHD. Executive functioning impairment, specifically attention shifting deficits, has been hypothesized as one such deficit (Corbett, Constantine, Hendren, Rocke, & Ozonoff, 2009). Further, deficits in attention shifting are hypothesized to partially explain the risk for increased externalizing problems in children with ASD and ADHD (Lawson et al., 2015).
Objectives:
We hypothesized that children with ASD would exhibit higher levels of externalizing behaviors than typically developing (TD) children and that this relation would be partially explained by their attention shifting ability. Additionally, we hypothesized that the link between diagnostic status and attention shifting would be conditional on their level of ADHD symptomatology.
Methods:
Participants were 162 children (3 to 6 years), their parents, and teachers. Sixty-nine children were diagnosed with ASD and ninety-three were TD. The Behavioral Assessment System for Children – Second Edition (BASC-2; Reynolds & Kamphaus, 2004) and the Child Behavior Questionnaire (CBQ; Rothbart, Ahadi, & Hershey, 1994) were completed by teachers to assess externalizing behaviors and attention shifting respectively. Parents completed the Conner's Parent Rating Scale (CPRS-R-S; Conners, 1997) to assess ADHD symptoms.
Results:
A moderated-mediation analysis was conducted using PROCESS (Hayes, 2013) to examine the conditional indirect effects of diagnostic status (ASD vs. TD) on externalizing behaviors through attention shifting, as moderated by ADHD symptomology on the alpha pathway. Findings revealed support for a full moderated-mediation model. Attention shifting skills, which were lower in the ASD group compared to the TD group, significantly mediated the relation between diagnostic status and externalizing problems at low (t = 7.70, SE = 1.76, CI = 4.22 – 11.28) and mean levels of ADHD symptoms (t = 5.13, SE = 1.22, CI = 2.93 – 7.67). However, at high levels of ADHD symptoms, attention shifting no longer accounted for the relation between diagnostic status and externalizing symptoms (t = 2.55, SE = 1.89, CI = -0.73 – 6.62).
Conclusions:
Our findings suggest that ADHD symptoms moderate the relation between diagnostic status and externalizing behaviors through attention shifting skills. At low and mean levels of ADHD symptoms, children with ASD had worse attention shifting skills than their TD peers, partially accounting for their elevated rates of externalizing problems. However, at high levels of ADHD symptoms, attention shifting no longer explained the relation between diagnostic status and externalizing problems. These results help to clarify the executive functioning profile of children with ASD. Attending to and shifting between relevant stimuli in their environment appears to be a marked deficit for these children, likely impacting their abilities to regulate their behavior. Attentional training targeting these skills may offer productive avenues for intervention to reduce externalizing problems in children with ASD.



20 **122.020** Facial Affect Recognition in Autism, ADHD and Typical Development

S. Berggren[1], *A. C. Engström*[2] *and S. Bolte*[3], *(1)Karolinska Institutet, Stockholm, Sweden, (2)BUP Södertälje, Child and Adolescent Psychiatry Stockholm,, Södertälje, Sweden, (3)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden*

Background:
Autism spectrum disorder (ASD) and Attention-Deficit Hyperactivity Disorder (ADHD) have been associated with explicit facial affect recognition (FAR) alterations, but comparative studies are scarce.
Objectives:
This study examined FAR accuracy and response times for overall and specific basic emotions FAR performance in whole face and eye-region stimuli.
Methods:
FAR was assessed in carefully matched samples of participants with ASD (n=35), ADHD (n=32) and typical development (n=32), taking into account possibly mediating effects of attentional functions and social communication problem severity. Results: Compared to TD, the ASD group performed less accurate and showed longer response times for general and specific FAR in both types of stimuli, mostly driven by problems in neutral and happy face identification. There were few differences between ASD and ADHD, and no differences between ADHD and TD. Cognitive distractibility explained a substantial proportion of variance of FAR performance in ASD and ADHD. Social communication problem severity and cognitive impulsivity had no impact on FAR performance. Conclusions: Findings confirm FAR alterations in ASD, but not ADHD, and endorse mediating effects of certain attention functions. FAR training seems clinically meaningful in ASD. Future studies should include control for visual attention, facial configuration skills, use naturalistic FAR material and also investigate implicit FAR.
Results:
Partial correlations between cognitive distractibility and face and eye test FAR accuracy and response time were essentially null associations for the TD group (r =-08 to .07, p>.70), but partly significantly negative in ASD and ADHD. In ASD, face and eye FAR accuracy was negatively correlated with cognitive distractibility (r = -.34 & -.44, p<.04). In ADHD, face and eye FAR accuracy and eyes test response time was negatively correlated with cognitive distractibility (r = -.31 to -.33, p<.05). Eye and face FAR accuracy and speed correlated highly negatively in TD (r = -.66 & -.73, p<.001) and ASD (r = -.60 & -.76, p<.001), but not in ADHD (r = -.15 & -.16, p=.75). Interestingly, in the ASD group, performance on the eyes test correlated negatively quality of eye contact on the ADOS (r = -.38, p =.02).
Conclusions:
In this study of explicit FAR, we found significant general and specific FAR difficulties in ASD for different stimuli regarding accuracy and response time, compared to TD, only few differences between ASD and ADHD, and no differences between ADHD and TD. Cognitive distractibility explained a substantial proportion of variance of FAR performance in ASD and ADHD. Future studies should aim to investigate FAR in ASD and ADHD using a model also integrating visual attention, facial configuration skills as

predictors as well as naturalistic FAR material and implicit FAR as dependent measures.

21 **122.021** Impact of Autism Diagnosis on Neural Systems of Nonverbal Fluid Reasoning in Adolescent Male Monozygotic Twins

L. Kalbfleisch[1], *J. Roberts*[2] *and A. Loughan*[3], *(1)Pediatrics, The George Washington University School of Medicine and Health Sciences, Washington, D.C., DC, (2)Johns Hopkins University School of Medicine, Baltimore, MD, (3)Virginia Commonwealth University School of Medicine, Virginia Commonwealth University School of Medicine, VA*

Background: Characterizing neural trajectories of fluid reasoning in special populations (including gifted) and in neurotypical children will sharpen our understanding of the influence of reasoning on the acquisition of a range of intellectual skills and talents. This skill is one of those enhanced or preserved at certain high levels of function in autism (Soulieres et al., 2009). Matrix reasoning, an identified construct of intelligence, has been acknowledged as a chief marker of changes in crystallized abilities, in addition to changes seen within real-world contextual thinking when you have enough information but not sufficient time to make decision (Kalbfleisch, Van Meter, and Zeffiro, 2006), and in academic settings including quantitative ability, declarative knowledge, and reading (Ferrer et al., 2009; Soulieres et al., 2009; Wright et al., 2008). Matrix reasoning tests have also been shown to better identify giftedness (i.e. intellectual aptitude in disadvantaged populations) at higher rates than culturally biased traditional intelligence tests (Naglieri, 1997). Furthermore, aspects of metacognitive ability are untouched in twice exceptional children with autism (Kalbfleisch & Loughan, 2011).
Objectives: The present study investigated the impact of two types of autism diagnoses (high-functioning autism versus Asperger's syndrome) on fluid reasoning (Ferrer, O'Hare, & Bunge, 2009; Kalbfleisch, Van Meter, & Zeffiro, 2006; Wright, Matlen, Baym, Ferrer, & Bunge, 2008) in a pair of adolescent male monozygotic twins. We report psychometric, behavioral, and neuro-functional differences of fluid reasoning assessed with a novel matrix reasoning task in the pair who presented as volunteers for an ongoing study of higher-level cognition in children with high-functioning autism. We report them here as a separate case due to their genetic identity, which lends an opportunity to examine demonstrative functional consequences of autism diagnosis on fluid reasoning.
Methods: We evaluated the impact of autism diagnosis on neural systems of nonverbal fluid reasoning in adolescent male monozygotic twins, age 16.3 years, using psychometric (WISC-IV, BRIEF) and functional neuroimaging methods utilizing a novel matrix reasoning task.
Results: Twin with high-functioning autism (HFA) displayed lower Full Scale IQ resulting from decreased verbal aptitude and clinically significant executive function deficits compared to the twin with Asperger's (ASP). Twins displayed comparable behavioral accuracy and speed during fluid reasoning. Conversely, neural systems in ASP correlated with right medial frontal cortex, posterior cingulate gyrus, and precuneus. Neural systems in HFA correlated with right superior and middle frontal gyri, right superior temporal gyrus and bilateral precuneus.
Conclusions: These functional results coincide with brain structure changes that currently define differential conditions on the autism spectrum in the medical literature. Our findings potentially demonstrate the functional consequences of differences in verbal ability and executive function in twins with two forms of autism. Furthermore, this approach presents a format for exploring the nature of twice exceptionality within a larger framework for mapping atypical brain development. We consider implications for the role of intelligence in the context of preserved and enhanced fluid reasoning ability in autism that leads to the presence and expression of certain talents and skills, sometimes described as twice exceptionality.

22 **122.022** Implicit Processing of Category Information in Autism

O. E. Parsons[1] *and S. Baron-Cohen*[2], *(1)University of Cambridge, Cambridge, England, United Kingdom, (2)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom*

Background: Statistical learning in low-level contexts is intact in autism. However, statistical learning in more complex contexts has not yet been investigated in autism. The tendency to generalize is reduced in autism and could lead to over-specificity in category formation. Statistical learning also operates at the semantic categorical level in the typical population. If statistical learning is atypical in autism in higher-level contexts, such as at the categorical level, then we should expect atypical predictive ability in individuals with autism.
Objectives: (1) To investigate whether individuals with autism implicitly process statistical regularities occurring in complex images to the same extent as typically developing individuals. (2) To assess whether learning occurs when these regularities are at the level of the semantic category.
Methods: 40 male adults with autism and 40 male controls (matched for age and IQ) took part. Participants were exposed to image streams consisting of natural scenes. The order of image presentation was dictated by a deterministic underlying structure based on the semantic categories of the scene images (e.g., images of mountain ranges would always be followed by images of bathrooms). Participants were randomly assigned to one of two conditions where the underlying structure occurred at the level of the individual image or occurred at the level of the image categories. In the first condition a single image was used to represent each semantic category. However, in the second condition a novel image was presented for each incidence of a particular semantic category. Thus statistical learning could occur in the first condition without attending to the semantic category, but not in the second condition. A cover task was used to ensure participants did not explicitly attend to image-order. A forced two-choice paradigm was then used to assess participant's ability to correctly identify images occurring in the correct order over foil sequences.
Results: Individuals with autism showed equal performance to controls when the underlying structure was based on individual images. This suggests that individuals with autism do not show any impairment in implicit learning even when the stimuli used are complex, real-world images. However, performance in the autism group was below controls when the structure occurred at the semantic level of the category.
Conclusions: Individuals with ASC do not automatically process complex images in the same way as controls. Specifically, the semantic context of images is not processed as much in people with autism compared to controls. This may reflect their greater attention to detail. These findings have implications for how environmental regularities are processed and for learning, in individuals with autism.

23 **122.023** Individual Differences in Executive Function Are Predictive of Autistic Children's School Readiness

L. Kenny[1], *H. Lichwa*[1], *E. Klaric*[1], *J. L. Brede*[1], *R. McMillin*[1] *and E. Pellicano*[1,2], *(1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)School of Psychology, University of Western Australia, WA, Australia*

Background: Long-term follow-up studies show that the developmental outcomes of autistic people are highly variable, even for individuals at the more able end of the autism spectrum. While some individuals go on to live independently, the majority fail to attain full-time employment or to enjoy fulfilling friendships. Explaining this variability is of critical import: to discover why developments take place in some areas and not in others, and especially in some children and not in others. One potential source of this variability may be autistic children's emerging executive function (EF): a set of higher-order processes, closely associated with the prefrontal cortex, which are necessary for regulating and controlling behaviour. EF is a promising candidate not least because poor EF is well documented in autism but also because research in typical development indicates that well-regulated EF (1) helps to shape young children's social awareness, (2) is predictive of pre-schoolers' school readiness and academic achievement and (3) is amenable to intervention. Furthermore, research has demonstrated longitudinal links between EF and another core neurocognitive function impaired in autism – theory of mind.
Objectives: The present study investigated the relationship between emerging executive abilities and school readiness in pre-school children with and without autism. Further, we examined the extent to which individual differences in executive skills were associated with a child's readiness for school in autism and typical development alike.
Methods: 30 preschool children on the autism spectrum (*M* age = 4.44 years; *SD*=1.02) and 30 typical children (*M* = 4.42 years; *SD*= .88), matched for age and ability, were assessed on a battery of tasks measuring components of EF, including set-shifting, working memory and inhibition, and school readiness (indexed by performance on the Bracken School Readiness Scale).
Results: Compared to typical children, autistic children performed significantly lower on the School Readiness Composite score, $F(1,58) = 8.13$, $p = .006$ and the School Readiness Social subtest, $F(1,58) = 63.46$, $p < .001$. Children on the autism spectrum also had more difficulty with set-shifting, $F(1,58) = 34.26$, $p < .001$, working memory, $F(1,58) = 30.72$, $p < .001$ and inhibition, $F(1,58) = 13.20$, $p = .001$. Additionally, and in line with our predictions, individual differences in autistic children's EF skills, especially in spatial working memory, were related to variation in their school readiness, just like they were in typically developing children
Conclusions: The findings from this cross-sectional study provide further support for the potential role of EF in explaining the variability in autistic children's functional outcomes, in this case, their readiness to learn at school. Intervention programmes to boost EF development in preschool children with autism – especially those that 'exercise' EF or rely on implicit rather than explicit instruction of such skills – should be a key priority for future research.

24 **122.024** Investigating Potential Biases in Self-Evaluations of Reading and Math Performance By Individuals with ASD, ADHD, and Typical Development

J. B. McCauley[1,2], *M. C. Zajic*[3], *H. K. Schiltz*[2], *L. E. Swain-Lerro*[3], *M. A. Harris*[2], *T. Oswald*[1], *N. S. McIntyre*[3], *K. Trzesniewski*[2], *P. C. Mundy*[4] *and M. Solomon*[5], *(1)University of California at Davis MIND Institute, Sacramento, CA, (2)Human Development, University of California at Davis, Davis, CA, (3)University of California at Davis MIND Institute, Davis, CA, (4)Education and Psychiatry, University of California at Davis, Sacramento, CA, (5)MIND Institute, Sacramento, CA*

Background: Self-evaluative abilities for academic competence are critical for student success. Biased self-evaluations have the potential to prevent children and adolescents from knowing when they need to work harder, and or get help from their teachers. Researchers have examined overly optimistic self-ratings of competencies, referred to as positive illusory biases (PIB), by comparing self-rated ability to performance. There is some evidence youth with autism spectrum disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) demonstrate PIB when assessing abilities on laboratory tasks. However, it is unclear if PIB occurs when children with ASD rate their abilities more generally on perceptions of their academic abilities in reading and math, and whether these biases are associated with self-esteem, implying they serve a self-protective function.

Objectives: To answer these questions, we: (1) examined the extent to which youth with ASD, ADHD and typical development (TYP) displayed PIB when making self-assessments of their reading and math achievement; and (2) tested whether there was a positive association between PIB and self-esteem, suggesting the biases are self-protective.
Methods: 98 youth, aged 9 to 17 (see Table 1), were administered assessments of their perceptions of their reading, and math abilities, and their general self-esteem using subscales from the Marsh SDQ (Marsh, 1992). Actual math ability was assessed with the Numerical Operations and Problem Solving subtests from the Wechsler Individual Achievement Test, 3rd edition (WIAT-III; Pearson, 2009). Reading fluency and comprehension was assessed using the Gray Oral Reading Tests, 5th Edition (GORT-V; Wiederholt & Bryant, 2012). Subtracting z-scored performance scores from z-scored self-rated abilities, we quantified the amount of bias to examine if positive biases were related to self-esteem. Bivariate correlations were performed using SPSS 22.
Results: All groups showed significant positive associations between self-rated ability on math and performance on WIAT-III Numerical Operations (Pearson's *r* ranged from .36 to .65). The ASD group did not, however, exhibit a similar relationship between their math self-ratings and WIAT-III Problem Solving ($r(35)=.16$, $p=.34$). Additionally, the ASD group did not show a positive association between self-rated reading ability and performance on fluency ($r(37)=.06$, $p=.70$) or comprehension ($r(37)=.09$, $p=.58$), and the ADHD group had an association between self-rated reading ability and fluency, but not comprehension ($r(23)=.23$, $p=.26$). On the contrary, the TYP group showed significant associations between self-rated abilities and performances in each domain. Finally, there was a significant positive association with self-esteem and positive bias scores in the reading domain in the ASD group ($r(37)=.33$, $p=.04$), suggesting that the function of positive biases may be self-protective for this group.
Conclusions: These results indicate that youth with ASD may be evaluating their math abilities in relation to arithmetic rather than problem solving ability, suggesting that they may need extra help identifying all abilities relevant to math. In addition, youth with ASD, and to some extent youth with ADHD, are not making accurate appraisals of their reading ability, but there is evidence that these biases are self-protective. Future work should develop self-assessments that help support these abilities for individuals with ASD.

Table 1
Sample Characteristics

	ASD (n=39)	TYP (n=34)	ADHD (n=25)
Males (%)	33 (85%)	22 (65%)	18 (72%)
Females (%)	6 (15%)	12 (35%)	7 (28%)
Chronological Age (SD)	12.75 (2.22)	12.82 (2.26)	13.01 (2.20)
Verbal IQ (SD)	96.97 (15.62)	110.56 (14.44)	100.96 (14.75)
Nonverbal IQ (SD)	104.41 (15.57)	117.06 (15.04)	100.68 (15.10)
Full-Scale IQ (SD)	100.48 (13.91)	115.59 (13.83)	100.96 (15.04)
ADOS-2 Total	10.46 (2.87)	NA	3.48 (3.88)
ADHD Comorbidity	8 (21%)	NA	NA

25 **122.025** Latent Profile Analysis Reveals Distinct Executive Function Profiles Across Children with ASD and ADHD

D. R. Dajani[1], *M. B. Nebel*[2,3], *S. H. Mostofsky*[4] *and L. Q. Uddin*[5], *(1)University of Miami, Miami, FL, (2)Department of Neurology, Johns Hopkins School of Medicine, Baltimore, MD, (3)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (4)Johns Hopkins School of Medicine, Baltimore, MD, (5)University of Miami, Coral Gables, FL*

Background:
Executive functions (EF), the mental control processes necessary to carry out goal-directed behaviors (Denckla, 1994), are impaired in both autism spectrum disorder (ASD) and attention deficit/hyperactivity disorder (ADHD). Although studies have attempted to delineate specific executive dysfunction profiles that discriminate ASD from ADHD (e.g., Sergeant et al., 2002), the high comorbidity of ADHD diagnoses in those with ASD (30%) complicates matters. As an alternative to considering DSM-based diagnoses, the scientific community is moving towards a neurobiological assignment of cognitive dysfunction in a manner consistent with the Research Domain Criteria (RDoc) put forward by NIMH (Insel, 2010).
Objectives:
The aim of the current study is to delineate subgroups of children based on patterns of EF strengths and deficits, or "EF profiles". We investigated a mixed group of typically developing (TD, 45%) children, children with an ASD diagnosis (4%), children with an ADHD diagnosis (29%), and ASD with comorbid ADHD (22%).
Methods:
A latent profile analysis was calculated using MPlus, with 10 indicators of executive function (8 subscales from the parent-report of the Behavior Rating Inventory of Executive Function (BRIEF; Gioia, 2002), the statue subscale of the Developmental Neuropsychological Assessment (Korkman & Kemp, 1998), and the backward digitspan subscale of the Wechsler Intelligence Scale for Children- IV (Wechsler, 2004)). Together, these indicators measure inhibition, shifting, working memory, and planning/organizing. Participants included 207 children (Females: $N = 45$) ages 8-13 years ($M = 9.98$, $SD = 1.22$) with average full-scale IQ ($M = 109.55$, $SD = 13.76$).
Results:
The model that best fit the data contained three classes (entropy: .92; Lo, Mendell, Rubin LRT for 3 *v* 2 classes: 234.95, $p = .02$). The first class ($N = 88$) had overall above average executive functions ("superior"). The second class ($N = 57$) had slightly below average scores on all of the EF indicators ("middle"). The third class ($N = 61$) had overall the poorest executive function, which was below average for their age ("low"). Interestingly, these classes did not reproduce the groups based on clinical diagnosis. Most TD children were in the "superior" class (89%), while the majority of ADHD children were split between the "middle" (47%) and "low" (46%) classes. Similarly, children with ASD were primarily in the "low" class (63%), with 35% in the "middle". EF classes predicted robust phenotypic differences between children. Specifically, the EF classes accounted for unique variance, over and above diagnosis, in anxiety and depression ($R^2 = .56$, R^2 *change*$=.04$, $p=.001$), social problems ($R^2 =.73$, R^2 *change*$=.07$, $p < .001$), attention problems ($R^2=.79$, R^2 *change*$=.08$, $p < .001$), and aggressive behavior ($R^2 =.58$, R^2 *change*$=.10$, $p < .001$).
Conclusions:
Using an RDoc framework, the present study examined EF in a mixed group of TD children and children with neurodevelopmental disorders. Importantly, the EF classes that emerged from latent profile analysis predicted variance in behavioral problems unique from diagnosis. Future studies should validate these EF classes biologically by investigating whether unique brain-based markers for EF dysfunction can be determined.

26 **122.026** Links Between Hyperfocused Attention, Pupillometry, and the Locus Coeruleus Across the Broader Autism Phenotype

A. S. DiCriscio *and V. Troiani, Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA*

Background:
Pupillometry measures changes in pupil dilation, which are tightly linked with activity in the Locus Coeruleus (LC). The LC controls baseline arousal as well as stimulus-locked, or "phasic", responses that focus attention in response to environmental cues. More specifically, a phasic LC-NE response is thought to induce a more strategic visual discrimination filter, which serves to restrict information processing to only the most relevant locations. Atypical attention has frequently been reported in autism spectrum disorders (ASD). In particular, individuals with ASD sometimes demonstrate superior performance in visual search and block design tasks, relative to age and IQ matched peers. One hypothesis suggests a 'hyperphasic' LC underlies heightened visual discrimination abilities and the inflexibility and hyperfocused attention that leads to restricted interests present in ASD.
Objectives:

The purpose of the current study was to critically test the relationship between performance on tasks requiring focused attention, traits associated with the Broader Autism Phenotype (BAP), and the link to the LC via pupillometry.
Methods:
Experiment 1: We used phenoytype and genotype data collected through the Simons Variation in Individuals Project (SVIP; www.simonsvipconnect.org) to examine the relationship between symptoms of the BAP and performance on visual discrimination tasks in 16p11.2 probands with a confirmed *de novo* deletion (*del*) or duplication (*dup*) (N=26; 15 males; mean age = 4.8±1.5), a copy number variant (CNV) known to increase the risk for ASD.
Experiment 2: We designed a Navon Figures eyetracking paradigm (i.e. large letter composed of small letters), requiring an individual to vary only the information attended to within an image. This controlled for low-level visual features such as luminance that impact pupil changes. Participants were healthy young adults (N=49; mean age =25.2).
Results:
Experiment 1: In children with 16p11.2 syndrome, average scores on a block design task were directly related to average scores on the Broader Autism Phenotype Questionanire (BAP-Q) (r=0.42, p<0.03). These results confirm a relationship between heightened visual discrimination abilities and the BAP.
Experiment 2: Participants display larger changes in task evoked pupil response when identifying local information (smaller letter) within objects relative to global information (larger letter) (p<0.001). We also show a relationship between relative change in pupil diameter (Local:Global conditions) and behavioral measures associated with the BAP, specifically the rigidity subscale, which measures flexibility and preoccupation with details (r=0.58, p<0.003). This effect was specific to stimulus-locked ('phasic') responses and was not linked to baseline pupil diameter.
Conclusions:
This work represents the first characterization of the specificity in phasic pupil response and the relationship with the BAP and suggests that mechanisms that control the earliest parts of visual selection are associated with autism traits. Ongoing data collection will characterize the pupil responses in children with 16p11.2 syndrome.

27 **122.027** Metacognitive Awareness of Facial and Vocal Affect in Higher-Functioning Children and Adolescents with Autism Spectrum Disorder

C. McMahon[1], *R. Schatz*[2], *J. Haut*[2], *A. Merrill*[2] *and T. Otero*[2], *(1)Hamilton College, Clinton, NY, (2)Indiana University - Bloomington, Bloomington, IN*

Background:
Metacognition is one's ability to monitor and assess one's own task performance (e.g., Jacobs & Paris, 1987). Two previous studies (McMahon et al., 2015; Sawyer et al., 2014) have examined metacognition of facial affect identification in individuals with Autism Spectrum Disorder (ASD). In McMahon et al. (2015), children and adolescents with ASD were impaired in metacognition relative to a comparison group; in Sawyer et al. (2014), adults with ASD did not show evidence of a metacognitive impairment, although a mild impairment in metacognitive control was observed.
Objectives:
The objective of this study was to assess metacognition of facial and vocal affect in children and adolescents with ASD. To the authors' knowledge, this is the first study to examine metacognition of vocal affect in individuals with ASD.
Methods:
Children and adolescents (ages 9-17) with typical development (n = 10) and ASD (n = 14) participated in this study. There were no significant differences between diagnostic groups on age, $t(22) = -1.20$, $p = 0.24$, verbal IQ, $t(22) = 1.74$, $p = 0.10$, performance IQ, $t(22) = 1.29$, $p = 0.21$, or gender, $\chi^2 (1, N = 24) = 0.97$, $p = 0.32$. Participants completed the Diagnostic Analysis of Nonverbal Accuracy 2 (Baum & Nowicki, 1997; Nowicki & Carlton, 1993); they were asked to determine the affect of 24 faces and 24 voices and indicate their degree of certainty (1 = very uncertain, 5 = very certain) for each affect selection. A hierarchical linear model was used to analyze the data, with degree of certainty and stimulus type (face/voice) assessed as stimulus-level predictors of affect accuracy and diagnosis, age, verbal IQ, and gender assessed as participant-level predictors of affect accuracy.
Results:
There was a significant effect of age, $t(22) = 2.57$, $p = 0.02$, and certainty, $t(1125) = 9.02$, $p < 0.01$, on accuracy of affect selection, such that older participants were more accurate in their affect selections and greater certainty in affect selection was associated with greater accuracy across all participants, regardless of diagnostic group. Finally, there was a marginal effect of stimulus type on accuracy of affect selection, $t(1125) = -1.86$, $p = 0.06$, which was qualified by an interaction between stimulus type and diagnostic group, $t(1125) = -2.15$, $p = 0.03$, such that all participants, particularly those with ASD, were more accurate in processing facial affect than vocal affect (see Table 1 and Figure 1).
Conclusions:
Contrary to the results of McMahon et al. (2015), this study suggests that children and adolescents with ASD do not have metacognitive impairments in monitoring facial or vocal affect. As the face processing task used in this study was simpler than the face processing task used in McMahon et al. (2015), individuals with ASD may have greater metacognitive impairments on more difficult affective processing tasks. Individuals with ASD had more difficulty identifying vocal affect than facial affect in this study, suggesting that future studies should explore the relation between metacognition and task difficulty for both facial and vocal affect identification tasks.

Figure 1. Interaction between stimulus type and diagnostic group on accuracy of affect selection.

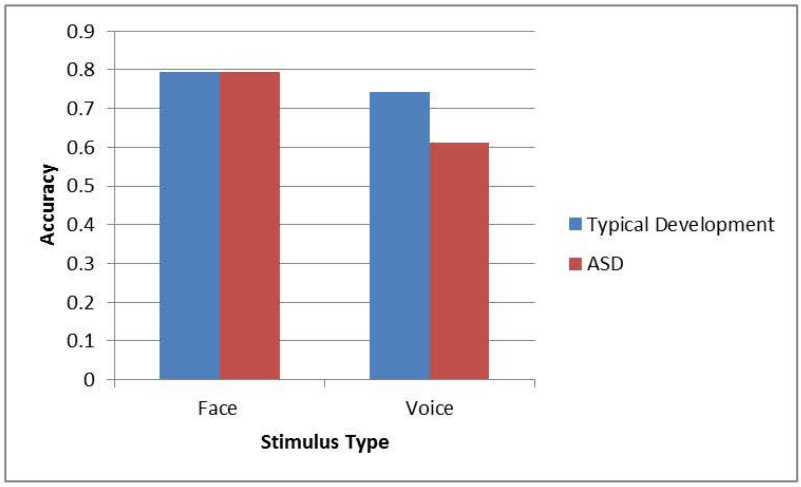


Table 1

Hierarchical linear model

Parameter	Model
	Fixed Effects
Intercept	
Intercept (β_{00})	1.35** (0.13)
Age (CGM; β_{01})	0.09** (0.04)
Slope for Confidence (CWC)	
Intercept (β_{10})	0.72** (0.08)
Slope for Stimulus Type	
Intercept (β_{20})	-0.36* (0.20)
Diagnosis (β_{21})	-0.49** (0.23)
	Variance Components

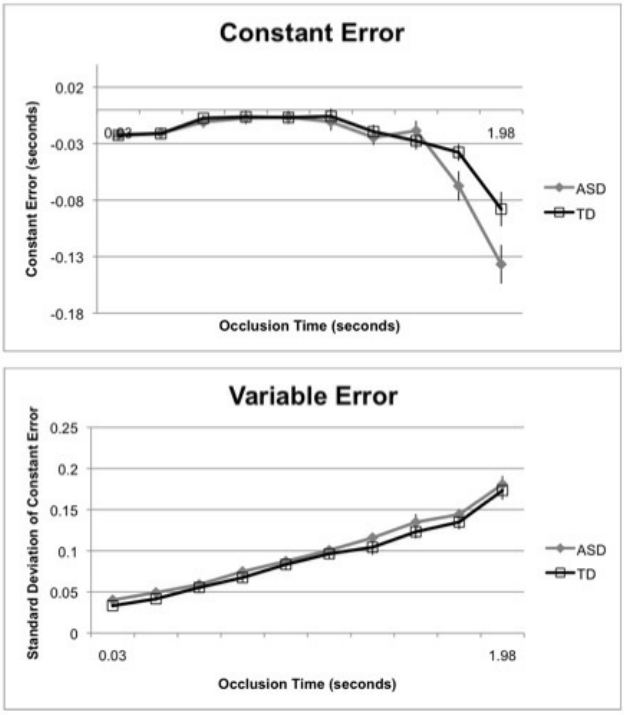
Note. Standard errors are in parentheses for fixed effects, and standard deviations are in parentheses for variance components. ** $p < 0.05$, * $p < 0.10$. CWC = Centered Within Context; CGM = Centered at the Grand Mean.

28 **122.028** Motion Prediction Abilities in Autism Spectrum Disorder

K. B. Schauder[1], *W. J. Park*[2], *O. Kwon*[2], *D. Tadin*[2] *and L. Bennetto*[1], *(1)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (2)Brain and Cognitive Sciences, University of Rochester, Rochester, NY*

Background: Individuals with autism spectrum disorder (ASD) prefer routine and have difficulties in unpredictable situations (e.g., social interactions). Emerging theories suggest that an underlying prediction impairment may contribute to ASD (Van de Cruys et al., 2014; Sinha et al. 2014). Prediction occurs at various information processing levels, making this account appealing to understanding ASD at a mechanistic level. However, it is crucial to determine the nature and extent of this impairment empirically. One ubiquitous type of prediction that has been studied in typical development is motion prediction, which requires estimating future object position based on experienced sensory information. Real world examples include predicting when a moving car will emerge from a driver's blind spot and knowing when to swing at a baseball. Motion prediction abilities have not yet been assessed in ASD.
Objectives: To investigate motion prediction abilities in ASD.
Methods: 20 children and adolescents with ASD and 20 age- and IQ- matched typically developing (TD) controls completed a standard motion prediction task. Participants viewed an object that moved across the screen and disappeared behind a visual occluder; their task was to press a button when they thought the object had arrived at the visual target at the end of the occluder. Speed of object motion (10-20 deg/sec) and occluder length (0.5-20 deg) varied independently across trials, which together determined occlusion time. Mixed Model ANOVAs were used to examine effects of occlusion time and diagnostic group on three common measures of prediction ability. *Constant error* represents the difference between participants' estimate and the actual time to target, with negative values representing a bias to respond too quickly.

Absolute error represents the discrepancy between actual and estimated time to target contact irrespective of under- or over- estimation. *Variable error* is the standard deviation of the individual's constant error, representing consistency of estimations across trials.
Results: For all three measures, there was a main effect of occlusion time indicative of increased error as prediction demands increase (all *p*'s < .001). For constant error, there was a significant group x occlusion time interaction ($F(9,38) = 3.22$, $p < .05$), in which the ASD group underestimated the stimulus's arrival to the target more than the controls at the longest occlusion times (> 1s). However, for absolute and variable error, group differences and group x occlusion time interactions were not significant.
Conclusions: Overall, individuals with ASD did not differ from those with TD in their abilities to estimate the time to target contact of a moving stimulus, suggesting that motion prediction abilities are not generally affected in ASD. However, greater underestimation in ASD at the longest occlusion times may represent a systematic bias or particular kind of prediction deficit at occlusion times longer than one second. Ongoing analysis of eye tracking data from this task will provide additional insights into tracking strategies used to perform this task. Although prediction deficits are not robustly apparent in this nonsocial, laboratory task, future studies should examine prediction abilities in ASD in social and other higher level processing domains.



29 **122.029** Neural Correlates Underlying Binding of Information in Autism: Preliminary Results

M. E. Leclerc[1,2], *S. Grot*[3,4], *I. Soulières*[5] *and D. Luck*[2,3], *(1)Psychiatry, University of Montreal, Montreal, QC, Canada, (2)Centre de recherche de l'Institut universitaire en santé mentale de Montréal, Montréal, QC, Canada, (3)Psychiatry, University of Montreal, Montréal, QC, Canada, (4)Centre de recherche de l'Institut universitaire en santé mentale de Montréal, 7331, rue Hochelaga, QC, Canada, (5)University of Quebec in Montreal, Montreal, QC, Canada*

Background: Working memory (WM) is a limited-capacity system devoted to temporary storage and short-term handling of information. Within the different components of working memory, the ability to combine various information, referred to as *binding*, is crucial for episodic memory and learning processes. There are two types of binding: the automatic form, for which associations between pieces of information are made unconsciously (information being presented already bound together), and the controlled form, for which these associations require a conscious effort. These two forms of binding are based on separate neural substrates: automatic binding is based on the functioning of the hippocampus, while controlled binding is based on the communication between the hippocampus and prefrontal cortex. Some studies have suggested preserved automatic binding capabilities in autistic individuals, while other studies have shown controlled binding difficulties. This profile of performance could result from alterations of the neural circuit connecting the prefrontal cortex and hippocampus.
Objectives: To investigate the cognitive and brain mechanisms underlying both automatic and controlled forms of information binding in autism, using functional magnetic resonance imaging (fMRI).
Methods: 13 autistic participants (diagnosed by a multidisciplinary team with ADI-R and ADOS-G) and 15 typically developed participants were recruited from the research database of a specialized clinic for autism diagnosis. Participants were matched on gender, IQ and age (18-40 years old). In an MRI scanner, participants performed the working memory experimental task, which consisted of the presentation of words and ellipses (indicating a spatial position) of different colors, to memorize. In the automatic condition, words were presented directly into ellipses. In the controlled condition, the words were presented in the center of the screen, separated from ellipses. Participants had to associate same color words and ellipses. Stimuli were presented for 3 seconds and participants had to maintain information for 10 seconds in WM. After this delay, a word was presented in a spatial position and participants had to decide whether the word/spatial position association was correct or not.
Results: Participants had significantly lower accuracy in controlled binding than in automatic binding, with no between-group differences. During encoding phase, typical participants presented greater levels of activity in the middle frontal gyrus for controlled binding, and in dorsolateral prefrontal cortex for automatic binding, compared to autistic participants. During maintenance phase, autistic participants showed greater levels of activity in the left median frontal gyrus, hippocampus and parahippocampal gyrus, for controlled binding, and in the parahippocampal gyrus and left inferior gyrus for automatic binding, compared to typical participants.
Conclusions: Despite similar performances, autistic and typical participants presented different patterns of cerebral activity. When encoding information, the different level of activity in prefrontal cortex suggests the use of different encoding strategies in the two groups. Typical participants probably used a more active strategy of manipulation of information to remember. However, when maintaining information in WM, greater activity in the hippocampus and prefrontal regions was found in autistic participants, suggesting more effortful strategies employed by autistic participants.

30 **122.030** Planning Skills in Autism Spectrum Disorder Across the Lifespan: A Meta-Analysis and Meta-Regression

L. M. Olde Dubbelink[1,2] *and H. M. Geurts*[3], *(1)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam, Amsterdam, Netherlands, (2)Dept. of Research, Development & Innovation, Dr. Leo Kannerhuis, Doorwerth, Netherlands, (3)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam; Dr. Leo Kannerhuis, Amsterdam, Netherlands*

Background: Planning is an important part of life as it both directs and evaluates the strategy we use to reach our pre-specified goals. People with autism spectrum disorder (ASD) are thought to encounter difficulty with planning. Experimental research, however, lacks consensus on the mastery of this skill in ASD. The last, narrative, review on this topic dates back to 2004 and concluded that people with ASD have planning difficulties and that age might influence planning (Hill, 2004). To date, however, the literature on planning in ASD has not been quantitatively reviewed, and still little is known about possible age-related effects on planning in ASD.
Objectives: By means of a meta-analysis and meta-regression, we aim to conceptualize (1) the magnitude of possible planning deficits in ASD; (2) potential age-related effects on planning; (3) which of the array of planning measures is most consistent in its findings; (4) whether intelligence levels have an effect on planning.
Methods: A systematic literature search identified 49 eligible studies with a combined sample size of 1737 people with ASD and 1600 typically developing (TD) controls (mean age range: 4.9-63.6 years). For each continuous outcome, a Hedges' *g*effect size was calculated. A positive effect size indicated poorer planning by the ASD group as compared to the TD group. Next, a random-effects meta-analysis was performed, followed by meta-regression techniques to examine moderating effects of age, type of task and IQ.
Results: The preliminary meta-analysis indicated that individuals with ASD perform worse on planning tasks as compared to TD controls (effect size 0.53). Age and type of

task did not seem to have an effect on planning. IQ was a relevant moderator (explaining 31.25% of the total heterogeneity), with smaller effects with increasing IQ. The residual heterogeneity between studies remained large and significant. Investigation of publication bias suggested missing studies with a negative effect. Although inclusion of these hypothetical studies would decrease overall mean effect size, the effect size would remain significant.
Conclusions: Our preliminary results of this meta-analysis on planning performance in ASD showed that people with ASD have indeed difficulty with planning. Furthermore, it showed that age does not moderate effects, while IQ does. However, a large amount of variation between studies remained unexplained. Thus, while people with ASD have planning problems across the lifespan, there are additional factors that influence their planning performance that need to be considered in future studies.

31 **122.031** Predictors of Adult Outcomes in Cognitively Gifted Individuals with Autism Spectrum Disorder

J. Kaboski[1], *J. Gilger*[2] *and M. Cain*[3], *(1)University of Notre Dame, Notre Dame, IN, (2)School of Social Sciences, Humanities & Arts, University of California - Merced, Merced, CA, (3)Psychology, University of Notre Dame, South Bend, IN*

Background: Although the past few decades have seen an increasing interest in gifted children with ASD, adult outcomes of this population remain a mystery. It may seem natural to presume that cognitively exceptional students would be successful in adulthood, regardless of their ASD diagnosis; however, there has not been any scientific confirmation of this presumption. This study is an attempt to fill this gap in the literature.
Objectives: The overall objective of this quantitative study was to (1) descriptively compare adult outcomes between gifted and non-gifted individuals with ASD and (2) identify key factors that predict postsecondary outcomes in gifted individuals with ASD.
Methods: This project utilized the National Longitudinal Transition Study 2 (NLTS2). The data were collected from a nationally representative sample of children who qualified for special education services under the primary diagnosis of autism. Participants were 13-17 of age at the start of the data collection and 21-25 at conclusion. Giftedness was defined as having either: (1) scored above 90thpercentile on any of the subtests on the Woodcock Johnson III achievement test; or (2) qualified for gifted/talented programs offered by the students' school. Regression analyses were performed on various adult outcomes: romantic relationship, employment, wage, college enrollment, and residential independence. All adult outcomes were analyzed using logistic regression except for wage, which could be modeled using linear multiple regression. All predictors were entered in one step.
Results: Of the 440 individuals with ASD in this sample, 62 (14%) met the criteria for gifted. Only 11% of the gifted, and 7% of the non-gifted reported ever being married or in a romantic relationship; this difference was not statistically significant. In all the other adult outcome domains, gifted adults demonstrated significantly favorable results compared to their non-gifted counterparts: higher employment rate, wages, residential independence, and college enrollment. Surprisingly, in the regression analysis using adult outcomes as dependent variable and giftedness as the primary predictor, giftedness was no longer significant when other factors such as maternal education and living skills were included in the model. Most notably, mother's college education was consistently significant for most of the adult outcome domains considered. The only exception was college enrollment: being gifted was significant - along with having a mother who graduated from college, utilizing educational services in childhood, and having higher mental functioning.
Conclusions: Cognitively gifted adults fared better than their non-gifted counterparts in a number of outcomes as predicted; however upon closer examination, it appears that their success may not necessarily be attributable to giftedness *per se* but to other factors that are correlated to giftedness, such as maternal college education and educational services received in childhood. Further exploration with a special focus on environmental factors that could serve as potential points of intervention – such as health insurance, school services, medication use, and characteristics of schools – will be reported in the full presentation.

Table 1. Sample Characteristics of Adults ages 21-25

	ASD plus Gifted N=62	ASD non-Gifted N=378	Z, t	*p*
Romantic Relationship	11%	7%	1.06	0.86
Dropped out of High School	8%	8%	0.00	0.50

32 **122.032** Reduced Spatial Suppression in ASD Children

*O. Sysoeva[1], I. A. Galuta[1], E. Orekhova[2], M. Davletshina[1] and **T. A. Stroganova**[3], (1)Autism Research Laboratory, Moscow State University of Psychology and Education, Moscow, Russia, (2)University of Gothenburg, Moscow, Russian Federation, (3)MEG-center, Moscow State University of Psychology and Education, Moscow, Russia*

Background: Paradoxically, as stimuli size increases the motion perception of high-contrast gratings deteriorates. This phenomenon is called "spatial suppression" and is believed to reflect center-surround neural inhibition (Tadin et al., 2003). The abnormal excitation/inhibition (E/I) balance has been implicated in Autism Spectrum Disorder (ASD), predicting the reduced spatial suppression in this population. To the best of our knowledge only one study examined spatial suppression in ASD individuals (Foss-Fieg et al., 2013). Although the reduction of spatial suppression in high-contrast stimuli was not found in this study, the authors suggested that reduction of spatial suppression in ASD can be masked by attenuated gain control, an inhibitory mechanism that underlies saturation of neural responses at high contrast, which characterize their ASD subjects. Additionally, the general enhanced sensitivity to motion of high-contrast stimuli in ASD was reported. Noteworthy, this study comprised only high-functioning ASD children with extremely high IQ scores (116.7±12.4), questioning the generalizability of the results into broader ASD sample.
Objectives: The aim of our study was to examine the spatial suppression and gain control in a broader sample of ASD children with wider range of IQ scores.
Methods: Subjects were 22 ASD boys and 32 TD boys, aged between 6 and 15 years with IQ ranging from 62 to 136: intellectual ability was assessed by the Kauffman Assessment Battery (Kauffman&Kauffman, 2004). Experimental groups did not differ by chronological age, but mean IQ score was higher in TD than ASD children (117.5±12.0 and 90.9±19.8, respectively). The experimental procedure was similar to those used by Foss-Feig et al., 2013. The stimuli were the drifting vertical sine wave

gratings of either small (2°) or big (12°) size, presented in high- (100%) or low- (1%) contrasts. The duration of stimuli presentation was adjusted using two interleaved one up two down staircases that converged on 71% correct performance. Participants were asked to judge the direction of motion. The logarithm of the obtained threshold was taken as a dependent variable for ANOVA analysis performed separately for high- and low- contrast condition with stimuli Size as within-subject factor and Group as between subject factor. To examine for gain control ANOVA with Contrast as within-subjects factor was applied to the thresholds for small stimuli obtained in low and high contrast blocks.
Results: In high-contrast condition the was significant Size by Group interaction ($F(1,52) = 5.49$, $p = 0.023$, $\eta 2 = 0.094$), with ASD children having smaller difference between thresholds obtained for small and big stimuli (spatial suppression) as compared to TD boys (log scaled: 0.18±0.19 and 0.30±0.19, respectively for ASD and TD). No group difference in low-contrast condition was found. The group also did not differ either in gain control or in general sensitivity to motion.
Conclusions: Our study provides evidence for a reduced spatial suppression in a representative sample of ASD boys comparing to their TD peers.

33 **122.033** Semantic and Visuospatial Analogical Reasoning in Autistic Children

E. Danis[1], *A. M. Nader*[1], *V. Courchesne*[2] *and I. Soulières*[1], *(1)University of Quebec in Montreal, Montreal, QC, Canada, (2)University of Montreal, Montréal, QC, Canada*

Background: Studies have demonstrated intact fluid reasoning abilities, such as relation manipulation and logical solution inference, in children with an autism spectrum disorder (ASD) when assessed with analogical visuospatial reasoning problems (Dawson et al., 2007). Similar performance between ASD and typically developing (TD) children has also been found when semantic analogical problems are presented with pictures (Morsanyi & Holyoak, 2010), but literature supports preferential use of visuospatial reasoning strategies in ASD individuals (Stevenson & Gernsbacher, 2013). Only a few studies used equivalent formats of semantic and visuospatial analogical problems to compare the performance of ASD and TD children on both types of problems. Furthermore, few studies assessed how analogical reasoning develops in autism, but little evidences suggest slower reasoning development in ASD individuals (Green et al., 2014).
Objectives: (1) To assess performance in semantic and visuospatial analogical reasoning in ASD and TD children. (2) To document reasoning development in autism.
Methods: 31 ASD and 42 TD children matched on age (6-13 years; *M*=10.00, *SD*=1.11) and on Raven's Progressives Matrices' percentiles (*M*=56.65, *SD*=24.66) completed 240 reasoning problems on a computerized task. Problems consisted of 2x2 matrices with last entry to be filled with one of the three responses options presented. Problems were composed of pictures and varied in content (semantic vs visuospatial) and complexity (0-, 1-, 2-relations to be manipulated to correctly solve the problem). Accuracy and reaction time (RT) were recorded. Mixed ANOVAs were conducted with Content and Problem Complexity as within-subject factors and the Group and Age (6-9, 10-13 years) as between-subject factors.
Results: In both ASD and TD groups, visuospatial content, increased complexity and younger age decreased accuracy and increased RT ($p<.05$). Moreover, for the 1-relation visuospatial problems, older children of both ASD and TD groups were more accurate than younger children ($p<.05$), while there was no significant difference between younger and older children for the semantic problems of the same level of complexity (1-relation). Overall, TD group (*M*=.89, *SD*=.08) was significantly more accurate than ASD group (*M*=.83, *SD*=.15), though the difference was relatively small. In terms of RT, ASD group (*M*=5485.84, *SD*=2113.11) was faster than TD group (*M*=6649.41, *SD*=1913.09) in the most difficult condition, 2-relations visuospatial problems ($p<.05$). There was a trend for ASD group being faster than ASD group in other conditions, but it did not reach significance.
Conclusions: Both ASD and TD groups showed a similar pattern of performance: increased accuracy with age, decreased accuracy with relational complexity and better accuracy for semantic than for visuospatial problems. In both groups, accuracy was lower for visuospatial reasoning problems than for semantic ones. While TD children were overall more accurate, ASD children were faster. Finally, considering language deficits and visuospatial reasoning strategies in autism, the present semantic over visuospatial advantage in ASD group suggests that the way problems are presented influences their performance. Pictured problems and matrix format seem to suit well their reasoning strategies.

34 **122.034** Sensorimotor Adaptation Underpins Imitation Learning of Biological Motion Kinematics in Autism Spectrum Disorders

N. C. Foster[1], *S. J. Bennett*[1], *J. Causer*[1], *D. Elliott*[1,2], *M. Andrew*[1] *and S. J. Hayes*[1], *(1)Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom, (2)Department of Kinesiology, McMaster University, Hamilton, ON, Canada*

Background: Internal action models underpinning social interaction are developed by imitating biological motion. Although processes subserving automatic imitation of biological motion are functional in autism spectrum (*autism)* disorders (Sowden et al., in press), they are suggested to be compromised during voluntary imitation (Williams et al., 2004). This is said to be based on processing difficulties associated with integrating sensorimotor information across repeated trials of imitating biological motion. To this end, we examined sensorimotor integration and adaptation using a novel methodology that displayed *atypical* and *typical* biological motion in a random (control) and fixed (experimental) trial order.
Objectives: (1) examine imitation of biological kinematics; (2) examine whether imitation of biological kinematics is facilitated by promoting sensorimotor integration
Methods: Twenty one (*neurotypical*) adults, and twenty one adults with *autism*, diagnosed by a clinical assessment and ADOS, participated in the study, which was approved by the local ethics committee. Participants imitated *atypical* and *typical* biological motion. During pre-test and post-test, *atypical* and *typical* stimuli were presented in a random trial order. During acquisition, the stimuli were presented in a fixed predictable trial order, which was counterbalanced between participants. Orthogonal planned comparisons were used to answer a number of *apriori* questions. Alpha was set at $p < 0.05$.
Results: The neurotypical *control* group imitated biological motion accurately in all phases of the experiment. The *autism* group imitated *atypical* biological motion more accurately during acquisition when stimuli were presented in a fixed order, compared to the pre-test when the trial order was random ($p < 0.05$). Moreover, they imitated *atypical* motion more accurately across acquisition blocks ($p < 0.05$), thus demonstrating sensorimotor adaptation. Learning was confirmed with the *autism* group imitating *atypical* motion more accurately in the post-test compared to the pre-test ($p < 0.05$).
Conclusions: Consistent with previous work (Hayes et al., 2015), imitation of *atypical* biological motion was impaired in *autism* when stimuli were presented in a random order in the pre-test. When processing was facilitated using a fixed trial order, adults with *autism* demonstrated sensorimotor adaption resulting in high fidelity imitation of *atypical* biological motion. The ability to imitate *atypical* biological motion remained when stimuli were subsequently presented in a random order in the post-test. This persistence demonstrated sensorimotor learning. We suggest the fixed trial order removed the requirement to upregulate and downregulate alternative action models relating to the different kinematic properties of the observed *atypical* and *typical* stimuli. Thus, sensorimotor integration and consolidation of the representation of *atypical* kinematics was likely facilitated through repeated trial-to-trial sensorimotor transformations of the inverse (motor plan) and feedforward (efferent copy) models. This process would have yielded further opportunity for trial and error learning by facilitating trial prediction, such that sensory visual input from the next *atypical* model would have be processed to further consolidate the developing representation. These adaptation and learning effects offer some of the most promising evidence against a core deficit in voluntary imitation of biological motion in autism.

35 **122.035** Severity Scores on the Autism Diagnostic Observation Schedule 2 Relate to Inhibitory Control in Children with Autism Spectrum Disorders

J. M. Buirkle[1], *G. Greco*[2], *T. Clarkson*[3] *and S. Faja*[4], *(1)Developmental Medicine, Boston Children's Hospital / Harvard Medical School, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Boston Children's Hospital: Harvard Med School, Boston, MA, (4)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background:
Deficits in executive functioning, one's ability to solve complex problems through managing conflicting information, are present in many individuals on the autism spectrum (Robinson, 2009). Specifically, this ability involves inhibition, set-shifting, decision making, and working memory. Poor executive functioning skills are known to correlate with reduced social abilities, more disruptive and aggressive behavior, poorer academic performances, and less successful outcomes in adulthood (see Diamond, 2013 for review). While executive functioning impairments have been acknowledged in autism spectrum disorder (ASD), few studies have looked at the direct relationship between one's executive functioning and their severity score on the Autism Diagnostic Observation Schedule 2 (ADOS-2).
Objectives:
To investigate whether ADOS severity comparison scores correlate with executive function abilities in children diagnosed with ASD.
Methods:
Participants were 19 children with ASD who ranged in age from 7 to 11 years old (15 males; 4 females), with IQs of 80 or above measured using the WASI-2 (Wechsler, 2011). Additional subjects are in the process of being recruited and tested. All participants received a clinical diagnosis on the autism spectrum, determined by DSM-V criteria (American Psychiatric Association, 2013) after administration of the ADOS-2 (Gotham, Risi, Pickles, & Lord, 2007) and the ADI-R (Rutter, Le Couteur, & Lord, 2003). ADOS-2 Comparison Scores were determined by taking the sum of the social affect and restricted repetitive behaviors raw scores and using the Conversion Table for Module 3. Comparison Scores range from 1 to 10, with increasing scores indicating a more severe diagnosis.
Executive Functioning was broken down into four separate tasks, each completed using a laptop computer: The Color-Word Stroop task measured inhibitory control (Perlstein, et al 1999), the Change Task assessed set-shifting (De Jong, Coles & Logan, 1995; Geurts et al., 2004), the Delay Discounting Task looked at decision making skills (Lamm et al, 2006; Richards et al., 2009), and the Backward Digit Span Task examined verbal working memory skills (Cohen,1997).
Results:
These preliminary results showed a strong negative correlation between the ADOS-2 Comparison Score and the Congruent-Incongruent Correct Reaction Time for the Stroop ($R= -0.70$; $p = .001$), which specifically measures inhibition of interfering information. None of the other three tasks correlated with ADOS symptom severity. However, analysis is ongoing with the continued enrollment of subjects.
Conclusions:

The ability of children on the autism spectrum to inhibit conflicting information, a key feature of executive functioning, is related to the severity of their autism diagnosis determined by the ADOS-2. This is consistent with previous literature that shows that inhibiting conflicting information is specifically impaired relative to other aspects of inhibition (Christ et al., 2007). This finding is important in better understanding the underlying features of autism spectrum disorders, and suggests that the development of interventions that target inhibitory deficits specifically may be helpful in reducing the severity of one's diagnosis.

36 **122.036** Sex Differences in Implicit Learning Among Youth with Autism

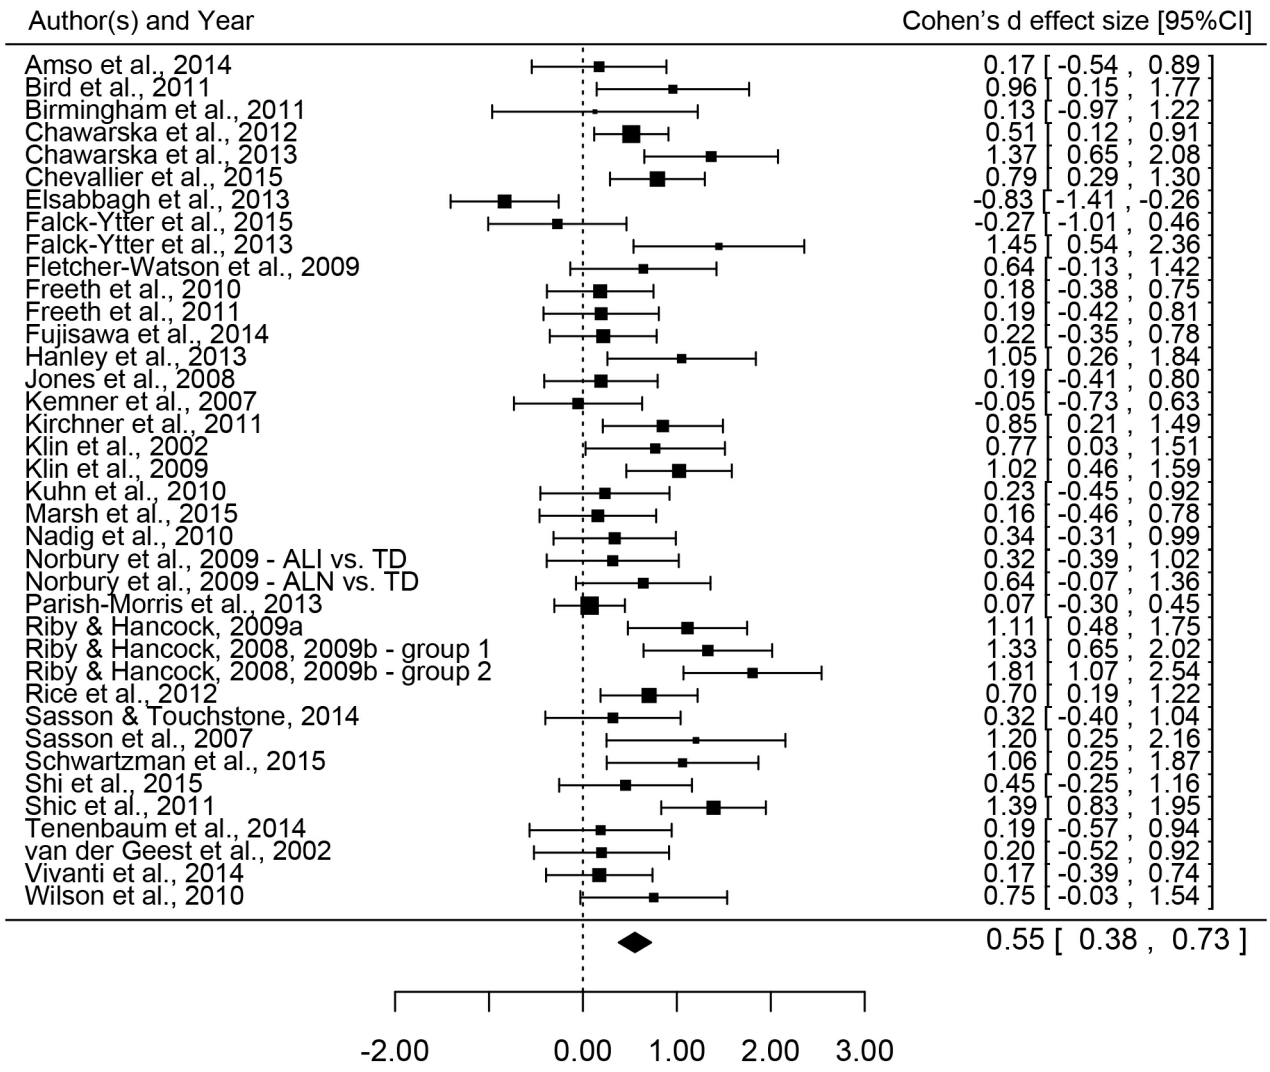
A. Clawson[1], *A. Kresse*[2], *E. J. Libsack*[2], *E. E. Neuhaus*[3], *C. M. Hudac*[4], *R. Bernier*[4], *E. H. Aylward*[2] *and S. J. J. Webb*[4], *(1)Brigham Young University, Provo, UT, (2)Seattle Children's Research Institute, Seattle, WA, (3)Seattle Children's Hospital, Seattle, WA, (4)University of Washington, Seattle, WA*

Background: Autism spectrum disorder (ASD) is a heterogeneous neurodevelopmental disorder more common in males than females. It is unclear to what extent impaired social processing in ASD differentially affects females relative to males. One way to examine the impact of social processing on behavior is through implicit learning in social and nonsocial contexts. Previous research suggests that youth with ASD display impaired implicit learning, suggesting poor behavioral control. No research has examined sex differences in implicit learning in ASD. Given that females with ASD may display reduced modulation to social information and experience greater functional impairment than males, females may display reduced implicit learning within social contexts.
Objectives: We examined sex differences in behavior (error rates, reaction times [RTs]) during an implicit learning task with social (emotive faces) or nonsocial (symbols) performance feedback. First, we examined implicit learning across trials and hypothesized that neurotypical controls would display increased accuracy and RT over time, while youth with ASD would not display behavioral modification across trials. We expected that females with ASD would display significantly reduced behavioral modification relative to males with ASD. Second, we examined the influence of feedback type on implicit learning. We hypothesized that females with ASD, but not males, would display reduced behavioral modification in response to social feedback relative to nonsocial feedback.
Methods: We collected data from 49 youth with ASD (21 female) and 32 neurotypical controls (15 female) ages 6-17. Behavioral data were collapsed into three blocks to examine learning across the task. Error rates and RTs were examined using Group (ASD, Control) x Sex (Female, Male) x Block (1^{st}, 2^{nd}, 3^{rd}) x Feedback (Social, Non-social) repeated measures ANOVAs.
Results: For error rates, the main effect of block was significant (F=7.3, p=.001), demonstrating expected increases in accuracy from Blocks 1-3. Main effects of Feedback, Group, and Sex were not significant (Fs<.94, ps>.34). The Block x Feedback x Group interaction was significant (F=6.03, p=.004). Youth with ASD displayed fewer errors for social than nonsocial feedback in Blocks 1-2, but more errors for social feedback in Block 3. Control youth displayed the opposite pattern, with more errors for social than nonsocial feedback in Blocks 1-2, but fewer errors for social feedback in Block 3. No other interactions were significant (Fs<2.6, ps>.08). For RTs, the main effect of block was significant (F=6.0, p=.004), with increasingly faster responses from the Blocks 1-2. Main effects of Feedback, Group, and Sex were not significant (Fs<.71, ps>.40) and no interactions were significant (Fs<2.92, ps>.06).
Conclusions: Youth with ASD and control youth displayed fewer errors and decreased RTs from the first to third block of the task, indicating intact implicit learning. Contrary to predictions, no Group or Sex differences in implicit learning were observed. However, when considering feedback type, youth with ASD made fewer errors to social feedback early in the task and more errors to nonsocial feedback late in the task than controls, possibly suggesting diminished sensitivity to social feedback. Differential implicit social learning in ASD may contribute to deficits in social processing.

37 **122.037** Social Attention in ASD: A Review and Meta-Analysis of Eye-Tracking Studies

M. Chita-Tegmark, *Boston University, Winchester, MA*

Background:
Determining whether social attention is reduced in Autism Spectrum Disorder (ASD) and what factors influence social attention is important to our theoretical understanding of developmental trajectories of ASD and to designing targeted interventions for ASD. Eye-tracking technology has facilitated research of social attention and results from experimental studies correlate with measures of social impairment and with autism symptom severity (Bird, Press, & Richardson, 2011; Chawarska, Macari, & Shic, 2012; Klin, Jones, Schultz, Vokmar & Cohen, 2002, Shic, Bradshaw, Klin, Scassellati, & Chawarska, 2011).
However, so far no consensus has been reached on whether social attention is fundamentally reduced or absent in individuals with ASD, with some studies showing significantly diminished attention to social information in ASD compared to typically developing (TD) controls (Klin et al., 2002; Kirchner, Hatri, Heekeren & Dziobek, 2011; Riby & Hancock, 2009; Riby, Hancock, Jones, Hanley, 2013; Rice, Moruchi, Jones, Klin, 2012; Shi et al., 2015; Shic, Bradshaw, Klin, Scassellati, & Chawarska, 2011), while other studies show no differences (Birmingham, Cerf & Adolphs, 2011; Freeth, Chapman, Ropar & Mitchell, 2010; Freeth, Ropar, Mitchell, Chapman, & Loher, 2011; van der Geest, Kemner, Camfferman, Verbate & van Engeland, 2002; Kemner, van der Geest, Verbaten, van Engeland, 2007; Kuhn, Kourkoulou, & Leekam, 2010; Marsh, Pearson, Ropar & Hamilton, 2015; Nadig, Lee, Singh, Bosshart & Ozonoff, 2010; Parish-Morris, Chevallier, Tonge, Letzen, Pandey & Schultz, 2013).
Objectives:
I conducted a meta-analysis examining data from 38 papers that used eye-tracking methods to compare individuals with ASD and TD controls. The goal for this meta-analysis was to search for quantitative answers to the following two questions: 1) Do individuals with ASD show overall diminished social attention? and 2) What are the factors that affect how they distribute their attention between social and non-social stimuli?
In my presentation, I will also show results from a more extensive meta-analysis project (which is currently in progress) investigating the visual processing of social stimuli and how ASD and TD controls distribute their attention differently towards the eyes, mouth, body and people's actions.
Methods:
In the meta-analyses mentioned above, I combined data from eye-tracking studies to calculate the overall effect size of the difference in social attention between individuals with ASD and TD controls. I also examined through linear meta-regression models the impact of eight factors on the difference in social attention between these two groups: age, non-verbal IQ matching, verbal IQ matching, motion, social content, ecological validity, audio input and attention bids.
Results:
Results show that individuals with ASD spend less time attending to social stimuli than typically developing (TD) controls, with a mean effect size of 0.55. Also, social attention in ASD was most impacted when stimuli had a high social content (showed more than one person).
Conclusions:
These meta-analyses provide an opportunity to survey the eye-tracking research on social attention in ASD and to outline potential future research directions, more specifically research of social attention in the context of stimuli with high social content.



38 **122.038** Social Cues Modulate Learning of Cue-Reward Association in Typically Developing Children and Adults: A Gaze-Contingent Learning Paradigm

***A. Vernetti**, T. J. Smith and A. Senju, Psychological Sciences, Birkbeck, University of London, London, United Kingdom*

Background: Attending to social signals is fundamental during social interactions, and failure to orient, attend and show preference for such signals is linked to atypical development of social cognition such as Autism. A possible mechanism underlying social orienting is the detection of the rewarding nature of social stimuli, as reward-related stimuli are shown to influence visual attention.
Objectives: To investigate the influence of associated reward on visual orienting to social and non-social stimuli in young typical developing children and adults, with the use of a novel gaze-contingent task to measure spontaneous orienting to these stimuli.
Methods: Sixty-four 3-4 year olds and sixty-four adults observed a stimulus display consisting of two peripherally presented dynamic cues and a centrally presented reward. Participants' eye movements were concurrently recorded with an eye-tracker, and the location of participant's fixation triggered the delivery of corresponding stimuli on-line. Fixation on each cue triggered a dynamic sequence of signals and subsequent delivery of a reward, which was a popular animated cartoon, or a penalty, a blank screen. Two different conditions were investigated. In a social condition, the videos of two persons were presented. An engaging person greeted and turned towards the centre of the screen while the other non-engaging person moaned and turned away from it. In a non-social condition, the videos of two dynamic spheres were presented. An engaging sphere was displaying an arrow associated with a winning jingle ("ding") and moving towards the centre of the screen while the other non-engaging sphere was displaying an arrow associated with a failing jingle ("dong") and moving away from it. Engaging cues triggered reward delivery for half the participants, and non-engaging cues for the other half of the participants.
Results: Both children and adults were able to learn the cue-reward association in all the conditions. Importantly, children learned the cue-reward association more rapidly and more efficiently in social and engaging condition than social non-engaging or non-social conditions. Similarly, adults learned the cue-reward association more rapidly and more efficiently in social and engaging condition than in social non-engaging condition. Unlike children, adults' performance did not differ between social engaging condition and in non-social conditions.
Conclusions: The results showed that the engaging nature of social cues facilitates both the speed and the efficiency of learning of cue-reward association, both in typically developing young children and in adults. It also demonstrated the utility of gaze-contingent learning paradigm to assess the role of social signal on a simulated social learning. Future research will benefit from this paradigm to study the relationship between social attention and learning in individuals with Autism.

39 **122.039** The Effect of Visual Perceptual Load on Auditory Detection Sensitivity in ASD

***J. E. Tillmann** and J. Swettenham, University College London, London, United Kingdom*

Background: According to the increased perceptual capacity account (Remington et al. 2009), individuals with ASD have an enhanced capacity for processing perceptual information. When the perceptual load of a task is high, capacity is exhausted in neurotypical controls and task-irrelevant stimuli are not processed. In contrast, individuals with ASD have spare capacity automatically processing task-irrelevant stimuli under conditions of high perceptual load. This has been demonstrated in the visual domain with studies measuring response competition effects (Remington et al, 2009), detection sensitivity (Remington, Swettenham & Lavie, 2012) and rates of inattentional

blindness (Swettenham et al. 2014). Recently, we have also demonstrated that increased perceptual capacity in ASD operates across sensory modalities. Increasing the perceptual load of a visual search task reduces awareness of an *unexpected* auditory stimulus to a lesser extent in children with ASD than in typically developing (TD) children (Tillmann et al. 2015).
Objectives: The current study investigated whether increasing the perceptual load in a visual search task has less of an effect on detection sensitivity for an *expected* (present on 50% of trials) auditory stimulus in ASD compared to TD individuals. Our previous study used an inattentional deafness paradigm, which involves awareness of a single, unexpectedly presented auditory stimulus, and a manipulation of perceptual load by altering the subtlety of a line discrimination task (Tillmann et al. 2015). Here we used a different measure of perceptual load (increasing visual search set-size) and asked participants to indicate the presence/absence of a tone on each trial, allowing us to measure detection sensitivity.
Methods: 20 TD adolescents and 19 adolescents with ASD matched for chronological age and non-verbal ability performed a visual search task (responding to target letter X or N in a search array) while simultaneously detecting presence/absence of an auditory tone embedded in noise (see Figure 1). Perceptual load was manipulated by increasing the number of additional visual stimuli in the search display (i.e. increasing the search set size). The intensity level of the auditory stimulus was just above each individual's pre-established auditory perceptual threshold, thus controlling for individual differences in perceptual sensitivity.
Results: When the perceptual load of the visual task was low (one or two items in the central search array), detection sensitivity for the auditory stimulus did not differ between groups. However, when the perceptual load was higher (four items in the search array) auditory detection sensitivity was significantly reduced in TD individuals compared to individuals with ASD, who maintained a high level of detection. At even higher levels of perceptual load, there was no difference in detection sensitivity between groups (see Figure 2).
Conclusions: The finding that auditory detection sensitivity in the ASD group was less affected by increasing the perceptual load of the visual task provides further support for the hypothesis that individuals with ASD have an increased perceptual capacity. We have also demonstrated that increased capacity affects processing across modalities, and that these effects cannot be explained by differences in response criteria (e.g. always responding "stimulus present").

Figure 1 Example trial with an auditory tone present in noise at set size four

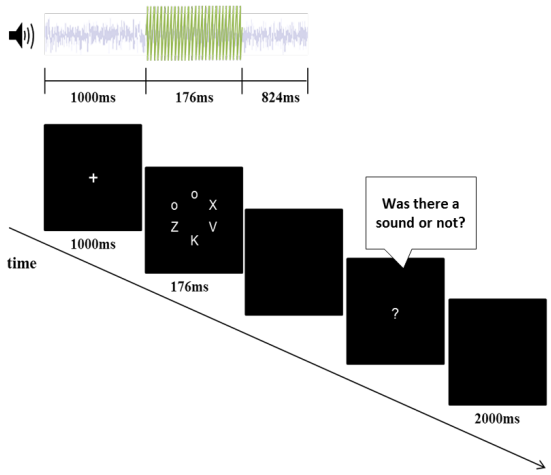


Figure 2 Detection sensitivity (d') as a function of set size and group (error bars: 95% CI)

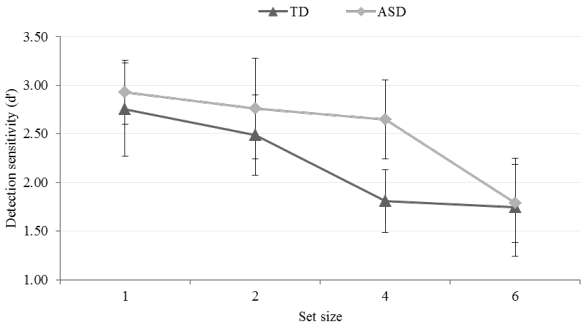

40 **122.040** The Effects on Inhibition of Cognitive Remediation Therapy in Patients with Autism Spectrum Disorder

M. Hajri[1], *Z. Abbes*[1], *H. Ben Yahia*[1], *T. Brahim*[2], *S. Halayem*[1] *and A. Bouden*[1], *(1)psychiatric hospital Razi, Tunis, Tunisia, (2)University of Monastir, Monastir, Tunisia*

Background:
Executive impairments associated with Autism spectrum disorder (ASD) are nowadays well known. Cognitive remediation is a new promising technique designed to improve the neurocognitive abilities damaged in some disorders such as schizophrenia. C
Objectives: considering the overlap between ASD and schizophrenia, we aimed in our study to apply the cognitive remediation program CRT (Cognitive Remediation Therapy) for children and adolescents with ASD and to evaluate its effectiveness on planning.
Methods:
Cross-sectional study involving children and adolescents with ASD according to DSM-5.The CRT program was conducted at the rate of one session per week of 45 minutes each. Outcome measure was inhibition assessed either by Hayling Sentence Completion Task or Colors and Animals Attention Test (CAAT).
Results:
Of the 25 patients included, 18 had reached the end of the program. Among them, 16 patients achieved the neuropsychological assessments tests after CRT, thus constituting our final sample. Their average age was 10, 87 years. The mean number of sessions performed was 22, 38. Ten patients were assessed by the means of the CAAT, and six by the means of Hayling Sentence Completion Task.
As for patients who performed Hayling Sentence Completion Task, the latency for sentences in part A was shorter after completion of CRT (32,8 seconds) than before it (38,25 seconds). As for part B, the latency was longer after CRT (41 seconds) than at baseline (35 seconds). Patients gave more correct responses after the program (14,8) than before it (10,33).
Concerning the CAAT, patients showed improvement on interference score which increased from 4.1 before CRT to 5,8 after achievement of the program.
Conclusions:
Cognitive remediation can be a promising new modality in the treatment of ASD. Further research is needed to better document its effects and the optimal conditions required for setting it up.

41 **122.041** The 'Light from Above' Prior Is Intact in Children on the Autism Spectrum

A. E. Croydon[1], *T. Karaminis*[1], *L. E. Neil*[1], *D. C. Burr*[2] *and E. Pellicano*[1], *(1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)CNR Institute of Neuroscience, University of Florence, Pisa, Italy*

Background: Sensory information entering the retina is inherently ambiguous. The brain makes sense of it by anticipating or predicting the sensory environment based on prior knowledge. Some authors have proposed that this predictive process may be atypical in autism, in that internal assumptions, or *priors,* may be under-weighted or less utilized than in typical individuals (Pellicano & Burr, 2012).
A robust internal assumption used by adults is the light-from-above prior (Sun & Perona, 1998), in which shading patterns on an object are interpreted as if the light source is located above (and slightly to the left) of an object, even when shading information is consistent with alternative light source locations.
Objectives:
We investigated whether children with autism use prior information to estimate the shape of an object, that is, whether they show the so-called 'light-from-above prior' to the same degree as typical children.
Methods: A group of autistic children (n=17) and a group of typical children (n=27), all aged 7 to 13 years, and matched in terms of age and intellectual ability, took part. Following Andrews et al. (2012), children were asked to judge the shape of a 7 hexagon stimulus – whether it appeared concave or convex. Within the context of a developmentally-appropriate game, they decided whether a bee should fill the cell with honey (if the stimulus was perceived to be concave) or not (if perceived to be convex). Twelve orientations of the hexagon stimulus were presented in a randomised order. Children completed 120 trials across 3 blocks. The testing room was lit only by the computer monitor to minimise environmental lighting cues.
Results: The relation between the proportion of convex judgements ('no' answers in our game) and stimulus orientation was estimated for each child using a multivariate logistic regression. The light source location most consistent with those judgements was then calculated for each child following the procedure in Andrews et al. (2012). Children's assumed light source direction ranged from -30.37˚ to -43.12˚. There were no significant group differences, $t(42) = -1.04$, $p = 0.30$.
Conclusions: Contrary to our expectations (cf. Pellicano & Burr, 2012), we found no significant differences in assumed light source position between autistic and typical children. Children on the autism spectrum seem to use prior assumptions to make sense of 3-dimensional information to the same degree as typically developing children. Future research should examine whether this prior is as adaptable (i.e., modifiable with training) in autistic children, as it is in typical adults (Adams, et al., 2004, 2010).

42 **122.042** Thinking Fast and Slow: Implications for the Autism Spectrum

M. Brosnan[1], *C. Ashwin*[2] *and M. Lewton*[1], *(1)University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:
Reasoning in people with Autism Spectrum Disorder (ASD) has been characterised as being slower and more effortful than controls. People with ASD show a more circumscribed reasoning bias, and often take longer to make decisions. These differences can be understood using Dual Process Theory, which proposes two major types of processes. Type 1 processing is rapid, effortless, parallel, and often involves non-conscious processing, while Type 2 processing is slower, more effortful, sequential, and often conscious in nature. It is assumed Type 1 processes are the default response during reasoning, unless intervened upon by Type 2 processes. The most widely used behavioural assessment of Type 1/Type 2 processing is the Cognitive Reflections Test (CRT), which involves answering reasoning problems that have a rapid, effortless Type 1 response which can either be provided or supressed by a subsequent slower effortful Type 2 response (or a wrong response provided). This simple task is well-suited to test reasoning styles in people with ASD and higher autism traits.
Objectives:
To present the CRT to those high and low on autism traits and those with a diagnosis of ASD using two different CRT formats: (1) a 'fast' condition which required participants to respond as quickly as possible within 20 seconds and designed to encourage Type 1 processing, and (2) a 'slow' condition which required participants to wait 20 seconds before being able to respond to the question to encourage Type 2 processing. It was expected the higher autism traits group and those diagnosed with ASD would show greater Type 2 processing compared to those lower in autism traits and controls, but that this difference in reasoning would change based on the manipulation of time.
Methods:
In Study 1, participants from a typical population (62 male, 58 female) completed an assessment of autism traits and the CRT in either the fast or slow condition. Participants were assigned to either a high or low autism traits groups using a median-split of their degree of autism traits. In Study 2, 23 (16 male, 7 female) students with a diagnosis of ASD completed the CRT in either the fast or slow condition.
Results:
In Study 1, significantly less Type 1 and more Type 2 responses were provided by the higher autism traits group compared to the lower autism traits group and in the slow condition compared to the fast condition (there was no interaction). In Study 2, again, there were significantly more Type 2 responses in the slow condition and a trend ($p<.1$) for more Type 1 responses in the fast condition.
Conclusions:
Taken together, the results showed that Type 2 processing is more dominant in those with higher autism traits, consistent with the idea that reasoning in ASD is characterised as dominated by Type 2 processing. The significant differences between the fast and slow conditions highlights that reasoning style can be manipulated based on context. Both findings are consistent with Dual Process Theory and may have implications for developing supportive environments where slow and effortful reasoning are problematic.

43 **122.043** Training Attention in Students with ASD Using a Multiple Object Tracking Paradigm: A Pilot Study

D. Tullo[1,2], *J. Guy*[3], *J. Faubert*[4] *and A. Bertone*[1,2], *(1)Educational and Counselling Psychology, McGill University, Montreal, QC, Canada, (2)Perceptual Neuroscience Laboratory for Autism & Development, Montreal, QC, Canada, (3)McGill University, Montreal, QC, Canada, (4)Université de Montréal, Montréal, QC, Canada*

Background: The ability to pay attention is a primary predictor of academic achievement (Duncan et al., 2007), while inattention is associated with problem behaviors and poor academic performance (Barriga et al., 2002). A deficiency in the subcomponents of selective and sustained attention are characteristic of atypically developing populations; specifically, in children with Autism Spectrum Disorder (ASD; Koldewyn, et al., 2013). Consequently, several cognitive-based training approaches have been developed to reduce problems of attention by targeting the subcomponent processes (Sonuga-Barke et al., 2014). Cognitive training is commonly achieved through implicit practice via repeated performance on tasks (Willis & Schaie, 2009). Here, we used Multiple Object Tracking (MOT) paradigm as a method of cognitive training. The reasons for this are threefold: first, MOT is considered to be the best empirical measure of object-based visual attention (Scholl, 2009); second, it is non-verbal in nature; and third, it is accessible to children of different ages and levels of cognitive functioning.
Objectives: We aimed to assess the efficacy of a training program using a MOT paradigm in adolescents with ASD. We asked the following questions: (i) will the performance of participants with ASD improve significantly with training, and (ii) will increased performance on the MOT paradigm transfer to another test of attention (i.e., *near-transfer*; Redick et al., 2014)?
Methods: Nine high-school students diagnosed with ASD (aged 12-17), and 15 students diagnosed with a neurodevelopmental condition other than ASD (learning disorder) were pre-assessed on the Wechsler Abbreviated Scale of Intelligence (WASI-II) and the Conners Continuous Performance Task (CPT-3). An experimental group (ASD: n = 6 & non-ASD: n = 6) received the MOT cognitive training program, while an active control group (ASD: n = 4 & non-ASD = 8) was trained on *2048* (a puzzle-like, math game). Both groups trained three times a week, over a period of five weeks, for a total of fifteen MOT or *2048* training sessions. Performance on the MOT task was defined as the average speed at which the participant could track three of eight target items. Post-training performance on the CPT-3 was compared to pre-training scores to measure an effect of transfer; groups switched training tasks and followed the same routine and post-test schedules.
Results: MOT performance doubled from the first to the last (fifteenth) training session for both the ASD and non-ASD group. This increase was similar to that found in typically-developing adolescents (Tullo et al., 2015). Preliminary analyses revealed that the improvement on the MOT task did not transfer to the CPT-3 task; this was not surprising given our small group size.
Conclusions: Results demonstrate that our MOT training is accessible to adolescents with ASD of different ages and levels of cognitive functioning. Our findings illustrate that adolescents with ASD are able to train attention on a non-verbal task similarly to those without ASD and typically-developing adolescents. We are presently analyzing whether the outcome measure of attention, and verbal- and non-verbal cognitive functioning of the participants with ASD is related to the effect of near transfer.

44 **122.044** Verbal and Spatial Working Memories in Children with High-Functioning Autism Spectrum Disorder, and Their Relationships with Symptom Severity and Adaptive Function

Y. A. Lin[1] *and C. H. Chiang*[2], *(1)National Chengchi University, Taipei City, Taiwan, (2)National Chengchi University, Taipei, Taiwan (Province of China)*

Background: Whether children with autism spectrum disorder present a deficit in working memory, a component of Executive Function (EF), remains controversial in past literatures. In Baddeley's model (1986), working memory is depicted as two slave systems, the phonological loop and the visuospatial sketchpad, under a central executive system. Recently, Williams et al. (2005) reported spatial working memory (SWM) impairment in 8- to16-year-olds with high-functioning autism spectrum disorder (HFASD); while their verbal working memory (VWM) was found unaffected. The present study further examines if similar patterns also exist in younger children with HFASD, and if psychopathology of ASD is associated with the patterns of working memory.
Objectives: We aim to (1) examine the verbal and spatial working memories in young children with HFASD, to (2) explore working memory challenges encountered in their daily activities, and to (3) examine the correlation between the performance of two working memories and symptom severity.
Methods: We recruited 30 children aged 7–10 years with HFASD, and 27 control participants (TD) with matched Age, Verbal, Performance, and Full Scale IQ. Diagnosis was verified with ADI-R and ADOS. All HFASD children met diagnostic criteria for ASD in DSM-5. The VWM was measured by Digital Symbol subtest (including forward and backward digit span) from WISC-III, and SWM was measured by Spatial Memory subtest from Leiter-R. The BRIEF (Behavior Rating Inventory of Executive Functions) was completed by parents for daily life executive performance of their children. Parents were also interviewed by using the VABS-II (Vineland Adaptive Behavior Scales, 2nd Edition) to assess the adaptive function of their children.
Results: The results showed that HFASD shows statistically significant scores in all subscales of BRIEF compared to TD. The most salient disparity was found in working memory subscale ($F(1,55) = 41.512$, $p = .000$). Moreover, we found a significant difference between the HFASD and TD in SWM, whereas HFASD performed poorly ($F(1,55) = 7.628$, $p = .008$) compared to TD. Nevertheless, no difference was found in forward- or backward-VWM. A strong correlation between SWM and backward-VWM was found ($r = .652$, $p < .000$). Although no correlation was found in working memories and autistic symptom severity, we found HFASD with higher performance on SWM had better performance IQ ($F(1,28) = 6.230$, $p = .019$) as well as higher socialization domain in adaptive function ($F(1,28) = 4.860$, $p = .036$).
Conclusions: The present study suggests parents' reports of working memory deficit in their autistic children was the most challenging issue among all other EF components, which is different from past studies. When IQ and age is matched, children with HFASD show only spatial working memory deficit. It indicates a dissociation between verbal and spatial working memory in HFASD, supporting the conclusion made by Williams et al. (2005). Although the deficit may not be explained by the psychopathology in ASD, it is associated with decreased socialization domain in adaptive function. Possible influencing factors and the implications for intervention to the spatial working memory in HFASD children are also discussed in details.

45 **122.045** Working Memory and Emotional Processing Related to Autistic Behaviors

S. Taylor[1], *C. Dickter*[2] *and J. Burk*[2], *(1)College of William and Mary, Glen Allen, VA, (2)College of William & Mary, Williamsburg, VA*

Background:
Autism Spectrum Disorder (ASD) is a developmental disorder characterized by deficits in communication, social, and motor skills (CDC, 2013). Research has demonstrated that individuals with Autism Spectrum Disorder (ASD) have working memory deficits that affect both short-term storage of information and application of that information

(Baddeley, 1992).
Objectives:
This study aimed to examine if the working memory deficit that has been identified among a clinically diagnosed ASD population is also present in a neurotypical, non-diagnosed population that displays either a small number or large number of autistic behaviors. The study also examined whether adding an emotional component to a working memory task affects participants' performance.
Methods:
A non-clinically diagnosed sample consisting of college student participants with a high number (n = 42) or a low number (n = 43) of autistic behaviors, as measured by the Autism Quotient (AQ; Baron-Cohen et al., 2001), was used. Working memory was tested using different forms of the standard n-back task. The standard n-back task presents a series of letters and requires the participant to indicate if the letter shown matches a letter previously presented (Koshino et al., 2005). In the current study, there were three conditions in which participants press a key if the letter matches the one presented first (0-back) in the series, was the one before it (1-back), or was two before it (2-back). In addition to administering this task, we created a modified n-back task that presented a series of faces expressing emotions as stimuli instead of letters, allowing us to examine the interaction between emotion processing and working memory.
Results: There were no main effects or interactions on the letter n-back tasks. On the emotion n-back task, the reaction times (RTs) of participants with fewer autistic behaviors specific to the attention to detail subscale did not significantly vary based on which emotion was being displayed, while the RTs for participants higher on this subscale varied based on emotion; $F(3, 25) = 3.17$, $p = .04$. As can be seen in Figure 1, participants high on the AQ attention to detail subscale were significantly slower when a fearful face was shown compared to either a happy, $t(29) = 2.96$, $p = .01$, or angry face, $t(30) = 2.37$, $p = .03$.
Conclusions:
As most studies examining ASD and memory use children or adolescents and compare neurotypical and autistic subjects, the comparison of neurotypical, college-aged participants with varying levels of autistic behaviors sets this study apart from previous work. This study revealed that performance on the letter working memory task was not affected by the level of autistic behaviors, while performance on the working memory task using emotion stimuli was impaired in those with a higher level of autistic behaviors. This finding supports the idea that autistic behaviors are on a spectrum and that they can affect working memory in nondiagnosed populations.

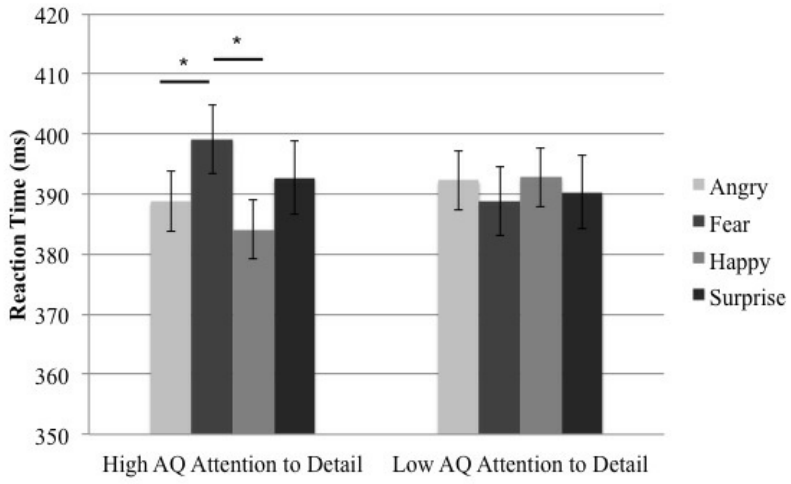

Figure 1. Reaction Time as a Function of Autistic Behaviors related to Attention to Detail and Emotion

46 **123.046** A Machine Learning-Based Approach to Detecting Autism Spectrum Disorder from Unstructured and Semi-Structured Medical Records

T. Smith[1], *J. Yuan*[2] *and J. Luo*[2], *(1)601 Elmwood Ave, Box 671, University of Rochester Medical Center, Rochester, NY, (2)Computer Science, University of Rochester, Rochester, NY*

Background:
Currently, no laboratory test for ASD exists, and the process of diagnosing the disorder is highly complex and labor intensive, requiring extensive expertise. As a result, few centers offer ASD diagnostic evaluations, and these centers have lengthy waiting lists.
Objectives:
We tested the feasibility and potential utility of a novel method for identifying children who may have ASD: natural language processing (NLP) with machine learning. This method involves developing computer algorithms to process and understand human communication. Specifically, we sought (1) to extract unstructured and semi-structured information from medical records and (2) to create an algorithm that analyzes records obtained prior to the initial diagnostic evaluation and accurately predicts which children do or do not receive an ASD diagnosis when evaluated by an expert clinician.
Methods:
We examined medical records from 199 children, age 2-5 years (56 who were later diagnosed with ASD, 143 with other developmental concerns). The records included (1) the referral form from the primary care physician, (2) intake questionnaires completed by the child's parent and teacher, (3) school reports (when available), and (4) phone intakes by clinic social workers. Diagnosis was ascertained from the clinician's evaluation report. Medical forms were saved on a HIPAA-compliant server, de-skewed (rotated to a right angle), and de-identified (automatically blanking areas containing personal information). Optical character recognition software was then used to extract hand-written and typed information from records. The following models were used to identify lexical features in the records: (1) Bag-of-Words (BoW, occurrence of a word in a document), (2) N-Gram (occurrence of a phrase in a document), (3) Term Frequency-Inverse Document Frequency (Tf-idf, a statistical measure used to evaluate how important a word is to a document), (4) Latent Dirichlet Allocation (LDA, a measure of the probability that a word occurs within a topic), and (5) Distributed Representation (Doc2Vec, a measure of meaning that is represented by a pattern of activity across multiple sources). Finally, using lexical features obtained from records, we employed support vector machine algorithms to classify each child as possibly having ASD or not.
Results:
We successfully extracted information and identified lexical features from all medical records. With 150 lexical features, accuracy of classification was 66.3% for BoW, 67.8% for N-Gram, 66.8% for Tf-Idf, 78.4% for LDA, and 83.4% for Doc2Vec. Positive predictive value was 40.4% for BoW, 43.1% for N-Gram, 41.4% for Td-Idf, 58.0% for LDA, and 64.6% for Doc2Vec. Sensitivity was 41.1% for BoW, 44.6% for N-Gram, 42.9% for Tf-Idf, 83.9% for LDA, and 91.1% for Doc2Vec.
Conclusions:
This study demonstrates the feasibility of extracting information and identifying lexical features from unstructured and semi-structured medical records. The most successful classification system, based on Doc2Vec, showed promising levels of accuracy, positive predictive value, and sensitivity. Analyses that involve a larger dataset are needed to improve the classification rate. With further development, the proposed framework could simplify and shorten the process of diagnosing ASD.

47 **123.047** ADOS Diagnostic Utility in Children with Low Mental Age

L. E. Miller[1], *C. Cordeaux*[1] *and D. A. Fein*[2], *(1)University of Connecticut, Storrs, CT, (2)Psychology, University of Connecticut, Storrs, CT*

Background: Many individuals with autism spectrum disorders (ASDs) have comorbid intellectual impairment, with some children presenting with low mental age (LMA), defined here as cognitive functioning at or below a 12-month level. However, few diagnostic tools are recommended for use in children below age 12 months, with the utility

of using common tools in diagnosing ASD in children with concurrent LMA not yet demonstrated.
Objectives: This study aims to assess the accuracy of a common diagnostic tool, the Autism Diagnostic Observation Schedule (ADOS), in diagnosing ASDs in toddlers with comorbid LMA.
Methods: Participants were drawn from a larger study on the early detection of ASDs, in which they received a developmental evaluation at the approximate age of two years. Cognitive level and autism symptomatology were assessed by the Mullen Scales of Early Learning (MSEL) and ADOS, respectively. Diagnoses were assigned according to DSM-IV-TR criteria, using clinical best estimate judgment of symptoms based on observation, history, and testing. ASD-LMA was given as a research diagnosis to children meeting criteria for Autistic Disorder (AD) or Pervasive Developmental Disorder, Not Otherwise Specified (PDD-NOS) who also demonstrated age-equivalent scores ≤ 12 months in MSEL Visual Reception, Expressive Language, and Receptive Language domains. The current study used Chi square tests to determine level of agreement between ADOS classification (i.e., Autism/AD, Autism Spectrum/PDD-NOS, Non-Spectrum) and clinical best estimate DSM-IV-TR diagnosis (i.e., AD, PDD-NOS) in children with ASD-LMA.
Results: 43 children (33 males; mean age 24.9 ± 4.45 months) were evaluated and diagnosed with ASD-LMA. 43 age-, gender-, and ethnicity-matched children meeting criteria for an ASD without concurrent LMA served as comparison. Independent-samples *t*-tests revealed significant group differences on all MSEL domains (all p's < .001), with the ASD-LMA group showing greater impairment as expected. Groups did not significantly differ on ADOS severity (p = .162). Agreement between ADOS classification and DSM-IV-TR diagnosis was slight but non-significant in the ASD-LMA group ($X^2(1) = 2.030$, p = .154, Cohen's kappa = .154). In the ASD-LMA group, the ADOS correctly classified all children as having an ASD but over-estimated severity level in 25.6% of children. 93.0% of children were classified by the ADOS as having AD, resulting in a non-significant Chi square. By comparison, agreement in the ASD group was significant, likely related to a greater spread in ADOS scores ($X^2(2) = 14.353$, p = .001, Cohen's kappa = .372). However, the ADOS misclassified 16.3% of children as not having an ASD. Overall, both groups showed similar percent agreement (ASD-LMA group = 72.1%, ASD group = 67.4%).
Conclusions: This study was designed to determine the utility of a commonly-used assessment tool (i.e., ADOS) in diagnosing ASDs in children with comorbid LMA. Overall, results support the use of the ADOS in children with LMA. However, since it appears to over-estimate symptom severity, the ADOS may not be useful in distinguishing between AD and PDD-NOS in children with LMA, especially when used at age two years. Thus, it is important to use testing data in combination with clinical best estimate judgment.

48 **123.048** Adaptive Behavior Profiles in Girls with Autism: A Comparison to Previously Published Profiles in Boys

C. A. Saulnier[1], *K. Koenig*[2], *B. Naqvi*[3], *J. M. Moriuchi*[4] *and A. Klin*[5], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Yale Child Study Center, New Haven, CT, (3)New York University, New York, NY, (4)Psychology, Emory University, Atlanta, GA, (5)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background:
The vast majority of research on adaptive behavior profiles in individuals with autism spectrum disorders (ASD) has been conducted on boys. Studies using the *Vineland Adaptive Behavior Scales* have shown Socialization skills to be most impaired, followed by Communication and then Daily Living Skills (Bolte & Poustka, 2002; Carter et al., 1998). In boys with ASD without cognitive impairment, adaptive skills tend to fall substantially below both IQ and age, with age being negatively correlated with adaptive behavior, suggesting a widening gap with age (Klin et al., 2007; Kanne et al., 2010).
Objectives:
This study compares a sample of girls with ASD evaluated at the Yale Child Study Center with a sample of boys of the same age range evaluated at Yale and published by Klin et al. in 2007. In the Klin study, 84 boys ages 8 to 18 years (Mean=12.4) of average intelligence (FSIQ=99.8; VIQ=104.7; NVIQ=94.5) exhibited significant adaptive deficits, with their Socialization Standard Scores on the Vineland falling more than 3 standard deviations below chronological and mental age (Mean=52.0). Age was negatively correlated with adaptive functioning, with older boys exhibiting a greater gap between cognition and adaptive behavior than younger boys. With the current study, our aim is to examine if girls with ASD exhibit similar profiles.
Methods:
Participants included 48 girls with ASD that received diagnostic evaluations through the Yale Developmental Disabilities Clinic. The sample was restricted to girls between the ages of 8 and18 years to match the Klin et al. sample (Mean Age=11.47; SD=2.63). IQ measures included the *Differential Ability Scales, Second Edition* and a combination of the Wechsler Scales for children for adults. The *Vineland Adaptive Behavior Scales, Expanded Form*was used to assess adaptive behavior. Similar to the boys in the 2007 paper, girls evidenced stronger Verbal IQ scores than Nonverbal (VIQ=94.76, SD=27.83; NVIQ=83.57, SD=23.95), with a Full Scale Mean of 85.94 (SD=25.25).
Results:
Results revealed significant delays in all adaptive areas with the following Vineland Mean Standard Scores: Communication=64.77 (SD=22.59); Daily Living Skills=53.02 (SD=21.66); and Socialization=56.65 (SD=15.0). Age Equivalent (AE) scores for Socialization were lowest, with a Mean Interpersonal AE=3.73 years (SD=2.25) – quite similar to the sample of boys in 2007 (Mean AE=3.2, SD=1.6). Pearson correlations indicated that Nonverbal IQ was related to more areas of adaptive functioning (Comm r=.56, p<.01; DLS r=.48, p<.01; Soc r=.34, p<.05) than Verbal IQ (Comm r=.62, p<.01). Age was negatively correlated with adaptive Socialization skills (r= -0.31, p<.05), consistent with results in boys.
Conclusions:
Results highlight the similarities in adaptive behavior profiles in girls compared to well-established profiles in boys. Though current studies are questioning if diagnostic profiles of girls could be qualitatively different than those in boys, our findings suggest that perhaps differences in symptomatology could be independent from more consistent cognitive and adaptive profiles. The substantial gap between cognition and adaptive functioning is similarly striking, as is the significant correlation between age and socialization skills suggesting that this gap widens with age. Implications for informing intervention will be discussed.

49 **123.049** An Examination of Cognitive and Adaptive Trends in Children with Autism Spectrum Disorder; A Comparison of Girls and Boys

A. Platner[1], *K. M. Stiles*[2], *N. Bhuiyan*[1], *C. Deguire*[2,3], *S. E. Gillespie*[1] *and S. Hoffenberg*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center and Children's Healthcare of Atlanta, Atlanta, GA, (3)Georgia School of Professional Psychology, Argosy University, Sandy Springs, GA*

Background: Despite the difference in prevalence of girls and boys with ASD, little research has investigated variations in developmental patterns between genders (Halladay et al., 2015). Whereas earlier research demonstrated significant gender discrepancies in developmental profiles for children with ASD, more current literature suggests comparable developmental profiles between girls and boys, although these findings lack consensus (Zwaigenbaum et al., 2012). Better understanding of gender differences will result in improved methods of detection and treatment.
Objectives: This study seeks to compare the developmental and adaptive profiles of girls and boys with ASD.
Methods: All children had a confirmed ASD diagnosis and were seen at an autism center, which serves a diverse geographic and socioeconomic population. Assessments included: (1) parent interview (2) assessment of cognitive/developmental abilities using the Mullen Scales of Early Learning or Differential Abilities Scales-2nd Edition, (3) adaptive assessment using the Vineland Adaptive Behavior Scales, 2nd Edition, Survey Interview, and (4) ASD assessment using the Autism Diagnostic Observation Schedule. Expressive and receptive language scores on the Mullen were averaged to obtain an overall verbal score. Developmental/cognitive scores were converted to z-scores to compare group means. Subsequently, a verbal domain (VD) was created by combining Mullen overall verbal scores and DAS-II verbal scores. Similarly, Mullen visual reception and DAS-II nonverbal scores were merged to create a nonverbal domain (NVD). Differences in measure values between the genders were considered for the raw values and after adjusting for age via general linear regression.
Results: Participants included 204 (49 female and 155 male) children between the ages of 21 and 151 months, with girls and boys having comparable mean ages, 49.3 (SD 20.4) and 51 (SD 21.7) months, respectively. Groups were similar with regard to race and ethnicity. There were no differences between genders on the Vineland-II domain or subdomain scores, with the exception of Domestic DLS which was higher in girls when adjusted for age (14.4 (SE 5.9) versus 11.3 (SE 5.0), p= 0.048). Moreover, there were no significant differences between genders on the DAS-II GCA, Verbal, and Spatial domains; however, boys scored significantly higher than girls on the DAS Non-Verbal domain after adjusting for age (83.4 (SE 40.2) versus 70.2 (SE 31.2); p=0.012). There were no significant differences between genders on the Mullen. When DAS-II and Mullen scores were taken together for both genders, there were no significant differences between overall IQ scores or the verbal/language scores. However, similar to the DAS-II data, boys scored higher than girls on the NVD (Z-Score:-1.9 (SD 1.4) versus -2.3 (SD 0.9); p=0.016).
Conclusions: This study supports the current literature suggesting that there are few differences in adaptive profiles between girls and boys with ASD. However, results of this study indicate that boys' nonverbal abilities were significantly better than girls. These findings highlight the importance of understanding diagnostic profiles of girls and boys with ASD in order to create the most beneficial treatment plan and intervention for each child. Further research should examine a larger sample size as well as children across different ages and developmental levels.

50 **123.050** An Investigation of the 'Female Camouflage Effect' in Autism Using a New Computerized Test Showing Sex/Gender Differences during ADOS-2

A. Rynkiewicz[1,2], *B. Schuller*[3,4,5], *E. Marchi*[3], *S. Piana*[6], *A. Camurri*[6], *A. Lassalle*[7] *and S. Baron-Cohen*[7], *(1)Department of Psychiatry, Medical University of Gdansk, Gdansk, Poland, (2)Centrum Diagnozy, Terapii i Edukacji SPECTRUM ASC-MED, Gdansk, Poland, (3)Machine Intelligence & Signal Processing Group, Technische Universität München, Munich, Germany, (4)Department of Computing, Imperial College London, London, United Kingdom, (5)Chair of Complex & Intelligent Systems,*

University of Passau, Passau, Germany, (6)Casa Paganini-InfoMus Research Centre DIBRIS, University of Genoa, Genoa, Italy, (7)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom

Background: Autism is diagnosed more frequently in males than in females. Females with autism may have been under-identified due to a male-biased understanding of autism but also females' camouflaging. This study presents an innovative computerized technique to objectively evaluate the nonverbal modality of communication (gestures) during two demonstration tasks of *ADOS-2*. We describe a new technique allowing automated coding of non-verbal mode of communication (gestures) and offering the possibility of objective, evaluation of gestures, independently of human judgment. This technique was used during two demonstration activities of *ADOS-2* (Autism Diagnostic Observation Schedule, Second Edition) and automatically measured participants' gestures, allowing computation of a *"Gestures Index"* (GI). This GI was compared between males and females with autism.
Objectives: To test if females with autism have a higher GI compared to males with autism.
Methods: High-functioning Polish girls (n=16) and boys (n=17) with autism or Asperger syndrome, aged 5-10, with an IQ average or above, and with fluent speech were assessed during two demonstration activities of Module 3 of *ADOS-2*, administered in Polish, coded using Polish codes. Children were also assessed with Polish versions of the *Reading the Mind in the Eyes* and *Faces Tests*. Parents provided information on the author-reviewed Polish research translation of *SCQ* (Social Communication Questionnaire, Current and Lifetime) and Polish version of *AQ* (Autism Spectrum Quotient, Child).
Results: Girls with autism had a higher GI than boys with autism during two demonstration activities of *ADOS-2*. Girls with autism made significantly more mistakes than boys with autism on the *Faces Test*. Current communication skills as reported by parents on the *SCQ* were significantly better in boys with autism than in girls. Both girls and boys with autism had improved in their social and communication abilities during their life. The number of stereotypic behaviours only significantly diminished in boys but not girls during their life.
Conclusions: Girls and boys with autism differ on the non-verbal communication dimension. The automatic analysis of their gestures shows that girls with autism present longer and faster gestures. Girls present longer gestures in shorter time. The study raises questions about parent-report screening measures such as the *SCQ*. As parents are not supervised when completing the *SCQ*, it is unclear whether they take into consideration non-verbal communication (gestures) when they judge their children's communication skills, or only their verbal communication. The results of the present study contribute to further understanding of the under-diagnosis of autism in girls.

51 **123.051** Applicability of the Autism Spectrum Screening Questionnaire Parent Form to 5-Year-Old Children

M. Adachi[1], *N. Takayanagi*[1], *S. Yasuda*[1], *S. Yoshida*[1], *M. Kuribayashi*[1], *A. Osato*[2], *T. Masuda*[3], *M. Tanaka*[3], *M. Saito*[2] *and K. Nakamura*[4], *(1)Research Center for Child Mental Development, Hirosaki University, Hirosaki, Japan, (2)Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (3)Faculty of Education, Hirosaki University, Hirosaki, Japan, (4)Hirosaki University Graduate School of Medicine, Aomori, Japan*

Background: The study of High-Functioning Autism Spectrum Disorder(HF-ASD) has reported that secondary maladjustment such as school refusal in school age is one of the serious problems of them. The Autism Spectrum Screening Questionnaire(ASSQ; Ehlers, Gillberg, & Wing, 1999) was developed to screen school children for HF-ASD. Although the ASSQ consists of only 27 items, it has shown both validity and reliability, with good sensitivity and specificity in clinical settings(Ehlers et al., 1999). The ASSQ could be appropriate for use as a population screening, as it short, it's easy for parents and teachers to complete. Although the ASSQ has been psychometrically tested in only 7-16-year-old children, an application for younger children than 7-year-old is also expected to make early detection of HF-ASD and prevent secondary maladjustment of them. From the clinical necessity, the ASSQ has been used in younger children than 7-year-old in clinical setting without standalization data(Kopp & Gillberg, 2011), therefore earlier application possibility of the ASSQ should be examined urgently.
Objectives: The purpose of our study was twofold: first, to study psychometric properties of the ASSQ before school age, and second, to evaluate the sensitivity, specificity, positive predict value(PPV) and negative predict value(NPV) on the ASSQ.
Methods: This study was conducted as a part of a larger study-the Hirosaki Five years check-up(HFC) study-assessing mental health among children in Hirosaki(*n*=2571). We sent ASSQ and other questionnaires to the parents of all children aged 5 in this city. The response rate was 74.6%(*n*=1919 boy=1002). In the HFC study, children were screened by multi-aspects in their difficulties; communication, behavior, motor skill, daily adaptation of children and their parent's stress. If children had showed higher score than cut-off scores in at least one screening, they were invited to additional assessments and the diagnostic interview by child psychiatrists. The children who met the DSM-5 criteria for a diagnosis of ASD were diagnosed as ASD(*n*=55, boy=35).
Results: The internal consistency for the entire ASSQ was good, with Cronbach's alpha of .853. The results of confirmatory factor analysis confirmed that the factor structure was the same for 5-year-old as it was for school-aged children(RMSEA=.050). The receiver operating characteristic(ROC) analyses were performed to assess the discriminant power of the ASSQ in distinguishing ASD from non-ASD cases, and it demonstrated favorable accuracy of identification of ASD(AUC=.91:95%CI=.85-.95). The present study suggested that using cut-off score of > 8 provided the most efficient screening with sensitivity of .85 and specificity of .90. For the cut-off of 9, PPV was .22, NPV.99.
Conclusions: The current study demonstrates the possibility that the ASSQ could identify ASD in the 5-year-old children with a certain degree of accuracy. Although NPV was excellent, showing that only few children fell below the cut-off scores, PPV was low. This problem has been also pointed out by the study of the school age(Mattila et al., 2009). Therefore, it should be emphasized that the ASSQ is a screening instrument, not a diagnostic instrument; all screening-positive children have to undergo diagnostic examinations.

52 **123.052** Are African American Girls with ASD More or Less Impaired Than Boys? It May be All about IQ

C. A. Saulnier[1], *J. Berman*[2], *G. Kneeland*[1], ***L. Pascarella***[1] *and B. Bostian*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Children's Healthcare of Atlanta, Atlanta, GA*

Background:
The field of autism has a tremendous need to better understand sex differences and the profiles of girls with autism spectrum disorders (ASD). To date, the largest phenotypic study investigating sex differences found that girls with ASD had significantly lower cognitive and adaptive skills than boys with ASD, and significantly more externalizing behaviors (Frazier, Georgiades, Bishop, & Hardan, 2014). Though there were more than 2000 individuals in the study, the sample was predominantly high functioning and roughly 75% White/non-Hispanic. Few studies have directly investigated sex differences within and across racial groups.
Objectives:
This study investigates sex differences in phenotyptic presentations in a sample of African American individuals with autism, including differences in cognition, autism symptomatology, and adaptive behavior.
Methods:
Participants included 97 African American individuals with autism (26 female and 71 male) ages 3-18 years (mean=7.78 years, SD=3.79). Measures included the *Differential Ability Scales, 2nd Edition* (DAS-II)*; the Mullen Scales of Early Learning, the Autism Diagnostic Observation Schedule, 2nd Edition* (ADOS-2)*; the Autism Diagnostic Interview, Revised* (ADI-R)*, and the Vineland Adaptive Behavior Scales, 2nd Edition, Survey Form* (Vineland-II).
Results:
Fifty-five percent of the sample had cognitive scores below 70 and 50% of mothers had a maternal education below college level. ANOVA analyses revealed no significant differences on IQ, ADOS, ADI-R, or Vineland-II scores between males and females for the full sample. However, when the sample was grouped by High IQ (IQ>70) and Low IQ (IQ<70), significant differences emerged. For the Low IQ group, there was a trend for girls having significantly lower verbal IQ scores [F(1,38)=3.32, p=.076], with a mean Verbal IQ of 36.10 (SD=9.63) compared to 45.40 (SD=15.07) for boys. Girls also had significantly lower Vineland Socialization scores (Mean=58.00, SD=6.25) than boys (Mean=65.32, SD=11.18) F(1,51)=4.66, p<.05. For the High IQ group, there were no significant differences in cognition, but girls had significantly higher Vineland Socialization score than boys (Girls Mean=75.46, SD=8.24; Boys Mean=67.00, SD=11.07) F(1,40)=6.06, p<.05. No significant differences were observed across samples in levels of autism symptomatology on the ADOS or ADI-R. However, regardless of sex, the Low IQ group had significantly higher ADOS CSS scores than the High IQ group [F(1,84)=4.35, p<.05].
Conclusions:
Results from the overall sample of African American school-aged individuals with ASD revealed no significant sex differences in cognition, autism symptomatology, or adaptive behavior. Sex differences emerged when the sample was split by cognitive level. Girls with ASD with cognitive impairment had significantly lower verbal abilities and adaptive socialization scores than boys, but girls without cognitive impairment had significantly higher adaptive socialization scores than boys – contrary to prior research. Of note, 58% of boys and 46% of girls fell into the Low IQ group, highlighting the discrepancies in percent of cognitive impairment in our African American sample compared to national estimates (e.g., CDC, 2012 prevalence of 38%). These findings suggest that cognition could play a stronger role in potential sex differences in ASD compared to, for example, symptom severity in African American individuals. Limitations and implications for further research will be discussed.

53 **123.053** Assessment Across Wide Age and Ability Ranges: Use of the Peabody Picture Vocabulary Test As a Proxy for Verbal IQ

K. Krasileva *and V. Hus Bal, Department of Psychiatry, University of California San Francisco, San Francisco, CA*

Background:
Children with Autism Spectrum Disorder (ASD) span the full range of verbal and nonverbal cognitive ability. A single study may implement multiple different cognitive instruments, including use of tests outside the standardized age range to derive estimates for children with Intellectual Disability (ID). Completing full cognitive batteries

requires significant time and expense that can be prohibitive to studies ascertaining large samples (e.g., genetic consortiums).
The Peabody Picture Vocabulary Test – 4thEdition (PPVT4) is a measure of receptive vocabulary designed for use with children and adults (Dunn & Dunn, 2007). It takes 10-15 minutes to administer and can be used as a proxy for verbal IQ in individuals who cannot complete full IQ assessments (Karns et al., 2011). Recent studies have demonstrated strong associations between PPVT4 and tests of nonverbal cognitive abilities in youth with Down Syndrome, ID or typical development (Phillips et al., 2014) and minimally verbal children with ASD (Plesa-Skwerer, 2015). No studies have yet investigated the convergent validity of the PPVT4 and other cognitive measures in children with ASD across the full range of abilities.
Objectives:
To compare the PPVT4 to measures of verbal (VIQ) and nonverbal IQ (NVIQ) in children and adolescents with ASD.
Methods:
Participants were 4-17 year-olds with ASD from the Simons Simplex Collection who completed the PPVT4 and a full cognitive battery (N=2420; 86% male). Verbal and nonverbal estimates were derived from a hierarchy of tests, most often the Differential Abilities Scale or Mullen Scales of Early Learning. Pearson correlations were calculated to examine associations between PPVT4 and VIQ and NVIQ. Children were divided by age (4-5, 6-12, 13-17), language (ADOS Module), cognitive level (VIQ<70 vs. >70; NVIQ<70 vs. >70) and test type (e.g., DAS, Mullen). Fisher r-to-z transformation was used to compare correlations across groups. PPVT4-VIQ differences were computed; differences greater than 15 points were considered discrepancies.
Results:
PPVT4:VIQ correlations were very strong (r=0.70-0.95, p<0.0001) across age, language, verbal and nonverbal abilities, and test type. The majority of children (77%) had PPVT4 scores within 15 points of their VIQ estimate. Only 4% had PPVT4<VIQ, whereas the remaining 20% had PPVT4 that exceeded VIQ by more than 15 points. A somewhat higher proportion of minimally verbal children (i.e., ADOS Module 1, 26%) had PPVT4>VIQ profiles compared to verbal children (19%, ADOS Module 2-4; X2=9.587, p=0.008). Notably, PPVT4:NVIQ correlations were also strong (r=0.80), though somewhat reduced in children with VIQ>=70 (r=0.54) compared to VIQ<70 (r=0.68, z=5.02, p<0.0001).
Conclusions:
Across children of varying ages, language and ability levels, the PPVT4 showed good convergent validity with VIQ estimates derived from multiple instruments. Further analyses are needed to understand the 20% for which the PPVT4 may overestimate verbal abilities. Nonetheless, these results suggest that the PPVT4 provides a good proxy for VIQ. This is particularly relevant for genetic studies ascertaining large samples across the full range of abilities, as using the PPVT can significantly reduce costs and allow time spent with participants to be dedicated to collection of other phenotypic measures.

Table 1
Sample descriptives and PPVT:IQ correlations by age, cognitive and language groups

	Descriptives [Mean (Std Deviation)]					Pearson *r**	
	N	Age	VIQ	NVIQ	PPVT4	PPVT:VIQ	PPVT:NVIQ
Entire Sample	2420	9.08 (3.56)	79.34 (30.23)	85.70 (25.40)	84.80 (29.03)	0.925	0.803
Age

54 **123.054** Assessment of Intellectual Functioning at Age of Diagnosis: Testability and Comparison of Available Tests

V. Courchesne[1], *C. Jacques*[2], *D. Girard*[3], *M. Descamps*[3], *L. Mottron, M.D.*[4] *and I. Soulières*[3], *(1)University of Montreal, Montreal, QC, Canada, (2)Universite du Quebec en Outaouais, Gatineau, QC, Canada, (3)University of Quebec in Montreal, Montreal, QC, Canada, (4)Centre d'Excellence en Troubles Envahissants du Développement, Montréal, QC, Canada*

Background: DSM-5 autism diagnosis now requires specifying the level of intellectual functioning. An assessment of adaptive behavior and IQ is therefore necessary at time of diagnosis. However, few IQ tests are available at this age and assessment of young autistic children bears many challenges (Akshoomoff, 2006; Rutter, 1986). In addition to this, there is a lack of studies regarding the use of IQ tests in preschool autistic children.
Objectives: To document the testability of young autistic, developmentally delayed and typically developing children. To compare the cognitive profile of these 3 groups on available IQ tests.
Methods: 40 autistic, 40 typically developing (TD) and 25 developmentally delayed (DD) children aged from 2 to 5 years old will be tested using the MSEL, Wechsler Preschool and Primary Scales of Intelligence (WPPSI-IV), Leiter-3, Raven Color Progressive Matrices (puzzle form) (RCPM). To date, 27 autistic, 27 TD and 12 DD children were assessed. Assessment sessions typically lasted 1h, but where shortened if the child could not remain attentive throughout the whole hour. We computed a testability ratio (number of tests completed/ number of assessment sessions) and registered the number of sessions necessary to complete each test. Finally, the performance on the completed tests was compared within subjects to determine the cognitive profile of each group depending on the test used.
Results: Within groups comparisons indicated that there was no significant difference between the number of sessions necessary to complete any of the tests in any of the three groups. Between group comparison indicated that tests including verbal assessment (MSEL and WPPSI-IV) required significantly more assessment sessions in autistic compared to TD children (all *p*s<.05), while it was not the case for the RCPM and Leiter-3 (all *p*s> .05). Neither Autistic nor TD group differed from DD group on this measure (all *p*s >.05). Also, the testability ratio was significantly lower in the autistic group compared to the TD group (p <.05), thus indicating that the number of tests completed by assessment session was lower in the autistic group. Other group comparisons were non-significant. Furthermore, the same ratio was significantly higher among participants who did not complete the study compared to those who did in the three groups (p<.0005). Finally, MSEL was significantly lower than Leiter-3 (p<.05) and RCPM (p<.01) in autistics, Leiter-3 was significantly lower than RCPM (p<.05) in DD and MSEL was significantly lower than RCPM (p<.05) in TD. All other tests did not differ (all *p*s>.05). Performance on the MSEL was the lowest in all groups.
Conclusions: MSEL, a test that is often used to assess intelligence level at age of diagnostic, seem to underestimate the potential of all groups. Even though non-verbal tests might increase testability and be easier to administer, assessment of young autistic children remains particularly challenging. Both the lack of knowledge about the validity of the available tests at age of early diagnosis and the difficulty to assess young autistics children leads us to question the relevance of assessing intellectual potential at such a young age.

55 **123.055** Automated Quantification of Stereotypical Motor Movements Occurring in Autism Spectrum Disorder

R. Kim[1], *Y. Kang*[2] *and H. Kim*[3], *(1)Science, Horace Mann School, Bronx, NY, (2)Peddie School, Hightstown, NJ, (3)Trinity School, New York, NY*

Background: The prevalence of autism spectrum disorder (ASD) has risen significantly in the last ten years, and today roughly 1 in 68 children have been diagnosed. Stereotypical motor movements exhibited by patients with autism—which include spinning, body-rocking, and hand-flapping—tend to alienate people and render social interaction difficult. Despite the growing number of individuals affected by autism, an effective, accurate method of automatically quantifying such movements remains unavailable.
Objectives: The focus of this research is to utilize Kinect v2, software developed by Microsoft to detect body movements, as a means of objectively and systematically tracking these movements.
Methods: The Kinect camera was used to film 12 actors, each performing the three movements. MATLAB and Visual Gesture Builder (VGB), a program that generates data on gesture detection, were used to analyze the skeletal structures in these recordings, after which the validity and reliability of the data were tested by comparing the outputs to that of manual grading.
Results: It was concluded that VGB analysis is a more accurate method of automatically quantifying the stereotypical motor movements than MATLAB.
Conclusions: Our findings suggest that Kinect is a potentially useful tool for automatically quantifying motor symptoms in patients with autism.

56 **123.056** Before Our Eyes: “Frankness” of the ASD Behavioral Presentation As a Research Construct

A. de Marchena[1] *and J. Miller*[2], *(1)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital*

of Philadelphia, Philadelphia, PA

Background:
Many individuals with ASD have a distinctive behavioral presentation that is recognizable within moments, a phenomenon we call “frankness” (i.e., frankly ASD). Clinicians have informally discussed this phenomenon for decades; however, it has never been delineated as a research construct, and thus has essentially gone unstudied. This is unfortunate, because if frankness is indeed a reliable, quantifiable behavioral phenomenon, its measurement could have both clinical and scientific utility. In the clinic, frank referrals might be triaged to expedited evaluations; in the lab, frankness could serve as a clinical correlate for basic research. Individuals with frank presentations may differ in important ways (e.g., underlying biology or response to treatment) that cannot be tested until frankness itself can be measured.
Objectives:
To survey the clinical community about frankness to develop hypotheses on how to operationalize and quantify frankness as a research construct.
Methods:
We created a 13-item frankness questionnaire. Clinicians with experience and qualifications to diagnose ASD were invited to participate; 151 eligible clinicians, from a range of disciplines (psychology, pediatrics, neurology, and psychiatry) responded. The questionnaire included demographic information about respondents, and covered several specific topics related to frankness, including familiarity with the phenomenon, estimates of the proportion of individuals with ASD who are frank and the speed at which frankness impressions are formed, and what behavioral features might be associated with frank presentations. Data were both quantitative and qualitative, so we used a mixed methods analytic approach (Creswell et al., 2011).
Results:
An overwhelming majority (97%) of clinicians who diagnose ASD were familiar with frankness. Clinicians estimated that 40% of the ASD population has a frank presentation. In general, clinicians formed these impressions quickly; 52% reported that they observe frankness within 10 minutes of patient interaction (and 74% within 20 minutes). These factors (i.e., proportion of cases deemed frank; speed of forming frankness impressions) varied with clinician experience: clinicians who had made more ASD diagnoses considered a greater proportion of cases frank, and formed their impressions more quickly, $F(2,101)=3.2$, $p=.045$. Clinicians reported on a number of specific behaviors that contribute to their impressions of frankness, including impaired reciprocity, quality of eye contact, atypical vocal prosody, presence of motor mannerisms, and atypical gait or posture, among others.
Conclusions:
Although unstudied empirically, “frank” presentations of ASD are highly familiar to diagnosing clinicians, suggesting a critical need for more research. Frank presentations appear to be based on a range of behaviors, including some that are central to the clinical characterization of ASD (e.g., impaired reciprocity), and others that are completely absent from the official symptomatology (e.g., atypical gait or posture). Clinicians report detecting frankness rapidly, especially when they have more experience diagnosing ASD, suggesting that expert clinicians may refer to an internal prototype that is refined over time. For our next steps, we plan to move beyond clinicians’ anecdotal reports, to test the hypotheses developed here (e.g., speed of frankness impressions, behaviors contributing to frankness) during real-world clinical evaluations and diagnosis.

57 **123.057** Can Primary Health Professionals' Input to Parent Reports Improve the Ability to Detect Children with ASD?

***K. Ebishima**, A. Stickley and Y. Kamio, National Center of Neurology and Psychiatry, Japan, National Institute of Mental Health, Tokyo 187-8553, Japan*

Background: Prior studies have demonstrated the effectiveness of detecting autism spectrum disorder (ASD) using parent-report questionnaires such as the M-CHAT at community-based health check-ups at age 18-24 months. However, one of the concerns about ASD screening based on parental reports is a high false negative rate.
Objectives: The aim of this study was to examine whether primary health professionals’ input to parent reports would improve the ability to detect children who are later diagnosed with ASD.
Methods: Our sample comprised 1220 children who received a 24-month health check-up that included the Japanese version of the M-CHAT (M-CHAT-JV) at a health center in Tokyo in 2008-2010. The M-CHAT-JV rating was threefold: “parent report only (M only)”, “parent report under public health nurse instruction (M+PHNi)”, and “parent report combined with PHN observation (M+PHNo)”. Diagnostic evaluation was done according to DSM-IV-TR together with ADI-R, ADOS, CARS, SRS and other developmental assessments repeatedly during age 2-5.
Results: Seventeen children were diagnosed with ASD. The number of screen-positives was 58, 34, and 55 using M only, M+PHNi, and M+PHNo, respectively. In addition to 13 children with ASD identified by M only, 2 children were newly identified by M+PHNi and 4 children by M+PHNo. A comparison between M only screen-positives (N=13) and screen-negatives (N=4) showed no significant differences in autism measurements at age 2, while M only screen-negatives scored significantly higher on the ADI-R RRB domain at age 3. M only screen-negatives tended to have higher DQs.
Conclusions: This study suggests that face-to-face instruction by public health nurses may decrease screen-positives and detect more children who were not identified by M only, while their quick behavioral observation may also help identify a greater number of children with ASD without decreasing screen-positives. Optimal ASD screening should be chosen considering a community’s resources and needs.

58 **123.058** Caregiver and Teacher Correspondence on Ratings of Problem Behaviors for Children with Autism Spectrum Disorder Receiving Community Mental Health Care

***N. Stadnick**[1,2], D. Loreaux[1,3], C. Chlebowski[1,2,4] and L. Brookman-Frazee[1,2,4], (1)Psychiatry, University of California, San Diego, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)Department of Psychiatry, Child and Adolescent Services Research Center, San Diego, CA, (4)Autism Discovery Institute at Rady Children’s Hospital – San Diego, San Diego, CA*

Background: Children with autism spectrum disorder (ASD) are served in multiple service settings (Brookman-Frazee et al., 2009), and have significant psychiatric comorbidity, particularly with disruptive behavior disorders (Simonoff et al., 2009). Multi-informant assessment of behavior problems is important to inform appropriately tailored treatment for children with ASD. Informant agreement is weak to moderate for behavior problems in children with ASD (Stratis et al., 2015). Factors shown to impact caregiver-teacher agreement broadly include educational setting and child clinical and sociodemographic characteristics (Berg-Nielsen et al., 2012; Pearson et al., 2012).
Objectives: This study: 1) examined the correspondence between the severity of caregiver and teacher ratings of problem behaviors in a sample of school-aged children with ASD receiving community mental health (MH) services, and 2) identified child characteristics associated with informant correspondence.
Methods: Data were drawn from baseline assessments of an ongoing randomized community effectiveness trial of AIM HI (“An Individualized Mental Health Intervention for ASD”), a clinical intervention targeting challenging behaviors in children with ASD conducted in community and school-based MH settings. This sample included 138 children ($M = 9.05$ years; 79% male) with existing ASD diagnoses, their primary caregivers, and teachers. Caregiver report of behavior problems was obtained using the Eyberg Child Behavior Inventory (ECBI; Eyberg & Pincus, 1999), which includes 36 items rated on a 7-point Intensity Scale that is converted into a *t*-score. Teacher report of behavior problems was obtained using the Sutter-Eyberg Student Behavior Inventory-Revised (SESBI-R; Eyberg & Pincus, 1999). Overall agreement between caregiver and teacher ECBI/SESBI-R Intensity scores was calculated first through the intraclass correlation coefficient (ICC). Intensity *t*-scores were then dichotomized into clinically significant versus non-clinically significant. Agreement was calculated using the kappa statistic followed by the McNemar test to compare the proportion of children whose problem behaviors were rated as clinically significant. Follow-up logistic regression analyses were conducted with child age, gender, ethnicity, ASD severity (as measured by the comparison score from the ADOS-2, Lord & Rutter, 2002), educational placement, and diagnostic comorbidity (as measured by an adapted MINI-KID, Sheehan et al., 1998) as predictors of agreement.
Results: Informant agreement on the severity of problem behaviors was poor, overall, as shown by the ICC of 0.16 on the ECBI/SESBI Intensity Scale. Poor agreement remained when examining clinically significant levels of problem behaviors, $\kappa = .19$, which falls below standards for fair agreement ($\kappa = 0.4$; Cohen, 1960). The proportion of caregiver ratings (62%) was significantly higher than the proportion of clinically significant teacher ratings (40%) ($p < .001$). Regression analyses indicated that older child age was associated with less agreement (OR = 0.79, $p < .05$) while greater number of non-ASD psychiatric disorders (OR = 1.31, $p < .05$) was associated with greater agreement.
Conclusions: Caregiver-teacher agreement of problem behaviors was poor in this sample of children with ASD receiving community MH services. Child age and degree of psychiatric comorbidity were associated with informant agreement of clinically significant problem behaviors. Findings have implications for optimally using multi-informant assessment to tailor MH care for children with ASD.

59 **123.059** Characteristic Features of Autism in the Nigerian Population

***T. A. Fagbayi**[1], J. E. Okpuzor[2] and A. Lesi[3], (1)University of Lagos, Lagos, Nigeria, (2)University of Lagos, Nigeria, Nigeria, (3)Department of Pediatrics, College of Medicine, University of Lagos, Lagos, Nigeria*

Background:
The African continent is yet to benefit from the advances made in autism research. This is partly due to misconception about the disorder and its aetiology and mostly due to lack of public awareness even amongst health care givers and the elite is not exonerated. Recently, in Nigeria the awareness of autism has increased tremendously especially in urban cities such as Lagos, however a lot still need to done on the proper description of the Nigerian autistic population so as to allow for tailored management.
Objectives:
The present study aims to describe the clinical presentations of individuals with autism in Nigeria.

Methods:
A content validated and researcher developed questionnaire, the Autism Phenotype Questionnaire (APQ) was designed highlighting characteristic features of autism. The APQ consists of 26 semi-structured items/questions divided into two sections. The first section comprises of questions on demographic data while the second section consists of 9 sub-categorical autistic features with a total of thirty-eight options each treated as a variable. A total of five special centers (4 private and 1 government owned) participated in the study and parents, care givers and attending therapists were the respondents of the study. All participants had been previously diagnosed with ASD using the DSM-1V (APA, 2000). Statistical analyses were done using IBM SPSS version 20.
Results:
With a Cronbach's alpha of 0.69, the APQ was deemed reliable for the study. A total of 110 dully filled questionnaire analyzed. Observed mean age was 9.14±5.92 years with an age range of 3-32 years and male: female ratio of 2.36:1. A total of 87.27% (96/110) of the cases had other unaffected siblings. The highest percentage age distribution was observed in the 5-9 years age group (50 %; mean ± SD - 6.852±1.459) this is a reflection of the late presentation to clinics of individuals with autism by their families and thus late diagnosis. Of all the associated features, sensory abnormalities (Self Stimulatory Sensory Behaviour) had the least percentage presentation (50%), followed by Self Injurius behaviour (SIB-58.2%), Sensitivities (80.9%), Tantrums (87.3%) and Self Stimulatory Motor Behaviour (89.1%). No significant difference was observed in the frequencies of reported features by gender and age-group classification with the exception of sensory impairment ($F = 4.264$. $df = 1$ $p = 0.039$) between gender.
Conclusions:
The late age of diagnosis of autism in Nigeria and other African countries could be as a result of the late help-seeking nature of affected families often due to societal stigmatization. We propose that the APQ can be utilized as a screening tool for autism in Nigeria as it is suitable for the average age of clinical presentation.

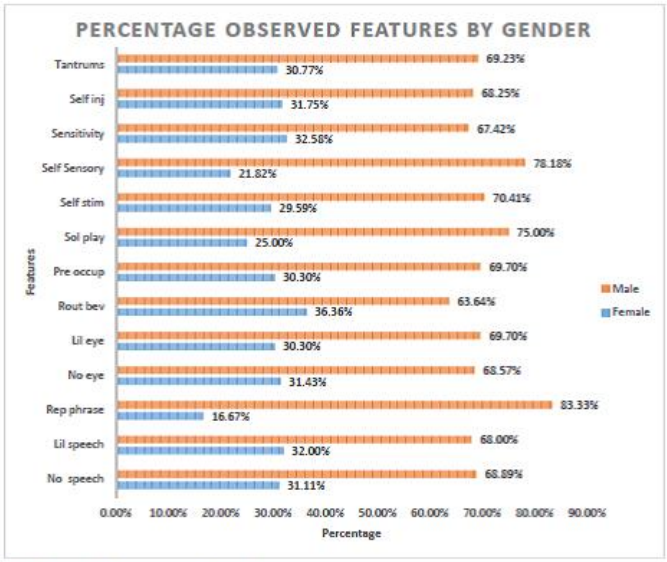

Table: Overall Percentage of Each Sub-category.

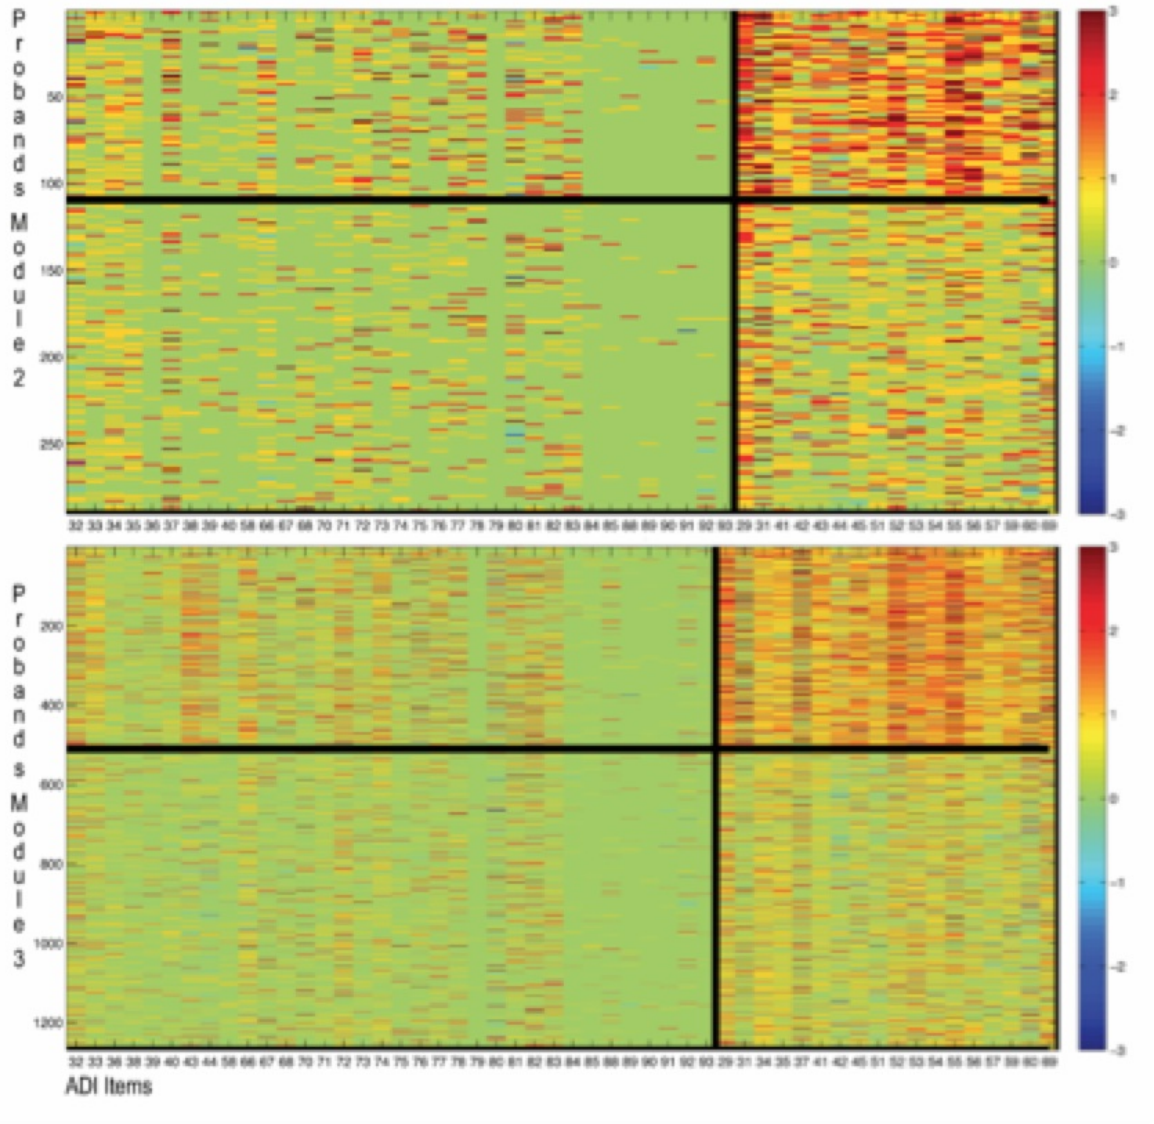
Section	Overall Percentage (%)
Speech	98.2
Eye Contact	91.8
Restricted Interest & Behaviour	93.6
Self Stimulatory Motor Behaviour	89.1
Self Stimulatory Sensory Behaviour	50.0
Sensitivities	80.9
Self Injurious Behaviour	58.2
Tantrums	87.3
Other Features	70.9

60 **123.060** Clinical Implications of the ADI As a Measure of Development in Children with ASD

***N. Navot**, S. J. J. Webb and R. Bernier, University of Washington, Seattle, WA*

Background:
Predicting future Autism Spectrum Disorder symptom level and developmental trajectory, is a primary goal for facilitating service development and supporting families. However, the heterogeneity within ASD and resulting prognostic opacity creates difficulties for clinicians seeking to provide quality information. Published longitudinal studies suggest several developmental trajectories of improving/worsening in symptom level. The Autism Diagnostic Interview was designed to provide a framework for collecting both the developmental history and current functioning within a diagnostic framework. Although not designed to examine symptom change over time, analyses with the ADI collected at one time point in large samples may illuminate changes in symptom presentation.
Objectives:
We describe autism symptom trajectories derived from individual item ADI-R data among 1629 verbal Simons Simplex Collection (SSC) children from age 6 to 16 years. Focusing on differences between current and 4-5 year functioning, we used cluster analytic approaches to grouping symptoms according to their change over time and compared the different clusters among participants with different levels of language.
Methods:
Data were obtained from the SSC. Only verbal participants that received ADOS Module 3 and Module 2 were included. Data were first analyzed for baseline age differences. For each item, current value as function of age at time of interview was plotted. Second, we created a *difference score (DS)* at the item level. For each item, the past score (PS) was subtracted from the current score resulting in a *difference score*(e.g., PS = 3; current = 1; DS = 2). To identify clusters of items that show similar patterns in DS or PS, we ran a double-way clustering on the DS and PS matrix: this allows clustering of the probands based on the ADI item values, as well as clustering of items based on proband values. We use K-means with K=2 for clustering. The different clusters of symptom level were compared between module 2 and Module 3 participants.
Results:
Our analyses show that several patterns of change over time can be detected from a single time point administration of the ADI-R. Most prominent, there is significant improvement in symptoms from 4-5 to current functioning. However, despite individual change, there is little difference in the degree of improvement by current age (72-192 months); older children did not demonstrate "more change" or were "more improved" than younger children in this age range. Clustering analysis reveals subgroups among ADI items, characterized by a different level of severity of symptoms and level of change over time. Those subgroups were different among Module 2 and Module 3 participants. Thus, pattern of severity of symptoms can provide important information about eventual language outcomes (i.e. whether the child will be appropriate for a Module 2 or 3 at age 6 to 16 years).
Conclusions:
Our analyses suggest that the ADI, when used with verbal children after the age of 6 years, may also provide the parent with prognostic information about the pathways that could be expected for particular symptoms and the probability of improvement of certain symptoms at various stages of development.

Figure 3 *Difference Score (DS)* Cluster Matrix for Module 2 probands (top) and Module 3 probands (bottom). The columns represent different ADI items and the lines represent individual probands. Black line marks the separation between clusters. Colors represents 7 {(-3)-(+3)) possible DS values



61 **123.061** Clinician Confidence, Child Characteristics and Accuracy: Screening for Autism Spectrum Disorder in Toddlers

D. Hedley[1], *N. Brewer*[2], *R. E. Nevill*[3], *M. Uljarevic*[4], *E. Butter*[5] *and J. A. Mulick*[6], *(1)School of Psychology and Public Health, La Trobe University, Melbourne, Australia, (2)Flinders University, Adelaide, SA, Australia, (3)The Ohio State University, Columbus, OH, (4)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia, (5)Nationwide Children's Hospital, Westerville, OH, (6)Pediatrics, The Ohio State University, Columbus, OH*

Background:
Professionals on the front line of identifying ASD make critical decisions that are likely to have long-term consequences for children and families. While screening instruments are available it has been suggested that experienced clinical judgment is more reliable in detecting ASD. Clinicians must account for factors such as family history, environment, comorbidity and differential diagnoses that cause overlaps in symptoms which can obscure diagnostic boundaries, and must integrate this information to identify probable diagnostic status which then informs important clinical decisions. Yet, little is known about the interplay between clinician and child factors that might influence these decisions, which potentially, may have a profound impact on prognosis.
Objectives:
Our aim was to examine the relationship between confidence and accuracy (CA) for clinicians' judgments and to assess the potential contribution of developmental and behavioral profiles to the CA relationship during developmental screening. Specifically, we explored a) the relationship between clinician confidence and accuracy of predicted diagnosis and b) the influence of child characteristics on clinicians' confidence.
Methods:
Participants were 125 children aged under 14-39 months (M = 28.62, SD =5.41) who presented for screening at a hospital child development center due to developmental concerns. One-hour long screening interviews were conducted by healthcare professionals. Following the screening interview professionals completed a questionnaire regarding whether or not they thought the child has ASD. Clinicians provided a risk estimate and a Likert scale was used to generate a confidence score. Diagnostic status and assessment results were retrieved from medical record review.
Results:
Experienced healthcare workers exhibited good sensitivity in identifying ASD. We identified a small but positive correlation between confidence and accuracy, r_τ (119) = .24, p = .003, with diagnosticity highest at confidence levels of 90-100%. Regression analysis identified parent report of unusual behaviors as the only significant predictor of clinician confidence (t = 2.376, p = .02, β = .395).
Conclusions:
Despite good sensitivity in clinician prediction of diagnosis, this sensitivity appears to come at the cost of over-classification of children who did not receive an ASD diagnosis. We identified a small but positive CA relationship in referred children, with diagnosticity for positive identifications highest in the 90% to 100% confidence band. The CA relationship was less well calibrated for negative identifications. Parent report of unusual behaviors was found to be the only significant predictor of clinician confidence, however this is not surprising in the light of the fact that a wide range of restricted and repetitive patterns of behaviors has been consistently reported among the earliest infant predictors of a later ASD diagnosis.

62 **123.062** Combining ASD-Specific Screening Tools to Capture Red Flags in 12 Month Old High-Risk Siblings

M. Lewis[1], *N. R. Brane*[1], *B. Kotlar*[1], *E. J. Wang*[2] *and A. M. Wetherby*[3], *(1)Marcus Autism Center, Atlanta, GA, (2)Pediatrics, Emory University, Atlanta, GA, (3)Florida State University Autism Institute, Tallahassee, FL*

Background:
The American Academy of Pediatrics recommends screening toddlers for ASD at 18 & 24 months. Closely monitoring children at higher risk (e.g. having a sibling with ASD) is especially critical (CDC, 2014) as approximately 20% of younger siblings are at an increased risk for developing ASD (Ozonoff, 2011), therefore requiring intensified developmental surveillance. By using a combination of screening tools as early as 12 months in a high-risk population with consideration for home and clinic settings, providers may identify subtle delays and ASD specific red flags at an earlier age. According to DSM-5 criteria, persistent deficits in social communication and social interaction occur across multiple contexts. Employing multi-source screening at 12 months may provide comprehensive yet efficient means to initiate earlier ASD intervention for infants deemed high-risk.
Objectives:
To examine how combination of clinical assessment, home observation, parent report and ASD-specific screening can be used in a complementary fashion to detect red flags starting as early as 12 months, ultimately testing a downward extension of current AAP guidelines in a high-risk sample.
Methods:
High-risk 12-month olds were assessed as part of a federally-funded longitudinal study examining siblings. Assessment batteries included 4 samples of early social behavior with consideration for multiple settings: a communication assessment, a video-recorded home observation, parent report measure, and an ASD-specific screening tool. The CSBS (Wetherby & Prizant, 2001) was used to assess communication development, the Systematic Observation of Red Flags of ASD (SORF; Wetherby & Woods, 2004), an ASD-specific screening tool, was used to rate symptomatology within CSBS and home observations. The Early Screening for Autism and Communication Disorders (ESAC; Wetherby, Woods & Lord, 2012), parent questionnaire, was used to collect information on early social communication and presence of repetitive behaviors. Using previous research collected from ESAC and SORF in 18-24 month-olds, cut-offs were determined, where a positive screen for 12-month siblings on at least 2 of 4 measures led to eligibility for an experimental intervention. Within our study, 17 (20 projected by May 2016) high-risk infants were deemed eligible for intervention based on positive screening utilizing these four measures. Comparisons between measures used to assess qualification for intervention were analyzed using the Chi-Squared test and Wilcoxon Two-Sample test.
Results:
Measures conducted in the clinic by highly trained clinicians were more likely to positively identify early ASD signs than the measure conducted in the home or parental report at the 5% significance level ($p<.005$). Of 17 infants who qualified for the intervention study 76% (n=12) qualified based on the CSBS and 100% (n=17) qualified based on the clinic SORF compared to 41% based on the ESAC (n=7) and 50% on the home SORF (n=8).
Conclusions:
Findings suggest that while the CSBS is examining communication, its structured tasks involving object temptations may reveal subtle social delays in high-risk 12-month olds to a trained clinician. Applying an ASD-screening tool to rate the communication sample of the CSBS, closely examining social behaviors and emerging repetitive behaviors, may expose earlier symptomatology and provide more quantitative assessment of red flags.

63 **123.063** Comparing Motor Abilities Using a Standardized Clinical Assessment (BOT-2) and Parent Report Questionnaires (MABC-2 and DCDQ) in Children with Autism Spectrum Disorder (ASD)

E. Bakshipour[1], *M. Kaur*[2], *S. Izadi-Najafabadi*[2], *S. Srinivasan*[2] *and A. N. Bhat*[2], *(1)Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE*

Background:
Autism Spectrum Disorder (ASD) is a multisystem disorder characterized by impairments in social communication skills and the presence of restricted and repetitive behaviors (American Psychiatric Association, 2013). Additional comorbidities include gross-motor (GM) and fine-motor (FM) impairments as well as cognitive/behavioral impairments (Srinivasan & Bhat, 2013). Invariably, there are discrepancies between parent and clinician estimates about the level of functioning of children with ASD. A comparison of motor functioning using parent and clinical estimates could highlight the gap in the understanding of functional capacities of children with ASD between the two stakeholders.
Objectives:
We aimed to compare parent and clinician perspectives regarding functional performance within the FM and GM domains in children with ASD using parent questionnaires and standardized clinical assessments.
Methods:
Thirty-seven children with ASD aged between 5 and 12 years participated in this study. We administered various FM and GM subtests from the Bruininks-Oseretsky Test of Motor Proficiency- 2nd Edition (BOT-2) and report the FM and GM composite performance. Parents of the participating children completed two motor questionnaires - Movement Assessment Battery for Children-2 (MABC-2) and Developmental Coordination Disability Questionnaire. Both questionnaires provide normative data on overall motor delays. Significant motor delays were scores below the 15th-18th percentile depending on the measure.
Results:
Based on BOT-2 data, 50% of the ASD sample had significant FM delays and 59.1% of the ASD sample had significant GM delays. Based on MABC-2 data, 75% of the ASD sample scored in the red zone (i.e.; below the 15th percentile) in terms of FM & GM performance. Based on DCDQ data, 84% of the ASD sample met criteria for a Developmental Coordination Disorder (DCD).
Correlations between BOT-2, MABC, and DCDQ indicated that both gross (r=0.78) and fine motor (r=0.61) scores of MABC-2 strongly correlated with those of DCDQ. However, both MABC-2 and DCDQ scores did not correlate with BOT-2 scores across GM and FM domains.
We also analyzed the percent of parents that agreed with the clinician's estimate of FM and GM delays. In general, 55% of the parents completely agreed and 18% of the parents partially agreed with the clinician's assessment of FM and GM delays in the ASD sample. In contrast, 27% of the parents disagreed and either overestimated or underestimated the motor skill performance of their children.
Conclusions:
A subset of parents' did not accurately assess their children's abilities as they were clearly off compared to clinician estimates. Parents of children with ASD are perhaps more concerned about their child's social skills and they may not pay enough attention to their motor skills. Strong correlation between the MABC and DCDQ confirms that parental perception of their children's motor function remains constant. Secondly, the skills assessed in the parent questionnaires are more functional in nature than the standard activities of BOT-2. Clinical measures such as the BOT-2 may not adequately assess motor functioning required for completing activities of daily living. Clinicians need to consider the use effective functional assessments to better evaluate functional motor performance of children with ASD.

64 **123.064** Correlations Between ADOS-2: Module 4 Comparison Severity Scores and Standardized Assessment Measures: A Preliminary Examination in Adults with Autism Spectrum Disorder

M. J. Morrier[1], *O. Ousley*[2], *M. J. Segall*[3], *E. Andari*[4], *J. F. Cubells*[5] *and L. J. Young*[4], *(1)1551 Shoup Court, Emory University, Atlanta, GA, (2)Psychiatry and Behavioral Sciences, Emory University School of Medicine, Decatur, GA, (3)Emory Autism Center, Atlanta, GA, (4)Emory University, Atlanta, GA, (5)Emory University School of Medicine, Atlanta, GA*

Background: The recent update to the *Autism Diagnostic Observation Schedule*(ADOS-2) included a comparison severity score (CSS) to use as a quantifiable measure of ASD severity independent of one's age and language functioning (Hus & Lord, 2014; Lord et al., 2012) to standardize the ADOS-2 total algorithm score for use as a dimensional measure of change. A recent article by Hus and Lord (2014) provided a revised algorithm and CSS scores for adults with ASD using Module 4. Comparison severity scores are reported in social affect (SA); restricted, repetitive behaviors (RRB); and Total ADOS-2 algorithm (Total) scores. This study examined the correlation between the CSS scores and individual characteristics of adults with ASD, as measured by standardized assessments of social responsivity reported by self and others, IQ, and memory. All measures were completed as part of an eligibility assessment for the Conte Center for Oxytocin and Social Cognition at Emory University.
Objectives: To examine the correlation between standardized measures and ADOS-2: Module 4 CSS scores in order to determine which measure might be the best predictor of CSS scores.
Methods: Twenty-two male adults with ASD participated (*M* age = 27 years, 1 month, *SD* = 4 years, 1 month; *M* WASI-II Full Scale = 115.48, *SD* = 39.79). Standardized measures included the SRS-2 Social Communication and Interaction (SCI), Restricted Interests and Repetitive Behavior (RRB), and the Total SRS-2 *t*-scores from the self and other reports; standard scores for WAIS-II Verbal Comprehension, Perceptual Reasoning, and Full Scale-4. WMS-IV scaled sores on the Logical Memory Immediate, Logical Memory Delayed, Visual Reproduction Immediate and Visual Reproduction Delayed subtests. CSS scores were determined from Hus and Lord (2104) article. To facilitate comparison across assessments, all standard scores with the exception of ADOS-2 CSS scores were converted to *z*-scores by using the formula (score-mean)/standard deviation.
Results: Bivariate correlations indicated that only IQ scores predicted the CSS scores. In particular, we found a negative correlation between both sub-domains of IQ (Verbal Comprehension and Perceptual Reasoning) and the SA CSS ($r = -.642$, $p < .01$; $r = -.531$, $p < .01$, respectively). Negative correlations were also found for IQ sub-domains

and the Total CSS (r = -.513, $p < .01$; r = -.442, $p < .05$, respectively). All other measures did not correlate with the CSS.
Conclusions: Our preliminary and exploratory results indicate that the CSS score of the ADOS-2: Module 4 is associated with intellectual abilities in adults with ASD. Our findings suggest that CSS or ADOS-2 scores are not necessarily reflecting only social functioning, but are also related to an individual's intellectual characteristics. Further replications are needed on a larger sample. To optimize use of the ADOS-2 CSS scores as measures of change, researchers may need to control for intellectual ability in psychopharmacological and behavioral intervention studies that target core ASD symptoms.

66 **123.066** Early Detection of ASD: A Meta-Analytic Study on the M-CHAT and Other Tools Used for Universal Toddler Screening

ABSTRACT WITHDRAWN

Background:
Great efforts are being focused on developing instruments for early detection. However, there is no agreement about the best instrument. In addition, some scientists and clinicians have questioned early universal screening, until an adequate instrument with good psychometric properties is available[1]
The two versions of the Modified Checklist for Autism in Toddlers (M-CHAT and M-CHAT-R/F) are the most internationally used ASD screening instruments[2] and when including the follow-up interview procedure have a high positive predictive value [3,4]. However, no meta-analytic study has provided information on the M-CHAT and other tools.
Objectives:
This study aims to describe and synthesize the psychometric properties of the ASD screening tools, at an international level, applied in general population at early ages. The main objective is to analyze if there are statistically significant differences from the M-CHAT and M-CHAT-R/F and other screening tools.
Methods:
A systematic literature review of peer-reviewed publications was conducted to identify studies published from January 1992 through April 2015. CINHAL, ERIC, PsycINFO, PubMed and WOS databases were searched. Effect size will be calculated using the hierarchical summary ROC (HSROC) model.
A hierarchical Cluster Euclidean distance using HJ-Biplot scores-Linkage Ward has been calculated based on data sensitivity, effectiveness of each screening tools and several similarity coefficients which evaluate the concordance between the results of the screening tool (Jaccard, Sokal and Sneath, Ochaiai and Sokal, Michener).
Results:
From the identified 1423 non-duplicate citations screened, 20 papers were selected for qualitative review (using Quadas-2). Fourteen studies were eligible for inclusion. The agreement between judges was adequate, kappa=0.643, p<.01.
As a preliminary finding we can differentiate two clusters; the first one shows a high concordance and is comprised of 11 studies. In this cluster are the majority of the studies done with the M-CHAT. In the second cluster we find studies with significant discrepancy between the results of the test and the reference standard.
Conclusions:
Many researchers around the world are working to establish good ASD screening practices.. The results of this study will help us to have a better understanding about the effectiveness of the different procedures for the early detection.

O'Connor*[1], *L. Colli*[1], *S. Al Balkhi*[1] *and R. Schachar*[9], *(1)McMaster University, Hamilton, ON, Canada, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)University of Toronto, Toronto, ON, Canada, (4)University of Calgary, Calgary, AB, Canada, (5)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (6)University of Western Ontario, London, ON, Canada, (7)Centre for Applied Genomics (TCAG), Hospital for Sick Children, Toronto, ON, Canada, (8)The Hospital for Sick Children, Toronto, ON, Canada, (9)Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (10)Psychiatry, University of Toronto Faculty of Medicine, Toronto, ON, Canada, (11)McMaster Children's Hospital/McMaster University, Hamilton, ON, Canada*

Background: Autism Spectrum Disorder (ASD), Attention Deficit Hyperactivity Disorder (ADHD), and Obsessive Compulsive Disorder (OCD) are childhood-onset neurodevelopmental disorders (NDDs) linked to deficits in brain development and function. Accumulating evidence suggests there is notable clinical and genetic overlap among the three NDDs, lending support to the idea of common, cross-disorder aetiologies. Despite the evidence, our current psychiatric classification paradigm continues to treat these NDDs as distinct diagnostic entities. Such a categorical approach may be limiting our research to identify homogeneous subgroups of children who share similar profiles, irrespective of their primary NDD diagnosis. An alternative approach that identifies dimensional phenotypes that cut across conventional NDD diagnostic categories can inform treatment processes and the search for common cross-disorder aetiologies. Two clinical phenotypes in NDDs that warrant close attention and may be suitable for such cross-disorder investigations are emotional (internalizing) and behavioural (externalizing) problems.
Objectives: To use the phenotypes of emotional and behavioural problems to identify informative subgroups of children across conventional NDD diagnostic categories (ASD/ADHD/OCD).
Methods: The sample consisted of 784 children with NDDs (319 ASD, 329 ADHD, 136 OCD; 74.9% males; mean age: 10.7 years) participating in the Province of Ontario Neurodevelopmental Disorders (POND) Network project. To identify subgroups, data on the Child Behavior Checklist (CBCL 6-18) syndrome scales – Anxious/Depressed, Withdrawn/Depressed, Somatic Complaints, Social Problems, Thought Problems, Attention Problems, Rule-Breaking Behavior, and Aggressive Behavior – were used in Hierarchical Clustering analysis. The optimal number of clusters was selected using the scree-plot criterion. Derived clusters were characterized using sex ratio, the child's age, social communication deficits (Social Communication Questionnaire; SCQ), obsessive compulsive behaviours (Toronto Obsessive Compulsive Rating Scale; TOCS) and adaptive behaviours (Adaptive Behavior Assessment System; ABAS-2)
Results: A 2–cluster solution provided the best fit to the data. Compared to those in Cluster 1, children in Cluster 2 (43% of sample) scored higher (within borderline or clinical range) on all CBCL syndrome scales ($p < .001$ for all) and total problems score (mean: 71.6 compared to 57.4; $p < .001$). The two clusters did not differ in terms of sex ratio or the child's age. The proportion of children from each primary diagnostic category in Cluster 2 was 45.5% of ASD, 45.9% of ADHD, and 30.1% of OCD. Within Cluster 2, children with ASD scored higher on the SCQ (mean ASD: 22.2 > ADHD: 10.2 and OCD: 7.7; $p < .001$) and had the lowest scores on the ABAS (mean ASD: 60.7 < ADHD: 75.7 and OCD: 80.1; $p < .001$). Children with OCD had the highest scores on the TOCS (mean OCD: 20.6 > ASD: -11.6 > ADHD: -19.9; $p < .001$).
Conclusions: Study findings suggest that emotional and behavioural problems are useful phenotypes for the identification of informative subgroups of children with NDDs that may benefit from cross-disorder treatments. At the same time, notable within-subgroup variability suggests that primary diagnostic categories (ASD/ADHD/OCD) provide useful information on unique phenotypes (e.g., social communication deficits, obsessive compulsive behaviors, and adaptive behaviors) requiring disorder-specific treatments. This work has the potential to inform research on the shared and unique aetiologies in NDDs.

68 **123.068** Factor Analysis of the Childhood Autism Rating Scale in Two-Year-Olds with ASD

E. Moulton[1], *M. Barton*[2] *and D. A. Fein*[2], *(1)University of Connecticut, Storrs, CT, (2)Psychology, University of Connecticut, Storrs, CT*

Background: The Childhood Autism Rating Scale (CARS) (Schopler, 1980) is a 15-item observation-based rating scale designed to accurately differentiate children with autism from those with developmental delays without features of autism. The CARS is a commonly used component of ASD diagnosis, yielding a single total score (15 to 60) that is reflective of overall symptom severity. Given that symptom severity varies across domains for children with ASD, the utility of the CARS may be extended by understanding factors that underlie its total score. At present, few factor analyses have been conducted on the CARS, and results are mixed.
Objectives: The current study seeks to extend existing research on the factor structure of the CARS utilizing a well-characterized sample of two-year-old children with a DSM-IV ASD diagnosis.
Methods: Developmental and diagnostic evaluations were conducted at approximately 26 months following positive screening on an autism-specific screener (MCHAT(-R)). The Autism Diagnostic Observation Schedule (ADOS), Mullen Scales of Early Learning (Mullen), Vineland Adaptive Behavior Scales (VABS II), and Childhood Autism Rating Scale (CARS) were completed. Diagnosis was assigned based on the clinical judgment of experienced clinicians. Children were included in the current study if they received

a diagnosis of Autistic Disorder (AD) or Pervasive Developmental Disorder, Not Otherwise Specified (PDD-NOS) (N=289). 217 (77.8%) children were male, and the sample was predominantly white (N=204, 73.1%). A factor structure evaluation of the CARS was conducted using principal axis factor analysis with promax rotation. Factors were retained utilizing the Kaiser criterion (1960). Items were considered to load on a factor if their loadings were .40 or above in the pattern matrix.
Results: CARS scores ranged from 20.0 to 48.5 (*M*=32.26, *SD*=5.22). Mullen Early Learning Composite (ELC) standard scores ranged from 41 to 120 (*M*=59.72, *SD*=12.01), with 71.6% of children demonstrating ELC scores of 70 or below (N=207). Principal axis factor analysis revealed three factors that accounted for 52.39% of the common variance among CARS items. The first factor is labeled *Social-Communication* and includes Relating to People, Imitation, Listening Response, Verbal Communication, Nonverbal Communication, General Clinician Impressions and Level/Consistency of Intellectual Response. The second factor is labeled *Emotion Regulation* and includes Emotional Response, Adaptation to Change and Fear/Nervousness. The third factor is labeled *Stereotyped Behaviors and Sensory Sensitivities* and includes Body Use, Object Use, Taste/Smell/Touch Response and Use, and Activity Level.
Conclusions: Factor analysis of the CARS in a sample of approximately two-year-old children with ASD and a broad range of intellectual abilities revealed three factors: *Social-Communication*, *Emotion Regulation*, and *Stereotyped Behaviors and Sensory Sensitivities*. These factors are conceptually meaningful, and are consistent with our current understanding of ASD as a multidimensional construct. Factors found in the current study are similar to those found in previous investigations conducted with four-year-olds with ASD, with some important differences that may reflect differences in symptom presentation between children of different ages. Utilizing age-appropriate factor scores, in addition to the CARS total score, may extend the utility of the CARS as a measure of ASD symptom severity.

69 **123.069** Feasibility of Developing an Algorithm to Derive Ratings of Social Communication Functioning (ACSF:SC) from ADOS Data

S. J. Gentles[1], *B. M. Di Rezze*[1,2], *P. Rosenbaum*[1], *L. Zwaigenbaum*[3], *M. J. C. Hidecker*[4], *S. Georgiades*[5] *and E. Duku*[5], *(1)CanChild Centre for Childhood Disability Research, McMaster University, Hamilton, ON, Canada, (2)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Communication Disorders, University of Wyoming, Laramie, WY, (5)McMaster University, Hamilton, ON, Canada*

Background: Modeled on the internationally recognized Gross Motor Function Classification System for cerebral palsy, our group developed and validated the Autism Classification System of Functioning: Social Communication (ACSF:SC). This descriptive classification system—based on WHO's International Classification of Functioning, Disability, and Health (ICF) framework—contrasts with traditional severity metrics by assessing abilities rather than deficits. The ACSF:SC allows parents or professionals to categorize children aged 3 to 5 into one of five meaningfully distinct levels of social communication functioning ability. It may be possible to extract relevant descriptive levels of social communication abilities from standardized tools routinely used in autism assessment and research (e.g., the Autism Diagnostic Observation Schedule [ADOS]). Being able to derive ACSF:SC ratings from such instruments would allow abundant earlier data to be translated into our unique validated indicator of children's level of social communication functioning, immeasurably increasing the value of such data for research purposes. Importantly, such ratings would enable the examination of longitudinal trajectories of social communication abilities among children with autism.
Objectives: We aim to develop an algorithm to derive ACSF:SC ratings from ADOS data. As part of this work, we will evaluate the reliability of ADOS-derived ACSF:SC ratings at progressive stages of algorithm development.
Methods: Preliminary results were obtained using a mini-Delphi method (i.e., a small group face-to-face multiple-round consensus method): first, to identify items from the ADOS that correspond to the ACSF:SC construct of social communication, and second, to map the scores available within each relevant ADOS item to ACSF:SC ratings to determine the range of ACSF:SC levels covered. We plan an expanded Delphi method exercise (70% agreement criterion) involving our interdisciplinary team (n=6).
Results: In preliminary work, three team members identified 15 relevant items from ADOS Module 2 corresponding to the ACSF:SC construct of 'social communication'; we also mapped the scores available within each relevant ADOS item to corresponding ACSF:SC ratings, determining the spread of ACSF:SC levels covered by that item. 100% consensus was reached after 2 rounds. Together all relevant ADOS items provided full coverage of the 5-level range of the ACSF:SC. Based on preliminary examination, some relevant ADOS items appear more information-rich, suggesting that weighting and possibly other 'if-then' conditions may be required in a final algorithm to convert relevant ADOS item scores to an overall ACSF:SC rating.
Conclusions: We describe methods for deriving a classification of social communication functioning from ADOS data. Preliminary results suggest this is definitely feasible. We will also present findings of the expanded Delphi method, and initial version of the algorithm to be developed using anonymized ADOS assessment data. This algorithm will be validated by assessing the correlation of the ADOS algorithm-derived ratings with paired ACSF:SC ratings from an existing dataset. The methodology outlined may provide a template for developing additional algorithmic means of deriving ICF-based functioning ratings in autism (beyond social communication) from data routinely collected by commonly used instruments like the ADOS—extending opportunities for secondary data analysis. A valid algorithm will enable longitudinal examination of social communication abilities.

70 **123.070** Gender Differences in the Age at Diagnosis of ASD

A. M. Petrou[1], *H. McConachie*[2], *D. Wilde*[1], *M. Johnson*[2] *and J. R. Parr*[2], *(1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Institute of Health and Society, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background:
Autism spectrum disorders (ASD) are more common in boys than girls. Several studies have shown gender differences in cognitive and clinical manifestations of ASD (Holtman et al., 2007) and in the prevalence of co-existing conditions (Hartley & Sikora, 2009) and motor difficulties (Carter et al., 2007). Girls are more likely than boys to have received a diagnosis if they also present with a learning disability than if they just present with ASD alone (Mandy et al., 2012; Van Wijngaarden-Cremers et al., 2013). Recently, there has been a growing awareness of ASD in girls, and a recognition that under-diagnosis is common.
Objectives:
To investigate gender differences in the age at ASD diagnosis: i) whether girls' age at diagnosis has reduced, compared to boys', across two age cohorts; ii) whether age at diagnosis differed between girls and boys diagnosed aged < 60 months or ≥ 60 months; and iii) whether certain ASD characteristics were associated with earlier diagnosis in girls.
Methods:
Data were available from two large representative UK databases: The Database of Children with Autism Spectrum Disorder Living in the North East (Dasl^{n}e) and the Autism Spectrum Database-UK (ASD-UK; Warnell et al., 2015). Age at diagnosis was first examined for 641 boys and 111 girls enrolled in Dasl^{n}e by Year of Birth across two time periods (1996-1999 and 2002-2005). Age at diagnosis was then examined for 2573 boys and 541 girls by Age at Diagnosis Group (< 60 months and ≥ 60 months) from Dasl^{n}e and ASD-UK, and the correlates between ASD characteristics, gender and age at diagnosis were examined (ASD severity measured by Social Communication Questionnaire (SCQ); learning (intellectual) disability; DSM-IV ASD diagnosis).
Results:
There was no overall significant gender difference in age at diagnosis comparing Year of Birth age cohorts (1996-1999: boys, median =58.4 months vs. girls, median =81.9 months; 2002-2005: boys, median =54.4 months vs. girls, median =62.6 months, $F(1, 748)=1.64$, $p=.20$). However, age at diagnosis for children who received their diagnosis aged ≥ 60 months was significantly lower for boys (median =90.8 months) than for girls (median =101.4 months) ($t(340)=-4.00$, $p<.001$). There was no difference between the ASD severity of girls and boys who were diagnosed aged < 60 months ($t(803)=.20$, $p=.84$) or those aged ≥ 60 months ($t(615)=1.15$, $p=.25$) (data from ASD-UK only). Girls who received their diagnosis aged ≥ 60 months were more likely than boys to have a learning (intellectual) disability ($X^2(N=1358)=13.33$, $p<.001$) and a diagnosis of autism than another type of ASD diagnosis ($X^2(N=1358)=12.15$, $p<.001$).
Conclusions:
Girls diagnosed with ASD at 5 years or older were, on average, diagnosed later than boys. Their age at diagnosis did not decrease significantly over the time period considered. Girls in this older group did differ in some ASD characteristics when compared with boys. Clinicians and researchers need to understand the qualitative differences in autism characteristics in girls and boys, how these differences impact on age at diagnosis, and whether specific characteristics can be used to identify girls with ASD at an earlier age.

71 **123.071** How Do Test-Taking Behaviors Influence WISC-4 Scores?

R. Tanabe[1] *and S. Okada*[2], *(1)Graduate school of Eduction, Hokkaido university, Sapporo-Shi, Japan, (2)faculty of education, Hokkaido university, sapporo-shi, Japan*

Background: Wechsler Intelligence Scale for Children-IV (WISC-IV) is one of the most reliable and widely used assessment tools in the world (Wahlstrom et al., 2012). Recently, many studies focused on the profiles of clinical data and identified the common characteristics in each clinical group (Wechsler, 2010). However, some researchers have stressed the importance of comprehensive assessment including ecological validity since there are differences in terms of WISC profiles even among children with ASD and ADHD (Oakland et al., 2012 Dairoku et al., 2011).According to Oakland et al. (2012), WISC-IV four domain scores are influenced by 3 test-taking behaviors such as "Avoidance", "Inattentiveness", and "Uncooperative mood". Furthermore, other studies revealed that characteristics such as ADHD and ASD are related to these scores (Okada et el., 2010, Oliveras-Rentas et al, 2012). Therefore, it is evident that WISC-IV scores are influenced by various factors such as test-taking behaviors, ASD and ADHD. Okada et al. (2015) reviewed the existing test-taking checklist and created new checklist called Test-taking behaviors checklist (TBC). It comprises "Emotional state", "Attentiveness", "Cooperative mood", "Comprehensive state", "Social interaction", and "Flexibility", and they proposed that "Social interaction" and "Flexibility" are related to behaviors of children with ASD during the test.
Objectives: To examine the impact of test-taking behaviors on FSIQ (Full-Scale IQ) and four domain scores of WISC-IV.

Methods: WISC-IV, TBC, Pervasive Developmental Disorders Autism Society Japan Rating Scale (PARS) , and Attention Deficit-Hyperactivity Disorder Rating Scare (ADHD-RS) were administered to 74 children (5-16year old), who visited counseling room, medical institution, etc. In Japan, PARS and ADHD-RS are used to assess ASD / ADHD symptoms.
Results: Firstly, from principal component analysis and internal consistency analysis by Cronbach's coefficient alpha, five scales except "Flexibility" of TBC are tested reliable for principal components score. However, "Flexibility " is not appropriate for the calculation of scores. Secondly, we created models, comprising "Emotional state", "Attentiveness", "Comprehensive state", and "Social interaction" that influence FSIQ and four domain scores. In these models we proposed that "Attentiveness" and "Comprehensive state" relate to age, PARS relates to "Social interaction", and ADHD-RS relates to "Attentiveness". The results of structural equation modeling (SEM) revealed that all models fit significantly and "Comprehensive state" is correlated with WISC-IVscores in all models. In addition, "Social interaction" and "Attentiveness" are moderately correlated with PARS /ADHD-RS.
Conclusions: In this study, the models were created with reference from previous studies, investigated analysis on the impact of FSIQ and the four domain scores of WISC-IV. Consequently, we found that test-taking behaviors influenced these scores to a small extent and "Comprehensive state" relates to all of these scores. Meanwhile, it revealed that "Social interaction" and "Attentiveness", which were supposed to relate to PSI/WMI, did not relate these index scores. We will discuss the interpretation-system from the perspective of the impact of test-taking behaviors.

72 **123.072** In the "Gray" Zone: Exploring the Diagnostic Course of Young Children with Unclear Presentation at Initial ASD Referral

F. van der Fluit[1], *M. Vu*[1], *S. W. Duvall*[1] *and L. Huang-Storms*[2], *(1)Oregon Health & Science University, Portland, OR, (2)Institute on Development and Disability, Oregon Health & Science University, Portland, OR*

Background: The benefits of early identification of autism spectrum disorder (ASD) and subsequent intervention have been well-documented in the existing literature. As a result, there has been an increasing interest in earlier evaluation and diagnosis of children with symptoms concerning for ASD. However, given the overlap of ASD with other developmental conditions (e.g., language disorder, developmental delay, behavioral difficulties), accurate identification can be difficult, especially in young children.
Objectives: To examine the diagnostic course of young children referred for ASD evaluation who did not clearly meet diagnostic criteria at initial evaluation.
Methods: Subjects include young children who were referred to a large, tertiary care medical center for an interdisciplinary evaluation of suspected ASD. All children included did not receive an ASD diagnosis at initial evaluation; however, all were deemed high-risk due to remaining prominent concerns for ASD and re-evaluation in 6-12 months was recommended. Only those children who returned for this recommended follow-up were included (n = 5). A descriptive review of diagnostic course and child characteristics was conducted.
Results: The average age at which children completed initial evaluation was 38 months (SD = 17.79 months; range = 27-69 months). All children received either a language disorder (n =1) or global developmental delay diagnosis (n = 4) at initial evaluation. A diagnosis of Disruptive Behavior Disorder was also provided for 2 children. Some qualitative factors which may have contributed to the difficulty of diagnosis at first evaluation included: very young age, behavioral profiles including isolated strengths, lack of early intervention or other treatment, and limited information about early development. Follow-up evaluation occurred on average 10.75 months after initial evaluation (SD = 3.40, range = 6-14 months). The average age at which children completed follow-up evaluation was 47 months (SD = 18.52 months; range = 37-80 months). All 5 children were diagnosed with ASD at follow-up; a developmental delay diagnosis remained appropriate for the 4 children previously categorized as such. Continued data collection will allow for assessment of additional relevant contextual factors. Further investigation of social communication difficulties captured by the administrations of the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) will be presented.
Conclusions: It appears initial sub-threshold concern for ASD manifested more clearly at re-evaluation in the children included in the present investigation, given that all children ultimately received an ASD diagnosis. Gaining insight into the factors related to delayed diagnosis in these young children with unclear initial symptoms may help inform clinical practice.

73 **123.073** Informant Discrepancies in the Assessment of ASD Symptoms of High-Functioning Children with ASD Using the SRS-2

J. P. Donnelly[1], ***A. K. Jordan***[2], *M. L. Thomeer*[1] *and C. Lopata*[1], *(1)Institute for Autism Research, Canisius College, Buffalo, NY, (2)University at Buffalo, SUNY, Buffalo, NY*

Background: Presentation of ASD characteristics can vary across contexts and in the presence of different raters. Rating scales used to assess such behavior across settings by multiple raters (e.g., parents and teachers) may reflect these influences, potentially complicating assessment, treatment planning and evaluation. The Social Responsiveness Scale (2nd Edition, SRS-2) is a rating scale designed to assess ASD-related symptoms including social-communication deficits and circumscribed and repetitive behaviors and interests. To date, parent-teacher discrepancies on this scale have not been comprehensively examined.
Objectives: The current study was conducted to comprehensively investigate discrepancies between parent and teacher ratings on the SRS-2 for children with HFASD.
Methods: *Participants.* Two informant groups (parents and teachers) provided 240 ratings of ASD-related symptoms on the SRS-2; child inclusion criteria – short-form IQ factor score >70; receptive or expressive language score ≥ 80; and score meeting ASD criteria on ADI-R. *Outcome Measure.* Parent and staff ratings – *Social Responsiveness Scale, 2nd edition (*SRS-2; assesses ASD features). *Procedures.* Parent and teacher raters completed the SRS-2 as part of a battery of pretest (baseline) measures. Each child was rated by one parent and one teacher. Rating forms were checked, scored and entered by independent research assistants. Data analyses included (a) sample means vs. estimated population means, (b) parent vs. teacher means, (c) classification accuracy of parent and teacher scores, (d) inter-rater agreement and consistency (ICCs, Pearson correlations, Bland-Altman plot, and regression), (e) examination of potential moderators of parent-teacher discrepancies.
Results: Both parent and teacher SRS-2 Total ratings were significantly higher than population means with large effect sizes ($t(119) = 24.77$, $p < .001$, $d = 2.47$; ($t(119) = 21.30$, $p < .001$, $d = 2.07$), respectively). Parents rated significantly higher than teachers for the SRS Total and four of five treatment subscales ($d = .25$-$.37$). Parent-teacher agreement was higher for the moderate and severe clinical severity categories. The parent-teacher reliability was low-to-moderate (ICC =.22 - .47, $r = .13$ -.33). The Bland-Altman plot of Total scores shows no systematic trend across difference scores and means. No significant moderators (age, IQ, language scores) were found.
Conclusions: Both informant groups provided ratings of elevated ASD symptoms for children, with significantly higher scores reported by parents than teachers. Differences appeared to be systematic, consistent across the range of scores, and not moderated by the child, parent, or teacher variables examined. Systematic informant discrepancies affect screening outcomes, diagnostic determinations and outcome assessments. Screening may be most effective when viewing any elevated parent or teacher score as potentially important. Diagnostic determinations and response to treatment uses may be more greatly affected. Evaluators should seek additional information from raters when substantial discrepancies are observed in order to help determine reasons for disagreement (e.g., understanding of items, perceptions of symptoms, true variability of symptoms across settings). Evaluators might benefit from considering different thresholds for each informant group when considering a diagnosis. Treatment providers should consider targeting different symptoms across settings if actual differences in behaviors and symptoms across settings are indicated.

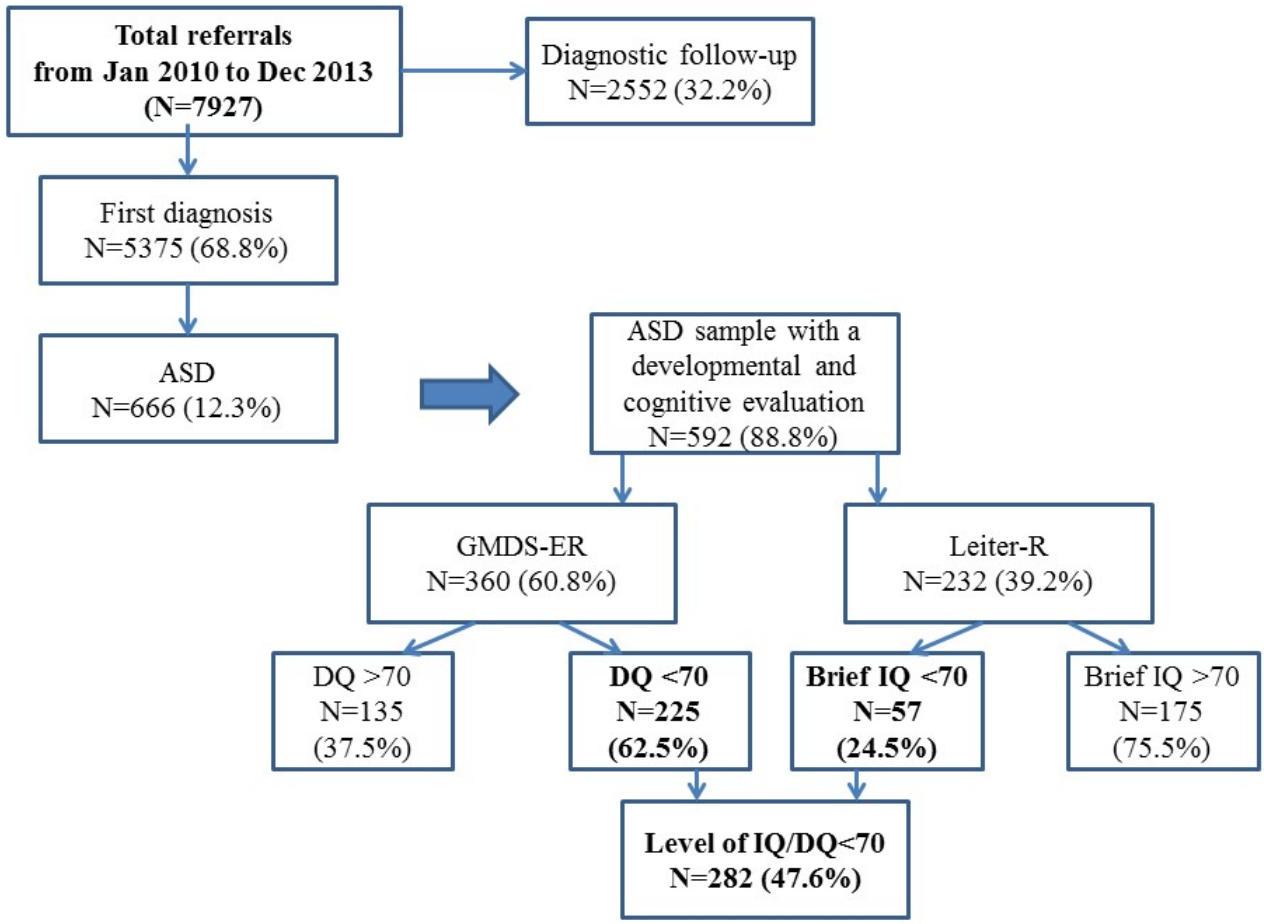
74 **123.074** Intellectual Disability in Autism Spectrum Disorder: Investigation of Prevalence in an Italian Sample of Children and Adolescents

V. Postorino[1,2], *L. M. Fatta*[2], *V. Sanges*[2], *G. Giovagnoli*[2,3], *L. De Peppo*[2,4], *S. Vicari*[5] *and L. Mazzone*[6], *(1)Department of Pediatrics, Marcus Autism Center, Emory University, Atlanta, GA, (2)Department of Neuroscience, I.R.C.C.S. Children's Hospital Bambino Gesù, Rome, Italy, (3)Neuroscience Department, L.U.M.S.A., Libera Università Maria SS. Assunta, Rome, Italy, (4)Department of Neuroscience, L.U.M.S.A., Libera Università Maria SS. Assunta, Rome, Italy, (5)Children Hospital Bambino Gesù, Rome, Italy, (6)Department of Neuroscience, I.R.C.S.S. Children's Hospital Bambino Gesu', Rome, Italy*

Background: Studies published so far have reported highly variable rates of Intellectual Disability (ID) prevalence in Autism Spectrum Disorder (ASD), ranging from 16.7% to 84%. It is worth to note that most of these studies investigated the epidemiology of ASD in general, and not specifically the prevalence of ID in ASD. Moreover, studies on the prevalence rates of comorbid ID in ASD in Italy are still lacking. In fact, to our knowledge so far only one study conducted in Italy investigated the co-occurrence of ASD and ID. In more detail, La Malfa et al. assessed the prevalence of Pervasive Developmental Disorder (PDD) in an Italian sample of 166 residents with ID, and reported a PDD rate in people with ID of 39.2%. Therefore, new insights on the prevalence of ID in ASD in this country are needed in order better understand the rates of comorbidity and their implication for treatment.
Objectives: The aim of the present study was to investigate the prevalence of ID analyzing developmental and cognitive test data (Griffiths Mental Developmental Scale-Extend Revised- GMDS-ER and the Leiter International Performance Test-Revised-Leiter-R) in a large sample of children and adolescents with ASD referred to an Italian National Children Hospital tertiary referral center from January 2010 to December 2013.
Methods: All patients referred to the Child Neuropsychiatry Unit for a diagnostic assessment were included in the present study. All of them underwent a complete diagnostic evaluation throughout a multidisciplinary team. The ASD diagnosis were based on clinical assessment, and in the majority of cases were corroborated by the ADOS-G. To assess the developmental and cognitive ability we used the GMDS-ER and the Leiter-R. Indeed, children's adaptive skills were assessed through the Vineland Adaptive Behavior Scale-Survey Form (VABS-SF).
Results: Recruitment procedure and participation rates are depicted in Figure 1. A total of 7927 patients referred for a diagnostic assessment (n=5375 for a first diagnosis, n=2552 for a diagnostic follow-up). Of them, 666 subjects were diagnosed with an ASD. 592 subjects with ASD performed a developmental or cognitive evaluation (n=360 the GMDS-ER, n=232 the Leiter-R). A total of 282 (47.6%) reported a DQ/Brief IQ <70. All of these subjects reported equivalent age below their chronological age in the VABS-SF skill domains.
Conclusions: To our knowledge, this study is the first epidemiological survey on the prevalence of ID in a large sample of Italian individuals with ASD, documenting the rates of a country for which these data were missing. Shedding light on the epidemiology of ID in ASD is a crucial issue for clinicians and researchers in order to better define methodological and conceptual problems that needs to be further addressed. In fact, underestimate intelligence ability in individuals with ASD could affect their opportunity in everyday life. Finally, given that researchers have reported that IQ is one of the good predictor of outcome, a reliable measurement of intelligence ability in autism is essential

in order to help clinicians to choose the most appropriate intervention and treatment strategy.

Figure 1. Recruiment procedure and participation rates.



75 **123.075** Longitudinal Stability and Change of Self-Reported Anxiety in Youth with ASD

H. K. Schiltz[1], *L. E. Swain-Lerro*[2], *M. C. Zajic*[2], *N. S. McIntyre*[2], *L. Springer*[3] *and P. C. Mundy*[4], *(1)Human Development, University of California at Davis, Davis, CA, (2)University of California at Davis MIND Institute, Davis, CA, (3)University of California at Davis, Davis, CA, (4)Education and Psychiatry, University of California at Davis, Sacramento, CA*

Background: Heterogeneity is a feature of Autism Spectrum Disorders (ASD). Co-occurring disorders such as anxiety further contribute to this variability (Gillott, Furniss, & Walter, 2001). However, concerns with ASD-specific challenges (e.g. language and cognitive skills) raise questions about the reliability of self-report of internalizing disorders such as anxiety as a tool for research with this population (Grondhuis & Aman, 2012). To address these questions, the stability and change of self-reported anxiety symptoms were examined in children with ASD compared to children with Attention Deficit Hyperactivity Disorder (ADHD) or typical development (TD) across a 15-month period of growth.

Objectives: 1) To examine diagnostic group differences across multiple dimensions of anxiety symptoms. 2) To compare diagnostic groups on test-retest self-report reliability. 3) To examine group differences in change of anxiety symptoms over time.

Methods: One hundred twenty-five 8- to 16-year-old children with ASD, ADHD or TD provided two sets of self-report on March's Multidimensional Anxiety Scale for Children (MASC; 1997, 2013) approximately 15 months apart. ASD was confirmed using the ADOS-2 and ADHD symptoms were confirmed with the Conners Parent Report scale. The mean ages of the ASD, ADHD, and TD groups were 11.4, 12.2, and 11.5 years, respectively. The mean IQs of the groups were 101, 100, and 115, respectively, and IQ was a covariate in analyses where appropriate.

Results: The groups differed on the MASC Total Anxiety and Physical Symptoms scales at both time points (TP, Table 1). The groups differed on the Anxiety Disorder index and Separation Anxiety at TP2. Post hoc analyses revealed the ASD group was higher on Total Anxiety than the TD group and higher on the Physical Symptoms than both the ADHD and TD groups at TP1. Post hoc analyses also revealed that the ASD group was higher on Total Anxiety and Physical Symptoms than both comparison groups at TP2. They were also higher on Separation Anxiety and the Anxiety Disorder Index than the ADHD group at TP2 (Table 1).

There was evidence of stability across the 15-month interval for self-report of Total Anxiety, Physical Symptoms, and Separation Anxiety in all groups (Table 2). Social Anxiety and the Anxiety Disorder index displayed evidence of stability in the ASD and TD groups.

Report of Physical Symptoms increased across time significantly for all groups (Table 1), but this increase was greatest for the TD group; $F(2,115)=3.42$, $p=0.04$. Total Anxiety also increased for the ASD and TD groups. The anxiety disorder index increased only for the ASD group; $F(1, 56) = 8.12$, $p =. 006$.

Conclusions: The results support the hypothesis that self-report in this subgroup of children with ASD provides meaningful information about trait-like individual differences in anxiety, and that school-aged children with ASD appeared to be at greater risk for significant increases in clinical levels of symptoms of an anxiety disorder than did children in the comparison groups. These observations bolster the need for more research on proactive monitoring and treatment of anxiety disorders in children with ASD.

Table 1: Time 1 and 2 MASC Data

	ASD (N= 57)		ADHD (N=28)		TD Controls (N=40)	
Variables	Time 1	Time 2	Time 1	Time 2	Time 1	Time 2

76 **123.076** Need a New DSM-5 ASD Assessment? Just AASC?

C. L. Hebert, *Spectrum Psychological Associates, Virginia Beach, VA*

Background:
The under-identification of high-functioning autism (HFA) in school age children is an ongoing problem, especially more able students with high-functioning autism (Wilkerson, 2010). Lost time due to under-identification or failing to provide needed services will diminish the developmental potential of children with ASD (Pool & Hourcade, 2011). More than half the children with autistic impairments, at the same levels as those with an ASD label, are not identified even though they have the same needs for support in educational settings (Russell et al., 2010).
Objectives:
The need to assess individuals with high-functioning autism is well demonstrated (Barnhill, 2007). A simple pre-screening assessment, with input from both a parent and an educator, would provide a method for identifying individuals in need of evaluation. The objective of this research is to design an assessment that is both DSM-5 compliant and easy to use.
Methods:
This study looks at existing data consisting of participant demographic data and item responses to the 272 question Ellis Functional Assessment (EFA) for high-functioning autism. The EFA is a measurement assessment that examines areas of functional difficulty for people with high-functioning autism. There were 538 participants in the

original study. The data set was later expanded to include 740 participants.
This data was analyzed using exploratory factor analysis to assess how many latent variables are included in the assessment. This information was used to design a short 15 to 25 question assessment pre-screen students for referral to the child study team for evaluation to receive special educational services for autism spectrum disorders. This assessment targets identifying students at the high-functioning end of the spectrum.
Confirmatory factor analysis (CFA) was used to test the model which was specified in advance to run the analysis (Thompson, 2010). The goal of CFA is to test a specific model or hypothesis (the shortened assessment) (Osborne, 2008).
Results: **:** The results for the final model of this confirmatory factor analysis produced a model with χ^2 = 8730.610, df = 655 (p < .001) and resulted in CFI = 1.00, NFI= 1.00 and RMEA = .243. After examining the Modification indices, the parameters with indices over 80 were freed and the resulting model was then analyzed. This produced a model with $\chi 2$ =3294.790, df = 627 (p < .001) and resulted in CFI = 1.00, NFI= 1.00 and RMEA = .104. This represents a significantly better fit ($\chi 2$ = 5435.82, df = 28, p < 0.00001). The assessment was also evaluated for internal reliability. This resulted in a Cronbach's Alpha = .941, indicating internal reliability.
Conclusions:
These five identified factors, covered the majority of the variance in the model and covered the most important aspects of ASD identified in literature. These factors cover all of the elements used for diagnosis in DSM-5. Because of the data in the EFA included behavior from early childhood the third requirement of DSM-V, symptoms must be present in the early developmental period is satisfied. The AASC is a valid, reliable screening instrument for Autism Spectrum Disorders.

77 **123.077** Parental Developmental Concerns of at Risk Underserved Young Children

*Y. Janvier[1], **J. Harris**[2], C. N. Coffield[3], M. Jimenez[4] and M. Zuniga[2], (1)Children's Specialized Hospital, Toms River, NJ, (2)Children's Specialized Hospital, Fanwood, NJ, (3)The Boggs Center on Developmental Disabilities, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (4)Children's Specialized Hospital, New Brunswick, NJ*

Background: Significant disparities have been identified among poor and minority children in the identification and treatment of ASD. Various factors may contribute to these disparities in identification. The first step in identification is to recognize a concern. While healthcare providers are in an excellent position to recognize developmental and autism-specific concerns, numerous studies have shown that they do not consistently screen for developmental concerns including autism and even when developmental concerns are identified by health care providers the majority of the children are not linked to services. Child care providers do not consistently screen development and very few screen for autism. Reliance on parents to recognize and express developmental concerns depends on parental awareness of red flag behaviors and the receptiveness of providers to listen to and act upon the expressed parental concern.
This study examined parental concerns for an at risk group of young children from low income, racial or ethnic minority and/or Spanish-speaking families.
Objectives: To better understand what concerns drive parents of young underserved children to seek developmental evaluation
Methods: The data was collected as part of a larger study to validate a new autism screening tool designed for use in a young underserved population. Subjects were 24 to 60 months and either were Medicaid or non-insured, non-white, Hispanic or whose primary language in the home was Spanish. Subjects were drawn from hospital-based developmental clinics and from Federally Qualified Health Centers. At risk for ASD status was based on parent/caregiver or healthcare provider concern about child's language, social, and/or behavioral development. Parents of subjects completed the new autism screening tool (Developmental Check-In-DCI), Modified Checklist for Autism in Toddlers-Revised (M-CHAT-R), Social Communication Questionnaire (SCQ), a medical history form, adaptive behavior measure (ABAS) and demographic information. The children were evaluated using the Mullen Scales of Early Learning and the ADOS--2. Clinical diagnosis was determined by licensed, experienced clinicians (developmental pediatrician, psychologist or advanced practice nurse based on patient history, observations and ADOS-2. Parental developmental concerns presented here were extracted from the DCI item "Do you have any concerns about your child's development or behavior? If so, please describe".
Results: Data will be analyzed using modified grounded theory in which themes are allowed to emerge from the data rather than imposed by the research staff. Parent responses will be read and coded. We will use the constant comparative method in which data is compared iteratively. Themes will be identified attending to factors such as repetition, emphasis and connections. We will compare themes across demographic characteristics as well as severity, clinical diagnosis of ASD, and setting.
Conclusions: The results of this study will provide important information about how parental concerns relate to autism screening and evaluation outcome among traditionally underserved young children. This information may then help to better train healthcare providers to recognize and solicit parental concerns, as well as to inform autism awareness campaigns aimed at low income, racial or ethnic minority or non-English-speaking communities.

78 **123.078** Predictive Factors in Special Education Eligibility for Children with ASD

***L. J. Dilly**[1] and C. Hall[2], (1)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA*

Background: As prevalence rates of autism spectrum disorders (ASD) in the United States reach 1 in 68 (1.5%), public schools are increasingly challenged with educating children with ASD through special education programs (Baio, 2014). Within the U.S., less than .5% of children ages 3-21 are eligible for special education services in the area of ASD (OSERS, 2014). Therefore, approximately 2 out of 3 children with a health diagnosis of ASD are not receiving special education services specific to their disability. This is consistent with findings that children with an ASD health diagnosis often do not have a ASD special education eligibility (Pinborough-Zimmerman et. al, 2012). Little is known about characteristics of children receiving special education versus those who do not. Related to health diagnoses of ASD, children with more severe symptoms have been identified as having younger age of diagnosis (Jo et. al, 2015; Mandell, 2005). In addition, identification rates of ASD are generally higher in white, non-Hispanic males (Baio, 2014; Pettygrove et al., 2013).
Objectives: This study examined the rate of special education eligibility for children diagnosed with ASD as well as factors that predict if a child diagnosed with an autism spectrum disorder receives special education services. It was predicted that children with more significant adaptive delays would receive special education services at higher rates. Higher levels of special education eligibility were also expected for white, non-Hispanic males.
Methods: Data from a clinical sample of 285 children ages 3-21 who were diagnosed with ASD at a regional autism center was used. Data from record review including information regarding age(M = 4.8; SD =2.27), race (White N = 111, Black N = 117; Hispanic N = 35; Other N =9), gender (male N = 256; female N = 24), and adaptive behavior scores. The overall adaptive composite scores from the Vineland-II and the ABAS-II were combined for use in the analyses (M = 69.0,SD =12.48). Chi-square and binary logistic regression analyses were used to consider the effect of race, gender, and adaptive abilities on special education eligibility.
Results: Within the sample, 67% of children diagnosed with ASD received special education services. Gender was not predictive, but minority status trended towards significance, with minority children having higher rates of IEP placement than Caucasian children (X^2 (1, N =272) = 3.49, p =.06). Children's adaptive abilities were predictive of special education eligibility (Wald = 5.27, p<.05)
Conclusions: Consistent with previous studies, many children diagnosed with ASD did not receive special education services. Gender was not predictive of special education eligibility, though there was a trend towards minority children being more likely to have special education eligibility than Caucasian children. This trend is interesting given that previous studies have found a later age of diagnosis for children from diverse racial backgrounds. Higher rates of special education eligibility among minority children may reflect the extent to which children have more universal access to special education services than clinical diagnostic services. Results also indicate that children with more significant impairment receive special education services.

79 **123.079** Predictors of Parent-Teacher Agreement on Emotional and Behavioral Problems and Autism Symptoms in Youth with ASD and Their Typically Developing Siblings

***E. A. Stratis**[1,2] and L. Lecavalier[1], (1)The Ohio State University, Columbus, OH, (2)The Kennedy Krieger Institute, Baltimore, MD*

Background: It is often desired to elicit information from multiple informants when conducting psychological assessments of children. However, agreement between informants is imperfect, typically falling in the moderate range. Discrepancies between informants reflect, in part, contextual variations in children's behavior. For typically developing (TD) youth, several variables predict these discrepancies, including child and parent demographic characteristics. Despite being widely studied in TD youth, few consistent predictors have been identified. Additionally, limited information is available regarding predictors of informant agreement in youth with autism spectrum disorder (ASD).
Objectives: This study evaluated the magnitude of parent-teacher agreement on emotional and behavioral problems and symptoms of ASD, while also considering a number of demographic and clinical features as predictors of agreement. Comparisons were made across youth with ASD and their TD siblings.
Methods: Data from 618 families in the Simons Simplex Collection were utilized for this project. All of these families had complete parent and teacher ratings for both the child with ASD and the TD sibling. The Achenbach System of Empirically Based Assessment (ASEBA) was used to measure behavior and emotional problems and the Social Responsiveness Scale (SRS) was used to measure ASD symptoms. Magnitude of agreement was investigated utilizing Pearson and Intraclass Correlations. Predictors of agreement were considered in hierarchical regression analyses, utilizing three types of parent-teacher discrepancy scores as outcome variables.
Results: For children with ASD, parent-teacher agreement fell in the moderate range (r ranging .26 to .36) with no significant differences across type of problem assessed (externalizing behavior, internalizing behavior, ASD symptoms). For TD siblings, agreement also fell in the moderate range (r ranging .22 to .33), and agreement was significant higher for externalizing problems than internalizing problems and ASD symptoms.
Predictors of agreement varied across children with ASD and TD siblings. For children with ASD, child IQ, parent reported emotional and behavioral problems, and parent and teacher report of ASD symptoms predicted parent-teacher agreement on the ASEBA scales. On the SRS, child IQ, child receptive language, clinician rated ASD

symptoms, adaptive behavior, and parent and teacher reported emotional and behavioral problems were significant predictors of parent-teacher agreement. For TD siblings, parent and teacher reported ASD symptoms, and parental race and education were the only consistent predictors of parent-teacher agreement on the ASEBA scales. On the SRS, child sex, child race, parent and teacher rated emotional and behavioral problems, parental education, and parental broader autism phenotype characteristics were predictors of parent-teacher agreement.
Conclusions: This study highlights that the magnitude of parent-teacher agreement is similar across children with ASD and TD children, although patterns of agreement vary across these populations. Further, the factors that influence parent-teacher agreement on emotional and behavioral problems and ASD symptoms may vary across children with ASD and TD children. This implies that past research in TD children cannot be simply extended to children with ASD, and further research is needed to clarify what factors are associated with informant agreement in children with ASD to identify when the use of multiple informants is the most critical.

80 **123.080** Principal Pathogenetic Components in Autism Spectum Disorder: A Validation Study

C. Brogna[1], *R. Sacco*[2], *S. Bruccheri*[1], *A. Costa*[1], *G. Barbieri*[1], *G. Ferrarelli*[1] *and A. M. M. Persico*[3,4], *(1)Child and Adolescent Neuropsychiatry Unit & Laboratory of Mol. Psychiatry and Neurogenetics, University Campus Bio-Medico, Rome, Italy., Rome, Italy, (2)Univ. Campus Bio-Medico, Rome, Italy, (3)Child and Adolescent Neuropsychiatry Unit, Lab of Molecular Psychiatry and Neurogenics, University Campus Bio-Medico, Rome, Italy, (4)Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy*

Background: Applying principal component analysis (PCA), we previously described four pathogenetic components: I) “circadian and sensory dysfunction”, II) "immune dysfunction”, III) “neurodevelopmental delay", and IV) "stereotypic behavior” (Sacco et al., 2010). These four pathogenetic components subsequently defined four patient clusters: a) ICS (immune abnormalities and some circadian and sensory issues); b) CS (major circadian and sensory dysfunction, with little or no dysimmunity); c) S (prominent stereotypies) and (d) M (patients with a mixture of all four components associated with developmental delay).
Objectives: To replicate and to extend these results using an independent sample.
Methods: PCA followed by correlation analysis was performed on 19 clinical and family history variables in an independent sample of 192 ASD patients admitted to our Unit subsequently to the previous recruiting period (Sacco et al., 2010). This sample includes 163 males and 29 females, mean age 10.6 years (SD ± 6.8), belonging to 163 simplex and 29 multiplex Italian families.
Results: PCA revealed a component structure similar, but more complex compared to the previous structure, now encompassing five components which altogether explain 50% of the total variance. These include: 1) a “developmental delay” component, including various developmental milestones (non verbal and verbal language development, social smile onset, independent walking, acquisition of bladder and bowel control). These variables were also related to a positive history of obstetric complications and/or repeated spontaneous abortions in the mother; 2) a “lower functioning” component including intellectual disability, motor and/or verbal stereotypies, self-injurious behaviors; 3) a “mixed” component including sleep disorders, abnormal pregnancy duration, history of regression and hypotonia; 4) an “allergic” component including allergies in the patient, history of obstetric complications and/or repeated spontaneous abortions in the mother, level of verbal language development, and hyperactivity; 5) an “autoimmune” component including a family history positive for autoimmune diseases, history of any infectious disease at autism onset (i.e., recurrent otitis, upper airway infections, etc), excessive pain tolerance.
Conclusions: This validation study confirms the existence of the “Developmental delay” and “Immune” components, which seemingly represent consistent patterns in the ASD clinical phenotype in addition to the “low functioning” component. Interestingly, the former “Immune” component from Sacco et al. (2010) splits here into two components, one “allergic” and one “autoimmune”, suggesting two different pathways underlying the dysimmune endophenotype in ASD. Despite an extreme and long-recognized clinical heterogeneity, the autistic phenotype can be partly, yet consistently dissected on the basis of simple clinical and family history variables, allowing future investigations over patient clustering, biomarker identification, developmental trajectories, therapeutic outcomes and strategies.

81 **123.081** Qualitative Study on Functioning and Disability in ASD -the Development of WHO ICF Core Sets

S. Mahdi[1], *S. Bolte*[2], *A. Fallman*[1] *and J. Hattestrand*[1], *(1)Karolinska Institutet, Stockholm, Sweden, (2)Department of Women's and Children's Health, Pediatric Neuropsychiatry Unit, Karolinska Institutet, Stockholm, Sweden*

Background: The International Classification of Functioning, Disability and Health (ICF) was initiated by the World Health Organization (WHO) to provide a comprehensive and universally accepted framework for the description of health-related functioning. The ICF is based on a bio-psycho-social model of functioning, comprising over 1600 categories related to various components of health, specifically; *Body functions, Body structures, Activities, Participation* and *Environmental factors.* Not all are, however, applicable to a certain health condition. It is therefore the process has been initiated to develop ICF Core Sets for Autism Spectrum Disorder (ASD); lists of generally-agreed-upon ICF categories pertinent to individuals with a certain health condition. From these core sets diagnostic instruments can be derived for broad research and clinical use.
Objectives: This study is the third in a series of four international empirical investigations to develop ICF Core Sets for ASD. The objectives of the current study were twofold: First, to use a qualitative approach to capture the perspectives of individuals with ASD, their parents, professional caregivers, teachers, and representatives from interest organizations on functioning and disability in ASD. Second, to identify the meaningful concepts mentioned by the different stakeholders, number and link them to the ICF-CY (Children and Youth-version of the ICF).
Methods: Participants (N = 33) were recruited in Sweden from clinics and organizations related to ASD. They were then asked to take part in group discussions/individual interviews pertaining to functioning and disability in ASD. Seven questions were administered and meaningful concepts were extracted from their responses and then linked to the ICF-CY by three independent researchers. Group discussions/individual interviews are also being done internationally, but these have not yet been included in the analysis as the data collection process is still ongoing.
Results: Thirty-three transcriptions were included in the analysis and 1649 meaningful concepts contained in these transcriptions were linked to 146 ICF-CY categories. To include the most relevant ICF-CY categories related to ASD, only those that were identified in at least 5 % of the transcriptions were reported. This left 109 categories for the final results, of which 33 were related to *Body functions*, 3 were related to *Body structures*, 40 were related to *Activities and Participation*, and 33 were related to *Environmental factors*. The five most frequently identified categories were *products and technology for personal use in daily living (73 %), higher-level cognitive functions (70 %), sound (64 %), dispositions and intra-personal functions (61 %)* and *immediate family (55 %).*
Conclusions: The broad variety of ICF-CY categories identified in the Swedish study site attests to the complexity of ASD and underlies the potential value of the ICF-CY as a framework to capture an individual's functioning in different life-domains. The current study, which will be completed once results from other international study sites have been included, will in combination with three additional studies (systematic literature review, expert survey and clinical study) provide the scientific basis for defining the ICF Core Sets for ASD for multi-purpose use in basic and applied research and every day clinical practice of ASD.

82 **123.082** Screening for Autism Spectrum Disorders in Very Low Birth Weight Preterm Infants

V. R. Lederman[1], *A. L. Goulart*[2] *and J. S. Schwartzman*[3], *(1)Universidade Presbiteriana Mackenzie, Sao Paulo, Brazil, (2)Pediatrics, Universidade Federal de São Paulo/ Escola Paulista de Medicina, São Paulo, Brazil, (3)Universidade Presbiteriana Mackenzie, Sao paulo, Brazil*

Background: Very low birth weight preterm infants are a high-risk group for ASD, although there is no agreement about the rate. ASD signs can be detected earlier in infancy, but screening that population in different moments can lead to different results, due to developmental delays that may be present.
Objectives: to screen very low birth weight preterm infants for ASD signs between 18 and 24 month of corrected age, and reassess the sample, 12 month later in order to verify the permanence or not of the ASD signs.
Methods: 60 families of very low birth weight preterm infants between 18 and 24 month of corrected age answered the M-CHAT questionnaire (Robins et al, 2001). After 12 months, the same families answered de ABC questionnaire (Krug et al, 1980).
Results: Screening the very low birth weight preterm infants at 18 to 24 month found a rate of 6,7% of positive results for ASD. A second screening, performed one year later found a rate of 5,2% of positive results, although not all the same children of the first evaluation presented those signs: in the first screening with M-CHAT, girls and boys had positive screening for ASD signs, and in the second screening, with the ABC questionnaire, only boys. Comparison of the positive screening results in both moments, show a low degree of agreement between the questionnaires, Fisher test, p=0,196, Kappa agreement coefficient =0,241 (p=0,063). Positive-screening children were evaluated by diagnosis protocol, and 3,5% of our sample met de DSM-5 (2013) criteria for ASD
Conclusions: : Very low birth weight preterm infants are an ASD risk group; although the rates can be lower than former reports. Screening at age of 18 months allows identification of developmental delays, independently of a future ASD diagnosis. However, a single screening at this age, can lead to false-positive results, due to developmental delays common to the premature condition. A second screening, around 30 month of age is recommended, which also guaranties inclusion of regressive ASD cases.

83 **123.083** Sensory Processing Profile and Autistic Symptoms As Predictive Factors in Neurodevelopmental Disorder Diagnosis

M. Glod[1], *D. M. Riby*[2], *E. Honey*[3] *and J. Rodgers*[4], *(1)Newcastle University, Institute of Neuroscience, Newcastle Upon Tyne, England, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)CNDS, Northumbria Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, (4)Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Unusual sensory responses have been consistently reported as common in autism spectrum disorder (ASD) and were recently included in the diagnostic criteria. Sensory difficulties are also common among individuals with other neurodevelopmental disorders, including Williams syndrome (WS, a genetic condition characterized by developmental delays, learning disabilities and cardiovascular problems). Cross-syndrome comparisons of sensory atypicalities and the evaluation of their

syndrome-specificity, however, have rarely been undertaken. This analysis would enable us to determine whether there are unique syndrome-specific sensory signatures, which in turn may assist with differential diagnosis and tailored interventions.
Objectives: The aims of this study were: (a) to examine and compare the sensory profiles in three groups of children and adolescents; those with a diagnosis of ASD without learning disabilities (LD), ASD with learning disabilities and those with WS; (b) to investigate whether autistic symptoms, including sensory processing scores can predict a group membership.
Methods: Parents of 21 children with ASD and LD, 22 parents of children with ASD (no LD) and 18 with WS, aged between 4 and 16 years were recruited. Parents completed the Sensory Profile (SP; Dunn, 1999) to provide information about their child's sensory experiences and the Social Responsiveness Scale – second edition (SRS-2; Constantino & Gruber, 2012) to assess the degree of social impairment in their child.
Results: No significant differences were found in sensory processing scores between the three groups. Regression analyses were undertaken with sensory quadrants (Low Registration, Sensory Sensitivity, Sensation Seeking, and Sensory Avoiding) and SRS-2 total score as factors. Multinomial logistic regression was not possible due to similarities between the ASD groups. Binary logistic regression models were run for WS and ASD without LD; and WS and ASD with LD individually. Models significantly predicted group membership. In the WS and ASD no LD model Low Registration (β=.345, S.E.=.158, p=.029), Sensory Sensitivity (β=.383, S.E.=.193, p=.048) and SRS-2 total score (β=.178, S.E.=.078, p=.022) were significant predictors in the model, while in the WS and ASD with LD model there were only two significant predictors: Low Registration (β=.201, S.E.=.092, p=.028) and SRS-2 total score (β=.154, S.E.=.057, p=.007).
Conclusions: The findings suggest that sensory profiles of children and adolescents with WS and ASD are very similar. High rates of general sensory atypicality generally, therefore, are not autism-specific, but are a common neurodevelopmental characteristic that do not reliably distinguishing between WS and ASD groups. Low Registration and Sensory Sensitivity related behaviours might, however, be more specific to ASD. Further work is needed to explore behaviours within the sensory profiles that can discriminate between neurodevelopmental disorders and which therefore should be included in diagnostic classifications.

84 **123.084** Stability and Change for Toddlers with Autism Spectrum Disorder before Age 2: A 1.5-Year Follow-up

C. C. Wu[1], *Y. M. Hou*[2] *and C. H. Chiang*[3], *(1)Department of Psychology, Kaohsiung Medical University, Kaohsiung, Taiwan, (2)Chia-Yi Christian Hospital, Chiayi City ,Taiwan, Taiwan, (3)National Chengchi University, Taipei, Taiwan (Province of China)*

Background: Autism spectrum disorder (ASD) is thought as an innate neurodevelopmental disorder and characterized by impaired social communication and social interaction, as well as restricted and repetitive patterns of behavior and interest. Once thought to be a rare condition, ASD has recently emerged dramatically. The prevalence of ASD increases significantly beyond than 1 in 100 children (APA, 2013; Baird et al., 2006; Centers for Disease Control and Prevention, 2014). The increasing prevalence rate is due to improved awareness of ASD and service availability, and also highlights the importance of the early identification. Knowing the importance of early identification, the American Academy of Pediatrics (AAP) has recommended that all toddlers should receive screening for autism before age 2 (Johnson et al., 2007).
Objectives: A diagnosis of children with ASD appears to be stable in children as young as age 3. However, few studies examined stability and change of diagnosis for young children with ASD, especially for toddler before age 2. In this current study, longitudinal design was used to examine stability and change of diagnosis for toddlers with ASD before age 2.
Methods: There were 98 participants who had all administrated both of the Screening Tools for Autism in Two-Year-Olds, Taiwan version (T-STAT) (Chiang et al., 2013) and Autism Diagnostic Observation Schedule (ADOS) (Lord et al., 1999) between 17 and 24 months of age (Time 1, mean chronological age = 21 months) and received diagnostic and developmental reassessment between 35 and 46 months of age (Time 2, mean chronological age = 40 months). At Time 2, all participants were assessed and diagnosed according to DSM and with reference to developmental history and current concerns from parents, results of cognitive and adaptive function measures, observations of the child, and the results of ADOS by a multidisciplinary team that included senior child clinical psychologists with Ph.D. degree and senior child psychiatrists.
Results: Based on classification of the T-STAT (cutoff = 2.25), the results showed that the sensitivity and specificity are .89 and .81, respectively. In addition, positive predictive value (PPV) is .88 and negative predictive value (NPV) is .92. However, based on classification of the T-STAT (cutoff = 2.50), the results showed that the sensitivity and specificity are .87 and .83, respectively. In addition, PPV is .82 and NPV is .88. Based on classification of the ADOS (Time 1), the results showed that the sensitivity and specificity are .91 and .90, respectively. In addition, PPV is .89 and NPV is .92.
Conclusions: The results of this current study showed that reliable diagnosis of toddlers with ASD could be made before age 2 and have good short-term stability. In addition, the results of the current study showed that both the T-STAT and ADOS are promising tools to differentiate toddlers with ASD and toddlers with developmental delayed before age 2.

Table 1 Classification between screening tools (Time 1) and clinical diagnosis (Time 2)

	clinical diagnosis (Time 2)	
screening tools (Time 1)	ASD group (n = 46)	DD group (n = 52)
T-STAT (cutoff = 2.25)		
ASD group	41(89.1%)	10(19.2%)
DD group	5(10.9%)	42(80.8%)
T-STAT (cutoff = 2.50)		
ASD group	40(87%)	9(17.3%)
DD group	6(13%)	43(82.7%)
ADOS (module 1)		
ASD group	42(91.3%)	5(9.5%)
DD group	4(8.7%)	47(90.4%)

85 **123.085** Standardized ADOS-2 Toddler and Module 1 Severity Scores in a Clinical Sample

D. Hedley[1], *R. E. Nevill*[2], *M. Uljarevic*[3], *E. Butter*[4] *and J. A. Mulick*[5], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)The Ohio State University, Columbus, OH, (3)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia, (4)Nationwide Children's Hospital, Westerville, OH, (5)Pediatrics, The Ohio State University, Columbus, OH*

Background:
The ADOS-2 is a comprehensive assessment instrument which forms part of the recommended "gold standard" for the assessment of Autism Spectrum Disorder (ASD). While the instrument is primarily designed to classify cases of ASD based on raw scores, it is also possible to derive an algorithm of symptom severity from total scores. Standardized *calibrated severity scores* (CSS) provide a metric of the severity of autism-specific symptoms and behaviors and, unlike raw scores, are reasonably independent of factors such as IQ (particularly Verbal IQ), language and age. Severity scores were formally introduced for Modules 1-4 in the ADOS-2 revision. Recently, Esler et al. (2015) calculated total and domain CSS for the ADOS-2 Toddler Module, but the algorithm has yet to be verified in an independent sample.
Objectives:
Our aim was to examine the reliability and clinical utility of the ADOS-2 CSS for the Toddler Module in an independent clinical sample. A sample of children assessed with Module 1 were included for comparison purposes. Specifically, we focused on the application of ADOS-2 CSS algorithms in children aged 3 years and under.
Methods:
The sample consisted of 176 children (male = 88.1%; M_{age} = 32.21 months, *SD* = 6.23, range = 17-46 months). Of the 176 assessments, 125 received a diagnosis of ASD

(71%), 44 (25%) received non-spectrum diagnoses and seven (4%) children did not receive any medical diagnosis. Participants received extensive developmental and diagnostic assessments. Final diagnostic status was based on best estimate clinical (BEC) judgement involving DSM-5 criteria, parent interview, and assessment results including the ADOS-2. The final sample included 80 Toddler Module assessments (non-Verbal, NV = 62; some words, SW = 18) and 107 Module 1 assessments (NV = 70; SW = 37).
Results:
The CSS was more stable than raw scores across age and language as evidenced by fewer significant differences between scores across modules. Younger non-verbal participants scored higher than other groups, however effect size was reduced for the CSS compared to total and domain raw scores. The CSS was highly correlated with the clinician completed CARS2-ST, but not with the parent completed Autism Spectrum Rating Scale (ASRS). Neither gender nor chronological age were found to be associated with raw scores or the CSS. Linear regression indicated that verbal DQ was a significant predictor for raw scores but not the CSS. Auditory comprehension and Child Behavior Checklist (CBCL) externalizing behavior were significant predictors of total and domain raw scores and the CSS. Raw and CSS RRB scores were significantly influenced by nonverbal DQ and auditory comprehension.
Conclusions:
Our findings are consistent with previous research suggesting that, in clinical populations, ADOS-2 standardized scores are less influenced by participant characteristics than raw scores. These results offer support for the introduction of the Toddler Module CSS into clinical practice.

86 **123.086** Teachers Are Important Too! Incremental Validity of BASC-2 TRS in Predicting DSM-5 Autism Spectrum Disorder Severity Ratings

K. S. Ellison, *M. B. Bundy, D. B. Wygant and J. S. Gore, Psychology, Eastern Kentucky University, Richmond, KY*

Background: The DSM-5 conceptualizes the diagnostic criteria of autism as existing along a dimensional framework. Diagnosing clinicians must identify severity levels based on the amount of support needed in the areas of Social Communication (SC) and Restricted/Repetitive Behaviors (RRB). One clinician method for ascertaining a summary of client behavior is the broadband behavior-rating scale. Receiving behavior rating input from multiple informants is imperative; allowing for data to be gathered beyond what can be obtained from a single informant and for behavior to be represented as it occurs in multiple contexts (Kamphaus et al., 2000). The Behavior Assessment System for Children, Second Edition (BASC-2), one widely utilized instrument, is a multidimensional measure assessing internalizing and externalizing behaviors as well as adaptive functioning.
Objectives: The current investigation evaluated and compared how both parents and teachers view and report behaviors of individuals with ASD utilizing the BASC-2 Parent Rating Scale (PRS) and Teacher Rating Scale (TRS).
Methods: This research used archival data from university clinic records. The sample contained 67 individuals with ASD (59 males and 8 females) with age ranging from 26 to 217 months. Two expert reviewers confirmed that participants met DSM-5 ASD criteria and assigned severity ratings. .
Results: We tested whether teacher ratings would account for incremental variance above and beyond parent ratings of rationally selected BASC-2 Subscales (Adaptability, Aggression, Atypicality, Functional Communication, Social Skills and Withdrawal) in predicting the Severity Ratings for SC and RRB. We examined hierarchical regression analyses in which the parent ratings were entered in the first block of the regression model and the teacher ratings were added second as predictors of SC and RRB (see Table 1 and 2 respectively). Overall, teacher ratings enhanced the parent ratings of Adaptability, Atypicality, Functional Communication, Social Skills and Withdrawal when predicting the severity of SC. Teacher ratings augmented the parent ratings of Atypicality, Functional Communication, and Withdrawal when predicting the severity of RRB. The order of predictors was reversed to determine if this pattern would be replicated. Results yielded a significant incremental addition of the parent ratings to the teacher ratings of Functional Communication and Social Skills in predicting SC; this result was also evident for Functional Communication, Social Skills, and Withdrawal in predicting the severity RRB.
Conclusions: Predominately, teacher reports accounted for more predictive variance in our sample; teachers are providing incremental information above what is provided by parents. This is not to say that parents are unnecessary in the assessment process. As previous research demonstrates, parent-completed behavior ratings are a necessary and integral part to understanding a child's behavior (Bergeron et al., 2008). The results indicate that having teachers rate a child with ASD on the BASC-2 is necessary *in addition to* having the parents rate the same child. Both the BASC-2 PRS and TRS had unique predictive variance for particular scales. This information shows that both parents and teachers provide their own unique data when rating individuals with ASD. Teachers have important, additional viewpoints that should be utilized.

Table 1.
Predicting Social Communication Severity Ratings

87 **123.087** Team Evaluation: A Streamlined Method for the Clinical Assessment of Autism Spectrum Disorder

J. Gerdts[1], *J. Mancini*[2], *T. Ward*[3], *S. Trinh*[4], *M. Thompson*[5], *C. Rhoads*[5], *K. Oshiro*[5], *J. Han*[4] *and R. Bernier*[4], *(1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Seattle Children's Autism Center, Seattle, WA, (3)Seattle Pacific University, Seattle, WA, (4)University of Washington, Seattle, WA, (5)University of Washington Autism Center, Seattle, WA*

Background: Diagnostic evaluations for autism spectrum disorder (ASD) are generally either multi-disciplinary or single discipline (often with a psychologist). While these evaluations are comprehensive, they likely contribute to long waiting lists across the country since they generally include multiple visits on separate days, possibly several weeks apart. This presents an opportunity to examine the essential features of diagnostic evaluations to create a streamlined process for some families and thereby alleviating wait times. At the Seattle Children's Autism Center (SCAC), we have developed an interdisciplinary team evaluation approach involving a series of appointments with two providers, allowing two families to be seen in a single day. Thus, it may be a viable option for decreasing cost and improving wait times.
Objectives: To explore and compare family satisfaction, evaluation hours, and diagnostic outcomes in team evaluations versus more traditional ASD diagnostic evaluation methods. We also examined team members' diagnostic confidence ratings.
Methods: Following an initial visit with a SCAC pediatric nurse practitioner, patients were triaged to one of three ASD evaluation tracks: multi-visit evaluation with a

psychologist (*"Psychology"),* visit with a physician generally preceded by speech-language testing *("MD Confirm"*), or interdisciplinary team evaluation described above ("*Team"*). See Figure 1 for visit information about tracks and Figure 2 for *Team* evaluation template. Medical records were reviewed from 346 *Team*, 60 *MD Confirm*, and 92 *Psychology* evaluations conducted in 2014-2015.

Results: In *Team* evaluations, 61% of cases were diagnosed with ASD, 29% were not diagnosed with ASD, and 10% required further information in order to come to a diagnostic decision. Clinician confidence ratings were available for 23% of cases and were highly correlated ($r = .83$, $p < .001$), with 63% of ratings being identical and 32% within 1 point. After excluding *Team* patients who required further information to come to a decision, ASD diagnostic rates were similar across evaluation models (*Team*: 68%, *MD*: 73%, *Psych:* 72%, $\chi^2(2) = 0.89$, $p = .64$). The *Team* model required, on average, 4 fewer billing hours compared to *Psychology* and approximately the same number of hours as *MD Confirm*. Family satisfaction data were collected on a random sampling of patients seen in the three tracks. Results of family surveys suggested the majority of families were satisfied with their experience (M=8.88 out of 10) and scores did not differ across diagnostic tracks, $F(2,62) = 0.32$, $p = .73$.

Conclusions: ASD Interdisciplinary Team Evaluations shortened billing time and resulted in diagnostic determination in 90% of patients. Family satisfaction and overall rate of ASD diagnosis were similar across ASD evaluation methods, and comparable to a previous report of a 61% ASD diagnostic rate in a different diagnostic center (Monteiro et al., 2015). A focused team approach to ASD clinical diagnosis appears sufficient for many patients and may decrease the number of hours required for evaluation, while maintaining consistency in diagnostic rates and without detriment to family satisfaction. Thus, incorporating the *Team* model into diagnostic centers may decrease billing costs and improve clinic wait times.

Figure 1. SCAC Diagnostic Evaluation Flowchart

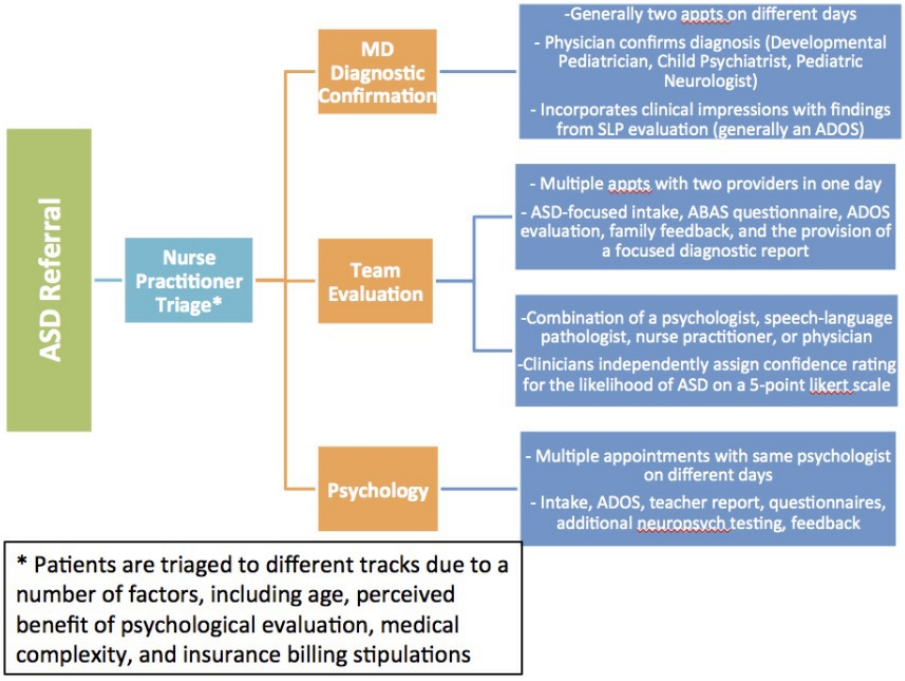

Figure 2. Team Evaluation Structure

	Clinician A	Clinician B
Hour 1	ADOS with Patient A *Hand off*	History with Patient B *Hand off*
Hour 2	ADOS with Patient B	History with Patient A
Hours 3 – 4	Rounds/write report	Rounds/write report
Hour 5*	Feedback with Patient A	Feedback with Patient B

* If diagnosis is unclear, the family is asked to return for a follow-up appointment(s) with one team clinician for further evaluation and/or to gather additional information (i.e., from teacher, other professional, etc) before making the diagnosis.

88 **123.088** Temper Tantrums in Preschool Age Children with and without Autism Spectrum Disorder

K. S. Davlantis[1], *G. Dawson*[1], *L. Franz*[1], *M. Sabatos-DeVito*[2], *E. Paisley*[1], *J. Newman*[1] *and H. Egger*[3], *(1)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (2)Duke University School of Medicine, Duke Center for Autism and Brain Development, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC*

Background: The presence of tantrums, aggressive behavior, and self-injury is related to significant parental stress and poorer long-term outcomes in children with autism spectrum disorder (ASD). Yet, very little is known about the frequency and nature of tantrums in young children with ASD and how they may differ from tantrums of neurotypical children.
Objectives: This project sought to characterize the frequency and nature of tantrums in preschool age children with ASD as compared to a representative community sample of neurotypical preschool age children.
Methods: This is a descriptive study of 25 children diagnosed with ASD (*M* age = 53.6 months, *SD* = 13.2 months; *M* IQ = 64.6, *SD* = 18.3) as compared to a representative community sample of 307 neurotypical children (*M* age = 40.8 months, *SD* = 14.4 months) recruited from pediatric primary care (percentages for the community sample are weighted back to the screened population sample of 1,073 children). Data collection is ongoing and additional data will be analyzed in the final study. The prevalence of non-destructive tantrums (i.e. episodes of temper, frustration, or upset manifested by shouting, crying, or stamping and non-destructive violence against property) and destructive tantrums (i.e. episodes of temper, frustration, or upset manifested by shouting, crying, or stamping and destructive violence or violence against oneself, other people, or

property), mean frequency of tantrums, and content of tantrums were measured using the Preschool Age Psychiatric Assessment (PAPA), a well-validated parent interview used to assess psychopathology in children ages 2 to 5 years. Chi-squared tests and general linear models were used to evaluate differences between groups.
Results: Thirty-three percent of neurotypical children versus 92% of children with ASD exhibited non-destructive tantrums over the three-month interview period (a significant difference at $p < .0001$). Twenty-six percent of neurotypical children versus 64% of children with ASD exhibited destructive tantrums over the same interval (a significant difference at $p < .0001$). Neurotypical children exhibited, on average, 9.3 tantrums over the three-month interview period, while those with ASD exhibited 49.8 tantrums over the same interval (a significant difference at $p < .0001$). The content of tantrums differed between groups, with children with ASD significantly more likely to engage in various behaviors (e.g., biting themselves).
Conclusions: Significant differences in the frequency and nature of tantrums were found between the ASD and neurotypical groups. While children with ASD exhibited more tantrums of both types, the primary difference was seen in the prevalence of non-destructive tantrums. The content of tantrums also differed between the groups, with children with ASD exhibiting significantly more of nearly every behavior assessed. This preliminary characterization of tantrums in children with ASD, as compared to neurotypical children, offers insight into a commonly-occurring associated symptom of ASD. Frequency and type of tantrums have been found to be associated with higher risk for mental health disorders in typical children. Future research is needed to examine the extent to which these early challenging behaviors are associated with later mental health and other behavioral outcomes in children with ASD.

89 **123.089** The Autism Mental Status Exam. Validation of a Spanish Version in Argentina

S. H. Cukier[1], *A. Rattazzi*[2], *V. M. Ensenat*[3], *M. C. Lopez*[4], *K. A. Gutson*[5], *J. I. Gomez de la Fuente*[2], *E. Zieba*[6] *and D. Grodberg*[7], *(1)PANAACEA, Buenos Aires, Capital Federal, Argentina, (2)PANAACEA, Buenos Aires, Argentina, (3)Pediatrics, British Hospital of Buenos Aires, Buenos Aires, Argentina, (4)Child and Adolescent Psychiatry, FLENI, Escobar, Argentina, (5)PANAACEA, Programa Argentino para Niños, Adolescentes y Adultos con Condiciones del Espectro Autista, Buenos Aires, Buenos Aires, Argentina, (6)Hospital Pedro De Elizalde, Buenos Aires, Argentina, (7)Yale Child Study Center, New Haven, CT*

Background: In many areas of Argentina, as in other Latin-American countries, physicians and institutions typically do not have the resources to train in or to administer comprehensive diagnostic observational assessments for patients suspected of ASD. This fact leads frequently to under and misdiagnosing leaving a very important amount of the population underserved, and preventing researchers from selecting representative samples for clinical and epidemiological research. The autism mental status exam (AMSE) is a free and brief eight-item observation tool that addresses this gap. The AMSE, designed at the Seaver Autism Center for Research and Treatment at the Icahn School of Medicine at Mount Sinai, structures the observation and documentation of signs and symptoms of ASD and yields a score. Excellent sensitivity and specificity was demonstrated in a population of high-risk adults and recently, in a population of 45 young children with social and communication concerns.
Objectives: To provide with a short and free diagnostic tool feasible to be used in middle –income countries such as Argentina by investigating the validity and inter-rater reliability of the Spanish version of the AMSE in a sample of local children and adolescents.
Methods: The AMSE was translated into Spanish, adapted to the local idiomatic expressions and back-translated into English. AMSE's test is now being performed in a population of 150 children and adolescents (age 18 months to 18 years) with social and communication concerns who are evaluated at four different autism centers in Argentina. The ADOS is to be used to estimate the most effective criterion cut-off on the AMSE for Argentine population. Each subject receives a developmental evaluation, including the AMSE followed by independent standardized assessment using the ADOS. Rapid Database Generator (RDG) toolset will be used to analyze the data, to determine cut off criteria, sensitivity and specificity of AMSE to predict the result from ADOS and DSM-5 diagnosis of ASD.
Results: A summary of the results including cut off criteria, sensitivity, specificity and inter-rater reliability will be presented, and also an analysis of regional similarities and differences. Preliminary results show good sensitivity (>95%), specificity (>95%) (using a cut-off of 5 points in AMSE), and inter-rater reliability (>80%) in this high-risk Argentine sample.
Conclusions: Preliminary findings suggest that the AMSE Spanish version provides a rapid and reliable observational assessment in high-risk Argentine population. This could have a direct impact in the care of patients with ASD by providing a free, standardized diagnostic tool for ASD. This project also addresses a research priority by reliably standardizing the phenotyping of children in under resourced international populations, since the use of the AMSE will lay the foundation for epidemiologic surveillance in populations that typically do not engage in research. Open-source and open access models also provide a way to facilitate global collaboration and training. Using tools like AMSE, the autism scientific community and clinicians worldwide should be able to deliver cost-effective services to everyone in need.

90 **123.090** The Development and Impementation of ASD Diagnostic Procedures in Nigeria

ABSTRACT WITHDRAWN

Background: The field is only beginning to understand how to identify ASD in non-Western populations. Simply translating instruments is not sufficient (Hableton, 1996); rather, they must be adapted to ensure construct equivalence, or the degree to which the measured construct has equivalent meaning across cultures. Construct, method and item biases are all important to consider in the adaptation of measures (Van de Vijver, F., & Tanzer, N. K., 1998).
Objectives: The project objective was to better understand the local norms in Lagos, Nigeria, in order to help the team at The Learning Place Centre (TLPC) develop an ASD diagnostic procedure. The acceptability and utility of the diagnostic procedure was qualitatively evaluated
Methods: TLP Centre in Lagos, Nigeria is an urban school and community-based autism center. They sought out AACTION Autism for assistance in developing a multidisciplinary diagnostic clinic. In the first phase of procedure development, we gathered qualitative information about the families who use the TLP Centre This occurred in conjunction with the Nigerian's team visiting Chicago. A culturally appropriate instrument (the Nigerian Autism Play Assessment- NAPA) was developed for use along with structured developmental interviews and medical history. The Nigerian team participated in general ASD training, as well as diagnostic evaluation overview. In the second phase, the team tested out the NAPA with 60 children ages 3-10 suspected of having ASD. The NAPA was refined based on feedback from TLP Centre staff.
The collected clinical information will be compared against DSM-5 and ICD-10 diagnostic criteria, and the team will arrive at diagnosis for each case. Reliability coders in the US, experienced ASD clinicians, will review the clinical reports (minus diagnosis) which includes data from medical and developmental histories, as well as the NAPA, and independently make the DSM-5 and ICD-10 diagnoses.
Results: We will present the results of the acceptability and fidelity of implementation from the field test. It is anticipated that an approach comparing information obtained via developmental history, the NAPA, and medical history with DSM-5 and ICD-10 diagnostic criteria will be useful and acceptable to the team. The inter-rater reliability between the TLP Centre raters and USA-based clinicians will be reported. The key aspects of the Nigerian culture that related to diagnostic process will be discussed.
Conclusions: Outcomes of the investigation will inform practices at the TLP Centre and throughout Africa, as the center actively participates in the Autism Society of West Africa meetings.

91 **123.091** The Difference of WISC-IV Profile Between ASD and TD Children in China

G. Li[1] *and Y. Du*[2], *(1)1551 Shoup Court , Room 334, Emory Autism Center, Atlanta, GA, (2)Shanghai Mental Health Center, Shanghai Jiaotong University School of Medicine, Shanghai, China*

Background: Autism spectrum disorder (ASD) is neurodevelopmental disorders characterized by severe deficits in social interaction and communication, an extremely limited range of activities and interests, and stereotypic and repetitive behavior according to DSM-5. Intelligence quotient (IQ) but not the core symptoms have been known to predict outcomes in autism. High functioning autism (HFA) has been used to describe individuals with AD whose IQ is above the intellectual disability range (70) since 1988. Many researches reported the IQ profile in High Functioning Autism (HFA). While there is no research about IQ profile reported in China. As ASD children are social deficit. We hypothesis is that HFA children scored lower on Verbal Comprehension Index and its subtests, no difference on other index and its subtests with TD children.
Objectives: This study aims to investigate the difference of IQ profile of HFA children and typically developing (TD) children in China.
Methods: The sample for the study was composed of 17 HFA children (14 males and 3 females; male: female ratio = 4.67:1) ranging in age from 6 to 16 years from Pediatric Outpatient of Shanghai Mental Health Center, Shanghai Jiaotong University School of Medicine. The children of control group were recruited in Shanghai. The control sample included 21 children (15 males and 6 females; male: female ratio = 2.5:1). The children's ages ranged from 6 to 16 years. Wechsler Intelligence Scale for Children (WISC-IV Chinese version) was used to rating the IQ profiles of children. All of the statistical analyses were performed using the Statistical Package for Social Sciences version 17.0.
Results: There was no difference of age (t = 0.593, P = 0.557) and sex (χ^2 = 0.643, P = 0.709) between the two groups. There was no significance between the two groups on block design (t = -1.808, P = 0.082) and digit span (t = -1.651, P = 0.110) . On other subtests, index scores, full scale IQ, HFA children scored significantly worse than TD children. The block design (=11.24+4.81), similarities (=11.18+4.89) was higher, while comprehension score was lowest (= 6.64 + 5.48) in ASD group.
Conclusions: The IQ profile of HFA children are different from TD children by WISC-IV in China.

92 **123.092** The PlacentASD® Test at Birth Predicts Subsequent Behavioral Outcomes

K. K. Quinlan[1], *K. O. Olive*[2], *K. M. Milano*[2] *and* ***H. J. Kliman***[2], *(1)Yale College, Yale University, New Haven, CT, (2)Dept. Ob/Gyn, Yale University, New Haven, CT*

Background: According to the Centers for Disease Control and Prevention (CDC), the average age of autism spectrum disorder (ASD) diagnosis in the US is over 4 years old, although methods are available to make the diagnosis at 2 years old. Early diagnosis and intervention have been shown to improve developmental outcomes in children

at a time when their brains are most responsive to modification. The PlacentASD® Test diagnoses ASD risk status at birth by evaluating the placenta of the newborn.
Objectives: We investigated the relationship between PlacentASD®-determined ASD risk status and the attainment of age-appropriate developmental milestones.
Methods: Fourteen newborn placentas were evaluated for the frequency of trophoblast inclusions to determine ASD risk status. Children were dichotomously divided into low-risk (having the same risk of developing ASD as the general population) or high-risk (having an increased risk of developing ASD). Two families were unable to be interviewed, both of which were determined to have children at low-risk for developing ASD. The remaining twelve families were interviewed between 2 and 24 months following delivery to assess motor (movement and physical development), language/communication, cognition (learning, thinking, and problem solving), and social/emotional behaviors of their child using published CDC milestone guidelines. The interviewer was blinded to the PlacentASD®results. Children were characterized as either neurotypical (achieving all age-appropriate behavioral categories) or delayed (delayed in any one or more behavioral categories). The Fisher exact probability test was used to compare the group outcomes.
Results: Of the twelve families who were interviewed, 5 children were at high-risk of developing ASD, while 7 children were at low-risk of developing ASD, as determined by PlacentASD® testing. All of the low-risk children were reported by their parents as having reached all appropriate behavioral milestones, while three of the five high-risk children had been diagnosed with developmental delays prior to 20 months of age. The other two high-risk children had reached all behavioral milestones at the time of the interview. Interestingly, two of the high-risk, developmentally delayed children, had undergone early intervention and progressed sufficiently to exhibit age appropriate behavioral milestones by the time they reached their second birthdays. Children designated as low-risk by the PlacentASD® Test were 4.5 times more likely to achieve normal developmental milestones compared to children designated as high-risk for ASD (LR: 4.5, 95% CI: 1.33–15.3; p = 0.045).
Conclusions: A low-risk determination by the PlacentASD® Test appears to predict neurotypical behavioral outcomes in children up to 24 months of age, while a high-risk determination poses a 4.5 times increased likelihood of children exhibiting developmental delays. Knowing that a child is at increased risk of developing ASD will allow parents and healthcare providers to initiate early intervention, which has the potential to normalize behavioral milestones.

93 **123.093** The Potential of Eye-Tracking As an Outcome Measure for Autism Intervention Studies

S. Fletcher-Watson[1] *and S. Hampton*[2]*, (1)University of Edinburgh, Edinburgh, Scotland, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom*

Background: Outcome measurement is a significant issue in autism intervention research. Among other concerns, it is possible that autism intervention trials may fail to detect change because of inadequate outcome measurement – either because changes occur in domains which are not measured or because the measures used are insufficiently sensitive. Short intervention periods may induce change in domains proximal to the intervention which would take longer to become apparent at the level of global symptom change. There is a need for objective measures, that can be administered by blinded researchers, to detect such proximal intervention effects.
Eye-tracking is a method which can be applied to non-verbal populations, to chart the development of cognition in early life, and to detect differences between typical and atypical populations in childhood, adolescence and adulthood. In both of these areas, eye-tracking is demonstrably pragmatic, objective and sensitive and can be administered blind. However eye-tracking is not normally used to evaluate response to intervention.
Objectives: To investigate whether eye-tracking can be used to detect subtle changes in eye-movements in response to repeated exposure to learning content.
Methods: Participants were 40 typically developing children, aged 20-25 months (mean = 23 months). We used a Tobii eye-tracker to assess free-viewing of**:** cartoon images from an iPad app called FindMe; cartoon images from other apps (close-generalisation)**;** photographs (distant-generalisation). All images were matched for level of complexity. Half the participants took home an iPad with the app for a period of 10 – 14 days. The FindMe app rewards participants for finding and touching the person within a scene. Then all participants returned to view the same stimuli again.
Results: Preliminary data (n=15) indicate that repeated exposure to visual content in an iPad app does change eye-movement patterns. For children in the app-exposure group, mean looking time on the person (FindMe images) increased by 80ms on average, while the control group had a looking time change of -3ms. In the final analysis we will report data on the relationship between level of exposure (e.g. amount of game play, highest level reached) and fixation patterns, as well as evidence of effects for close- and distant-generalisation stimuli.
Conclusions: This proof-of-concept study indicates that repeated exposure to learning content can, even in a very short period of time, lead to changes in fundamental behaviours which are indicative of underlying cognition. We will interpret results in the light of the potential future application to meaningful outcome measure in autism intervention, especially where interventions are mediated by technology.

94 **123.094** The Relationship Between Joint Attention, Play and Imitation Skills, with Cognitive Outcomes in Preschoolers with Autism Spectrum Disorder

H. C. Koh*, G. Swee, J. Ong, W. Q. Teoh and S. B. Lim, Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore*

Background:
Research evidence suggests that presence of early social behaviours such as joint attention, imitation and play skills, are associated with better cognitive and language outcomes in children with Autism Spectrum Disorder (ASD), although these findings need further replication with larger clinic samples.
Objectives:
This study aims to determine i) how joint attention, play and imitation skills are associated with cognitive abilities of children with ASD at 2-4 years old, and ii) how early social behaviours, cognitive abilities of children with ASD at 2-4 years old are associated with cognitive abilities of the children at 5-6 years old, in a clinic sample.
Methods:
A retrospective medical records review was conducted for 484 children with ASD who underwent a diagnostic assessment at 2-4 years old from 2009-2011 within a child development specialist clinic in Singapore. Measures of joint attention, play and imitation skills were taken from the Autism Diagnostic Observation Schedule (ADOS), which was the standard behaviour observation tool used for ASD diagnostic evaluations within the clinic. A variety of cognitive assessments were used to measure cognitive abilities of the children at 2-4 years old and at 5-6 years old. Standard scores that provide estimates of a child's non-verbal reasoning abilities were used where available. The children's cognitive assessment results were categorized into Adequate (IQ≥80) or Delayed (IQ<80). A proportion of the children completed a cognitive assessment at 2-4 years old (*n*=291, 246 boys), as cognitive assessments were optional for ASD diagnostic evaluations. A smaller selection of those children had their cognitive assessment results at 5-6 year old available in their medical records (*n*=187, 160 boys).
Results:
Logistic regression analyses indicate that ratings on functional and make-believe play significantly predicted cognitive assessment results at 2-4 years old, and ratings on initiation of joint attention and a child's cognitive assessment results at 2-4 years old significantly predicted cognitive assessment results at 5-6 years old.
Conclusions:
Children with ASD who demonstrated better play with toys/objects were more likely to have adequate cognitive assessment results at 2-4 years old. Children who obtained adequate cognitive assessment results at 2-4 years old, were more likely to show similar results at 5-6 years old. Children with ASD who were better at initiating joint attention with others at 2-4 years old, were more likely to have adequate cognitive assessment results at 5-6 years old. Children who direct others' attention to objects of interest to them, may respond better to cooperative learning approaches, which can better facilitate their cognitive development.
These results highlight significant relationships between joint attention and play, for cognitive abilities of children with ASD. Interventions that target joint attention and play in children with ASD can be further investigated to determine if developing joint attention and play skills in children with ASD can improve their cognitive outcomes.

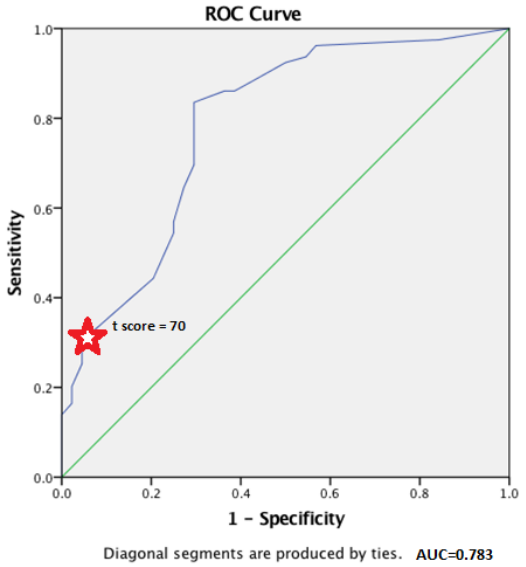
95 **123.095** The Validity of the Child Behavior Checklist in Identifying Anxiety Disorders in Children with ASD

A. Bennett[1]*, M. C. Souders*[2]*, L. R. Guy*[3]*, K. Rump*[4]*, J. Worley*[5]*, H. E. Dingfelder*[6]*, J. C. Bush*[7]*, A. McVey*[8]*, C. M. Kerns*[9]*, J. Miller*[10]*, J. Herrington*[11] *and M. Franklin*[12]*, (1)Child Development, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Clinical Genetics Center, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (4)The Center for Autism Research, Philadelphia, PA, (5)CHOP, Blue Bell, PA, (6)University of Pennsylvania, Philadelphia, PA, (7)Indiana University, Bloomington, IN, (8)Marquette University, Milwaukee, WI, (9)A.J. Drexel Autism Institute, Philadelphia, PA, (10)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (11)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (12)Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: While there is increased awareness of the impact of elevated anxiety rates in ASD, there are few well-validated screening measures for identifying DSM-based anxiety disorders in children or adolescents with ASD. The Child Behavior Checklist (CBCL) is a parent-completed behavioral screening measure that has been used in several autism registry networks, including the Autism Speaks Autism Treatment Network (AS-ATN), the Center for Disease Control (CDC) Study to Explore Early Development (SEED), and the Simons Foundation Autism Research Initiative (SFARI). It is also often used in clinical settings as a behavioral screening measure for children. For these reasons, data on the validity of the CBCL in predicting true anxiety disorders in children with ASD could have a significant influence on clinical practice as well as ASD research initiatives.
Objectives: The objective of this study was to examine the validity of the CBCL anxiety subscale in children and adolescents with ASD versus typically developing controls (TDCs). Ratings on the CBCL were used to predict DSM-driven anxiety disorder diagnoses established via psychodiagnostic interviewing (the gold-standard Anxiety Disorder Interview Schedule [ADIS]).
Methods: 204 children were recruited through two studies following a two-by-two factorial design, including children with (ASD) and without ASD (TDC) and with (ANX) and without (NON) an anxiety disorder (ASDANX: N = 79; ASDNON: N = 44; TDCANX: N = 18; TDCNON: N = 30; mean age = 11 years). ASD diagnosis was confirmed through research-reliable ADOS and parent interview. Anxiety diagnoses were determined by the ADIS. The ASDANX and TDCANX groups presented with a range of anxiety

disorders, including social anxiety disorder, generalized anxiety disorder, separation anxiety disorder, and specific phobia. None of the groups differed in general cognitive ability or age. Subjects in the ASD groups did not differ in core symptoms of ASD (measured by the Social Responsiveness Scale [SRS]). Sensitivity and specificity of CBCL in predicting anxiety disorder status was examined via multinomial logistic regression (MLR) and receiver operating characteristic (ROC) curves, carried out separately for the ASD and TDC groups.
Results: CBCL Anxiety subscale t-score of 70 was highly predictive of anxiety disorder diagnosis among children with ASD (Chi Square = 61.97, p < .01) on MLR. CBCL successfully classified ASD participants as ANX or NON with an overall accuracy of 79%. Sensitivity (86% true positive rate) was superior to specificity (68% true negative rate). ROC curve had AUC=0.783. Although fairly robust, these predictive rates were lower than the predictive rates of anxiety disorder among TDCs for this study (94% and 93%, respectively).
Conclusions: The CBCL Anxiety subscale has good convergent validity with gold standard diagnostic tools designed to measure common anxiety disorders in children and adolescents. The relatively higher rate of sensitivity versus specificity indicates that the CBCL may prove more valuable in identifying co-occurring anxiety disorder in children with ASD rather than in ruling anxiety out. Further research is needed to determine if a different t-score or separate ASD-Anxiety subscale should be created to identify the unique features of Anxiety in children with ASD.

Fig. 1



96 **123.096** The Value of the AQ in Outpatient Mental Health Service

*M. L. Bezemer and **E. M. Blijd-Hoogewys**, Autism Team, INTER-PSY, Groningen, Netherlands*

Background:
In clinical practice, the Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001) is often used to measure the degree to which adults exhibit autistic traits and to decide whether further ASD assessment is required (case identification).
The AQ is a self-report questionnaire. Since self-insight might be diminished in individuals with ASD, the perspective of an informant is important. Therefore, an AQ Dutch spouse-version was developed (Blijd-Hoogewys, 2014).
There is debate on whether there are gender differences concerning the expression of autistic traits, and whether these differences influence case identification.
Objectives:
The aim was to study the value of the AQ as an instrument for case identification, comparing self-report and spouse-report, and gender differences.
Methods:
The sample consisted of Dutch patients with a suspected ASD and an average intelligence. They were referred to a specialized ASD outpatient mental health service.
In total, there were 194 AQ self-reports (n = 106 men, n = 88 women) and 49 AQ spouse-reports (n = 26 men, n = 23 women). AQ-scores were analyzed, using a clinical cut-off point of 26 (dichotomous scoring).
Results:
There was no significant difference in AQ-score between self-report and spouse-report (M = 28.08, SD = 9.14; M = 27.02, SD = 8.03 respectively; t = .61, df = 96, p = .54).
Concerning the classification of the AQ-score as clinical (≥ 26) or non-clinical, there was a moderate agreement between self-report and spouse-report (κ = .58, p < .001).
The AQ-scores of men and woman did not differ significantly on the self-report (M = 25.06, SD = 9.28; M = 25.51, SD = 9.11 respectively; t =-.34, df = 192, p = .73). They did differ significantly on the spouse-report (men: M = 29.60, SD = 6.57; women: M = 24.13, SD = 8.67; t = 2.50, df = 47, p =. 02).
Results of the self-reports showed a relation between AQ-score above/below cut-off and the presence/absence of an ASD-diagnosis (X^2 = 28.15, df = 1, p < .001). Overall, 76% of participants with clinically elevated AQ-scores were diagnosed with ASD (versus 38% of participants with non-clinical AQ-scores). The predictive values of the AQ differed for men and women. For men, sensitivity was 58% and specificity was 66% (PPV = 0.73, NPV = 0.50). For women, sensitivity was 73% and specificity was 82% (PPV = 0.80, NPV = 0.75). The same pattern was seen in spouse-reports.
Conclusions:
The AQ is moderately valuable for case-identification in an outpatient mental health service. The AQ self-report and AQ spouse-report give roughly similar information about autistic traits. There are gender differences though; female spouses report their men to exhibit more ASD traits than reported by the men themselves. Also, the AQ self-report of women seems to be more predictive for an ASD diagnosis than those of men.
Note that the AQ is not intended to be diagnostic. If there are clinically significant levels of autistic traits, a comprehensive diagnostic evaluation is warranted.

97 **123.097** Timing of ASD Diagnosis: Demographic Factors of Influence

***E. J. Libsack**[1], A. Kresse[1], E. E. Neuhaus[2], S. Trinh[3], R. Bernier[3] and S. J. J. Webb[3], (1)Seattle Children's Research Institute, Seattle, WA, (2)Seattle Children's Hospital, Seattle, WA, (3)University of Washington, Seattle, WA*

Background: The average age of diagnosis among children with Autism Spectrum Disorder (ASD) exceeds 4 years, often with a significant lag between parent first concern and diagnosis. While studies have investigated the impact of demographic factors on likelihood of ASD diagnosis, their impact on the timing of diagnosis is less clear. Girls and high functioning children may be more likely to experience significant diagnostic delays given current (and historic) public perception of the disorder.
Objectives: Data are from a multi-site study focusing on multimodal neurogenetic exploration of girls (and boys) with ASD. In a sample of children with ASD without intellectual impairment, we explore the effects of parental education, household income, child gender, and child birth-order on parent report of the timing of ASD diagnosis.
Methods: Preliminary data were analyzed from one site and included 43 children (26 males; 8-17 years) with ASD (mean IQ=104.4, SD=21.2). Parents completed a demographic questionnaire, medical history interview, and Autism Diagnostic Interview Revised. In order to analyze the influence of child gender, we matched a subsample of 17 ASD males and 17 ASD females on age and IQ. Additional data from other sites will be included in the final analyses.
Results: Children who had two parents with less than a bachelor's degree (non-BA), were diagnosed with ASD at a significantly later age (M=111.7, SD=52.9) than children with one parent with at least a bachelor's degree (BA-1; M=66.8, SD=31.2, p=.02), and children with two parents with at least a bachelor's degree (BA-2; M=66.8, SD=32.6,

p<.01). Children in the non-BA group also experienced a significantly longer delay (M=109.2, SD=24.5) from age of parental first concern to age of ASD diagnosis, than children in the BA-1 (M=51.8, SD=28.7, p<.01) and BA-2 (M=58.5, SD=37.4, p<.01) groups. There was no effect of household income on timing of diagnosis.
In our IQ- and age-matched subsample, time between age of first concern and ASD diagnosis was marginally longer for females (M=76.1, SD=44.5) than males (M=52.8, SD=30.3, p=.09). Later-born females (M=108.3, SD=32.6) were diagnosed with ASD at a later age than later-born males (M=58.5, SD=29.5, p=.04).
Conclusions: Children whose parents have more formal education were diagnosed with ASD at an earlier age and experienced a shorter delay between parent concern and ASD diagnosis. These findings suggest that higher parent education, separate from household income, influenced timing of diagnosis. Males also experienced a marginally shorter wait time between parents' first concern and ASD diagnosis than females, particularly for later-born children. Gender did not significantly effect age of ASD diagnosis, but data collection is on-going and additional data from 3 other sites will be available. Together, our findings suggest an influential role of both parent education and child gender in the timing of ASD diagnosis even within children with higher functioning ASD outcomes.

98 **123.098** Two Validation Studies of a Performance Validity Test for Autism Spectrum Disorder

L. M. Olde Dubbelink[1,2], *A. M. Scheeren*[1], *A. G. Lever*[1] *and H. M. Geurts*[3], *(1)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam, Amsterdam, Netherlands, (2)Dept. of Research, Development & Innovation, Dr. Leo Kannerhuis, Doorwerth, Netherlands, (3)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology, Brain and Cognition, University of Amsterdam; Dr. Leo Kannerhuis, Amsterdam, Netherlands*

Background: People seeking treatment for psychological symptoms can feign or exaggerate their functioning in order to receive external incentives such as financial aids or reduced responsibility for criminal actions. To detect malingering and increase diagnostic accuracy, performance validity tests (PVT's) are used in (neuro)psychological assessments. Currently, no PVT exists for autism spectrum disorder (ASD). Therefore, in two studies, we examined whether the Morel Emotional Numbing Test (MENT), a simple emotion recognition test, has potential as a PVT for ASD in adulthood. As intelligent adults with ASD usually do not have difficulties in recognizing simple emotions, we hypothesized that they would perform near to perfect on the MENT. Furthermore, we hypothesized that instructed malingerers would perform poorly on this test.
Objectives: To examine the validity of a simple emotion recognition task, the MENT, as a PVT for adults with ASD.
Methods: In Study 1, 19 adults with ASD and 19 typically developing (TD) controls(age: 27-54; IQ>80) completed the MENT. In Study 2, 26 TD students instructed to simulate ASD and 26 TD controls (age: 18-46) completed the MENT.
Results: In Study 1, Bayesian hypotheses testing showed that adults with and without ASD performed equally well on the MENT. In Study 2, group comparisons demonstrated that instructed malingerers made more errors on the MENT than those instructed to do their best. Moreover, instructed malingerers performed worse on the MENT than adults with ASD. ROC curve analyses demonstrated that a cut-off point of 7 errors reached a specificity of 100% and a sensitivity of 96%.
Conclusions: These study findings suggest that the MENT may be considered as a PVT for ASD, because it appears to be face-valid measure of ASD, is insensitive to ASD (i.e. has high specificity), and detects malingerers by luring them to perform beneath their true level of ability (i.e. has high sensitivity). However, one should note that these findings are preliminary as the performances of intelligent adults with ASD (Study 1) may not generalize to individuals with ASD with lower intellectual abilities or a broader age range. Moreover, performances of healthy students instructed to malinger as reported in Study 2 may not be comparable to the performances of those suspected of malingering in a real diagnostic setting. Therefore, we encourage future research on the validity of the MENT as a PVT for ASD in a clinical or a forensic context.

99 **123.099** Validation of Eye Gaze Response to Dynamic Social Stimuli As Biomarker Related to Social Communication for Clinical Trials Involving Children with ASD

B. P. Rardin[1], *M. Murias*[2], *S. T. Major*[1], *M. Sabatos-DeVito*[3], *J. Newman*[1], *K. S. Davlantis*[1] *and G. Dawson*[1], *(1)Duke Center for Autism and Brain Development, Duke University School of Medicine, Durham, NC, (2)Duke University, Durham, NC, (3)Duke University School of Medicine, Duke Center for Autism and Brain Development, Durham, NC*

Background: Eye-gaze tracking (EGT), a non-invasive and objective measure of an individual's gaze response to visual stimuli, is easy to administer and has been shown to differentiate autism spectrum disorder (ASD) from other populations across the age span. It has been demonstrated that children with ASD show differential gaze patterns and attention when presented with socially salient stimuli, an important finding given that social communication deficits are a core feature of ASD. EGT has been proposed as a potential stratification or early efficacy biomarker in clinical trials assessing treatments for social communication impairments in children with ASD. However, its correlation with well-validated measures of social communication impairments has not yet been established.
Objectives: The study examined the degree to which eye-gaze patterns towards social stimuli are correlated with well-validated parent-report measures of social communication that are commonly used in clinical trials with children with ASD.
Methods: Participants were 25 children diagnosed with ASD based on the ADOS-2 and ADI-R (M age = 4.47 (+/- 1.10) years; M NVIQ = 64.3 (+/- 24.6)). EGT data were collected using the Tobii TX300 system at a sampling rate of 120 Hz. Participants were shown a three-minute video stimulus that included an actress and distractor toys (Chawarska et al. 2012). Two subjects were excluded due to noncompliance. Data analysis was constrained to time periods when the actress on the video directed speech toward the child. Dependent variables were proportion of time viewing the video presentation and proportion of time spent viewing actress. Analyses examined the correlations between the EGT variables and measures of social communication derived from the Vineland Adaptive Behavior Scales (Vineland-II), PDD Behavior Inventory (PDDB-I), and Behavior Assessment System for Children (BASC-2).
Results: The proportion of time viewing stimuli was highly correlated with the PDDB-I – Expressive Social Communication Abilities Composite score (r=0.72, p<0.001), PDDB-I – Expressive/Receptive Social Communication Abilities Composite score (r=0.68, p<0.001), and the Vineland-II – Expressive Communication Composite score (r=0.69, p<0.001). The proportion of time spent viewing the actress was strongly correlated with the BASC-2 – Functional Communication score (r=0.69, p<0.001), PDDB-I – Expressive Social Communication Abilities Composite score (r=0.73, p<0.001), PDDB-I – Expressive/Receptive Social Communication Abilities Composite score (r=0.68, p<0.001), and the Vineland-II – Expressive Communication Composite score (r=0.76, p<0.001). Notably, neither EGT measure was correlated with the PDDB-I Autism Composite score, a measure of broad ASD symptoms, (r=0.19 and 0.25, respectively).
Conclusions: Eye-gaze responses to dynamic social stimuli were found to be strongly and consistently correlated with well-validated parent-report measures of social communication. EGT variables did not correlate with broader autism symptom measures that include repetitive/restricted behaviors, suggesting that the EGT variables were specifically related to social communication impairments. Given the relative ease of using EGT with children with ASD, these findings support the ability of eye-gaze in response to dynamic social stimuli to serve as a non-invasive and objective biomarker of social communication in clinical trials. The present study is ongoing, and a final analysis will be conducted on a larger sample of children with ASD.

Poster Session
124 - Medical and Psychiatric Comorbidity
5:30 PM - 7:00 PM - Hall A

100 **124.100** A Case Study of the Gut Microbiome in ASD: Correlation of Microbial Profiles with GI and Behavioral Symptoms

R. A. Luna[1,2], *A. Magee*[1,2], *J. K. Runge*[1,2], *A. Venkatachalam*[1,2], *M. Rubio-Gonzales*[1,2] *and J. Versalovic*[1,2], *(1)Texas Children's Microbiome Center, Texas Children's Hospital, Houston, TX, (2)Department of Pathology & Immunology, Baylor College of Medicine, Houston, TX*

Background: Gastrointestinal (GI) disorders are now widely recognized as a clinical symptom of autism spectrum disorder, and research into the microbiome-gut-brain axis is beginning to reveal the interconnectivity between GI pain and potential behavioral challenges. Large studies in well-controlled cohorts are needed to provide the baseline dataset for this population, but there can be much learned from individual case studies, especially those with a longitudinal component. As a prelude to a much larger study underway, a single child with autism was followed over a 2-week period, including daily stool collection, alongside a neurotypical sibling for comparison.
Objectives: The objectives of this case study were to 1) evaluate current sequencing and analysis strategies to assess the microbial profile in a child with autism compared to an unaffected sibling, 2) correlate GI symptoms, stooling pattern, and diet diaries as well as available behavioral data over a 2-week period, and 3) identify organisms of interest for exploration in a larger dataset in the future.
Methods: Over a 2 week period, daily stool samples (plus one additional sample) were collected from the child with ASD with a single stool sample collected from an unaffected sibling. Next-generation sequencing (454 and Illumina) of the V1V3 and V4 variable regions of the 16S rRNA gene was performed, and resulting sequences were quality filtered, assigned to operational taxonomic units (OTUs), and classified based on comparison to the Greengenes database. Individual species of interest in ASD as well as OTUs of significance related to the child with ASD and absent in the unaffected sibling were identified.
Results: Principal component analysis revealed clear separation between the 15 samples obtained from the child with ASD compared to the unaffected sibling. Three organisms (individual OTUs) previously reported in autism were identified in the microbial profile of each of the 15 ASD samples but absent in the microbial profile of the unaffected sibling: *Sarcina ventriculi*, *Barnesiella intestihominis*, and *Clostridium bartlettii*. In addition, distinct differences were seen in the microbiome of the ASD child during days 6-8, a period where GI symptoms were reported (pain and diarrhea). Of note, the detection of *Haemophilus parainfluenzae*appeared to coincide with the onset of the GI episode. Beyond the correlation of GI symptoms with changes in the microbiome, that period also coincided with a trend toward behavior challenges, specifically an increase in self-injurious behavior. A separate 2-day period exhibiting the same microbial profile did not coincide with a change in GI symptoms but was accompanied by the same increase in self-injurious behavior, suggesting the possibility of GI pain that was not reflected in a change in stooling pattern.

Conclusions: While in-depth studies of the gut microbiome in autism that are underway will generate the critical mass of data needed as a comparison dataset, this case study illustrates the benefit of longitudinal sampling of a single patient in parallel with collection of clinical metadata (behavioral, gastrointestinal, and dietary). Microbiome characterization shows great potential as a companion diagnostic in the evaluation of individuals with autism spectrum disorder.

101 **124.101** A Profile on Healthcare Utilization during the First Year of Life in Children with Autism Spectrum Disorder

G. Liu[1], *L. Kong*[1], *D. Leslie*[1] *and M. Murray*[2], *(1)Public Health Sciences, Penn State College of Medicine, Hershey, PA, (2)Psychiatry, Penn State Hershey, Hershey, PA*

Background: The prevalence of autism spectrum disorder (ASD) has been increasing at an alarming rate. Despite the fact that there has been mounting evidence suggesting that ASD can be traced back to as early as the second trimester of pregnancy, most children with ASD are not diagnosed until age 4 or older. While studies from recent decades have presented substantial evidence on the effectiveness and importance of early detection and intervention, there has been little progress in identifying early markers to identify children at high risk of developing ASD.
Objectives: In this study, we use a large, national claims database to comprehensively examine the healthcare utilization history of children during their first year of life. The goal of this study is to develop an understanding on the medical profile of ASD-affected children during infancy and identify early indicators that are associated with the ASD risk.
Methods: Using claims data from the MarketScan® Commercial Claims and Encounters database (2005-2013), we identified children who were born in this period and were followed up for at least one year. We constructed a cohort of children with at least two separate diagnoses of ASD (ICD 9 codes 299.0x and 299.8x), as well as a control cohort of children with no ASD diagnosis before the age of 6. We linked their medical and demographical information to establish a complete medical profile of their first year since birth. We constructed the following healthcare utilization measures for the first year since birth: (1) healthcare expenditures (adjusted to year 2013 dollars), (2) in-/out-patient encounters, (3) hospital length of stay (in days), and (4) emergency department (ED) visits. Furthermore, we calculated the number of ED visits during the first 6 months and used multivariable logistic regression to determine the association between the number of ED visits and age at initial ASD diagnosis.
Results: We identified a total of 274,141 children, of whom 7,959 (2.9%) had ASD. Healthcare utilization measures during the first year of life showed significant differences (p-value <.0001) between children with ASD and those without. On average, ASD children had higher healthcare costs, more in-/out-patient encounters, longer stay in hospitals and more ED visits. In particular, the multivariable logistic regression confirmed that the frequency of ED visits in the first 6 months is significantly associated with the risk of being diagnosed with ASD later on, after controlling for gender, geographic region and residence (urban vs. rural). Compared with children without any ED visit in the first 6 months, the adjusted odd ratios (confidence intervals) of ASD risk for 1, 2, 3, and >3 ED visits were 1.24 (1.16-1.33), 1.39 (1.22-1.58), 1.93 (1.58-2.37) and 3.27 (2.63-4.06), respectively.
Conclusions: Children who were later on diagnosed with ASD had distinct patterns of healthcare utilization even during their infancy. They used more healthcare services than non-ASD children; even as early as within 6 months after birth, well before any clinically identifiable ASD symptoms were able to manifest.

Table 1. Healthcare utilization during the first year of life in children with and without ASD.

	ASD (n=7,959)	Non-ASD (n=xx)
Medical cost		
Mean (sd)	20,556 (100,018)	8,481 (46,094)
Median(25th-75th)	4,042 (1,986-8,257)	3,018 (1,539-5,202)
Number of encounters		
Mean (std)	15.5 (14.2)	12.4 (8.7)
Median(25th-75th)	12 (8-18)	11 (7-16)
Length of hospital stay		
Mean (std)	7.2 (18.4)	4.1 (10.0)
Median(25th-75th)	3 (2-4)	2 (2-3)
ED visits		
Mean (std)	0.51 (1.17)	0.36 (1.00)
Median(25th-75th)	0 (0-1)	0 (0-1)

102 **124.102** ADHD Diagnosis and Treatment Among ADHD Children with and without ASD

B. Zablotsky*, M. D. Bramlett and S. J. Blumberg, National Center for Health Statistics, Hyattsville, MD*

Background: Children diagnosed with autism spectrum disorder (ASD) are commonly diagnosed with other co-occurring developmental, psychiatric, neurological and medical conditions (Levy et al., 2010). The most prevalent psychiatric co-occurring condition is attention-deficit/hyperactivity disorder (ADHD), with approximately one in two children with ASD also having ADHD (Zablotsky et al., 2015). Parents of children diagnosed with ASD frequently report obstacles in accessing and receiving care for their child's ASD (Kogan et al., 2008). However, little is known about how a child's ASD may affect the ability to receive care for other mental health conditions, more specifically whether a diagnosis of ASD may make receipt of services for ADHD easier or more difficult among children with both conditions.
Objectives: 1) Compare the age of ADHD diagnosis and the age of first ADHD medication between children currently diagnosed with ADHD and ASD to children currently diagnosed with ADHD without ASD, 2) Explore whether ADHD treatment barriers and parental satisfaction of their child's ADHD management and treatment vary by whether a child is currently diagnosed with ASD.
Methods: Data are drawn from the 2014 National Survey of the Diagnosis and Treatment of Attention-Deficit/Hyperactivity Disorder and Tourette Syndrome (NS-DATA), a follow-up to the 2011-2012 National Survey of Children's Health. Households with a child between the ages of 4-17 and currently diagnosed with ADHD were eligible for the current study (n=2,464). Children currently diagnosed with ASD and ADHD (n=352) were compared to those who were diagnosed with ADHD without ASD (n=2,112). Prevalence estimates were calculated using Stata 13.1 SE, which accounted for the complex survey design of the NS-DATA. Differences between children with and without current ASD were compared using multivariate logistic regression, controlling for differences between the groups in demographics, ADHD severity, and the impact of the child's ADHD on the family. Interaction terms were used to test whether the effects of covariates differed by whether the child had ASD or not.
Results: Among children with ADHD, those with ASD were diagnosed with ADHD at an earlier age and started treatment with medication for ADHD at an earlier age. Approximately 11% of children with ADHD had trouble obtaining treatment for their ADHD regardless of whether the child was currently diagnosed with ASD. Additionally, children in the two groups had parents who were equally satisfied with the ADHD treatment and management their child receives.
The effects of most covariates did not differ by whether the child has a current ASD diagnosis, with two exceptions: girls had a later age of first ADHD medication than boys, unless they had ASD, in which case they had a younger age than boys; and non-Hispanic black children had a higher unmet treatment need than all other children if they had been diagnosed with ASD.
Conclusions: The presence of ASD may prompt diagnostic services for a developmental disorder at an earlier age. However, after receiving an ADHD diagnosis, children with ASD do not appear much different than children without ASD.

103 **124.103** Adaptive Behavior Impairments Vary with Depression Status in Adolescents and Young Adults with ASD

R. N. Crist[1] *and K. Gotham*[2], *(1)Psychiatry, Vanderbilt University School of Medicine, Nashville, TN, (2)Vanderbilt University, Nashville, TN*

Background:
Adaptive behavior is an important index of functioning in autism spectrum disorder (ASD), and has been shown to predict adult outcomes within this population (Howlin, 2000). ASD is associated with high rates of impairment in adaptive behavior (Rydén & Bejerot, 2008). Despite highly variable symptom expression and intellectual functioning within ASD, existing literature supports a general pattern in the adaptive behavior profiles of adults with ASD, with relative strengths in daily living skills and to a lesser extent communication, and relative weaknesses in socialization (Farley et al., 2009; Kanne et al., 2010).
Other clinical populations, such as adults with depression, tend to experience impaired adaptive functioning as well (Lowe et al., 2008). Empirical evidence suggests high rates of psychiatric comorbidity in ASD across the lifespan, with depression a particularly common co-occurring condition for adults with ASD (Lugnegard et al., 2011). Despite the known negative effects of ASD and depression singularly on adaptive behavior skills, the combined impact is unclear.
Objectives:
This study aims to assess the relation between depression and adaptive behavior in adolescents and adults with ASD. By comparing adaptive behavior profiles of those with and without co-occurring depression, we hope to comment on the effects of depression on adaptive behavior within the ASD population.
Methods:
Participants included 50 adolescents and adults with ASD (16-35 years) and verbal IQ ≥ 70. ASD diagnosis was confirmed via parent completion of the Autism Diagnostic Interview-Revised (ADI-R; Rutter et al., 2003), as well as administration of the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2000). Parents also completed the second edition of the Vineland Adaptive Behavior Scales (Sparrow et al., 2005) to assess participants' adaptive functioning in the domains of Daily Living Skills, Communication, and Socialization. Participants completed the Beck Depression Inventory, 2nd edition (BDI-II; Beck et al., 1996) to assess depressive symptoms.

Results:
Verbal IQ was not significantly different between depressed (DEP) and non-depressed (ND) participants. The depressed subsample tended to be slightly older (M=22.5 years, SD=4.3, compared to M=20.2 years, SD=3.8 in the ND group), however group differences were not significant (t(48)=1.67, p=.099). Vineland composite adaptive behavior scores were found to be significantly lower among the depressed sample (M=62.4, SD=12.8 vs. M=74.5, SD=13.1 in ND) when controlling for the effects of age (F(2,46)=3.43, p=.041). Within specific domains, Vineland Daily Living standard scores were significantly lower in the depressed subsample (F(2,47)=5.94, p=.005), as were Communication domain scores (F(2,46)=14.23, p=.000). Vineland Socialization domain scores were not significantly different between groups when controlling for age. BDI-II scores showed a significant negative correlation with both Daily Living (r=-.361, p=.010) and Communication (r=-.410, p=.003) domain scores, but were not significantly correlated with Socialization scores.
Conclusions:
This study provides evidence that comorbid depression exacerbates adaptive functioning impairments in adults with ASD. Furthermore, these data suggest that co-occurring depression is associated with diminished adaptive behavior skills in areas that otherwise tend to be relative strengths within ASD (Daily Living Skills and Communication), providing evidence for unique functional impairments related to this psychiatric comorbidity.

104 **124.104** Addressing Intolerance of Uncertainty in Anxious Young People with Autism Spectrum Disorder

J. Rodgers[1], *E. Honey*[2], *M. H. Freeston*[3] *and A. Hodgson*[4], *(1)Newcastle University, Newcastle University, Newcastle, United Kingdom, (2)CNDS, Northumbria Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, (3)Psychology, Newcastle University, Newcastle, United Kingdom, (4)Newcastle University, Newcastle, United Kingdom*

Background: Anxiety is a significant problem for many children with a diagnosis of autism spectrum disorder (ASD). Children with ASD frequently present with multiple anxiety disorders concurrently therefore treatments targeting underlying anxiety mechanisms may be most efficacious. Over the last five years our group has worked towards providing a theoretically informed formulation of anxiety in ASD. This work has focused on a consideration of a well-established model of anxiety: the Intolerance of Uncertainty Model. *Intolerance of uncertainty* (IU) is a construct associated with a range of anxiety disorders. It is a 'broad dispositional risk factor for the development and maintenance of clinically significant anxiety' in neurotypical populations. The concept of IU has utility not only to theoretically inform understanding of the factors underlying the development and maintenance of anxiety, but has also been shown to be a beneficial target for treatment. Intervention studies with neurotypical individuals with high IU provide evidence that reduction of IU is associated with reduction in anxiety. Cognitive behavioural treatments for clinically anxious patients have been developed which emphasise treating the cognitive *process* rather than the cognitive *content* of anxiety, specifically by aiming to increase patients' tolerance for uncertainty and thereby achieving more sustainable change. Over the past five years research has investigated the relevance of IU to anxiety in ASD. This work indicates that IU is a key construct in anxiety in children and adolescents with ASD, which may account for the increased vulnerability to a range of anxiety disorders in this population.
Objectives: Our objective was to develop and evaluate the feasibility and acceptability of a parent group intervention targeting IU for young people with ASD.
Methods: **Phase One**: Focus group were undertaken to inform the development of the intervention materials and trainers' manual. An eight week manualised intervention programme was developed; *CUES, Coping with Uncertainty in Everyday Situations*. The treatment aimed at providing parents of children with ASD, with effective strategies to reduce their child's IU in everyday situations. **Phase Two**: The intervention was delivered in two staggered parent intervention groups to eight parents of children with ASD, aged between 8 and 12 years. The intervention included in-session activities and homework tasks. Baseline and outcome measures assessing child and parent anxiety and IU were completed. Individual follow-up interviews were undertaken with parents to ascertain acceptability and feasibility.
Results: Attendance at and retention to the intervention programme was good. Findings demonstrated the intervention to be acceptable and feasible to families. Parents reported a reduction in their own and their child's intolerance of uncertainty and anxiety subsequent to participation on the programme.
Conclusions: The findings indicate that parents of young people with ASD view an intervention which focuses on intolerance of uncertainty to be valid and meaningful. The data available indicate that CUES may have promise as a targeted package to assist young people with ASD and their families to manage their responses to uncertainty.

105 **124.105** An Investigation of Eye Color and Autism: The Distribution of Iris Coloration Among Children with ASD in the United States

K. Callahan*, University of North Texas Kristin Farmer Autism Center, Denton, TX*

Background: The etiology of autism still lacks definitive genetic, neurochemical, or neuroanatomical markers to enable reliable diagnosis and improved early intervention. However, investigations of eye color have received increased interest among epidemiologists. Iris coloration has been associated with the phenotype of multiple genetic disorders, including albinism, schizophrenia, and Waardenburg, Angelman, and Prader-Willi Syndromes. It is also related to risk of macular degeneration, glaucoma, and melanoma. Melanin-based coloration is implicated in physiological, morphological, and behavioral traits. Researchers have identified significant correlations between eye color and behavior in animals and humans, including significant differences in physiological reactivity between light-eyed and dark eyed persons, suggesting a possible role of neuromelanin. Although eye color genes are located on chromosomes of interest in autism, and researchers have determined that melanin may play a role in Ascending Reticular Activation System functions related to arousal among individuals with ASD, little research has investigated possible relationships between eye color and autism.
Objectives: The purpose of this study was to investigate the distribution of iris coloration within a national sample of children with ASD in the United States, and determine relationships between eye color in ASD and the general population. The relationship between eye color and severity levels in the core deficits of autism (communication, socialization, and restricted/repetitive behaviors) was also examined.
Methods: Direct observations of the eyes of 162 children with ASD were conducted at autism centers in Hawaii, California, Colorado, and Texas using a systematic observation protocol. Eye colors were categorized into seven categories ranging from blue to black. Data collectors were required to complete training and demonstrate mastery of eye color ratings before conducting observations. Intervention fidelity checklists were completed for all observations, and interobserver reliability observations were conducted for approximately 80% of participants (overall agreement level of 87%). Clinical supervisors rated the severity levels of autism symptoms for each participant, and parents were asked if they have observed unusual characteristics related to their child's eyes (e.g., eyes change color during periods of extreme behaviors).
Results: Chi-square tests for goodness of fit were conducted to determine if there were statistically significant differences between the eye color distribution of the sample of children with ASD, and the general distribution of eye color in the United States as reported by Soni and Neuhoff (1985) and to check if autism symptom severity levels were related to eye color categories. There was statistical significance for iris coloration ($p<.05$). Dark eyes (black, brown, hazel) were over-represented in the ASD sample, and there were significantly fewer blue and green eyed persons with autism compared to the national population. There was no trend in symptom severity by eye color category, with non-significant results in communication, socialization, and behavior.
Conclusions: The possible significant over-representation of dark eyed individuals with ASD in a national U.S. sample warrants further investigation. Additional analyses of eye color data, including expected levels by ethnicity, are underway. Additional studies of the role of melanin could result in increased understanding about iris coloration as a possible genetic marker or correlate in ASD.

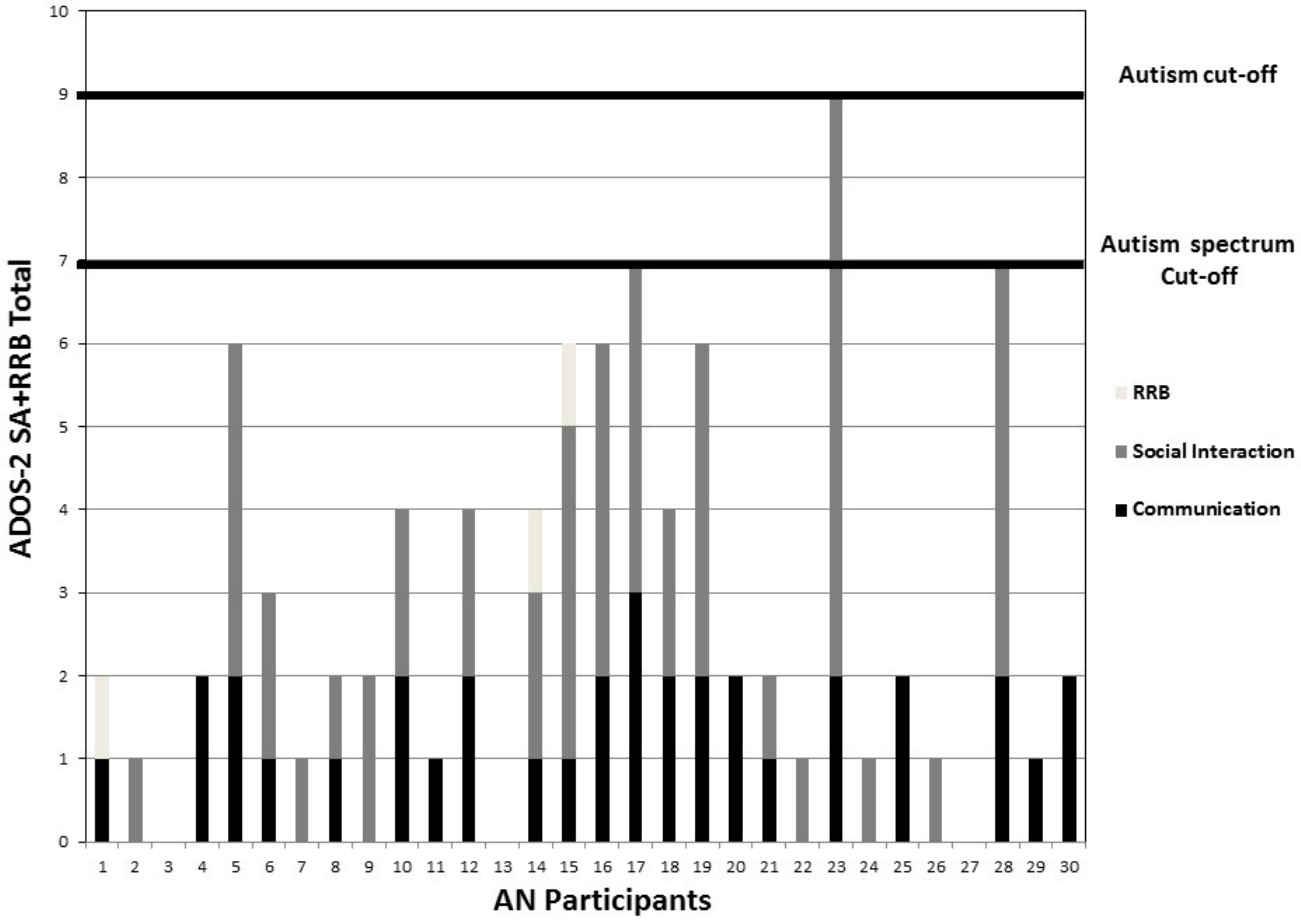
106 **124.106** Anorexia Nervosa and Autism Spectrum Disorder: Is There an Association?

V. Postorino[1], *L. Scahill*[2], *V. Zanna*[3], *M. Castiglioni*[3], *L. De Peppo*[4], *L. M. Fatta*[3], *S. Vicari*[5] *and L. Mazzone*[6], *(1)Marcus Autism Center, Emory University, Atlanta, GA, (2)Pediatrics, Marcus Autism Center, Atlanta 30329, GA, (3)Department of Neuroscience, I.R.C.C.S. Children's Hospital Bambino Gesù, Rome, Italy, (4)Department of Neuroscience, L.U.M.S.A., Libera Università Maria SS. Assunta, Rome, Italy, (5)Children Hospital Bambino Gesù, Rome, Italy, (6)Department of Neuroscience, I.R.C.S.S. Children's Hospital Bambino Gesu', Rome, Italy*

Background: Recent studies have reported a high level of autistic traits in population with anorexia nervosa (AN). Moreover, a number of cognitive features associated with Autism Spectrum Disorder (ASD) has been described in AN samples. However, it is unclear to what extent these are manifestations of ASD or whether they are the manifestations of the starvation phase of the illness. To date, few studies have used contemporary methods to confirm the diagnosis of ASD.
Objectives: The aim of the present study was to examine the presence of ASD in a group of AN during the starvation phase using the gold-standard diagnostic measure for autism (i.e., ADOS-2). We also compared the level of autistic traits and the performance on a common social perception task across four groups: AN, ASD, and two gender- and age-matched control groups (C-AN, C-ASD).
Methods: 30 female AN participants in the acute phase of illness, 27 male ASD participants and two healthy, age and gender-matched controls groups (n=35 females; n=30 males) were enrolled in this study. Controls were screened for AN with the Eating Attitude Test-26 and the Eating Disorder Invenory-3. The ADOS-2 Module 3 was administered by a psychologist trained to research reliability to the AN and the ASD groups. Parents of all individuals completed the Autism Spectrum Quotient (AQ). Subjects completed the NEPSY-II social perception domain (i.e., Theory of mind-TOM and Affect Recognition-AR).
Results: Of the 30 AN participants evaluated using the ADOS-2, 1 was classified on the ADOS algorithm as having autism (Social Affect-SA=9, Restricted/Repetitive Behaviors or Interests-RRB=0, Overall Total-OT= 9); two scored in the ASD range (SA=7, RRB=0, OT=7 both participants)(Figure 1). The remaining participants scored below the ADOS threshold for ASD. Moreover, no similarity between the AN and the ASD groups were detected on the AQ (total and sub-scores) (AN: AQ Total: 18.17 ± 5.92, ASD:AQ Total: 29.6± 6.45, t=5,272, p<0.001) and the NEPSY-II domain. On the other hand, the ASD group had higher scores only on the AQ social skill subscale compared to the C-ASD group (t=3,927, p<0.001). Whereas the C-AN scored higher on the AQ attention to detail (t=-2,082, p=.043), communication (t=-1,138, p=.022) and imagination (t=-1,155, p=.020) subscales and on the NEPSY TOM domain (t=-,813, p=.012) compared to the AN group.
Conclusions: To our knowledge, this is the first study evaluating an AN sample during the starvation phase using the ADOS. Only 10% of subjects in the AN group scored above the conventional ADOS threshold. In these three AN subjects, none was rated above threshold for RRB. On the AQ, none of the AN subjects exceeded the threshold, suggesting low level of autistic traits. On the social perception domain tasks, the ASD group showed significantly greater impairment than the AN group. Our findings do not

support the presence of autistic traits in individuals with AN. Further longitudinal studies are needed in order to determine the association between these conditions.

Figure 1. Scores on the ADOS-2 of the AN participants



107 **124.107** Anxiety and Satisfaction with Life in Young Adults with Autism Spectrum Disorder

I. C. Smith[1], *R. Elias*[2] *and S. W. White*[1], *(1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA*

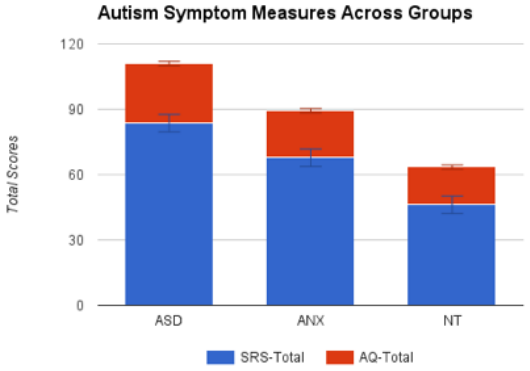
Background:
The comorbidity of anxiety and ASD in children and adolescents is well established (van Steensel, Bogels, & Perrin, 2011). Extant literature on comorbid anxiety symptoms as they manifest in adults with ASD is limited, but preliminary evidence suggests rates of comorbidity comparable to those found in children and adolescents (Lugnegard et al., 2011; Maddox & White, 2015). Anxiety disorders and ASD have each been demonstrated to have substantial impact on quality of life in adults independently (Jennes-Coussens, Magill-Evans, & Koning, 2006; Mendlowicz, 2000), but the relationship between anxiety and satisfaction with life in samples with ASD has not yet been established.
Objectives:
The purpose of this study was to investigate the relationship between anxiety symptoms and satisfaction with life in a sample of emerging adults entering a college transition support program. We hypothesized that satisfaction with life would significantly and negatively correlate with anxiety symptoms.
Methods:
Data from the current study were collected prior to enrollment in a randomized controlled trial of a college transition support program for adolescents and young adults with ASD. The sample currently consists of 11 individuals (17-24 years old; 8 males) with ASD, though we anticipate a large sample (n = 25) by May 2016. All participants had a confirmed diagnosis of ASD based on the ADOS-2 (Lord et al., 2012) and were cognitively high-functioning (IQ>80). The Anxiety Disorders Interview-Client Version (ADIS-5; Brown & Barlow, 2014) was used to assess for presence of comorbid anxiety. Participants completed the Satisfaction with Life Scale (SWLS; Diener et al., 1985) and parents completed the Adult Behavior Checklist (ABCL; Achenbach & Rescorla, 2003).
Results:
Anxiety disorders were highly prevalent in the sample, with all participants meeting criteria for diagnosis of at least one anxiety disorder. Social Phobia was the most prevalent diagnosis, with 8 of 11 (73%) individuals meeting diagnostic criteria. Other diagnoses included specific phobias (5 of 11, 46%), GAD (4 of 11, 36%), and OCD (3 of 11, 27%). A Pearson correlation between the SWLS and the anxiety problems subscale of the ABCL was not significant, $r(9) = .10$, $p = .78$. However, the correlation between the SWLS and the anxiety/depression subscale of the ABCL was large and significant, $r(9) = -.65$, $p = .03$. The correlation between the SWLS and the withdrawn subscale of the ABCL was also large and significant, $r(9) = -.65$, $p = .03$.
Conclusions:
The current findings partially support a relationship between anxiety symptoms and satisfaction with life in young adults with ASD. Given that no significant relationship was found between the anxiety problems subscale, but significant correlations were found for the anxious/depressed and withdrawn subscales, it is possible that depressive symptoms contribute more to poor satisfaction with life than anxiety symptoms. Such results are surprising given the relatively low comorbidity of depression as compared to anxiety in ASD. While these results should be interpreted with caution due to the small sample size, further research is warranted on the effect of anxious and depressive symptoms on satisfaction with life in ASD.

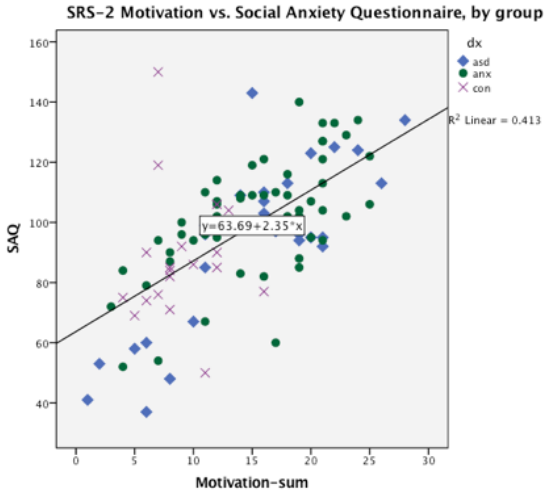
108 **124.108** Anxiety in Autism and Autism in Anxiety: Symptom Overlap on the SRS-2 Adult Self-Report

A. Ward[1], *C. Nielson*[1], *K. G. Stephenson*[1], *M. Maisel*[1], *T. P. Gabrielsen*[1], *M. H. Freeston*[2], *J. Rodgers*[3], *M. South*[1] *and S. B. Gaigg*[4], *(1)Brigham Young University, Provo, UT, (2)Psychology, Newcastle University, Newcastle, United Kingdom, (3)Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)City University London, London, United Kingdom of Great Britain and Northern Ireland*

Background: There is growing awareness that common autism symptom measures including the ADI-R (van Steensel et al. 2013), ADOS-G (Pine et al., 2008) and SRS (Cholemkery et al., 2014; Puelo & Kendall, 2011) may overlap with other non-diagnostic constructs including anxiety and mood symptoms. On the one hand, knowing about co-occurring social difficulties may be useful for treatment in mood and anxiety disorders. On the other hand, these findings raise questions about the discriminant validity of hallmark symptoms of autism from other associated features. Previous studies in this area have been with children. To our knowledge, there is little or no work in this area for adults, where anxiety and autism symptoms may converge more strongly.
Objectives: We aimed to characterize the overlap of autism and anxiety symptoms using two separate autism symptom measures in ASD, anxious, and non-anxious adults.
Methods: Participants included adults diagnosed with ASD (*n*=39; ASD group); first-time visitors to a university counseling center who scored high on intake surveys of

anxiety (*n*=56; ANX group); and a sample of university students with no psychiatric history (*n*=37; NT group). Participants all completed the self-report Social Responsiveness Scale-Second Edition (SRS-2) and the Autism Spectrum Quotient (AQ) in addition to IQ testing and a battery of emotion symptom questionnaires.
Results: Strong, significant correlations were found between ASD and anxiety measures in all three groups. One-way ANOVA indicated significant main effects for diagnosis on both the AQ and SRS total scores. Post-hoc analyses showed that the ANX group scored significantly higher than the NT group but significantly lower than the ASD group on both measures. The ANX raw scores mean and standard deviation (68 ± 24) indicates that many in this group are scoring in a range thought to indicate autism diagnosis. The SRS-2 *Motivation*subscale, which includes items related to social approach and social discomfort ("I avoid starting social interactions with other adults;" "I enjoy making small talk (casual conversation) with others") did not differentiate between ASD and ANX groups. In both the ASD and ANX groups, the Motivation scale was most strongly correlated with social anxiety measures but these were not significantly correlated in the NT group.
Conclusions: The SRS-2 and AQ have been shown to discriminate between ASD and typically developing (TD) individuals. Our data also indicates higher autism symptom scores in an ASD vis-á-vis anxious sample of adults, but likewise shows that the ANX group had markedly elevated scores on both measures. This seems to be at least partially driven by high scores on the Motivation subscale, which includes a number of items related to social anxiety. Further work to separate autism versus anxiety-related social behaviors can inform clinical intervention—including the need to explicitly treat social anxiety in adults with ASD—as well as research into the overlap of anxiety in autism.





109 **124.109** Assessing Anxiety Symptomatology in Children with ASD Using Existing Measures: Is the Spence Children's Anxiety Scale- Parent Version a Useful Tool?

I. Magiati[1], *J. W. Lerh*[2], *M. J. Hollocks*[3], *M. Uljarevic*[4], *J. Rodgers*[5], *H. McConachie*[6], *A. Ozsivadjian*[7], *M. South*[8,9], *A. V. Van Hecke*[10], *A. Y. Hardan*[11], *R. A. Libove*[11], *S. R. Leekam*[12] *and E. Simonoff*[13], *(1)Department of Psychology, National University of Singapore, Singapore, Singapore, (2)Psychology, NATIONAL UNIVERSITY OF SINGAPORE, Singapore, Singapore, (3)King's College London, London, England, United Kingdom of Great Britain and Northern Ireland, (4)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia, (5)Newcastle University, Newcastle Upon Tyne, United Kingdom, (6)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (7)Guy's Hospital, London, United Kingdom, (8)Brigham Young University, Provo, UT, (9)Psychology and Neuroscience, Brigham Young University, Provo, UT, (10)Marquette University, Milwaukee, WI, (11)Stanford University, Stanford, CA, (12)School of Psychology, Cardiff University, Cardiff, United Kingdom, (13)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Assessing anxiety in ASD is challenging, because of core ASD features and anxiety symptom overlap and both traditional as well as varied manifestations of anxiety in ASD (Ozsivadjian et al., 2012; Kerns et al., 2014). Kerns and Kendall (2012) called for the validation of anxiety measures in ASD, but it is currently unclear whether ASD-specific measures are needed or existing ones are reliable and valid. There is to date no informant- or self-report anxiety checklist developed or validated specifically to assess anxiety in this population, but a growing number of studies in the last few years have begun to examine the use of existing measures.
Objectives: To examine the internal consistency and convergent, divergent and discriminant validity and to explore the factor structure and clinical usefulness of the Spence Children Anxiety Scale-Parent Version (SCAS-P). This paper presents final analyses of a larger sample than previously reported in an earlier preliminary presentation (Magiati et al., 2015).
Methods: Data from 12 studies from the UK, Singapore and the USA were pooled together. Participants were caregivers of 870 youth with a professional diagnosis of ASD, Autism, Asperger's syndrome or PDD-NOS (87.7% males; 95% had a diagnosis of ASD; mean age=11.6 years, SD = 2.77) most of whom had at least one measure of autism symptomatology available. IQ data were available for 278 participants and another 238 had adaptive functioning scores. All but 21 clinically anxious help-seeking youth were recruited from special schools, other community or ASD diagnostic settings.
Results: Items from the total SCAS-P scale and from all but the Physical Injury subscales (α=.55) were internally reliable (all α>.75). The SCAS-P total and subscale scores had convergent validity with the Developmental Behavior Checklist (DBC) anxiety subscale (r=.32-.64; n=238). The clinically anxious subsample (n=21) had significantly higher total, generalized and social anxiety scores compared to the remaining participants. The existing SCAS-P six-factor structure was not a good fit for data obtained from 435 randomly selected participants in this sample and thus a principal components analysis (PCA) was carried out. Thirty of the 38 items loaded on five factors (social/ generalized anxiety, separation, obsessive compulsive, somatic symptoms and specific phobias) explaining 57.9% of the variance. A confirmatory factor analysis of the revised structure was re-run for the other half of the sample, but it was not a good fit.
Conclusions: The original SCAS-P full scale and subscales had excellent internal consistency and showed good evidence of convergent, divergent and discriminant validity, with the exception of the Physical injury subscale. Despite its promising psychometric properties, the lack of an adequate factor structure fit is concerning and suggests that future research should look into modifying and re-evaluating the SCAS-P for use in children with ASD.

110 **124.110** Association Between Autistic Traits and Suicidality in a Sample of University Students

S. Yilmaz[1], *S. Herguner*[2] *and S. Kılınç*[1], *(1)Meram Faculty of Medicine, KONYA, Turkey, (2)Meram Faculty of Medicine, NE University, Konya, Turkey*

Background: The high prevalence of anxiety disorders and depression within the autism spectrum disorder (ASD) population is widely recognized. However, few data have been published on suicidal thoughts and behaviors (i.e., suicidal ideation, plan, or intent or a past suicide attempt) in youth with ASD. **Objectives:** This study examined the role of three potential mediating variables in the relationship between autistic traits and suicidality in the general population. The purpose of this study was to examine autistic trait direct and indirect effect on depression and suicidality. **Methods:** Participants included 320 university students (155 males, 165 females) ranging in age from 18 to 42 (M = 21.2, SD = 2.40). Depression symptoms and suicidality of the participants were assessed using the Beck Depression Inventory. The Autism spectrum quotient (AQ) was used to assess autistic traits. Multiple Logistic regression analyses were conducted to assess suicidality predictors. Structural Equation Modeling was conducted to asses AQ direct and indirect effect on Suicidality. **Results:** The first model of Logistic regression AQ Attention to Detail and Communication subscale are related to suicidality , attention switching is a negatively related to suicidality. The second model, depression related to suicidality, AQ Attention Switching negatively related to suicidality. Other subscales have not significant predictor effect on suicidality. In the Structural Equation Modeling AQ Attention to detail and communication effect suicide indirectly (via depression), Attention switching's effect is negatively but directly on suicidality. **Conclusions:** This study provides preliminary evidence that effect of Autistic trait on suicidality may be related to autistic trait depression relationship.

111 **124.111** Associations Between Cytokines, Endocrine Stress Response, and Gastrointestinal Symptoms in Autism Spectrum Disorder

B. J. Ferguson[1], *S. Marler*[2], *L. L. Altstein*[3], *E. B. Lee*[2], *M. O. Mazurek*[4], *A. McLaughlin*[5], *K. Hartnett*[6], *E. A. Macklin*[7], *E. McDonnell*[3], *D. J. Davis*[6], *A. Belenchia*[6], *C. H. Gillespie*[6], *C. A. Peterson*[8], *M. L. Bauman*[9], *K. G. Margolis*[10], *J. Veenstra-Vander Weele*[11] *and D. Q. Beversdorf*[12], *(1)Radiology, University of Missouri, Columbia, MO, (2)Vanderbilt University, Nashville, TN, (3)Massachusetts General Hospital Biostatistics Center, Boston, MA, (4)University of Missouri - Columbia, Columbia, MO, (5)Pediatrics, St. Louis University, St. Louis, MO, (6)University of Missouri, Columbia, MO, (7)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (8)Nutrition & Exercise Physiology, University of Missouri, Columbia, MO, (9)Boston University School of Medicine, Boston, MA, (10)Columbia University, New York, NY, (11)New York State Psychiatric Institute / Columbia University, New York, NY, (12)University of Missouri, Columbia, Columbia, MO*

Background: Many children and adolescents with Autism Spectrum Disorder (ASD) have significant gastrointestinal (GI) symptoms, but the etiology is currently unknown. Some individuals with ASD, show altered reactivity to stress, as well as altered immune markers, particularly stress-responsive cytokines including TNF-α and IL-6.
Objectives: To assess potential relationships between GI symptoms and stress response, we examined whether GI symptoms are associated with increases in stress-associated endocrine and cytokine biomarkers in ASD. We hypothesized that positive relationships would exist between GI symptomatology and cortisol, TNF-α, IL-6. Furthermore, we conducted exploratory analyses to examine the effects of the presence or absence of key co-occurring medical and psychological conditions on these relationships in ASD.
Methods: A sample of 120 individuals aged 6-18 with ASD that are enrolled in the Autism Treatment Network at the University of Missouri Thompson Center for Autism and Neurodevelopmental Disorders and the Vanderbilt Kennedy Center participated in the study. Participants provided pre- and post-stress salivary cortisol samples to measure the endocrine stress response, and a pre-stress blood sample to measure levels of interleukin 6 (IL-6) and tumor necrosis factor alpha (TNF-α). To assess the response to stress, cold pressor and vibrotactile stimulation were applied to the hands in independent trials. Upper and lower GI tract symptomatology were assessed using the Questionnaire on Pediatric Gastrointestinal Symptoms, Rome III. Exploratory analyses were conducted between measures of intelligence, key co-occurring conditions in ASD, and IL-6, TNF- α, and pre- and post-stress cortisol to examine potential relationships.
Results: Lower GI tract symptoms were significantly associated with post-stress cortisol concentration. This relationship between cortisol response to stress and GI functioning was greater for children who had a history of regression or loss of skills that were previously acquired. Exploratory analyses also revealed significant correlations between cortisol change score, IQ, and inappropriate speech. In contrast, lower GI tract symptoms were not associated with levels of TNF-α or IL-6. Significant correlations were found, however, between TNF-α and IL-6 and irritability, socialization, and IQ.
Conclusions: These findings suggest that individuals with ASD and lower GI tract symptoms may have an increased response to stress, but this effect is not associated with concomitant changes in stress-associated cytokines. This relationship with stress may be relevant for future individualization of treatment of lower GI tract symptoms in ASD. The relationship between endocrine stress reactivity and lower GI tract symptoms in children with loss of skills, as well as the relationships between cortisol, IL-6, and intelligence in ASD, warrant further investigation.

112 **124.112** Associations Between Sleep and Behavioral Problems in Children with ASD

M. O. Mazurek[1] *and K. Sohl*[2], *(1)University of Missouri - Columbia, Columbia, MO, (2)University of Missouri - Thompson Center, Columbia, MO*

Background:
Children with autism spectrum disorder (ASD) are at high risk for sleep disturbance. These problems have a significant impact on daytime functioning; however, the relationships between sleep and behavioral dysregulation in children with ASD are not fully understood. This is an important consideration, given that children with ASD experience high rates of behavioral problems, including aggression, irritability, hyperactivity, and inattention. A large body of literature has demonstrated that sleep disturbance is associated with these types of behavior problems in typically developing children. Surprisingly, however, the relationship between specific types of sleep and behavioral problems in children with ASD has received relatively little empirical attention, as noted in a recent review.
Objectives:
The purpose of the current study was to examine the relationships between distinct types of sleep and behavioral problems in children with ASD. The specific behavior problems selected for examination were aggression, irritability/hostility, inattention, and hyperactivity, given their particular clinical relevance in the ASD population. The primary hypothesis was that sleep problems would be associated with daytime behavioral disturbance among children with ASD. The secondary research aim was to identify the specific types of sleep symptoms that were most closely related to each behavioral problem.
Methods:
Participants included 81 children and adolescents with ASD recruited through an interdisciplinary academic medical center. Participants ranged in age from 3 to 19 years (*M* = 10.3, *SD* = 3.8), and the majority of children in the study were male (86.4%). All participants had been previously evaluated and diagnosed by an interdisciplinary team, comprised of a physician and psychologist, using standardized diagnostic tools (i.e., ADOS or ADOS-2), cognitive and adaptive skill assessment, and clinical interview. Measures for the current study included selected subscales of the Children's Sleep Habits Questionnaire, the Children's Scale for Hostility and Aggression: Reactive/Proactive, and the Vanderbilt Attention Deficit/Hyperactivity Disorder Parent Rating Scale.
Results: In bivariate correlations, sleep problems were associated with all four types of behavior problems of interest, including physical aggression, irritability, inattention, and hyperactivity ($p < .05$ to $p < .001$; small to medium effect sizes). Backward stepwise linear regression models revealed that distinct sets of sleep problems predicted each behavior problem, with different combinations of variables accounting for between 22 and 32% of the variance in behavior problems across statistical models. Importantly, the night awakenings score was a significant predictor in three of four models (i.e., physical aggression, inattention, and hyperactivity).
Conclusions:
Sleep disturbance is associated with behavioral dysregulation among children with ASD. Of particular note, night awakenings appear to have the most consistently strong association with daytime behavior problems, even after controlling for the effects of age and sex. Future research is needed to develop more targeted treatments for these conditions and to identify patterns of change over time.

113 **124.113** Attention-Deficit/Hyperactivity Disorder Is Common in Autism Spectrum Disorder and Negatively Affects the Clinical Presentation

D. A. Zachor[1] *and E. Ben Itzchak*[2], *(1)Tel Aviv University / Assaf Harofeh Medical Center, Zerifin, Israel, (2)Ariel University, Givat Shmuel, Israel*

Background:
The co-existence of autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) has recently been supported by the DSM 5. The prevalence rate of ADHD symptoms within ASD populations has been reported to be between 16-50%, significantly more than in the general population (7-10%). The impact of having ASD and ADHD on the severity of the clinical presentation has been investigated in only a few studies. More severe ASD symptoms, emotional instability, poorer adaptive skills and poor academic achievements positively correlated with the existence of ADHD symptoms.
Objectives:
1. To assess the rate of ADHD symptoms in a population diagnosed with ASD
2. To compare the clinical presentation in a subgroup with only ASD diagnosis to a subgroup with ASD and ADHD symptoms.
Methods:
The study included 155 participants, diagnosed with ASD, age range 4:0-10:8y (M=6:7; SD=20.8m) and with male:female ratio of 6.4:1. All the participants underwent comprehensive medical, cognitive and behavioral assessments using standardized tests. Autism symptom severity was measured using the Autism Diagnostic Observation Schedule calibrated severity scales (ADOS CSS). ADHD symptom severity was measured using the Conners Teacher ADHD rating scale-the long form (CRS-R). Standard scores > 60 on any of the different DSM-IV ADHD subscales are considered significant for ADHD symptoms.
Results:
Using the Teacher CRS-R, of the ASD population, a score > 60 was noted for 66% on the DSM ADHD total score subscale, for 66.5% on the DSM Inattention subscale and

for 46.5% on the DSM Hyperactive–Impulsive subscale.
We then divided the entire ASD group into two subgroups, one without ADHD symptoms (ASD-ADHD) (n=75; mean age=6:3y)) and the second with ADHD symptoms (ASD+ADHD) (n=80; mean age=6:5y). The two subgroups were compared for age, sex, autism severity, cognitive level and anxiety symptoms. The two subgroups were not significantly different in age. A trend for lower male:female ratio (relatively more girls) was observed for the subgroup ASD+ADHD (4.7:1) compared to the subgroup ASD-ADHD (9.7:1) (p=.7).
Looking at cognitive measures, the ASD+ADHD subgroup had significantly lower IQ scores (M=86.3, SD=19.1) than the subgroup ASD-ADHD (M=93.0, SD=19.4) (p<.05). Examining the verbal and non-verbal IQ scores revealed that only for the non-verbal IQ scores, the ASD+ADHD subgroup (M=95.7, SD=18.9) had significantly lower scores than the ASD-ADHD subgroup (M=105.0, SD=18.9) (p<.05).
A high prevalence of anxiety symptoms, measured by the Anxiety subscale scores of the CRS-R, was noted for the two subgroups. The prevalence was significantly higher for the subgroup ASD+ADHD (65.9%) than for the subgroup ASD-ADHD (35.6%) (p<.001). Comparison of autism severity using the ADOS-CSS measure revealed no significant difference between the two studied subgroups.
Conclusions:
A high rate of ADHD symptoms was noted in ASD in comparison with the general population. In ASD with ADHD, inattention was the most commonly reported symptom. The clinical presentation in ASD with ADHD is characterized by lower cognitive ability and more anxiety symptoms; however autism severity is not affected. In light of the negative effects of ADHD on the clinical presentation, it is highly important to diagnose and treat ADHD in ASD.

114 **124.114** Autistic Traits in Women with Primary Dysmenorrhea

*H. Toy[1], A. Hergüner[2], S. Simsek[1] and **S. Herguner**[1], (1)Meram Faculty of Medicine, NE University, Konya, Turkey, (2)Konya Research and Training Hospital, Konya, Turkey*

Background: Recent studies showed that women with ASD had higher rates of androgen related conditions, including delayed menarche age, irregular menstrual cycle, delayed menarche age, unusually painful periods, and excessive menstrual bleeding. Previously, we found elevated levels of autistic traits in females with polycystic ovary syndrome. Objectives: In this study, we investigated the autistic traits in female university students with primary dysmenorrhea (PD). Methods: The Autism Spectrum Quotient (AQ) was used to measure autistic traits and Brief Symptom Inventory (BSI) for evaluating anxiety and depression levels. The dysmenorrheal pain was measured in each individual by a Visual Analogue Scale (VAS), coded from 0-10. Seventy women with PD (VAS >6) and 70 with no PD (VAS <3) enrolled into the study. Results: There were no differences between groups in terms of age, duration of education and marital status. Women with PD had higher AQ Total and AQ Attention Switching scores than subjects without PD. Pearson analysis revealed that AQ Total and AQ Attention Switching scores were correlated with VAS, after controlling for anxiety and depression. According to the linear regression, VAS was predicted by AQ Attention Switching subscale. Conclusions: Our findings showed that women with PD had more autistic traits than age-matched women who reported no PD. These findings suggest that there may be a common mechanism between dysmenorrhea and autistic traits.

115 **124.115** Biophysiology and Standardized Measures of Anxiety in Adolescents with ASD

***R. B. Grossman**, J. Mertens, E. Zane and K. Neumeyer, Emerson College, Boston, MA*

Background:
Current estimates place the comorbidity of anxiety and autism spectrum disorder (ASD) between 11% and as high as 84% (White et al. 2009). Comorbid anxiety may compound difficulties in social relatedness inherent in ASD and lead to further isolation and social awkwardness (Myles et al. 2001). But the relationship between biophysiologic markers of anxiety, children's self-reported anxiety levels, and parental perceptions of their child's anxiety levels is poorly understood. Current data indicate both a difference in parent- and self-reported anxiety levels of children with ASD (Steensel, et al. 2012), and an unclear relationship between social stressors and biophysiologic signs of arousal (Levine et al., 2012).
Objectives:
To analyze biophysiologic markers of arousal in response to the Trier Social Stress Test (TSST, Kirschbaum et al. 1993), as well as the relationship between parent- and child-reported anxiety levels in children with and without ASD.
Methods:
Participants were 12 children with ASD and 28 TD children, matched for age (mean 13:6, range 10:8-17:9), sex, IQ, and language ability. All participants completed the Brief Fear of Negative Evaluation Straightforward Items questionnaire (BFNE, Carleton et al. 2006) and parents and children completed the Screen for Child Anxiety Related Emotional Disorders (SCARED, Birmaher et al. 1999).
The TSST involves two tasks: A story telling activity, where participants must prepare and then present an imaginative narrative based on a short story fragment, and a math task, requiring sequential subtraction of 13 from 1,022. Participants must complete both tasks in front of a panel of non-responsive judges and are told that their performance will be assessed and compared to the performance of all other children who have participated in this task. We used a Biopac system to record electrodermal activity and extracted the number of skin conductivity responses during each of the TSST tasks as well as a low-anxiety baseline.
Results:
Preliminary analysis of 6 participant in each diagnostic cohort shows significantly higher rates of skin conductivity responses indicating heightened anxiety levels in both groups during the story and math sections of the TSST as compared to baseline ($p < 0.05$ for all comparisons) and no significant between-group differences for any of the measured activities.
Analysis of the standardized measures revealed no significant between-group differences in reported anxiety for the BFNE or the SCARED. However, within-group correlations revealed significantly greater agreement between scores on the parent and child forms of the SCARED in the ASD compared to the TD group ($p = 0.015$)
Conclusions:
The lack of between-group differences on standardized tests of anxiety and biophysiologic measures suggests that children with high-functioning autism respond comparably to their TD peers when asked to perform in a socially stressful environment. Interestingly, parents of children with ASD appear to be more aware of their children's anxiety levels, as indicated by high correlations between parent and child SCARED scores, while parents of TD children – who presumably spend less time worrying about their children's ability to function in a social context – tend to over- or under-estimate their children's anxiety levels.

116 **124.116** Bone Accrual in Boys with Autism Spectrum Disorder

***A. Neumeyer**[1], N. Cano Sokoloff[2], E. McDonnell[3], E. A. Macklin[4], C. McDougle[2] and M. Misra[5], (1)Lurie Center for Autism Massachusetts General Hospital, Lexington, MA, (2)Pediatrics, Massachusetts General Hospital, Lexington, MA, (3)Massachusetts General Hospital Biostatistics Center, Boston, MA, (4)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (5)Pediatric Endocrinology, Massachusetts General Hospital/ Harvard Medical School/ Harvard Medical School, Boston, MA*

Background: In children with Autism Spectrum Disorder (ASD), bone mineral density (BMD) and cortical thickness are reported to be lower than in typically developing controls (TDC) in cross-sectional studies.
Objectives: Our objective was to prospectively assess bone accrual over a four-year period in adolescent males with ASD compared to TDC during the critical adolescent years when bone accrual rates are at their highest.
Methods: 36 males (19 ASD, 17 TDC) were enrolled at study initiation. Over four years, eleven participants (5 ASD, 6 TDC) were lost to follow-up. Thirteen participants (6 ASD, 7 TDC) were subsequently added for the follow-up visit to total 25 ASD, 24 TDC, (10.8± 1.7y and 11.7± 1.9y respectively). BMD was measured at the hip and lumbar spine using dual-energy X-ray absorptiometry (DXA) in 2011 and 2015. In 2015, whole body BMD was also measured for returning and new participants. BMD Z-scores were calculated using Hologic pediatric databases. We collected the medical history, activity questionnaires, food records, and fasting calcium, phosphorus, and 25(OH) vitamin D levels. Bone accrual rates were calculated for 14 ASD (10.8± 1.7y at baseline and 14.71± 1.7y at follow up) and 11 TDC (11.2± 1.5y at baseline and 15.2± 1.6y at follow up) who participated at both time points. Data are represented as mean (SE).
Results: Tanner stage, BMI z-scores, height z-scores and, serum vitamin D and calcium did not differ between groups at baseline and follow up. Boys with ASD had lower BMD Z scores than controls at (i) the lumbar spine at baseline [-1.01(0.23) vs. -0.14(0.24), $P < 0.009$] and follow-up [-1.16(0.31) vs. -0.17(0.35), $P < 0.04$], (ii) the total hip at baseline [-0.69(0.28) vs. 0.04(0.23), $P < 0.025$] and follow-up [-1.27(0.32) vs. -0.18(0.36), $P <0.027$] and (iii) femoral neck at baseline [-1.57(0.18) vs -0.51(0.18), $P <0.001$] and follow-up [-1.52(0.29) vs. -0.32(0.33), $P < 0.009$], and for the whole body less head at the follow-up visit [-1.25(95% CI -1.68, -0.82) vs. -0.48(95% CI -0.91, -006)]. Bone accrual rates did not differ between ASD and TDC at any site. Vitamin D intake from food was lower in ASD vs. TDC at baseline [5.09(0.99) vs. 9.27(1.01) mcg/day, $P < 0.006$], but not at follow-up. Calcium intake at baseline and follow-up did not differ between groups. In addition, a lower proportion of ASD vs. TDC were categorized as being "very physically active" at both baseline (16% vs. 75%, $P < 0.001$) and follow-up (14.7% vs. 74.8%, $P < 0.01$).
Conclusions: This is the first study to prospectively examine BMD in adolescent boys with ASD compared with controls. Participants with ASD continued to have lower BMD during adolescence compared to controls, but bone accrual (change in BMD over time) did not differ between groups. Further studies are needed to (i) evaluate the long-term consequences of decreased BMD in ASD, (ii) evaluate BMD in females and adults with ASD, and (iii) assess the effect of interventions to improve BMD in individuals with ASD.

117 **124.117** Cardiac Autonomic Measures during Baseline Resting Conditions in Autism Spectrum Disorders: Two Meta-Analyses

***L. Verhoeven**[1], H. M. Geurts[2,3] and I. Smeekens[1,4,5], (1)Dr. Leo Kannerhuis, Doorwerth, Netherlands, (2)Dutch Autism & ADHD research center (d'Arc) Dept of Psychology,*

Brain and Cognition, University of Amsterdam; Dr. Leo Kannerhuis, Amsterdam, Netherlands, (3)Dept. of Research, Development & Innovation, Dr. Leo Kannerhuis, Doorwerth, Netherlands, (4)Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Centre, Nijmegen, Netherlands, (5)Karakter, Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands

Background: Cardiac autonomic markers such as heart rate (HR) and heart rate variability (HRV) are increasingly being related to behavioral characteristics of autism spectrum disorder (ASD). Theories such as the neurovisceral integration model (Thayer & Lane, 2000) and the polyvagel theory (Porges, 2001, 2007) also relate cardiac autonomic functioning to appropriate social and environmentally adjusted behavior. Two recent reviews (Benevides & Lane, 2015; Klusek, Roberts & Losh, 2015) have provided qualitative descriptions of research findings so far regarding baseline levels of cardiac autonomic functioning as well as cardiac autonomic reactivity to different kinds of tasks in individuals with ASD. In general, they report mixed results regarding baseline functioning and some evidence for altered cardiac autonomic reactivity to tasks. Unfortunately quantitative analyses, such as meta-analyses, are lacking.
Objectives: The aim of the present review was to improve current knowledge on cardiac autonomic functioning in baseline conditions among individuals (all ages) with ASD by means of meta-analyses.
Methods: Two meta-analyses were conducted to investigate whether individuals with ASD differ from typically developing individuals regarding their baseline levels of heart rate (meta-analysis 1) and heart rate variability (meta-analysis 2). For this purpose, systematic searches were conducted among the databases of PsychINFO, Web of Science and PubMed for the period 1990 - august 2015.
Results: Regarding HR, ten studies could be included with a total sample size of 339 ASD participants and 291 control participants. For HRV, 15 studies were included with a total sample size of 537 ASD participants and 410 control participants. Results of the meta-analyses revealed that individuals with ASD have higher heart rate (g = 0.68) and lower HRV (g = -0.46) in baseline conditions than typically developing individuals without ASD, irrespective of age and intellectual functioning. While the heart rate findings seem very robust, the heterogeneity with respect to the studies focusing on HRV was large. This implies that the HRV findings need to be interpreted cautiously.
Conclusions: The present results of heightened HR and lowered HRV in baseline conditions among individuals with ASD provide a theoretical basis for the lack of adaptation and unresponsiveness to environmental challenges frequently encountered in individuals with ASD, for example in social situations. This theoretical basis relies on the described assumptions of the neurovisceral integration model and polyvagel theory that cardiac autonomic functioning is related to appropriate social and environmentally adjusted behavior.

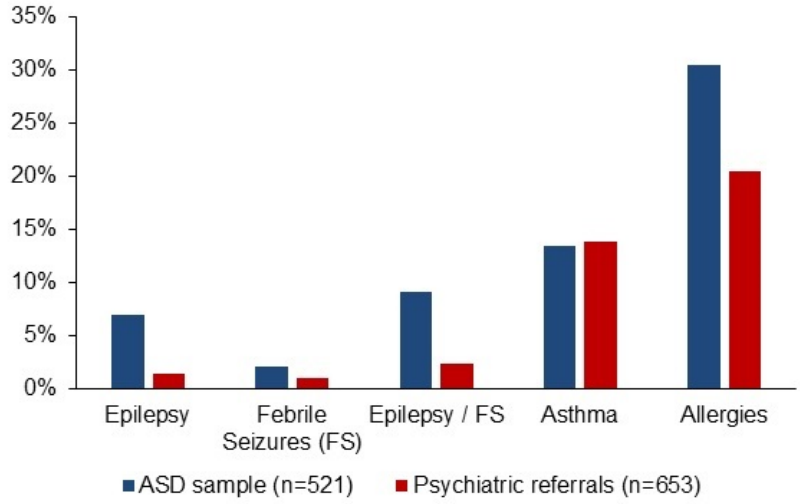
118 **124.118** Clinical Correlates for Seizure Disorder, Asthma, and Allergies in Youth with ASD Versus Psychiatric Referrals

K. D. Gadow *and R. J. Weber, Stony Brook University, Stony Brook, NY*

Background: In this study we sought to compare rates of three relatively common co-occurring medical conditions known to add to caregiver burden in a large group of children with autism spectrum disorder (ASD) and a comparison sample of non-ASD neuro-atypical psychiatric outpatient referrals. Such a comparison would address at least in part the question of whether the seemingly higher rates of these conditions was peculiar to ASD or more generally associated with CNS dysfunction. Equally important was the desire to determine if the clinical correlates of these medical conditions differed in these two groups of youth, which would suggest that the biologic substrates of neurobehavioral syndromes and co-occurring medical conditions interact to result in unique clinical presentations.
Objectives: To examine comparative rates of seizure disorder, asthma, and allergy in youth with ASD versus typically developing peers and their association with clinical correlates and other types of psychopathology.
Methods: This study examined the rates of these conditions in a large sample of consecutively referred youth with ASD (n=521) and an equally large sample of youth referred for psychiatric outpatient evaluation (n=653). Caregivers completed a developmental history questionnaire (parents) and a well-validated psychiatric symptom severity and impairment rating scale (parents, teachers).
Results: Rates of seizure disorder and allergies, but not asthma, were significantly higher in the ASD group than psychiatric referrals (Figure 1, Panel A), and this was also case when the groups were limited to children (6-12 years) with IQs ≥70 (Figure 1, Panel B). In the total sample, approximately one fourth (23%) of youth with ASD with either allergies or asthma had both disorders, and the rate of co-occurrence was higher for the comparison group (33%) (Figure 2). Within each diagnostic group, there were no differences in ASD severity between children with or without epilepsy, asthma, or allergy; however, there were significant interactions for epilepsy (repetitive behaviors) and asthma (communication). In the ASD sample, children with epilepsy had more severe schizophrenia symptoms, and psychiatric referrals with allergy had more anxiety and depression symptoms (parent's ratings) but *less*severe aggression (teachers' ratings). Epilepsy and asthma associations with treatment (i.e., psychotropic medication, special education) were unique to ASD; youth with ASD and epilepsy were more likely be receiving these treatments than ASD youth without epilepsy, though for non-ASD youth treatment did not differ for those with and without epilepsy. In the ASD sample, youth with asthma less often received special education, but no such association was present in non-ASD psychiatric referrals.
Conclusions: Compared with a heterogeneous group of non-ASD neuro-atypicals, youth with ASD are at differentially greater risk for seizure disorder and allergy. Furthermore, youth with ASD with and without seizure disorder, asthma, or epilepsy evidence a different pattern of associations with clinically relevant (e.g., psychiatric symptoms) and ecologically valid variables (e.g., treatment), and these relations vary depending on the type of co-occurring illness, all of which underscores the value of considering the notion of unique clinical presentations within neurodevelopmental disorders for furthering our understanding of nosology.

Figure 1: Distribution of epilepsy, febrile seizures, asthma, and allergies in youth with ASD and non-ASD outpatient psychiatric referrals.

Panel A: Full sample.



Panel B: Sub-sample, all 6-12 years old with IQ ≥ 70.

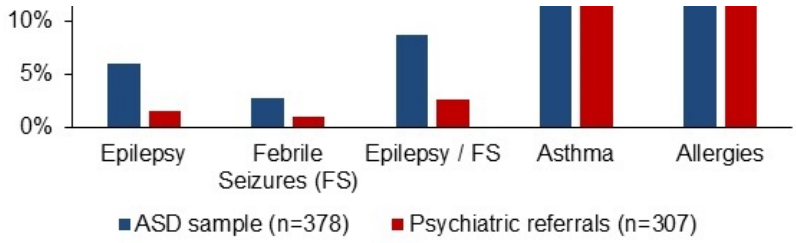


Figure 2: Co-occurrence of seizure disorder, allergies, and asthma in youth with ASD and outpatient psychiatric referrals.

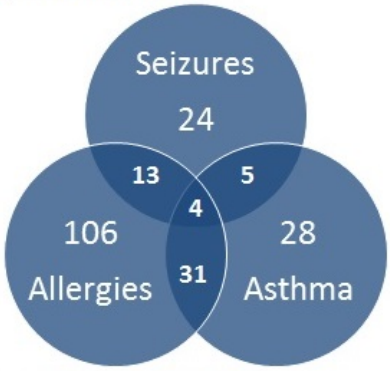
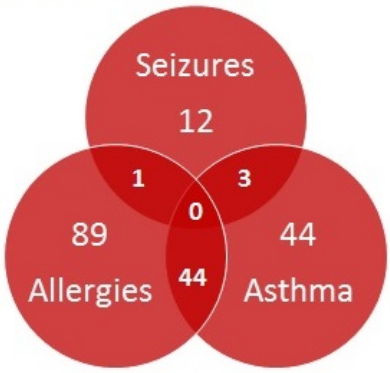
Panel A: ASD sample. Affected n=211.



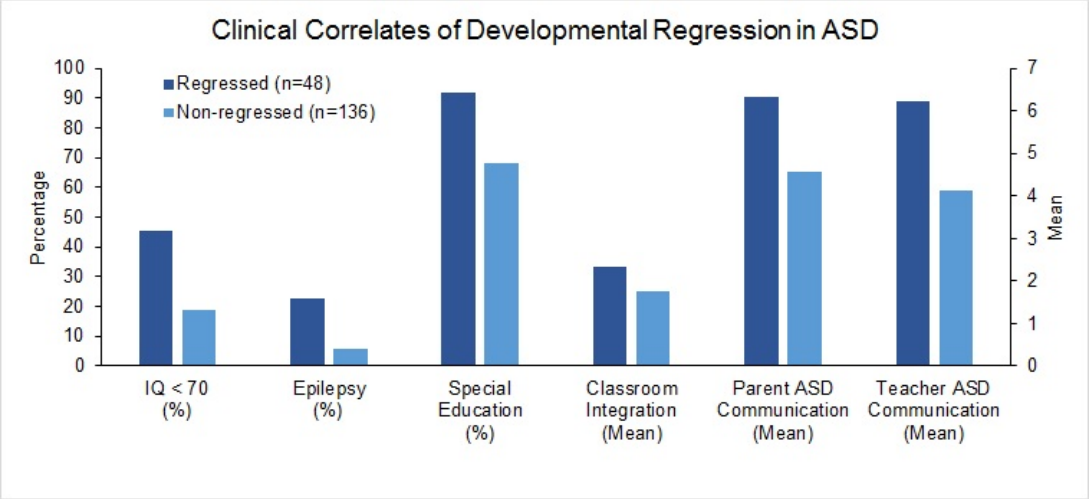
Panel B: Psychiatric referrals. Affected n=193.



119 **124.119** Parent-Reported Developmental Regression in Autism Spectrum Disorder: Epilepsy, Intellectual Disability, Schizophrenia Symptoms, and Special Education

R. J. Weber, *E. Kang, T. Rosen, G. Perlman and K. D. Gadow, Stony Brook University, Stony Brook, NY*

Background: A minority of youth with autism spectrum disorder (ASD) are reported to experience loss of pre-acquired skills during the preschool years. A recent meta-analysis puts the rate of developmental regression at 32% with a mean onset of 1.78 years (Barger, Campbell, & McDonough, 2013). Among the most consistent findings characterizing this ASD subgroup are greater severity of intellectual and ASD symptoms relative to non-regressed peers. However, little research has addressed the association of non-ASD DSM-defined psychiatric comorbidity with developmental regression, plausible particularly as it pertains to schizophrenia spectrum disorder symptoms (SSD) given preliminary evidence supporting a clinically relevant sub-group within the broader ASD phenotype (Gadow & DeVincent, 2012).
Objectives: 1. To determine whether a brief parent report of developmental regression provides clinically helpful information about youth who are referred for evaluation in a developmental disabilities outpatient clinic. 2. To examine the association of SSD with developmental regression and explore associations with specific symptoms.
Methods: Case records for consecutive referrals to a university hospital developmental disabilities clinic were screened for children between 6 and 18 years old at time of evaluation diagnosed with ASD. Caregivers completed ratings of psychiatric symptoms (parents, teachers) and a background history questionnaire (parents). Separate chi-square tests (categorical variables), *t* tests (continuous variables), and Mann-Whitney *U*tests (ordinal variables) data were conducted to examine group differences.
Results: Parents of 48 youth indicated that their child had experienced developmental regression in communication and/or social skills by the age of 36 months; parents of 136 youth reported that their child had not experienced regression. The developmentally regressed group were more likely to have intellectual disability; more severe ASD communication deficits; diagnosis of epilepsy; and to be receiving special education services and in more socially restrictive settings than non-regressed youth (see Figure). Youth in the regressed group were rated by parents as having significantly greater SSD symptom severity (t=2.41, p=.017); however, teachers' symptom severity ratings did not significantly differ between groups. The regressed group was also more likely to be impaired by SSD symptoms according to both parents' (χ^2=7.66, p=.006) and teachers' ratings (χ^2=6.35, p=.012). Analyses of individual symptoms showed that parents' ratings for youth in the regressed group were significantly greater than the non-regressed group for disorganized behavior (U=2420.0, p=.018) and avolition (U=2368.0, p=.012).
Conclusions: The findings support the clinical utility of asking parents about their child's early developmental history during initial diagnostic evaluations, specifically perception of developmental regression, as a history of regression indicates increased risk for a more impacted clinical course (e.g., intellectual disability, epilepsy, ASD communication deficits, special education, and social exclusion in special services), and owing to its typical age of onset, may be of value in procurement of early intervention. Youth with regression were more likely to experience greater severity of and impairment from SSD symptoms than youth without regression, specifically disorganized behavior and negative symptoms. It is noteworthy that these symptoms, as is the case with developmental regression, correlate with ASD symptom severity whereas positive symptoms and disorganized thinking do not (Gadow, 2013).



120 **124.120** Continuity, Change and Predictors of Anxiety Symptoms in a Community Sample of Children and Youth with ASD: A Prospective Follow-up Study

*E. J. Teh, G. Tan and **I. Magiati**, Department of Psychology, National University of Singapore, Singapore, Singapore*

Background: Many individuals with ASD experience high rates of anxiety, but mixed findings have so far been reported in the literature regarding anxiety's relationship with other individual characteristics (i.e. age, gender, cognitive and adaptive functioning, ASD symptomatology). Few studies have examined whether the relationship between ASD and anxiety symptoms may be "fractionable", that is whether ASD social/communication or stereotyped behavioural symptoms may be differentially associated with anxiety. Furthermore, most existing studies have been cross-sectional and continuity and change in anxiety symptoms in prospective study designs has not yet been sufficiently explored.
Objectives: (i) to examine continuity and change in caregiver reported anxiety symptoms of young people with ASD; (ii) to examine the predictive value of earlier child characteristics in explaining and predicting anxiety 12-18 months later, considering the two domains of ASD symptomatology independently; and (iii) to explore whether the relationship between anxiety and ASD symptomatology is uni- or bi-directional.
Methods: Participants were caregivers of 54 children and youth aged 6 to 17 years (88.9% males) with a clinical diagnosis of ASD, Asperger's syndrome or PDD-NOS recruited from special schools in Singapore. Data was collected on adaptive functioning, anxiety symptoms (using the Spence Children's Anxiety Scale- Parent Version; SCAS-P) and other emotional or behavioural problems at Time 1 and then 12-18 months later. 241 children participated in the study at Time 1 (Magiati et al., 2015), of whom 164 agreed to be contacted at follow-up and fifty-four (33% response rate) completed the measures at Time 2. Hierarchical regression analyses examined the incremental predictive value of earlier child variables (age, gender, adaptive functioning, autism symptoms and Time 1 anxiety) on Time 2 anxiety symptoms.
Results: Mean total and subscale anxiety rates were generally stable from Time 1 to Time 2, except for social anxiety symptoms, which significantly increased over time. Age, adaptive functioning and earlier repetitive/stereotyped behaviors, but not earlier social/communication ASD symptoms, were significant predictors of later total anxiety scores. However, when Time 1 anxiety was included as a covariate, the variance in Time 2 anxiety scores was fully explained by earlier total anxiety scores. The same pattern of findings was found for generalized anxiety, panic/agoraphobia and obsessive-compulsive SCAS-P subscale scores. Only for separation anxiety symptoms did earlier stereotyped behavioral ASD symptoms significantly predict later separation anxiety over and above baseline separation anxiety scores and all other child factors examined. Time 1 anxiety scores, however, did not predict Time 2 stereotyped ASD symptoms, suggesting the relationship may be unidirectional.
Conclusions: Anxiety symptoms in young people with ASD remain generally stable over time without intervention, while social anxiety increases. Only Time 1 ASD repetitive behavior, but not social/communication, symptoms predicted anxiety one year later, after age and adaptive functioning were controlled for. However, this relationship was fully explained by earlier anxiety scores predicting later anxiety scores, with the exception of separation anxiety. Given our small sample size and exclusive use of caregiver-report measures, we recommend replication with larger samples and use of multiple-informant measures to validate and extend our preliminary findings.

121 **124.121** Decreased Immune Regulation in Children with ASD Who Experience GI Symptoms

***D. Rose**[1], M. Careaga[2], H. Yang[3], H. Hughes[3], J. Van de Water[4], A. Fasano[5] and P. Ashwood[6], (1)UC Davis M.I.N.D. Institute, Sacramento, CA, (2)UC Davis/MIND Institute, Sacramento, CA, (3)UCD MIND Institute, Sacramento, CA, (4)University of California at Davis MIND Institute, Davis, CA, (5)Pediatrics, MassGeneral Hospital for Children, Charlestown, MA, (6)UC Davis, Sacramento, CA*

Background: Multiple studies have reported increased prevalence of gastrointestinal (GI) symptoms in children with autism spectrum disorders (ASD) and one recent study estimated that children with ASD are 6 to 8 times more likely to have persistent GI symptoms including: diarrhea, constipation, alternating bowel habits, gassiness or bloating, vomiting and abdominal pain have been reported in numerous studies. In addition, intestinal and peripheral inflammation, altered microbiome profiles, and impaired intestinal permeability have been observed in children with ASD who experience GI symptoms.
Objectives: To assess immune dysfunction and relationship to behavior in children with ASD with and without GI co-morbidities.
Methods: Over a hundred children participated in our study and were placed into one of four study groups based on responses from two questionnaires: children with ASD who experience GI symptoms of irregular bowel habits (ASD^{GI}) and children with ASD who do not have a history of GI symptoms (ASD^{NOGI}) compared to typically developing children with GI symptoms (TD^{GI}) and typically developing children without a history of GI symptoms (TD^{NOGI}). Peripheral blood mononuclear cells (PBMC) were isolated from participant's blood, stimulated *in-vitro* for 24 hrs and supernatants were assessed for cytokine production via Luminex multiplex assays. Behavioral assessments and diagnosis were performed by trained clinicians.
Results: Our data show children in the ASD^{NOGI} group demonstrated elevated innate immune responses, including increased levels of IL-1α, IL-1β and TNFα after stimulation with Toll-Like receptor (TLR)-4 ligands compared to TD^{NOGI} controls. The ASD^{GI} group produced increased levels of the mucosal relevant cytokines IL-5, IL-15 and IL-17 compared to ASD^{NOGI} following TLR-4 stimulation. The production of the regulatory cytokine TGFb1 was decreased in all stimulatory conditions in children with ASD^{GI} compared with children in either ASD^{NOGI} or TD^{NOGI} groups. While diagnostic scores from the ADOS were not different between ASD groups we did find that children in the ASD^{GI} group have worse scores on the Aberrant Behaviors Checklist (ABC) subscales in: Irritability, Hyperactivity and Social Withdrawal. We also report finding positive correlations between TLR-4 stimulated innate cytokines IL-1 α, IL-1β and TNFα and worsening behavioral scores on the ABC.
Conclusions: While immune responses in children with ASD and GI symptoms were generally similar to children with ASD without GI symptoms, we did find evidence of reduced regulatory cytokines and increased mucosal related cytokines in the ASD^{GI} group that may suggest that children with ASD and GI symptoms have a unique imbalance between regulatory and inflammatory pathways.

122 **124.122** Descriptive Study of Individuals with Pitt-Hopkins Syndrome (PTHS)

***K. C. Guest**[1], S. E. O'Kelley[1], E. Rahn[2], K. D. Krubinski[1], B. A. Modi[1], A. Kennedy[2] and D. Sweatt[2], (1)Psychology, University of Alabama at Birmingham, Birmingham, AL, (2)Neurobiology, University of Alabama at Birmingham, Birmingham, AL*

Background: Limited clinical studies of individuals with PTHS have shown developmental delay and severe intellectual disability, motor difficulties (delayed or not walking), and autistic symptoms (Sweatt, 2013; Van Balkom et al., 2012). PTHS is caused by disruption (mutation or deletion) of transcription factor 4 (TFC4, located on chromosome 18). Haploinsufficiency, or inheriting only one working copy of TCF4 causes PTHS. Approximately, 200-300 documented cases of PTHS exist worldwide. Though characterized as an 'atypical' ASD, individuals with PTHS demonstrate a number of symptoms similar to those diagnosed with autism including: difficulties in pretend play, social interactions, verbal and nonverbal communication; sensitivity to sensory information; and behavioral problems like aggression and tantrums. The current study focuses on presenting preliminary descriptive information of individuals with PTHS within a well-defined genetic sample.
Objectives: The purpose of the research is to describe 10 individuals with PTHS living in the US participating in the current study. Specifically, information on the child's age, diagnosis/diagnoses, gender, race and ethnicity, loss of skills, intervention and education history, displays of aggression and tantrums, as well as family history of ASD and maternal/paternal education levels will be explored.
Methods: Parents of individuals with PTHS interested in participating completed a comprehensive demographic interview by telephone. Currently, 26 families have enrolled in the study and preliminary data are presented on the 10 families that have completed the study to date.

Results: The study contains 6 males and 4 females who had been diagnosed with PTHS. The average age of the individuals at the time of their initial demographic interview was 5.85 years with a range of 2.0-17.33 years. The majority of the participants were Caucasian (90%) and Non-Hispanic/Latino (80%). In addition to a PTHS diagnosis, many children were also diagnosed with Developmental Delay (80%), Speech Language Disorder (80%), Intellectual Disability (50%), Learning Disability (50%), and Epilepsy (40%). Only one child was co-diagnosed with ASD. Only three individuals had a reported loss of language skills at some point during development. All of the individuals with PTHS were currently receiving speech therapy, occupational therapy, and were either receiving, or had received, Early Intervention services in the past. Almost all (90%) were receiving physical therapy services. A low frequency of aggression to adults (20%), aggression to peers (30%), and no aggression to strangers were reported. However, a majority (60%) of individuals were reported to display temper tantrums ranging in frequency from 1 time per day to 2-3 times per week. Mothers and fathers in the sample were well-educated. None of the fathers of individuals with PTHS and only one of the mothers reported a family history of ASD.
Conclusions: Since PTHS is so rare, it is vitally important that researchers and clinicians understand the descriptive information of individuals with this syndrome in more detail in order to differentiate the clinical presentation from that of other developmental disabilities and to guide more informed recommendations for intervention.

123 **124.123** Determinants of the SLEEP and Eating Problems in NEWLY-Diagnosed Preschool Children with Autism Spectrum Disorder

A. Bilgic *and S. Herguner, NE University, Konya, Turkey*

Background: Children with autism spectrum disorder (ASD) are known to suffer from significantly more sleep and eating problems than typically developing children, but less is known about the determinants of these problems especially in early ages.
Objectives: This study evaluated the relationships of severity of ASD, behavioral problems, sensory hypersensitivity, and parental psychiatric symptoms to severity of sleep and eating problems in preschool children with ASD.
Methods: The sample consisted of 46 newly-diagnosed children with ASD aged 21–63 months. The ADI-R was used to measure the severity of ASD and parents reports on a range
of scales were collected.
Results: According to regression analyses, there were regression relationships between lower ADI-R communication scores and more sensory processing impairment in movement area to
higher emotional overeating scores, higher maternal somatization scores to higher food responsiveness scores, more sensory processing impairment in taste/smell area to lower
enjoyment of food and higher satiety responsiveness scores, more sensory processing impairment in visual area to higher slowness in eating scores, and higher paternal hostility and child irritability scores to higher emotional undereating scores. Regarding to eating problems, a positive association between streotypic behavior and sleep problems in these children was observed.
Conclusions: Findings of this study suggest that a variety of variables such as severity of ASD, coexisting behavioral problems, sensory hypersensitivity, and parental pscyhiatric status may have an impact on child eating behaviors in preschool children with ASD. However, only streotypic behaviors showed a relationship with sleep problems in these children.

124 **124.124** Development of the Anxiety Scale for Children – ASD (ASC-ASD)

J. Rodgers[1]*, S. Wigham*[2]*, H. McConachie*[3]*, M. H. Freeston*[4]*, E. Honey*[5] *and J. R. Parr*[6]*, (1)Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Newcastle University, Newcastle upon Tyne, NE1 4LP, United Kingdom of Great Britain and Northern Ireland, (3)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Psychology, Newcastle University, Newcastle, United Kingdom, (5)CNDS, Northumbria Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, (6)Institute of Health and Society, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Many children with ASD experience high levels of anxiety. There is a lack of suitable anxiety measures for people with ASD. Most measures have not been developed for this population. It is now generally accepted that existing anxiety measures may require adaptation to more accurately capture the varied manifestations of anxiety often associated with ASD, including anxiety related to sensory hypersensitivity, intolerance of uncertainty and ASD-specific phobias. A widely used, well validated measure of anxiety for typically developing children is the Revised Child Anxiety and Depression Scale (RCADS).
Objectives: (i) to modify the RCADS to include items related to uncertainty, sensory anxiety and phobias; (ii) to investigate the factor structure, reliability and validity of the adapted measure with a representative sample of children and parents.
Methods: Participants were 177 children with ASD and no intellectual disability, aged 8-16 years (mean 11.1, SD=2.1) years, and their parents, recruited from a representative national research database (ASD-UK).The RCADS is a 47-item measure of anxiety and depression with six subscales: panic, separation anxiety, Obsessive Compulsive Disorder (OCD), generalised anxiety disorder (GAD), social phobia and depression. An adapted version of the RCADS was created with the addition of items relating to sensory anxiety, intolerance of uncertainty and phobias. Content validity was refined during focus groups with parents. Children completed the child version of the adapted measure and the Screen for Anxiety and Related Emotional Disorders (SCARED). Parents completed parental-report versions of the adapted measure, the SCARED and the Repetitive Behaviour Questionnaire (RBQ), Short Sensory Profile (SSP), the Strengths and Difficulties Questionnaire (SDQ), and the Child Depression Inventory (CDI-2). Parents and children completed the new measure again one month after initial administration.
Results: The original RCADS anxiety items were analysed to determine whether the original factor structure was replicated. OCD items did not load on a distinct factor and were excluded from further analyses. The remaining 41 RCADS anxiety items were combined with the new items and further factor analyses undertaken. Items with factor loadings <.5 were excluded. Twenty four items loaded on four factors in both child- and parent- report versions: Performance Anxiety, Anxious Arousal, Separation Anxiety, and Uncertainty, forming the new measure the Anxiety Scale for Children- ASD (ASC-ASD). Internal consistency of the ASC-ASD subscales and total scores was excellent (Cronbach's alphas ranging from .85 to .94). One month test-retest reliability was excellent for both versions (r = .84 and r =.82). Convergent validity was demonstrated with significant correlations between the ASC-ASD and SCARED, SSP, RBQ and the emotion subscale of the SDQ. Correlations with the CDI were significant, but weaker, demonstrating divergent validity.
Conclusions: Results provide evidence for the need to adapt anxiety measures for young people with ASD and support emerging evidence for the importance of uncertainty in the presentation of anxiety in ASD. The ASC-ASD is one of the first reliable and valid ASD specific anxiety measures which captures aspects of anxiety relevant to ASD that are absent in other measures; replication and extension is required in novel samples.

125 **124.125** Does the Collaborative and Proactive Solutions Model Explain Aggressive Behavior in Children with Autism Spectrum Disorder without Intellectual Disability?

P. Cleary[1]*, B. B. Maddox*[2]*, E. S. Kuschner*[1]*, L. R. Guy*[3]*, R. T. Schultz*[4]*, J. Miller*[2] *and B. E. Yerys*[5]*, (1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (4)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Center for Autism Research, Philadelphia, PA*

Background:
Aggression in children with autism spectrum disorder (ASD) is common, with 68% showing aggression toward family members and 49% toward non-family members at some point during their lifetime. Importantly, IQ is not correlated with aggression, highlighting that children with ASD without an intellectual disability (ID) exhibit high levels of aggression. This is a significant problem as aggressive behavior requires higher levels of psychiatric care and places both the aggressor and their target at risk for physical injury. In school-age children without ASD or ID, there is an evidence-based cognitive behavioral treatment for aggression – Collaborative & Proactive Solution (CPS) – that posits a model of five lagging skills that contribute to aggressive and challenging behaviors. This model specifies impairments in executive function (EF), language, emotion regulation (ER), cognitive flexibility, and social skills as contributors to aggression. No studies have looked at whether the CPS model explains aggression in school-age children with ASD without ID.
Objectives:
To evaluate the CPS model in school-age children with ASD without ID.
Methods:
A sample of 147 children with ASD participated in this study (Mean age=9 years, 2 months; Full-Scale IQ=101.37). ASD was diagnosed using DSM-IV criteria and confirmed with ADI-R/ADOS. All measures are parent-report. Aggression was quantified using the Behavioral Assessment System for Children, Second Edition (BASC-2) Aggression subscale. The EF domain included the Behavior Rating Inventory of Executive Function (BRIEF) Inhibition, Shifting, Working Memory, and Planning scales. The Language domain included the Vineland Adaptive Behavior Scales, 2nd Edition Receptive and Expressive Language scales. The ER domain included the BRIEF Emotional Control scale and the BASC-2 Anxiety and Depression scales . The Cognitive Flexibility domain included the Repetitive Behaviors Scale-Revised Compulsive, Ritual, and Sameness scales. The Social Skills domain included the BRIEF Monitor scale, BASC-2 Social Skills scale, and the Social Responsiveness Scale's Total score. We examined whether each domain successfully predicted aggression above and beyond age and IQ. We also examined the independent contribution of each domain, relative to the other four domains.
Results:
Children with ASD had a mean Aggression T-score of 52.22 (Range 35-97; SD=10.91), with 23.8% having scores in the borderline range (T>60) and 6.8% in the clinical range (T>70). Linear regressions showed that all CPS domains explained significant variance in aggression above age and IQ ($R^2\Delta$s=.09 to .39). The total CPS model explained almost half of the variance related to aggression (R^2=.473, *Adjusted* R^2=.402), and showed significance for unique variance in EF ($R^2\Delta$=.041) and ER ($R^2\Delta$=.147).

Within these two domains, the BRIEF Inhibit Scale and BASC-2 Depression Scale explained a significant amount of variance.
Conclusions:
This study shows that impairments in EF and ER domains relate to aggression in school-age children with ASD without ID. Our results validate the CPS model of aggression. Future studies should test whether the CPS treatment is effective for reducing aggression and challenging behaviors in children with ASD without ID.

126 **124.126** Early Life Influences and Child Weight Outcomes in the Study to Explore Early Development (SEED)

T. V. Kral[1], *J. L. Chittams*[2], *C. B. Bradley*[3], *J. L. Daniels*[4], *C. G. DiGuiseppi*[5], *S. L. Johnson*[6], *J. Pandey*[7], *J. A. Pinto-Martin*[8], *N. Rahai*[9], *A. Ramirez*[10], *L. A. Schieve*[11], *A. M. Thompson*[12], *W. Thompson*[11], *G. C. Windham*[13], *W. E. York*[14], *L. Young*[15] *and S. E. Levy*[7], *(1)University of Pennsylvania School of Nursing, Philadelphia, PA, (2)Biostatistics Consulting Unit, University of Pennsylvania School of Nursing, Philadelphia, PA, (3)Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of North Carolina, Chapel Hill, NC, (5)Epidemiology, University of Colorado - Denver, Aurora, CO, (6)University of Colorado Denver, Aurora, CO, (7)Children's Hospital of Philadelphia, Philadelphia, PA, (8)Biobehavioral Health Sciences, University of Pennsylvania School of Nursing, Philadelphia, PA, (9)Center for Public Health Initiatives, University of Pennsylvania, Philadelphia, PA, (10)Study to Explore Early Development, University of Pennsylvania School of Nursing, Philadelphia, PA, (11)National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, (12)Office of Nursing Research, University of Pennsylvania School of Nursing, Philadelphia, PA, (13)California Department of Public Health, Richmond, CA, (14)Nursing Research, University of Pennsylvania School of Nursing, Philadelphia, PA, (15)School of Nursing, PA-SEED, CADDRE, Philadelphia, PA*

Background: Maternal pre-pregnancy obesity, excess gestational weight gain, and rapid weight gain during early infancy have all been associated with an increased risk of childhood obesity in typically developing children. Given the high prevalence of overweight/obesity among children with Autism Spectrum Disorder (ASD), there is a pressing need to examine early life influences on child weight outcomes in this population.
Objectives: To examine the associations between 1) maternal pre-pregnancy weight status, 2) gestational weight gain, and 3) rapid weight gain during infancy and weight outcomes in children classified as ASD, developmental delay (DD), and general population controls (POP).
Methods: SEED is a multi-site case-control study of children, aged 3-5 years, who were classified as ASD (n=668), DD (n=914), or POP (n=884). Maternal weight outcomes were derived from a maternal interview; child weight outcomes were ascertained from medical records (birth to 6 months) and a dysmorphology exam (age 3-5 years). Maternal pre-pregnancy body mass index (BMI) was calculated as weight (kg) divided by height (m) squared. Maternal gestational weight gain was compared to the Institute of Medicine (IOM) guidelines for weight gain during pregnancy, and categorized as meeting or not meeting (above or below) the recommendations. Child age- and sex-specific weight and BMI percentiles and z-scores were calculated using the WHO Growth Charts (birth to 24 months) and the CDC Growth Charts 2000 (>24 months). Rapid weight gain was defined as a change in infant weight-for-age z-scores from birth to 6 months greater than 0.67 SDs.
Results: After adjusting for case status, mothers who were overweight/obese prior to pregnancy were 2.40 (95% CI: 1.98, 2.91) times more likely to have an overweight/obese child at ages 3-5 years as compared to mothers who were underweight/normal-weight prior to pregnancy (P<0.0001). Adherence to the gestational weight gain recommendations was a significant predictor of child weight status at ages 3-5 years (P=0.043). Mothers who exceeded the weight gain recommendations during pregnancy were 1.30 (95%CI: 1.06, 1.61) times more likely to have an overweight/obese child at ages 3-5 years as compared to mothers who met the weight gain recommendations (P=0.014). There also was a significant relationship between rapid weight gain during infancy and case status. Children in the ASD group showed the highest frequency of rapid weight gain (35.9%) when compared with children in the DD (31.0%) and POP (28.3%) groups (P=0.02). Among children with ASD, those with rapid weight gain during infancy showed a higher frequency of overweight/obesity at ages 3-5 years than those without (35.6% vs. 18.3%; P=0.0007).
Conclusions: The findings from this study suggest that maternal pre-pregnancy overweight/obesity and excess weight gain during pregnancy were significant risk factors for overweight/obesity in their children. Children with ASD experienced rapid weight gain during infancy with a greater frequency compared to children in the DD and POP groups, which may contribute to their higher weight status later in life. Subsequent analyses will parse out the independent and combined contributions of these maternal and child risk factors to childhood obesity while also controlling for possible confounders.

127 **124.127** Effect of Comorbid ADHD on IQ and Adaptive Behavior in Children with ASD: Implications for Outcomes and Treatment

C. Montiel-Nava[1,2], *Z. Gonzalez*[1], *J. A. Chacin*[3] *and L. Palacios-Cruz*[4], *(1)Psychology, La Universidad del Zulia, Maracaibo, Venezuela, (2)Center for Graduate Studies, Universidad Latina, Panama, Panama, (3)La Universidad del Zulia, Maracaibo, Venezuela, (4)National Institute of Psychiatry, Mexico DF, Mexico*

Background: The conceptualization of ASD as a comorbid disorder with ADHD has been surrounded by controversy. The paucity of studies that compare comorbid patterns in children with ASD has added to such debate, specifically in connection to ADHD. Several reports show moderate to high ADHD prevalence among children with ASD, identifying ADHD as the most common comorbidity for this group of children. A better understanding of the comorbidity between both entities should, therefore, give rise to an appropriate sequence of intervention goals.
Objectives: The aim of this study was to establish comorbidity rates of ADHD in Venezuelan children with ASD and to describe clinical phenomenology in both groups (ASD and ASD+ADHD) and the implications of the comorbidity for treatment decisions.
Methods: Diagnostic and demographic data for children between two and seven years of age were collected as part of an epidemiological study of autism in Venezuelan children. The assessment protocol included the Raven's Progressive Matrices Test and ADOS. Parents completed the VABS and ADI-R. Clinical manifestations of ADHD were evaluated using the Spanish version of the Conners' Parent Rating Scale – Revised (CPRS-R).
Results: The assessment was completed by 103 children, of whom 65% (n=67) were diagnosed with ASD, while 35% (n=36) met criteria for an additional diagnosis of ADHD. Among the comorbid cases, 23 (64 %) were of the combined subtype, 3 (8 %) predominantly inattentive, and 10 (28 %) predominantly hyperactive-impulsive. Diagnosis was found to have no main effect on the ASD symptoms' measures of communication (p=0.55), reciprocal social interaction (p=0.277), and play and stereotyped behaviors (p=0.112). Diagnosis had a main effect on IQ (p=0.04); children from the comorbid group scored lower (86.71) than those from the pure group (90.62). By contrast, diagnosis had no effect on the adaptive functioning measures: daily living skills (p=0.255), communication (p=0.109), and socialization (p=0.135).
Conclusions: The clinical presentation of ADHD in children with ASD has been found to be similar to the typical presentation of ADHD. This is of paramount relevance due to the availability of treatment. To date, there are few treatments for the core symptoms of ASD, while there is a wide scope of options for the treatment of ADHD. Thus, when a child presents with both diagnoses, the identification of ADHD offers more comprehensive treatment options, which impact adaptive functioning and quality of life. The results of this study reveal once again the heterogeneity of the clinical expression of ASD as a frequent phenomenon and not just the exception. Our results suggest that, in pediatric mental health settings, the condition of comorbidity is expected between ASD and ADHD. The data obtained do not support the idea of different clinical syndromes for ASD depending on the presence of an ADHD comorbid condition.

128 **124.128** Examining the Factor Structure of the Spence Children's Anxiety Scale – Parent Version in Children with Autism Spectrum Disorder

K. Jitlina[1], *B. Zumbo*[1], *P. Mirenda*[1], *P. Szatmari*[2], *S. E. Bryson*[3], *E. Fombonne*[4], *I. M. Smith*[5], *T. Vaillancourt*[6], *J. Volden*[7], *L. Zwaigenbaum*[8], *S. Georgiades*[9], *E. Duku*[9], *M. Elsabbagh*[10], *T. Bennett*[9] *and A. Thompson*[9], *(1)University of British Columbia, Vancouver, BC, Canada, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)Oregon Health & Science University, Portland, OR, (5)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (6)University of Ottawa, Ottawa, ON, Canada, (7)University of Alberta, University of Alberta, AB, Canada, (8)University of Alberta, Edmonton, AB, Canada, (9)McMaster University, Hamilton, ON, Canada, (10)McGill University, Montreal, PQ, Canada*

Background: Anxiety disorders are estimated to occur in approximately 40% of youth with ASD, and represent one of ASD's most highly comorbid psychopathologies (van Steensel et al. 2011). The assessment of anxiety in ASD is problematic because ASD-specific characteristics, such as social skill impairments and alexithymia, may alter the experience of anxiety in this population (Kerns & Kendall, 2012). Consequently, the appropriateness of anxiety assessment tools originally developed for typically developing children cannot be assumed in ASD. Research examining the psychometric properties of existing anxiety measures in ASD samples is emerging. Initial evidence for the reliability of the Spence Children's Anxiety Scale – Parent Report (SCAS-P; Spence, 1999) - a widely used anxiety rating scale - has been demonstrated in two samples of children with ASD (Magiati et al., 2015; Zainal et al., 2014). Support for a six correlated factor structure in the SCAS-P (separation anxiety, social phobia, generalized anxiety, panic attacks and agoraphobia, obsessive-compulsive disorder, physical injury fears) has been found in community and clinical samples (Arendt et al., 2014; Nauta et al., 2004). However, the SCAS-P's factor structure when used with children with ASD has not yet been examined.
Objectives: The purpose of this study was to examine the factor structure of the Spence Children's Anxiety Scale – Parent Report (SCAS-P) in children with ASD.
Methods: Data were drawn from the Canadian Pathways in ASD study (N=421) and included children whose parents who had completed all 38 items of the SCAS-P (n=167; 83.1% boys; mean age 7.74 years old [SD=.22]). All children had a diagnosis of ASD based on DSM-IV criteria and confirmed with ADI-R/ADOS. Confirmatory factor analysis (CFA) using robust weighted least squares estimation was used to examine the fit of the previously supported six-correlated factor model, and four other theoretically guided models (Arendt et al., 2014; Nauta et al., 2004). If the CFA did not result in model fit, principal axis factoring (PAF) using direct oblimin rotation was used to explore an alternative plausible structure. Parallel analysis guided factor selection.
Results: CFA suggested the model only partially met criteria (CFI=.888, TLI=.878, RMSEA=.040, [CI 90% .031-.048; Test of close fit p=.983], SRMR =.117). PAF suggested a six-factor solution best described the data, explaining a 48.3% of the variance. Four factors emerged: physical symptoms of autonomic arousal; panic, agoraphobia, and compulsive behaviors; social phobia; and separation anxiety. Two factors had mixed item groupings: the first was comprised of items relating to separation anxiety and physical symptoms; and the second contained items related to obsessions, compulsions, and generalized worries. Four items (13, 21, 23, 30) had small loadings <|.3| on all factors.
Conclusions: CFA on five SCAS-P factor structures previously suggested in community and clinical samples did not show a good fit in a small sample of children with ASD.

As a follow up, exploratory analyses resulted in an alternative six-factor solution, with four items not showing strong loadings onto any factors. The findings are discussed with regards to the nature and assessment of anxiety in ASD.

129 **124.129** Exploring Anxiety and Executive Function Among School-Aged Children with ASD

G. Greco[1] *and S. Faja*[2]*, (1)Boston Children's Hospital, Harvard Medical School, Boston, MA, (2)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: The prevalence of anxiety in children with autism spectrum disorder (ASD) is higher than that of the general population. Previous research has found that between 22-84% of children with ASD are affected by at least one anxiety disorder (Vasa & Mazurek, 2015). Many individuals with ASD also exhibit significant difficulties with executive function (EF). To our knowledge, only two studies have investigated the connection between anxiety symptoms and EF in children with ASD, one of which included adolescents aged 14-16 years (Hollocks, et al. 2014) and the other used only parent report measures (Lawson, et al., 2015).
Objectives: The first objective was to determine whether diagnostic groups of school-aged children differed on a parent reported measure of children's anxiety. A second goal was to explore the relation between EF performance and anxiety symptoms in children ages 7-11 with ASD.
Methods: Participants included 28 children with ASD and 33 children with typical development (TD) all between 7-11 years of age. The groups were age, sex, and IQ-matched. Executive function was measured using parent report from the Behavioral Rating Inventory of Executive Function (BRIEF) and two computer-based tasks, the Change Task and Stroop Task. The Change Task included "Go" trials, which were a two-choice reaction time task, and "Change" trials, which added an additional stop signal that designated when children should stop and press a third button. During the Stroop Task, words were presented in pseudo-random order in red, green, yellow, and blue and children responded to the color the word was written in, even when the word introduced conflicting information (e.g., *blue* written in *red*). Anxiety was measured via parent report on the Child Behavior Checklist (CBCL).
Results: Groups differed significantly on scales of anxiety, $t(58) = 4.02$, $p < .001$, anxious depression, $t(58) = 3.29$, $p = .002$, and internalizing problems, $t(58) = 4.00$, $p < .001$, with parents of children with ASD reporting higher scores on all three measures. Within the ASD group, children with worse BRIEF shifting scores were rated as being more anxious, $r = .44$, $p = .02$. Stop signal reaction time, which indicates latency of inhibition, was correlated with CBCL subscales of anxiety, $r = .41$, $p = .05$, anxious depression, $r = .57$, $p = .004$, and internalizing problems, $r = .50$, $p = .01$. Lower inhibition on the Stroop Task was also correlated with higher reported anxiety symptoms, $r = -.48$, $p = .02$.
Conclusions: We found that children with ASD had significantly higher ratings of anxiety when compared to TD children, which supports previous research that individuals with autism are affected by comorbid anxiety. Additionally, within the group with ASD, measures of EF, specifically inhibition and shifting, were correlated with parent reported levels of child anxiety. This relationship may indicate that inhibition and shifting play a role in the behavioral functionality of individuals with ASD, which is exhibited as anxiety. We expect to have data for approximately 20 more children with ASD by May.

130 **124.130** Exploring Relationships Between Negative Cognitions and Anxiety Symptoms in Youth with Autism Spectrum Disorder

A. Keefer[1,2]*, N. L. Kreiser*[1,2]*, V. Singh*[1]*, A. Blakeley-Smith*[3]*, A. Duncan*[4]*, S. Hepburn*[5]*, C. Johnson*[6]*, L. G. Klinger*[7]*, A. T. Meyer*[8]*, J. Reaven*[9] *and R. A. Vasa*[1,2]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)School of Medicine, Johns Hopkins University, Baltimore, MD, (3)Univ. of Colo. Denver-JFK Partners, Aurora, CO, (4)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)University of Colorado / JFK Partners, Aurora, CO, (6)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (7)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (8)University of North Carolina, Carrboro, NC, (9)Univ. of Colorado Denver-JFK Partners, Aurora, CO*

Background: Negative cognitions (NC) are central to the conceptualization and treatment of anxiety disorders in youth without ASD (Beck & Rush, 1985; Davis et al., 2011) and demonstrate relationships with anxiety symptoms, intolerance of uncertainty (IU), and worry (McEvoy et al., 2014). In ASD, meta- and socio-cognitive impairments raise questions about the role of NC in the phenotype of anxiety, and modified cognitive-behavioral interventions (MCBT) often place less emphasis on addressing NC. Yet, two recent studies found that youth with ASD reported more NC than anxious and non-anxious youth without ASD, and NC predicted severity of anxiety, depression, and disruptive behaviors (Farrugia et al., 2006; Ozsivadjian et al., 2013). These findings, coupled with data showing that about one third of youth with ASD do not respond to MCBT (Vasa et al., 2014), suggest that further research on the relationship between NC and anxiety is needed to guide interventions.
Objectives: The objectives of this study are: 1) To examine relationships between negative cognitions (NC) and anxiety symptoms, worry, and intolerance of uncertainty (IU) (Aim 1), and 2) To assess predictors of negative cognitions (NC) in youth with anxiety and ASD (Aim 2).
Methods: Forty-one children and adolescents with ASD, ages 8 to 14 years participated in the Face Your Fears MCBT group therapy program as part of a multi-site treatment study (Reaven et al., 2011). The diagnoses of ASD and anxiety were established using standardized instruments. NC were assessed using the Children's Automatic Thoughts Scale (CATS; Schniering & Rapee, 2002), a self-report measure comprised of four sub-categories: physical threat, social threat, personal failure, and hostile intent. Children also completed measures of IU (IUS-C), anxiety (SCARED), and worry (PSWQ-C) preceding the intervention. Spearman Rho correlations were conducted to examine Aim 1. Multiple linear regressions were run to examine Aim 2.
Results: Preliminary analyses indicated moderate to strong relationships between NC and anxiety symptoms (Total NC: $r = 0.56$, $p < 0.001$; NC sub-categories: $r = 0.33$ - 0.64, $p < 0.05$) and IU (Total NC, $r = 0.52$, $p < 0.001$; NC sub-categories $r = 0.34$ - 0.54, $p < 0.05$). All NC sub-categories ($r = 0.44$ - 0.51, $p < 0.05$) except hostile intent were associated with worry (Table 1) (Aim 1). Results of the regression analyses showed that anxiety and IU were each independently associated with NC (Table 2) (Aim 2). Age, gender, and IQ were not significant predictors of NC and were excluded from the model.
Conclusions: Results support previous literature indicating a relationship between NC and anxiety symptoms in ASD youth. New findings from this study show that IU and worry are associated with NC, implicating NC as a significant component of anxiety in youth with ASD. IU may be key in the development of NC and may be a treatment target. Further analysis of interaction effects to differentiate relationships between NC and anxiety associated variables will be pursued. Relationships between specific NC (i.e., item-level analysis) and anxiety disorders, IU, and worry will be investigated.

Table 1

Spearman Correlations between Negative Cognitions (Sub-category and Total), Anxiety, Worry, and IU

131 **124.131** Extreme/ 'Pathological' Demand Avoidance: An Examination of the Behavioural Features Using a Semi-Structured Interview

E. O'Nions[1], *E. Quinlan*[2], *A. San José Cáceres*[2], *E. Viding*[3] *and F. Happé*[4], *(1)Division of Psychology and Language Sciences, University College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)University College London, London, United Kingdom, (4)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background:
Extreme/'pathological' demand avoidance is a term coined by Elizabeth Newson to describe children within the autism spectrum who exhibit an unusual pattern of behaviour. The key characteristics of this group include (1) an obsessive resistance to complying with everyday demands; (2) an apparent ability to use behaviour strategically to subvert requests (e.g. distraction, socially shocking behaviour); (3) an obsessive need for control, including domineering behaviour towards peers and adults; (5) a tendency to perceive themselves as having adult status; (6) a tendency to adopt others' roles when interacting; and (7) obsessive behaviour, often targetted at particular people. Intriguingly, reports suggest that those with PDA respond to different educational and management approaches than most individuals with autism – in particular spontaneity, humour and flexibility (Newson, Le Marechal & David, 2003). As such, there is a pressing need to better characterise the phenotypic profiles of these individuals to inform intervention studies targeting specific management approaches.
Objectives:
Whilst interest in extreme/'pathological' demand avoidance is increasing apace in the UK, to date, relatively little systematic examination of the phenotypic profile has taken place. The objective of this study was to identify descriptive behavioural features from semi-structured interviews conducted with parents of 24 children aged 8-16 years who exhibit substantial features of extreme/'pathological' demand avoidance, identified on the basis of indicators from the Diagnostic Interview for Social and Communication Disorders (DISCO) (Wing & Gould, 2002; O'Nions et al., 2015).
Methods:
Qualitative analysis using a general inductive approach (Thomas, 2006) was used to analyse the data. Four manuscripts were coded by two researchers, using open coding to highlight salient features. Preliminary codes formed the coding structure for further interviews, and additional themes or sub-themes added over the course of a full review of all interviews. Codes were then grouped into categories based on relatedness, and groups reorganized until they formed coherent themes, resulting in 11 major themes and 60 sub-themes. Subsequently, all interviews were reviewed, and the presence of each identified sub-theme coded for each individual case.
Results:
The results of the analysis highlight key behavioural traits, illustrative examples, and emergent themes. Common themes that resonate with clinical descriptions of extreme/'pathological' demand avoidance include use of 'strategic' behaviour to avoid everyday demands, a lack of awareness of social hierarchy (e.g., of own/others' age or status), and a lack of concern for one's own reputation evident in socially shocking behaviour. Obsessive controlling behaviour towards others, often parents, was frequently reported, in addition to extreme changes in mood. Descriptions from parents also highlight the range of manifestations of avoidance behaviour, perceived triggers, and patterns of early development seen in individuals with these traits.
Conclusions:
This study provides an important step towards deepening our understanding of the behavioural profile in individuals with substantial features of extreme/'pathological' demand avoidance, and highlights the very significant behavioural challenge that these individuals present.

132 **124.132** Facing Puberty: Menses in Females with Autism Spectrum Disorder

W. T. Eriksen[1], *M. C. Souders*[2], *R. Frasso*[3] *and J. A. Pinto-Martin*[4], *(1)University of Pennsylvania School of Nursing, West Chester, PA, (2)Clinical Genetics Center, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Public Health Initiatives, University of Pennsylvania, Philadelphia, PA, (4)Biobehavioral Health Sciences, University of Pennsylvania School of Nursing, Philadelphia, PA*

Background: As children with Autism Spectrum Disorder (ASD) age, challenges posed by their diagnosis are supplemented with the common challenges of growing up (Fong, Wilgosh, & Sobsey, 1993; Seltzer et al., 2003). Puberty may pose unique challenges for females with ASD, who face the additional challenges with the onset of

menses. Age at menarche and menstrual symptom presentation are known risk factors for significant mental and physical health concerns across the lifespan, including breast cancer, coronary heart disease, adolescent depression and social anxiety (Stoll, Vatten, & Kvinnsland, 1994; Lakshman et al., 2009; Blumenthal et al., 2009; Kaltiala-Heino et al., 2003). Recent findings suggest that females with ASD may experience menarche incongruent to and have more severe menstrual symptoms than their peers (Burke et al., 2010; Hamilton, Marshal, & Murray, 2011; Hamilton et al., 2012; Ingudomnukul et al., 2007; Knickmeyer et al., 2006; Pohl et al., 2014; Whitehouse et al., 2011). These findings strongly recommend a more in-depth and detailed exploration into puberty and its manifestation in females with ASD.
Objectives: (1) Characterize the onset and presentation of menses for females with ASD, (2) illustrate potential differences in onset and presentation of menses between females with ASD and their typically developing (TD) peers, and (3) compare reporting of menstrual symptoms between daughters and their parents.
Methods: Web-based surveys on age at menarche and menstrual symptoms using both self- and parent-report on the daughter. Autism networks, including research communities, electronic newsletters and community events, are used to identify parents of and females with and without ASD under the age of 18, who have experienced menarche, and have had at least one cycle in the previous six months.
Results: Preliminary Analyses (n = 9, anticipated n = 200): Participants were predominately non-Hispanic White (77.8%); daughters were aged 14-16 years and all parents participating were mothers. Females with ASD reported earlier age at menarche (M = 12.63 ± 1.24 years) compared to their TD peers (M = 14.25 ± 1.06 years); ASD Parents reported slightly later age at menarche (M = 12.96 ± 1.71 years), whereas TD Parents reported slightly earlier age at menarche than their daughters (M = 13.81 ± 1.16 years). Notably, females with ASD reported greater levels of pain related to their cycle (M = 7.5 ± 0.71: 1-10 Scale) than their peers (M = 6.50 ± 2.12) and both ASD and TD parents reported much lower levels of menstrual-related pain for their daughters (ASD: M = 2.5 ± 0.71; TD: M = 4.67 ± 4.62). Further, females with ASD endorsed more words to describe menstrual pain, such as stabbing, cramping and aching, and reported more emotional symptoms related to their cycle, such as feeling teary, withdrawn, and overwhelmed.
Conclusions: Females with ASD may experience menarche earlier and may have more physical, behavioral and emotional symptoms related to their cycle than their typically developing peers. Both ASD and TD parents tended to under-estimate key menstrual variables, suggesting that parent-report of menses and menstrual symptoms in these populations should be carefully interpreted.

133 **124.133** Gender Differences in Medical and Behavioral Co-Morbidities in Children Ages 6-17 Years with ASD

I. Zamora[1], *A. Shui*[2] *and L. Yin*[3], *(1)USC/CHLA, Los Angeles, CA, (2)Massachusetts General Hospital, Boston, MA, (3)Pediatrics, Children's Hospital Los Angeles/Keck School of Medicine of USC, los angeles, CA*

Background: ASD occurs 5 times more among boys (1 in 42) than girls (1 in 189). The evidence for gender differences in regards to the behavioral presentation and co-morbid diagnoses between boys and girls with ASD is mixed. However, some previous research findings have yielded some gender differences, which has implications in the diagnosis and management of girls with ASD (Kirkovski, Enticott, & Fitzgerald, 2013; Frazier & Georgiades, 2014, May, Cornish & Rinehart, 2013; Van Wijngaarden-Cremers et al, 2014) .
Objectives: This project is an observational study to determine if differences in the prevalence of medical and behavioral co-morbidities by gender in children ages 6-17 years with ASD exist.
Methods: Autism Speaks Autism Treatment Network Registry data contributed by 17 sites in North America was used for analysis. The sample included 416 (15.29%) females and 2305 (84.71%) males with a diagnosis of ASD (Pervasive Developmental Disorder, Autistic Disorder and Asperger's Disorder). Over 80% of the sample was Caucasian/White, 3.85% Asian, 6.88% African-American and 6.45% other/multiracial. Average age of the sample at the time of enrollment was 9.62 years (SD=2.81). The outcome variables included severity of symptoms, adaptive functioning, behavioral presentation, and medical co-morbid diagnoses. Descriptive statistics or tabulations of outcome variables and covariates potentially associated with sex were run overall and by sex. Any potential outcomes and covariates with significant sex associations at the 0.05 level were analyzed using adjusted linear or logistic regression models. Race and IQ were included as covariates in subsequent adjusted models.

Results: Girls had a higher prevalence of obsessive-compulsive disorder and were less likely to be underweight. Girls were also reported to have a higher rate of behavioral challenges related to aggressive behavior, anxiety, and taste/smell sensitivities. In unadjusted analyses, ADHD medication use was lower among girls although the prevalence of ADHD was similar between boys and girls. Girls also had lower calibrated ADOS severity scores. There were no differences between girls and boys regarding age of first concern and age of diagnosis.

Conclusions: Girls ages 6-17 years with ASD may present more often with OCD or behavioral challenges compared to boys. These differences in findings highlight the unique needs of girls with ASD and have important implications in their medical and behavioral care.
Acknowledgment: This Network activity was supported by Autism Speaks and cooperative agreement UA3 MC11054 through the U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Research Program to the Massachusetts General Hospital. This work was conducted through the Autism Speaks Autism Treatment Network.

134 **124.134** Genomic and Electrophysiologic Factors Contributes to Clinical Endophenotypes in Autism and Epilepsy Populations

G. Barnes, *University of Louisville School of Medicine, Louisville, KY*

Background: Autism spectrum disorders (ASD) are known to have complex inheritance patterns such as copy number variants (CNVs), single gene disorders, and rare mutations of common synaptic genes. Alteration in interneuron enriched genes may explain why perturbations of GABAergic circuitry have been implicated in common neurodevelopmental disorders such as autism (ASD), intellectual disability, and epilepsy. Defects in GABAergic migration, cell numbers, and circuit formation are found in animal models of autism and epilepsy.
Objectives: Our central hypothesis is that temporal and spatial specific expression of GABAergic signaling pathways contributes to the influence of sleep disruption on epileptiform discharges, seizure expression, and expression of clinical endophenotypes in autism populations.
Methods: A unique database of autism epilepsy subjects (223), autism alone subjects (221), and epilepsy alone (242) was compiled by recording data from the medical records of 686 pediatric patients from Vanderbilt University and the University of Louisville. Comparisons were made between ASD alone, epilepsy alone, and ASD + epilepsy groups.
Results: Epilepsy alone (11.8 yrs), and autism-epilepsy subjects (11.5 yrs) were significantly older than ASD alone subjects (9.9 yrs, $p<0.0001$ ANOVA) with a male predominance in ASD groups (4-5: 1 M:F ratio in ASD groups vs 1:1 ratio in epilepsy alone group), $p<0.0001$). Even though there was a slightly significant difference in age of seizure onset (Epilepsy only 57 months vs ASD-Epilepsy, 62 months, $p<0.05$) and less % REM sleep (11% vs 16 to 18% for ASD groups, $p<0.04$), there were no difference in resistance to anti-seizure medications. Cognitive impairment plays a more significant role in autism epilepsy subjects (IQ=64) more so than the ASD alone (74), or epilepsy alone subjects (78, $p<0.006$). We did note that those with ASD + Epilepsy had a higher rate of detectable CNVs on clinical microarray testing (41%) than ASD alone (30%, $p<0.08$). In general, time at autism diagnosis was similar among the two ASD groups. Epilepsy subjects were significantly older when regression occurred (50 months, $p<0.007$) than those with ASD. Parent of children with ASD-Epilepsy reported more self injury and worse language use ($P<0.008$) on the Parental Concern Questionnaire than parents with ASD alone. Finally, consistent with parental reports of age at walking or talking, Vineland Adaptive Behavioral Adaptive Scales measures of Adaptive Composite as well as subscores (ADLs, Social, Communication, Motor) were significantly higher in ASD alone subjects ($p=0.04$ to 0.001) than ASD+ epilepsy subjects. However there were no differences among the two ASD groups on the Childhood Behavioral Checklist.
Conclusions: Taken together, these data suggest that distinct subgroups within the autism and epilepsy populations have associated genomic variants which may impinge strongly on function of unique neural circuits and expression of clinical endophenotypes.

135 **124.135** Ideas Improving Diagnosis of Anxiety in Autism Spectrum Disorders

C. Sudrijan, *James's St, Trinity College Dublin, Dublin, Ireland*

Background: Children with high-functioning autism spectrum disorders (ASDs) are at high risk for developing psychiatric symptoms, with anxiety disorders among the most commonly co occurring. Cognitive behaviour therapies (CBTs) are considered the best practice for treating anxiety in the general population. Modified CBT approaches for children with high-functioning ASD and anxiety have resulted in significant reduction of anxiety following intervention. Facing your Fears (FYF) is a standardized cognitive behavioural group treatment with parental involvement with the purpose of decreasing anxiety symptoms in children with high functioning ASD. The intervention is designed to target more specific social, separation and generalized anxiety symptoms in ASD population. The program comprises core components of CBT psychoeducation, awareness of negative thoughts, somatic management of physical symptoms of anxiety, graded exposure. Physiological data collected during exposure can inform whether the treatment enact changes in the patients' responses to anxious situations.
Objectives: To detect if there is physiological change in response/or during exposure to anxiety provoking stimuli that correlate with behavioural measures in children with ASD and Anxiety. (b) To detect if the change in the physiological response that correlate with behavioural measures of anxiety are still maintained after completion of FYF intervention.
Methods: Four children with a confirmed diagnosis of ASD and Anxiety and an IQ above 80 and their parents were enrolled in the 14 weeks FYF program. Independent clinical evaluators completed behavioural (Screen for Child Anxiety Related Disorders, Anxiety Disorders Interview Schedule for DSM IV) and neurocognitive (Emotion Recognition Task, Visual Dot Probe) pre- and post intervention condition. Biological parameters, such as salivary cortisol is collected pre- and post graded exposure, whereas physiological ones such as: Heart Rate, Galvanic Skin Response, Respiration and Voice is collected during the graded exposure using BioSignalPluX equipment. Baseline values for salivary cortisol are established by collection of saliva samples 3 times per day in two consecutive days. Collection of the physiological parameters 10

minutes prior graded exposure provides the baseline values for Heart Rate, Galvanic Skin Response, Respiration Rate and Voice. Behavioral measures of anxiety prior, during and post exposure are stated using Subjective Units of Distress (SUD).
Results: The estimated findings of this pilot study regard the variation of the physiological parameters in response to anxiety provoking stimuli that correlate with behavioural mesures in the presence of anxiety disorders in individuals with ASD. Results will also inform whether the changes in physiological and neurocognitive measures are still maintained after 3 months of completion FYF intervention.
Conclusions: The output of the study will consist on a comprehensive evaluation of manifestations of anxiety in children with autism and anxiety identifying specific targets and strategies for interventions. As a second output of this pilot study is to attain a greater specification in assessment of anxiety in ASD population augmenting behavioural measures with physiological measures.

136 **124.136** Identifying Task Specific Subgroups in Autism Spectrum Disorder (ASD)

S. Sarabadani[1,2], *A. Kushki*[1] *and A. A. Samadani*[1,2], *(1)Bloorview Research Institute, Toronto, ON, Canada, (2)Biomedical Engineering (IBBME), University of Toronto, Toronto, ON, Canada*

Background: Atypical autonomic nervous system (ANS) activations are commonly observed in individuals with autism spectrum disorder (ASD). These atypical activations are often manifested in irregularities in cardiac activities and the function of sweat glands.
Objectives: The goal of this study is to identify subgroups of individuals with ASD by analyzing their physiological signals in order to discriminate between specific tasks. The tasks address one of the affected domains of ASD which is anxiety.
Methods: 40 children with ASD participated in this study. We measured electrocardiogram (ECG) and electrodermal (EDA) activities from participants while they performed a sequence of different tasks including: baseline, stroop task, baseline, public speaking task, and baseline. The task in baseline was watching video. Public speaking and stroop tasks were performed in order to elicit anxiety.
Results: ECG and EDA observations were represented in terms of various time and frequency meta-features. Feature clustering with different parameters and number of clusters was then performed to examine the pair-wise separability of the tasks for the ASD group. A weak statistical correspondence between the cluster membership of the resulting clustering and the pairs of tasks under investigation was found in all pair-wise cases.
Conclusions: The lack of separability between pairs of tasks, evaluated in this work, might indicate that ASD population demonstrates non-discriminative electrocardiogram and electrodermal activations while engaged in these tasks. Other physiological observations (e.g. respiratory) might be needed to separate the tasks.

137 **124.137** Improving Certainty about Uncertainty in ASD? Confirmatory Factor Analysis of the Intolerance of Uncertainty Scale (12) in ASD Adults

C. J. Kipp[1], *E. Anderberg*[1], *D. N. Top*[2], *K. G. Stephenson*[1], *M. Maisel*[1], *J. Rodgers*[3], *M. H. Freeston*[4], *M. South*[1,5] *and S. B. Gaigg*[6], *(1)Brigham Young University, Provo, UT, (2)1190 North 900 East, Brigham Young University, Provo, UT, (3)Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Psychology, Newcastle University, Newcastle, United Kingdom, (5)Psychology and Neuroscience, Brigham Young University, Provo, UT, (6)City University London, London, United Kingdom of Great Britain and Northern Ireland*

Background: Intolerance of Uncertainty (IU) impairs the capacity to function in ambiguous contexts including situations of unpredictable change. IU is commonly observed in people who have high levels of anxiety, including many people diagnosed with autism spectrum disorder (ASD). The 12-item Intolerance of Uncertainty Scale has been validated with good psychometric properties on normative undergraduate samples. However, people with autism seem to experience anxiety differently than non-ASD samples and new autism-specific measures of anxiety are appearing. We investigated whether IU might similarly differ in ASD samples by examining the factor structure of the IUS-12 in adults diagnosed with ASD.
Objectives: This study examined the established two-factor IUS-12 using confirmatory factor analysis. These two subscales include: the Prospective IU scale, which reflects a desire for predictability, anxiety about future uncertainties, and active engagement in seeking to increase certainty; and the Inhibitory IU scale, a measure of avoidance and paralysis in response to present uncertainties. We examined evidence for this structure as well as the overall total IUS total score.
Methods: Participants for this study consisted of 74 adults diagnosed with Autism Spectrum Disorder (ASD) recruited from two separate sites in the USA and UK. Multiple CFA analyses were performed using STATA 14 to assess the construct validity of the IUS. We performed hierarchical (second-order) CFA and a bi-factor CFA using the maximum-likelihood estimator to examine the relationship between the total IUS scores and its proposed subdomains. In the event that these models did not converge or fit properly, we then performed first-order CFAs for the total score, covaried sub-scale scores, and individual CFA for each sub-scale.
Results: CFA analyses of the hierarchal and bi-factor models did not converge after 10,000 iterations, indicting that neither model was appropriate given the available data. Though the total score CFA and the covaried sub-scales CFA did converge properly, both models showed inadequate fit. Individual sub-scales CFA showed that the Inhibitory sub-scale fit properly with no modifications. The Prospective sub-scale fit properly after dropping one item (#4; “One should always look ahead so as to avoid surprises”) and covarying one set of error terms. Many participants commented that it was difficult to respond to the questions because a) they included abstract rather than concrete scenarios and b) the respondents’ degree of uncertainty varies across situations.
Conclusions: Several recent studies have shown that IU is a useful construct for mediating anxiety and repetitive behaviors in ASD samples. However, the current structure of the IUS-12 does not provide a good overall fit for this pooled sample, though the brief Inhibitory subscale works better. As with ongoing work to create autism-specific measures of anxiety, more refinement of the IU construct and measures may be helpful to understand what aspects of uncertainty are most relevant in ASD.

138 **124.138** Incidence and Effects of Feeding Problems in Children with Symptoms of Autism Spectrum Disorder

A. B. Barber[1], ***M. M. Gosa***[2] *and E. Henderson*[2], *(1)University of Alabama, Tuscaloosa, AL, (2)Communicative Disorders, University of Alabama, Tuscaloosa, AL*

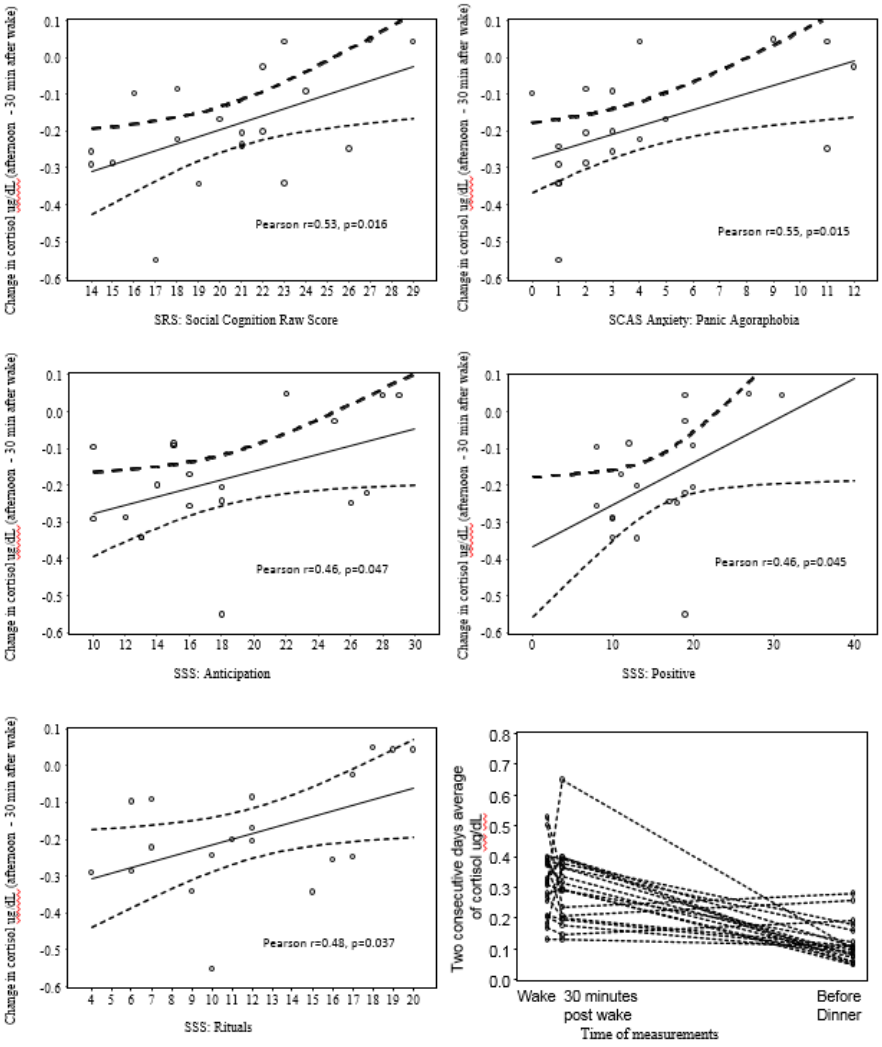
Background: Sensory processing dysfunction (SPD) is a known feature of Autism Spectrum Disorder (ASD). In children with ASD, SPD often manifests itself in extremely limited variety of dietary intake and increased dependence upon processed carbohydrate sources as their main energy source.
Objectives: This research project sought to describe the incidence and characteristics of feeding problems in a cohort of children being evaluated for possible ASD at an on-campus diagnostic clinic at a large public university.
Methods: Subjects, aged two to six years of age, were recruited from a university-based ASD Clinic. As part of the evaluation, parents completed the following measures to provide general information about their child’s symptoms, feeding and dietary habits, parent’s total stress level, and their child’s sensory responses: history form, 24 hour diet recall, *Sensory Profile* (Dunn, 1999), *Behavioral Pediatric Feeding Assessment Scale* (BPFAS) (Crist & Napier-Phillip, 2001), *Parenting Stress Index- Short Form (3rd Edition)* (PSI-SF) (Abidin, 1995), and the *Childhood Autism Rating Scale (2nd Edition)* (CARS™-2) (Schopler & Van Bourgondien, 2010). Additionally, if subjects could be conditioned height and weight measures were collected from standardized methods.
Results: In a sample of 29 children aged two to six years of age referred for evaluation of ASD, 48% (n=14/29) received a diagnosis of ASD and 35% (n=10/29) had significantly higher total frequency scores of problematic feeding behavior on the BPFAS. Forty percent of subjects with anthropometric data were classified as obese (n= 8/20) and of those subjects classified as obese, there was a significant positive correlation with higher scores on the BPFAS and increased consumption of processed foods. Analysis of 24-hour dietary recall information revealed a mean of 9.3 different foods consumed per day. Average intake of fresh fruit, vegetables, and minimally processed protein sources was just 2.25 foods in a 24-hour period, or just 24% of average number of foods consumed per day. Thirty-eight percent of subjects consumed no whole food sources in a 24-hour period. Average intake of processed and packaged foods, including foods consumed from fast food establishments, was found to be 7.39 foods per day, or more than 75% of the number of foods consumed per day. Thirty five percent of subjects received the majority of their daily intake of processed foods from carbohydrate sources, such as bread, potato chips, and French fries.
Conclusions: Data from this project reveal alarming trends with regard to incidence of obesity, reliance on processed food sources for majority of daily food intake, and minimal consumption of whole foods. These results suggest an immediate need for increased parent support and possible therapeutic intervention to reduce the number of problematic mealtime behaviors, reduce the percentage of obesity in this cohort, and increase the variety of food sources consumed.

139 **124.139** Individual Differences in HPA Axis Activity in Youth with Autism Spectrum Disorder: Relations to Stress, Anxiety, Social Responsiveness and Adaptive Skills

Z. Pan[1], *R. Gabriels*[2], *B. Dechant*[3] *and D. A. Granger*[4], *(1)Pediatrics, University of Colorado Denver school of medicine, Aurora, CO, (2)Children's Hospital Colorado, Aurora, CO, (3)University of Colorado - Denver, Aurora, CO, (4)Institute for Interdisciplinary Salivary Bioscience Research, Arizona State University, (3) Johns Hopkins University School of Nursing, Bloomberg School of Public Health, and School of Medicine, Phoenix, AZ*

Background:
Theorists speculate that individual differences in the reactivity and regulation of the hypothalamic-pituitary-adrenal (HPA) axis may provide clues as to the determinants of risk and resilience. Developmental science champions salivary cortisol to operationalize individual differences in the activity of the HPA axis (Granger et al., 2012). More than three decades of research reveals links between salivary cortisol and atypical behavior in youth (e.g., Granger et al., 1994; 1996; Gordis et al., 2006; Chen et al., 2014). Taken together, studies link salivary cortisol to distress, negative affect, and social anxiety, and show that variation in the expression of cortisol-behavior relationships is highly dependent on social contextual forces. Children with Autism Spectrum Disorder (ASD) may show variable dysregulation of diurnal patterns (e.g. Corbett 2008; Gabriels et al., 2013). Surprisingly, the depth of our knowledge about the association between environmentally sensitive physiological systems, such as the HPA axis, and adjustment in youth with ASD is very shallow. Advancing our understanding of the correlates and concomitants of HPA axis activity in ASD may have implications for individual

differences in developmental trajectory or treatment effectiveness, or both.
Objectives:
This study evaluated the association between activity of the HPA axis and stress, anxiety, and social responsiveness in youth with ASD**.**
Methods:
Saliva (later assayed for cortisol) was sampled three times a day (waking, 30 minutes post wake, and before dinner) for two consecutive days in 20 participants (19 males; 7-17 years; Parent report of the children's social responsiveness, anxiety and stress were obtained respectively using the *Social Responsiveness Scale* **(SRS),** Spence Children's Anxiety Scale (SCAS), and Stress Survey Schedule for Persons with Autism and Other Developmental Disabilities **(SSS)** (Essau 2002, Constantino 2012, Goodwin 2013)**.**
Results:
The cortisol diurnal decline was associated with SRS social cognition raw score (r = 0.53, p=0.016), SCAS panic agoraphobia (r = 0.55, p=0.015) and three SSS subscales: anticipation (r=0.46, p=0.047, positive (r=0.46, p=0.045), and rituals (r =0.48, p=0.037). Figure 1 presents the scatter plot and linear regression line.
Conclusions:
This preliminary study suggests that individual difference in the diurnal decline of cortisol in ASD patients may be associated with anxiety, stress and social responsiveness.



140 **124.140** Internalizing Psychopathology: Relations to Executive Functions in Young Children with Autism Spectrum Disorder

J. Berg[1,2]*, B. Wilson*[1] *and J. Kim*[1]*, (1)Clinical Psychology, Seattle Pacific University, Seattle, WA, (2)Psychiatry, UCLA Semel Institute, Los Angeles, CA*

Background: Children with ASD exhibit significantly higher rates of internalizing psychopathology including anxiety and depression than typically developing (TD) peers (Solomon et al., 2012). Psychiatric comorbidity in ASD increases with age and is associated with more negative outcomes overall. There is a paucity of research examining neurocognitive factors that may impact psychological outcomes for this population (Hollocks et al., 2014). Deficits in executive functioning (EF) are present in children with ASD (Hill, 2004) and associated with internalizing problems in TD populations (Koenigs & Grafman, 2009; Price & Drevets, 2012) and children with other neurodevelopmental disorders (Kelly et al., 2012). Neuropsychological deficits may partially explain the higher incidence of internalizing psychopathology in children with ASD and undermine children's adaptive responses to stress imparting greater vulnerability to poor mental health outcomes.
Objectives: The current study examines whether EF mediates the relation between developmental status and internalizing problems in young children.
Methods: Participants included 66 children ages 36 to 85 months with 40 children in the TD group (57.5% male) and 26 children in the ASD group (84.6% male). EF measures included an ecologically valid rating scale and performance-based neuropsychological task. Children completed the Tower of Hanoi-Revised (TOH-R; Welsh, Pennington, & Groisser, 1991) and parents completed the BRIEF (Goia, Isquith, Guy, & Kenworthy, 2000) or BRIEF-P (Gioia, Espy, & Isquith, 2003) Plan and Shift subscales measuring planning skills and cognitive flexibility. Parents reported on children's internalizing problems on the BASC-2-PRS (Reynolds & Kamphaus, 2004).
Results: Analyses utilized Hayes and Preacher's macro (2013), PROCESS, to test a multiple mediation model in which developmental status is associated with internalizing problems through EF with Shift, Plan, and ToH-R variables as parallel mediators. Bootstrapping results (5,000 resamples and 95% bias-corrected and accelerated CIs) supported our model (R^2= .470, F(5,55) = 9.741, p< 0.001) and indicated the predictor variables jointly accounted for 47% of the variance in internalizing problems. Significant indirect effects were found for Shift (point estimate= 1.215, SE = .301, 95% CIs[.652, 1.837]) and Plan (point estimate= .526, SE = .171, 95% CIs[.194, .869]). No significant indirect effect was found for ToH-R (point estimate= -.101, SE=.094, 95% CIs[-.340, .035]). Results indicate BRIEF Plan and Shift are significant mediators of the association between developmental status and internalizing problems whereas ToH-R did not play a mediational role.
Conclusions: The current study found a substantial indirect effect of parent reported child planning skills and cognitive flexibility on the association between ASD and internalizing problems. Performance on a neuropsychological task did not play a significant mediational role suggesting ecologically valid measures of EF may have more significance in the mechanisms underlying the association between internalizing symptoms and ASD. Research exploring the impact of neurocognitive factors on internalizing problems in individuals with ASD is limited and this is the first study to explore these relations in young children. These findings may inform interventions and potentially improve psychiatric outcomes for these children.

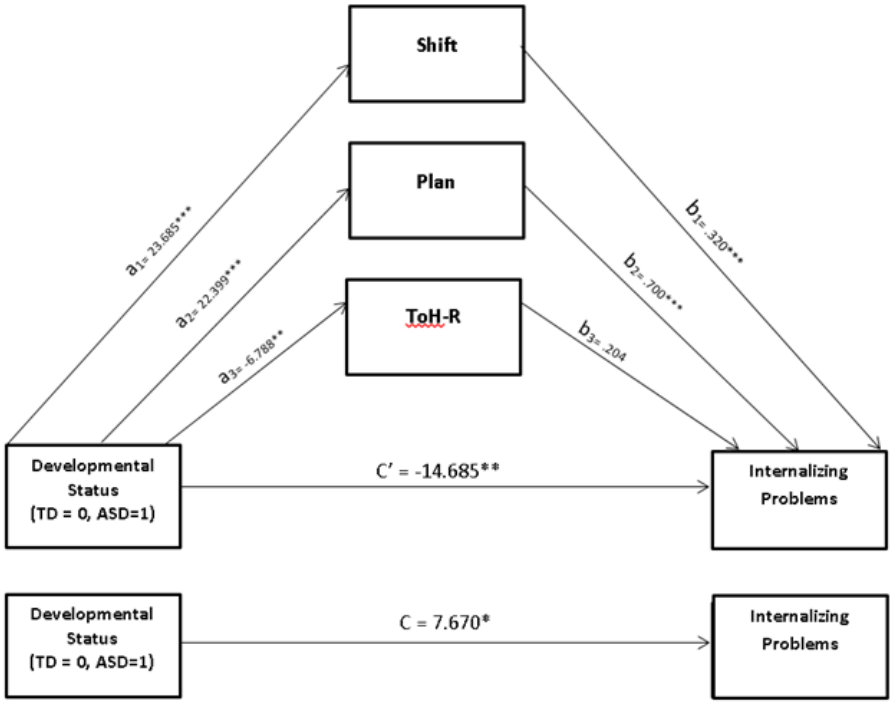


Figure 1. Multiple mediation model of developmental status, executive functioning, and internalizing problems displaying unstandardized coefficients. ToH-R = Tower of Hanoi performance scores, Plan = BRIEF Plan Subscale, Shift = BRIEF Shift Subscale. $P^* < .05$, $P^{**} < .01$, $P^{***} < .001$

141 **124.141** Longitudinal Predictors of Co-Occurring Anxiety in Children at Increased Familial Risk for ASD

B. Milosavljevic[1], *E. Shephard*[2], *T. Gliga*[3], *G. Pasco*[4], *E. J. Jones*[5], *F. Happé*[6], *M. H. Johnson*[7], *T. Charman*[1] *and T. B. Team*[8], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, London, England, United Kingdom, (3)Birkbeck College, London, United Kingdom of Great Britain and Northern Ireland, (4)Institute of Psychiatry, London, United Kingdom of Great Britain and Northern Ireland, (5)CBCD, Birkbeck College, University of London, London, United Kingdom, (6)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (7)Birkbeck, University of London, London, United Kingdom of Great Britain and Northern Ireland, (8)Birkbeck, University of London, London, United Kingdom*

Background:
Co-occurring anxiety is highly prevalent in individuals with ASD and their family members. Yet the shared neurocognitive correlates and early childhood predictors of these two conditions remain unclear. Research on the predictors of anxiety in children without ASD suggests that early difficulties with attentional flexibility and regulation of temperament may be markers of later development of anxiety. However, there is presently a scarcity in longitudinal research exploring the pathways leading to the development of anxiety in individuals with ASD.
Objectives:
This prospective longitudinal study aimed to explore the symptoms and longitudinal predictors of anxiety in children at increased familial risk for ASD. The aims of the study are to examine if 1) increased anxiety is observed among children at high-risk for ASD; 2) there are differences in anxiety symptoms among high-risk children who meet diagnostic criteria for ASD and those who do not; 3) difficulties with attentional disengagement and temperament in early life are associated with the development of anxiety within high-risk children.
Methods:
Symptoms of anxiety were measured at age 6-8 in a cohort of children at high-risk (HR) for ASD, who have been studied prospectively since infancy. Anxiety symptoms were measured using the Spence Children's Anxiety Scale parent-report (SCAS-P). Anxiety symptoms were compared between high-risk children who met DSM-5 criteria for ASD (HR-ASD; n=15), high-risk children without ASD (HR-no ASD; n=27) and low-risk controls (LR; n=37). Disengagement time on the Gap/Overlap task measured at 7m, 14m and 36m was used to explore the relationship between early attention and later anxiety. Finally, early temperament was measured using parent report at 7m, 14m, 24m and 36m with the Infant Behaviour Questionnaire (IBQ), Early Childhood Behaviour Questionnaire (ECBQ) and Child Behaviour Questionnaire (CBQ).
Results:
The HR participants exhibited higher anxiety than LR across SCAS-P subscales. Furthermore, the HR-ASD group had significantly higher anxiety compared to LR, and there was a trend for higher anxious symptoms in HR-no ASD than LR (Figure 1). Within the high-risk group, disengagement times on the Gap/Overlap task at 14m and higher levels of Negative Affect (NA) in toddlerhood were associated with increased anxiety at 6-8 years (Table 1).

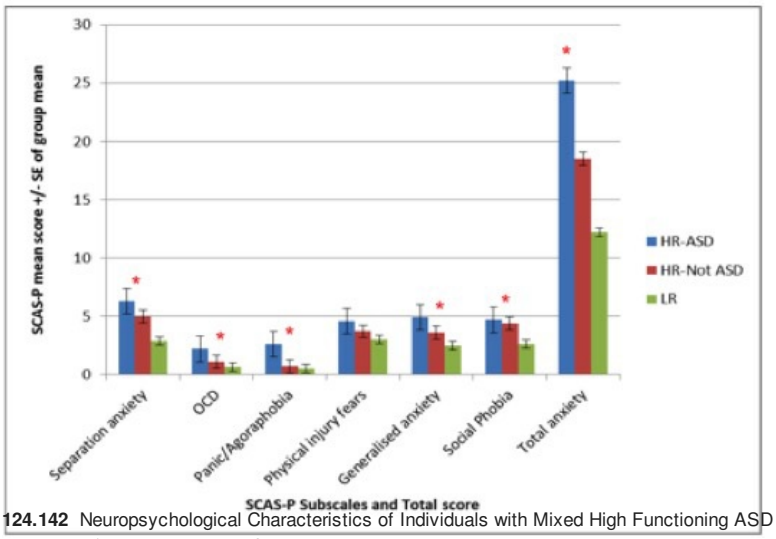
Table 1 Associations between anxiety, attentional disengagement and temperament

SCAS-P subscale	*Negative Affect 7m*	*Negative Affect 14m*	*Negative Affect 24m*	*Negative Affect 36m*	*Disengagement 14m*
Separation Anxiety	.13	.14	.19	.20	.22
OCD	-.05	.24	.40*	.38*	.22
Panic/Agoraphobia	.04	.22	.54**	.41*	.06
Physical Injury Fears	.10	.13	.29	.18	.36*
Generalised anxiety	.14	.32*	.46*	.42*	.24
Social phobia	.13	.39*	.54**	.37*	.22
Total anxiety	.11	.31*	.51**	.41*	.28

*p<.05 **p<.01

Conclusions:
Children at risk for ASD, particularly those who develop the condition themselves, exhibit increased anxiety. Among HR children, difficulty regulating attention and negative emotionality in infancy and toddlerhood are associated with the development of anxiety. This suggests that the pathways to developing anxiety are similar within children with ASD and their siblings as they are in non-ASD populations.

Figure 1 Anxiety symptoms in HR-ASD, HR-no ASD and LR at age 6-8 years



142 **124.142** Neuropsychological Characteristics of Individuals with Mixed High Functioning ASD and ADHD

C. Colombi[1] *and M. Ghaziuddin*[2]*, (1)Psychiatry, University of Michigan, Ann Arbor, MI, (2)Psychiatry, University of Michigahn, Ann Arbor, MI*

Background: Clinical heterogeneity is a well-established characteristic of ASD. It is estimated that 75% of individuals with ASD present associated medical conditions, genetic syndromes, mental health or developmental disorders (Ghaziuddin, 2008). In addition to the social communication impairment and the presence of restricted and repetitive behavior, a large portion of individuals with ASD presents symptoms of ADHD. While the comorbidity of ASD and ADHD is well known in the clinical realm, relatively little research has examined the neuropsychological profiles of children with mixed ASD and ADHD.
Objectives: To examine the neuropsychological characteristics of individuals with ASD + ADHD and those with ASD only.
Methods: 57 individuals with high functioning ASD (FSIQ > 70) were enrolled in the study. The sample consisted of 22 children with ASD and 25 children with ASD + ADHD (age 7 to 13). The battery administered to all participants comprised the Wechsler Scales of Intelligence, the Child Behavior Checklist (CBCL), the "Reading the Mind in the Eyes" (Baron-Cohen, 2001) used to evaluate empathy, the Purdue Pegboard Test used to evaluate manual dexterity, and the Tower of London Test used to evaluate planning.
Results: The groups did not differ in FSIQ, VIQ, or PIQ. ADHD symptoms (t = - 2.19; p = .03) and anxiety symptoms (t = -1.95; p = .05), as measured by the CBCL, were higher in the group of children with ASD + ADHD in comparison to the group with ASD only. Moreover, after controlling for FSIQ, children with ASD + ADHD showed significantly lower scores, in comparison to children with ASD only, in Working Memory (F = 4.52; p = .04) and marginally significantly lower scores in the "Reading the Mind in the Eyes" Test (3.48; p = .70). There were not significant differences in the Purdue Pegboard Test or in the Tower of London Test between the groups.
Conclusions: Our results showed significant differences in the neuropsychological characteristics of children with ASD + ADHD in comparison to those with ASD only. This suggests that having ADHD brings further challenges to individuals with ASD. Our findings may have implications for clinical assessment as well as intervention.

143 **124.143** Overlapping Symptoms of Bipolar Disorder in Children and Adolescents with Autism Spectrum Disorder

G. Singh[1]*, E. Anabalagan*[2]*, K. Sohl*[3]*, C. P. Gregory*[1] *and R. M. Brown*[4]*, (1)University of missouri-columbia, columbia, MO, (2)UC Davis, San fransico, CA, (3)University of Missouri - Thompson Center, Columbia, MO, (4)University of missouri-columbia, Columbia, MO*

Background: ASD is a developmental disorder arising in early years, whereas BD is primarily a cyclic affective disorder it is estimated that 1 in 68 children have ASD. The prevalence of ASD has risen significantly leading to increased awareness and research. Research indicates an increased prevalence of psychiatric comorbidities in autism. However, there is limited research on the overlapping symptoms of conditions similar to ASD that may be confounding accurate diagnoses. In BD and ASD, there are numerous symptoms that have significant overlap, especially when diagnosed during childhood. Some studies have been done on the prevalence of the BD and ASD and their correlation but the conclusions are conflicting and no clear results are available.
Objectives: The objective of the study is to compare the clinical characteristics of Bipolar Disorder (BD) and Autism Spectrum Disorder (ASD). Children diagnosed with ASD often have mood lability, aggression and sleep disturbances. Thus, whether these presentations are an entirely separate entity or characteristics of ASD itself raises a question of the extent of the overlap of symptoms and its diagnostic significance.
Methods: Data was analyzed from 100 CYASD diagnosed with autism during the calendar year 2012-2013. All patients analyzed received diagnosis and care at an Autism Speaks Autism Treatment Network Center of Excellence, affiliated with an academic medical center. Demographic information and specific variables were analyzed including age of diagnosis, delays in social skills and communication, presence of repetitive behavior, restricted interests, sensory issues, aggression, mood lability, depression, mania, thought disorder, family history of BD, ASD or disorders, toilet training, pregnancy and IQ. The criteria for assessing mood lability was the presence of emotional dysregulation in the form of temper tantrums, difficulty with transitions, rigid behaviors, easy irritability, internalizing and externalizing behaviors.
Results: In our study, 50% of individuals had aggressive behavior, 95% had mood lability, 66 % had sleep disruptions and 5% of the children had depression but none of them had been diagnosed with classic mania, hypomania, hallucinations or thought disorder. 31% had family histories of BD and 29% had family histories of ASD
Conclusions: In our study, half of our patients had aggression, one third had sleep disruptions and 95% had symptoms of mood lability. Pediatric bipolar disorder seldom presents with classic cyclic symptoms of mania and depression and more often presents with mixed features and rapid cycling. These symptoms are similar to those that can be seen in pediatric bipolar disorder and may predispose them to over diagnosis of BD. Whether these presentations are a separate BD or characteristics of ASD is an area of controversy and scientific debate. Further investigation of patients with co-morbid ASD and bipolar disorder is needed on a larger scale to determine this. Current treatment of these two disorders differs greatly. This emphasizes the importance of prompt recognition and an accurate early diagnosis, which would allow for better, more economical, and more efficient outcomes benefiting both the physician and the patient.

144 **124.144** Parent, Teacher and Self-Report of Behavioral and Adaptive Functioning in Youth with ADHD and ASD

K. E. Wagner *and K. M. Antshel, Psychology, Syracuse University, Syracuse, NY*

Background: Autism spectrum disorder (ASD) and attention deficit / hyperactivity disorder (ADHD) are common neurodevelopmental disorders which share some similar symptoms of social, emotional, and attention deficits. Once considered an exclusionary criterion for ADHD, there is now compelling evidence that behavioral characteristics of ADHD are observed in a large proportion of individuals with ASD. While much data have been published about ADHD and ASD individually, far less data have been published about the comorbid state (ASD+ADHD) and those data that have been published have been plagued by a lack of information about school behavior and functioning as well as small sample sizes. Thus, large scale efforts to investigate ASD+ADHD that include teacher report are sorely needed, especially an investigation of how the comorbid state compares to ASD and ADHD in isolation.
Objectives: The current investigation is a descriptive study comparing parent, teacher and self-reported behavior and functioning in three groups of children and adolescents: youth with ADHD, youth with high levels of ASD symptoms and youth with ADHD+high levels of ASD symptoms. Rather than assess a dichotomous ASD diagnosis, a decision was made to consider a Research Domain Criteria (RDoC) framework for high levels of ASD symptoms using the RDoC domain of Social Communication.
Methods: Participants were recruited from several large outpatient child and adolescent psychiatry specialty clinics housed within an urban academic medical center. Each participant for the current study received a rigorous psychiatric diagnosis made with the Kiddie-Sads-Present and Lifetime Version (K-SADS-PL) for the ADHD cohorts and the Autism Diagnostic Interview - Revised (ADI-R) for the high levels of ASD symptom cohorts. Participants consisted of 364 youth with ADHD alone, 81 children with high levels of ASD symptoms alone, and 38 children with a clinical diagnosis of ADHD and a high level of ASD symptoms. The Behavior Assessment System for Children – 2nd edition (BASC-2) parent, teacher and self-report measures served as the primary outcome measure.
Results: With regard to behaviors, the profile of ratings were generally consistent between parents and teachers and were significant for an externalizing disorder profile with ADHD cohorts and an internalizing disorder profile within the ASD symptoms cohorts. Children in all three groups self-reported less behavioral symptoms than adults. With regard to functioning, the parent and teacher data suggest a linear relationship between the three groups: the ADHD group was rated as the least impaired and the ADHD+ASD symptoms group was rated as the most impaired.

Conclusions: Careful clinical evaluation for the presence of ASD symptoms in individuals with ADHD (and vice versa) is recommended. ADHD is associated with an externalizing profile in youth with high levels of ASD symptoms. This is consistent with ADHD in the non-ASD population. The comorbid state was the most functionally impaired. This finding suggests that treatments designed to intervene with this common comorbid state represent a clinically significant line of investigation.

145 **124.145** Comparison of Two Screening Instruments for Additional Psychopathology in Children with Autism Spectrum Disorder

S. Chandler[1], *G. Baird*[2], *F. Salazar*[3] *and E. Simonoff*[4], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (3)Department of Child Psychiatry, South London and Maudlsey NHS Foundation Trust, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: High rates of co-occurring psychiatric disorders have consistently been reported in older children, adolescents and adults with autism spectrum disorders. These rates are four to six times higher than those reported in the general population and higher than those found in the studies with children with intellectual disability. The most commonly co-occurring disorders include anxiety, obsessive compulsive disorder and ADHD. More recent studies have reported similarly high rates in younger children with autism. Psychiatric disorders can worsen autism symptoms, interfere with education and reduce benefits of behavioural therapies. However, in younger children emotional and behavioural problems associated with these disorders are often assumed to be “part of autism” and are not systematically elicited by clinicians at diagnosis. Early identification of comorbid problems is crucial in the management of ASD as the impact of these additional problems can be reduced using a range of evidence-based interventions. A number of screening instruments are available for use in general populations but few have been validated for use with children with ASD.
Objectives:

- To explore whether the factor structures previously reported for the Developmental Behaviour Questionnaire (DBC) and the Profile of Neuropsychiatric Symptoms (PONS) in people with intellectual disability and general population samples, are found when used within a community sample of children with ASD.
- To test the validity of the DBC and PONS in relation to DSM-IV diagnoses elicited by a gold standard psychiatric diagnostic interview.
- To assess which questionnaire parent/carers found most suitable for describing their child’s emotional and behavioural problems.

Methods: The DBC and PONS were completed by parent/carers of 227 children with ASD, aged 4-9 years old. Intellectual ability and autism symptomatology were also assessed. DSM-IV psychiatric diagnoses were elicited for a stratified subsample of 101 children using the Preschool Age Psychiatric Assessment (PAPA).
Results: Exploratory factor analysis (EFA) of the DBC generated a 5-factor solution accounting for 53% of the total variance; the 5 factors were similar to the disruptive/antisocial, self-absorbed, communication, anxiety and social relating subscales previously reported. EFA of the PONS generated a 4-factor solution accounting for 93% of the total variance, broadly mapping onto the domains of neurodevelopmental disability, behaviour and emotional dysregulation, psychoses and personality dysfunction, anxiety and depression as previously reported. The relationship between the questionnaire measures and DSM-IV diagnoses as measured by the PAPA, will be presented using receiver operator characteristics (ROC) analysis and logistic regression.
61% of parents said they preferred the DBC to the PONS, 38% preferred the PONS and 1% expressed no preference.
Conclusions: The factor structures of the DBC and the PONS are similar in this ASD population to those already reported in other populations. The ROC analyses will determine the validity of both questionnaires in measuring additional psychopathology in young children with ASD, and thus point to whether either instrument could be recommended as part of the routine care of children with ASD at/following diagnosis.

146 **124.146** Personality Profiles in Intellectually Able Adults with ASD

K. B. Harrison[1], *M. Reddy*[2], *A. Engstrom*[1] *and K. A. Loveland*[3], *(1)Psychiatry & Behavioral Sciences, University of Texas Health Science Center Houston, Houston, TX, (2)Psychiatry and Behavioral Sciences, University of Texas Health Science Center Houston, Houston, TX, (3)University of Texas Medical School, Houston, TX*

Background:
Persons with high-functioning autism spectrum disorders (ASD) may go undiagnosed into adulthood, when they then present for evaluation because of increasing difficulties in adjustment or mental health. In addition to the social deficits of ASD, many experience clinically significant anxiety, depression, executive functioning deficits and other problems. However, the co-occurrence of other disorders with ASD in intellectually able adults can lead to confusion when they are assessed, resulting in misdiagnosis of disorders they do not have (e.g., bipolar disorder diagnosed because of outbursts), or a failure to detect ASD. Careful and clinically informed assessment is necessary to clarify the clinical picture.
The Personality Assessment Inventory (PAI, Morey 1991, 2007) is a valid, reliable self-report instrument often used to help identify psychopathology in adults, including adults with ASD. However, to date there are no studies that examine patterns of PAI scores of intellectually able persons with ASD.
Objectives:
This study is designed to investigate PAI scale and subscale patterns from responses of adults who meet DSM-IV/DSM-5 criteria for ASD, and then compare them to PAI scores from a smaller sample of adults with other clinical diagnoses to determine profile similarities and differences. A primary objective of this study is to provide evidence of PAI score patterns linked to ASD which can then be used for clinical application.
Methods:
Data were collected from 112 archival PAI records from two sources: an outpatient clinic which specializes in diagnosing ASD in adults, and a county psychiatric hospital. There were 75 participants with DSM-IV/DSM-5 ASD (33% F), and 25 participants with Other Psychopathology (32% F). Distribution of ages was similar between groups.
Data were analyzed from 11 clinical scales and associated subscales.
Results:
Adults with ASD had mean Borderline elevations on scales for Anxiety, Anxiety Related Disorders, Depression, and Schizophrenia. In the subscales, Cognitive and Affective Anxiety, and Cognitive and Affective Depression were Borderline elevated, and Schizophrenia Social Detachment was clinically elevated. MANOVA comparing the ASD and Other Psychopathology groups found significantly higher scores (greater psychopathology) for persons with ASD on the Anxiety scale and Cognitive and Affective Anxiety subscales and on the Schizophrenia Social Detachment subscale.
Conclusions:
Results suggest that on average, intellectually able adults with ASD have a distinct pattern of elevations on the PAI both when compared to norms for the PAI. The pattern identified suggests that significant anxiety and depression, especially the cognitive and affective symptoms of both, are likely to be reported by adults with ASD. The mean clinical elevation on the Schizophrenia scale in this group, when examined in light of the subscales, indicates that they are reporting withdrawal and detachment rather than psychosis. The comparison with the inpatient group, though preliminary, supports these findings. Further research comparing with other populations on the PAI as well as non-self-report instruments will be needed to confirm the validity of this pattern.

147 **124.147** Physical Growth Pattern from Birth to Age 6 of Children with Autism Spectrum Disorder Compared to Typically Developing Children

J. Zhang[1], *M. D. Fallin*[1,2,3], *H. E. Volk*[1,3], *D. M. Caruso*[4], *A. Riley*[1], *R. Landa*[2,5], *R. Angomas*[6], *C. Pearson*[6], *M. Silverstein*[6] *and X. Wang*[2,7], *(1)Johns Hopkins Bloomberg School of Public Health (JHBSPH), Baltimore, MD, (2)Johns Hopkins School of Medicine, Baltimore, MD, (3)Wendy Klag Center for Autism and Developmental Disabilities, JHBSPH, Baltimore, MD, (4)Center on the Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD, (5)The Kennedy Krieger Institute, Baltimore, MD, (6)The Boston University Medical Center, Boston, MA, (7)Center on Early Life Origins of Disease, Department of Population, Family, Reproductive Health, JHBSPH, Baltimore, MD*

Background: Cross-sectional data suggest that children with autism spectrum disorder (ASD) may be at higher risk of being overweight or obese (OWO), but results from longitudinal studies are limited and inconsistent. There is a lack of prospective birth cohort studies on physical growth patterns in ASD as compared to typically developing (TD) children.
Objectives: To assess whether longitudinal physical growth patterns, measured by attained levels and velocity of body mass index (BMI), weight and height, differ between ASD children and TD children in the Boston Birth Cohort (BBC), where children were enrolled at birth and followed prospectively through childhood at Boston Medical Center in Massachusetts.
Methods: This study included a total of 1,927 children from the BBC. Weight and height were measured by trained medical staff during well-child visits from birth to age 7. Age-gender specific BMI, weight and height z scores were defined by the World Health Organization (0-2 years old) and the Center for Disease Control and Prevention (2-18 years old) growth charts; and were further categorized as < 5th percentile (underweight), 5th – 85th percentile (normal weight), 85th-95th percentile (overweight) and > 95th percentile (obese). ASD cases (n=107) were defined based on ICD-9 codes of physician diagnosis in the electronic medical records (over 80% were diagnosed by relevant specialists). Spline regressions were used to characterize the growth patterns from birth to age 7; and mixed effects models were used to estimate and compare the slopes of the BMI, weight and height z score trajectories of ASD and TD children respectively. Finally, logistic regressions were used to compare the odds of being OWO between ASD and TD children at birth, age 2 and age 6 respectively. Important covariates were adjusted in the regression analyses.
Results: The prevalence of OWO increased with age in both ASD and TD children. ASD children started with lower weight at birth, but manifested more rapid weight gain in the first year of life as demonstrated by their higher velocity of BMI (P=0.04) and weight z score (P<0.001) compared to TD children. The growth curve of ASD children crossed TD around age 1, and then surpassed that of TD children. Both crude and adjusted logistic regressions indicated that the ASD children had a higher risk of becoming OWO than TD children at age 6 (OR=1.68, 95%CI: 0.93-3.04, P=0.09). In contrast, the pattern of height growth was comparable between ASD and TD children during the first 6 years of life.

Conclusions: Despite lower weight at birth, children with ASD had faster weight gain during the first year of life, and their growth curve surpassed that of TD children by age 1 and remained higher through age 7. In addition, the risk of OWO was higher in ASD children comparing to their TD counterparts. In light of numerous health risks associated with OWO, our study highlights the need for early prevention of OWO among ASD children, in addition to further etiologic research into the overlapping pathways of physical growth and neurodevelopment.

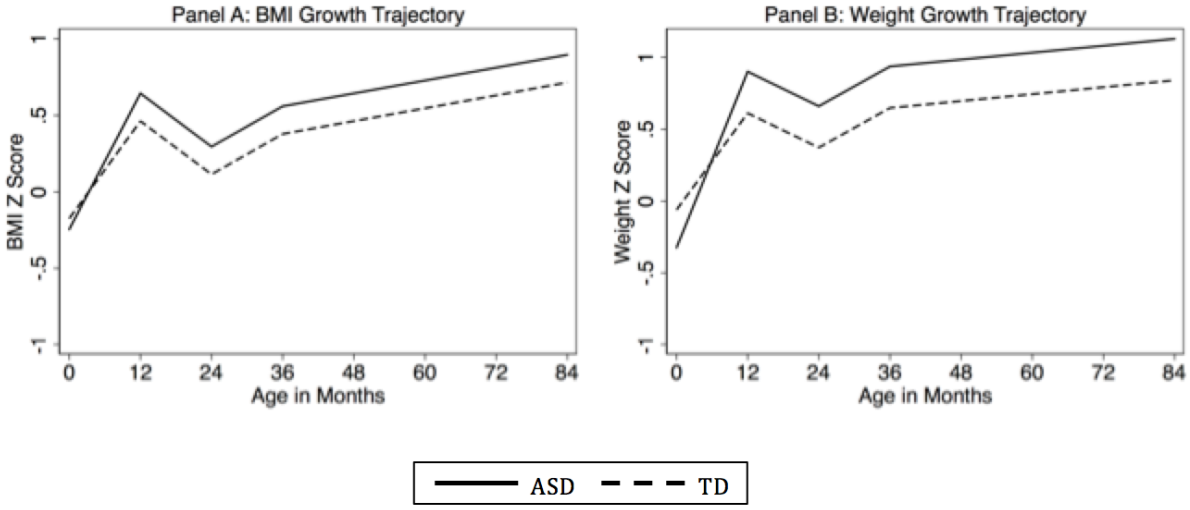


Figure1: BMI and weight growth trajectories

Table 1: Adjusted odds ratios of being overweight or obesity (OWO) comparing ASD to TD children at birth, age 2 and age 6*

	Odds Ratio	95% CI	P-value
Birth	0.79	(0.23,2.74)	0.71
Age 2	1.07	(0.61,1.90)	0.81
Age 6	1.68	(0.93,3.04)	0.09

*This model adjusted preterm birth and low birth weight status, maternal education, breastfeeding status, maternal smoking and drug use, maternal obesity and diabetes status.

148 **124.148** Predicting the Presence of Challenging Behaviours at 16 Years Old Using a Population Based Sample of Individuals with Autism Spectrum Disorder (ASD)

R. Kent[1], *V. Carter Leno*[2], *T. Charman*[3], *S. Chandler*[4], *C. Jones*[5], *F. Happé*[6], *G. Baird*[7], *A. Pickles*[2] *and E. Simonoff*[3], *(1)Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (2)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)School of Psychology, Cardiff University, Cardiff, United Kingdom, (6)Social Genetic and Developmental Psychiatry, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (7)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: 'Challenging behaviours' such as aggression, self-injury and non-compliance occur at high rates in children and adolescents with ASD and have been shown to significantly impact on caregivers' stress and individual's daily living and social development. Identifying risk and protective factors for challenging behaviours in individuals with ASD may increase our understanding of the causes and presentation of these behaviours, providing opportunities for interventions.
Objectives: To identify whether any characteristics frequently evaluated in youth with ASD can be used to predict challenging behaviours. Using a longitudinal sample, associations between participant characteristics measured at age 12 and later challenging behaviour at age 16 is explored.
Methods: A longitudinal, population-based cohort [The Special Needs and Autism Project (SNAP); Baird, Simonoff, Pickles, Chandler, Loucas, Meldrum & Charman, 2006] of youth with ASD (N=94) was used to study predictors of challenging behaviours. Challenging behaviours were measured at 16 years old using six parent rated items from the Profile of Neuropsychiatric Symptoms (PONS; Santosh, Gringas, Baird, Fiori & Sala, 2015): self-injury, aggression, labile mood, antisocial behaviours, oppositionality and explosive rage. A hierarchical multiple regression was used to investigate which participant characteristics at 12 years old predicted later Challenging Behaviour score. The variables in each step are described below:
1) Ability level: IQ, adaptive functioning (Vinelands Adaptive Behaviour Scales), receptive and expressive language (Clinical Evaluation of Language Fundamentals).
2) Autism severity: clinician ratings of ICD-10 symptoms, the Social Communication Questionnaire and the Social Responsiveness Scale.
3) Emotional and behavioural problems: Parent and teacher reports of hyper-activity, emotional symptoms and conduct problems were collected using the Strengths and Difficulties Questionnaire.
4) Additional psychiatric diagnoses: Diagnoses according to the Child and Adolescent Psychiatric Assessment (CAPA) were grouped into three categories: ADHD; oppositional or conduct disorder; any emotional diagnosis.
Results: Fifty one percent of parents reported adolescents with a clinical diagnosis of ASD to have one or more challenging behaviours that occurred frequently or interfered with everyday life. The most frequent behaviour was oppositionality (40%), followed by aggression (28%) and explosive rage (20%). IQ and language level did not significantly predict later challenging behaviour and nor did the addition of autism severity measures in Steps 1 and 2 of the hierarchical regression. The addition of teacher and parental reports of behavioural and emotional problems produced a significant predictive model and significantly improved the variance explained ($\Delta R^2 = 0.28$, $p<.01$). The addition of CAPA diagnoses improved the model further ($\Delta R^2 = 0.11$, $p<.05$.).
Conclusions: In this population-based sample, challenging behaviours at 16 years old were prevalent and predicted by previous co-occurring mental disorders and emotional and behavioural symptoms. The presence of co-occurring psychiatric disorders are predictive over and above parental and teacher reports of behaviour and therefore those meeting criteria for psychiatric diagnoses may be especially at risk of challenging behaviours. These findings are in contrast with findings from non-ASD

populations where lower IQ, functioning and language level predict challenging behaviours. With replication these findings may highlight behaviours to identify individuals for early interventions.

149 **124.149** Predictors of Poor Sleep Quality in Youth and Young Adults on the Autism Spectrum

ABSTRACT WITHDRAWN

Background: Poor sleep quality, primarily insomnia is known to be common in children and younger adolescents with autism, with up to 80% of individuals being affected. Emerging research indicates that sleep difficulties can have chronic course, continuing into older adolescence and adulthood. Research has started to explore the risk factors behind sleep difficulties in the autism population with findings suggesting that they may be associated with both core symptoms of autism, including sensory sensitivities and repetitive behaviours, and with comorbid conditions such as ADHD, anxiety, depression and gastro-intestinal symptoms. Recent proposals have particularly singled out the key role of anxiety and depression, at least in relation to insomnia symptoms.
Objectives: Our aim was to explore the relative contributions of anxiety and depression, sensory sensitivities, emotional awareness and somatic symptoms in predicting sleep quality in young people with autism.
Methods: Participants were drawn from the Autism CRC Longitudinal Study of School Leavers with autism (www.autismcrc.com.au), which commenced in 2015 and is ongoing. Currently 38 youth with autism, aged 15-25 years, 24 males (M_{age} = 17.46 years, SD = 2.15) and 14 females (M_{age} = 18.86 years, SD = 3.23) have completed demographic information, the Autism Quotient-28 item form (autism traits), COMPASS (somatic symptoms), DSM-5 dimensional anxiety scale, PHQ-9 (depression), Glasgow Sensory questionnaire (GSQ), and Levels of Emotional Awareness – short form (LEAS) and the Pittsburgh Sleep Quality Index (PSQI) as a measure of sleep quality.
Results: Full data for 32 participants are available to date; square root transformations were used for non-normal variables. Correlational analyses showed that all variables except autism traits, r = .31, p > .05, and emotional awareness, r = -.10, p > .05, were significantly (all p < .001) and strongly (all r > .50) associated with sleep quality. Next, a hierarchical multiple regression with sleep quality as the dependent variable was conducted. ASD traits were entered at step 1, and explained 10% of the variance, F (1, 30) = 3.34, p = .078. Sensory sensitivity was entered at Step 2, explaining an additional 19.2% of the variance, F change (1, 29) = 7.87, p = .009. The addition of anxiety and depression at step 3 explained an additional 23.8% of variance, R squared change = .24, F change (2, 26) = 6.84, p = .004. Somatic complaints was entered at step 4 but did not explain any additional variance, F change (1, 26) = 0.02, p = .891. The final model explained 53.1% of the variance in sleep quality, F (5, 26) = 5.88, p < .001, with depression being a unique significant predictor, $beta$ = .43, p = .047.
Conclusions: Preliminary results indicate that sensory sensitivity, anxiety and depression are strongly contributing to the maintenance of poor sleep quality in autism. This is in line with research in non-autistic populations suggesting that psychopathology and sleep are reciprocally related, while sensitivity to environmental stimuli can have a negative effect on sleep. These findings indicate potential future avenues for management of sleep problems in the autism population.

150 **124.150** Preliminary Findings from a Clinical Multi-Center Study on Individuals with Autism Spectrum Disorders, Intellectual Disability and Psychiatric Disorders

S. B. Helverschou[1], *E. Myrbakk*[2] *and T. L. Bakken*[3], *(1)Oslo University Hospital, Oslo, Norway, (2)Psychiatric Resource Team, Nordland Hospital, Bodø, Norway, (3)Psychiatric Department for intellectual disability / Autism, Oslo University Hospital, Oslo, Norway*

Background:
Despite the assumed higher prevalence of psychiatric disorders in individuals with Autism Spectrum Disorders (ASD) and intellectual disability (ID) compared to the general population, specialized mental health services for this population remain scarce and professional competence is limited. The development of psychiatric interventions adapted to the needs of individuals with ASD and ID is also a neglected area of research.
In Norway, a national network for professionals in charge of providing specialized and supplementary mental health services to individuals with ASD and ID was established in 2007. Eight centers which are spread around the whole country participate. A clinical treatment study was started in 2010 and recruitment is still in progress.
Objectives:
The study was established to contribute to valid psychiatric diagnoses and individually tailored services for individuals with ASD and ID in need of specialized mental health services. Specific aims were to report on and evaluate the characteristics by the participants and their environment, proportion of co-occurring psychiatric diagnoses, the delivery and adaptations of psychiatric interventions for these individuals, and differences in services between the centers.
Methods:
Patients with ASD and ID who are referred to one of the participating centers with behavior problems or suspicion of psychiatric disorders are recruited to the study. The patients are assessed three times, at referral, after one year and after two years.
Assessments include background and characteristics, behavior problems, psychiatric symptoms and diagnoses, environmental factors, interventions provided, and evaluation by care staff and family members.
Results:
More than 120 participants have been recruited, and some preliminary findings from the assessment at referral (T1) will be presented; background and characteristics including level of ID and ASD symptoms; distribution of psychiatric disorders, associations between behavior problems and mental disorders. Preliminary analysis indicate that about one third of the patients are female, the patients' age vary from 13 – 57 years (M=30.1, SD=10.1), about one third have severe / profound ID and two thirds have moderate / mild ID, and almost one third of the patients were not diagnosed with a co-occurring psychiatric disorder.
Conclusions:
The participants recruited to the study are a heterogeneous group. Mental disorders seem to be especially associated with behavior problems. The study design provide data that gives the possibility of addressing different research questions and may contribute to the understanding of psychiatric disorders in ASD and ID and potentially effective, and individualized interventions.

151 **124.151** Prevalence and Predictors of ADHD in Adolescent Males with FXS and ASD

S. L. O'Connor[1], *S. McGrath*[2], *J. Ezell*[2], *C. Smith*[2], *L. Abbeduto*[3] *and J. Roberts*[1], *(1)Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC, (3)MIND Institute, UC Davis, Sacramento, CA*

Background: Fragile X Syndrome (FXS) is the leading known genetic cause of Autism Spectrum Disorder (ASD). The behavioral phenotype of FXS is marked by challenging behaviors and symptoms such as inattention, hyperactivity, and hyper arousal related to Attention Deficit/Hyperactivity Disorder (ADHD). Approximately 60% of males with FXS, and 28-53% of children with ASD display features of ADHD. However, no study has determined diagnostic rates of ADHD in FXS or ASD with most studies relying on broad band rating scales reflecting the presence of specific behaviors. Also, no work has contrasted ADHD in FXS to idiopathic ASD (non-FXS).
Objectives: In the present study, we characterize the prevalence and predictors of ADHD using a DSM-based diagnostic interview with group contrasts. Our focus is on adolescent males with FXS and those with ASD given the high prevalence of ADHD in these populations.
Methods: Participants included 30 males with FXS and 7 males with ASD, 16-23 years-of-age. The Children's Interview for Psychiatric Symptoms-Parent Version (PChIPS), a DSM based semi-structured parental interview was used as a diagnostic measure of ADHD with Inattentive, Hyperactive and Combined types specified. Chronological age, Leiter-Revised nonverbal IQ growth scores, and severity scores from the ADOS-2 were used as predictors of ADHD diagnostic estimates in logistic regression models.
Results: Our results show that 40% of the FXS group met diagnostic criteria for a DSM diagnosis of ADHD, whereas 71% of the ASD group met (t (9.1) = 1.52, p > .05). Preliminary analyses indicate across the FXS and ASD groups respectively, 27% versus 57% met for Inattentive, 7% versus 14% met for Hyperactive, and 13% versus 0% met for Combined Type. Results from logistic regression models indicate that chronological age, nonverbal IQ and autism severity did not predict any type of ADHD in either the FXS or ASD group (p > .05). In logistic models reflecting predictors for individual subtypes in FXS, autism severity approached significance for Inattentive type (B=-0.35, p=0.08) with a moderate effect size (r = -0.33) and also for Hyperactive type (B=0.978, p= 0.11), with a large effect size (r=.67). In contrast these predictors did not approach significance for the ASD group.
Conclusions: These findings suggest that diagnostic rates of ADHD in adolescents with FXS are lower than symptom prevalence estimates reported in childhood, and higher in ASD although not to a significant degree. Our finding that the rate meeting diagnostic criteria in FXS is lower than symptom prevalence is consistent with general patterns of higher symptom presentation on screening, broad-band measures and lower prevalence on more discreet diagnostic criteria. Our rate of 71% meeting diagnostic criteria for the ASD group could reflect the small sample. A lack of relationship between autism features and ADHD suggests that these disorders are distinct indicating that both assessment and treatment efforts should potentially be tailored to surveil and treat both of these disorders. We aim to add an additional 10 participants with ASD by May 2016.

152 **124.152** Relationship Between Subtypes of Restricted and Repetitive Behaviors in Sleep Disturbance in Autism Spectrum Disorder

R. J. Hundley[1], *A. Shui*[2] *and B. A. Malow*[3], *(1)11101 Doctors' Office Tower, Vanderbilt University Medical Center, Nashville, TN, (2)Massachusetts General Hospital, Boston, MA, (3)Vanderbilt University, Nashville, TN*

Background: Sleep disturbance is common in children with autism spectrum disorder (ASD) and behavioral contributors often exist. We examined the association of two types of restricted and repetitive behaviors (RRBs), repetitive sensory motor (RSM) and insistence on sameness (IS), with sleep problems in children with ASD.
Objectives: The study aimed to detect RSM and IS behaviors within a registry of children with ASD. We sought to understand the association of latent RSM and IS variables with parent reported sleep disturbance. We hypothesized that higher rates of RSM would be associated with more sleep disturbance and that higher rates of IS would be

associated with better sleep. We controlled for prevalent markers of sleep disturbance in ASD, including age, cognition, and total autism severity.
Methods: Data were extracted from the Autism Speaks Autism Treatment Network (AS-ATN) registry. Registry participants included children ages 2-17 who met classification for an ASD based on the Autism Diagnostic Observation Schedule (ADOS) and DSM-IV-TR. Measures included the ADOS, Autism Diagnostic Interview-Revised (ADI-R), Vineland, and the Children's Sleep Habits Questionnaire (CSHQ). Standardized intelligence scales also were administered. The final dataset included 339 children whose parents had completed the ADI-R and CSHQ. As previous exploratory analyses support the construct validity of RSM and IS, a confirmatory factor analysis (CFA) was conducted for selected ADI-R RRB items. RSM and IS severity scores were calculated from the individual items and the mean score for each scale was computed. Total sleep problems from the CSHQ was regressed against RSM and IS severity scores, while controlling for previously determined correlates of sleep disturbance, including age, IQ, and measures of overall autism severity (i.e., communication scores from the Vineland and social affect totals from the ADOS). Potential covariates were included in the model if they were significant at the 0.15 alpha level.
Results: CFA of selected items from the ADI-R detected RSM and IS in this dataset. The proposed model fit well (CFI = 0.90, SRMR =.06, RMSEA = .05). All factor loadings were statistically significant (t values >3, p <.05; Table 1). IS was significantly associated with total sleep problems after controlling for other known markers. When controlling for communication ability, total sleep problems increased by about 2.3 units for each unit increase in IS. For each unit increase in RSM, total sleep problems increased by about three points. This association was no longer significant when controlling for communication skills. Comprehensive results, including association of RSM and IS to CSHQ bedtime resistance and sleep onset scales are presented in Table 2.
Conclusions: Our findings yield validity to previous research indicating that RRBs can be parsed into factors, including RSM and IS. To the best of our knowledge this was the first study to assess health behavior, specifically sleep disturbance, in relation to these constructs. The association of RSM, IS, sleep problems, and developmental functioning was complex and further study is warranted. Better understanding of the behavioral challenges of children with ASD at nighttime may contribute to better sleep and improved daytime functioning.

Background: Being overweight (OW) or obese (OB) is common in the general population, with almost 1/3 of children affected. Existing literature indicates that school-age children with autism spectrum disorder (ASD) or developmental disorders (DD) are at greater risk for OW or OB. These findings and corresponding risk factors have not yet

been addressed in large populations of preschool children (< 6 years old).
Objectives: We examined child weight outcomes in preschool children, across ASD, DD, and population control (POP) groups and the association between severity of ASD symptoms and OW or OB.
Methods: The Study to Explore Early Development (SEED) is a multi-site case-control study of children (3-5 years), comparing 3 groups: ASD (n=668), DD (n=914), and POP (n=884). Children in the DD and POP groups did not have a diagnosis of ASD. All children had parent interviews (medical and treatment history), cognitive assessment, behavioral screening questionnaires and child anthropometric measurements (during dysmorphology exam). Children in the ASD group had comprehensive ASD diagnostic evaluations (ADOS and ADI-R) and clinician-completed DSM-5 checklists with severity of symptoms noted, ranging mild to severe. Child age- and sex-specific BMI percentiles and z-scores were calculated using CDC Growth Charts 2000, and classified with BMI-for-age: underweight (UW) <5th percentile; normal-weight 5th to <85th percentile; OW and OB > 85th percentile. Associations between group membership and demographics were determined using chi-square tests. The association between obesity and group membership and severity of ASD symptoms was measured using a logistic regression model, with a p-value of <0.05 as significant. All analyses were conducted in SAS version 9.3 (SAS Institute, Cary, NC).
Results: Children in the ASD group had the highest percentage of males (81.7%) compared to DD (65.1%) and POP (53.1%) and were less likely to be white (57.5%), compared to DD (65.1%) and POP (69.9%). A chi-square test found a significant association between group membership and child weight status (p<0.0005). Children with ASD and DD had the highest frequency of OW or OB (ASD 27.5%, DD 25.0%) compared to POP children (19.5 %). Compared to POP children, children with ASD had 1.57 (CI: 1.24, 2.00) times the odds of being OW or OB (p= 0.002), and children with DD had 1.38 (CI: 1.10, 1.72) times the odds of being OW or OB (p = 0.001). There was a significant positive association between severity of ASD symptoms and weight status based on the Mantel-Haenszel chi-square test (p = 0.026).
Conclusions: Our findings suggest that children aged 3-5 years with ASD or DD have higher odds of being OW or OB than children in the POP group. Children in the ASD group with more severe symptoms of ASD were more likely to be OW or OB. Further analyses will be completed to parse out the contribution of other demographic, medical, developmental, behavioral, and treatment factors to the increased risk of OW or OB. Understanding factors associated with or contributing to excess weight gain will provide important information for clinicians and families caring for children with ASD and DD.

154 **124.154** Reliability and Validity of the Autism Spectrum Addendum to the Anxiety Disorders Interview Schedule (ADIS/ASA)

C. M. Kerns[1], *P. Renno*[2], *E. Crawford*[3], *R. Mercado*[3], *B. Garvin*[4], *J. Danial*[5], *P. C. Kendall*[6], *J. J. Wood*[2] *and E. Storch*[7], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)University of California Los Angeles, Los Angeles, CA, (3)Temple University, Philadelphia, PA, (4)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (5)UCLA, Woodland Hills, CA, (6)Psychology, Temple University, Philadelphia, PA, (7)University of South Florida, St. Petersburg, FL*

Background: Assessing anxiety in autism spectrum disorder (ASD) is inherently challenging due to overlapping (e.g. social avoidance, repetitive behavior) and ambiguous symptoms across these conditions. Ambiguous features include social fearfulness without awareness of social evaluation, excessive worry about novelty and change, and phobic responses to unusual stimuli, such as men with beards, specific sounds, or toilets. How such symptoms are conceptualized across measures and clinicians may have an impact on research findings, especially given that the majority of anxiety measures are neither designed nor validated in ASD samples. Notably, data regarding the prevalence and characteristics (e.g. cognitive ability, age, ASD severity) associated with anxiety in youth with ASD is inconsistent (Van Steensel et al., 2011), partially due to inconsistent measurement and differentiation of symptoms across studies (Kerns & Kendall, 2012). The *Autism Spectrum Addendum* (ASA) is a set of clinical guidelines and supplementary items designed to facilitate use of the *Anxiety Disorders Interview Schedule – parent version*(ADIS; Silverman & Albano, 1996), a semi-structured diagnostic interview, for children with ASD. The ASA provides a structured approach to differentiating traditional anxiety disorders (i.e. Social Phobia, Separation Anxiety, Generalized Anxiety) in ASD and also measures the ambiguous fears and worries that arise in this population.
Objectives: To assess inter-rater reliability as well as convergent and discriminant validity of the ADIS/ASA.
Methods: The parents of 70 cognitively-able (IQ>70) children (ages 8-13 years, *M*age=10.67, *SD*=1.64) with ASD completed the ADIS/ASA along with a battery of other behavioral measures as part of a screening evaluation for a randomized clinical trial comparing two cognitive-behavioral therapies for anxiety. A second rater independently observed and scored recordings of the original interviews. Inter-rater reliability as well as convergent and discriminant validity of the ADIS/ASA with other measures were assessed.
Results: Inter-rater agreement for specific ASA items (ICC=.82-.96), traditional anxiety (ICC=.85-.98), and ambiguous anxiety severity ratings (ICC=.87-.95) was excellent. Agreement was also good to excellent regarding principal diagnoses (κ =.82), the presence of clinically significant traditional anxiety (κ =.67-.91), and ambiguous anxiety (κ =.77-.90). Pearson correlations indicated convergence of the most severe ADIS/ASA anxiety severity ratings (traditional or ambiguous) with Pediatric Anxiety Rating Scale totals (PARS; *r*=.52, *p*<.01). ADIS/ASA traditional anxiety ratings converged with the Child Behavior Checklist (CBCL) anxiety subscale (*r*=.35, *p*<.01), but diverged from Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) comparison scores (*r*=-.02, *n.s.)* and CBCL Attention (*r*=.023, *n.s.*) and Aggression subscales (*r*=-.16, *n.s*). By comparison, the severity of ambiguous ADIS/ASA symptoms was significantly correlated with ADOS-2 severity ratings (*r*=.31, *p<.02)*, but not the CBCL anxiety (*r*=.03, *n.s.*), Attention (*r*=.08, *n.s.*) or Aggression (*r*=.11, *n.s.*) subscales.
Conclusions: Findings indicate that the ADIS/ASA provides consistent measurement of traditional as well as more ambiguous anxiety-like symptoms in children with ASD across different raters. Additionally, the ADIS/ASA shows adequate convergent and discriminant validity with other measures. Implications for future studies of the treatment, prevalence and phenomenology of anxiety in ASD will be discussed.

155 **124.155** Resting Autonomic Activity in Children with Autism Spectrum Disorders and Matched Controls with and without Comorbid Anxiety

V. Parma[1,2,3], *N. Cellini*[4], *L. R. Guy*[5], *A. McVey*[6], *K. Rump*[7], *J. Worley*[8], *J. C. Bush*[9], *J. Miller*[10] *and J. Herrington*[11], *(1)SISSA, Trieste, Italy, (2)CHOP, Center for Autism Research, Philadelphia, PA, (3)Clinical Neuroscience, Karolinska Institutet, stockholm, Sweden, (4)Department of General Psychology, University of Padova, Padova, Italy, (5)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (6)Marquette University, Milwaukee, WI, (7)The Center for Autism Research, Philadelphia, PA, (8)CHOP, Blue Bell, PA, (9)Indiana University, Bloomington, IN, (10)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (11)The Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Anxiety disorders are common among children with autism spectrum disorder (ASD). Both anxiety and ASD are associated with abnormal physiological activity. To date, few studies have investigated the autonomic profile of participants with ASD at rest and none has systematically assessed how the co-occurrence of formal anxiety disorders and ASD modulates resting physiological activity.
Objectives: The aim of the present study was to evaluate sympathetic and parasympathetic activity at rest in children and adolescents with ASD with and without comorbid anxiety. We also aimed to compare their autonomic profile, as well as parental and subjective reports of anxiety symptomatology, with the profiles of typically developing controls (TDC), matched for gender, age and presence of clinically relevant anxiety.
Methods: ASD was determined based on results from the ADOS, developmental interview or ADI-R, and clinical judgment. Both ASD and TDC participants received the Anxiety Disorders Interview Schedule (ADIS). Based on these data 4 subgroups were identified: ASD with comorbid anxiety (ASDanx, N=22), ASD and no anxiety (ASDnon, N=15), TDC with comorbid anxiety (TDCanx, N=16) and TDC and no anxiety (TDCnon, N=22). Participant ages ranged from 8 to 17 years old and were comparable across groups. In only the ASDanx group, males significantly outnumbered females. Autonomic parameters were assessed during a 5-minute resting state collected while the child was watching neutral nature scenes. Skin conductance level (SCL), a stable proxy for sympathetic activity in children with ASD (Schoen et al. 2008), and the proportion of high frequency component of heart rate variability (HRV), a proxy of parasympathetic activity, were calculated. Parents and children were asked to complete the Screen for Child Anxiety Related Emotional Disorders (SCARED); the overall score was used as a subjective evaluation of anxiety.
Results: Reduced sympathetic and parasympathetic activity at rest was found in ASD as compared to TDC. In particular, the analysis of sympathetic activity revealed a paradoxical hypo-arousal in ASDanx participants. Moreover, the analysis of the parasympathetic cardiac activity showed that in TDC (but not in ASD) anxiety promotes tachycardia. Overall, ASD groups showed lower parasympathetic activity, in line with the idea of inflexible physiological reactivity. Regression analyses suggest that the concurrent consideration of physiological responses as well as parent, and self-reports allows for an efficient categorization of the 4 subgroups.
Conclusions: Anxiety in ASD was associated with abnormal sympathetic and parasympathetic activity which, in association with parent and self-reports, allowed for efficient diagnostic categorization. As expected, the TDCanx group showed elevated levels of sympathetic activity. On the contrary, children with ASD and comorbid anxiety presented an atypically blunted autonomic profile. This suggests that anxiety in ASD may be related to different mechanisms than in TDC. In addition, the combination of autonomic profile and anxiety report measures might constitute a marker of anxiety in ASD. These findings emphasize the need for further investigations of the physiological activity of ASD and anxiety, since identification may facilitate the selection of effective treatments.

156 **124.156** Risk and Protective Factors of Depression in Children with ASD Tendency in Japan

N. Takayanagi[1], *M. Adachi*[1], *S. Yasuda*[1], *S. Yoshida*[1], *M. Kuribayashi*[1] *and K. Nakamura*[2], *(1)Research Center for Child Mental Development, Hirosaki University, Hirosaki, Japan, (2)Hirosaki University Graduate School of Medicine, Aomori, Japan*

Background: Children with ASD were tend to have difficulties in social communications and friendships in school, therefore they are at risk of secondary disabilities such as depression. Previous studies showed that rumination such as repetitive focus on their distress would increase depressive mood and skills of problem solving would decrease it. It is necessary to examine risk and protective factors of depression in children with ASD.
Objectives: The present study aims to examine risk and protective factors of depression in children with ASD tendency.
Methods: 3,678 children (1,868 boys, 1,810 girls) in public schools completed the Japanese version of the Depression Self-Rating Scale for Children short-form, the Strengths and Difficulties Questionnaire (peer problems subscale), the Social Maladjustment Scales (achievement, teacher and family), the Social Support Scales (peer and

adult) and the Response Style Questionnaire for Middle School Students (problem solving, rumination, avoidance and distraction), and their parents completed the Autism Spectrum Screening Questionnaire short-form.
Results: We divided the children into two groups according to the ASSQ short-form cut-off score; 367 boys in ASD tendency group (ASDtG-boys), 1501 boys in control (control-boys), 227 girls in ASDtG (ASDtG-girls) and 1583 girls in control (control-girls). We conducted a gender × ASSQ group ANOVA on the DSRS-C total score. Main effects of gender and ASSQ group were significant, but interaction was no significant. The result showed that girls were more depressive than boys ($F(1,3674) = 48.07$, $p < .001$, $\eta^2 = .013$), and ASDtG was more depressive than control ($F(1,3674) = 130.12$, $p < .001$, $\eta^2 = .034$). Then, we conducted a multiple regression analysis to examine whether these variables affect depression in each gender and ASSQ groups. In the results, these variables explained a significant amount of the variance of depression in all groups ($R^2 = .458–.613$). In the all groups, SDQ peer problems (β = .235–.329, $p < .001$) and rumination (β = .227–.309, $p < .001$) showed positive effects on depression significantly, and peer support (β = -.247–-.166 $p < .001$) and distraction (β = -.229–-.125, $p < .001$) showed negative effects significantly. Regarding ASD tendency in the same gender, ASDtG-boys showed avoidance as a positive effect (β = .108, $p < .001$) significantly and adult support as no significant effect on depression. On the other hand, avoidance did not show significant effect and adult support showed a negative effect (β = -.160, $p < .001$) significantly in control-boys. In addition, ASDtG-girls showed that grade and problem solving were no significant, although grade was a significant positive effect (β = .118, $p < .001$) and problem solving was a significant negative effect (β = -.107, $p < .001$) in control-girls.
Conclusions: The current study showed that children with ASD tendency would have different risk and protective factors of depression from controls, although they had the same factors partially. Peer support and distraction would decrease depression in all children, and for children with ASD, suitable coping strategy and support would be effective.

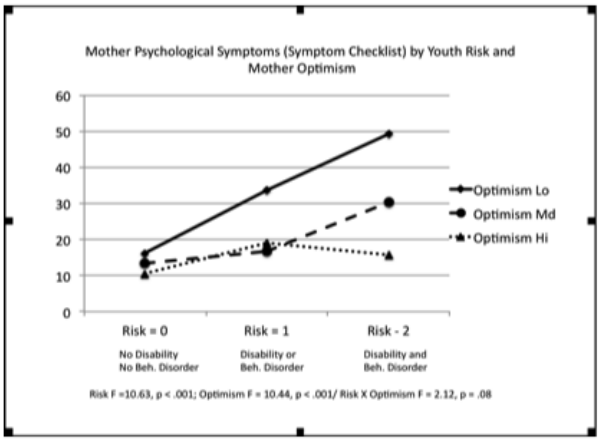
157 **124.157** Silver Linings: Optimism and Positivity As Buffers of Stress and Lower Well-Being in Mothers of Adolescents with ASD and Co-Morbid Disorders

J. Blacher[1] *and B. L. Baker*[2]*, (1)University of California - Riverside, Riverside, CA, (2)UCLA, Los Angeles, CA*

Background:
Evidence suggests that dispositional optimism is beneficial to one's health (Carver et al., 2010; Peterson, 2000) and helps maintain positivity during adverse times (Taylor et al., 2010). Specific to mothers of children with ASD or intellectual disability, maternal optimism relates to increased positive affect, decreased negative affect, and more adaptive coping strategies (Blacher et al., 2013). However, these youth have heightened behavior disorders relative to youth with typical cognitive development (Baker & Blacher, 2015), and their parents have further heightened stress related to these disorders. Little is known about how maternal optimism buffers the increased stress and lower sense of well-being experienced by mothers of adolescents with ASD and co-morbid behavior disorders.
Objectives:
We will consider the role of optimism in mothers of teens: (1) Does mothers' optimism relate to disability status (ASD, intellectual disability (ID) and typical development (TD)? (2) Does optimism buffer the increased stress and psychological difficulties experienced by mothers of youth presenting varying levels of risk? (3) Does the relationship between youth behavior disorders and parenting stress hold across adolescence (ages 13 to 15), and does optimism moderate this relationship at both time-points?
Methods:
This report is drawn from the Collaborative Family Study, a 15-year longitudinal study of behavior and mental disorders in children with or without ID/ASD. We report findings from age 13 and 15 assessments; the sample (N=195) contains youth with TD (IQ >84, n=100), ID (IQ <85, n=40), and ASD (n=58). The primary measure of behavior disorders was the Child Behavior Checklist. Other measures included the Family Impact Questionnaire Positive and Negative sub-scales; Symptom Checklist; and Life Orientation Test. A three-level risk index was determined from the presence of (a) ID and/or ASD, and (b) disruptive behavior diagnoses ADHD and/or ODD. Risk = 0/low (Neither a nor b); 1 (either a or b), or 2/high (both a and b).
Results:
Q1. Mothers' optimism was modestly (but significantly, p=.04) related to group status (TD>ID>ASD). The presence or absence of co-morbid disruptive behavior disorders (ADHD or ODD) was not related to dispositional optimism. **Q2**. To study the personality trait of dispositional optimism as a buffer of the relationships between child challenges and maternal well-being, we divided optimism scores into high (optimistic), medium, and low (pessimistic) thirds. The figure (one example) illustrates that psychological symptoms increased dramatically with increasing child risk. Optimism did not make a difference at "low-risk", but at "high-risk" mothers with low optimism (pessimism) reported a greater than 2.5 times increase in psychological symptoms. **Q3**. Youth behavior disorders and mothers' stress both *decreased* significantly from age 13 to 15, and significantly moreso in the ASD group. We will report the role of maternal optimism in these changes over time.
Conclusions:
Child disability status and child behavior problems/mental disorders take a psychological toll on mothers. However, the personality trait of dispositional optimism buffers these (child risk - parent adjustment) relationships. Not all parents are impacted similarly by youth disability and/or problem behaviors; there is a silver lining for those with more positive perceptions.



158 **124.158** Suicidality in Adolescents and Adults with and without an Autism Spectrum Condition

L. Van Dongen[1] *and S. A. Cassidy*[2]*, (1)Maastricht University, Maastricht, Netherlands, (2)Coventry University, Coventry, England, United Kingdom*

Background: Recent research has shown that adults with Autism Spectrum Conditions (ASC) report significantly increased rates of suicidality compared to the general population and other clinical groups. Self-reported autistic traits and history of depression have been shown to be significant risk factors for suicidal ideation, plans and attempts in this clinical group (Cassidy et al., 2014). However, there is still very little research exploring suicidal ideation, suicide plans, suicide attempts or non-suicidal self-injury in those with ASC and the associated risk factors. It is also unknown whether autistic traits are a risk factor for suicidality in the general population.
Objectives: 1) To compare the rate of suicidality, and non-suicidal self-injury in adolescents and adults with ASC to; a) typically developing (TD) adults, and b) a previous patient sample diagnosed with Asperger Syndrome (AS) in adulthood; 2) To explore risk factors for suicidality and non-suicidal self-injury in adolescents and adults with and without ASC.
Methods: 25 adolescents and adults with ASC were recruited from a Belgium clinic, and 43 adolescents and adults without ASC were recruited from online adverts. Participants completed an online survey including the Autism Spectrum Quotient (AQ), age diagnosed with ASC, lifetime experience of suicidal ideation, suicide plans, suicide attempts, and non-suicidal self-injury.
Results: Mean age of ASC diagnosis was 21.4 years (range 13-45, SD 10.7). Participants with and without ASC were matched on age (p=0.2) and education status (p=0.6). Self-reported rates of suicidal ideation in the current ASC sample (60%) were not significantly different to rates reported in a UK clinic sample diagnosed with AS in adulthood (66%, p=0.5). Compared to the TD group, participants with ASC were significantly more likely to report lifetime experience of suicidal ideation (60% vs 25.6%, OR 1.8, p<0.01); suicide plans (32% vs 4.7%, OR 3.5, p<0.01); and non-suicidal self-injury (28% vs 7%, OR 2.3, p=0.02); but not suicide attempts (16% vs 4%, p=0.1). In the TD group, self-reported autistic traits were significantly correlated with lifetime experience of suicidal ideation (p=0.01), suicide plans (p<0.001), and suicide attempts (p<0.01), but not non-suicidal self-injury (p=0.26).
Conclusions: Results confirm consistently high rates of suicidal ideation in adolescents and adults with ASC, in approximately two thirds of patients. Participants with ASC in the current sample were significantly more likely to have experienced suicidality and non-suicidal self-injury than age and education matched controls. Self-reported autistic traits were also a significant risk factor for suicidality in the general population. These results suggest an association between autistic traits, and increased risk of suicidality. This highlights the need for heightened vigilance for suicidality in people with ASC.

159 **124.159** The Longitudinal Course of Mood and Psychosocial Functioning in Youth with Comorbid Bipolar and Autism Spectrum Disorders

X. Borue[1]*, C. A. Mazefsky*[2]*, T. Goldstein*[1]*, B. Rooks*[3]*, M. K. Gill*[1]*, M. Strober*[4]*, M. B. Keller*[5]*, D. Axelson*[6]*, S. Yen*[5]*, R. S. Diler*[1]*, D. A. Axelson*[1]*, B. Goldstein*[1] *and B. Birmaher*[1]*, (1)Western Psychiatric Institute and Clinic, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)University of Pittsburgh, Pittsburgh, PA, (4)David Geffen School of Medicine, University of California, Los Angeles, CA, (5)Butler Hospital, Brown University School of Medicine, Providence, RI, (6)Nationwide Children's Hospital, The Ohio State University College of Medicine, Columbus, OH*

Background: Autism Spectrum Disorder (ASD) is often clinically associated with disturbances of mood and emotion. There is growing evidence of elevated rates of comorbidity between ASD and other psychiatric disorders, particularly Bipolar Disorder (BP). The recognition and treatment of comorbid BP in individuals with ASD, despite its clinical importance, has been hampered by a dearth of phenomenological data. A small number of cross-sectional studies suggest increased impairments and a higher prevalence of atypical features, but little is known about the longitudinal course of BP in youths with ASD.
Objectives: To provide the first longitudinal characterization of mood and psychosocial functioning in youth with comorbid ASD and BP.
Methods: The Course and Outcome of Bipolar Youth (COBY) study recruited youths ages 7 to 17 years with DSM-IV BPI, II, or operationally-defined BP-NOS. Subjects were comprehensively assessed using structured diagnostic interviews and a wide range of non-overlapping measures covering multiple dimensions of functioning. This study included a total of 368 youths with at least 4 years of follow-up (average ~9 years) using the Longitudinal Interval Follow-up Evaluation. Subgroup analysis was conducted, comparing youth with (BP+ASD) and without ASD on clinical presentation, percentage of time with mood symptomatology, and psychosocial functioning.
Results: Thirty youth (~8%) met DSM IV criteria for ASD. Duration of BP symptoms prior to entry into the study was ~4 years for both groups, but BP+ASD youth were, on average, 2 years younger at symptom onset and intake. As is typically observed in clinical cohorts, the male to female ratio was ~1:5 for BP+ASD youth vs 1:1 for BP youth. Additional diagnostic comorbidity was common, with 87% of BP+ASD youth also meeting criteria for ADHD. Similar to previous studies, BP+ASD youth had significantly higher T-scores on several syndrome scales of the intake Child Behavior Checklist including; withdrawn, social, thought, and attention problems. Over time, the proportion of predominantly euthymic youth in both groups increased and episode recurrence decreased. BP+ASD youth spent significantly more time with sub-syndromal mixed symptoms and had worse psychosocial functioning, especially with respect to friendships. Distribution between BP subtypes and lifetime worst episode severity were similar for both groups. BP+ASD youths exhibited typical BP mood symptoms but were found to have a higher prevalence of social withdrawal, poor mood reactivity (activity-related transient improvements in negative mood), and a broad range of manic symptoms (e.g. grandiosity, elated and labile mood, distractibility, and motoric activation). Differences between BP and BP+ASD youth on most factors were most prominent during the first few years and decreased over time.
Conclusions: Youth with comorbid BP and ASD exhibited typical BP mood symptoms but earlier onset, mixed symptom presentation, and additive functional impairments. Significant amelioration of clinical symptoms and psychosocial impairment occurs over time, suggesting that early recognition and treatment of mood disorders in youth with ASD may improve clinical outcomes.

160 **124.160** The Presence of Gastrointestinal Symptoms in Parents of Individuals with Autism Spectrum Disorder

J. Barstein[1]*, A. Bedell*[2]*, N. Dunbar*[1]*, L. Keefer*[2] *and M. Losh*[1]*, (1)Department of Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Division of Gastroenterology and Hepatology, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Gastrointestinal (GI) symptoms are four times as common in ASD than controls (McElhanon, 2014), and may exacerbate the behavioral and psychosocial

symptoms of the disorder (Mazurek, et al. 2013; Maenner et al. 2012; Peters et al. 2014). However, it is unclear how GI symptoms relate to the underlying causes of ASD. Evidence suggests an association between GI symptoms and ASD candidate genes (Campbell et al., 2006; Bernier et al., 2014), and family studies show aberrations in intestinal bacteria in siblings (Finegold et al., 2010; Gondalia et al., 2012; Parracho et al., 2005). This study built on previous work by examining the presence of GI symptoms in both individuals with ASD and their parents.
Objectives: To examine the familiality of GI symptoms in ASD by investigating the rate of symptoms in individuals with ASD and their parents, and how such features may relate to behavioral and psychosocial features.
Methods: Seventeen individuals with ASD and 35 parents (22 mothers, 13 fathers) were administered a battery of questionnaires to characterize a range of GI symptoms associated with functional or organic disorders of the digestive system. Functional disorders (FGID) include those that cannot be explained by structural or tissue abnormality (e.g., Irritable Bowel Syndrome, IBS) while organic disorders have known, physical, etiology (e.g., Crohn's Disease). GI symptoms were examined in relationship to previously collected phenotypic assessments of depression, anxiety, executive functioning, sensory sensitivity, pragmatic language, and social cognition.
Results: Forty three percent of individuals with ASD and more than half (63%) of parents met criteria for a GI disorder. While epidemiological studies have not been conducted to establish population based rates, this is substantially higher than 10-20% prevalence rates reported for IBS (the most common of FGIDs) in the general population. Higher rates of pragmatic language differences were noted among both individuals with ASD ($p=.07$) and parents ($p<.05$) who met criteria for a GI disorder, compared to those without a GI disorder. Parents who met criteria for a GI disorder also demonstrated greater sensory sensitivity, a higher likelihood of generalized anxiety disorder, and stronger social cognitive abilities (p's < .05) relative to ASD parents without GI disorders. Parents with a GI disorder were significantly more likely to have children with a GI disorder ($p<.05$).
Conclusions: Results document a high prevalence of GI disorders in individuals with ASD as well as their parents, suggesting studying GI symptomatology may help further our understanding of the complex etiology of ASD. The relationship between pragmatic language deficits and GI disorders is consistent with prior studies in ASD and adds to our understanding of underlying causes of ASD from a familial perspective. The presence of GI symptoms in parents corresponds with important behavioral and psychosocial profiles, complementing prior studies documenting relationships between GI symptoms and features of ASD in probands. This study contributes to a growing body of research supporting evidence of the gut-brain connection in ASD (Hsiao, 2013).

161 **124.161** The Relation Between Autism Symptom Severity and Family History of Psychiatric and Neurodevelopmental Disorders

D. Morriss[1,2], *H. Tokajian*[3], *A. H. Gerber*[2], *E. M. Morrow*[2,4], *T. F. Anders*[2] *and S. J. Sheinkopf*[2,3], *(1)Alpert Medical School of Brown University, Providence, RI, (2)Rhode Island Consortium for Autism Research and Treatment (RI-CART), Bradley Hospital, East Providence, RI, (3)Brown Center for the Study of Children at Risk, Women & Infants Hospital, Providence, RI, (4)Department of Molecular Biology, Cell Biology and Biochemistry and Institute for Brain Science, Brown University, Providence, RI*

Background: It is known that Autism Spectrum Disorder (ASD) is associated with family history of psychiatric disorders in addition to rates of autism and other neurodevelopmental disorders. Studies disagree about which psychiatric disorders are most prevalent in families of those with ASD, although epidemiological studies support a link between autism and familial mood and anxiety disorders (Smalley, McCracken, & Tanguay, 1995). Research indicates relationships between positive family history and higher IQ or increased functional ability (Mazefsky, Williams, Minshew, 2008; Robinson, et. al 2014). Studieshave yet to examine how family psychiatric history may correlate to measures of autism severity.
Objectives: To investigate whether the presence of psychiatric and neurodevelopmental disorder history in first- and second-degree relatives in a population of children and adolescents diagnosed with ASD is related to autism severity in the proband.
Methods: Participants were children and adolescents with ASD (n = 338, 3-17 years old) selected from a state-wide autism patient registry (80.5% male, mean age 9.9 years). ASD diagnoses were confirmed by the Autism Diagnostic Observation Schedule (ADOS). Family history of psychiatric and neurodevelopmental disorders was obtained through parental interviews. The presence of psychiatric and neurodevelopmental disorders in first- and second-degree relatives was summed to create four composite variables (i.e, sum of psychiatric disorders and neurodevelopmental disorders in 1^{st} and 2^{nd} degree relatives). The psychiatric family history composite consisted of fifteen disorders (e.g., mood and anxiety disorders), and the neurodevelopmental disorder composite consisted of eight disorders (e.g., ASD, Learning Disabilities, Intellectual Disability). Estimates of proband symptom severity were based on the caregiver-completed Social Responsiveness Scales, 2^{nd}Ed. (SRS-2) total T scores and the ADOS standardized severity score. Gender-controlled linear regression was used to investigate the relationship between family history of psychiatric and neurodevelopmental disorders and autism severity scores.
Results: First-degree family history of psychiatric disorders was related to increased symptom severity on the SRS-2 measure (*beta* = .159, $p = 0.009$). There was no significant relation between first- or second-degree family history of neurodevelopmental disorders and SRS-2 severity measure, nor a significant relation between family history of neurodevelopmental disorders or psychiatric disorders and ADOS symptom severity. Follow up analyses of psychiatric disorders revealed that first-degree family history of depression was significantly associated with higher SRS-2 scores, even after statistical correction ($t(290) = -3.31$, $p = .001$), while no other disorders showed a statistically significant trend.
Conclusions: The increase in presence of family history of psychiatric disorders in first-degree relatives was related to an increase in severity of social deficits in the autism spectrum measured by the SRS-2. These findings implicate a positive psychiatric family history as a higher genetic liability toward autism severity, but we also must consider the possibility that an increase in more "problematic" behaviors in children may contribute to a reporting bias in parental psychiatric disorders such as depression or anxiety. Our results support existing research that stresses the importance of investigating psychiatric family history as a potential contributing factor to behavioral ASD phenotypes.

162 **124.162** The Relationship Between Food Selectivity, Gastrointestinal Dysfunction and Biomarkers in Autism Spectrum Disorder

R. Enten[1], *E. Gal*[2] *and Y. Latzer*[3], *(1)Occupational Therapy, University of Haifa, Haifa, Israel, (2)University of Haifa, Timrat, Israel, (3)Public health, University of Haifa, Haifa, Israel*

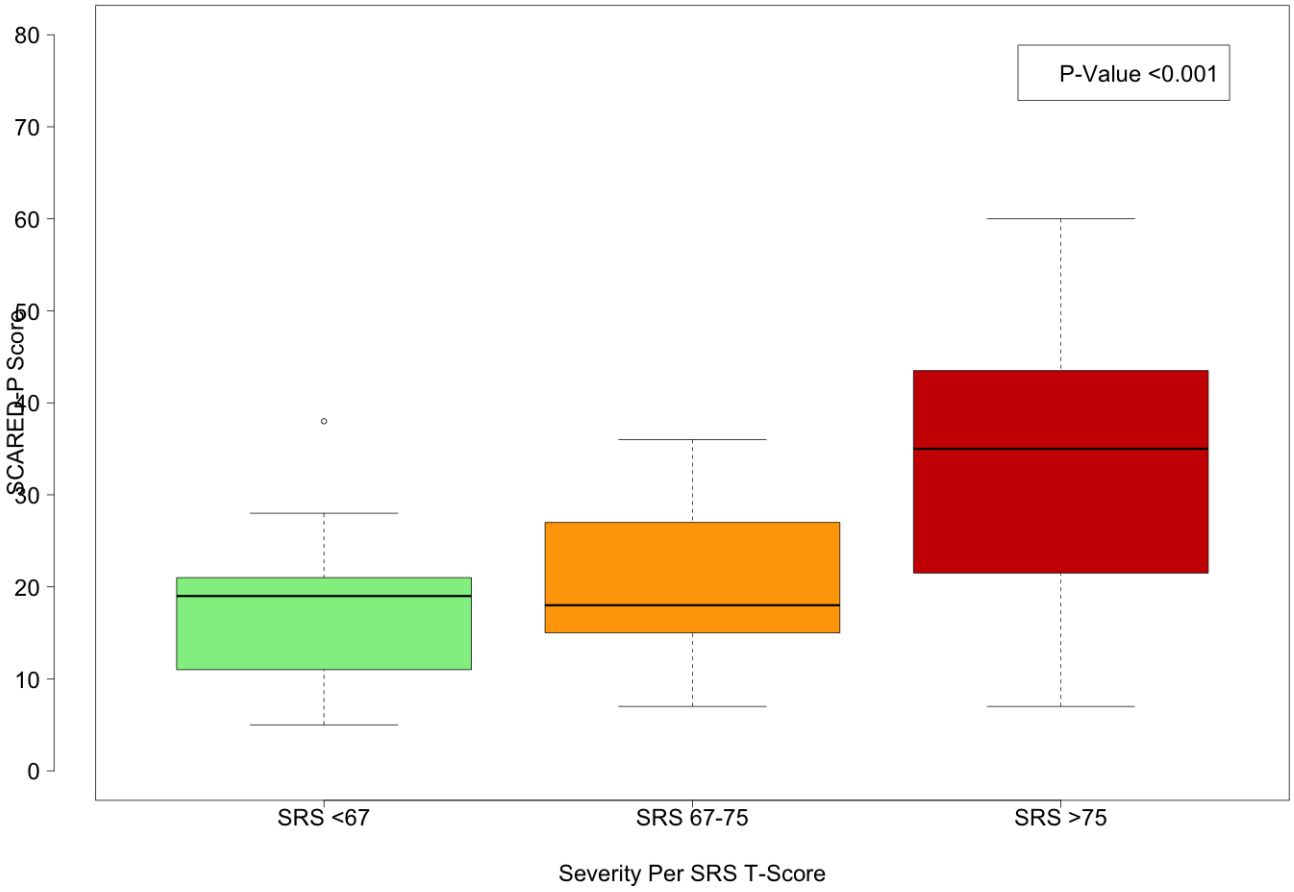
Background: Autism spectrum disorder (ASD) is a clinically heterogeneous, multi-system disorder with a variety of comorbidities, commonly including eating and feeding problems, with many children on the autistic spectrum suffering from some manifestation of food selectivity or picky eating. Though these problems are typically addressed through behavior-based, therapeutic approaches, increasing evidence shows they may be organic in nature, and linked with underlying gastrointestinal dysfunction (GID) and other biochemical imbalances such as immune dysregulation, inflammation, impaired detoxification, oxidative stress, mitochondrial disease/dysfunction and more. While eating problems in ASD are thought to cause health problems and can even, at times, be life threatening, it has not yet been investigated whether food selectivity is related to specific biomarkers appearing in early childhood, nor has the connection between food selectivity and GI function been explored.
Objectives: The aims of the study were to: (1) identify & characterize urine-based biomarkers of children with ASD (2) identify whether specific biomarkers and GI problems in children with ASD are correlated with food selectivity.
Methods: An anonymous review of the clinical charts of 68 children with a diagnosis of ASD, was performed. Participant ages ranged from 3-7 years. Descriptive statistics were used to illustrate the percentage of participants whose results were above the normal range for each metabolite. Metabolites for which greater than 25% of the children had elevated levels are reported in this study. Chi square test was used to assess the correlations between parental report of food selectivity and elevated metabolites as well as parental report of GI symptoms and elevated metabolites.
Results: All 68 children had at least one elevated organic acid metabolite, and the mean number of elevated metabolites was 9.5 (SD = 5). Of the 53 metabolites assessed, 15 metabolites were elevated in 25% or more of the population studied and 20 metabolites were elevated in between 10-24% of the population. The rest of the metabolites were elevated in under 10% of the population. Parents of 60% of children reported food selectivity. 47% of parents who reported food selectivity also reported GI symptoms in their children. Food selectivity was found to be correlated with elevated Vanillylmandelic acid (VMA) (28.1% elevated; $^{2}\chi_{(1)}=4.24$, P=0.4)), Suberic acid (26.9% elevated; 2χ)(1)=4.89, P=0.3)), 3-oxoglutaric acid (43.5% elevated; $2\chi(1)=3.59$, P=0.6), Arabinose (80.9% elevated; $2\chi)(1)=3.73$, P=0.05), and Oxalates (43.3% elevated; $(2\chi)(1)=3.77$, P=0.5).
Conclusions: This study highlights the relationship between food selectivity, GID and select organic acid metabolites, raising the possibility that food selectivity, at least among certain cases of ASD, may be the result of unbalanced gut bacteria, and associated symptoms. Future studies should explore whether the presence of elevated biological metabolites related to GI health may be able to predict food selectivity.

164 **124.164** The Relationship of Anxiety and Reciprocal Social Impairment in Autism: A Comparison Study of the Scared and SRS

W. D. Lohr[1], *T. Wiemken*[2], *R. Kelley*[2], *K. Daniels*[3], *P. G. Williams*[1], *G. M. Kuravackel*[1] *and L. L. Sears*[1], *(1)Pediatrics, University of Louisville School of Medicine, Louisville, KY, (2)Medicine, University of Louisville School of Medicine, Louisville, KY, (3)Psychology, Spalding University, Louisville, KY*

Background: There is increased recognition and interest in psychiatric comorbidity in Autism Spectrum Disorders (ASD). Anxiety is frequently seen in ASD but it is not clear if the two conditions are separate or if symptoms of anxiety are part of the essential features of ASD such as social impairment and restrictive, repetitive behaviors. The complex interplay of anxiety and core social communication deficits in ASD warrants additional attention.
The Screen for Child Anxiety Related Disorders (SCARED) is a well-established screening instrument for anxiety in youth and shows promising results in its application to children with ASD. The Social Responsiveness Scale (SRS-2) has been used to identify and study the severity of social communication deficits in ASD in a quantitative fashion. Comparing results of these two instruments in subjects with ASD provides opportunities to better understand the relationship between ASD and anxiety in this population.
Objectives: The purpose of the study was to determine how parental and child reports of anxiety and are related to social impairment in subjects with ASD. By examining

how individual items and treatment subscales of the SRS-2 relate to measures of anxiety on the SCARED, we hoped to understand better which core symptoms of ASD were most highly associated with parent and child reports of anxiety.
Methods: 100 patients age 8 to 18 years with a clinical diagnosis of ASD without intellectual disability were recruited from clinic sites. Participants and parents completed the SCARED child and parent forms and the SRS-2. SCARED parent and child total scores and diagnostic factor subgroups were compared to SRS-2 categories of severity by using the Mann-Whitney U-test or Analysis of Variance. Random Forest models were used to identify individual SRS items important for classifying children as anxious for parent and child SCARED scales separately. Poisson regression models measured the predictive ability of each of those variables to detect anxiety.
Results: Parents rated children with ASD and more severe levels of social impairment as having more anxiety. This pattern holds across all diagnostic subtypes represented by the SCARED. There were no significant correlations between levels of social impairment and child reports of anxiety.
Random Forest analysis associated parents' reports of restrictive, repetitive behavior and emotional dysregulation on the SRS-2 with high parental ratings of anxiety. However, regression analysis showed none of these items significantly predicted anxiety based on parent SCARED.
Random Forest analysis associated parent reports of preoccupations and lack of observed social behavior on the SRS-2 with high child reports of anxiety. Parental reports of clinging to adults and having unusual sensory interests or stereotypical play significantly predicted child ratings of the presence of an anxiety disorder.
Conclusions: The SCARED and SRS-2 can be used to understand the nature of anxiety in ASD. Ratings of anxiety in autism correlate with core autistic symptoms as well as externalized behavior. Parents and children associate anxiety with different types of social impairment. The relationship of anxiety and autism may be best understood by non-linear measures.



165 **124.165** Threat Interpretation and Anxiety in Autistic Children and Their Mothers

L. E. Neil, *A. E. Croydon and E. Pellicano, Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom*

Background:
Anxiety has been shown to be associated with cognitive biases such as negative interpretations of ambiguous situations in non-autistic individuals. Children on the autism spectrum often experience high levels of anxiety but well validated self-report measures of anxiety-related cognitions in this population are lacking.
Objectives:
We investigated for the first time the validity of an ambiguous scenarios interview, widely used in studies of anxiety in non-autistic children (Barrett et al., 1996; Creswell et al., 2014; Waite et al., 2015), with a group of autistic children. We also examined the relationship children's interpretations had with their own and their mothers' levels of anxiety.
Methods:
Twenty-six cognitively able children with autism, aged between 6 and 14 years, were presented with a series of 12 ambiguous scenarios such as: "You see the school principal walking around the playground and s/he has been asking other children where you are". Children were asked how upset they would be in the situation (on a scale of 1-10) and offered a choice between a non-threatening and threatening interpretation of what was happening (coded 0 or 1). Eighteen mothers completed the same questions in regards to their autistic child. Typically developing children completed the same questions for comparison.
Children and mothers completed the Spence Children's Anxiety Scale (SCAS). Mothers completed the Beck Anxiety Inventory.
Results:
Autistic children's reports of how upset they perceived they would be in response to the 12 scenarios showed good internal consistency (α = .87) as did their threat interpretations (α = .80). Autistic children's reports of how upset they perceived they would be in response to the scenarios showed a significant, positive association with their self-reported anxiety (r = .56, p =.01); but their threat interpretations did not (r = .21, p = .27). Mothers reported that autistic children would be significantly more upset (t (17) = 3.13, p =.01), and would perceive significantly more threat (t (17) = 2.53, p = .02) in the scenarios than autistic children self-reported. While maternal and self-reported child threat interpretations correlated significantly (r = .48, p = .046); reports of how upset children would be did not (r = .22, p = .38). In a multiple regression analysis, only mothers' own anxiety (β = .86, p =.01), and not mothers' reports of their children's anxiety (β = -.05, p =.85), significantly predicted mothers' reports of how upset children would be in the scenarios. There was a trend for children with autism to perceive greater levels of threat (M = 4.15; SD = 3.06) than a smaller group (N = 15) of typical children (M = 2.67; SD = 2.23; t (39) = 1.65, p = .11) across the 12 situations.
Conclusions:
The ambiguous scenarios interview is a viable tool for assessing threat-related cognitions in autistic children. Given evidence which suggests maternal expectations of children's distress can promote the development of anxious cognitions in non-autistic children over time (Creswell et al., 2006), maternal cognitions, in addition to children's cognitions, may prove useful targets for intervention.

166 **124.166** Verbal Ability and Worry in Children with Autism Spectrum Disorder

P. Renno[1], *J. J. Wood*[1], *J. Danial*[2], *S. E. Whitham*[3], *S. Klebanoff*[4] *and K. Zielinski*[5], *(1)University of California Los Angeles, Los Angeles, CA, (2)UCLA, Woodland Hills, CA,*

(3)University of California, Los Angeles, Los Angeles, CA, (4)Education, UCLA, Los Angeles, CA, (5)University of California Los Angeles, Hermosa Beach, CA

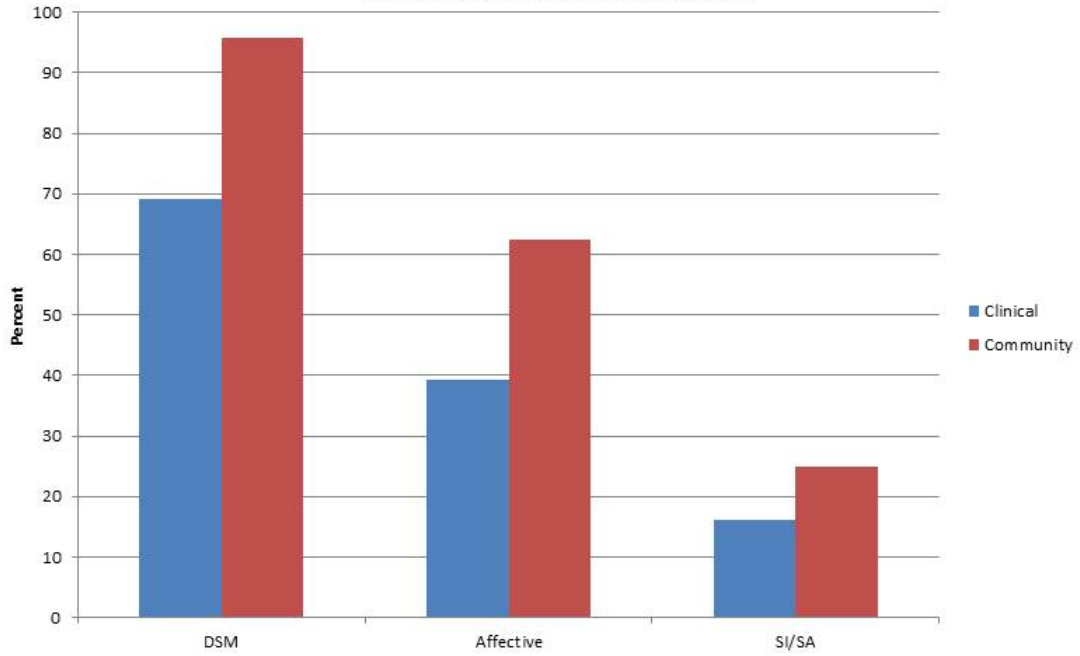
Background: Recent reports suggest anxiety disorders co-occur in 40% of children with autism spectrum disorder (ASD; van Steensel et al., 2011); however, the relation between anxiety and ASD is still being examined. The literature suggests several factors, such as cognitive ability and functional language, which may be related to greater anxiety and worry in children with ASD (Sukhodolsky et al., 2008). While some studies have found anxiety to be more common in children with ASD and average to high intellectual abilities (Sukhodolsky et al., 2008), other studies have found anxiety to be more prevalent in children with ASD and lower intellectual abilities (van Steensel et al., 2011).
Objectives: The current study aimed to investigate the relation between anxiety symptoms, cognitive ability, and verbal fluency in children with ASD.
Methods: Participants were 65 children with ASD (IQ > 70), aged 8-13. Cognitive ability was assessed with the Wechsler Intelligence Scale for Children-IV (WISC-IV) and verbal fluency was assessed with the Delis-Kaplan Executive Function System (D-KEFS). A parent-report of anxiety symptoms (Child & Adolescent Symptom Inventory-4) was also collected.
Results: Correlational analyses indicated strong relations between verbal fluency and the CASI-4R generalized anxiety subscale ($r = 0.411$, $p < 0.01$) and the CASI-4R 20-item anxiety subscale ($r = 0.371$, $p < 0.01$). Additionally, verbal scores on the WISC-IV were significantly correlated with the CASI-4R generalized anxiety subscale ($r = 0.362$, $p < 0.01$).
Conclusions: These findings suggest that in youth with ASD and IQ > 70, higher verbal ability is associated with greater anxiety and generalized worry. These results suggest that children with ASD who have strong verbal skills may be more susceptible to verbally-based types of anxiety and preservative thought. Future research should continue to look at other factors, (e.g., impaired executive functioning) which may be related to increased risk of anxiety in youth with ASD.

167 **124.167** Who Are We Missing: Why Would a Community-Derived Sample of Children with ASD Have Higher CBCL Symptoms Than Clinic-Based Samples?

A. C. Armour[1], *J. F. Strang*[2], *K. M. Dudley*[3], *L. Mohamed*[4], *R. E. Shafran*[5], *C. Rothwell*[6,7], *J. Safer-Lichtenstein*[8], *J. L. Martucci*[9], *A. Verbalis*[10], *S. Seese*[6], *L. Kenworthy*[11] *and L. G. Anthony*[10], *(1)Children's National Medical Center, Arlington, VA, (2)Children's National Medical Center, Silver Spring, MD, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC, (4)Yale Child Study Center, New Haven, CT, (5)Department of Psychology, Columbia University, New York, NY, (6)Center for Autism Spectrum Disorders, Children's National Medical Center, Rockville, MD, (7)Catholic University of America, Washington, DC, (8)Georgetown University, Washington, DC, (9)Neuropsychology, Children's National Health System, Rockville, MD, (10)Children's National Medical Center, Rockville, MD, (11)Children's Research Institute, Children's National Medical Center, Rockville, MD*

Background: Children with Autism Spectrum Disorders (ASD) have increased rates of mood and anxiety symptoms and suicidal ideation and attempts (SI/SA). The available literature indicates demographic characteristics (age 10+, male, African American/Black, Hispanic/Latino, low SES) and psychological characteristics (depression, teasing/bullying, aggression, impulsivity and anxiety) as risk factors for SI/SA in ASD. In order to probe levels of disparity of care, a school-based program that did not require previous diagnosis of ASD was compared to a group of youths who received clinical evaluations in a specialty clinic or were referred from a clinical setting for research testing.
Objectives: To compare Child Behavior Checklist (CBCL) syndrome scales, DSM scales, and SI/SA item endorsement between clinical and community groups and among different levels of maternal education.
Methods: Parents of 147 youth with ASD (female=19), age 5.92-19.17 (M=10.29, SD=2.5), FSIQ 62-149 (M=103.79, SD=19.43), who met CPEA criteria for 'broad ASD' on the ADI-R and/or ADOS, completed CBCL on their children. 123 families were evaluated in a clinical setting, and 24 families were evaluated in a community setting. Maternal education in 7 categories was used as a proxy for SES; 74.8% of mothers in the clinic sample and 56.5% of mothers in the community sample have a college or graduate education. Clinical and community groups did not differ significantly on sex or IQ; 11.6% of the clinical sample and 21.7% of the community sample is African American/Black. Group differences were explored with Chi-square and independent sample t-tests.
Results: 15.6% of individuals had parent-reported SI/SA. 83.7% of individuals showed clinical elevation on CBCL syndrome scales overall, 73.6% showed clinical elevation on CBCL DSM scales overall, and 43.1% showed clinical elevation on the affective problems scale. Endorsement of SI/SA items was associated with significantly higher CBCL anxiety ($t(26.42) = -2.36$, $p<.05$) and depression t-scores ($t(145) = -2.81$,$p<.01$).
There was no significant difference between clinical and community groups on endorsement of suicide items and overall CBCL syndrome scale elevation. Among maternal education levels, there were no significant differences on CBCL syndrome and DSM scales or SI/SA endorsement, possibly because such a large percent of the group was highly educated.
There is a significant difference ($p<.01$) on overall CBCL DSM scale elevation between community and clinical groups (chi square). Examination of DSM scale categories indicated that significant differences exist between clinical and community groups on CBCL clinical level affective problems (t-score ≥65, $p<.05$) (chi square). This holds true when considering the continuous CBCL affective problem data with an independent sample t-test ($t(142) = 2.49$,$p<.01$).
Conclusions: Although significant differences based on SES were not found, there were differences between clinical and community samples (see Figure 1). Based on a relatively small sample of community data, significantly more DSM symptomatology was reported by parents. Future directions include expanding the sample size of the community group and understanding what services this group is and is not receiving.

Figure 1: Percent of ASD youth with elevations for CBCL overall DSM Scale, Affective Problems, and SI/SA items in clinical and community groups.



168 **124.168** "Emodiversity" in Individuals with Autism Spectrum Disorder

A. C. Samson[1], *J. Bryjova*[2], *J. M. Phillips*[3], *J. Gross*[4] *and A. Y. Hardan*[3], *(1)Swiss Center for Affective Sciences, University of Geneva, Geneva, Switzerland, (2)Department of Psychology, University of Fribourg, Fribourg, Switzerland, (3)Stanford University, Stanford, CA, (4)Department of Psychology, Stanford University, Stanford, CA*

Background: There is mounting evidence that individuals with Autism Spectrum Disorder (ASD) have emotional disturbances, difficulties identifying and labeling own emotions (alexithymia), and emotion dysregulation. However, the precise nature of emotional disturbances in ASD is still not very well understood.
Objectives: The goal of the present study is to examine "emodiversity" for the first time in ASD. This is an emotional index that measures richness and complexity of an individual's emotional experiences, taking into account the degree to which an individual can characterize an emotional experience with precision (emotional granularity). Our goals were to: (1) document differences between individuals with ASD and typically developing (TD) participants, (2) relate emodiversity in positive and negative emotions to emotion understanding of positive and negative emotions, alexithymia, and ASD symptom severity; and (3) assess the extent to which positive and negative emodiversity, alexithymia, and ASD symptom severity contributed to problematic behavior.
Methods: Forty-one high functioning individuals with ASD and 35 gender and age group-matched typically developing (TD) controls (age range 8-20 years) as well as their parents were interviewed to assess positive and negative emodiversity and emotion understanding. In addition, parents filled out questionnaires to assess symptom severity (Social Responsiveness Scale), alexithymia (Toronto Alexithymia Questionnaire) and problematic behavior (Child Behavior Checklist). All analyses were controlled for participant's age, sex, and IQ.
Results: Compared to TD participants, individuals with ASD had lower positive and higher negative emodiversity, lower emotion understanding of positive and negative emotions, increased levels of alexithymia, symptom severity, and problematic behaviors. Positive emodiversity was positively associated with understanding of positive emotions and negatively with symptom severity. Negative emodiversity was negatively associated with the understanding of positive emotions and positively with symptom severity. Emodiversity (positive and negative) was not associated with alexithymia, indicating that both capture different emotional components. Interestingly, besides ASD symptom severity, parent reported emodiversity significantly predicted problematic behaviors in multiple regression analyses. Alexithymia did not further contribute to the explanation of problematic behavior in the present study.
Conclusions:
Emodiversity seems to be an important new concept to study in ASD and might have clinical relevance. However, additional investigations are needed to better understand emodiversity in ASD and how it is related to other emotional components in larger samples that include lower functioning individuals.

Poster Session
125 - Service Delivery/Systems of Care
5:30 PM - 7:00 PM - Hall A

169 **125.169** A Mixed Methods Approach to Describing Family Navigation As a Service Model within the Autism Speaks Autism Treatment Network

K. Kubicek[1], *D. S. Murray*[2], *K. Kuhlthau*[3], *D. L. Coury*[4], *D. Zand*[5] *and M. D. Kipke*[1], *(1)Children's Hospital Los Angeles, Los Angeles, CA, (2)Autism Speaks, Boston, MA, (3)General Academic Pediatrics, Massachusetts General Hospital, Newburyport, MA, (4)Nationwide Children's Hospital, Columbus, OH, (5)Saint Louis University, St Louis, MO*

Background:
Family navigation (FN), is an effective service model used across medical specialties, to assist families in accessing the clinical and support services for pediatric patients as well as relevant family members.
In 2014, the Autism Speaks Autism Treatment Network (ATN) required funded sites to integrate FN services into their clinic sites. Given the variation in services across the network and the limited research in the use, effectiveness and scope of FN services in ASD, the ATN initiated a study to better understand the current implementation of FN across the Network.
Objectives: 1) Develop an operational definition of FN for the network**, 2**) Describe the common service models of FN within the ATN; and 3) Identify potential best practices and appropriate outcome measures to evaluate the effectiveness of a FN model for children with autism spectrum disorders.
Methods: The ATN convened a workgroup comprised of parents and professionals to develop the appropriate research design. A mixed-methods approach was determined to be the most appropriate to capture both breadth and depth of the FN service models across the currently funded 14 ATN sites. This included: a survey of the primary family navigator at each site (N=13); three focus groups with family navigators (N=26); a survey of the site principal investigators at each site (N=12) and two focus groups with parents (N=12). Data were triangulated to fully describe the FN model across the ATN.
Results: We identified a number of similarities and differences across sites. Family navigators spend most of their time providing referrals for community services (100%),

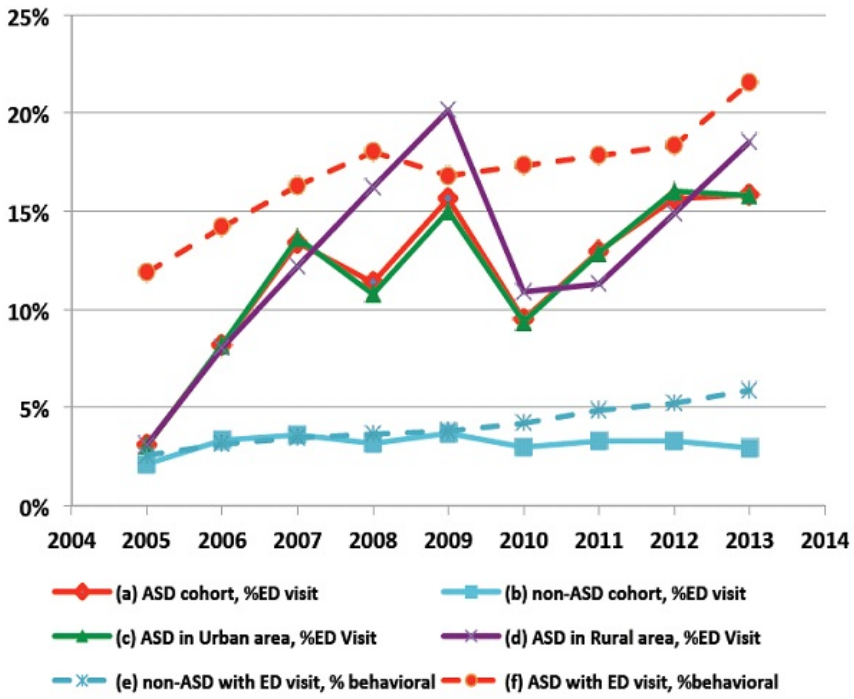
educating parents on available options and the service system (92%) and helping to empower families (62%). They felt that coaching parents to be effective advocates is one of their most important responsibilities. Social workers or similar professional staff are used as family navigators at most sites. Most sites agreed that a parent or similar paraprofessional offers different insights and empathy for family members; however given that some referrals must be made by a licensed or certified individual, a hybrid model was identified as being the most promising. Navigators often experience challenges meeting the needs of diverse families including linguistic needs and understanding cultural norms. Navigating school systems and IEPs are among the most common needs of parents followed by respite care, access to services and education. Few sites are currently tracking outcomes related to FN.
Conclusions: Respondents agreed that FN is an important and valuable service for families. Next steps include identifying appropriate outcome measures (parental stress, activation, satisfaction, impact on cost, access) and service delivery strategies (e.g., referrals to FN, staffing, education) through a new prospective study. This will assist in identifying core components of FN best practices that can be shared across the Network.

170 **125.170** A Profile on Emergency Department Visits in Adolescents with Autism Spectrum Disorders

G. Liu[1], *L. Kong*[1], *D. Leslie*[1] *and M. Murray*[2], *(1)Public Health Sciences, Penn State College of Medicine, Hershey, PA, (2)Psychiatry, Penn State Hershey, Hershey, PA*

Background: The prevalence of ASD started to increase dramatically about a decade ago, and now the first wave of these children have approached adolescence and early adulthood. While early diagnosis and intervention have been the focus of scientific and clinical community, the population of adolescents with ASD has not received the same attention. Although various ASD related healthcare services have been designed to better serve this population, it is relatively unknown how well they are being served.
Objectives: In this study, we use a large, national healthcare claims database to compare the healthcare utilization history (in-/out-patient medical records) of adolescents with and without ASD, with a focus on emergency department (ED) visits. The goal of this study is to provide an understanding of the physical and mental health well-being of adolescents with ASD.
Methods: Using the healthcare claims data from MarketScan®, we identified subjects aged 12-21 during each year of 2005-2013. In each annual cohort, we constructed an ASD cohort of adolescents with at least two separate diagnoses of ASD (ICD 9 codes 299.0x and 299.8x) through the entire study period (2005-2013) and a non-ASD cohort of those without ASD diagnosis during the study period. We constructed the following annual measures: (a) proportion of adolescents with ASD having ED visit ; (b) proportion of adolescents without ASD having ED visit; (c) proportion of urban adolescents with ASD having ED visit; (d) proportion of rural adolescents with ASD having ED visit; (e) proportion of adolescents having a behavioral ED visit among those non-ASD adolescents with any ED visits; and (f) proportion of adolescents having a behavioral ED visit among those ASD adolescents with any ED visits.
Results: We observed a consistent increase in the percentage of ASD patients among all adolescents who visited emergency department, from 0.28% in 2005 to 0.85% by 2013. While the percentage of subjects in non-ASD cohort who had ED visits have been fairly stable at around 3%, the percentage in ASD cohort steadily increased from 3.1% in 2005 to 15.8% by 2013. Although rural adolescents with ASD showed a similar pattern in ED visit to those living in urban areas, it took a sharp jump from 14.9% in 2012 to 18.5% in 2013, compared to 16% among urban adolescents with ASD. Among subjects with ED visits, behavioral health service-related ED visits increased from 11.9% in 2005 to 21.6% by 2013 among adolescents with ASD, compared to a more modest increase from 2.6% to 5.9% among adolescents without ASD.
Conclusions: Our study showed a disconcerting increase in the proportion of adolescents with ASD who had ED visits over the recent decade or so. We also observed a drastic increase in ED visits primarily associated with behavioral health service, suggesting an ASD-related mental health crisis. Finally, adolescent ASD patients living in rural areas experienced a large increase in ED visits, suggesting that this may be a particularly vulnerable population.

Figure 1. Pattern of Emergency Department (ED) visit during 2005-2013: % of ED visits (a)-(d), and % of behavioral ED service in those with ED visit (e)-(f).



171 **125.171** A Statewide Needs Assessment Survey for School-Age Children with Autism Spectrum Disorder

S. Trost[1], *S. Srinivasan*[2], *L. O'Regan*[1], *A. Ekbladh*[3], *B. Freedman*[4] *and A. N. Bhat*[2], *(1)Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE, (3)Center for Disability Studies, University of Delaware, Newark, DE, (4)University of Delaware Center for Disabilities Studies, Newark, DE*

Background:
Autism Spectrum Disorder (ASD) is a multisystem disorder leading to primary impairments in social communication development as well as comorbidities in perceptuo-motor, cognitive, and behavioral skills (American Psychiatric Association, 2013; Bhat, Landa, & Galloway, 2011). In recent years there has been an increase in prevalence of ASD, with 1 in every 68 children in the US being diagnosed with ASD (Centers for Disease Control and Prevention, 2014). Given this increasing prevalence, there is a pressing need to understand the specific health care needs of children with ASD and their families as well as the challenges and barriers they face in accessing health care services.
Objectives:
In 2011, the Center for Disabilities Studies (CDS) at the University of Delaware conducted a statewide comprehensive needs assessment survey for caregivers of school-age children with ASD. The survey was meant to guide the formulation of a strategic plan to improve services for children with ASD and their families.
Methods:
277 caregivers of school-age children with ASD completed the needs assessment survey in online or paper form. The survey obtained information about areas related to the diagnosis, educational status, living status, service needs, and community participation of school-age children with ASD.
Results:
Over half of this sample had a diagnosis of ASD and another quarter had a diagnosis of Asperger Disorder. In addition, over 80% of this sample had additional diagnoses, most commonly, developmental delay, attention deficit hyperactivity disorder, learning disability, anxiety, obsessive compulsive disorder, and intellectual delay. In terms of

living status, around 95% of children lived with their parents or relatives. In terms of educational status, around 90% children had an individualized education plan (IEP) and around 65% caregivers were satisfied with their child's IEP. The survey suggested that around 90% children were independent in feeding themselves and around 60% were independent in dressing themselves, requesting things, and indicating their needs to caregivers. In terms of health care services, caregivers indicated the need for more speech therapy, physical/occupational therapy, social skills training, and behavioral interventions over and above what the children were currently receiving. The survey also revealed that the various barriers faced by families of children with ASD in terms of accessing health care services included cost of services, shortage of service providers, as well as transportation and scheduling issues.
Conclusions:
Results of the survey highlighted the main issues faced by children with ASD and their families. Caregiver responses to the survey indicated a dire need for specific medical and rehabilitation services for school-age children with ASD.

172 **125.172** A Survey on Mitigating Barriers to Dental Care for Children with Special Health Care Needs By Providing Dental Treatment Under General Anesthesia

L. Orsini[1], *R. Turchi*[2], *S. Shah*[2], *M. Kondrad*[3], *J. J. Kim*[4] *and D. L. Robins*[5], *(1)Pennsylvania Chapter of the American Academy of Pediatrics, Media, PA, (2)Drexel University, Philadelphia, PA, (3)St. Christopher's Hospital for Children, Philadelphia, PA, (4)Department of Epidemiology, Drexel University, Philadelphia, PA, (5)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Children and youth with special health care needs (CYSHCN) experience unique challenges in accessing health care. Among the greatest unmet needs among this population is dental care. Dental caries is the most common chronic disease in children, and children with developmental disabilities are more likely to have unmet dental needs than typically developing children[i],[ii]. Barriers for CYSHCN accessing dental care may include but are not limited to: body movements, repetitive behaviors, and self-injurious behavior. Some CYSHCN experience excessive sensitivity involving their face/mouth influencing diet, nutrition, teeth brushing, speech, and routine dental check-ups. Providing dental treatment to this population may be challenging, thus warranting general anesthesia as the only mechanism to deliver the necessary dental treatment. This study seeks to examine and understand the experience and satisfaction of parents/caregivers of CYSHCN requiring general anesthesia for routine dental examinations.
Objectives: The purpose of this preliminary study was to review survey results from parents with CYSHCN to understand the barriers of dental care for CYSHCN and to evaluate the effectiveness of providing dental and medical treatment under general anesthesia. This pilot study may inform future clinical procedures of CYSHCN by facilitating comfort of the patient and family.
Methods: Parents/caregivers of CYSHCN (*n*=25; 14 with ASD, the other 11 with neurological, genetic, and developmental disorders) completed a survey to understand: CYSHCN's experience with dental treatment under general anesthesia, barriers they encountered, and other feedback regarding their clinical encounter. In this sample of parents, 10 (4 with ASD) had children who were placed under general anesthesia and 15 reported on general issues but not a specific experience.
Results: The majority of respondents indicated challenges in accessing routine dental treatment for their child (76%). The most common barrier to getting dental treatment for a CYSHCN was intolerance of the child for dental treatment (76%). Other frequently listed barriers included: paucity of experienced dentists to treat CYSHCN (20%), inconvenient appointment time (8%), transportation challenges (8%), unaccepted dental insurance (4%), and unable to obtain medical clearance for dental treatment (4%). Of the 10 parents (40%) with children who had undergone dental treatment under general anesthesia, seven (70%) reported an excellent experience (on a five-point scale from excellent to poor) with the services and the remainder (30%) reported a very good experience with these services.
Conclusions: Survey responses confirm CYSHCN experience a variety of challenges in accessing routine dental care. The most significant barriers to address, include the child's intolerance to dental care and lack of dentists experienced with CYSHCN. Additionally, these responses demonstrate resounding satisfaction of the parents whose children received dental care under anesthesia, although the small study warrants replication. Overall, when CYSHCN cannot tolerate dental procedures, anesthesia is a feasible strategy to support this needed care.

173 **125.173** ASD-Related Networks: The Rare Epilepsy Network

J. M. Buelow*, Epilepsy Foundation, Landover, MD*

Background:
Patient-Centered research is now will improve the quality and relevance of research for those it is meant to serve. While most national research organizations have tried to incorporate a patient- or participant-centered approach, the Patient-Centered Outcomes Research Institute is focused on research and outcomes that matter to patients. PCORnet is a national patient-centered research network of databases of patient-driven data. At the very core of PCORnet—and the differentiating factor between PCORnet and other data bases—is the patient. PCORnet has the potential to change the way research is conducted. The Rare Epilepsy Network is one such database that is driven by and for patients or their caregivers. Autism is known to be a comorbid condition in epilepsy.
Objectives: This panel is aimed at 1: Informing participants about patient-centered research and related national initiatives; 2. Discussing and demonstrating current rare epilepsy participant-centered programs and research; 3. Discussing synergy between patient-centered research networks; and 4. Discussing opportunities and challenges for integration of patient-centered and clinic/hospital-centered outcomes

174 **125.174** Age of Diagnosis of Autism Spectrum Disorder in an Ethnically Diverse Population before and after the 2007 AAP Recommendation for Universal Screening

M. D. Valicenti-McDermott[1,2], *L. H. Shulman*[1,2] *and R. M. Seijo*[1,2], *(1)Pediatrics, Montefiore Medical Center, Bronx, NY, (2)Albert Einstein College of Medicine, Bronx, NY*

Background: Children with Autism Spectrum Disorder(ASD) benefit from early diagnosis and intervention services. In 2007 the American Academy of Pediatrics(AAP) recommended pediatricians perform screening for ASD at the 18 and 24 month child visits. However, the U.S. Preventive Services Task Force recently concluded there is not enough evidence to recommend universal autism screening of young children for whom no concerns of ASD have been raised by their parents or clinical provider. Children who are Latino or African American are already being diagnosed later and families may be less aware of ASD symptoms, the impact of such recommendation on the age at diagnosis in an ethnically diverse population is important, but unknown.
Objectives: To compare the age at diagnosis of ASD in two groups, those children born before 2005, prior to universal screening recommendations, and those born in 2005 or later, who would have been of age to undergo ASD screening by 24 months based on the 2007 AAP recommendation.
Methods: Review of all children initially diagnosed with ASD from 2003 to 2012 in a University Affiliated Developmental Center. Data included demographic and clinical characteristics. Statistics included chi-square, t-test, non parametrics, and logistic regression
Results: We identified 512 children,78% boys, 16%White, 47%Hispanic, 26%African-American, 38% bilinguals(English/Spanish). Of 512, 295(58%) were born before 2005 and 217(42%) were born during 2005 or after. The mean age at diagnosis of children born before 2005 was 46±15months and those born during or after 2005 was 31±12 months($p<.001$). The percentage of children diagnosed with ASD after age 3 decreased from 63% in the group born before 2005 to 26%($p<.001$). This decline occurred across all ethnic groups (White 55% to 27%; Hispanic 76% to 23%; African-American 73% to 32%). The association between diagnosis with ASD after age 3 and being born before 2005 remained significant after adjusting for demographics and clinical characteristics (OR=4.2;95thCI 1.7-10.3).
Conclusions: In this ethnically diverse population, children who were born before the AAP recommendation for universal screening were diagnosed with ASD significantly later that those born after the AAP recommendation. It is unclear at this point if this was entirely the result of pediatrician universal screening but, since 2007, children are being diagnosed with ASD earlier.

175 **125.175** An ASD-Specific Training Model for Medical Staff to Support Provision of ASD-Friendly Medical Care

L. Dewey[1] *and E. Bernabe*[2], *(1)Nemours/Alfred I duPont Hospital for Children, Wilmington, DE, (2)Nemours/AIDHC, West Chester, PA*

Background: Children with Autism Spectrum Disorder (ASD) often present with complex medical concerns necessitating use of a medical home model in providing comprehensive care for these patients. However, providing medical care through an ASD-friendly framework is more challenging than with other children with complex medical needs (Brachlow et al., 2007). Children with ASD present with unique behavioral needs when requiring medical procedures and prolonged inpatient hospitalizations. Medical providers often need to modify how care is delivered to support patients with ASD by implementing behavior management strategies (e.g., use of visual schedules, choices about care, behavioral motivators, preparation before procedures, etc.; Thompson & Tielsch-Goddard, 2014). However, medical staff often lack the training and confidence to provide medical care through an ASD-friendly framework that includes empirically-validated behavioral interventions.
Objectives: The objectives of the study were to: 1) describe an ASD-specific training model and potential feasibility in a hospital setting; and 2) preliminarily explore if staff's confidence improved after ASD-specific training.
Methods: Social workers in a children's hospital attended two one-hour trainings two weeks apart provided by ASD-focused psychologists during the social workers' weekly rounding meetings. The first training focused on understanding ASD (n=18), and the second training focused on empirically-validated behavioral interventions (n=14). At both trainings, the social workers completed a questionnaire (6 questions on a 1-5 Likert Scale; summed for total score) developed by the authors that assessed

understanding and confidence of ASD-friendly care. At the second training, two additional questions focused on utility of the training were included. The data were analyzed using descriptive statistics and independent sample t-test (due to the anonymous completion of the questionnaires at both trainings).
Results: Social workers found both trainings to be useful (M = 4.2 out of 5, SD = .91; M = 4.5 out of 5, SD = .51) and reported a high likelihood of using the information (M = 4.1 out of 5, SD =.99). Additionally, preliminary data from the questionnaires suggested that staff confidence in providing ASD-friendly care and implementing behavioral interventions showed non-significant improvement (training 1: M = 17.33, SD = 4.2; training 2: M = 23.5, SD = 3.99; p = .877).
Conclusions: ASD-focused training for medical staff is feasible; training can be provided during convenient times for staff by professionals with pre-existing ASD knowledge. Encouragingly, medical staff found the trainings useful, and they reported a high likelihood to implement the behavioral interventions discussed during the trainings. Preliminary data suggest that ASD-specific training might improve staff confidence, which has been identified as a barrier for medical staff in providing medical care through an ASD-friendly framework. Results of this study support training endeavors to meet the unique needs of hospitalized patients with ASD.

176 **125.176** Autism and Vaccines: Are Siblings Affected?

E. Agbese[1,2]*, D. Velott*[1] *and D. Leslie*[1,2]*, (1)Public Health Sciences, Penn State College of Medicine, Hershey, PA, (2)Center for Applied Studies in Health Economics, Penn State College of Medicine, Hershey, PA*

Background: After a 1998 study in England incorrectly showed a link between autism and the measles, mumps and rubella (MMR) vaccine, parents became concerned about vaccinating their children. This study led to a decrease in vaccination rates and an increase in measles, mumps, rubella and other vaccine-preventable diseases in England and other countries. Although the original article has since been invalidated by several studies and subsequently retracted, the decrease in vaccination rates persists. In the United States, parents can easily obtain both medical and non-medical exemptions from school vaccine requirements for their young children. Communities with low vaccination rates continue to be at higher risk for disease outbreaks. Although previous studies have documented that parents with at least one child with autism spectrum disorder (ASD) may delay or decline vaccination for subsequent children, these studies suffer from the limitations of small sample sizes and parent self-report.
Objectives: To compare the vaccination rates of the immediate younger siblings of children with ASD to those of immediate younger siblings of children without ASD using a large national healthcare claims database.
Methods: Data for the study came from the MarketScan® Commercial Claims and Encounters database, a national health insurance claims database of over 40 million privately insured individuals. Immediate younger siblings of children with ASD aged 0 to 6 were identified and matched to immediate younger siblings of children without ASD. Children in both groups were matched based on age, sex and order of birth. Vaccination rates for both groups were determined using ICD-9 codes to identify receipt of any recommended vaccine (any vaccine) and individual vaccines of interest (MMR, influenza, hepatitis A/B, and chicken pox). The proportions of children who received studied vaccines were compared across groups using t-tests. In addition, generalized estimating equations regression was used to determine whether the effect of group (ASD vs. control) remained after controlling for other child and family characteristics.
Results: A total of 5,048 case-control pairs were included in the study. Vaccination rates for all studied vaccines were significantly lower among children with an older sibling with ASD than among matched controls. After controlling for other covariates, immediate younger siblings of children with ASD remained significantly less likely to receive any vaccine (OR=0.86; 0.79-0.93), MMR (OR=0.72; 0.66-0.80), influenza (OR=0.79; 0.73-0.86), hepatitis A/B (OR=0.82; 0.75-0.90), and the chicken pox vaccines (OR=0.80; 0.73-0.87).
Conclusions: Immediate younger siblings of children with ASD are significantly less likely to receive recommended vaccinations compared to immediate younger siblings of children without ASD. This is especially true of the MMR vaccine, the subject of the invalidated 1998 study. Our results suggest that in addition to their current efforts, public health officials and clinicians need to tailor vaccine education specifically to parents of children with ASD.

177 **125.177** Barriers and Facilitators to Treating Sleep Problems in Children with ASD: Gathering Parent and Health Care Professional Perspectives Via Online Synchronous Focus Groups

K. M. Tan-MacNeill[1]*, I. M. Smith*[2] *and P. Corkum*[3]*, (1)Dalhousie University, Halifax, NS, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (3)Dalhousie University & IWK Health Centre, Halifax, NS, Canada*

Background: Sleep problems are prevalent in children with autism spectrum disorder (ASD), occurring in 50-85% (Reynolds & Malow, 2011). Behavioural sleep problems (i.e., insomnia) have a widespread negative impact on children and their families. Although behavioural interventions are recommended to treat insomnia in children with ASD, little is known about parents' and healthcare professionals' (HCPs) beliefs about sleep problems in ASD, and access to, uptake of, and implementation/provision of insomnia treatments.
Objectives: 1) To explore barriers and facilitators experienced by parents of children with ASD in access to and uptake of behavioural treatments for children's insomnia. 2) To explore barriers and facilitators experienced by HCPs in accessing and providing behavioural insomnia treatment. 3) To explore the utility of online, synchronous audio/video focus group methodology.
Methods: We used a mixed-methods, online focus-group/interview design, recruiting participants from Canadian rural and urban communities. Participants were 22 parents of 4- to 12-year-olds with ASD and behavioural sleep problems (without intrinsic physiological sleep disorders) and 16 healthcare professionals (occupational therapists, clinical psychologists, developmental paediatricians, nurses) who work with children with ASD and sleep problems. Parents and HCPs participated separately in focus groups or individual interviews, which followed semi-structured topic guides focusing on sleep knowledge, familiarity with evidence-based sleep treatment (HCPs only), access to sleep treatment, uptake (parents) and implementation (HCPs) of treatment. Perceived acceptability of an online parent-directed behavioural sleep intervention was the final topic for both parents and HCPs. Participants completed a user feedback survey to assess the utility of the online method. Focus groups/interviews were transcribed and qualitatively analyzed in NVivo using conventional content analysis (coding for key themes). Descriptive statistics were used to characterize the sample. Additional interviews with Board Certified Behaviour Analysts (BCBAs) are in progress (ending November 2015).
Results: Preliminary coding revealed key themes emerging from both parents and HCPs: 1) sleep problems and treatment are perceived as exceptionally challenging, intensive, involved, and demanding compared to other problems and their treatment; 2) consistency with routines and perseverance are keys to success; 3) the multifactorial nature of sleep problems complicates treatment; 4) treatment must be highly individualized; 5) recognizing sleep's impact on the whole family is important; 6) awareness of sleep and how to access help is limited. Individual barriers and facilitators were identified for the following topic areas: A. Parents – Seeking and accessing treatment; B. Parents – Uptake/implementation of treatment; C. HCPs – Knowledge about and access to evidence-based treatment; D. HCPs – Providing evidence-based treatment.
Conclusions: Preliminary results suggest that parents and HCPs endorse common barriers and facilitators to effective treatment of sleep problems in children with ASD. Major barriers are lack of knowledge/awareness and support, and systematic limitations; flexibility, education, and support are major facilitators. Online synchronous audio/video focus groups had utility as a research method, but effectiveness and user experience were subject to factors beyond the researcher's control (e.g., participants' internet connections). Results will inform the development of an online behavioural intervention for insomnia, *Better Nights, Better Days for Children with Neurodevelopmental Disabilities*.

178 **125.178** Building Specialized, Elderly-ASD Specific Residential Care for People with ASD Moving into Old Age

L. A. Jensen[1] *and D. Allen*[2]*, (1)Specialist Area Autism, Hinnerup, Denmark, (2)GHA Autism Supports, Albemarle, NC*

Background:
The first generation of children diagnosed with ASD is now becoming elderly. Very little consideration has been given to ASD housing for those aging with ASD even though the people with ASD are becoming elderly now and the decades to come. Therefore *X*, Denmark and *Y*, US have inspired each other on minding the gap on how to build residential care to meet the unique needs of this target population based on their knowledge and experience with elderly individuals with ASD due to the fact that ASD manifests itself in different ways being elderly.
Objectives:
To build new residential care facilities based on *X's* and *Y'*sown collection of results on elderly with ASD with the aim of enhancing the target group's overall quality of life and supporting the challenges of aging like lack of mobility and ill-health.
Methods:
Based on the Danish "Model Program for Sheltered Housing Designed for Elderly People with Autism", which the Danish organization Realdania helped to develop in 2010, *X*has built Seniors House. Ever since the initial brainstorming of the construction there has been a focus on user involvement, including core employees with key knowledge on elderly individuals with ASD, elderly people with ASD and their relatives. Also in the project steering group Autism Denmark and the Danish National Board of Social Services have been involved.
In the US *Y*has done intense studies on nursing homes and other long-term care options and discovered that there are no programs in the US designed and/or equipped to meet the medical, neurological, and safety needs of aging individuals with ASD.
Results:
In 2014 *X* opened Seniors House - Denmark's first specialist environment designed uniquely for four elderly people with ASD. The involvement of people with ASD in Seniors House is evident in the choices made in both architecture and interior design. For example, *X's* research showed that elderly people with ASD liked the idea of having dark, somewhat sheltered rooms, wooden materials, overall the colour green, having a sitting area outside their door so that they can be part of a group from a distance, watching the life outside their home, minding their social challenges which are more profound being elderly.

In the US *Y* has developed its building-model for individuals with ASD who are aging and have significant medical issues which includes on-site health care services, telemedicine, health-monitoring, new technology and farm animals. The facilities break ground in late 2016 or early 2017.
Conclusions:
X's Seniors House in Denmark and the future *Y's* Long Term Care Project in the US, both serve as important building projects on how to create specialized long-term care for aging individuals with ASD. The vision of the two building projects is to function as knowledge platforms and sources of inspiration for other buildings for the similar target group.

179 **125.179** Challenges for Translating Early Intervention Evidence into Practice in ASD Community Settings

T. Iacono[1], *K. Hudry*[2], *J. L. Spong*[1], *C. Dissanayake*[3], *D. Trembath*[4] *and S. Erickson*[5], *(1)La Trobe University, Bendigo, Australia, (2)Olga Tennison Autism Research Centre, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (4)Menzies Health Institute Queensland, Griffith University, Gold Coast, Australia, (5)La Trobe University, Melbourne, Australia*

Background: Translating evidence-based diagnostic and intervention practices for Autism Spectrum Disorders (ASD) into community settings is especially challenging in low-resource settings, even those situated in high-income countries. Successful translation will depend on funding streams that dictate service-delivery, and the knowledge, skills and attitudes of service providers. The focus of this study was on the potential to translate ASD early interventions found effective in research settings to a community setting.
Objectives: Our aim was to explore the ASD service delivery context within a regional town (population 107,000). We further sought to evaluate the potential use of telehealth to upskill clinicians in evidence-based intervention delivery, and consider its potential uses in supporting service provision for families located at least 2 hours by private or public transport from the nearest metropolitan centre.
Methods: Restricting the study to one regional town, we obtained data on all ASD services in a geographic area, whose residents ranked high on a disadvantage scale (983, SEIFA). Mixed methods included structured interviews with a senior representative of each service, and surveys of clinicians and families about service access and provision, and attitudes towards telehealth. Five organisations participated, providing 15 services to children aged 0-6 years. Fifteen clinicians and 19 families completed surveys. Eight clinicians (Early Childhood Advisors, Occupational Therapists, Speech-Language Pathologists) from one service participated in semi-structured interviews.
Results: *Service models*: Most services were funded through autism support packages (with caps per child); two were fully fee-paying. Two provided a diagnostic service only and among the others, assessments for goal setting either were not provided, or only if requested by families for a fee. Most provided multi-disciplinary supports, but clinicians tended to work as individuals providing centre-based and in-home direct intervention, and consultation services. Referral pathways to diagnostic services varied, but often began with a GP. One diagnostic service used telehealth. *Diagnosis and Interventions*: The mean age of ASD diagnosis was reported by both clinicians and families as 3 years. Interventions were described in broad terms only (e.g., behavioural, family-centred), without evidence of structured or evidence-based programmatic approaches. Most families received an hour a week of intervention per fortnight; many received less. *Attitudes to Telehealth*: Both clinicians and families were open to telehealth, but largely for consultative services. Interviewed clinicians were interested in learning new skills and finding out about new strategies, and some wanted to learn about recent research. They saw telehealth as a possible way to link with expertise, but few saw value in its use in delivering their services.
Conclusions: Most families in this regional town received services that were far removed from best practice regarding early diagnosis, frequency and intensity of intervention, and evidence-based strategies. This situation is likely to reflect that found elsewhere in this and in other developed countries. Shifting service provision towards evidence-based practices requires fundamental changes to funding mechanisms, and expert support to service providers. Knowledge gained from efforts to translate best-practice into low-resource settings in high-income countries offers the potential to inform translation into settings in low-income countries.

180 **125.180** Characteristics of Patients with Autism Spectrum Disorders Who Successfully Initiate Behavioral Intervention Services

N. M. Shankute[1], *M. N. Davignon*[2], *C. K. Yoshida*[1], *M. L. Massolo*[1] *and L. A. Croen*[1], *(1)Division of Research, Kaiser Permanente, Oakland, CA, (2)Kaiser Roseville Medical Center, Roseville, CA*

Background: Evidence-based treatments rooted in Applied Behavior Analysis (ABA) have been shown to lead to favorable outcomes in children with autism spectrum disorders (ASD). Research evaluating the effectiveness of behavioral treatments is vast but very little is known about which individuals benefit the most from these treatments. As the prevalence of ASD continues to increase and with most states expanding insurance mandates to provide evidence based behavioral treatments, it would be advantageous to characterize the barriers and facilitators to treatment in order to better serve this population.
Objectives: To describe the patient characteristics associated with initiating behavioral treatments among a large and diverse insured ASD population referred for behavioral intervention services.
Methods: The study population is comprised of 380 Kaiser Permanente (KP) members from northern California with ASD aged 2-22 years who were referred for ABA treatment services to Easter Seals Bay Area (ESBA) between February-May 2014. ESBA is the largest vendor providing ABA treatment services for KP northern California members. Patients were grouped based on whether they ever initiated or never initiated treatment within 12 months of the date of referral to treatment. We compared the ever versus never initiated treatment groups with respect to sex, race/ethnicity, age at referral to treatment, and ASD status of siblings using chi-squared tests. Mean age at referral to treatment was compared between the two groups.
Results: The majority of patients referred for ABA were between the ages of 5-11 years of age (32% 2-4, 48% 5-11, 14% 12-15, 6% 16-22), male (82%), white (37%), and the

only child in the family with an ASD diagnosis (88%). Overall, 12% of patients referred for ABA never initiated treatment. Among those, 56% never completed the first step, which is an in-person assessment by the vendor; the remaining 44% completed the assessment and were recommended a treatment plan but failed to initiate treatment. Among the 88% of referred patients who started treatment, 25% subsequently discontinued treatment within 12 months of the referral. Patients who initiated treatment were similar to patients who did not initiate treatment with respect to sex (male: 81% vs 82%) and race/ethnicity (White: 37% vs 38%; Asian: 29% vs 27%; Hispanic: 17% vs 22%; Black: 6% vs 7%; Other: 10% vs 7%), and having a sibling with ASD (12% vs 9%). However, patients who initiated treatment were more likely than patients who did not initiate treatment to be <5 years of age at referral (34% vs 20%). The mean age at treatment referral (7 years vs 9 years) was lower among individuals who initiated treatment compared to those who didn't.
Conclusions: Demographic characteristics did not distinguish between the ever versus never initiated treatment groups. Other factors that may contribute to treatment initiation and engagement, including referral sources, parental characteristics, and timing of services will be presented.

181 **125.181** Co-Located Behavioral Assessment Services for Children with ASD in Pediatric Primary Care Settings

***K. Herrington**, J. F. Hine and Z. Warren, Vanderbilt University, Nashville, TN*

Background: Within primary care, use of an integrated delivery model is on the rise as being the optimal method of providing behavioral-health services. Research suggests co-located behavioral-health providers within primary care settings result in earlier diagnosis and management of a range behavior problems (Chomienne, et al., 2011). Furthermore, physician satisfaction research shows that having the ability to refer patients for rapid assessment and intervention has a major positive impact on their practice (Clatney, et al., 2008). Few studies have examined physician satisfaction of integrated ASD-specific behavioral services into pediatric primary care practices
Objectives: The current work examined (1) the feasibility of incorporating ASD-specific assessment and brief treatment services in two primary care clinics (academic faculty clinic, resident clinic) and (2) physician satisfaction with services.
Methods: We physically embedded a psychology provider in two separate primary care clinics associated with our academic medical center (faculty practice, resident clinic). These providers were physically present in the primary care setting one day per week and made explicitly available for the purposes of providing follow-up to ASD-related concerns (e.g., screening failures, diagnostic issues, behavioral consultation). To assess feasibility we tracked the nature and type of referrals, show rates, age/latency rates related to diagnosis, and surveyed providers about the benefits and challenges of the embedded service. Surveys included a 1-5 point Likert Scale assessing satisfaction with these services meeting the needs of the referred families, the quality of services, and collaborative practices. Physicians were also asked their level of agreement with statements regarding whether integration of behavioral-health providers improves the quality and continuity of healthcare, frees up more time to address medically related issues, reduces added healthcare costs, increases show rates, and increases their own ability to identify and manage behavioral health concerns.
Results: Across the initial 32 weeks of implementation, the integrated behavioral services program was able to see over 60 children with a wide range of behavioral and developmental concerns – with some children seen across repeated sessions. Show rates for the embedded behavioral service program were considerably higher (91.7%) than those within affiliated tertiary referral clinics at the host university (<75%). For children referred for assessment of ASD, latency to evaluation and diagnosis was considerably shorter. All patients referred for ASD evaluation received a diagnosis within 1-2 months of referral with current wait-times for tertiary clinic assessment averaging 6-12 months. Provider feedback indicated significant improvements related to quality and continuity of care and decreased waits for service. However, this feedback also indicated concerns regarding financial viability of the program over time, as well as concerns about limited nature of referral service (i.e., 65% of referral issues for embedded service were not related to ASD.
Conclusions: This study provides preliminary support for the value of embedded, co-located behavioral services in meeting the needs of children with ASD in primary care settings. Such models of care may reduce waits, age of diagnosis, and reduce other service barriers encountered by individuals with ASD and their families seeking services through referrals to traditional tertiary care facilities.

182 **125.182** Combining Web-Based Learning, Interactive Instruction and Remote Supervision to Train Community-Based Providers in a Parent Coaching Intervention for ASD

***A. Wainer**[1], K. Pickard[2] and B. Ingersoll[2], (1)Rush University Medical Center, Chicago, IL, (2)Michigan State University, East Lansing, MI*

Background:
There is increasing evidence supporting the effectiveness of parent coaching interventions targeting social communication skills in young children with autism spectrum disorder (ASD), and both parents and providers hold positive views about this intervention approach. Unfortunately, formal parent coaching programs are highly under-utilized in community settings. A challenge to dissemination and implementation is that a provider must demonstrate knowledge of the intervention strategies, and the skills to effectively teach and support parents in their use of the strategies. Many early intervention providers are trained to work directly with children, yet are not as familiar with adult learning principles or methods for providing parents with feedback and coaching. Recent advances in distance learning suggest that the use of computer and internet technology may help to increase access to training and support for community-based providers. Prior to large scale dissemination of these training protocols, a better understanding of the extent to which providers learn and effectively use parent coaching strategies from such a protocol is critical.
Objectives:
An innovative and systematic training protocol was developed to introduce community-based providers to Project ImPACT, a parent coaching intervention aimed at increasing social communication skills in young children with ASD. The protocol includes web-based instruction, brief interactive workshops, and remote skype consultation/supervision. Initial research suggests that this training protocol is feasible, acceptable and effective for learning the Project ImPACT intervention techniques. The current research aimed to determine the extent to which providers found the same protocol to be acceptable and effective for learning the *parent coaching strategies*. Additionally, this research examined the sustainability of Project ImPACT after the use of this training protocol.
Methods:
Fifteen community-based providers participated in the study. The training protocol included: 1) a web-based Project ImPACT tutorial; 2) a one-day interactive workshop about the intervention techniques; 3) three remote skype supervision/feedback sessions about intervention techniques ; 4) a one-day interactive workshop about parent coaching; and 5) three remote skype supervision/feedback sessions about parent coaching. Providers completed questionnaires and videotaped provider-family interactions at 6 time points: *Time 1* (baseline); *Time 2* (after the web-based tutorial); *Time 3* (after the first interactive workshop); *Time 4* (before the second interactive workshop)*; Time 5* (after the second interactive workshop); and *Time 6* (six-month follow-up).
Results:
The community-based providers found this training protocol to be feasible, acceptable and effective. Providers also demonstrated improvements in fidelity of the Project ImPACT intervention techniques and parent coaching strategies. The majority of providers have continued to use Project ImPACT; however, some barriers to training and to the sustainability of the parent coaching program were identified.
Conclusions: This study provides evidence for the acceptability and effectiveness of a training protocol integrating internet-technology, in-person instruction and remote supervision to train community-based service providers in an evidence-based parent coaching intervention for children with ASD. Results suggest that a program like this may serve to overcome barriers to the use of parent coaching programs in community settings, and may ultimately increase access to evidence-based intervention services for children with ASD in the community.

183 **125.183** Community Training Outreach: The Utah Network for Early Autism Response

***S. S. Manwaring**[1], T. Cardon[2], A. J. Fischer[1], S. Cunningham[1], A. Stevens[1], A. V. Kirby[1], R. West[3], S. Iverson[4], B. Robinson[5], C. Guy[6], M. Reidy[7], D. Burgon[1] and T. P. Gabrielsen[8], (1)University of Utah, Salt Lake City, UT, (2)Utah Valley University, Vineyard, UT, (3)Utah State University, Logan, UT, (4)Washington State University, Pullman, WA, (5)Primary Children's Hospital, Salt Lake City, UT, (6)Wyoming Institute for Disabilities (WIND), University of Wyoming, Laramie, WY, (7)University of Texas Medical Branch, Galveston, UT, (8)Brigham Young University, Provo, UT*

Background: The rising prevalence of autism spectrum disorder (ASD) creates critical need for widespread expertise to recognize and respond to earliest signs of the disorder. The Autism and Developmental Disabilities Monitoring Network (ADDM; Biao, 2014) reported that Utah had the lowest proportion (33%) of children with ASD receiving comprehensive evaluations prior to age 3 among eleven sites surveyed (based on health/education records). The median age of ASD diagnosis in Utah, as reported by ADDM, was 53 months of age. Solving these problems requires novel solutions to capacity issues, roles, and gaps in knowledge about screening and early symptoms among the broader early childhood community.
Objectives: The aim of this study was to examine professional practices and competencies around early identification and treatment of ASD prior to and following a one-day, intensive, interactive training to professionals across Utah who work with children under 5 years of age. We sought to improve recognition of subtle signs and ASD symptoms in early childhood, increase comfort levels talking about ASD risk with parents, and increase knowledge about systematic screening, follow up and referral.
Methods: A free, one-day, interdisciplinary training was offered in 3 urban/suburban and 3 rural/semi-rural locations statewide during summer 2015. Participants included pediatric health care providers, early childhood educators, and early intervention and special education professionals, totaling approximately 500 statewide. Training was provided by ASD specialists (all faculty members at major universities) with extensive training and clinical experience in early diagnosis and treatment of ASD. Prior to the workshop, attendees completed a survey (based on Swanson et al., 2013) about current practices, prior knowledge and participation in early ASD identification and intervention. The survey is also being administered at 4, 8 and 12 months post-workshop, to identify changes in practice. The first two follow-up phases will be completed by 12/28/15 and 4/28/16, respectively.
Results: Preliminary data analyses indicated that prior to training, the majority of professionals reported they were not comfortable identifying risk for ASD (72%), screening

for ASD (66%), or discussing ASD diagnoses with families (74%). Twenty percent of professionals reported they currently screen children for ASD using the M-CHAT; 33% of those who screen reported using the M-CHAT follow-up questionnaire, and 15% using the M-CHAT reported they screen all children they see. Other screeners were used by 53%, primarily the Ages and Stages Questionnaire. Following positive screens, 49% of respondents reported they typically refer to early intervention or for further evaluation. In relation to treatment of ASD, 65% of attendees reported they were "not at all" comfortable speaking to parents about ASD evidence-based practices. Post-workshop changes in each of these areas will be reported.
Conclusions: The need for early child professionals to increase their level of training and comfort in screening, early identification, and evidence-based practice statewide is substantial and may be related to the identification of children younger than 3. Community training outreach from specialists at university centers may be one effective approach to address these needs and increase ASD identification rates before age 3.

184 **125.184** Concern May Not Equal Action: Outcome Data in a Universal ASD Screening Sample

T. P. Gabrielsen[1], *M. E. Villalobos*[2], *M. Farley*[3], *L. Speer*[4], *N. Buerger*[5] *and J. Miller*[6], *(1)Brigham Young University, Provo, UT, (2)TEACCH Autism Program University of North Carolina Chapel Hill, NC, Asheville, NC, (3)Waisman Center-University of WI, Madison, WI, (4)Cleveland Clinic, Cleveland, OH, (5)University of Utah, Salt Lake City, UT, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Recently, the US Preventative Services Task Force (USPSTF) issued a call for more research on effects of universal screening for autism spectrum disorder (ASD). This call came in a draft statement indicating insufficient evidence exists for recommending autism screening for all children. Instead, the USPSTF supported screening for ASD in the presence of a concern. The American Academy of Pediatrics immediately issued a re-affirmation that universal screening of toddlers at 18 and 24 months was best practice in addition to screening any time there is a concern. Although studies have looked at universal screening, and others have looked at outcomes from early intervention, no studies have been conducted that link children identified through universal screening to their outcomes.
Objectives: This study provides a detailed examination of actions and outcomes within a small group of screen-identified children from a large community sample, including re-evaluations after third birthdays.
Methods: Participants (n=42, aged 15-33 months) were typically developing controls and children who screened positive following universal autism screening within a large community pediatric practice (n=796). Three children in the sample were referred for ASD evaluation prior to universal screening. Diagnostic evaluations including ADOS at time of screening (n=42) and after 36 months of age (n=22) were performed to determine group status (autism [n=14], language delay [n=14], or typical [n=14] after initial evaluation). Licensed psychologists with toddler and autism expertise, unaware of group status, analyzed 10-minute video samples of participants' original autism evaluations. Raters were asked for autism referral impressions based solely on observations to determine concern about atypical behaviors. Data regarding medical histories, concerns, and risk factors at the time of screening, and eventual actions following screening and evaluation were gathered, as were assessments of cognitive and adaptive abilities at initial evaluation and at follow up during the fourth year of life.
Results: Although concerns of parents or others were prevalent in the autism group (12/14 children), the presence of concerns did not translate to action for many parents (only 7/14 in the autism group had discussions with physicians prior to screening). Prior to universal screening, 3 of the children were referred to early intervention based on concerns for ASD, 2 were referred for speech or feeding. Following universal screening, 9 children were enrolled in services, 1 did not enroll, 1 was eventually not diagnosed with ASD, and 3 Spanish-speaking families were lost to follow up after identification, so outcomes are unknown. In the language delay group, 5 families enrolled in speech services following universal screening, 2 did not, 1 enrolled prior to screening, 6 were lost to follow up. Children in language and autism groups had improved or stable cognitive scores with few exceptions, and mixed adaptive score changes.
Conclusions: Screening in the presence of concerns is supported, but many parents within the sample did not take action on concerns prior to universal screening. The universal screening process may have accelerated identification of children with ASD, resulting in earlier intervention enrollment and stable or improved cognitive and adaptive outcomes.

185 **125.185** Cost-Effectiveness Analysis of Wait Time Reduction for Intensive Behavioral Intervention in Ontario

C. Piccininni[1] *and M. Penner*[2], *(1)Queen's University, Kingston, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: In Ontario, the Autism Intervention Program funds intensive behavioral intervention (IBI) for children severely affected by autism spectrum disorder (ASD). Accessing IBI before age four is associated with significantly better outcomes compared with later access; however, the average wait time (WT) for this program is 2.7 years. There have been no analyses modeling the lifetime cost-effectiveness of reducing the WT for IBI.
Objectives: The objective of this study was to perform a cost-effectiveness analysis (CEA) comparing WT reduction and elimination to the current status quo over the lifetime from both provincial government and societal perspectives.
Methods: Published wait list statistics were used to calculate the average IBI starting age for the current WT, reduced WT (halved), and eliminated WT. CEA model inputs were derived from published literature. The target population was children diagnosed with severe ASD. The outcome modeled was independence measured in dependency-free life years (DFLYs) to age 65. To derive this, the mean expected IQ was modeled for each comparator based on probability of early (< age 4) or late (4 or older) access to IBI. Probabilities of having an IQ in the normal (70+) or intellectual disability range (< 70) were calculated. Each IQ stratum was assigned a probability of achieving an Independent (60 DFLYs), Semi-Dependent (30 DFLYs) or Dependent (0 DFLYs) outcome. Costs were determined for both provincial government and societal perspectives and were taken from government publications. Parameters were inputted into a decision analytic model, with an annual discount rate of 3% applied to costs and DFLYs. Incremental cost-effectiveness ratios (ICERs) were determined for each strategy from both perspectives. One-way and probabilistic sensitivity analyses were performed to assess the impact of uncertainty in the model.
Results: From the provincial government perspective, eliminated wait time dominated the other two strategies, generating the most DFLYs for $6,500 less per individual to age 65 than current wait time and $2,700 less than the reduced wait time. From the societal perspective, eliminated wait time again dominated the other strategies, generating the most DFLYs with lifetime savings of $38,000 per individual compared with current wait time and $16,200 in savings compared with reduced wait time. From both perspectives, ICER outputs were most sensitive to uncertainty in the probability of achieving a post-treatment IQ score greater than 70 and the probability of an Independent outcome when post-treatment IQ was greater than 70. Probabilistic sensitivity analyses comparing the eliminated to reduced WT strategies from both perspectives each showed a 57% probability of a positive ICER (increased costs and DFLYs), with a 21% probability of cost-savings and increased DFLYs.
Conclusions: The results suggest that an investment to eliminate wait times could produce eventual cost-savings as well as improved independence. Funding expanded program capacity would optimize the likelihood of positive outcomes, improve future independence, and lessen the lifetime cost burden from provincial and societal perspectives.

186 **125.186** Depression in Parents of Children Diagnosed with Autism Spectrum Disorder

A. Cohrs[1,2] *and D. Leslie*[1,2], *(1)Public Health Sciences, Penn State College of Medicine, Hershey, PA, (2)Center for Applied Studies in Health Economics, Penn State College of Medicine, Hershey, PA*

Background: Raising a child with autism spectrum disorder (ASD) can be challenging for many parents and may potentially have an impact on their personal health. The challenges in identifying, accessing, and paying for ASD services, given the nature of these children's needs, available resources, and complex financing arrangements, can place a substantial burden on caregivers. Previous studies have examined how ASD in children can affect parents' health, but they are limited by small sample sizes and patient self-report.
Objectives: The objective of this study was to determine whether there is an association between having a child with ASD and diagnosis of depression in the child's mother and/or father. We also determined whether the age of the child, as well as the number of children in the family, was associated with a diagnosis of depression in the parents.
Methods: Retrospective analysis of health insurance claims data from the 2011 MarketScan database was performed. ICD-9 codes were used to determine a primary or secondary diagnosis of ASD in children ages 0-17 and a diagnosis of depression in the parents of those children. Rates of parental depression among children with ASD were compared to those of an age and gender matched control group of children without ASD. Chi-square and logistic regression analyses were performed to determine the association of having a child with ASD on parental depression, controlling for child and parent characteristics.
Results: There were 42,662 case-control dyads, resulting in 85,324 unique families. Among all families, 12,237 (14.3%) had at least one parent with a diagnosis of depression. A diagnosis of depression was more than twice as common in parents of children with ASD (20.2%) than in parents who did not have a child with ASD (8.5%). After controlling for other child, parent, and family characteristics, having a child with ASD almost tripled the odds (OR: 2.83; 95% CI: 2.71-2.96) of parental depression. Mothers of children with ASD were 3 times more likely to have a diagnosis of depression than mothers of children without ASD (OR: 3.01; 95% CI: 2.86-3.17), and fathers of children with ASD were 2.4 times more likely to have a diagnosis of depression than fathers of children that did not have ASD (OR: 2.44; 95% CI 2.27-2.62). In addition, risk of depression increased when there was more than one child with ASD in the family (OR: 1.42; 95% CI: 1.27-1.60) and with child age.
Conclusions: Both mothers and fathers of children with ASD were at increased risk of having depression than parents of children without ASD. Furthermore, the risk of depression increased if the parents had more than one child with ASD and with child age. Support and education should therefore be provided to both mothers and fathers of children with ASD.

187 **125.187** Determinants of Wait Time for Autism Spectrum Disorder Diagnostic Assessment in Canada

M. Penner[1], *E. Anagnostou*[2] *and W. Ungar*[3], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada,*

(3)Hospital for Sick Chidlren, Toronto, ON, Canada

Background: The increasing prevalence of autism spectrum disorder (ASD) diagnoses and a shortage of skilled practitioners have contributed to substantial wait times for diagnostic assessment. These wait times occur during an important window for social learning and may result in suboptimal developmental outcomes. Identifying factors related to provider characteristics and assessment practices may help to streamline the assessment process, reducing wait times.
Objectives: The objective of this study was to identify determinants of wait times for ASD diagnostic assessment in Canada.
Methods: An online national survey was conducted through the Canadian Paediatric Society's Developmental Paediatrics, Community Paediatrics, and Mental Health sections, which were identified as the groups of pediatricians most likely to encounter children with suspected ASD. Participants were asked for demographic information and whether they diagnosed ASD. Those who diagnosed ASD were asked about the elements of their assessment, duration of assessment, and wait times. A linear regression was performed using natural log transformed total wait time (time from referral to communication of the diagnosis to the family) as the dependent variable. Hypothesized explanatory variables included assessment duration, type of assessor (general pediatrician, developmental pediatrician, other), use of a multi-disciplinary team, accepting referrals from primary care physicians, catchment area, province of practice, and number of years in practice.
Results: The overall response rate for the survey was 14% (91 completed surveys out of 639 individuals solicited). Fifty-seven participants indicated that they diagnosed ASD in their practice (62.6%) and were included in the analysis. This sample was 66% female (n=38, versus 19 males) with a median age of 52 (range 29 to 77). The median reported total wait time was 208 days (interquartile range 119, 365). Bivariate analyses for total wait time identified assessment duration (Spearman r = 0.31, p = 0.02), type of assessor (Kruskal Wallis chi-squared = 3.66, p = 0.16), and province (Kruskal Wallis chi-squared = 13.67, p = 0.19) as potential explanatory variables. Assessment duration was significantly associated with type of assessor (Kruskal Wallis chi-squared = 5.59, p = 0.003) so these variables were not tested together in the model. Assessment duration was the only variable that remained significant when tested in the regression model (p = 0.002) and accounted for 15% of the variance in the model. The back-transformed mean adjusted total wait time was 254 days (95% confidence interval 214, 302).
Conclusions: Canadian wait times for ASD diagnostic assessment are substantial, encompassing over eight months from referral to communication of the diagnosis to families. The amount of time spent on the assessment is a significant determinant of wait time, highlighting the need for efficient assessment practices.

188 **125.188** Development of a Clinically Integrated Return of Results Protocol for Genetics Research in Autism

I. Peltekova[1,2,3], *L. Stern*[4], *D. Buhas*[5] *and M. Elsabbagh*[6], *(1)Integrated Program in Neuroscience, McGill University, Montreal, QC, Canada, (2)Developmental and Behavioural Pediatrics, Montreal Children's Hospital, Montreal, QC, Canada, (3)Psychiatry, Autism Research Program, Montreal, QC, Canada, (4)Montreal Children's Hospital, Montreal, QC, Canada, (5)Genetics, Montreal Children's Hospital, Montreal, QC, Canada, (6)McGill University, Montreal, PQ, Canada*

Background: The rapid advancement of genomic research in autism is due to the growing participation of children with autism and their families, and to the implementation of increasingly powerful genomic tests. Some tests, namely microarrays, are now a standard part of the clinical assessment of children with autism. Results of these tests may have significant value for families, as they can impact diagnosis, prognosis, health surveillance and reproductive decisions. Within large-scale genetic research studies, disclosure of incidental findings is a standard ethical conduct. However, the increasing complexity of individual child and family results, coupled with their variable clinical significance, present a challenge for how and when to communicate genetic findings (Knoppers et al. 2010). Despite several theoretical discussions, there is very limited empirical research tracking impact of genetic findings on clinical care (Fernandez et al. 2013, Johnson et al. 2012).
Objectives: Consistent with recent recommendations for large scale research studies to declare a specific process for Return of Results (RoR) (Knoppers et al. 2010, Wolf et al. 2012), our goal was to develop a contextually-sensitive protocol, that considers local health systems characteristics and constraints.
Methods: We convened a work group to develop a RoR protocol for a data collection site that participated in two large-scale genetics studies. Over 400 families have been enrolled in studies where advanced sequencing methods are increasingly revealing complex individual child and family results.
Results: The work group considered that general ethical standards, such as confidentiality and protection of minors, were insufficient to fully inform RoR. They identified and formulated more specific directives to guide the RoR protocol: (1) families must have consented to receiving individual findings, (2) findings must be clinically actionable, (3) care pathways potentially resulting from RoR must be clear and accessible to families, (4) likelihood of family confusion and stress resulting from the findings or due to delays in access of subsequent care must be monitored and minimized, and (4) potential impact on health systems resources must be monitored.
Conclusions: Our resulting RoR protocol is contextually sensitive and integrates RoR from research with healthcare capacity and constraints. Current empirical application of this protocol provides guidance for the integration of next-generation sequencing methods into clinical care.

189 **125.189** Do Teachers Teach Social Skills to Students with Autism Spectrum Disorder and Students with Intellectual Disabilities?

K. Kemp[1] *and H. M. Chiang*[2], *(1)Rhode Island College, Providence, RI, (2)Teachers College Columbia University, New York, NY*

Background: Individuals with autism spectrum disorder (ASD) and individuals with intellectual disability (ID) have social skills deficits. Students with ASD and students with ID are eligible to receive free and appropriate special education and relevant services under the Individuals with Disabilities Education Act. However, little is known if these students receive social skills interventions in schools and the types of social skills interventions that they receive in school.
Objectives: This study aims to answer these research questions: (1) Do teachers of students with ASD or ID teach social skills to their students? (2) Are there relationships between teacher characteristics and whether or not teachers teach social skills to these students? (3) Are there relationships between student characteristics and whether or not teachers teach social skills? (4) What are the student and teacher factors predictive of social skills of these students? (5) What kind(s) of social skills instructional strategies do teachers use? (6) What are the barriers that teachers face when teaching social skills to these students? (7) What resources or supports do teachers need?
Methods: Fifteen general education teachers and 51 special education teachers participated in this study. They were asked to complete a questionnaire about their use of social skills instructional strategies in their classroom, and a social skills assessment for their student. A total of 51 students with ASD (mean age = 10.85 years) and 15 students with ID (mean age = 11.9 years) who ranged in age from 5-18 years were identified by participating teachers.
Results: This study found (1) Of the 66 participating teachers, 71.2% reported that they taught social skills to students with ASD or ID. (2) There was no significant difference between special education teachers and general education teachers in offering social skills interventions to their students. (3) There was no significant difference between student characteristics and whether or not teachers provided social skills interventions to them. (4) No teacher characteristics were predictive of students' social skills. (5) Having friends and showing more than 20 functional words were predictive of students' social skills. (6) The three most frequently used strategies were prompting, reinforcement, and modeling. (7) The two most infrequently used strategies were Pivotal Response Training and video modeling. (8) Teachers tended to rank the strategies which are easy to use as effective. (9) The most common barriers for teaching social skills in schools were a lack of time for designing social skills interventions and a lack of appropriate curriculum. (10) Time and curriculum were reported as the most needed resources.
Conclusions: Teachers did provide social skills interventions to students with ASD and students with ID. However, not every teacher of students with ASD or students with ID did so. Lack of time and curriculum seem to be the reasons accounting for this. Thus, supports in relation to these two areas should be provided to teachers. Teachers tended to rank the strategies that were not easy to use as less effective. Thus, usability should be considered when developing new social skills interventions.

190 **125.190** Early Intervention Providers in the Field: Barriers and Incentives to Professional Development and Coaching in Evidence-Based Practices for Autism Spectrum Disorder

E. Chapman[1], *N. D. Bond*[1], *S. K. Fuhrmeister*[1], *J. L. Stapel-Wax*[2], *T. Ryan*[3], *S. E. Gillespie*[4], *M. Costo*[1] *and K. Terry*[1], *(1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Atl, GA, (3)Marcus Autism Center, Duluth, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA*

Background: Minimal information is known about factors that influence early intervention providers' participation in professional development. Exploring these factors can help predict participation in adult learning activities that are designed to promote the utilization and implementation of evidence-based practices for children with Autism Spectrum Disorder (ASD). Evidence-based early intervention plays a vital role in helping children at risk for developing ASD obtain their fullest developmental potential. Professional development that includes coaching is linked to immediate skill development and an increased chance that newly learned skills are sustained over time in the real-world setting (Rusby et al. 2013).
Objectives: This project aimed to explore barriers and incentives that might influence Early Intervention Providers' participation in a 30-hour online course on evidence-based practices for infants and toddlers with Autism Spectrum Disorder (ASD) and/or 12 months of coaching on evidence-based practices for ASD in a hybrid format which includes both face-to-face coaching and virtual coaching. Factors examined in this exploratory study include demographic variables, education level and interpersonal factors such as family obligations and lack of time.
Methods: This study examined barriers and incentives to participation in both the online training modules and coaching for 45 early intervention providers across the state of Georgia who voluntarily participated in an Early Intervention Providers Needs Assessment Survey. This was a convenience sample. The survey utilized consisted of 9 questions, which were a combination of multiple choice/multiple answers. Participants were also given the opportunity to provide text responses to reflect barriers and incentives that were not listed.
Results: Statistical results of the survey indicate that lack of time and work obligations are often the greatest barriers to participation in both the online training modules and coaching for this population. Being able to earn CEUs and financial incentives were the best motivators for participating in both forms of professional development (online training and coaching). Only 1/5 (20%) of the providers surveyed had completed all four modules of the online training. However, 2/3 (66.7%) of the participants indicated that they had the desire to be coached on evidence-based practices for infants and toddlers with ASD.

Conclusions: These findings offer a preliminary look at the unique factors influencing early intervention providers' participation in professional development related to evidence-based practices for infants and toddlers with ASD. Results from this study can lead to further research on professional development and training tailored to fit the needs of this population.

191 **125.191** Echo Autism: Bringing Best Autism Care to Primary Care

K. Sohl[1], *A. Curran*[2], *R. M. Brown*[3] *and M. O. Mazurek*[4], *(1)University of Missouri - Thompson Center, Columbia, MO, (2)University of Missouri, Columbia,, MO, (3)University of Missouri, Columbia, MO, (4)University of Missouri - Columbia, Columbia, MO*

Background:
Children with Autism Spectrum Disorder (ASD) have limited access to comprehensive medical care in their communities. Children from underserved populations and regions face even greater disparities in access to diagnostic and treatment services. Primary care providers (PCP) report low self-perceived competency and a high need for education about medical management of children with autism. Given limited resources for specialty care, there is a need to increase capacity for PCPs to provide best practice autism care in primary care. Extension for Community Healthcare Outcomes (ECHO®) is a model of telehealth that builds local capacity by teaching best practices using case-based learning, video technology, and outcome evaluation. ECHO Autism was developed in partnership with The Autism Intervention Research for Physical Health/ Autism Treatment Network (AIRP/ATN) to disseminate evidence-based screening and management guidance to community providers.
Objectives: The objective of this project was to recruit PCPs to participate in a 6 month pilot of ECHO Autism to determine if this model was effective in 1) increasing PCP self-efficacy with identification of ASD symptoms in children between 12 months and 18 years of age and 2) increasing PCP self-efficacy in assessing and treating common medical and psychiatric comorbidities in children with autism.
Methods: Fourteen PCPs were recruited to participate in ECHO® Autism clinics facilitated by an interdisciplinary team of autism and behavioral experts. During two hour, biweekly clinics, the expert team facilitated discussion and provided feedback for two PCP generated case-based presentations and delivered a didactic presentation, augmenting case-based learning. Practice behavior and self-efficacy in screening and medical management of children with ASD were measured at baseline and post-intervention. Wilcoxon signed-rank tests were performed with significance set at $p < 0.05$.
Results: Improvements in Total Self-Efficacy from pre-test (M = 177.15, SD = 46.59) to post-test (M = 227.43, SD = 21.59; $Z = -3.06$, $p = .002$) were noted. Improvements in Self-Efficacy were also observed in each of the subscales, including Screening, (Z = -260, p = .009). Resources (Z = -3.11, p = .002), Medical (Z = -2.68, p = .007), Psychiatric (Z = -3.06, p = .002), and Additional (Z = -2.87, p = .004). The percentage of pediatricians reporting full compliance with American Academy of Pediatrics (AAP) guidelines for autism screening increased from 30% to 60% following participation in ECHO Autism.
Conclusions:
The ECHO Autism model is an effective model to improve primary care provider self-efficacy with identification and management of autism. This real-time, interactive model offers an efficient and effective support system and fosters networking between all participants. As cases are presented and didactics delivered, PCPs increase their comfort, knowledge and confidence in screening, assessing and treating children and youth with ASD and other developmental concerns. ECHO Autism also is a promising model to improve compliance with AAP screening guidelines. Future research should focus on demonstrating sustainable practice change in primary care that results in improved access and outcomes for individuals with autism.

192 **125.192** Emergency Psychiatric Service Use and Continuity of Care Among Youth with Autism Spectrum Disorder

L. Kalb *and E. Stuart, Johns Hopkins School of Public Health, Baltimore, MD*

Background: Previous research suggests youth with Autism Spectrum Disorder (ASD) are at increased risk for emergency psychiatric service use, including both inpatient psychiatric hospitalizations and psychiatric emergency department (ED) visits. However, the few studies that have addressed this topic suffer from serious methodological limitations and are quite limited in scope.
Objectives: To examine differences in the probability and conditional rate of both inpatient psychiatric hospitalization and psychiatric ED visits between youth with ASD and youth with Attention Deficit-Hyperactivity Disorder (ADHD). Additional outcomes included differences between groups regarding: 1) the likelihood of readmission within 30 days, 2) length of stay, and 3) probability of an outpatient mental health appointment 30 days before and after service use.
Methods: Data for this study came from 64,700 and 529,662 adolescents (ages 12-17 years) with ASD or ADHD, respectively, enrolled in the 2010-2013 MarketScan Commercial Claims Database. To be included, youth must have at least two ICD-9-CM claims of ASD (299) or ADHD (314), at least 1 year of continuous enrollment, and no history of substance abuse or stay in a long-term residential facility. Psychiatric services were identified by the presence of a primary psychiatric diagnosis (290-314.XX) or E/V code (e.g., suicide). The Area Resource File (ARF) was joined to the Marketscan dataset to provide information on geographical indicators of race, income, and density of outpatient and inpatient services. A multivariate two-part regression model was used to assess the probability (logit) and conditional rate (gamma) of service use while adjusting for demographic, enrollment, and geographic characteristics. All other objectives were addressed using multivariate linear or logistic regression models.
Results: 1 in 12 adolescents with ASD used an urgent psychiatric service, representing greater than a two-fold higher probability of use for psychiatric hospitalization (5% vs. 2%; aOR = 2.5, 95% CI: 2.4-2.6) and for psychiatric ED visits (4% vs. 2%; aOR = 2.2, 95% CI: 2.1-2.3) compared to those with ADHD. Conditional on service use, the ASD group had a 14% and 11% increased rate of hospitalization (IRR = 1.14, 95% CI: 1.1-1.2) and ED (IRR = 1.11, 95% CI: 1.08-1.44) visits, respectively. Longer inpatient and ED stays, and an increased likelihood of re-visiting both settings within 30 days was also found among youth with ASD (all p<.001). Receipt of an outpatient mental health services 30 days before or after an ED visit or hospitalization was high (~80%) and similar between groups (p>.05).
Conclusions: This is the first prospective cohort study to assess the interplay between inpatient, ED, and outpatient psychiatric service use among youth with ASD or ADHD. Youth with ASD used more emergency psychiatric services for longer periods of time compared to youth with ADHD. Increased psychiatric ED use among those with ASD is particularly disconcerting since only 10% of these visits resulted in hospitalization, leaving the family to manage the difficult behavior at home without additional resources or treatment options. These data also challenge the notion that emergency psychiatric services use is simply due to poor connections to outpatient mental health providers.

193 **125.193** Enhanced Screening Methods Increase Percentage of Children with ASD Diagnosed in a Clinical Setting

C. Hall *and S. Hoffenberg, Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA*

Background:
Current guidelines from the Academy of Pediatrics (2010) recommend that children suspected of having Autism Spectrum Disorders (ASD) should receive a comprehensive evaluation. As one of the only specialty clinics in our state, and one that serves a diverse and often economically disadvantaged population, our clinic is faced with high demand for diagnostic assessments. Historically, all children referred for an autism evaluation received a full psychological assessment in our clinic, which led to very long waiting lists. In 2012, 896 children were referred for diagnostic assessment, and 299 of these were evaluated during a one year period. Of those children, only 53% were found to meet DSM Criteria for ASD. Given this high rate of children who did not have ASD, significant changes were made in 2013/2014 to our screening and triage efforts, with the goal of focusing our diagnostic assessment appointments on children who were most in need of diagnostic assessment, specifically to assess for ASD.
Objectives:
The present study examines whether specific methods of triage and screening helped to reserve diagnostic testing appointments for children with symptoms specific to ASD. More specifically, it examines the utility of reviewing records and conducting a comprehensive diagnostic interview prior to full evaluation.
Methods:
During 2013/2014, we added new procedures to our intake process. First, we began to request records (e.g. school IEP's, previous testing, pediatrician's notes and rating scales) at the beginning of the process. Records were reviewed by a clinical intake team that determined whether the child showed symptoms indicative of ASD. Children whose records indicated that an evaluation was warranted were scheduled for a diagnostic interview. A full assessment (i.e., cognitive/development measure, adaptive measure, and ADOS-II) was scheduled after the interview only when clinically indicated.
Results:
In the year subsequent to the intake changes (October 2014 to October 2015), 2,346 referrals were reviewed by the team. Based on the review of records, 860 children were referred out to community providers or referred straight to treatment programs in the center, rather than being scheduled for an assessment. Of the remaining children, 920 received a diagnostic interview and 632 (69%) of these were brought back for a full testing battery. Of those receiving full diagnostic assessments, 68% met diagnostic criteria for autism spectrum disorder.
Conclusions:
Utilizing an initial record review and diagnostic interview enabled the clinic to refer out a full 1061 children (45% of the initial referrals) to more appropriate services. Of the children who were scheduled into full diagnostic assessment appointments, 68% met criteria for ASD, as compared to the 53% who met criteria previous to the enhanced intake efforts. These procedures have refined our ability to identify children who are showing red flags for ASD and helped to reserve lengthy testing appointments for children most in need. As the need for autism assessment and treatment planning rises across the globe, this work furthers the goal of finding ways to efficiently and accurately identify children with ASD so that important intervention efforts can begin as soon as possible.

194 **125.194** Examining Transition and Vocational Pathways in ASD: Perspectives of Individuals with ASD and Parents

D. B. Nicholas[1], *M. Clarke*[2,3], *L. Zwaigenbaum*[4], *K. C. Lowe*[2,5], *S. Hodgetts*[4], *W. Mitchell*[6], *C. A. McMorris*[7], *R. Zulla*[1] *and T. M. Jubenville*[5], *(1)University of Calgary,*

Edmonton, AB, Canada, (2)Sinneave Family Foundation, Calgary, AB, Canada, (3)Uni, Calgary, AB, Canada, (4)University of Alberta, Edmonton, AB, Canada, (5)University of Calgary, Calgary, AB, Canada, (6)The Ability Hub, Calgary, AB, Canada, (7)York University, Toronto, ON, Canada

Background: Adolescents with Autism Spectrum Disorder (ASD) are at risk for suboptimal trajectories to and within adulthood, potentially leading to marginalization, underachievement, and an impaired quality of life. Beyond the potential imposition to basic human rights, investments made earlier in development are at risk of misalignment if a successful transition to, and opportunities within, adulthood are not in place. Further straining transitional and vocational processes, supports for adults with ASD are currently constrained. Despite often having marketable skills, adults with ASD are often deemed unable to gain meaningful employment.
Objectives: To address these gaps, two complementary studies have explored: (i) the transition from adolescence to adulthood and (ii) vocational support pathways in ASD. Study objectives include examination of the process of transition to adulthood in ASD as well as employment. Aims of this program of research entail an evidence-informed model for effective transitioning, as well as factors that inhibit or conversely promote effective supports for employment access and retention.
Methods: Utilizing a grounded theory approach (within a larger study), qualitative interviews were conducted with a sample of youth and adults with ASD and parents. Findings from interviews with adults with ASD (>17 years of age) and their parents will be presented. Interviews address participant experiences and aspirations relative to their transition to adulthood in ASD and salient issues associated with employment success and barriers. Recommendations and guidelines are being iteratively developed for enhanced transition and vocation planning in ASD.
Results:
Findings offer a portrayal of impediments and determinants to positive outcome. Young adults with ASD and their caregivers characterize existing services as insufficient or inappropriate relative to individual need and desire for comprehensive support in adulthood. Services are deemed to often be inaccessible and/or not well-known. There is a reported lack of available knowledge about existing services and travel to/from services are prohibitive for some individuals/families. Services are reported as insufficient for addressing broader social issues that affect employment sustainability and community integration (e.g., social reciprocity, coping skills, mental health, navigation). Parents report multiple challenges including uncertainty and worry about the future of their adult child; difficulty trusting others as part of the 'circle of care', and struggles 'letting go' regarding the adult child's transition to greater independence and/or integration in the community. Adults with ASD similarly describe services they receive as not sufficiently meeting the scope of their support needs and are deemed to be variably inaccessible.
Preliminary results guide transition and vocation planning, and identify these program components as crucial for youth and adults with ASD and their families. Transition and vocation support emerges as requisite and incremental in nature, with a focus on actual and anticipated need, goal setting, and activity/targeted outcome planning. Recommendations for transition and vocation support delivery will be offered in the presentation, as will implications for program and policy development.
Conclusions: Critically examining and recalibrating aims, methods and outcomes related to transition and vocation are integral to optimizing the developmental trajectory of youth and adults with ASD.

195 **125.195** Exploring the Relationship Between Referral Source, Evaluation Setting, and Cognitive/Behavioral Characteristics in Children Referred for Psychological Evaluation

E. L. Wodka[1]*, A. Pittenger*[2] *and S. Erklin*[3]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)The Kennedy Krieger Institute, Baltimore, MD, (3)Outpatient Pediatrics, Northwestern Medicine, Winfield, IL*

Background: There has been little research completed to better understand the process by which children are referred for psychological evaluation. Some have argued that pediatricians and primary care physicians are in a unique position to identify (and refer) "at-risk" children. Other research suggests that parental concerns may serve as a useful tool in the identification and referral of children with developmental and behavioral concerns.
Objectives: This study aims to explore the demographic and clinical characteristics of children who were seen for (neuro)psychological evaluations in a large clinical outpatient specialty setting. We hypothesize that caregiver-referred children will present with a different symptom profile than those referred by professionals.
Methods: Participants included 845 children (M_{age}=10.5, *SD*=3.3, *Range*=5-21 years) who received (neuro)psychological evaluation and were diagnosed with autism spectrum disorder (n=94), attention deficit hyperactivity disorder (ADHD; n=620), and/or anxiety (n=41). Demographic information (age, race, sex, and type of insurance) and clinical information (cognitive, behavioral, and adaptive functioning) were extracted from our clinical database. Chart review was completed to confirm diagnosis, assess for missing data, and document referral source (coded as either "caregiver" or "professional"). Cognitive functioning was measured using one of the Wechsler Scales (i.e., WPPSI-IV, WISC-IV, or WAIS-IV). Participants with both Verbal and Performance IQ < 70 were excluded (FSIQ: *M*=88.5, *SD*=16.0). Information on externalizing, internalizing, and adaptive behaviors was obtained using composite scores on the Behavior Assessment Scale for Children (BASC-2) and Adaptive Behavior Assessment System (ABAS-2).
Results: Referral groups were defined as those referred by professionals (63%) or caregivers (29%). There were no significant differences in behavioral symptoms or intelligence scores between referral groups. However, children referred by caregivers had significantly better adaptive scores (ABAS-2, General Adaptive Composite: *M*=76.8, *SD*=16.5) than those referred by professionals [(*M*=73.9, *SD*=16.3), *t*(742)=2.3, *p*=.03]. Results show a significant difference in both the number of diagnoses (single versus comorbid) based on referral source (X^2 (1, *N*=773) = 10.4, *p*<.01), as well as the type of diagnosis (autism versus ADHD) (X^2 (1, *N*=698) = 11.4, *p*<.01), with professionals being more likely to refer children with comorbidities and ADHD. Professionals were also more likely to refer children with public insurance than private insurance (X^2 (1, *N*=771) = 8.0, *p*=.02).
Conclusions: Overall, professionals were more likely to refer children for (neuro)psychological evaluation than their caregiver. Those children referred by professionals were somewhat more involved, having lower adaptive functioning, increased diagnostic comorbidities, and lower SES. Additionally, professionals were more likely to refer children with ADHD than their caregivers, while parents and professionals were equally likely to refer children with ASD. While, there is not a predominant difference in clinical presentation that is associated with referral source, professionals should be aware that families of lower SES may not be effectively recognizing or voicing their child's needs. Further, parents of children with ASD may be in a better position to recognize more subtle symptoms of ASD that do not present in brief office visits. Future investigation into effects of age and type of referring professional (e.g., medical provider vs. school personnel) is suggested.

196 **125.196** First Steps: Parent Education to Support Family Empowerment

J. Mancini*, Seattle Children's Autism Center, Seattle, WA*

Background:
Receiving the news that your child has been diagnosed with autism spectrum disorder (ASD) can be a devastating moment for many families. Immediately after the diagnosis, a common model of care is to conduct a feedback session to provide information related to autism, recommendations related to therapies and school services, and a list of resources. Families do not process that information well and often, families do not receive adequate follow-up care. To help fill this void of information following a diagnosis, a model to provide parent education (entitled First Steps) has been developed at our center that includes small group psycho-educational classes designed to provide relevant information. First Steps is an important component of our service delivery model which includes step one: the diagnostic evaluation, step two: First Steps Parent Education, and step three: routine follow-up care with medical providers.
Objectives:
The objective of this poster is to present a model of parent education and support that has been developed to provide information to professionals at other centers serving children with ASD. Specifically, details related to a three-part psychoeducational class will be provided including information related to content, structure, cost, support, and objectives for parent learning. Data collected via completion of pre- and post-class questionnaires by participants will be presented to provide information related to changes regarding feelings of parental stress and family empowerment. Information will also be provided regarding adapting the curriculum for non-Native English speakers and multi-cultural families and video-teleconferencing to increase participation for distant families.
Methods:
Two measures, the Parenting Stress Index/Short Form (PSI/SF) and the Family Empowerment Scale (FES) were completed by a subset of class participants pre- and post-participation to provide information related to possible changes in these areas. The independent variable is participation in the psycho-educational class. The dependent variables are, 1) Scores on the PSI/SF, and 2) Scores on the FES. Paired samples t-tests were used to analyze changes in these dependent variables.
Results:
Findings indicate that parents experienced increased feelings of empowerment following participation in the psycho-educational class. Results indicate statistically significant improvement as measured by the FES ($p < .01$). Results did not indicate statistically significant change as a group as measured by the PSI/SF ($p > .05$) though results of some questionnaires completed post-participation indicated a decrease in stress in some families.
Conclusions:
The follow-up care for families receiving the news that their child has ASD is often insufficient. Participation in a series of classes designed to provide information and support has been developed and will be presented here as a model for other centers serving individuals with ASD. Results indicate that changes can occur in a parent's feelings of empowerment following participation in the classes, which can lead to positive outcomes. Parent education can be an important component to service delivery to support families who have children with ASD.

197 **125.197** Foster Care Placement Among Medicaid-Insured Children with Autism

Z. Cidav[1]*, M. Xie*[1] *and D. S. Mandell*[2]*, (1)University of Pennsylvania, Philadelphia, PA, (2)University of Pennsylvania School of Medicine, Philadelphia, PA*

Background: Existing literature suggests that children with disabilities are at increased risk for child maltreatment and subsequent involvement with child welfare. Little is known, however, about how entry into foster care differs for children with autism spectrum disorder (ASD) compared with children with other disabilities and children without disabilities.
Objectives: to estimate the risk of foster care placement among children with autism ages 2 to 18 years and compare it with the risk for children with intellectual disabilities (ID) and children without either diagnosis.
Methods:
We used National Medicaid claims data from 2001 through 2007. The sample included 117310 children who had been diagnosed with ASD (ICD code 299.xx) during the study period, 192378 children who had been diagnosed with intellectual disability (ICD codes 317.xx – 319.xx), 31487 children who had been diagnosed with both, and a sample of 336549 children who had been diagnosed with neither, matched to the rest of sample on state of residence. A washout period of 12 months was used to ensure that children in the sample had no previous foster care placement. The dependent variable, entry into foster care, was defined as three continuous months in which the reason for Medicaid eligibility was specified as "foster care."
We compared the unadjusted risk of entering foster care for each of the four groups. Discrete time logistic regression analysis was used to estimate the adjusted associations between diagnostic group and risk of foster care entry, controlling for age, sex, race/ethnicity, other diagnoses and healthcare service use. In secondary analyses, we examined specific patterns of healthcare service use that were associated with foster care placement among children with autism.
Results: Analyses are ongoing. Preliminary results suggest that 3.5% of children diagnosed with ASD entered foster care during the study period, compared with 1.6% of other children. Among children with ASD, those who experienced a psychiatric hospitalization or were on multiple psychotropic medications were more likely to end up in foster care. Those whose families received respite care were less likely to end up in foster care.
Conclusions:
Children with ASD are at twice the risk of entering foster care than other children. Hospitalizations especially may be an important warning sign of a family in crisis, and the need to provide additional supports. The results of this study beg the question of why children with ASD are entering foster care, and what treatments, family supports and policies could be put in place to prevent it.

198 **125.198** Gender Disparities in the Allocation of Special Education Services

M. Dean[1], *J. Williams*[2], *R. Harwood*[3] *and C. Kasari*[4], *(1)California State University, Channel Islands, Camarillo, CA, (2)Semel Research Institute, UCLA, Los Angeles,, CA, (3)Maternal and Child Health, Health Resources and Services Administration, Rockville, MD, (4)University of California Los Angeles, Los Angeles, CA*

Background:
Research suggests that our difficulties identifying and diagnosing girls with ASD without cognitive impairment (Girelli et al, 2010; Shadduck et al., 2009) may be due to a male bias in our perception of ASD. Girls are described as being better able than boys to "camouflage" their symptoms of ASD (Dworzynski et al., 2012), and yet, The Liability Threshold Model suggests that the less frequently affected gender will be more severely impacted (Tsai, Stewart, & August, 1981). Both perceptions highlight a gap in our ability to recognize ASD in girls. While practitioners look for severe presentations of ASD symptoms, girls with milder forms of ASD mask their challenges. Consequently, girls with ASD are at risk for under identification, and a lack of access to services. Research is needed to examine possible gender discrepancies in the allocation of special education services at school.
Objectives:
The purpose of this study is to examine gender-related disparities in the provision of special education services for students with ASD. If girls receiving special education services have severe symptoms of ASD, then gender differences will be evident in the number of related services listed in the Individual Education Plans (IEP) of children with ASD who are primarily educated in the general education setting.
Methods:
We examined the related services listed in the IEPs of children with ASD (n=3,966) in a large urban school district. Related services refer to additional supports needed for students with disabilities to benefit from special education. There were a total of 34 categories. Categories were coded as "resource", or "non-resource". "Resource" is only available for children with disabilities who are educated in the general education setting. Students qualifying for "resource", require additional academic (language arts or math), or other (social skills, prevocational education etc.) supports in order to benefit from their placement. "Non-resource" services are available to all children with disabilities, regardless of placement. There were a total of 31 non-resource services, including speech and language therapy, occupational therapy, adapted physical education, physical therapy, or behavior intervention.
This study examined IEP data from children with ASD who received resource services, and were therefore educated in the general education setting (pre-k=75, elementary=2064, secondary=1827). We combined the types of services ("resource'; "non-resource") to calculate the total number of related-services a child received in one school year. We used ordinal logistic regression to examine the effect of school category (pre-k, elementary, secondary) on gender and related services, and gender on related services.
Results:
Gender differences were evident; boys received significantly fewer related services than girls ($p < 0.02$). School category was not significant, and there was no interaction of school category and gender.
Conclusions:
These findings suggest that when girls are identified, their presentation of ASD symptomatology is severe. More research is needed to determine if the under-representation of girls with ASD without cognitive impairment is due to girls masking their symptoms, and due to staff bias in finding only girls with more significant issues.

199 **125.199** Impact of the New DSM-5 Criteria for ASD on the Number of Children Receiving Autism Specific Funding: An Analysis of Change in Incidence over Time

C. A. Bent[1], *J. Barbaro*[2] *and C. Dissanayake*[3], *(1)La Trobe University, Melbourne, VIC, Australia, (2)La Trobe University, Melbourne, Victoria, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Changes made to the autism diagnostic criteria over time reflect our changing understanding of these conditions, as informed by research and clinical practice. The most recent iteration of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) was released in May 2013, amid much controversy. Foremost was the concern that a subgroup of individuals who previously met DSM-IV criteria for a Pervasive Developmental Disorder (PDD) may no longer meet the DSM-5 criteria for Autism Spectrum Disorder (ASD). This outcome could potentially have implications for ongoing service provision and funding eligibility. While previous research has provided important insights into the potential impact of the DSM-5 on prevalence estimates and the sensitivity of the revised diagnostic criteria, no studies have yet examined the population-level impact of the DSM-5 on the number of children receiving diagnoses in the community, and accessing autism support services.
Objectives: This study aimed to examine: (1) change over time in the estimated annual incidence of children diagnosed with ASD and registered to receive autism specific funding, and (2) trends in the number of diagnoses across PDD diagnostic groups, prior to and following the introduction of the DSM-5.
Methods: De-identified data for 32,199 children aged under 7 years who were registered with the Helping Children with Autism Package (HCWA) in Australia from January 2010 to June 2015 was utilised. Eligibility criteria for HCWA requires diagnoses to be consistent with the DSM-IV or DSM-5 and confirmed by a Paediatrician, Psychiatrist or a multidisciplinary team. The annual incidence of children diagnosed with ASD and registered with HCWA was calculated by dividing the total number of children registered each year, by the estimated population of children the same age.
Results: The estimated annual incidence of children diagnosed with ASD and registered to receive autism specific funding increased from 20 per 10,000 in 2010 to 34.2 per 10,000 in 2013. Following the introduction of the DSM-5 in 2013, the estimated annual incidence of ASD plateaued, with no significant difference in incidence evident from 2013 to 2015 (see Figure 1). Final results will also include an Interrupted Time Series Analysis to determine if this reflects a significant deviation from the overall trend of increasing diagnoses over time. A significant reduction in the proportion of Asperger's Disorder and PDD-Not Otherwise Specified was observed from 2013, in line with the removal of these subtypes from the DSM-5.
Conclusions: Diagnostic criteria comprise an important element of the service environment that influences clinical behaviour and ensuing diagnoses of ASD in the community. The findings suggest that the more stringent DSM-5 criteria may curb the trend of increasing diagnoses over time. However, further monitoring is required to assess the ongoing influence of the changes on diagnostic practice. Implications regarding access and availability of funding and support services will be discussed.

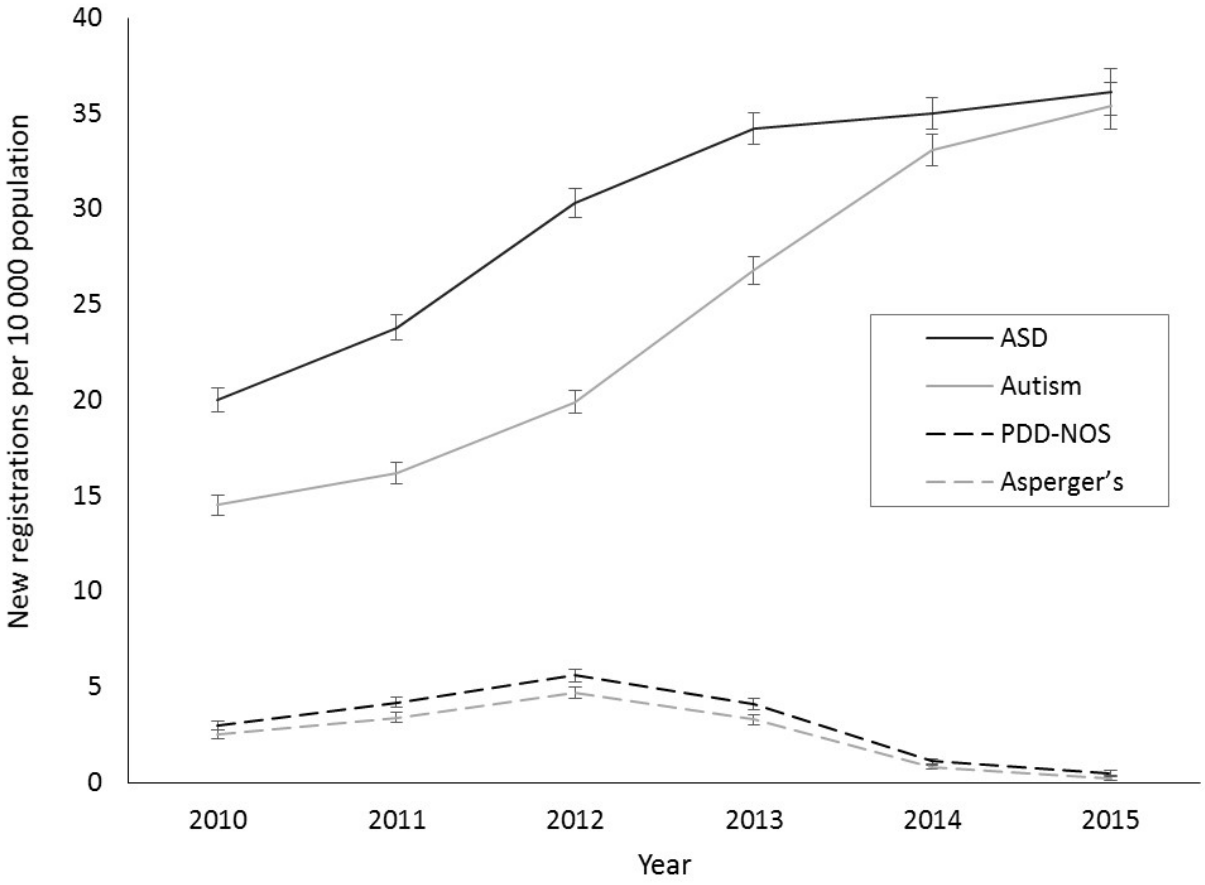

Figure 1. Change in the estimated annual incidence of Autism Spectrum Disorder diagnoses of children registered with the Helping Children with Autism Package in Australia from 2010 to 2015. Error bars represent 95% confidence intervals.

200 **125.200** Leisure Activity Enjoyment Among Children with ASD

C. L. Hilton[1], *D. M. Collins*[2] *and M. Eversole*[2], *(1)University of Texas Medical Branch, Galveston, TX, (2)Occupational Therapy, University of Texas Medical Branch, Galveston, TX*

Background:
Activity enjoyment is a fundamental component of participation in activities. The use of child-preferred activities has long been used to promote social participation among children with ASD (Koegel, Dyer & Bell, 1987; Taylor & Fisher, 2010).
Objectives:
Research questions addressed were:
What are the patterns of leisure activity enjoyment for children with autism spectrum disorders (ASD) compared to those of typically developing (TD) children?
How do patterns of leisure activity enjoyment compare across age groups between TD children and those with ASD?
What is the relationship between severity and leisure activity enjoyment in children with ASD?
Methods:
We used a case-control comparison research design to compare activity enjoyment between children with ASD and TD children. Participants consisted of 131 children (ASD = 67, TD = 64) between the ages 6 and 13 years recruited through parent and professional contacts known by the principal investigator and through parent support group meetings, group e-mail lists, newsletters for parents of children with ASD, and flyers about the study posted at sites of service providers for children with ASD. This study used the *Children's Assessment of Participation and Enjoyment* (King et al., 2004), a child interview, to compare levels of leisure activity enjoyment. The *Social Responsiveness Scale, 2nd Edition* (SRS-2; Constantino & Gruber, 2012), a parent questionnaire, is a quantitative measure of traits associated with autism, and was used to quantify autism severity.
A within-group comparison of activity enjoyment for children with ASD was completed using descriptive statistics to rank sum activity enjoyment for each of the 55 specific activities. A Pearson product moment correlation coefficient (Portney & Watkins, 2009) was used to identify enjoyment of any of the activity categories that were correlated with SRS-2 scores for the children with ASD. Differences in activity enjoyment were compared by age group using an ANOVA to compare age groups in the TD children and those with ASD.
Results:
The TD children enjoyed *formal activities* and *physical activities* significantly more than the children with ASD. Symptom severity was negatively related to enjoyment of *overall activities, formal activities, physical* and *social activities* in children with ASD. Older children with ASD enjoyed *overall, informal, recreational*, and *self-improvement* activities significantly less than younger children, but no differences were seen across age groups in TD children. Most notable among specific activities was that children with ASD enjoyed *swimming* significantly more than the TD children.
Conclusions:
Having a better understanding of preferred activities among children with ASD can help to better prepare professionals regarding potential motivators for participation in interventions and in less preferred activities. Using child preferred activities has been shown to be a valuable motivator for many activities that are less participated in and less preferred among children with ASD.

201 **125.201** Linking Clinic and Hospital Data with Patients and Families

ABSTRACT WITHDRAWN

Background: Patient powered research presents unique opportunities to blend patient-derived data with clinic and hospital data. States are currently developing health information exchanges that can link with such data to provide range of measurable health outcomes.
Objectives: Linkage of patient and clinical data for broad measurement of health outcome.
Methods: Current models of linkage of patient-report and clinical data will be reviewed, including active projects in the states, including Michigan.
Results: NA
Conclusions: Trusted health information exchange, as being developed in PCORnet, will provide new research opportunites for the health community, including autism

researchers.

202 **125.202** Meeting the Needs of Families Affected By Autism Spectrum Disorder through Delivery of a Best-Practice Model of Care Coordination

R. McNally Keehn[1], *R. Rodgers*[2] *and J. W. McAllister*[3], *(1)Pediatrics, Indiana University School of Medicine, Indianapolis, IN, (2)Pediatrics, Indiana School of Medicine, Indianapolis, IN, (3)Children's Health Services Research, Indiana University School of Medicine, Indianapolis, IN*

Background: Families of children with autism spectrum disorder (ASD) report significant problems accessing health care and support services. The care needs of children with neurodevelopmental disabilities are straining the capacity of the healthcare service system. Programs that offer accessible, evidence based care coordination services are critical for improving child, family, and system outcomes. Pediatric care coordination is defined as a patient and family-centered, assessment driven, continuous, team-based activity designed to meet the bio-psychosocial needs of children and youth, while enhancing person and family care-giving skills and capabilities.
Objectives: The objectives of this study are twofold: 1) to **c**haracterize the unmet needs of children with ASD and 2) to determine whether a best-practice model of care coordination can assist families and clinicians in addressing these needs.
Methods: This study was completed as a part of a broader ongoing pilot study which employs an implementation science approach to evaluate the effectiveness of a best practice model of care coordination with children with neurodevelopmental disabilities and their families. A service model of care coordination, as put forth by McAllister (2014), was delivered to a subset of 60 children ages 2-8 years (mean age: 5.1 years; 85% male) diagnosed with ASD and their families. The care coordination intervention is delivered by a dyad consisting of a clinician and care coordinator in a children's hospital outpatient setting. Prior to and during a planned care visit, a Shared Plan of Care (SPOC) is jointly completed with the family. The SPOC includes a comprehensive medical summary and a set of negotiated actions (i.e., goals and strategies to address unmet needs and enhance family advocacy skills) generated together between the family and team. Following the planned care visit, these unmet needs are addressed during a three-month period of care coordination.
Results: Categories of reported unmet needs among families include: developing an understanding of the child's diagnosis and developmental level, referrals for subspecialists to address co-morbid medical needs, navigating/advocacy related to special education, enrollment in behavioral and rehab services, increased communication with primary care/community care network, and accessing needed health care financing resources (mean total unmet needs = 7.6). Of the families who have completed the care coordination intervention to date, 74% of unmet needs have been addressed (i.e., goals completed or in progress) by the end of the three month period. Data collection is ongoing; data will be presented on relative frequencies of unmet needs across categories as well as whether categorical differences exist with regard to types of needs met though the care coordination intervention.
Conclusions: Unmet needs of families of children with ASD are reported across medical, psychosocial, educational, community, and financial domains. This best-practice model of care coordination provides a promising approach to family-centered service delivery to address the critical unmet needs of children with ASD and their families. Addressing these unmet needs holds the potential to improve child outcomes, reduce family burden, and lower system costs over the child's life course.

203 **125.203** Methods for Quantifying Medical and Financial Benefits of Acute Behavioral Response during Inpatient Hospitalizations for Children with ASD

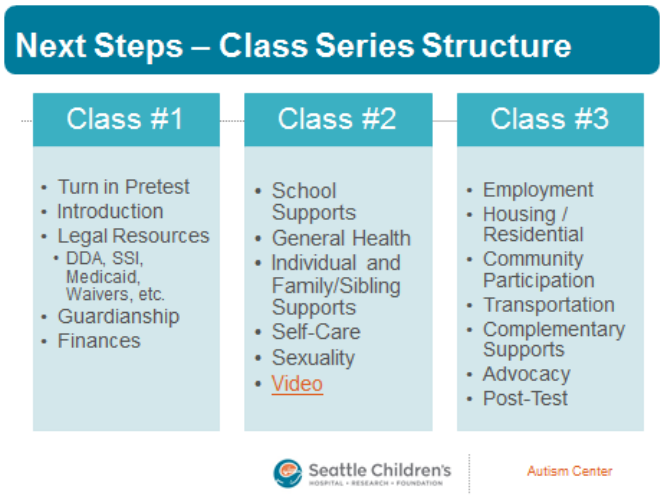
S. Marler[1], *J. E. Staubitz*[2], *P. Juarez*[3], *Z. Warren*[1], *L. L. Altstein*[4], *E. A. Macklin*[5] *and K. Sanders*[6], *(1)Vanderbilt University, Nashville, TN, (2)Pediatrics, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Massachusetts General Hospital Biostatistics Center, Boston, MA, (5)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (6)Vanderbilt, Nashville, TN*

Background: With an estimated prevalence of 1 in 68 (CDC, 2014), the inpatient care of children with Autism Spectrum Disorder (ASD) represents a critical public health issue. Although there have been advances in awareness and treatment of ASD in medical settings, children with ASD still have higher rates of acute healthcare utilization, an increased burden of unmet needs, and decreased satisfaction with care received (Lajonchere et al., 2012; Croen et al., 2006; Siegal et al., 2014). These patients frequently present with more severe behaviors (i.e. aggression, self-injury, etc.) than children without ASD and due to this, often remain hospitalized beyond medical clearance. While hospitalized, these children typically require increased levels of staffing and intensive interventions (e.g. physical/chemical restraint).
Hospitalization beyond medical clearance holds a negative financial return for hospitals. The cost of hospitalizing this population is much higher due to prolonged stay and increased staffing, with many charges remaining unreimbursed. There has been little study of inpatient care or interventions designed to improve hospitalizations in ASD. Innovative programs to reduce problematic behaviors of children with ASD in inpatient settings have the potential to improve outcomes on both child and system. While methods for quantifying change on the behavioral level are widely available, the availability of relevant financial data is far less common.
Objectives: As part of a larger study investigating the effect of brief Analogue Functional Analysis (AFA) on hospitalization for children with ASD, we studied the ability to draw relevant financial data from existing electronic medical records (EMR) to quantify care and potential cost of hospitalization.
Methods: This single site, pilot study involved a sample of 36 children with ASD and aggressive behaviors, ages 6-18, admitted to either a medical or psychiatric inpatient unit. Participants were randomized into a treatment group (receiving brief AFA and behavioral intervention) or a control group. We evaluated which primary data on medical, treatment, and financial factors were available from the EMR and administrative financial data to better understand additional methods/metrics necessary for quantifying impact of intervention.
Results: There were several relevant cost-related variables available via EMR. We were able to quantify length/total cost of hospitalization, use of physical/chemical restraint, and staffing ratios for all patients. However, it was not possible to extract reliable data with the EMR indexing the amount of time spent by ABA interventionists while implementing intervention. To assess this resource/cost we required specific datalogs from behavioral providers. Other challenges replicated known findings in previous work (e.g., quantifying "human" costs, staff costs; separating costs of behavior challenges from medical need). We were able to quantify re-hospitalization for all patients within our facility; however, determining the medical vs. behavioral necessity of hospitalization was not feasible.
Conclusions: It is becoming increasingly apparent that bolstering behavioral services for children with ASD in hospital settings will require demonstrating both clinical and cost efficacy. This pilot work documented that (1) novel metrics/methods are needed to ensure resources around behavioral interventions are captured and (2) separating medical and behavioral expenditures within financial data also require innovative methods.

204 **125.204** Next Steps – Improving Transition Outcomes through Caregiver Education

D. M. Eaton[1], *R. Oti*[1], *G. Stobbe*[1], *K. Davis*[1] *and A. Owens*[2], *(1)Seattle Children's Hospital, Seattle, WA, (2)University of Washington, Seattle, WA*

Background: Within the next 15 years, an estimated 500,000 children in the United States with autism spectrum disorder (ASD) will enter adulthood. Additionally, there has been limited research into adult services and outcomes. As a result, a challenge faces clinicians in providing families with evidenced-based transition tools in a manner that allows caregivers to build resiliency in becoming creative and flexible consumers for their young adult children. We have developed and implemented three consecutive 90 minute classes entitled "Next Steps," focused on educating caregivers about transition related topics in small group settings. The lecture material is tailored to two distinct trajectories: 1) "Steps To Independence" for caregivers of those likely to pursue post-secondary education, and 2) "Life Long Learning" for caregivers of those who will access programs through age 21 and require life-long supports.
Objectives: To assess caregiver satisfaction with the curriculum of the Next Steps classes. To measure caregiver concerns pre- and post-class participation.
Methods: Course evaluations were collected at the end of the third class regarding participant satisfaction related to class design and curriculum content. A survey questionnaire called *Transitions Daily Rewards and Worries Questionnaire* (Glidden & Jobe, 2007) was also used, which rates 28 statements such as "I am excited by the prospects for my child's future," on a Likert scale of 1 to 5 (Strongly Disagree to Strongly Agree). This was mailed at the time of scheduling and collected before the first class began. The questionnaire was re-administered after completing the third class.
Results: Course evaluation and quantitative pre- and post-questionnaire data collection is ongoing. Currently we have 25 participant course evaluations (N = 25). The average rating for the question "How would you rate the overall quality of content presented?" was a 4.72 out of 5 (3 = "good", 4 = "very good" and 5 = "excellent") with 19 participants (76%) indicating "excellent," 5 (20%) indicating "very good," and 1 (4%) indicating "good." To open-ended questions such as "Were the topics covered relevant? Meaningful? Did you learn something new?" 92% of participants indicated "yes" or an equivalent comment (e.g. "Topics were relevant, meaningful, helpful, resourceful," and "I learned a lot, thanks!"). Themes of responses have included "increase in hope for my child" and "I learned from other parents and the instructor." For the *Transitions Daily Rewards and Worries Questionnaire*, currently we have 18 participants (N=18) who completed both the pre- and post-test. There was limited change pre-test to post-test among respondents and any change present was bi-directional.
Conclusions: Transition to adulthood for ASD individuals poses unique challenges to caregivers. Administering transition-related curriculum in small group settings is not only feasible but is well received by participants. Differentiating the curriculum based on trajectories is necessary in order to tailor the course material appropriately. Feedback from caregivers has been overwhelmingly positive. Future direction includes improving our understanding of long-term impact of course participation and broadening delivery of the Next Steps course to additional demographics.



205 **125.205** Oral Health Care and Challenges Facing Dentists and Families of Children with Autism Spectrum Disorder (ASD) in Dental Clinics in the Kingdom of Saudi Arabia (KSA)

H. M. Al Dhalaan[1], *K. A. Alhammad*[2], *M. S. Zakaria*[3] *and H. A. Masadomi*[4], *(1)King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, (2)Riyadh college of dentistry and pharmacy, Riyadh, Saudi Arabia, (3)centre for autism research, riyadh, Saudi Arabia, (4)Research Centre, Riyadh college of dentistry and pharmacy, Riyadh, Saudi Arabia*

Background:
Autism is a developmental disorder characterized by deficits in social interaction and communication skill.
ASD families are facing difficulties maintaining good oral health and dental care. Delivering Dental care to this population is also a challenge to the dentist. In this study we try to explore some of these challenges.
Objectives: The study aimed to identify the following
1. Challenges facing dentists during dental evaluation and procedures for ASD patients
2. Challenges facing families of ASD patients in finding suitable dental clinics
3. Explore the level of dentist knowledge about ASD
Methods:
A cross-sectional study. A self-administrated survey & questionnaires distributed in different regions of KSA. Targeting: ASD Families (17 questions) and Dentist. (26 questions).
Professional https://www.surveymonkey.com/r/S79X9LM
Family's https://www.surveymonkey.com/r/Y93FJPN
The questionnaires were formulated in Arabic and English languages and distributed. Up to date, 80 dentists and 97 families completed the survey
Results:
> 85 % of dentist respondents were from the Central and Eastern regions. Most of the participating dentists were general practitioners while 1/3 were specialists and consultants. While 72% of ASD Families respondents are living in the central region.
> 65% of the dentists had no or minimal knowledge about ASD and more than 80% of the dentists never participated in ASD continuing education courses. 25% of the dentists had behavior control protocols for ADS patients in their clinics.
86% of ASD families had difficulties finding suitable dental clinics. 65% of the ASD children visited dentists only for pain management. 41% of ASD children were denied treatment in the dental clinics. 97.5 % of dentist reported that they did not or rarely treat ASD patient. <3% of dentist regard them self as expert in handling and treating ASD patient .55% of ASD patients visited private dental clinics. 77% stated that no health insurance for dental care.
>50% of dentist used General anesthesia and comprehensive treatment plans modality to treat ASD patients.
81% of dentists reported that the hand piece and the syringe with needle, as tools are most common trigger for behavioral difficulties. 93% of the dentists believed that "sound" was the most common trigger of adverse reaction in ASD patients while 75% believed that it was "touch" as a sensory stimulation.
Results also showed the most common oral conditions were bruxism and attrition and the most common oral finding was dental caries with high prevalence of gingivitis.
Conclusions: sample size is small and the study still on going, preliminary results indicate the dental care for ASD population is poor with lack of dentist experience.
Oral health instructions should be given to ASD patients and their families. Dental management of ASD should be included in dental undergraduate education in KSA. There is a need for a "standard protocol" in the management of ASD patients in dental clinics in KSA
A specialized dental clinic must be developed to improve the dental treatment experience for ASD children.

206 **125.206** Parents' Beliefs about Autism: A Link to Intervention Services in English and Spanish Language Proficient Families

N. M. Reyes[1], *O. J. Lindly*[2], *A. E. Chavez*[3], *K. Macias*[4], *A. Folan*[5], *K. Smith*[6], *A. M. Reynolds*[5] *and K. Zuckerman*[7], *(1)Box C-234, University of Colorado - Denver, Aurora, CO, (2)Oregon State University, Portland, OR, (3)Oregon Health and Science University, Portland, OR, (4)UCEDD Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA, (5)University of Colorado - Denver, Aurora, CO, (6)Children's Hospital Los Angeles, Pasadena, CA, (7)Oregon Health & Science University, Portland, OR*

Background: Previous research suggests that there are language disparities in service utilization among families of children with Autism Spectrum Disorder (ASD). Specifically, children in Limited English Proficient (LEP) families tend to use fewer intervention services than children from English Proficient (EP) families. In an effort to understand what might explain these differences, this study examined parents' beliefs about ASD and treatment use in both Spanish-speaking LEP families compared to EP families.
Objectives: This study had three aims: (1) to investigate differences in beliefs about ASD between families with limited English proficiency (LEP) and families with English proficiency (EP), (2) to examine links between these beliefs and treatment use, and (3) to investigate the predictive value of these beliefs on treatment use
Methods: This study included a probability sample of 262 mothers and their children with ASD, 168 with English Proficiency (EP), and 94 with limited English proficiency (LEP) from Oregon, California, and Colorado. One parent per family completed a telephone or self-administered survey in English or Spanish. Parents were asked questions about their beliefs about their child's ASD, including ASD severity, ASD as a lifelong condition, consequences of ASD on their child's life, whether ASD was a mystery to them, whether they had the power to change their child's ASD, and whether challenges related to ASD can be decreased with treatment. Parents also reported the number of hours of ASD-related intervention per week their child received, categorized as: none, <1 hour, 1-4 hours, 5-10 hours, 11-20 hours, and 20 hours or more.
Results: Regarding the beliefs about ASD, mothers with LEP reported more often than mothers with EP that ASD was a mystery to them. In the EP group, number hours of intervention were significantly associated with mothers' beliefs about the child's ASD severity, ASD consequences on the child, and whether ASD is a mystery. In the LEP group, number of hours of intervention were linked to ASD severity and the power to change their child's ASD. Finally, in a multivariate model assessing the association between beliefs and number of hours of intervention, the belief that ASD has consequences on a child's life predicted greater treatment hours in the EP group but not on the LEP group.
Conclusions: These analyses showed that LEP and EP families differed in their beliefs about ASD; however, maternal beliefs were more strongly associated with variation in treatment hours among families with EP. It is possible that factors, such as access to health and educational therapy services, may more strongly predict treatment hours in families with LEP. Overall, findings suggest that providers should take parent beliefs into account when caring for children with ASD from diverse backgrounds, since these beliefs may be associated with treatment use.

207 **125.207** Pathways to Early Autism Diagnosis and Intervention

M. Martinez[1], *K. Thomas*[2], *R. Christian*[3], *R. Edmondson Pretzel*[4] *and S. R. Hooper*[5], *(1)Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Cecil G. Sheps Center for Health Services Research, Chapel Hill, NC, (3)Carolina Institute for Developmental Disabilities, Chapel Hill, NC, (4)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Allied Health*

Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background:
Families of children with an ASD have more difficulty accessing and using services compared to families with children with other mental health care needs (Vohra, Madhavan, Sambamoorthi & St. Peter, 2014). The Autism CARES Act of 2014 introduced legislation to reduce barriers to screening, diagnosis and treatment however little is known about pathways that lead to earlier diagnosis and intervention. The Anderson model of health care utilization (Aday & Anderson, 1975) provides a framework to organize and examine factors associated with earlier access to autism services.
Objectives:
The purpose of this study is to identify pathways associated with early screening, assessment and intervention that can be utilized to develop a system of service that provides early intervention for autism spectrum disorders (ASD) and other developmental disabilities in order to facilitate children's ability to reach their maximum potential. The target audience includes researchers, stakeholders and policy makers.
Methods:
Data from the 2014-2015 North Carolina Needs of Young Children with Autism Survey are presented that represent over 450 families with a child diagnosed with an ASD. Descriptive statistics and logit modeling analyzed de-identified demographic, diagnostic and service use information using the Anderson health care utilization framework. Pathways to early intervention as well as models predicting early parent recognition of concerns, who first recognized concerns, time to diagnosis, and early intervention are presented.
Results:
Early parent recognition is associated with parents sharing concerns with more providers prior to a child's initial ASD diagnosis ($p < .005$), ASD presentations with lower levels of functioning ($p < .005$), parents (vs. providers) first recognizing a concern ($p < .005$), and type of providers conducting initial autism assessment ($p < .05$). Who first recognized developmental concerns was associated with parent completion of an autism screener at their doctor's office ($p < .01$) and minority child race/ethnicity ($p <.05$). Early diagnosis was associated with ASD presentations with lower functioning ($p < .001$), type of provider ($p < .05$) conducting ASD assessment, and autism screening ($p < .05$). Early intervention was associated with ASD presentations with lower functioning ($p < .05$) and type of providers conducting initial autism assessment ($p < .05$).
Conclusions:
Parents who recognized concerns early were more likely to enter a pathway to earlier child diagnosis and intervention, particularly in cases of prompt initial diagnosis. This appears to be associated with type of provider conducting initial autism assessment and severity of child functioning, reflecting quicker pathway entry for families who are swiftly connected with specialists as well as autism presentations with greater functional impairment that may be easier to identify. When providers initially recognized developmental concerns, families were more likely to enter a pathway to quicker diagnosis and earlier intervention.
It is important for policy makers to support and increase autism awareness among parents and providers, routine autism screening and follow-up, strategies to improve provider recognition for minority and higher functioning children, and availability of specialists trained to conduct early diagnostic assessments

208 **125.208** Pcornet- Creating a National Network of Patient-Powered Research Networks

***S. F. Terry**, Genetic Alliance, Washington, DC*

Background: The Patient-Centered Outcome Research Institute has developed a national clinical research network comprised of Patient Powered Research Networks and Clinical Data Research Networks, known as PCORnet. This network strives to conduct patient centered research that focuses on priorities most critical to individuals, families and communities. It creates opportunities for collaborative research on health conditions, connecting researchers and participants for research tied to the unique interests of those affected.
Objectives: Creation of a new and unique model of national clinical research aimed at addressing the needs and concerns of those affected by medical conditions.
Methods: PCORnet's structure and organization will be reviewed. Current and future planned initiatives will be discussed.
Results: NA
Conclusions: PCORnet creates a new national clinical research model to address the needs and interests of participants, clinicians, and researchers for rapid, large population investigation of criticial health conditions and concerns.

209 **125.209** People with Autism Spectrum Disorder in Criminal Justice and Mental Health Systems: Improving Recognition and Developing Preliminary Guidelines

***C. M. Murphy**[1], G. M. McAlonan[2], J. Harvey[3], E. L. Woodhouse[4], D. M. Robertson[5], S. Whitwell[6], A. Carrier[6], A. Forrester[6] and D. G. Murphy[7], (1)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Science, IoPPN, KCL, London, United Kingdom, (3)Department of Forensic and Neurodevelopmental Sciences, IoPPN, KCL, London, United Kingdom, (4)Forensic & Neurodevelopmental Sciences, King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (5)Adult Autism Service/Behavioural Genetics Clinic, Maudsley Hospital, London, United Kingdom, (6)Department of Forensic and Neurodevelopmental Sciience, IoPPN, KCL, London, United Kingdom, (7)Sackler Institute for Translational Neurodevelopment, Department of Forensic and Neurodevelopmental Sciences,, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background: People with autism spectrum disorder (ASD) are vulnerable to social and mental health difficulties that can result in contact with the criminal justice system (CJS) as victims of crime, offenders, or because of misunderstandings in communication and behaviour. Although ASD is common, the number of people with ASD who offend is unknown. However, it is thought likely that ASD is over-represented and under-recognised in the CJS. Moreover, despite increasing ASD awareness, in the UK there is no tailored ASD training for criminal justice mental health service (CJMHS) staff at a local (or national) level. Hence interactions between the CJS and people with ASD may be unnecessarily distressing, unsuccessful and costly.
Objectives: To improve recognition of ASD in South London amongst mental health and CJS teams and, with the ASD community, to draft the first guidelines for support of people with ASD within the CJS. Further, to produce a free-access film regarding ASD and the CJS for widespread dissemination.
Methods: To facilitate joint working, professionals working with people with ASD and in the CJS (including barristers, police, probation, prison and youth offending) were invited to an ASD CJS workshop. The workshop included invited speakers and small group sessions to gather expert opinions for inclusion in the guidelines. Additionally, views of people with ASD with experience of the CJS and their families were gathered via a focus group. The workshop and family focus group were filmed. Finally, training in ASD was provided to local CJMHS staff and their views on ASD and the CJS were compared in pre-and post-training focus groups.
Results: Recommendations and opinions gathered during the workshop and family focus group were included in local guidelines regarding best identification and management of people with ASD in the CJS. The free-access film will also be widely disseminated. Pre- and post training questionnaires completed by CJMHS staff indicated they felt significantly more able to identify people with ASD in the CJS, communicate with people with ASD in the CJS and to safely manage anxiety and agitation in people with ASD in the CJS. Further, CJMHS staff reported significant improvements in their understanding of the comorbid mental health difficulties of some people with ASD that may contribute to behavioural difficulties and misunderstandings in the CJS. They also were better informed on routes to access specialist clinical care and support groups for people with ASD.
Conclusions: Brief training can be effective in raising awareness and safe management of people with ASD in the CJS. This may lead to short-term (development of sustainable, on-line, free training materials) and long-term (reduced costs to the individual, judicial and health systems) cost savings. Guidelines including identification of barriers to awareness and care for people with ASD in the CJS, solutions to overcome barriers and increased awareness of ASD will enable people with ASD who become known to the CJS to be better understood and have their needs met. This, with better direction to appropriate care pathways, may result in significant cost savings to the individual and society.

210 **125.210** Pilot Test of a Model for Remote Provision of Evidence-Based Services for Rural Families of Children with Autism Spectrum Disorder

***K. M. Simcoe**[1], M. Martinez[2], A. Stainbrook[3], P. Juarez[1] and Z. Warren[4], (1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center-Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (3)Vanderbilt Kennedy Center, Nashville, TN, (4)Vanderbilt University, Nashville, TN*

Background:
Early Intensive Behavioral Intervention (EIBI) is recommended as an intervention of choice for young children with Autism Spectrum Disorder (ASD), but services can be challenging for many families to access. Research suggests that Caregivers have the ability to acquire and implement intervention strategies with their children with ASD. Video-teleconferencing can be used to teach Caregivers to use a naturalistic language intervention and remote technology can also be used to train Early Interventionists (EIs) on Caregiver coaching strategies.
Objectives:
The objectives of this pilot study are to evaluate the feasibility and impact of using a remote consultation model to train Caregivers and EIs in non-rural and rural areas on evidence-based strategies.
Methods:
Approximately 90 families will be provided with services following participation in a psychological evaluation for ASD. Families of children under three who are referred by Tennessee Early Intervention System (TEIS) to Vanderbilt Kennedy Center's Treatment and Research Institute for Autism Spectrum Disorders (TRIAD) for a psychological evaluation and are living in any county within the Greater Nashville and South Central districts of Middle TN are eligible. All participating families receive two home-based

evaluation support sessions led by a professional in the field of applied behavior analysis which include focused consultation and training on evidence-based practices for children with ASD.
Families residing in select counties are eligible for expanded services, including two additional home visits. These families are already receiving services from an EI through TEIS. Participation of the EI in these two sessions is required to ensure the training of the EI in evidence based behavior analytic strategies is adequate. During these sessions, the Consultant will work with the Caregiver and EI to implement strategies recommended previously. The service will also include two bi-weekly clinic visits that will include the EI, Caregiver and remote attendance of the TRIAD Consultant. Remote clinic visits are held at a community clinic closer to participants' homes than the TRIAD clinic. During these two visits, the TRIAD Consultant will remotely observe interactions while providing feedback and recommendations in real-time for EI and Caregiver. The EI will continue to serve the family throughout the TRIAD service and consult with the TRIAD Consultant remotely. Following the completion of the service, remote consultation will be provided to the EI for up to two hours per month for six months or until the child turns three years old.
Behavioral and social validity data will be collected on skill acquisition by the child, skill acquisition by Caregivers and EI's, and Caregiver and EI satisfaction with services.
Results:
Preliminary results indicate that Caregivers and EIs are satisfied with the services that they receive. In addition, Caregivers are able to implement interventions to promote skill acquisition. Finally, EIs implement strategies learned with 75-100% of their other clients.
See attached preliminary data for additional information.
Conclusions:
Preliminary data is not complete enough to allow conclusions to be drawn. Data will continue to be collected through April 2016. We anticipate a total of twelve participants in this pilot study by that date.

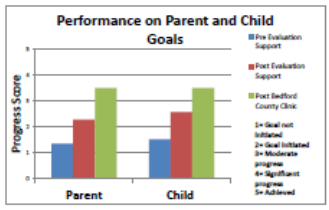


Figure 1 shows pre and post ratings on caregiver and child goals per Evaluation Support (N=6), Post Evaluation Support (N=3), and Post Bedford County Clinic Services (N=1).

Figure 2 provides mean Clinical Global Impression (CGI) ratings by both caregivers (N = 3) and interventionists (N=3) for families receiving Evaluation Support services.

Caregiver Survey	1 (poor) - 4 (excellent)
Caregiver Confidence	3.5
Child Improvement	3.9
Satisfaction with Service	3.2

Figure 3 provides the mean rating on a caregiver survey (N=3) regarding child progress, confidence implementing strategies discussed, and satisfaction with services during Evaluation Support service.

Early Interventionist Survey	1 (strongly disagree)-4 (strongly agree)
Satisfaction with Service	3.5
Effectiveness of recommendations	3.7
Generalization to other families	3.5

Figure 4 provides the mean ratings on a survey sent to EIs (N=2) who completed the Bedford County service with a family.

211 **125.211** Pre-Professional Preparation of Speech-Language Pathologists to Serve Individuals with ASD Across the Lifespan

K. P. Wilson[1], *J. Preis*[2], *G. Chasson*[3], *A. C. Jozkowski*[4] *and C. Shotto*[1], *(1)Department of Audiology, Speech-Language Pathology, and Deaf Studies, Towson University, Towson, MD, (2)Department of Speech-Language-Hearing Sciences, Loyola University Maryland, Baltimore, MD, (3)Department of Psychology, Towson University, Towson, MD, (4)Department of Occuptional Therapy and Occupational Science, Towson University, Towson, MD*

Background: With the rising incidence of autism spectrum disorder (ASD; Baio, 2014) and the aging of the existing population of individuals on the spectrum, there is a pressing need for clinical professionals trained and experienced to work with individuals with ASD across the lifespan. Individuals on the spectrum interact with a variety of professionals and community members throughout their lives. Disconcertingly, studies show that pre-professional students in health care disciplines lack even a basic understanding of diagnostic criteria for ASD (e.g., Freedman, 2014; Price, 2013) and have very little experience with adults on the spectrum, in particular. Despite speech-language pathologists' training in typical and atypical development of language and social communication, research shows a lack of preparation and misconceptions about ASD among practicing professionals in the field.
Objectives: This study aims to (1) describe the preparation levels of graduate speech-language pathology (SLP) master's students across two regional universities, (2) examine the impact of a unique clinical teaching model at one university that includes hands-on experience with adults with ASD, and (3) suggest practices for optimal clinical education in the area of ASD across the lifespan.
Methods: This study utilized a longitudinal design with data collected at multiple time points across students' graduate education (baseline and following each semester). Dependent variables include the following, as self-reported by student participants (n=140) through survey completion: (1) feelings of preparedness related to treating clients with ASD across age ranges and settings, (2) knowledge of characteristics and diagnostic criteria of ASD, (3) additional contact with individuals on the spectrum sought

outside of assigned clinical experiences, and (4) openness/attitudes regarding adult peers on the spectrum. This presentation will focus on the change in student responses across time and following specific clinical experiences to offer implications and suggestions for clinical preparation strategies.
Results: Preliminary results indicate that SLP students lack significant experience with individuals with ASD prior to graduate school, and with adults with ASD in particular. The majority of participants reported more positive perceptions of their prior experience with children with ASD as compared to their experiences with adults with ASD. Analysis of longitudinal data indicates only minimal increase in feelings of preparation to treat clients with ASD over time, with the majority responding that they felt only moderately competent in their clinical preparedness in ASD after both their first and second semesters of graduate school. Gaps in preparedness and knowledge regarding adults with ASD were more marked. Analysis of the impact of a unique hands-on model of clinical education with adults with ASD is ongoing with preliminary results showing trends towards significant impact of the program. Results will be reported and discussed.
Conclusions: With 80% of participating students reporting interest in working with clients with ASD, it is clear that additional ASD experience and education is needed. Initial results elucidate this gap and point to specific areas of need and interest for SLP master's students. Implications and suggestions will be geared towards university educators in clinical fields that serve individuals with ASD across the lifespan.

212 **125.212** Priority Service Receipt of Individuals with ASD Across the Lifespan: Findings from a Canadian National Survey

J. K. Lai[1] *and J. A. Weiss*[2]*, (1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, Canada*

Background: Across the lifespan, individuals with Autism Spectrum Disorder (ASD) have many health, community, and social service needs. These create age group-specific challenges in navigating service sectors. Further, individuals with ASD often have a high level of service need, which are often left unmet, compared to other individuals with disabilities of similar age. Knowing which services are currently considered priorities by caregivers, and identifying correlates and barriers to having those needs met, will shed light on the resource gaps in the care and support of individuals with ASD and inform policies to improve service access.
Objectives: The objective of this study was to identify differences in priority service receipt of individuals with ASD and the clinical, sociodemographic and systemic correlates of obtaining priority services across the lifespan.
Methods: An online survey was administered across Canada through the Canadian Autism Spectrum Disorders Alliance, completed by 3251 caregivers reporting on 3319 family members with ASD. Analysis was done in an age-stratified manner. Current service use was operationalized as any service used in the last 6 months, from a list of 23 community and health services and an "other" category that was recoded as needed. Participants also identified their current top 5 (priority) needs from the same list of services. We calculated the number of priority needs that were currently met as a proportion of priority receipt.
Results: Across the entire sample, 1048 of 3319 individuals (31.6%) had none of their priority needs met and 682 individuals (20.5%) had at least half of their priority needs met. The number of priority receipts decreased across the lifespan ($F(4,3318)=21.7$, $p<.001$); with preschool aged and elementary school age children receiving more priority services (respectively 1.9 ± 1.3 and 1.5 ± 1.3; mean ± SD) compared to adolescents and adults (1.2 ± 1.3). Priority receipt was correlated with various factors. In all age groups, the number of parent-directed service receipts was positively correlated with priority receipts. In preschool children, priority receipt was also related to ability to afford services ($p<.001$). In elementary school children, priority receipt was negatively correlated with child age ($p<.001$), the number of behavioural concerns ($p=.006$) and psychiatric diagnoses ($p=.003$) but positively correlated with the ability to afford services ($p<.001$), less barriers experienced ($p=.002$) and access to government funding ($p<.001$). In contrast, adolescent priority receipt was positively related to child age ($p<.001$), the number of chronic physical health conditions ($p=.025$), the presence of behavioural concerns ($p=.024$) and intellectual disability ($p<.001$), and access to government funding ($p<.001$). For adults, priority receipt was related to the presence of intellectual disability ($p<.001$) and the number of behavioural concerns ($p=.042$).
Conclusions: The results show the alignment of receipt with addressing priority needs in a large sample of individuals with ASD. Future analyses will identify how sociodemographic, clinical need, and systemic factors function together to predict priority service receipt in each age group.

213 **125.213** Right Kids, Right Time, Right Services: Developmental Surveillance in Early Childhood Education Settings

B. Mozolic-Staunton[1]*, J. Barbaro*[2]*, M. Donelly*[1] *and J. Yoxall*[1]*, (1)School of Health and Human Sciences, Southern Cross University, Bilinga, Australia, (2)La Trobe University, Melbourne, Victoria, Australia*

Background: Children who are at risk for autism spectrum disorder (ASD) would benefit from early identification and access to early intervention, as this takes advantage of children's early brain plasticity and improves outcomes for families and children. ASD can be reliably detected in children as young as 18 months of age, although developmental surveillance practices are inconsistent in community health settings and many developmentally vulnerable children are not identified until late preschool or school age. Childcare settings present an ideal yet underutilized opportunity for ongoing developmental surveillance and appropriate, timely referral of young children to allied health supports.
Objectives: This study aims to *implement* and *evaluate* a system for identifying young children who have early signs of Autism Spectrum Disorder (ASD) and other developmental challenges in early childhood education and care centers in regional Australia. Using the Social Attention and Communication Surveillance (SACS; Barbaro & Dissanayake, 2010), a highly reliable developmental monitoring system which has recently been developed and validated with maternal child health nurses in Australia, this study aims to improve the health and wellbeing of children who are showing early signs of ASD by increasing the capacity of those professionals working closely with young children and families on a daily basis to accurately and efficiently identify which children would most benefit from specialized early intervention services.
Methods: Early childhood educators were trained and supported to completed developmental surveillance using SACS-R in their centres every 6 months over an 18 month period. Any child identified as being at risk for developmental challenges received comprehensive developmental assessment including Autism Diagnostic Observation Schedule (ADOS-2). Specificity, sensitivity, positive and negative predictive values of SACS-R and common parent report measures was determined using regression and receiver operating characteristic (ROC) curve analysis. Qualitative survey and interview data collected from participating educators and families provides information related to the perspective of educators on their role in the process of developmental surveillance and a deeper understanding of the nature of any barriers preventing families from accessing evidence-based early intervention supports in a timely manner.
Results: The inter-rater reliability of early childhood educators compared with maternal child health nurses is high (98%). Specificity, sensitivity and positive predictive value of SACS-R administered prospectively in natural groups of young children by early childhood educators is significantly higher when compared with commonly used parent report measures in accurately detecting the early signs of ASD in children aged 12 months- 4 years.
Conclusions: Understanding the effectiveness of current and emerging screening and surveillance tools and processes available to early childhood educators is critical in supporting their involvement in early identification of young children with ASD and has implications for policy and practice across the health and early childhood education sectors for timely, efficient and widely available early detection.

214 **125.214** Satisfaction with Care Coordination Program for Families of Children with Autism Spectrum Disorders

M. H. Pinkett-Davis[1]*, V. Singh*[2]*, A. Schrembs*[3] *and R. Landa*[3]*, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD, (3)The Kennedy Krieger Institute, Baltimore, MD*

Background:
Care Coordination (CC) services provided in the context of a medical home, emphasize an "accessible, continuous, comprehensive, family-centered, coordinated, compassionate and culturally effective" (American Academy of Pediatrics, 2002) approach to care. CC services can be important for families of children with autism spectrum disorder (ASD) (Carbone, Behl, Azor, & Murphy, 2010), especially in the presence of additional co-occurring medical or mental health conditions (Carbone, Behl, Azor & Murphy, 2010). This highlights the need for specialty clinics to provide these services to families.
To evaluate the benefit of implementing CC services in a clinical setting, its utility for helping families understand the child's diagnosis, connect to community resources, and benefit from coordination of care must be examined.
Objectives:
Assess participants' preliminary feedback about the CC program and define aspects of the program that they found most helpful.
Methods:
The sample for this analysis is part of an ongoing study that is currently enrolling families of children with ASD at Kennedy Krieger Institute's Center for Autism and Related Disorders (CARD). 92 of the 225 enrolled families have completed the study and, thus, have completed the post measures between September 2014 and September 2015. Assessment of the demographic profiles found the sample to be fairly representative of CARD's clinical population with respect to age, parent education, race and socioeconomic status.
Parents were given an opportunity to provide qualitative feedback via online survey on the aspects of the program that they found most helpful. These responses were coded by two independent coders and differences were resolved by discussion.
Results:
Approximately 99% of participants identified the CC program to as helpful. Based on their comments, seven independent themes (care coordination, overall and community resources, psycho-education, general support, availability and other) emerged.
There were differences in parent reporting of themes based on the whether the child had a previous ASD diagnosis. Parents in this group found psycho-education (chi square=5.25 p=0.02) and the general support (chi square=5.59 p=0.02) from the program most helpful. Also parents with less than Bachelor's level education found community resources (chi square=6.63 p=0.04) to be more helpful than those with bachelor's level education or higher. There were no differences in reporting based on age, race and SES.

Conclusions:
The analysis suggests that most families found the program to be helpful and would continue to benefit from these services throughout the child's lifetime. The themes that emerged in our analysis were expected given the primary targets of our program. However, an unexpected finding was that the general supportive nature of the care coordination alone was helpful for a large proportion of the families. These comments speak to the very basic need for families of children with ASD to feel connected to a network of support that can assist them in meeting their child's needs.
We recognize the inherent need to differentiate services based on individual families' needs. Further analysis of participant feedback and program utilization will assist us in determining how to best customize CC services in the future.

Table 1. Demographic Characteristics

Demographic Characteristic	N=92
Age of child (mean, SD)	7.06 (3.5)
Sex (%)	
Male	86

215 **125.215** School Placement Outcomes and Services at Preschool, Kindergarten, and School-Age for Children Diagnosed with ASD before Age Three Years

P. Towle[1] *and A. E. Ausikaitis*[2]*, (1)Westchester Insitute for Human Development, Valhalla, NY, (2)Cerebral Palsy of Westchester, Rye Brook, NY*

Background: Longitudinal studies of children with autism spectrum disorder (ASD) tend to focus on stability of diagnostic outcomes. Given the broad spectrum of functioning with ASD, there is a need to know more about functional outcomes such as school placements as well as distribution of different disability levels.
Objectives: To examine the school placement of children diagnosed early at three points in time: preschool, kindergarten, and school age. In addition, educational placements were compared among those with moderate to severe disability, milder disability, and who no longer met criteria for ASD at school age.
Methods: Participants were 56 children identified through an early intervention chart review as being diagnosed with ASD under age 3 years (Time 1 M=25.15, range 13 – 35 mos). 82% were male. Parents were recruited to fill out a set of questionnaires when their children were 7 – 16 years old (Time 2 M=10 yrs 7 mos). Measurements included (1) an extensive parent questionnaire including items about school placement history, current learning problems and school services received; (2) GARS-3; (3) Autism Spectrum Rating Scales (4) Vineland Adaptive Behavior Scales-II. A subset of children also were evaluated directly using the ADOS-2 and brief forms of the WISC-IV or the Leiter-2. Each participant was placed in a school-aged severity outcome category based on all available information. Agreement between judgments based on questionnaire material was kappa (w)=.83. A reliability substudy was conducted to validate the judgment-based ratings with in-person Best Estimate Diagnosis. Agreement between judgments and Best Estimate Diagnosis was 91%.
Results: Time 2 diagnostic distribution was 48% falling in the ASD with Moderate/Severe Disability category, 32% in the ASD with Mild Disability category, and 20% in the No ASD/Social Communication/Learning Disability category. For preschool settings, all children in the two ASD groups were in special education settings with many services. For the eventual No ASD group, all but one were also receiving services, but a smaller proportion were in self-contained classes. In kindergarten, the majority of the two ASD groups received from some to extensive services, but fewer were exclusively in self-contained settings. However, members of the eventual No ASD group were in less restrictive settings than the two ASD groups in kindergarten, and over half had no to only some services. About one-third still received a significant amount of services, however. By school age, all of the Moderate/Severe group were in special education settings, with 75% in highly restricted settings. For the Mild group, half were in regular public school settings with services, whereas the other half were in more restricted settings. The No ASD group had half the children in regular classes, and the rest in a variety of low-restriction settings.
Conclusions: This is the first study to describe school placements at three points in time, according to different severity levels of outcome, for a community sample of children diagnosed early with ASD. It gives insight into the time it takes for the children with the most favorable disability outcome to function with fewer educational supports.

216 **125.216** Service System and Cognitive Outcomes for Young Children with Autism Spectrum Disorder in a Rural Area of Taiwan

C. H. Chiang[1]*, C. L. Chu*[2]*, C. C. Wu*[3] *and Y. M. Hou*[4]*, (1)National Chengchi University, Taipei, Taiwan, (2)Psychiatry, National Cheng Kung Universitity and Hospital, Tainan, Taiwan, (3)Department of Psychology, Kaohsiung Medical University, Kaohsiung City, Taiwan, (4)Chia-Yi Christian Hospital, Chiayi City ,Taiwan, Taiwan*

Background: Chiayi is a rural county located in southwestern Taiwan, the early intervention (EI) service system for autism spectrum disorder (ASD) was possible underserved. Thereby, the effectiveness of its early intervention (EI) service system for autism spectrum disorder (ASD) should be studied in detail.

Objectives: The first aim of the present study was to survey the unitization of EI sources for families in the Chiayi area. The current survey was conducted via a monthly telephone call to avoid parental recall bias. The types and amount of EI received over 1.5 years in children who had ASD and developmental delays (DD) within a narrow age range of 24 to 36 months initially would be assessed. The second purpose of the study was to investigate an association between EI and subgroups of high and low/moderate learners in both ASD and DD groups, and to elucidate how the factors of initial cognitive function and EI impact on the consequent outcomes.
Methods: Seventy-one children of ASD (n = 35) and developmental delay (DD, n = 36) aged 2.5 (time 1, T1) were referred from the only one EI Reporting and Referral Center in Chiayi and followed at ages 4 years old. Cognitive abilities were evaluated using the Mullen Scales of Early Learning (Mullen, 1995) Diagnosis was verified with ADI-R, ADOS, and clinical diagnoses for ASD with DSM-5.

Results: The results showed that, regarding EI services utilization, the total hours per week which these children received were relatively low and varied. Second, while separating the high or low/moderate learner subgroups in the ASD and DD groups, it was found that, after controlling the baseline scores, the children in the higher learner group improved significantly in all of the domains and ELS in MSEL in both the ASD and DD groups. However, only in the DD group, the regular preschool experience and the parental SES could contribute to the improvement of scores.
Conclusions: The current study demonstrated that young children with ASD and DD living in a rural area of Taiwan receive limited and lower quality services. Although the initial data showed that both children with ASD and DD could improve on all of the domains of cognitive function, the children with ASD seem to require more autism-specific services to improve their development in a rural area. Some suggestions are provided to the government, medical, educational and social welfare systems in the future.

217 **125.217** Service Usage, Needs, and Obstacles for Adults Living and Not Living with Family: A Message Regarding Public Policy

K. M. Dudley[1], *L. G. Klinger*[2], *J. L. Mussey*[3] *and M. R. Klinger*[4], *(1)TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC, (2)Psychiatry, University of North Carolina TEACCH Autism Program, Chapel Hill, NC, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Greensboro, NC, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Individuals with autism spectrum disorder (ASD) have substantial difficulty accessing services (Kraus et al., 2003; Kogan et al., 2008), and many of their service needs go unmet (Chiri & Warfield, 2012). However, the majority of studies have focused on children with ASD, and studies with adults have generally only included individuals in their twenties (Shattuck et al., 2012). Thus, there is very little research on service needs of adults with ASD. Even less is known about how service needs for those in middle adulthood may differ depending on their living situation, which is important due to the high number of adults with ASD living with family caregivers (Krauss et al., 2005).
Objectives: The current study investigated the service use in a large sample of adults diagnosed with ASD as children between 1970 and 1999 at the UNC TEACCH Autism Program. Specifically, this study compared services received, unmet needs, and obstacles that impacted service usage for adults living with family caregivers compared to those not living with family caregivers.
Methods: Caregiver surveys were completed for 189 adults with ASD (21-64 years of age; *M* age=35.5). All participants were diagnosed with ASD during childhood (initial evaluation *M* age=7.22). Caregivers of adults with ASD completed a survey that included 34 questions about service usage. Analyses examined differences in service usage, unmet needs, and obstacles attaining services for those living with family members and those not living with family (including those living independently, in supervised housing, a group home, or institution).
Results: As adults, 47% of individuals with ASD lived with family members. Analyses indicated that those living with family members received significantly fewer services than those not living with family members. Specifically, they received less support with independent living skills (24% family, 62% non-family; X^2=14.97, p<.001), psychological care (23% family, 57% non-family; X^2=17.41, p<.001), social work (23% family, 49% non-family; X^2=7.40, p=.007), and transportation (26% family, 70% non-family; X^2=19.89, p<.001). Furthermore, adults living with family members were reported to have significantly more unmet needs than those not living with family members (65% family, 43% non-family; X^2=9.96, p=.007). Families with adults living at home reported more struggles in knowing where to find services (36% family, 11% non-family; X^2=13.68, p<.001). These findings hold when comparing individuals living at home to different types of residential categories for those living outside the home (e.g., those living with family members received fewer services than those living independently).
Conclusions: These data indicate that adults living with family members receive approximately half the amount of services as adults who are living outside the family home. Further, adults living with family are reported to have a greater unmet need for services and difficulty knowing where to access services. With approximately half of this adult sample living with family, these results have clear implications for public policy; we need to work to increase services for middle-age adults with ASD living with family and knowledge regarding where to find these fundamental services.

218 **125.218** South Carolina's Use of Presumptive Eligibility to Improve Early Identification and Intervention for Young Children with ASD

D. A. Rotholz[1], *A. M. Kinsman*[2], *J. M. Charles*[3], *K. Musick*[4] *and K. K. Lacy*[5], *(1)Center for Disability Resources (UCEDD), Columbia, SC, (2)Greenville Health System, Greenville, SC, (3)Pediatrics, Medical University of South Carolina, Charleston, SC, (4)South Carolina BabyNet (Part C), Columbia, SC, (5)South Carolina Department of Disabilities and Special Needs, Columbia, SC*

Background: Implementing practices through which young children at risk for ASD receive early intervention as young as possible poses significant challenges for pediatricians, service providers and the systems responsible for early intervention. AAP efforts have addressed the rationale for and recommended practices through which children can be identified, screened and referred for diagnostic evaluation for ASD. However, these recommendations for screening in pediatric practices are significantly more difficult to implement than would be considered ideal. Concern has also been raised that use of brief assessment models would result in increased errors in definitive classification (Swanson et al 2013) and that it may not be realistic for service systems to revise eligibility and service models to accommodate the use of a briefer assessment model.
Objectives: While these concerns are well founded, this poster provides an example of the successful implementation of a statewide two-tiered screening model with accompanying training and policy efforts that provided for “presumptive eligibility” for early intensive behavioral intervention (EIBI) for young children at risk for ASD via the Part-C program in South Carolina (BabyNet).
Methods: Under the South Carolina BabyNet and presumptive eligibility procedures, the Modified Checklist for Autism (M-CHAT, Robins, Fein, Barton & Green, 2001) is administered to children based upon recommended guidelines adopted by BabyNet .If the M-CHAT is failed, the child is immediately referred for the M-CHAT follow up questions and the Screening Tool for Autism in Toddlers and Young Children (STAT, Stone, Coonrod & Ousley, 2000). The STAT is then administered by professionals who have completed STAT training and are determined eligible to administer by the SC Department of Disabilities and Special Needs (DDSN). Children determined to be at risk for ASD based on the STAT are presumed eligible for EIBI services funded through BabyNet. EIBI services are then initiated in conjunction with a referral for a full ASD diagnostic evaluation. If the evaluation results in a formal diagnosis of ASD or determination of eligibility through South Carolina’s DDSN, the child continues to receive EIBI through BabyNet and continue then with DDSN after age 3.
Results: Implementation of this process has increased the number of children determined eligible for and receiving EIBI services through BabyNet from 61 children in 2011 prior to implementation of presumptive eligibility to 267 children determined eligible through presumptive eligibility and 294 children total receiving EIBI services at the current time. The false positive rate of children identified through presumptive eligibility but not subsequently diagnosed with ASD via comprehensive evaluation is approximately 1%.
Conclusions: Presumptive eligibility for EIBI has proved to be dramatically effective in South Carolina for serving young children at risk for ASD. While this contradicts the “conventional wisdom” that use of a screening process would produce high false positive rates, the results in South Carolina are likely due to the two-tiered screening system that includes quality control measures for the STAT training and STAT provider eligibility.

219 **125.219** Stakeholder Perspective on Transition Planning for Youth with ASD

L. A. Ruble[1], *C. Snell-Rood*[2], *M. W. Jackson*[3], *W. H. Wong*[1], *Y. Yu*[4], *A. D. Rodgers*[1], *J. ". A. Odom*[1] *and J. H. McGrew*[5], *(1)University of Kentucky, Lexington, KY, (2)Behavioral Sciences, University of Kentucky, Lexington, KY, (3)Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (4)Indiana University-Purdue University, Indianapolis, IN, (5)Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background:
Although federal law mandates that all youth with disabilities in special education have transition plans to facilitate the “hand-off” to adult services, research on transition planning and implementation indicates we are falling short for students with autism spectrum disorder (ASD). Specifically, transition planning for youth with ASD is poorly understood, and little is known about how transition is actually perceived and experienced directly from the perspective of stakeholders.
Objectives:
To describe stakeholder perspectives on (i) the strengths and weaknesses of existing state/local policies, procedures, services, and resources and the changes needed to support effective transition, and (ii) concerns associated with adult services such as housing, social security, health insurance, transportation.
Methods:
Participants (n=42) were individuals with ASD, parents, teachers, school administrators, adult service providers, and state policy makers from the offices of Vocational Rehabilitation (OVR), Special Education, Medicaid, and Developmental Disabilities. A total of 10 focus groups were conducted. Each 1-hr session was recorded and transcribed for coding and analysis. Qualitative content analysis was oriented around identifying deductive themes in the data. Agreement for themes was assured with a minimum of two research analysts collaborating on the transcript-based analysis. After reading the transcripts, the team composed an initial codebook and revised the codes

through a consensus-based iterative process. Once each coding pair reached inter-rater reliability of at least 80%, codes were applied to the rest of the interview independently. Coders worked in pairs to apply codes line by line to the text. A total of 15 content codes were identified.
Results:
*(i) Strengths and weaknesses of state policies, procedures, services, and resources that exist or are needed: S*everal criticisms of state policies and procedures emerged from the interviews, especially for the OVR which is not very involved with transition planning. Participants criticized OVR for limited support for adult education and vocational training, and lack of knowledge about ASD. Participants critiqued schools' inadequate funding for appropriate transition assessment tools and community based instruction. Some felt educators and administrators were resistant to adjusting curricula for applied skill development for students withi a regular diploma. Stakeholders were concerned that students pursuing the alternative assessment/diploma track would have difficulty obtaining a job; yet the use of the word "diploma" might misrepresent the student's skill set. Finally, participants advocated for the need for an experienced navigator to guide the student and his/her family throughout the transition process.
(ii) Concerns about adult services: Participants reported a lack of knowledge about the role of OVR in transition, services available after transition, and how to access services. Participants emphasized the need for parents to apply for Medicaid waiver services early. Many commented that adult service providers lacked understanding of ASD and consequently had difficulty providing appropriate services. Finally, transportation was a challenge for participants seeking services in rural areas.
Conclusions:
Stakeholder perspectives on transition planning emphasized better involvement of OVR, curricular changes based on individual student needs, support for parent navigation, better trained service providers, and access to services- important factors necessary to consider in intervention research.

220 **125.220** Supporting Children with Autism Spectrum Disorder (ASD) on the Day of Surgery: A Balancing Act

S. L. Snow[1,2], *J. Chorney*[2], *M. Latimer*[2] *and I. M. Smith*[3], *(1)Dalhousie University, Halifax, NS, Canada, (2)IWK Health Centre, Halifax, NS, Canada, (3)Dalhousie University / IWK Health Centre, Halifax, NS, Canada*

Background: Children with autism spectrum disorder (ASD) appear to be especially vulnerable to distress around the time of surgery and managing distress can be particularly challenging for both parents and healthcare providers to manage (e.g., Bultas et al., 2012). More research is needed to better understand the surgery-related experiences of children with ASD, and to identify practices for ensuring that services are responsive to the unique needs of this growing population of healthcare service users.
Objectives: To gather the perspectives of parents and healthcare providers who have been directly involved with children with ASD undergoing surgery, and gain deeper insight into the surgery-related experiences of children with ASD, their families, and healthcare providers.
Methods: Purposive sampling was used to recruit 7 nurses and 8 physicians (surgeons & anesthetists) with Day Surgery experience with children with ASD, as well as 8 parents of children with ASD who had undergone Day Surgery. Participants engaged in semi-structured interviews that focused on (1) how perioperative distress presents in ASD, and consequences of such distress, (2) management approaches to preparing or supporting children with ASD, (3) how surgical services could be altered to better serve children with ASD and their families, and (4) barriers and facilitators to improving Interpretive description (Thorne, 2008) was the qualitative framework; themes were identified in the transcripts. Strategies such as constant comparison, peer debriefing, stakeholder meetings, and consulting expert readers were used to establish the trustworthiness and credibility of the findings.
Results: Three main themes were identified, in addition to an overarching metaphor of the child, family and health providers experience during the surgical course as a "delicate balancing act". The first theme: "Finding your footing" described how child, parent, and healthcare provider factors (e.g., anxiety, tolerance of uncertainty, and self-efficacy) set the foundation for surgery-related experiences; "Keeping each other steady" highlighted how interpersonal dynamics among children with ASD, their parents, and healthcare providers (e.g., working alliance) further shape the surgical experience; "Seeing straight ahead" captured how systemic factors (e.g., hospital environment and policies) complicate, as well as provide opportunities for the delivery of surgical care to children with ASD and their families.. A six-minute video animation was built to provide a visual representation and facilitate dissemination of these findings.
Conclusions: Parents and HCPs provided a nuanced and multi-faceted understanding of how individual, interpersonal, and systematic factors interact and shape the surgery-related experiences of children with ASD, their families, and healthcare providers. Findings underscored the complexities associated with trying to keep children with ASD, their parents, and healthcare providers balanced throughout the surgical course, while also shedding light on opportunities for interventions and clinically feasible practices that may help families and parents to successfully navigate this delicate balancing act.

221 **125.221** Systematic Review of Clinical Guidance Documents for Autism Spectrum Disorder Diagnostic Assessment

E. Anagnostou[1], ***M. Penner***[2] *and W. Ungar*[3], *(1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Hospital for Sick Chidlren, Toronto, ON, Canada*

Background: The reported increase in prevalence of autism spectrum disorder (ASD) has also increased the demand for ASD diagnostic assessments. Clinical guidance documents play an important role in shaping these diagnostic assessment practices.
Objectives: The objective of this study was to perform a systematic review of clinical guidance documents for ASD diagnostic assessment, comparing and contrasting their quality and content.
Methods: The systematic review of guidance documents included documents published from 2000 to present by Canadian, American and UK health and educational professional associations, as well as documents published by governments in Canada or the UK. Professional association statements, practice parameters, and practice guidelines were included as clinical guidance documents. Documents pertaining only to management of ASD, as well as literature reviews and commentaries were excluded. MEDLINE, EMBASE, PsychINFO, CINAHL and ERIC were searched. Search terms included Child Development Disorders, Pervasive; Asperger Syndrome; and Autistic Disorder; these were combined with Diagnosis. Titles and abstracts were screened for eligibility based on their applicability to ASD diagnostic assessment. All documents with titles and/or abstracts that were relevant underwent full text review with application of the inclusion and exclusion criteria. One reviewer extracted relevant information from each document and assessed for quality using the Appraisal of Guidelines Research and Evaluation, 2nd edition (AGREE-II) tool.
Results: A total of 837 unique documents were retrieved, of which 24 were considered relevant and underwent full-text review. Of these, nine documents met the inclusion criteria and were included in the analysis. Two of these documents were no longer endorsed by their professional associations. The mean total score on the AGREE-II for all included documents was 68.6 (s.d. = 11.9, range 45, 89). Domain scores from the AGREE-II showed relatively high quality in Scope and Purpose (mean 90.6, s.d. 10.2) and Clarity of Presentation (mean 89.9, s.d. 10.6). Scores were lowest in Applicability (mean 42.7, s.d. 23.4) and Rigor of Development (mean 51.6, s.d. 25.8). Six of the nine documents strongly recommend a multidisciplinary team (MDT) for diagnostic assessment, while the remaining three state that MDT assessment is ideal. The guidelines varied substantially in their recommended personnel for diagnostic assessment, from no stated recommendations to a list of recommended MDT members. There was little supporting evidence for MDT and personnel recommendations. Recommended tools varied from no recommended tools to recommendations that multiple specified tools be completed. Only three of the documents included recommended wait times for assessment, all of which were from governments or non-profit associations.
Conclusions: Multiple guidance documents have been published for ASD diagnostic assessments, with varying quality and recommendations. The substantial variation in quality and content likely stems from insufficient evidence supporting diagnostic assessment practices. Further empiric evidence is needed to support diagnostic decision making in ASD and should include analysis of systems impacts, such as wait times.

223 **125.223** The Feasibility of Implementing and Assessing Acute Behavioral Interventions in an Inpatient Setting for Children and Adolescents with ASD: Challenges and Lessons

S. Marler[1], *J. E. Staubitz*[2], *P. Juarez*[3], *Z. Warren*[1], *L. L. Altstein*[4], *E. A. Macklin*[5] *and K. Sanders*[6], *(1)Vanderbilt University, Nashville, TN, (2)Pediatrics, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Massachusetts General Hospital Biostatistics Center, Boston, MA, (5)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (6)Vanderbilt, Nashville, TN*

Background: Children with Autism Spectrum Disorder (ASD), while hospitalized, frequently present with severe behaviors (i.e. aggression, self-injury) and due to this, often remain hospitalized beyond medical clearance. These behavioral challenges associated with ASD have resulted in perceived suboptimal treatment in inpatient settings by children, families, and providers (Scarpino et al., 2010; Kopecky et al., 2013). The inability of current systems to adequately respond to behaviors often limits the ability of children to be safely discharged. Though steps have been made toward improving treatment of ASD in medical settings, these children still have higher rates of hospitalization and an increased burden of unmet needs (Lajonchere et al., 2012; Croen et al., 2006; Siegal et al., 2014). There have been few studies of interventions designed to improve hospitalization for this population, leaving questions regarding the ideal organization of care unanswered. Although utilizing the principles of Applied Behavior Analysis (ABA) for assessing and treating challenging behavior can significantly impact functioning of individuals with ASD (Weitlauf et al., 2014), behavioral professionals with ABA-specific training are rarely incorporated into inpatient treatment plans. The development and implementation of innovative care programs to reduce problematic behaviors of children with ASD in inpatient settings has the potential to improve outcomes for all involved.
Objectives: Our aim was to investigate the feasibility of implementing and assessing the efficacy of brief Analogue Functional Analysis (AFA) in an inpatient setting for children with ASD to guide care during, and hopefully improve, hospitalization. We sought to evaluate if the proposed level of support and specialized care is possible during hospitalizations, or if additional components must be added and analyzed in future studies.
Methods: This single site, pilot study attempted to enroll and randomize 40 children with ASD , ages 6-18, admitted to either a medical or psychiatric inpatient unit, with severe challenging behavior(s). Participants were randomized on a 1:1 basis into a treatment group (receiving brief AFA and behavioral intervention) or a control group

(receiving “treatment as usual”). Feasibility was assessed by enrollment/completion data as well as staff, parent, and clinician ratings of challenges and successes during hospitalization.
Results: We recruited 36 children over a brief enrollment period (approximately six months) in both medical (41.7%) and psychiatric facilities (58.3%), with 19 completed, 12 lost to follow-up, and 5 pending 3-month follow-up. Major challenges endorsed by clinicians involved in the protocol included: communication challenges with staff, availability of appropriate/safe space for AFA on medical floors, challenges conducting randomization for services, and availability of behavioral services increasing parental desires to stay in hospital.
Conclusions: Although several challenges to implementing behavioral intervention in an inpatient setting were identified, we were successful in conducting a randomized intervention in these inpatient settings. The most significant challenges related to integrating behavioral staff/procedures into an already-established treatment flow and obtaining efficacy data from parents. The latter is not surprising given the pervasive disruption of having a hospitalized child, but highlights the need for novel methods, procedures, and tools that will yield higher levels of efficacy data capture over time.

224 **125.224** The Impact of Demographics on Service Utilization Among Youth with Autism Spectrum Disorder

*R. Gott[1], **C. R. Shoff**[2] and P. Xaverius[3], (1)Saint Louis University, Clayton, MO, (2)Pediatrics, Saint Louis University, Saint Louis, MO, (3)Epidemiology, Saint Louis University, Saint Louis, MO*

The Impact of Demographics on Service Utilization among Youth with Autism Spectrum Disorder
Background: Early intervention improves the behavior and the developmental outcomes of individuals with autism spectrum disorder (ASD) but there is currently no standard for the type, amount and duration of treatment. Previous research has documented disparities in access to care for youth with ASD, but it is unclear how service utilization may vary by race/ethnicity, parental income and education.
Objectives: To identify how disparities in race/ethnicity, parent socioeconomic status and insurance type affect medical and therapy services for individuals with ASD.
Methods: Between 2008-20015 the Autism Treatment Network (ATN) collected data on almost 7000 youth with ASD, ages 2-17 from United States and Canada. Using data collected through the ATN Registry, we described the sample and performed bivariate analysis to determine relationships between race, ethnicity, SES variables and use of medication, as well as complementary or alternative therapies, behavioral, speech/language, occupational, and physical therapy services.
Results: Race and ethnicity were significantly associated with receipt of speech/language services (ST), occupational therapy (OT) and physical therapy (PT) at baseline ($p<0.05$). Hispanics were less likely to use all services (53.1% vs. 60.4% ST, 40.3% vs. 47.1% OT, 11.6% vs. 15.6% PT). Service utilization also was associated with insurance type. For all categories, those with no insurance were less likely to use services (34.2% vs. 61.3% ST, 28.1% vs. 48.3% OT, 10.0% vs. 15.9% PT). Household income was significantly associated with all service categories ($p<0.05$), with behavioral, speech/language and occupational services increasing as income increased. Race and ethnicity, household income, caregiver education, any private insurance status and household income were also associated with using complementary/alternative medications ($p<0.05$).
Conclusions: Patterns of service utilization vary with race/ethnicity and socioeconomic status. In many instances Caucasians, those with a higher income, and those with any type of insurance were more likely to receive services. The same trend exists for complementary/alternative medication usage. This suggests that youth with ASD from low-income households are at a greater disadvantage. Future research studies should explore how disparities in service utilization affect outcomes of individuals with ASD.

225 **125.225** The Role of Professional Responses to Parental Concern in Predicting the Timeliness of Autism Spectrum Disorder Diagnosis

***C. A. Bent**[1], J. Barbaro[2] and C. Dissanayake[3], (1)La Trobe University, Melbourne, VIC, Australia, (2)La Trobe University, Melbourne, Victoria, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: A substantial gap exists between the age that a reliable and accurate diagnosis of Autism Spectrum Disorder (ASD) is possible, and the age that the majority of children currently receive a diagnosis. Previous research has identified factors associated with the age at diagnosis of ASD; including clinical features, parental concerns as well as community level characteristics such as socioeconomic status and service availability. Families’ interactions with health services may also act as a barrier or enabler to early diagnosis; with later diagnoses found to be associated with a greater number of professional consultations. However, less is known about the role of professionals’ behaviour and responses to parental concerns in predicting the timeliness of ASD diagnosis.
Objectives: This study aimed to examine the role of families’ interactions with health services and professional responses to parental concerns in the prediction of the timeliness of ASD diagnosis.
Methods: 185 parents/caregivers with a child with ASD completed a purpose-developed online survey which included questions on child characteristics, severity of ASD symptoms (measured using the Social Communication Questionnaire), family demographics, parental concerns, type and number of professionals consulted and professional responses. Correlations were initially conducted to examine relationships between variables and hierarchical regression analyses were conducted to predict the timeliness of ASD diagnosis. The final paper will include data collected up until the end of December 2015.
Results: On average, parents’ reported becoming concerned about their child’s development at 25 months, first seeking professional advice at 35 months, and receiving an ASD diagnosis at 63 months. Shorter delays in the time between seeking professional advice and obtaining a diagnosis were associated with more active professional responses (e.g., raising concerns about child development, making a referral, administering a screening tool or developmental assessment). While more passive professional responses (e.g., advising the child was too young to diagnoses, not to worry or to wait and see) were associated with greater delays in ASD diagnosis. Controlling for child age at the time of the survey, active responses to parental concerns and the overall number of professional consultations were significant unique predictors of timeliness of ASD diagnosis, with the overall model accounting for 52% of variance. Severity of ASD symptoms, family socio-economic characteristics and family history of ASD were not meaningfully associated with timeliness of diagnosis.
Conclusions: Substantial delays were reported between parents first seeking professional advice regarding their child’s development, and child age at ASD diagnosis. Active professional responses to parental concerns may reduce delays in diagnosis. These findings reiterate the importance of developmental surveillance, which provides a structure within which parents and primary health care professionals can raise concerns regarding a child’s development.

226 **125.226** The Role of Self-Efficacy When Preparing Teachers in Autism Spectrum Disorders

***J. Salt** and K. Johnsen, Have Dreams, Park Ridge, IL*

Background:
Research has begun to look at self-efficacy effects during teacher training. Recently, we added a *autism specific* self-efficacy measures to our training evaluation protocol. Our program is an intensive training based on structured teaching principles. The 5-day, interactive training provides opportunities to receive in-vivo supervision and feedback from experienced trainers. Through hands-on construction of visual supports, participants create a classroom, work with children with ASD and teach the autism curriculum.
Objectives:
This study investigated the effectiveness of the training model to increase teachers competence in delivering the autism curriculum. The study addressed:
(i) teacher change in self-competence to teach the autism curriculum
(ii) the relationship of teachers initial self-efficacy to outcome
(iii) the relationship of teachers self-efficacy to skills gained during training and professional experiences prior to training.
Methods:
Participating teachers (n= 46) completed two questionnaires pre and post training:
(i) The ‘structured teaching competence’ questionnaire contains three sections: concrete level (early learner); intermediate level; abstract level (advanced learner.) Participants answered questions regarding their ability to provide interventions for that child. The final questionnaire had 15 questions; maximum score 90.
(ii) The Autism Self-Efficacy Scale for Teachers (ASSET; Ruble et al., 2013) is a 30-item self-report measure designed to assess ASD specific knowledge and skills. Each question is rated on a 1-100 scale.
Teachers provided information on their educational qualifications and experience with ASD.
Results:
(i) T-test revealed that there was a significant ($p<.01$) increase in competence scores pre and post training at each level of development (concrete, intermediate, abstract).
(ii) Baseline ASSET scores were divided by the mean to create high and low self-efficacy groups. To compare group performance on the structured teaching measure, scores were entered into a repeated measures multivariate analysis of variance, with time (pre, post) as the within subjects repeated measure and group (high, low SE) as the between factor. There was no significant group by time interaction effects at any level of development.
(iii) Final ASSET scores were divided by the mean score to create high and low self-efficacy groups. To determine the relationship of prior experience and competence gained on teacher self-efficacy, data was entered in a logistic regression model with group membership (high and low self-efficacy) as the dependent variable, and lifetime number of ASD students, educational level, years teaching and final competence score as covariates. Both total score (OR= 1.2, $p<.05$) and educational level (OR = 9.6, $p<.05$) significantly predicted self-efficacy group membership.
Conclusions:
These results provide support for the effectiveness of our training. Teachers increased their confidence in their ability to teach the autism curriculum, at any level of ability, to individuals with ASD. Teachers in both the low and high self-efficacy groups increased their scores on both measures over the training period. Results indicate that

experiences prior to training do not significantly impact outcome. Therefore even experienced teachers can increase their autism intervention self-efficacy by attending an intensive training. Further research will explore if educational level or self-efficacy predicts *implementation* of specific strategies in the classroom following training.

227 **125.227** Therapy and Medication Use in Young Children with Autism: A Secondary Data Analysis from the Autism Speaks-Autism Treatment Network

D. Ziskind[1], *A. Bennett*[1], *A. F. Jawad*[2] *and N. Blum*[1], *(1)Developmental & Behavioral Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Guidelines suggest that young children with Autism Spectrum Disorder (ASD) should receive intensive psychosocial interventions. Additionally, associated symptoms may be treated with psychotropic medications. However, actual intervention use by young children with ASD has not been well characterized.
Objectives: The aim of this study was to describe interventions received by young children with ASD ≥6 months after diagnosis. The association with socio-demographic factors was also explored.
Methods: Data were used from the Autism Speaks- Autism Treatment Network (AS-ATN), a research registry of children with ASD which includes 17 sites in the U.S. and Canada. AS-ATN participants undergo a standardized diagnostic evaluation and receive treatment recommendations from Autism specialists. Parents report services and medications being used at follow-up visits. This study used data from 12/2007 to 12/2013 and included 1354 subjects aged 36-72 months.
Results: Most young children (91%) received psychosocial interventions but only 36% received behavioral-based therapy. The median total hours per week of therapy was only 5.0 hours (range 0-65; interquartile range 1.5-14) and of those who received behavioral-based therapies, the median hours per week received was only 4.6 hours (range 0.1-50, interquartile range: 2-12). 50% of subjects received <5 hours per week of therapy and only 18% reported receiving >20 hours per week of therapy. Demographic factors found to be associated with increased total therapy intensity included younger age, non-Hispanic/ Latino ethnicity, higher parental educational level and geographic location in the Northeast or Southern U.S. Additionally, 22.4% of subjects were on ≥1 psychotropic medication and the most commonly prescribed medications were α-agonists Demographic factors found to be associated with increased psychotropic medication use included older age, Black/ African American race, lower parental education and living in Canada.
Conclusions: Relatively few young children with ASD diagnosed at high quality academic centers are receiving evidence-based behavioral therapies and few are receiving psychosocial interventions at the recommended intensity. There is significant regional and socio-demographic variability in psychosocial intervention and psychotropic medication use. Additionally, the class of medications most commonly prescribed has not been extensively studied in this population. Further research is needed to support current prescribing practices and to improve access to evidence-based treatments for young children with ASD.

228 **125.228** Training Needs of Health Professionals Working with Adults on the Autism Spectrum

K. van Dooren[1,2], *T. Parkin*[3], ***S. J. Girdler***[4,5], *A. Urbanowicz*[6,7], *M. Ciccarelli*[3,6] *and N. Lennox*[6,8], *(1)Queensland University, Queensland Centre for Intellectual and Developmental Disability, South Brisbane, Australia, (2)Cooperative Research Centre for Living with Autism Spectrum Disorders, long Pocket, Brisbane, Australia, (3)School of Occupational Therapy and Social Work, Curtin University, Bentley, Australia, (4)School of Occupational Therapy and Social Work, Curtin University, Perth, WA, Australia, (5)Cooperative Research Centre for Living with Autism Spectrum Disorders (Autism CRC), Brisbane, Australia, (6)Cooperative Research Centre for Living with Autism Spectrum Disorders, Long Pocket, Brisbane, Australia, (7)University of Queensland, Queensland Centre for Intellectual and Developmental Disability, South Brisbane, Australia, (8)The University of Queensland, Queensland Centre for Intellectual and Developmental Disability, South Brisbane, Australia*

Background: Approximately 1 in 134 Australians are living on the Autism spectrum, yet only 1% of research in Autism focuses on adults. The limited research available suggests that adults on the Autism spectrum have unique health needs and may exhibit poorer physical and mental health outcomes in comparison to the general population. Additionally, health professionals working in the area often experience challenges at systems, education and training levels when working with these adults on the spectrum.
Objectives: To undertake an assessment of the needs of Australian health professionals in relation to their provision of care to adults on the Autism spectrum.
Methods: We recruited 78 health professionals from across Australia, using purposive and snowballing approaches, to complete an online survey about providing health care to adults on the Autism spectrum. The survey consisted of 39 open-ended and closed questions and was open for completion from December 2014 to February 2015. Questions sought information on health professional and patient demographics, self-assessment of health professional competence and training needs. Descriptive data analysis was performed on closed questions. Open-ended data were analysed using content analysis.
Results: The 78 health professionals came from a broad range of health professions. Most commonly the professionals worked as a nurse (18%), other including psychiatrists (18%), occupational therapist (14%), psychologist (13%) or medical practitioner (13%). The vast majority 79% (62/78) were female, with most aged 45-64 years (63%), 28% aged 25-44 years, 6% aged 18-24 years and 3% aged 65 years or older.
On average, health professionals (n=68) saw 22 (SD 27) adults on the Autism spectrum every year, who had a mean age of 32 (SD 19) years. More than half of the adults on the Autism spectrum (60%, 41/68) also had intellectual disability and only 14% (10/69) attended appointments on their own. Health professionals were asked to rank up to three of the most common medical conditions of the adults they cared for and these included mental health, general health including check-ups, gastrointestinal, neurological and metabolic.
Two thirds (62%, 48/78) of the health professionals agreed or strongly agreed with the statement “I feel competent providing care to adults with ASD”. Most frequently, professionals stated an interest or knowledge of Autism helped them provide services to the adults they cared for but that a lack of training, knowledge, time, experience and resources made it difficult for them to provide this care. The majority (83%, 54/65) strongly agreed or agreed that they would like more training specific to caring for adults on the spectrum and the most preferred modes of receiving training were workshops, webinars, electronic and hard copy reading material, and online courses. Areas identified for training included behaviour management, mental health, communication and teaching.
