108 **161.108** Visual Working Memory and Filtering Ability in Individuals with Autism Spectrum Disorder

K. E. Bodner[1]*, N. Cowan*[2] *and S. E. Christ*[2]*, (1)Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (2)Psychological Sciences, University of Missouri, Columbia, MO*

Background: Past investigations have reported impaired working memory performance in individuals with Autism Spectrum Disorder (ASD) (Geurts, de Vris, & van den Bergh, 2014). It remains unclear, however, to what extent the previously observed performance differences reflect a decreased memory capacity, difficulties with preventing irrelevant information from filling capacity (i.e., filtering ability), and/or disruption in focused attention.
Objectives: The current study assessed the contribution of core processes (e.g. working memory capacity, attention, and visual filtering abilities) to visual working memory performance in adolescents and adults with and without ASD.
Methods: Data from 48 subjects (24 with ASD; 24 without ASD) between 16 and 24 years old were analyzed. Estimated Full Scale IQ for all subjects was >80. Participants completed a computerized paradigm designed to systematically assess capacity, attention, and visual filtering abilities during visual working memory performance (Cowan et al., 2011; Mall et al., 2014). Subjects were shown visual arrays consisting of 2, 3, 4, 6, or 8 colored stimuli (circles and/or squares). After a short delay, memory for the color of one of the stimuli was probed (same or different color). Importantly, subjects were informed beforehand that the one of the shapes (e.g., circles; high frequency probes) was more likely to be probed compared to the other shape (e.g., squares; low frequency probes), allowing them to allocate their attention and filtering accordingly. Three different blocks of trials were presented: [1] trials with only one shape (100% high frequency probes), [2] trials with both shapes but only one shape probed (100% high frequency probes), and [3] trials with both shapes and both shapes probed (75% high frequency and 25% low frequency probes). Eye tracking data was simultaneously collected.
Results: Results revealed comparable estimates of overall working memory capacity between groups (maximum mean capacity: ASD = 3.81 and non-ASD = 3.84), $F(1,46) < 1$, $p = 0.44$, $h_P^2 = 0.01$. However, performance for individuals with ASD was more impacted by increases in attention and visual filtering demands than individuals without ASD. Individuals with ASD also allocated their attention differently than non-ASD individuals and spent less time looking at relevant information, especially as the task increased in complexity (e.g., 25% versus 38% of time looking at relevant information for 8 stimuli), $F(1,46) = 4.11$, $p = 0.01$, $h_P^2 = 0.08$. The ASD group had more difficulty filtering distracting information in the most challenging condition (8 stimuli, high/low frequency), $t(46) = 2.19$, $p = 0.03$, Cohen’s $d = 0.63$. Specifically, individuals with ASD were less effective at allocating working memory capacity to the high versus low frequency stimuli in comparison to individuals without ASD.
Conclusions: Â Findings suggest that visual working memory performance is similar between individuals with and without ASD when cognitive demands are low, but individuals with ASD are detrimentally affected when the cognitive load increases (increased attention and visual filtering demands). Given the complexity of our environments and need to filter visually distracting information, these findings may shed light on ASD-related difficulties in day-to-day functioning and provide a focus for intervention.

109 **161.109** 'Sticky' Attention in Children and Youth with Autism Spectrum Disorder: General Deficit or Task Dependent?

C. A. McMorris[1] *and J. M. Bebko*[2]*, (1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)York University, Toronto, ON, CANADA*

Background: Individuals with autism spectrum disorder (ASD) have difficulty disengaging and shifting their attention or what has been termed 'sticky' attention. This 'sticky' attention has been hypothesized as a general deficit of the broader ASD phenotype, and can aid in early identification. Researchers to date have only examined endogenous and exogenous attention abilities, or when the cue to shift and disengage attention is externally provided. However, in everyday attention situations, decisions to disengage or shift are often generated internally, in the absence of external cues, such as when scanning a scene. This self-generated, "autogenous attention," is a focus of the present study. Due to the implications of attention on later social and language development, a richer understanding of attention abilities in individuals with ASD is critical.
Objectives: Â The primary objective was to evaluate whether disengagement and shifting abilities in children and adolescents with ASD are characterized by a general deficit. We did this by evaluating two different types of attention, exogenous and autogenous attention. How task stimuli impact attention was also studied, that is, whether the type of task, the content of stimuli, and the level of complexity of the stimuli impact participants' attention abilities. Lastly, we explored how specific demographic characteristics and clinical variables, including cognitive level, were related to attention abilities of children with ASD and typically developing (TD) children.
Methods: Â Two groups of children, ages 6 - 15 years, participated in the present study. The current samples included 20 TD children and 18 children with a diagnosis of ASD. The TD children were group-matched to children with ASD based on their chronological age and intellectual ability. The participants' attention abilities were measured using a novel eye-tracking attention task, that determined autogenous and exogenous attention abilities. Task stimuli varied based on complexity (modality of the information, motion of the stimulus), and the degree of synchrony in the stimulus. Demographic and clinical variables were measured using a formal cognitive assessment and parent-report measures.
Results: Findings from multi-level modeling analyses indicate that participants with ASD took longer time to fixate, and had fewer fixations than TD children, suggesting that 'sticky' attention characterizes this population, but only in certain circumstances. In other conditions there was no evidence to support 'stickiness'. A number of task-specific variables (e.g., attention type, trial type, stimuli type, and stimuli motion and synchrony) and participant-specific variables (chronological age and verbal cognitive ability) predicted performance on the attention task in both groups.
Conclusions: Overall, findings from the present study do not support previous research indicating inferior disengaging and shifting abilities in children with ASD, as attention abilities varied based on attention type and other task-dependent variables, including task stimuli. Thus, the current findings do not provide clear support for the hypothesis that 'sticky' attention is a general deficit in children with ASD. As a result, its potential as a diagnostic marker is questionable, or, at best, limited to very specific stimulus parameters.

Poster Session
162 - Interventions - Pharmacologic
5:00 PM - 6:30 PM - Golden Gate Ballroom

110 **162.110** A Pilot Dose Finding Study of Pioglitazone in Children with ASD

L. Capano[1]*, J. A. Brian*[1]*, D. Mankad*[1,2]*, S. Smile*[1]*, L. Genore*[1]*, R. Hastie Adams*[1]*, A. Iaboni*[1]*, D. Odrobina*[1]*, A. Dupuis*[3] *and E. Anagnostou*[2]*, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada*

Background:
Only two medications have approval for use in autism spectrum disorder (ASD), (risperidone and aripiprazole) and they treat irritability and aggression. However, there are no pharmaceutical treatment options for the core symptoms of autism. Importantly, we have not been able to impact the developmental trajectory of children with ASD, likely because we are not targeting the underlining pathophysiology. Pioglitazone is a promising compound that targets multiple pathways implicated in ASD such as immune dysregulation, oxidative stress, mitochondrial dysfunction, and NMDA inhibition.
Objectives:
The objective of this pilot study of pioglitazone was to elucidate the maximum tolerated dose and safety, provide early data supporting efficacy, and identify appropriate measures sensitive to change in children with ASD ages 5-12 years old. We hypothesized that pioglitazone would be well tolerated at the maximum dose of 0.75mg/kg once daily.
Methods:
We conducted a 16-week prospective cohort, single blind, 2-week placebo run-in dose-finding clinical trial between June 2013 and September 2015. Interested potential participants (131) were phone screened, 35 consented, 28 participants initiated treatment, and 25 completed treatment. A modified dose finding method was used to determine safety and dose response among three dose levels: 0.25mg/kg, 0.5mg/kg, and 0.75mg/kg once daily. Classical dose-finding escalations were done in groups of five participants, with five participants studied at the first dose level (0.25mg/kg once daily), five participants were studied at the second dose level (0.5mg/kg once daily), and the final 18 participants were studied at the maximum dose level (0.75mg/kg once daily).
Results:
Maximum tolerated dose: There were no serious adverse events (SAEs) and as such the maximum tolerated dose within the range tested was determined to be 0.75mg/kg once daily.
Safety: Overall, pioglitazone was well tolerated. Two participants discontinued intervention due to perceived non-efficacy and one due to the inability to tolerate interim blood work during the study. Adverse events (AEs) were of mild to moderate severity. Three participants experienced mild neutropenia. In one participant this was a pre-existing condition, in another it resolved while staying on medication and in the third it only presented during the final visit and spontaneously recovered. As such, it was deemed to be unrelated to the study intervention.
Early evidence of efficacy: One participant was a responder after 2 weeks of placebo and was removed from the analysis. Regression analyses showed statistically significant improvements within group for social withdrawal and repetitive behaviors, as well as externalizing behaviors as measured by the Aberrant Behavior Checklist (ABC) and Repetitive Behavior Scale –Revised (RBS-R), and after multiple comparisons correction, but not in anxiety or social responsiveness. Forty-six percent of those enrolled were deemed to be global responders. Of particular interest, high pro-inflammatory cytokine levels at baseline as well as changes during the study were correlated with treatment response.
Conclusions:
Pioglitazone is well-tolerated and shows a potential signal in measures of social withdrawal, repetitive behaviors, and externalizing behaviors. High levels of pro-inflammatory cytokines at baseline are associated with treatment response. Randomized controlled trials using the confirmed dose are warranted.

111 **162.111** Changes in Sleep Habits during Drug Treatment of ASD

R. K. Abramson[1], *A. V. Hall*[2], *C. A. Stuck*[2], *S. Ravan*[3], *J. Charles*[4], *J. Williams*[5] *and L. DeVane*[4], *(1)University of South Carolina School of Medicine, Columbia, SC, (2)Neuropsychiatry and Behavioral Sciences, University of South Carolina School of Medicine, Columbia, SC, (3)University of South Carolina, School of Medicine, Columbia, SC, (4)Medical University of South Carolina, Charleston, SC, (5)Developmental-Behavioral Pediatrics, University of South Carolinla School of Medicine Greenville, Greenville, SC*

Background: Children with Autism Spectrum Disorder(ASD) are at high risk for two major family stressors: sleep disorders and problem behaviors, including irritability. A NICHD funded biomarker study of aripiprazole versus risperidone with a primary focus of treating irritability in children with autism also evaluated sleep pre and post treatment for irritability.
Objectives: (1) Using the Children's Sleep Habits Questionnaire(CSHQ), was there a difference between the number of African Americans(AA) versus the number of Caucasians(C) with no sleep problems? (2) Did children with an IQ<70 have similar sleep scores as children with an IQ≥70? (3) Was there a difference between AA and C in IQ? (4) Did children with sleep problems differ on Aberrant Behavior Checklist(ABC) subscales from children with no sleep problems? (5) Was there a medication effect on pre versus post treatment CSHQ total scores? (6) Was there a treatment effect on sleep latency and night time awakening?
Methods: Inclusion criteria for this double-blind, placebo controlled study were children aged 6-17 with an ASD diagnosis, an ABC irritability score ≥18, and not currently taking or previously treated with aripiprazole or risperidone. Screening included developmental and medical history, the Vineland Adaptive Behavior Scale, the Autism Diagnostic Observation Schedule, the Autism Diagnostic Interview-Revised and the Stanford-Binet-5 IQ Test. Parents of children screen positive for ASD completed the CSHQS and the ABC before children were randomized to drug treatment and at study completion.
Results: This preliminary study included 45 children, 60% C and 40%AA. There was no difference in the number of AA versus C with a sleep score <41. Mean pre-post study sleep scores of AA children did not differ from those of C children. Sleep scores for children with an IQ<70 versus those with IQ≥70 were not statistically different. There was no difference between the mean IQ of C and AA children. By ANOVA, the ABC Lethargy, Stereotypy, Hyperactivity and Inappropriate Speech subscale scores did not differ between children with sleep versus no sleep problems. A difference in the Irritability subscale score in sleep versus no sleep problems approached significance (F=3.34, p=0.07). For the total sample of children on aripiprazole or risperidone, the pre-drug sleep score was significantly worse than the post-drug score, t(44)=5.01, p<0.00l). CSHQ total mean scores of children on aripiprazole(n=23) versus risperidone(n=22) were compared. Risperidone performed significantly better than aripiprazole in addressing sleep disturbance, t(31.11)=2.11, p<0.04). The two drugs did not differ in treatment of CSHQ sleep latency or night time awakening scores. Pre-drug sleep latency scores were significantly worse than post-drug scores, t(44)=-3.07, p<0.0036. There was a trend towards significance for decreased night-time awakening post treatment, t(44)=179, p<0.08.
Conclusions: In children with high irritability, problems with sleep versus no sleep problems approached significance. Sleep scores for children with IQ<70 versus those with IQ≥70 were not statistically different. Both medications significantly reduced CSHQ problems with sleep. Risperidone performed significantly better than aripiprazole overall. However, there was no difference between the two in improved outcome for sleep latency and a trend for decreased night-time awakening.

112 **162.112** Effectiveness of Propranolol for Treating Anxiety and Aggression in Children and Adolescents with Autism Spectrum Disorder

I. K. Sagar-Ouriaghli[1], *K. Lievesley*[1], *J. Tarver*[1], *F. Fiori*[2] *and* ***P. Santosh***[1,2,3], *(1)Institute of Psychiatry, Psychology & Neurosciences, King's College London, London, United Kingdom, (2)Centre for Interventional Paediatric Psychopharmacology and Rare Diseases; Child and Adolescent Mental Health Services, South London and Maudsley NHS Foundation Trust, London, United Kingdom, (3)HealthTracker Ltd, Gillingham, United Kingdom*

Background: Autism spectrum disorder (ASD) is a multifactorial disorder, and currently, there are no routinely prescribed medications that can improve core symptoms in patients with ASD (Santosh and Singh, 2016). The current clinical practice is to target the symptoms of co-occurring disorders associated with ASD such as hyperactivity, irritability, anxiety, psychosis, depression, aggression, and/or repetitive behaviour. Anxiety and aggression management is critical in optimising outcomes in at least 40-50% of children and adolescents with ASD. Anecdotal evidence has pointed towards the beneficial effects of the prototypical beta-blocker propranolol for managing the symptoms of anxiety and aggression in children and adolescents with ASD; however, further clinical effectiveness studies are warranted to explore this.
Objectives: To assess clinical effectiveness of propranolol in reducing anxiety and aggressive symptoms in children and adolescents with ASD
Methods: This service evaluation project was approved by the South London & Maudsley NHS Foundation Trust, UK. All children with ASD treated in the Centre for Interventional Paediatric Psychopharmacology and Rare Diseases (CIPPRD), a national specialist service in the United Kingdom that specializes in the psychopharmacological management of complex disorders and rare diseases were screened to identify patients being treated with propranolol. From 180 children within the clinic, 27 were diagnosed with ASD and were prescribed propranolol - 4 of these were discharged from the clinic, resulting in 23 eligible children aged between 8-19 years. Parents and clinicians in the CIPPRD routinely complete a series of web-based questionnaires using the HealthTracker™platform, in order to capture information on clinical effectiveness of treatments used in routine clinical care.
Results: The mean daily dose of propranolol was 44.67+/-22.31mg and mean duration of use was 24.00+/-12.71 months. The pre- and post-treatment measures on the Profile of Treatment Response (POTR) measuring symptoms and side-effects, Clinical Global Impression scales, and Therapeutic Efficacy Index revealed a significant reduction in 'anxiety,' 'aggression,' and 'explosive rage' with propranolol treatment. The main side-effect was increased appetite. The mean CGI-Improvement scores for propranolol treatment was 1.61+/-0.78 and the Efficacy Index was 3.16+/-1.05, suggesting very good efficacy. The results show that 'emotional, behavioural, and autonomic dysregulation' (EBAD), is an important aspect in difficult-to-manage ASD, which responds to treatment with propranolol.
Conclusions: This study provides further supportive evidence for the use of propranolol for managing the symptoms of anxiety and aggression in children and adolescents with ASD. It also shows that beta-blockers can be used when managing EBAD in ASD with previously poor treatment outcomes. Given the current findings, further exploration for the use of propranolol for anxiety and aggression symptoms in children and adolescents with ASD is warranted.

113 **162.113** Immune Response to Pregnenolone Treatment in Adults with Autism Spectrum Disorder – Preliminary Analysis from an Open-Label Study

L. K. Fung[1], *J. Siebert*[2] *and A. Y. Hardan*[1], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)CytoAnalytics, Denver, CO*

Background:
Pregnenolone (PREG) is the precursor of endogenous pharmacologically active neurosteroids. We recently reported the results of an open-label trial of PREG in the treatment of adults with autism spectrum disorder (ASD). We found that PREG reduced the levels of irritability and associated aggressive behaviors as measured by the Aberrant Behavior Checklist – Irritability subscale (ABC-I). PREG was also found to be well-tolerated by study participants. We hypothesize that responders of PREG will have a different immune biosignature, as compared to non-responders.
Objectives:
To explore the association between response to PREG and plasma concentrations of immune biomarkers before and after 12-week trial of oral PREG.
Methods:
PREG was initiated at 50mg twice daily in weeks 1 and 2, then increased by 50mg twice daily every 2 weeks to a final dose of 250mg twice daily which was maintained from weeks 9 to 12. Primary outcome measure was the ABC-I. Response was defined as change of ABC-I of 7 or greater. The plasma levels of 62 cytokines and other immune biomarkers were measured by Luminex Multiplex Analyses (LMA; at the Human Immune Monitoring Center at Stanford University) before and after PREG treatment in our open-label trial in adults with ASD. LMA is a simultaneous analysis of multiple analytes from the same sample using differentially dyed beads. Two-tailed student t-tests were performed to compare selected pro-inflammatory cytokines between responders and non-responders. Multivariate analyses, including decision tree analyses and elastic net regression, of the immune biomarker data before and after PREG treatment were performed.
Results:
Twelve individuals with ASD (mean age 22.5 years) participated in this open-label study. PREG yielded improvement in the primary measure, ABC-I [17.4±7.4 at baseline; 11.2±7.0 at 12 weeks (p=0.028)]. Six participants were found to be responders to PREG treatment, while the rest of the six participants did not reach the responder criteria. Preliminary decision tree analysis suggested that participants can be cleanly classified into responders and non-responders based on baseline levels of IL-31 and fibroblast growth factor β (FGFβ). Targeting the cytokines known to have increased levels in individuals with ASD (IL-1β, IL-6, IL-8, IFN-γ, eotaxin and MCP-1), the levels of the selected cytokines at baseline and post-treatment were statistically indistinguishable. In exploring the plasma levels of other immune biomarkers in the open-label PREG study, the responders were found to have significantly lower levels of plasminogen activator inhibitor 1 (PAI-1) post-treatment, compared to non-responders (p=0.042). Elastic-net regression did not yield meaningful results on either pre- or post-treatment LMA data.
Conclusions:
Preliminary LMA analysis found that specific immune biomarkers were associated with reduction of ABC-I. These findings suggest that effectiveness of PREG might be related to baseline levels of IL-31 and FGFβ. Additional research is needed to replicate these findings in a controlled trial.

114 **162.114** Improvement of Receptive Language but Behavioral Worsening with Combined Donepezil and Choline Treatment

L. Gabis[1], *R. Ben-Hur Chayu*[2] *and D. Ben Shalom*[3], *(1)Sheba Medical Center, Rehovot, Israel, (2)Child Development, Sheba Medical Center and Ben Gurion University, Tel Hashomer, Israel, (3)Linguistics and Cognitive studies, Ben Gurion University, Beer Sheva, Israel*

Background: Social communication impairment is a core feature of autism spectrum disorder (ASD) with no effective pharmacologic treatment. Donepezil treatment was evaluated as such and showed to have a minimal effect on language in children with autism.
Objectives: In order to enhance the effect of Acetyl Choline activity and inhibition, we added the substrate of Choline to Donepezil treatment in a double blind randomized study of 60 children and adolescents with Autism Spectrum Disorder. Efficacy, safety, and tolerability of oral Donepezil + Choline (D&C) combination were assessed.
Methods:
This study was a 9 months randomized, double-blind, placebo-controlled trial of 12 weeks incremental and add- on oral D&C in youth with ASD, preceded by 3 months baseline evaluation and followed by 6 months of wash- out, with subsequent follow up. Study participants were youth between the ages of 5-16 years with ASD, randomized to active drug or placebo in a 1:1 ratio, with the target dose Donepezil 5 mg + Choline as a crushed mixture. Donepezil was administered to the treatment group during the first 12 weeks (2.5 mg/day increased to 5 mg/day after 2 weeks). The Choline dietary supplementation (350mg) was added for the last 4 weeks**,** both crushed to powder by the pharmacy. Follow up was performed at three months and at nine months (after 6 months wash-out). Placebo powdered tablets were provided at in the same amounts and schedules as the control group. The primary outcome measure of efficacy was language measure. Secondary measures included adaptive functioning as measured by Vineland subscales, executive function measured by BRIEF, and social – behavioral skillsÂ measured using ATEC and CGI. Before removing the randomization, both examiner and parent reported his impression about group attendance (placebo vs. D&C). At nine months, the placebo group was notified and continued open- label D&C treatment by same protocol. The one arm crossover follow ups will be reported separately.
Results:
Sixty patients were enrolled (D&C = 29, placebo = 31, age 9.5 years + 3.1, 73% male and IQ 60 + 25). There were no significant differences at baseline between groups in all demographic and clinical variables. Six patients did not continue after initial evaluation due to compliance issues or urgent need for psychotropic medication, 6 did not complete the study (3 due to side effects), 48 completed treatment and 46 completed washout measurements. The frequency of adverse events was high (52%), with no significant difference between groups. However, there were significant differences in the type**s** of side effects with more sleep disturbance, GI side effects, headache and slightly more agitation in the treatment group. 62% of parents correctly guessed group belonging. The daily personal skills**,** as measured by Vineland subscale, and health/ physical behavior of the treatment group worsened significantly compared to placebo. After wash- out, all differences diminished except significant and persistent improvement in receptive language skills (p= 0.003).
Conclusions: Combined Donepezil- choline treatment may improve language skills in youth with ASD, however, temporary worsening of behavior is a significant side effect of this treatment.

115 **162.115** Metformin for Medication-Associated Weight Gain in Youth with Autism Spectrum Disorder

L. K. Wink[1], *K. C. Dominick*[2], *E. Pedapati*[3], *E. Fox*[1], *C. Buck*[1], *R. Adams*[1], *L. McClellan*[1] *and C. A. Erickson*[1], *(1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Division of Psychiatry, Cincinnati Children's Hospital Medical Center, CINCINNATI, OH, (3)INSAR Cincinnati Children's Hospital Medical Center, Anderson, OH*

Background:
Aggression, self-injurious behavior, and severe tantrums (referred to as “irritability”), are common targets of pharmacotherapy in youth with autism spectrum disorder (ASD). Placebo controlled trials have demonstrated the efficacy of risperidone and aripiprazole for treatment of ASD-associated irritability, resulting in FDA-approval of these medications. Unfortunately, antipsychotic treatment is associated with weight gain, changes in glucose and lipid metabolism, and poor cardiovascular outcomes, and youth with ASD may be at particular risk for these adverse effects. Emerging evidence suggests that metformin may have a role in treating medication-associated weight gain in youth with ASD.
Objectives:
In this study, we completed a retrospective chart review of youth with ASD treated with metformin targeting medication-associated weight gain with goal of deepening our understanding of the impact of this drug in our patient population.
Methods:
Via systematic review of electronic medical records, we identified 57 individuals with ASD age 2-20 years treated with metformin between July 2012 and February 2016. Demographic data, concomitant medications, metformin treatment duration, metformin dose, and BMI z-score at initiation and end of treatment were collected. Paired sample *t*-tests were used to evaluate change in BMI z-score with metformin treatment. A series of repeated ANOVA’s tested age, sex, duration of treatment, dose (initial and final) as possible moderators of BMI z-score change.
Results:
Participants were primarily male (81%), Caucasian (88%), and suffered from cognitive impairment (67%) and a disruptive behavior disorder (95%). Mean age was 13.6 (SD=2.7) years, mean duration of treatment with metformin was 1.96 (SD=1.7) years. Metformin doses ranged from 250 mg to 2000 mg, with mean starting dose of 772 mg (SD=361) and mean final dose 1173 mg (SD=536 mg). Ninety-one percent of participants received concomitant treatment with an antipsychotic throughout duration of metformin treatment, and nearly half received treatment with an antidepressant, alpha-2 agonist, or sleep aid. There was no change in frequency of concomitant medications by drug class over duration of study (all McNemar tests *p*s>0.15).
Mean baseline BMI z-score was 1.85 (SD=0.6), and mean final BMI z-score was 1.81 (SD=0.7). There was no significant change in BMI z-score between time points (*t*-value=0.58, *p* ns). Only metformin starting dose moderated change in BMI z-score from start to finish (F (1, 55)=4.25, p<0.05). Participants with metformin starting dose less than 1000 mg had no significant change (paired sample *t*-value=1.35, *p*>ns) in BMI z-score from start (M=1.63 (SD=0.7) to finish (M=1.72 (SD=0.7), whereas participants treated with starting dose 1000 mg or greater demonstrated significantly decreased BMI z-score (paired sample *t*-value=1.98, *p*>0.05) from start (M=2.06 (SD=0.5) to finish (M=1.85 (SD=0.6).
Conclusions:
In this naturalistic sample, metformin treatment appears to stabilize BMI z-score, but does not result in significant reduction of BMI z-score. Treatment dose appears to potentially moderate the effect of metformin, with higher starting doses resulting in greater reduction in BMI z-score over the course of treatment. Further work is indicated to determine the safety and efficacy of metformin as a treatment for medication-associated weight gain in youth with ASD.

116 **162.116** Microbiota Transfer Improves Gastrointestinal and Autism Symptoms: An OPEN Label Study

*D. W. Kang[1], **J. B. Adams**[1], A. C. Gregory[2], T. Borody[3], L. Chittick[4], A. Fasano[5], A. Khoruts[6], E. Geis[1], J. Maldonado[1], S. McDonough-Means[7], E. Pollard[1], S. Roux[4], M. J. Sadowsky[6], K. Schwarzberg Lipson[8], M. B. Sullivan[9], J. G. Caporaso[8] and R. Krajmalnik-Brown[1], (1)Arizona State University, Tempe, AZ, (2)Ohio State University, colombus, OH, (3)Centre for Digestive Diseases, Five Dock, Australia, (4)Ohio State University, Colombus, OH, (5)Massachusetts General Hospital, Cambridge, MA, (6)University of Minnesota, Minneapolis, MN, (7)Integrative Developmental Pediatrics, Tucson, AZ, (8)Northern Arizona University, Flagstaff, AZ, (9)University of Arizona, Tucson, AZ*

Background: Autism Spectrum Disorder (ASD) is a complex neurobiological disorder that impair social interactions and communication and lead to restricted, repetitive and stereotyped patterns of behavior, interests, and activities. The causes of this disorder remains poorly understood, but gut microbiota, the 10^{13} bacteria in the human intestines, have been hypothesized to impact ASD because ASD-afflicted children often suffer gastrointestinal (GI) problems that correlate with ASD severity, and many previous studies have reported abnormal gut bacteria in children with ASD. The gut microbiome-ASD connection has been tested in a mouse model of ASD where the microbiome was mechanistically linked to abnormal metabolites and behavior. Similarly, a study of children with ASD found that oral non-absorbable antibiotic treatment improved GI and ASD symptoms, albeit temporarily. Here, we conducted a small open label clinical trial to evaluate the impact of Microbiota Transfer Therapy (MTT) on GI and ASD symptoms of 18 ASD-diagnosed children.
Objectives: Determine the safety and possible efficacy of MTT for treating GI and ASD symptoms.
Methods: An open-label clinical trial of MTT involved a two-week antibiotic treatment, a bowel cleanse, and then an extended duration of fecal microbiota transplant (FMT) using a high initial dose followed by daily lower maintenance doses for 7-8 weeks.
Results: The Gastrointestinal Symptom Rating Scale (GSRS) revealed an approximately 80% reduction of GI symptoms at the end of treatment, including significant improvements in symptoms of constipation, diarrhea, indigestion, and abdominal pain, and all those benefits remained improved at 8 weeks after treatment. Similarly, clinical assessments showed that behavioral ASD symptoms improved significantly, and remained improved at 8 weeks after treatment ended.
Conclusions: This exploratory, extended-duration treatment protocol thus appears to be a promising approach to improve GI and behavioral symptoms of ASD. Improvements in GI symptoms and ASD symptoms persisted for at least 8 weeks after treatment ended, suggesting a long-term impact.

117 **162.117** Multi-Site Randomized Controlled Trial of Fluoxetine in Children and Adolescents with Autism (FAB)

Background:
Selective serotonin reuptake inhibitors (SSRIs) are commonly prescribed 'off -label' for children with Autism Spectrum Disorder (ASD) despite caution regarding their use. To date, clinical trials examining the use of SSRIs in ASD have been limited by small sample sizes and inconclusive results. The efficacy and safety of SSRIs for moderating repetitive stereotyped mannerisms in children with ASD is yet to be examined.
Objectives:

1. To determine the efficacy of low- dose fluoxetine compared to placebo, for reducing the frequency and severity of restricted, repetitive and stereotypic behaviours in children and adolescents with an Autism Spectrum Disorder (ASD).Â
2. To assess the safety of using low- dose fluoxetine.Â
3. To explore the relationship between the effectiveness of low- dose fluoxetine and the serotonin transporter genotype.

Methods:
The FAB study is a multi-site randomized controlled trial. As at October 2016, 142 participants aged between 7.5-17 years with a confirmed DSM-IV-TR diagnosis of ASD have been recruited and randomized over a 6 year period. Following pre- assessment, eligible participants are randomized to either placebo or active fluoxetine groups with medication being titrated upwards over a four-week period. Reponses to medication are monitored on a weekly/fortnightly basis using the Clinical Global Impressions Scale (CGI). The primary outcome measure is the Children's Yale-Brown Obsessive Compulsive Scale- Modified for Pervasive Developmental Disorders (CYBOCS-PDD) at 16 weeks. Secondary outcome measures include the Aberrant Behaviour Scale (ABC), Spence Children's Anxiety Scale Parent version (SCAS-P) and the Repetitive Behaviours Scale (RBS-R) also at 16 weeks. Participants were also invited to undergo genetic testing for SLC6A4 allele variants via a cheek swab. Outcome will be compared between the groups using linear (continuous outcomes) and logistic (binary outcomes).
Results:
Please note, at the time of this abstract submission results were not available but will be available during the conference time period in May 2017.

Conclusions:
The FAB study is the first adequately powered randomized controlled trial to specifically investigate the efficacy and safety of low dose fluoxetine for restricted, repetitive and stereotyped behaviours in children with ASD.

118 **162.118** Open Label Clinical Trial of Sulforaphane in School-Aged Children with Autism with Metabolomic Biomarkers

S. Bent[1], *T. Warren*[2], *F. Widjaja*[3], *K. Dang*[1], *J. W. Fahey*[4], *J. Kinchen*[5], *J. Buckthal*[6], *B. S. Cornblatt*[7] *and* ***R. Hendren***[8], *(1)University of California, San Francisco, San Francisco, CA, (2)Psychiatry, University of California, San Francisco, San Francisco, CA, (3)UCSF, San Francisco, CA, (4)Johns Hopkins University, Baltimore, MD, (5)Metabolon, Inc., Durham, NC, (6)Metabolon, Inc., Laguna Hills, CA, (7)Nutramax Laboratories Consumer Care, Inc., Edgewood, MD, (8)University of California San Francisco, San Francisco, CA*

Background:
Children with ASD have been found to have elevated markers of oxidative stress and impaired antioxidant function compared to children without autism. A previous study has shown a significant improvement in ASD symptoms after supplementing children with autism with sulforaphane; known to cause transcriptional up regulation of genes that control oxidative stress. This study reports changes in behavior of children with autism following sulforaphane supplementation.
Objectives:
The objective of this study was to explore parent- and teacher-reported changes in behavior of children with ASD following sulforaphane supplementation. A second objective was to examine the metabolomic profiles of children with ASD who supplemented with sulforaphane, comparing responders and non-responders to their siblings who did not supplement, in order to look for biomarkers that might better indicate the mechanism by which sulforaphane acts in the body.
Methods:
This was an open-label, 12-week study examining the effects of sulforaphane in children ages 5 to 22 years with clinically diagnosed autism. All subjects were enrolled at the Oak Hill School in San Anselmo, California, and had a diagnosis of ASD, or were siblings of enrolled students. The clinical diagnosis of autism was established by meeting *DSM-IV* criteria. The ASD group was given a dose of sulforaphane determined by weight, while siblings did not take the supplement. Behavioral assessments of children with ASD were collected using the Aberrant Behavior Checklist (ABC) and the Social Responsiveness Scale (SRS) at screening and close-out (week 12) from parents and teachers. Urine samples were collected from the ASD group and from their siblings, and metabolites were analyzed and compared.
Results:
Of 20 ASD subjects enrolled, five dropped out from the study because of the inability to ingest the sulforaphane tablets. Subjects with a decrease of four or more points on the ABC (n=8) were identified as responders to sulforaphane. Responders exhibited a 26.7-point decrease in total ABC ($p<0.001$) and an 18.6-point decrease in SRS ($p=0.001$) at close-out (Week 12), compared to non-significant increases of 2.9 points in ABC and 0.9 points in SRS for non-responders. Metabolomics of all subjects and siblings showed that responders had higher levels of sulforaphane-cysteine, sulforaphane, and sulforaphane N-acetyl-cysteine in their urine after supplementing than did non-responders. There were no adverse effects reported during the study and at the one-month follow-up after completion.
Conclusions:
Sulforaphane was well tolerated and seems to improve ASD symptoms as measured by ABC and SRS. There may be a subgroup of children with ASD who show a strong response to sulforaphane, while others may not show a significant response based on metabolic profile. Metabolomic analysis confirms different metabolites found in urine of responders versus non-responders in this study, and would be a future direction to pursue in research on sulforaphane in children with ASD.

119 **162.119** Psychopharmacologic Intervention for Adults with Autism Spectrum Disorder: A Systematic Literature Review

***L. Taylor**, De Crespigny Park, Denmark Hill, King's College, London, London, United Kingdom; School of Psychology, University of Western Australia, CRAWLEY, Australia*

Background: The increased recognition of psychiatric and behavioural disorder in adults with autism spectrum disorder (ASD) has been associated with more frequent use of psychopharmacologic intervention in this population. Indeed, evidence from recent research indicates that up to 81% of adults with ASD take at least one psychotropic medication, with a high proportion of these individuals taking three or more medications. The primary indicator of psychotropic medication use in this population is behavioural disturbance, often in the absence of a diagnosed psychiatric disorder. However, limited evidence supports the effectiveness of these interventions for adults with ASD.
Objectives: The objective of this review was to synthesize the literature that has explored the efficacy of psychotropic medication in reducing behavioural disturbance in adults with ASD. A secondary objective was to describe the strength of the evidence for psychopharmacologic intervention in this population.
Methods: An electronic database search of PubMed was conducted in January 2015. The literature search yielded 366 articles. Articles were included in the review if they met the following criteria: (1) the article described at least one adult (>18 years) with (a) a confirmed diagnosis of ASD, Autistic Disorder, Asperger's Disorder or Pervasive Developmental Disorder-Not Otherwise Specified, or (b) reported clinical features typical of ASD, (2) the article described at least one outcome measures, and (3) the article was published in English in a peer-reviewed journal.
Results: Â Forty-three studies were included in the analysis. The results indicated that Only two psychotropic medications, risperidone and fluoxetine, met Reichow et al.'s (2008) criteria for promising evidence-based interventions for reducing irritability and repetitive behaviour associated with ASD in adults. Evidence from two placebo-controlled trials, in addition to one case series, indicated that fluoxetine results in a reduction in repetitive and obsessive-compulsive behaviour in adults with ASD. Similarly, the results of two placebo-controlled trials, in addition to two small open-label trials, indicate that risperidone may be effective in reducing repetitive, aggressive and self-injurious behaviour in adults in this population. The efficacy of all remaining agents has been investigated in case studies or small open label trials, so the evidence base for these interventions cannot be established.
Conclusions: Despite high rates pf psychopharmacologic intervention in ASD, there are few psychotropic medications which can be considered to have an established evidence base. Given the lack of evidence-base for psychopharmacologic intervention for adults with ASD, there is an imperative to conduct placebo-controlled trials that measure the safety, efficacy and tolerability these interventions when used to treat features associated with ASD. It is also necessary to establish clinical guidelines governing the use of psychopharmacology in this population.

120 **162.120** Systematic Screening of Pharmacological Compounds in Human Pluripotent Stem Cells-Derived Neurons to Identify Patient-Oriented Treatment for Autism: A Proof of Concept

*H. Darville[1], A. Poulet[2], F. Amsellem[3], L. Chatrousse[1], J. Pernelle[1], C. Boissart[1], T. Bourgeron[4,5], M. Peschanski[6], **R. Delorme**[3] and A. Benchoua[7,8], (1)iSTEM, Evry, France, (2)iStem, Evry, France, (3)Institut Pasteur, Paris, France, (4)Neuroscience, Institut Pasteur, Paris, France, (5)Université Paris Diderot, Paris, France, (6)iSTEM, Corbeil-Essonnes, France, (7)Neuroplasticity and Therapeutics, CECS/ISTEM/AFM, Evry, France, (8)CECS/ISTEM/AFM, Evry-cedex, France*

Background:
Autism spectrum disorders (ASD) affect millions of individuals worldwide but the heterogeneity of the symptoms lead to therapeutic intervention choices often based on 'trial and error'. A versatile yet relevant cellular model developed to rationally screen among hundreds of therapeutic options in a patient-oriented manner would help improving clinical practice.
Objectives:
Here we investigated whether neurons differentiated from pluripotent stem cells can provide such a tool using ASD associated to *SHANK3* haploinsufficiency as a proof of principle.
Methods:
Pharmacological FDA approved compounds (N=205) were screened first for their potential to increase *SHANK3* mRNA content in neurons differentiated from control human embryonic stem cells using Taqman probes in a fully automated process. Successful compounds were then challenged for efficacy at correcting pathological phenotypes in neurons differentiated from individuals with deleterious *SHANK3* point mutations using the induced pluripotent stem cell derived from the patients.
Results:
Among the 205 compounds tested, 15 increased significantly SHANK3 expression, including 6 FDA-approved drugs. Further investigation demonstrated that 2 of the latter, lithium and valproic acid, efficiently increased SHANK3-containing synapses and neuronal connectivity. These 2 drugs were efficient at correcting functional phenotypes associated with *SHANK3* haploinsufficiency in patient-derived neurons. Lithium pharmacotherapy was then tested in one patient. After one year, a clinically-significant decrease in symptom severity has been observed.
Conclusions:
Pluripotent stem cells-derived neurons can help define more specific treatment for autism by focusing on gene or pathway correction rather than on symptoms. They allow the pre-screening of hundreds of therapeutic options on patients-derived neurons, thus increasing the chance of success of a candidate treatment.

121 **162.121** The Effects of Four Weeks of Intranasal Oxytocin on Social Responsiveness and Repetitive and Restricted Behaviors in Autism Spectrum Disorders: A Randomized Controlled Trial

S. Bernaerts[1,2]*, C. Dillen*[1]*, J. Steyaert*[2,3] *and K. Alaerts*[1,2]*, (1)Department of Rehabilitation Sciences, University of Leuven, KU Leuven, Leuven, Belgium, (2)University of Leuven, Leuven Autism Research consortium, Leuven, Belgium, (3)Department of Neurosciences, University of Leuven, KU Leuven, Leuven, Belgium*

Background:
Autism spectrum disorders (ASDs) are characterized by impairments in social communication and interaction and repetitive and restricted behaviors. To date, no pharmacological treatment exists targeting the core symptoms of ASD, yet the past years, the pharmacological use of a neuropeptide, called oxytocin (OT), has gained increasing interest from the research community to explore its potential for elevating the core social deficits in ASD. OT is known to play a pivotal role in a variety of complex social behaviors by promoting a prosocial attitude and interpersonal bonding. Previous studies showed that exogenously administered OT can affect trust and feelings of attachment insecurity, reduce repetitive and restricted behaviors and increase social cognition.
Objectives:
A double-blind randomized placebo-controlled trial with thirty-four young adult men with ASD (17 OT/ 17 Placebo (PL)) was conducted to assess behavioral effects of OT therapy (i) at baseline; (ii) after four weeks of daily nasal spray administration; and (iii) four weeks post-treatment to assess potential retention effects.
Methods:
Doses of 24 IU oxytocin (Syntocinon®, Sigma-tau) or placebo nasal spray (PL) (saline natrium-chloride solution) (3 puffs in each nostril) were administered daily for four weeks.
Primary outcome measures to assess treatment effects included the Social Responsiveness Scale (SRS) and the Repetitive Behavior Scale – Revised (RBS-R). Secondary outcome measures included assessments of changes in attachment (State Adult Attachment Scale (SAAM); Inventory of Parent and Peer Attachment (IPPA)); assessments of changes in mood state (Profile of Mood States questionnaire (POMS)); and assessments of changes is reports of quality of life (World Health Organization Quality of Life questionnaire (WHOQOL)). All participants were characterized using IQ and ADOS-scales. Thirty-four male individuals with ASD are currently enrolled in the study and recruitment is still ongoing.
Results:
After four weeks of OT nasal spray administration, self-reports on repetitive and restricted behaviors (RBS-R) were shown to be tentatively reduced in the OT group, not in the PL group ($F(1, 31)=3.83$, $p=0.06$) and of note, the effect of OT persisted until one month after the treatment (retention: $F(1, 31)=4.02$, $p=0.05$). Immediately after the four weeks of treatment, we found no significant effects of OT on social functioning as assessed using self- and informant-based reports of the SRS. Interestingly however, at the retention session, a significant effect was revealed for the informant-based SRS ($F(1, 22)=4.90$, $p=0.04$), indicating that clear improvements in social responsiveness emerged one month after cessation of the actual treatment (specifically for reports of social motivation ($F(1, 22)=4.71$, $p=0.04$) and social communication ($F(1, 22)=7.39$, $p=0.01$)).
For the secondary outcome measures, only tentative effects were revealed, indicating improvements in self-reports of attachment immediately after the four-week treatment ($F(1, 32)=3.32$, $p=0.08$) (IPPA) and improvements in the experience of social relationships at the retention session one-month post-trial ($F(1, 31)=3.07$, $p=0.09$) (WHOQOL).
Conclusions:
The observed improvements after four weeks of daily treatment with intranasal OT in our primary outcome measures (assessing social responsiveness and repetitive and restricted behaviors) indicate that OT can induce long-term behavioral changes in individuals with ASD that outlast the time of intervention.

122 **162.122** The Effects of Oxyotcin on Socially Rewarded Learning in Autism Spectrum Disorder

A. T. Wang[1]*, S. Soffes*[2]*, J. Zweifach*[2]*, L. Soorya*[3]*, J. D. Buxbaum*[1]*, A. Kolevzon*[1] *and J. A. Bartz*[4]*, (1)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Ferkauf Graduate School of Psychology, Yeshiva University, Bronx, NY, (3)Rush University Medical Center, Chicago, IL, (4)Department of Psychology, McGill University, Montreal, QC, Canada*

Background: The neuropeptide oxytocin plays an important role in social cognition and behavior and has emerged as a promising candidate for targeting social impairment in ASD. While several studies have shown beneficial effects of oxytocin on core social deficits in ASD only a few studies have examined the underlying neural mechanisms. The social motivation hypothesis of autism posits that core deficits arise from an early failure to attach reward value to social stimuli. Despite converging evidence that important functional interactions exist between oxytocin and dopaminergic reward circuits, no studies have directly examined the effects of oxytocin on reward processing in ASD. Previous research has shown that, relative to typically developing children, those with ASD exhibit impairment in reward-related learning as well as reduced frontostriatal response to social reward (Scott-Van Zeeland et al., 2010).
Objectives: This study examined the acute effects of oxytocin on socially rewarded learning and the associated neural circuitry in ASD.
Methods: In a double-blind, placebo-controlled crossover study, 17 adults with ASD underwent functional magnetic resonance imaging (fMRI) after receiving a single dose (24 IU) of intranasal oxytocin or placebo on 2 days separated by 3-5 weeks. The fMRI paradigm, adapted from Scott-Van Zeeland and colleagues, was a probabilistic learning task that required participants to view fractal-like images and classify them into “Group 1” or “Group 2”. Social feedback (e.g., a smiling or sad face for correct and incorrect reward trials, respectively) was provided after each response to guide the learning of stimulus-response associations.
Results: Although the task was designed to allow for improvement in classification accuracy, participants’ performance remained at chance levels over the course of the placebo scan, suggesting a deficit in implicit learning consistent with Scott-Van Zeeland et al. Furthermore, we found no effect of oxytocin on implicit learning. At the neural level, social feedback was associated with activity in “social brain” regions, such as the fusiform gyrus bilaterally, the orbitofrontal cortex, and the inferior frontal gyrus (Brodmann’s Area 44), following both oxytocin and placebo administrations. No selective effects were observed for oxytocin relative to placebo in response to social feedback across both correct and incorrect trials. However, when examining the neural response to positive vs. negative social feedback (i.e., happy vs. sad faces), oxytocin yielded significantly greater activity than placebo in the striatum, the medial prefrontal cortex, and the fusiform gyrus.
Conclusions: These findings are consistent with recent work in healthy controls showing that oxytocin may selectively bias attention to positive social cues (Domes et al., 2013). While some studies suggest that oxytocin results in enhanced social brain activity more broadly in ASD, we observed a selective effect of oxytocin in response to happy faces following rewarded trials. The lack of improvement in implicit learning following oxytocin could reflect task difficulty or insufficient dosing or length of treatment. Future research should examine the effects of different doses of oxytocin, as well as sustained and augmentative treatment effects.

123 **162.123** Trends in the Use of Psychotropic Medication for Children with Autism Spectrum Disorders on Kentucky Medicaid

***W. D. Lohr**, Y. Feygin, G. C. Liu, M. J. Smith, M. D. Stevenson, D. W. Davis, P. G. Williams, C. Woods and J. Myers, Pediatrics, University of Louisville, Louisville, KY*

Background:
Children with Autism Spectrum Disorder (ASD) are often treated with multiple medications despite limited evidence of efficacy. Existing data of controlled trials of psychotropic medications (PM) show children with ASD have lower response rates than typically developing children and higher rates of side effects. The treatment of children with ASD with polypharmacy including antipsychotic medications (APM) is a public health concern important to providers and policy makers.
High rates of PM use for youth with ASD have been reported in several studies with increased trends in polypharmacy influenced by regional differences, age, and psychiatric comorbidity. Rates of polypharmacy in ASD are markedly higher for youth in foster care. However, studies are needed to document more recent trends.
Objectives:
This poster will examine recent trends of PM use, APM use, and interclass polypharmacy for children with ASD receiving KY Medicaid including those children in foster care. The influence of seizures and intellectual disability on these rates will also be examined.
Methods:
Medicaid claims from 2013-2015 for diagnosis of ASD were analyzed for children <18 years old and stratified by foster care, intellectual disability and seizure disorders. Polypharmacy was defined by interclass polypharmacy from at least 2 classes for ≥90 days with less than a 7-day gap.
Results:
The total number of youth < 18 with ASD on Kentucky Medicaid was 6952 in 2013, 7674 in 2014, and 8715 in 2015. The number of these youth treated with a PM for > 90 days was 2720 (39.1%) in 2013, 3727 (48.6%) in 2014 and 4186 (48.0%) in 2015. The number of youth treated with APM for > 90 days was 1308 (18.8%) in 2013, 1649 (21.4%) in 2014 and 1633 (18.7%) in 2015. The number of youth receiving interclass polypharmacy > 90 days was 1585 (22.8%) in 2013, 2179 (28.3%) in 2014, and 2392 (27.4%) in 2015. Less than half of children received psychosocial therapy.
All rates of PM, APM use, and polypharmacy are much higher for those children with ASD in foster care. For example, the rate of APM use for children 13 to 18 years old with ASD in foster care was 59.5% in 2015 compared to 27.1% for same aged children in Medicaid non-foster. Rates of polypharmacy with ≥ 4 medications are much higher for children with ASD and a diagnosis of seizures, (for 2015, 24.4% of children with ASD and seizures vs. 12.5% for children with ASD without seizures.) Rates of polypharmacy do not appear significantly influenced by the presence of intellectual disability.
Conclusions:
The rates of PM use and rates of interclass polypharmacy in youth with ASD on KY Medicaid are in line with estimates from other states but show a marked increase from 2013 to 2015. Rates of polypharmacy in ASD are influenced by the diagnosis of seizures but not intellectual disability. Continued monitoring for quality and safety indicators of PM use is needed for children with ASD on KY Medicaid and for those in foster care.

Poster Session
163 - Molecular and Cellular Biology
5:00 PM - 6:30 PM - Golden Gate Ballroom

124 **163.124** Autism-Linked Gene Products Form an Activity-Dependent Signaling Network at the Synapse

***S. E. Smith**, University of Washington, Seattle, WA*

Background: Among the hundreds of genes that contribute to autism risk, there is significant enrichment of genes expressed at the synapse. These genes include neurotransmitter receptors, scaffolds, and signal transduction molecules that bind to each other, often using protein-protein interaction motifs that can be modified by activity-inducible kinase activty. However, it is not clear how or if the protein products of these genes act together to perform a coordinated cellular function.
Objectives: To define activity-dependent changes among a protein interaction network composed of autism-linked, synaptic gene products.
Methods: We used quantitative multiplex immunoprecipitation and computational modeling of dynamic protein-protein interaction networks to define a "protein interaction network signature" associated with various experiemental manipulations, including neuronal stimulation (with KCl, glutamate, or specific agonists) or autism-linked genetic insults.
Results: We developed a synaptic multiplex assay based on the protein products of autism candidate genes, measuring ~400 binary interactions. Genes were selected based on genetic linkage with autism, synaptic localization, known interactions with other autism risk factors, and antibody availablilty. Using this technology, we first stimulated wild-type neurons with KCl or glutamate, and found activity-dependent changes in 20+ protein-protein interactions (PPIs) among this network of autism-linked proteins. We then performed a screen of 7 different mouse models of autism, and found altered protein-protein interactions in each ASD model (compared to wild-type littermates). Some altered PPIs were shared among models, some were unique to certain models. We found significant enrichment of activity-dependent PPIs among those that were identified in the ASD models. Focusing on 3 ASD models (Shank3, FMR1, & Ube3a overexpressing mice) we find genotype-specific differences in the PPI network response to activity. Principle component analysis shows seperation of experimental groups by both genotype and stimulation status, while our statistical analysis identified specific interactions driving PCA seperation. Finally, we treated FMR1 neurons with mGluR antagonists known to correct morphological and behavioral deficits, and observed corresponding changes in the PPI signiture, suggesting a mechanism of drug action.
Conclusions: The protein products of autism-linked genes form a dynamic, activity-dependent protein interaction network at the glutamate synapse. Disruption of information flow through a protein interaction network comprised of synaptic ASD-linked genes may contribute to autism pathogenesis.

125 **163.125** Autism-Related Mutations in the CEP290 Gene Alter Cell Signaling at the Primary Cilium.

M. Kilander *and Y. C. Lin, Hussman Institute for Autism, Baltimore, MD*

Background: Whole exome sequencing has identified mutations in the centrosomal protein CEP290 in individuals with autism. This large protein is a crucial component in the formation and function of the primary cilium and thus is one of the main risk genes in ciliopathies, e.g. Joubert Syndrome, Meckel Syndrome and Bardet-Biedl Syndrome. Interestingly, defects in cerebellar development and autistic traits are occasionally observed in these ciliopathy patients, however, in combination with severe multi-organ dysfunctions phenotypes. The primary cilium is a microtubule rich cell protrusion important for cell proliferation, differentiation and migration. Moreover, the primary cilium serves as the confined compartment for selective cell signaling and for cell-environment communication. Sonic Hedgehog (Shh) signaling, a biological pathway necessary for proper tissue development and maintenance, is preferentially localized to the primary cilium and is essential for proliferation of granule cell progenitors (GCP) during cerebellar development. However, to date little is known about the role of the primary cilium in neurodevelopment and in the establishment of mature neural circuits. In addition, the role of CEP290 in regulating brain function is still unclear.
Objectives: Here, we test the hypothesis that autism-associated mutations in CEP290 alter the function and molecular structure of primary cilium on cerebellar GCPs and ultimately affect their proliferation or differentiation during critical stages of brain development.
Methods: We employ live cell imaging, immunocytochemistry and molecular techniques to assess the changes in morphological, proliferative and cell signaling mechanisms caused by mutations in *CEP290*. Using the IncuCyte™ (Essen Bioscience) automated cell monitoring system we are able to perform detailed analysis on changes in proliferation and migration, as well as neurite formation and establishment in cell cultures expressing CEP290 mutant proteins.
Results: Overexpressed CEP290 wildtype as well as mutant proteins localize to the base of the primary cilium in NIH/3T3 cells and do not perturb ciliary formation. However, we find that cell proliferation rates are affected. When using a Shh response reporter, Glix8-EGFP, we observe that cells expressing CEP290 mutants show defects in response to Shh stimulation. Moreover, fluorescence recovery after photobleaching (FRAP) analysis of the mobility of proteins present in the primary cilium indicates that mutant CEP290 might play a role in disruption of the dynamics of the ciliary molecular signaling platform needed for proper Shh pathway activation.
Conclusions: Our present research suggest a link between autism-associated mutations in the *CEP290* gene and abnormal ciliary protein dynamics and Shh signaling. Thus, our ongoing investigation will aim to provide novel insight on the function of the primary cilium in neurological conditions and in regulating brain development.

126 **163.126** Comparative Expression Analysis of Autism-Associated Cadherin Superfamily Members

J. A. Frei[1]*, Y. C. Lin*[2] *and G. J. Blatt*[3]*, (1)Neuroscience, Hussman Institute for Autism, Baltimore, MD, (2)Hussman Institute for Autism, Baltimore, MD, (3)Hussman Institute for Autism, Inc., Baltimore, MD*

Background:
Cell adhesion molecules (CAMs) play crucial roles in neural circuit formation. The cadherin superfamily is one of the largest families of CAMs containing more than one hundred molecules, including classical cadherins type I and II, protocadherins, and atypical cadherins. The type I classical cadherin N-cadherin/CDH2 is the most well-studied member to-date. N-cadherin functions throughout the development of nervous system including neurite outgrowth, axon guidance, synaptogenesis, spine morphogenesis and plasticity. Although there is only little known about the function of other cadherins they have been strongly implicated in autism. A genome wide association study performed by the Hussman Institute for Human Genomics identified the classical cadherin type II CDH8, CDH9 and CDH11, the protocadherin family member PCDH9 and the atypical cadherin FAT1 as candidate risk genes. This suggests that cadherin signaling pathways could be disrupted and may display increased vulnerability in autism.
Objectives:
As a first step toward understanding the central role of cadherins in the etiology of autism, we focus on CDH8, CDH9, CDH11, PCDH9 as well as FAT1 and investigate the expression pattern of these cadherins in specific brain areas, cell types and their subcellular localization during development. This comparative expression analysis could provide novel insights into common and distinct functions of these cadherins in neural circuit formation.
Methods:
SDS-PAGE and Western blot analyses were performed to evaluate the protein expression of CDH8, CDH9, CDH11, PCDH9 and FAT1 in the developing mouse brain of embryonic day 14 (E14), postnatal day 0 (P0), P7, P14 and P21 and adult as well as in different brain areas. To analyze the cellular localization, primary neurons from different brain regions were cultured for 4 days *in vitro* and co-stained for cadherins and neuronal marker MAP2.
Results:
Temporal expression analysis in the developing mouse brain revealed increased expression of CDH8, CDH11 and PCDH9 from stages P7 to P14. In contrast, CDH9 expression peaked earlier in development between E14 and P7. The expression pattern of FAT1 was distinct from the other cadherins as its level was high at E14, decreased at P0 and was elevated again from P7 throughout P21. Analysis of specific brain areas showed that CDH8, CDH11 and PCDH9 were prominently expressed in the cortex, hippocampus and midbrain/striatum whereas FAT1 expression was restricted to the cerebellum. In line with these results, cellular localization of CDH8, CDH9, CDH11, PCDH9 and FAT1 expression was observed in the dendrites of cortical and cerebellar granule neurons, respectively.
Conclusions:
Our results revealed similar expression profile among CDH8, CDH11 and PCDH9, with distinct expression patterns for CDH9 and FAT1. A peak of cadherin expression between P7 and P14 as well as cellular localization in dendrites is consistent with the proposed functions of cadherins in dendritogenesis and synaptogenesis. The brain areas that revealed the highest cadherin levels overlap those reported as associated with autism. Taken together, this analysis highlights that cadherins of different subfamilies are expressed in a developmental time window and in brain areas that are often affected in autism.

127 **163.127** Cyfip1 Regulates Presynaptic F-Actin Polymerization and Synaptic Vesicle Release during Development.

C. Morrison[1], *K. Hsiao*[2], *D. L. Benson*[3] *and O. B. Gunal*[4], *(1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Rockefeller University, New York, NY, (3)Icahn School of Medicine at Mount Sinai, New York, NY, (4)Dept of Psychiatry, Rutgers New Jersey Medical School, Newark, NJ*

Background: Copy number variations in *CYFIP1* have been associated with multiple developmental brain disorders including autism spectrum disorders and schizophrenia. In Angelman and Prader-Willi syndromes chromosome deletions including *CYFIP1* have been associated with more severe symptoms than deletions sparing it. *CYFIP1* encodes a cytoplasmic protein, Cyfip1 (cytoplasmic FMRP interacting protein), which has two distinct functions:
i) Suppressing mRNA translation initiation.
ii) Promoting the generation of branched F-actin filaments at the plasma membrane as a component of the WAVE regulatory complex (WRC).
Objectives: While regulation of protein translation and actin polymerization are highly independent processes, they are both essential for the generation of normal synapses. Based on this we asked whether Cyfip1 coordinately regulates both processes when synapses are first forming.
Methods: To examine the role of Cyfip1 in synapse development, we assayed several parameters of synapse composition and function in hippocampus or in hippocampal neurons cultured from mice haploinsufficient for *Cyfip1* and compared the data to wild type littermates (all on a C57BL/6J background). Mechanistic studies were carried out in neurons cultured from rat hippocampus in which Cyfip1 levels were reduced using shRNA and then rescued with full length Cyfip1 resistant to the effects of the knockdown or Cyfip1 mutant constructs. Presynaptic function was assessed in field recordings of Schaeffer collateral synapses in CA1 or in cultured neurons using synapto-pHluorins or FM-dye uptake and release. Distribution of synaptic markers and F-actin were evaluated in fixed sections or in cultured neurons using immunostaining or tagged Phalloidin, respectively, using masks generated in Image J or SynD for image analysis. Differences between groups were compared using Prism. We are currently testing whether F-actin is driven into distinct or alternate patterns when Cyfip1 levels are reduced using super-resolution microscopy.
Results: Our data show that reducing levels of Cyfip1 serves to increase presynaptic terminal size and increase release probability in field recordings in mice hippocampal slices. shRNA knockdown of Cyfip1 that is restricted to presynaptic neurons recapitulates these effects in contrast to postsynaptic knockdown, which had no effect. The effects of Cyfip1 knockdown can be rescued by co-expression with a full length Cyfip1 protein or by a Cyfip1 mutant lacking the ability to suppress protein translation. A mutant unable to interact with WRC was unable to rescue the effects on synapses. The data observed also shows that in neurons having reduced levels of Cyfip1, F-actin intensity is greater at presynaptic terminals, but unchanged elsewhere in the neurons.
Conclusions: Our data support that in developing synapses Cyfip1 regulates synaptic vesicle cluster size and release probability via its participation in the WRC. Reduced Cyfip1 levels lead to a selective increase in the levels of presynaptic F-actin suggesting the recruitment of an alternate or compensatory actin polymerization pathway. Hence, pathway dependent small molecule inhibitors of actin polymerization may ultimately have therapeutic potential.

128 **163.128** Deciphering Regulatory Networks of Autism Risk Genes: High Resolution Networks Using Ex Vivo and In Vivo Models of Neurodevelopment.

R. Muhle[1], *W. Niu*[2], *K. Yim*[3], *S. Abdallah*[4], *G. Hill-Teran*[3], *M. Krenzer*[3] *and J. Noonan*[3], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Neurology, Univeristy of Michigan, Ann Arbor, MI, (3)Department of Genetics, Yale University, New Haven, CT, (4)School of Medicine, Yale University, New Haven, CT*

Background:
Recent gene discovery efforts in autism spectrum disorder (ASD) have identified regulatory genes such as the chromatin remodeler *CHD8* to be important new contributors to ASD etiology. These and other ASD risk-associated genes are enriched in co-expression networks built from studies of gene expression in human midfetal cortex, suggesting that ASD pathogenesis may result from perturbation of member genes of these regulatory networks. Recently, we demonstrated that CHD8 regulates other ASD risk genes in human brain and human neural stem cells (hNSCs). Strikingly, CHD8 target genes are enriched for ASD risk genes that regulate gene expression, such as *POGZ* and *CHD2*, and this targeting is also detectable in mouse cortex.
Objectives:
To investigate ASD risk associated regulatory networks with high temporal and spatial resolution, we have undertaken studies to globally map regulatory targets of ASD risk-associated chromatin modifiers at an early stage of human neurodevelopment, and in specific cell types and brain regions during mouse embryonic cortical development.
Methods:
We are mapping the binding sites of CHD8, POGZ, and CHD2 in hNSCs using ChIP-seq. To facilitate uniform ChIP-seq methods, we have incorporated epitope tags using genome editing. To characterize global CHD8 targets in the developing mouse brain, we have generated a mouse line with a cre-activated epitope tag to allow purification of CHD8 complexes from specific cell types using cre driver lines.
Results:
Genome editing in hNSCs integrates epitope tags into the endogenous loci of selected ASD risk genes consistently and robustly. ChIP-seq performed with antibodies directed to the epitope tag in CHD8-tagged cells verifies ChIP-seq performed with native antibodies, and identifies additional ASD risk genes as CHD8 targets. Genome editing in mouse embryos has generated a similar epitope-tagged Chd8 gene in mice, and we are engaged in on-going efforts to characterize the Chd8 binding sites in specific cell-types using ChIP-seq.
Conclusions:
Correlation of ASD risk gene target maps with each other, and with maps of specific active and/or repressive histone modifications, will identify genes and regulatory elements commonly targeted by other ASD risk genes that are impacted by the CHD8 regulatory network.

129 **163.129** Establishment of a Human Induced Pluripotent Stem Cell-Based Model of Kleefstra Syndrome

V. Roman[1], *S. Berzsenyi*[1], *J. Kobolák*[2], *Z. Ábrahám*[1], *H. X. Avci*[3], *I. Bock*[2], *B. Hodoscsek*[1], *E. V. Tárnokné*[1], *Z. Bekes*[1], *A. Chandrasekaran*[2], *A. O. Dorota*[4], *E. Varga*[2], *C. Nemes*[2], *B. Koványi*[1], *P. Dezső*[1], *T. Szél*[1], *L. Fodor*[1], *K. Németh*[5], *A. Balázs*[5], *A. Dinnyés*[2], *G. Levay*[1], *B. Lendvai*[1] *and J. Nagy*[6], *(1)Gedeon Richter Plc., Budapest, Hungary, (2)BioTalentum Ltd., Gödöllő, Hungary, (3)University of Szeged, Szeged, Hungary, (4)Szent István University, Gödöllő, Hungary, (5)Autism Foundation, Budapest, Hungary, (6)Molecular Cell Biology, Gedeon Richter Plc., Budapest, Hungary*

Background: Kleefstra syndrome (KS) is a rare genetic disorder that presents with a clinical phenotype including developmental delay, childhood hypotonia as well as distinctive facial features and may be associated with symptoms of autism spectrum disorder (ASD). Investigations using the induced pluripotent stem cell (iPSC) technique to model homogeneous populations of autism-related syndromes with well-known, monogenic backgrounds have been done in Fragile X, Rett, Phelan-McDermid and Timothy syndromes yet, there has been no report on in vitro modeling of KS.
Objectives: The aim of the present study was to establish a patient-derived in vitro disease model of KS accompanied by ASD (KS+ASD) using the iPSC technology.
Methods: Blood samples from a patient with KS+ASD carrying a premature termination codon mutation in the euchromatic histone lysine methyltransferase 1 (EHMT1) gene and two healthy subjects were taken after ethical approval and obtaining written informed consent. Diagnosis of the subjects was confirmed with ADOS and ADI-R. Mononuclear cells were isolated from the blood and genetically reprogrammed by a non-integrating gene delivery system. Differentiation of iPSCs into neuronal precursor cells and glutamatergic neurons was induced by a dual-SMAD inhibition protocol. Neurite morphology was measured by using an Operetta® High Content Imaging System (PerkinElmer). EHMT1 gene expression was investigated by using reverse transcription-quantitative PCR and Western blotting.
Results: The iPSCs showed embryonic stem cell morphology, normal karyotype, expressed pluripotency markers, and were able to spontaneously differentiate into cells of the three germ layers. iPSCs were successfully differentiated into neurons; this was demonstrated by neuron specific immunolabeling for MAP2 and NF200, electronmicroscopic visualization of synapses and electrophysiological detection of ionic (sodium, potassium) currents and action potentials. Determination of EHMT1 mRNA and protein expression demonstrated functional haploinsufficiency of the gene in the patient-derived cell cultures. iPSC-derived neuronal cell cultures were investigated in order to detect any substantial phenotypical differences between neurons originated from the KS+ASD case and neurotypical subjects. Neurite morphology was significantly compromised on multiple endpoints, including full and maximal length of neurites, number of neurite roots and endings in the KS+ASD condition in comparison to controls. The number of dendritic protrusions (filopodia or immature dendritic spines) was also reduced in the KS+ASD cultures compared to controls. Calcium currents evoked by glutamate did not differ between KS+ASD and controls however, administration of acetyl-choline induced larger calcium currents in the KS+ASD cell cultures. Gene expression patterns of 180 ASD-associated candidate genes were investigated by qRT-PCR, showing significantly altered expression of ARX, SIX3, and HCN1 genes relative to both controls.
Conclusions: The present iPSC-derived neuronal cultures represent an excellent in vitro model system for KS which may serve to obtain a better understanding of the underlying pathophysiology of KS and potentially that of ASD.

130 **163.130** Folic Acid Attenuates Fragile x Mental Retardation Protein Expression in Lymphoblastoid Cells By Activating DNA Methyltransferases

M. Junaid[1], *G. LaFauci*[2], *S. Kuizon*[1], *S. A. Rotondo*[1] *and S. Khan*[1], *(1)Developmental Biochemistry, New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (2)Developmental Biochemistry, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY*

Background: Autism spectrum disorders (ASDs) a group of highly heterogeneous, neurodevelopmental disabilities characterized by impairments in social interactions; deficits in verbal communication; and stereotyped, repetitive patterns of behaviors, have a current prevalence of 1 in 68 children. Reports have indicated that their etiology includes shared heritability and environmental factors, many of which remain elusive. Gender disparity, in that boys are 4.5 times more likely than girls to have an ASD, has been reported, suggesting the involvement of the X chromosome or of defects in genomic imprinting as plausible causes.
Objectives: We examined whether environmental epigenetic dysregulation during gestational development plays any contributing role in ASD. Specifically, we studied the effects of excessive folic acid (FA) supplementation on gene expression, which may play a role in fetal brain development, culminating in the onset of psychiatric conditions later in life. FA is an essential vitamin recommended during pregnancy for the prevention of neural tube defects in infants, which also induces epigenetic changes in gene-regulatory DNA sequences. Prescriptions for daily doses of FA, along with the presence of FA in over-the-counter medicines and energy drinks, together with enriched flour, are providing an excessive supply of FA, the physiological significance of which to the developing fetus is unknown. We have previously shown widespread dysregulation of gene expression in lymphoblastoid cells and in the C57BL mouse model after excessive FA supplementation.
Methods: In the present study, we used a combination of Western blot analyses, DNA sequencing following bisulfite treatment of genomic DNA, and enzyme assays in lymphoblastoid cells to identify the effect of excessive FA supplementation on the expression of the *FMR* gene.
Results: We found a time- and concentration-dependent decrease in the expression of the fragile X protein (FMRP) in response to FA supplementation. The decreased FMRP expression persisted for more than 48 hours after the withdrawal of FA, suggesting a possible lasting epigenome modification. Bisulfite sequencing of DNA from cells treated with low- and high-FA-supplemented cell cultures revealed the methylation of specific cytosine residues around the promoter region and transcription initiation site, indicating possible enzyme-mediated epigenetic modifications. Furthermore, we found that FA supplementation stimulated the activities of the DNA methyltransferases (DNMTs) 1, 3A, and 3B in lymphoblastoid cell extracts. These enzymes are involved in genomic DNA methylation.
Conclusions: These results demonstrate that FA supplementation of lymphoblastoid cells can cause stimulation of DNMTs that contain FA as coenzymes, leading to the increased methylation of specific cytosine residues in the gene promoter, thereby affecting protein expression.

131 **163.131** Gene Expression Profiling of PTEN Knockout Embryonic Cultured Neuron Shows Differential Expressed Genes Overlapping with Human Autism Candidate Genes Converging to Common Pathological Pathways

S. K. Cheung[1], *C. W. Wong*[1], *M. Y. Or*[1], *K. Y. Yang*[1], *Z. Dong*[2], *S. R. Badea*[3], *A. S. L. Cheng*[1], *B. Feng*[1], *K. W. R. Choy*[2], *R. C. C. Chang*[3], *S. K. W. Tsui*[1], *J. P. H. Burbach*[4] *and A. M. L. Chan*[1], *(1)School of Biomedical Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)Department of Obstetrics and Gynaecology, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (3)School of Biomedical Sciences, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, (4)Brain Center Rudolf Magnus, Department of Translational Neuroscience, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Patients with PTEN Hamartoma Tumor Syndrome (PHTS) harboring germ line PTEN mutations are known to be associated with autism spectrum disorders (ASDs). Studies in PTEN knockout mice demonstrated defects in different social interaction behaviors and the critical role of the phosphatidylinositol 3-kinase (PI3-K) signaling pathway. Neuromorphological studies showed that PTEN loss could lead to macrocephaly, enlarged neuronal cell bodies with hypertrophic dendrites and axonal tracts with increased number of synapses. Microarray and transcriptomic studies of neurospheres and neural tissues with PTEN loss were reported, respectively. However, the spectrum of downstream genetic elements which govern these neuromorphological and behavioral changes are still not fully characterized.
Objectives: We sought to determine the gene expression profile of PTEN knockout neurons in order to delineate possible molecular mechanisms underlying the neuropathological changes which lead to ASDs.
Methods: Primary neurons from E15.5 frontal cortices of wild-type and nestin-positive neural progenitor specific PTEN knockout mice were obtained and cultured for 5 days or 14 days. RNA samples were harvested from three control and three PTEN knockout neurons from littermate mice and analyzed by HiSeq transcriptome sequencing. In order to identify functional pathways affected by PTEN deletion, differential expressed genes (DEGs) were analyzed by gene ontology and pathways enrichment. To further investigate ASDs related pathway dysfunctions, DEGs with q-value <0.05 were compared with ASDs associated genes from the SFARI repository. Common genes from both lists were further analyzed by pathways enrichment.
Results: Over four hundred upregulated and around one hundred downregulated DEGs were identified comparing primary neurons with or without PTEN. Comparing all genes with q<0.05 and ASDs associated genes from the SFARI repository, almost two hundreds common genes were identified. Amongst these, thirty-one DEGs (including both up- and down-regulated) with fold change >2 were identified. Both gene lists converged at common functional pathways – focal adhesion and extracellular matrix-receptor interaction – which are also the top two enriched pathways within individual gene lists.
Conclusions: Â Our results show genes and related functional pathways that are perturbed with PTEN deletion in neuron. The comparison with ASDs associated genes helps us to focus on pathways that are commonly shared and affected in ASDs. Furthermore, these results can allow us to focus on genes and molecular pathways that may be responsible for the neuropathological changes. Their further functional characterization may generate novel targets for treating this neurodevelopmental disorder.

132 **163.132** Immune Cellular Phenotypes in Blood of Children with Autism Spectrum Disorder- a Pilot Study

S. Basheer[1], *S. C. Girimaji*[2], *S. Srinath*[3], *T. A.M.J van Amelsvoort*[4], *M. M. Venkataswamy*[5] *and V. Ravi*[5], *(1)National Institute of Mental Health and Neurosciences, Bangalore, Karnataka, INDIA, (2)Child and Adolescent Psychiatry, National Institute of Mental Health and Neurosciences, Bangalore, India, (3)NIMHANS, Bangalore, INDIA, (4)Maastricht University, Maastricht, Netherlands, (5)National Institute of Mental Health and Neurosciences, Bangalore, India*

Immune cellular phenotypes in blood of children with Autism spectrum disorder- a pilot study

Background:
Immunological abnormalities has been proposed to contribute to the pathophysiology of Autism Spectrum Disorder (ASD). In order to further elucidate this role, there is a need to study the immunological parameters in a comprehensive manner in ASD.
Objectives:
To study the immune cells in the peripheral blood of children with ASD in comparison with typical developing children.
Methods:
Twenty children (3 to 12 years of age) with ASD (DSM 5 criteria), were recruited from Child and Adolescent Psychiatry services, National Institute of Mental Health and Neurosciences, Bangalore. Age and sex matched twenty typically developing children were recruited as controls. The frequencies of various subsets of T cells, B cells, Monocytes, Natural Killer Cells and Dendritic Cells in the peripheral blood were characterised using 26 markers according to Human Immunology Project Consortium guidelines.
Results:
On preliminary analysis, we did not find any significant difference in subsets of Monocytes, Dendritic cells, Natural Killer cells and B cells in children with ASD when compared to typical developing children. There are few differences between the 2 groups in some of the subsets of T cells.
Conclusions:
There appears to be no difference in innate and humoral immune cell subsets in children with ASD in our study. Larger studies with higher sample size are required to validate this finding. Further, immune changes in T cells found in our initial analysis adds on to the previous literature that implicates T cell abnormalities in ASD. Final results of our study will be discussed.

133 **163.133** Innate Immunity in Autism Spectrum Disorders with Digestive Difficulties

M. Parellada[1], *M. J. Penzol*[2], *A. Alcon*[3], *K. McDowell*[4], *L. Monteagudo*[3], *J. C. Leza*[4] *and B. García-Bueno*[5], *(1)Hospital Gregorio Marañón, IiSGM, CIBERSAM, Madrid, Spain, (2)Child and Adolescent Psychiatry, Hospital Gregorio Marañon, CIBERSAM, IISGM, Madrid, Spain, (3)Hospital Gregorio Marañon, CIBERSAM, IISGM, Madrid, Spain, (4)Pharmacology, Universidad Complutense, Madrid, Spain, (5)Pharmacology, Universidad Complutense, CIBERSAM, Madrid, Spain*

Background:
Among patients with Autism Spectrum Disorders (ASD), there is a high percentage suffering from functional Gastrointestinal Disorders (fGID). Some fGID have been thought of reflecting a systemic proinflammatory status. Evidence from different sources points towards the possibility that systemic innate immune/inflammatory mechanisms play an important role in some cases of ASD. The link between these potentially linked physiopathological markers has been hardly studied.
Objectives:
To explore whether a subset of children with ASD and fGID shows abnormalities in the Toll-like receptors (TLR4) proinflammatory signalling pathway.
Methods:
This study included 53 subjects: 35 children with ASD (15 without- and 15 with fGID) and 20 controls (13 with and 5 without fGID). Mean age was 6.33 (range 3-10). 90 % were male. ASD was diagnosed following the AACAP recommendations (Volkmar, 2014) and fGID were assessed with the ROMA-III. Innate immune system: we assessed i and ii) Toll-like receptors 2 and 4, ii) Myeloid differentiation primary response gene 88 (MyD88), inicial element of this pathway and iv)TIR-domain containing protein TRIF (the sole adaptor of TLR3). Bivariate analyses were conducted in order to compare the levels of the different markers between subjects with ASD and without ASD and patients with and without fGID. ANCOVA analyses were conducted, with each marker as independent variable, and fGID status as covariate, to check for differences between ASD and no-ASD groups (fixed factor).
Results:
Kruskal-Wallis statistic showed that patients with ASD had higher PBMC levels of MyD88 than controls (31.77 and 17.72 respectively, chi-square 9.837, p=0.002). TLR-2 and TLR-4 were non-significantly higher in ASD than in controls (TLR2: 28.91 vs 23.28 p=0.071; TR4: 29.74 vs 21.67, p=0.071) and significantly higher in patients with fGID than in patients without fGID: TLR-4 (21.15 vs 36.65, p=0.000); TLR2 (30.76 vs 20.80 p=0.023). ANCOVA analysis confirmed that there was a diagnostic group effect on My88D and a fGID effect on TLR4 and TLR2 (See Table).
Conclusions:
There seems to be a systemic proinflammatory status in patients with fGID irrespective of the presence of a diagnosis of ASD. ASD patients, irrespective of the presence of fGiD, show makers of activation in very early steps of the innate immune system. It seems worth studying the immunological pathophysiology of ASD for the ultimate goal of finding distinct subgroups of patients that can benefit for specific interventions.
Bergeron JD,Â et al Dev Neurosci.Â 2013;35(6):504-15.
Lucas and Maes Mol Neurobiol 2013: 48:190–204

134 **163.134** Investigating E6AP Target Genes in Autism Spectrum Disorder

C. Amadei[1], *J. El Hokayem*[2], *M. Alessandri*[3] *and Z. Nawaz*[1], *(1)Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL, (2)John Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (3)University of Miami, Coral Gables, FL*

Background: ASD has been found to be associated with duplication or triplication of the UBE3A gene, which encodes for E6-associated protein (E6-AP, an E3 ubiquitin ligase). Mice with three copies of UBE3A exhibit core ASD features and humans with Dup15q share many symptoms with ASD. However, the few E6-AP ubiquitination substrates found do not explain ASD pathology. Our lab has identified and characterized E6-AP as a coactivator of estrogen receptor (ER) α signaling. Estrogens (E2) affect learning, memory and many other brain processes via ERs, which are transcription factors.
Objectives: This study tests the hypothesis that deregulation of E6-AP-mediated ERα transcriptional signaling in the brain leads to the development of ASD. The project aims are to identify E2-dependent E6-AP target genes in neurons and to study the role of these target genes in the pathogenesis of ASD. Identification of new molecular pathways that are transcriptionally regulated by E6-AP will broaden our understanding of ASD.
Methods: Potential E6-AP target genes were identified by microarray of MCF-7 breast cancer cells. Cells from the mouse neuroblastoma Neuro2a cell line or mouse hippocampus were cultured. Cells were transfected with E6-AP or had E6-AP knocked down by siRNA and then were treated with physiologically relevant doses of estrogen, the ER antagonist tamoxifen, or vehicle. Assays included western blot, co-immunoprecipitation, chromatin immunoprecipitation, luciferase assay, qRT-PCR, and microscopy.
Results: 1) E6-AP and ER colocalize in mouse HPC neurons. 2) E6-AP and ERα translocate to the nucleus of Neuro2a (N2a) cells upon E2 treatment. 3) E6-AP and ERα complex in N2a. 4) E6-AP is essential for E2-ER-activated Cyp26b1 gene expression (encoding for a retinoic acid (RA) catabolizing enzyme essential to the learning, memory, and neurological pathways that are impaired in ASD) in N2a and for RA receptor β expression (Figure 1). 5) Putative E2 Responsive Element (ERE) motif from the Cyp26b1 promoter is functional in a luciferase reporter gene assay (Figure 2). 6) ER and E6-AP are recruited to the Cyp26b1 ERE in N2a resulting in transcription of Cyp26b1. 7) The learning and memory gene for prostaglandin E receptor 4, PTGER4, is also E6-AP and E2-dependent. 8) The learning and memory gene for the NPY receptor, NPY1R, is also E6-AP and E2-dependent.
Conclusions: We have identified 3 memory and learning genes that are transcriptionally regulated by E6-AP and E2-dependent: Cyp26b1, PTGER4, and NPY1R. This is evidence that these 3 genes may be altered in ASD, leading to learning and memory symptoms. Cyp26b1 is crucial to the levels of retinoic acid, which is important for neurodevelopment, in the brain. PTGER4 allows phosphorylation of glycogen synthase kinase 3 (GSK3). GSK3 has a large role in apoptosis and has been implicated in neuropsychiatric disorders such as Alzheimer's Disease and Bipolar Disorder. The NPY receptor functions in cell signaling, increasing calcium signaling and blocking adenylate cyclase. Further testing in rodent models will be necessary to confirm these promising findings and elucidate the molecular pathways for pharmacologic manipulation.

135 **163.135** Metabolic Profiling of the Children's Autism Metabolome Project (CAMP)

***R. Burrier**, J. King, A. M. Smith, R. Alexandridis, P. West, D. Sugden, M. Ludwig, L. Feuling and E. Donley, Stemina Biomarker Discovery, Madison, WI*

Background:
ASD is a complex spectrum of neurodevelopmental disorders with heterogeneous underlying genetic, metabolic, and environmental causes. The CAMP (ClinicalTrials.gov Identifier NCT02548442) study, the largest clinical study using metabolomics based methodologies, is being conducted to validate biomarkers identified in three previous studies of banked blood samples and to better understand the metabolism of children with ASD. Metabolomic analyses of ASD may be useful in identifying biomarkers that can provide insight into the role that biochemical disorders, the gut microbiome, dietary and environmental factors play in ASD. The metabolic signatures of ASD can be useful in parsing the broad autistic spectrum into more homogeneous and clinically significant subtypes. Better understanding of metabolic subtypes or metabotypes of ASD can lead to early diagnosis, development and selection of more precise therapeutic intervention, as well as better understand of the efficacy of current interventions within metabotypes.
Objectives:
Conduct broad, discovery-based metabolomics profiling of CAMP subjects to reveal predictive metabolic signatures and discover metabolic subtypes of ASD. Identify metabotypes which can identify at least 50% of the ASD patient samples with a positive predictive value (PPV) of greater than 90%. Validate the metabolites identified as potential biomarkers of metabotypes of ASD in previous studies in the CAMP study.
Methods:
Plasma was obtained in sodium heparin tubes from children aged 18 to 48 months. Samples were analyzed using 4 orthogonal LC/HRMS-based methods as well as GC-MS to measure a broad range of metabolites through both targeted and non-targeted metabolomics methods. The patient samples were split into a training set of samples utilized for discovery profiling and a test set used for evaluation of the diagnostic signatures discovered in the training set. Univariate, multivariate and machine learning methods were applied to the training set to identify the most predictive set of metabolic features capable of classifying plasma samples as being from ASD or typically developing (TD) children. The molecular signatures were evaluated in the test set to determine their classification performance.
Results:
The metabolomics analysis of the 1500 CAMP subject samples is currently underway. In three separate clinical studies, comprising nearly 500 ASD and TD individuals, we demonstrated that metabolic profiling can be used to identify biomarkers associated with ASD as well as to elucidate metabotypes of ASD. These signatures contained both previously reported metabolic changes associated with ASD as well as novel, unreported changes. This poster will present results from the analysis of CAMP samples and potential of metabolites to discriminate ASD from non-ASD individuals.
Conclusions: Applying a paradigm such as this to identify metabolic signatures associated with ASD and elucidate their biochemical implications may be useful in developing diagnostic tests to detect ASD in children at an earlier age and for improving outcomes through personalized treatment. This approach will provide novel information on the biochemical mechanisms involved in ASD and the potential to identify targets for new therapies designed to treat the unique metabolic profile of the metabotype of the individual.

136 **163.136** Modeling Motor Neuron Deficits in a Family with Phelan-Mcdermid Syndrome and Autism Spectrum Disorder

***S. S. F. Gau**[1], C. Chou[2] and H. C. Kuo[3], (1)Psychiatry and Medical Genetics, National Taiwan University of Hospital & College Medicine, Taipei, Taiwan, (2)Psychiatry and Medical Genetics, NATIONAL TAIWAN UNIVERSITY HOSPITAL & COLLEGE OF MEDICINE, Taipei, AB, Taiwan, (3)Institute of Cellular and Organismic Biology, Academia Sinica, Taipei, Taiwan*

Background:
Several studies have found copy number variation (CNV) plays a role in autism spectrum disorder (ASD), especially rare CNV which has been found to carry larger effects than common variations.
Objectives:
This work aims to identify the pathological impact of ASD-related CNVs found only in the cases especially in a family with Phelan-Mcdermid Syndrome (PMS) and ASD harboring *SHANK3* deletion.
Methods:
First, we conducted a case-control association study in a sample of 335 individuals with a clinical diagnosis of ASD, confirmed by the Chinese version of the Autism Diagnostic Interview-Revised, and 1093 healthy controls after quality control checked. All the genetic samples of all the subjects were analyzed with Affymetrix SNP 6.0 for the CNVs. Second, after CNV discovery we conducted a gene expression analysis of lymphoblastoid cell lines (LCLs). Also, human motor neuron derived from induced pluripotent stem cells (hiPSCs) from patients with PMS and ASD are used as a cellular model of ASD.
Results:
Among the genes found only in the cases, 32 genes were reported to have the association with neuropsychiatric disorders. CNVs both duplication and deletion of genes may influence gene expression level in LCLs. The mRNA expression levels of 7 genes, *HDAC4*, *SND1*, *ABAT*, *SLC38A10*, *GNB1L*, *RPL10,* and *RAB39B,* were changed by CNVs in LCLs. Additionally, the oxygen consumption rate (OCR) is reduced in motor neurons derived from PMS-1 and PMS-2 patient ($P<0.001$ and $P<0.01$, respectively).
Conclusions:
Combining our recent publication (Yin et al., 2016) and this work, we suggest that case-only CNVs may play an essential role underlying the pathogenesis of ASD. Mitochondrial dysfunction may contribute to motor deficits in PMS and ASD.

137 **163.137** Novel Transcripts Identified from iPSC-Derived Cortical Neurons Generated from Individuals with Idiopathic Autism

D. Dykxhoorn[1], *J. El Hokayem*[2], *D. Van Booven*[2], *M. A. Pericak-Vance*[2] *and H. N. Cukier*[3], *(1)University of Miami Miller School of Medicine, Miami, FL, (2)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (3)John P. Hussman Institute for Human Genomics, Department of Neurology, University of Miami Miller School of Medicine, Miami, FL*

Background: Autism spectrum disorder (ASD) is a heterogeneous, neurodevelopmental condition characterized by irregularities in social interaction, verbal and non-verbal communication, and repetitive stereotyped behaviors. Understanding of ASD has been restricted by a lack of model systems that faithfully replicate all of the features of autism pathophysiology. Induced pluripotent stem cells (iPSCs) provide an attractive model to examine the cellular and molecular changes that underlie ASD. Previous RNA-seq analysis in our laboratory from cortical neurons derived from iPSC lines of individuals with idiopathic ASD and controls has identified sets of coding transcripts that are differentially expressed (DE). These results demonstrated an enrichment of DE genes in pathways including neuronal fate specification, extracellular matrix interactions, and axonal functionality. However, these coding RNAs represent only a small fraction of the total transcripts identified.
Objectives: The purpose of our current study is to identify novel transcripts, such as spliced isoforms and noncoding transcripts including long intergenic non-coding (LINC) RNAs, antisense transcripts, and circular RNAs that are differentially regulated in ASD-specific iPSC-derived cortical neurons compared to control neurons.
Methods: iPSC lines were created from peripheral blood mononuclear cells (PBMCs) and developed from a number of individuals with autism and controls. These iPSCs lines were differentiated into cortical neurons and RNA was extracted at several time points post initiation of differentiation (day 35, day 85 and day 135). RNA-seq analysis was performed using the HiSeq 2500 and significantly differentially expressed genes were identified at each of the time points using edgeR software. Further informatics analyses were used to identify novel spliced isoforms (eg. MapSplice) and noncoding transcripts (eg. lncrnadb.com and circbase.org) differentially expressed in ASD compared to control neurons.
Results: A wide variety of novel transcripts were identified that did not match the predominant coding RNAs, including alternatively spliced isoforms of coding genes and non-coding RNAs. Differential expression of alternative spliced isoforms that distinguish ASD and control neurons were identified at each time point. These can be categorized into different groupings such as missed exons, alternative exons, and retained introns. Noncoding transcripts were differentially expressed between the neurons from ASD and control neurons, including antisense RNAs (e.g. *DLGAP1-AS1* and *POU6F2-AS2*) and long intergenic noncoding RNAs (e.g. *LINC01139*). In addition, we were able to identify circular RNAs in our dataset. This included the well characterized *CDR1-AS*, also known as *ciRS-7*, a circular RNA highly expressed in the central nervous system that functions as a sponge for *miR-7* (Memczak, et. al., 2013, *Nature*).
Conclusions: The results of this study show that there is a diversity of transcripts that are differentially expressed in cortical neurons derived from ASD-specific and control iPSC lines. This enrichment for novel transcripts, particularly noncoding transcripts, suggests potential novel gene regulatory roles in ASD.

138 **163.138** Plasma Metabolome, PON1 Status, Environmental Exposures and Childhood Autism

J. Sotelo[1], *I. Hertz-Picciotto*[2] *and C. Slupsky*[1,3], *(1)Nutrition, University of California at Davis, Davis, CA, (2)University of California at Davis, Davis, CA, (3)Food Science and Technology, University of California at Davis, Davis, CA*

Background: Few studies have examined Autism Spectrum Disorder (ASD) and the interplay between genetics and environmental factors. The paraoxonase 1 (PON1) gene regulates the breakdown of organophosphate (OP) pesticides in the body and serves as an important antioxidant. PON1 levels may be affected by single nucleotide polymorphisms (SNPs), therefore individuals with certain PON1 SNPs plus environmental exposure during pregnancy may be at an increased risk for having a child with autism.
Objectives: The objective of this study was to examine a possible gene-environment interaction that focuses on prenatal environmental exposures and child metabolic vulnerability as a consequence of polymorphisms in the PON1 gene.
Methods: All children (n=400) in the present study including children with Autism Spectrum Disorder (ASD; n=200), and typically developed control children (TD; n=200) are part of a large ongoing population-based case-control CHARGE (CHildhood Autism Risk from Genetics and Environment) Study. Blood plasma metabolome profiles were obtained by Nuclear Magnetic Resonance (NMR) spectroscopy. Untargeted metabolomics analysis using Chemomx NMR Suite 8.1 was used to identify and quantify 69 metabolites in each sample including amino acids, organic acids, sugars and other compounds. Concentration of PON1 were determined by ELISA kits (Cloud Clone Corp), and paraoxonase activity was measured using commercially available assay kits (Molecular Probes Inc.). SNP data, and environmental exposure data was previously collected in the CHARGE Study.
Results: Children with ASD had higher levels of lactate, a metabolic waste product, and higher levels of the amino acids: alanine, serine, glycine, and tryptophan, consistent with mitochondrial dysfunction, and altered energy metabolism. In addition, ASD was associated with higher levels of uridine, a component of RNA previously reported to be inversely correlated with methylation capacity. Although we did not find a significant difference in the PON1 concentration and paraoxonase activity of children with ASD compared to controls, we did find that PON1 SNPs in coding and non-coding regions significantly affected its plasma concentrations. Moreover, there were a disproportionate number of children with ASD and specific PON1 SNPs that correlated with maternal organophosphate and pyrethroid exposures.
Conclusions: Â Our results add to the growing body of literature indicating autism is associated with an altered metabolic state compared to typically developed controls. These results suggest that maternal environmental exposures during pregnancy in combination with genetics may impact a child's metabolic outcome. Further studies are needed to understand how the metabolome affects neurodevelopmental outcome, or conversely if neurodevelopmental outcome affects the metabolome.

139 **163.139** Role of a Circadian-Relevant Gene, NR1D1, in Brain Development: Possible Involvement in the Pathophysiology of Autism Spectrum Disorder

M. Goto[1]*, M. Mizuno*[2]*, A. Matsumoto*[1]*, Z. Yang*[1]*, E. F. Jimbo*[1]*, H. Tabata*[2]*, K. I. Nagata*[2] *and T. Yamagata*[1]*, (1)Jichi Medical University, Shimotsuke, Japan, (2)Developmental Research, Aichi Human Service Center, Kasugai, Japan*

Background: Autism spectrum disorder (ASD) is frequently accompanied by comorbid conditions, and associated with problems in the early developmental period including hyperactivity, panic, self-injury and sleep disturbance. Among them, sleep disruption such as insomnia or a short sleep cycle is one of the most common and distressed problems. In our previous study (Yang *et al*. 2015), we screened ASD patients with and without sleep disorders for mutations in the coding regions of circadian-relevant genes, and detected mutations in several clock genes including *NR1D1* (Nuclear receptor subfamily 1 group D member 1). Thus, circadian-relevant genes likely represent impaired molecular clock mechanisms that potentially contribute to the etiology of ASD. Meanwhile, *NR1D1* is located on 17q11.2, which was shown to be a region susceptible to ASD. As for the neuronal function, while synaptic activity induced the distribution of Nr1d1 to the spine and dendrite in wild-type mice, *Nr1d1*-knockout mice displayed abnormal behaviors such as marked hyperactivity, impaired response habituation in novel environments, deficient contextual memories and impairment in nest-building ability. The above observations raise the possibility that NR1D1 is crucial for synaptic functions and is a causal gene candidate for ASD and other neurodevelopmental disorders.
Objectives: We elucidated the role of Nr1d1 in the corticogenesis and contribution to ASD.
Methods: Sequence analyses of NR1D1 was done in ASD patients to detect mutation. And also, we performed *in vivo* analyses; *in situ* hybridization of Nr1d1 in developing mouse brain, and time-lapse imaging of migration of Nr1d1-deficient neurons.
Results: We identified three new substitutions, including a *de novo* heterozygous mutation, c.1499G>A (p.R500H) in ASD patients that was not detected in control individuals. We then examined the role of NR1D1 in the development of the mouse cerebral cortex. Acute knockdown of mouse *NR1D1* by *in utero* electroporation caused abnormal positioning of cortical neurons during corticogenesis. This aberrant phenotype was rescued by wild type NR1D1, but not by the c.1499G>A mutant. Time-lapse imaging revealed that the abnormal positioning was due to impaired migration. Moreover, knockdown of *NR1D1* also suppressed axon extension and dendritic arbor formation of cortical neurons, while the proliferation of neuronal progenitors and stem cells at the ventricular zone was not affected.
Conclusions: NR1D1 plays a pivotal role in corticogenesis via regulation of excitatory neuron migration and synaptic network formation, besides the role in circadian rhythm formation. Addition to the detection of *de novo* mutation in ASD patient, functional defects in NR1D1 suggested to relate to ASD pathophysiology.

140 **163.140** Salivary Oxytocin Levels in Young Children with Autism Spectrum Disorders (ASD) Compared to Healthy Controls

S. M. Kaku[1]*, R. Christopher*[2]*, S. C. Girimaji*[3] *and S. Srinath*[4]*, (1)Clinical Neurosciences and Child and Adolescent Psychiatry, National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore, India, (2)Neurochemistry, NIMHANS, Bangalore, India, (3)Child and Adolescent Psychiatry, National Institute of Mental Health and Neurosciences, Bangalore, India, (4)NIMHANS, Bangalore, INDIA*

Background: Evidences from literature in oxytocin, imply possible beneficial effect of oxytocin administration on social and communicative dysfunctions seen in ASD and their neural underpinnings. The lower levels of plasma oxytocin in ASD have been demonstrated in few studies in children and adolescents with ASD in comparison with typically developing children. Studies investigating salivary oxytocin levels in children with ASD have shown that oxytocin is lower in ASD than typically developing controls, rise in salivary oxytocin levels after social interaction and elevation of oxytocin levels in the saliva after intranasal administration thus influencing social cognition.
Objectives: This study attempted to 1) investigate the levels of oxytocin in the salivary samples of young children with ASD and compared with healthy controls and 2) the correlation of oxytocin levels to symptom severity scores measured by Childhood Autism Rating Scale (CARS).
Methods: 24 children diagnosed with ASD (mean age-4.6 years) and 18 age matched controls were recruited for the study. CARS was applied and severity scores were calculated for each subject with ASD. Saliva samples were collected using chewable cotton rolls. Samples were stored at -80 degree Celsius until further assay. Oxytocin levels were estimated by ELISA using commercial kits.
Results: Children with ASD had a mean salivary oxytocin level of 47.9706 µIU/mL. The mean oxytocin levels in the controls were 29.5866 µIU/mL. Between cases and control, cases had significantly higher oxytocin levels in the saliva – $p<0.009$. There was no significant correlation between symptom severity measures by CARS scores (Mean – 38.1) and oxytocin levels of children with ASD.
Conclusions: This study showed that children with ASD had higher levels of oxytocin compared to controls. There was no significant correlation between symptom severity and oxytocin levels. While most studies have shown lower levels of plasma and salivary oxytocin in children with ASD, few studies have shown no differences between the groups. However, this study showed higher levels of oxytocin in the ASD group which is unusual. Some notable differences from past studies are that, this study included 3 to 5 years old children with low functioning ASD. ELISA was done using the direct assay method. Saliva was not lyophilized during storage. Significant differences exist between values observed in similar populations and are likely due to methodological differences, ethnic variability, socio-economic differences; thus making comparison between studies difficult. In conclusion, use of saliva sample for oxytocin estimation in ASD and its role as a robust marker is debatable. Further studies to replicate and/or validate findings in similar samples are needed, in order to draw translatable evidence.

141 **163.141** Serum Metabolome Profile in GI Symptomatic ASD Children: A Pilot Study

S. J. Walker[1]*, D. Leavitt*[2] *and A. Krigsman*[3]*, (1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Wake Forest University, Winston Salem, NC, (3)Pediatric Gastroenterology Resources of NY & Texas, Far Rockaway, NY*

Background: We have previously shown that children with ASD and gastrointestinal (GI) inflammation display a unique gene expression profile both in GI biopsy tissue and peripheral blood, when compared to non-ASD GI-symptomatic children without GI inflammation. The differential gene expression patterns identified in peripheral blood can provide clues as to the pathobiology that underlies the inflammation and/or ASD. To explore this hypothesis further we have assayed serum from the same individuals to determine if the metabolite profiles: (1) also differ significantly between the groups and, (2) if they provide additional mechanistic insight.
Objectives: The goal of this study was to measure serum metabolite profiles in GI-symptomatic children with ASD and ileocolonic inflammation (ASD^{IC+}) and from GI-symptomatic typically developing children (without evidence of ileocolonic inflammation; TD^{IC-}), in order to compare metabolite levels between these groups.
Methods: Â Global metabolite profiles were determined in serum samples derived from 40 individuals as follows: (a) the "control" group (TD^{IC-}) consisting of 14 males and 5 females and, (b) the "case" group (ASD^{IC+}) consisting of 17 males and 4 females. Sample processing involved metabolite extraction, followed by ultrahigh performance liquid chromatography-tandem mass spectroscopy (UPLC-MS/MS). Raw data were extracted, peak-identified and QC processed. Compounds were identified by comparison to library entries of purified standards or recurrent unidentified entities. Following log transformation and imputation of missing values, if any, with the minimum observed value for each compound, Welch's two-sample t-test was used to identify biochemicals that achieved statistical significance ($p\leq0.05$), as well as those approaching significance ($0.05<p<0.01$).
Results: The present dataset comprises a total of 612 compounds of known identity (named biochemicals) measured in 40 individual serum samples. A comparison between the 2 groups showed that 292 metabolites (48%; 72 higher and 200 lower in ASD^{IC+} compared to controls) reached a level of statistical significance and another 36 metabolites (12 higher/24 lower in ASD^{IC+}) approached significance. Many of these metabolite level differences between ASD and TD samples have been reported in other studies, while some of the individual findings here are either in disagreement, or are altogether new, compared to published reports. Overall, the data showed that the two groups were distinguishable (i.e. significantly separated) by principal component analysis and the ASD^{IC+} profiles, as a group, appeared to be more heterogeneous. Using the primary groupings of "case" and "control", random forest analysis resulted in a predictive accuracy of 95% for the serum samples.
Conclusions: Comparison of metabolome profiles between ASD^{IC+} and TD^{IC-} showed that levels of nearly half of the serum metabolites are statistically significantly different between the two groups and that these metabolome profiles are largely phenotype-specific. Moreover, many of the specific metabolite level differences have previously been reported in metabolome studies comparing ASD and control samples, however in some cases the changes we found are either discordant or novel compared to published reports. This is not surprising since our pilot study examined differences in serum from children with ASD *and* gastrointestinal inflammation to serum from children with neither condition.

142 **163.142** The Children's' Autism Metabolome Project (CAMP): Anatomy of a Clinical Study Employing Metabolomics to Identify Novel Metabolic Subtypes of Autism Spectrum Disorder (ASD)

E. Donley*, J. King, A. M. Smith, P. West, R. Alexandridis, D. Sugden, M. Ludwig, L. Feuling and R. Burrier, Stemina Biomarker Discovery, Madison, WI*

Background:
ASD is a complex spectrum of neurodevelopmental disorders with heterogeneous underlying genetic, metabolic, and environmental causes. The CAMP (ClinicalTrials.gov Identifier NCT02548442) study, the largest clinical study using metabolomics based methodologies, is being conducted to validate biomarkers identified in three previous studies of banked blood samples and to better understand the metabolism of children with ASD. Metabolomic analyses of ASD may be useful in identifying biomarkers that can provide insight into the role that biochemical disorders, the gut microbiome, dietary and environmental factors play in ASD. The metabolic signatures of ASD can be useful in parsing the broad autistic spectrum into more homogeneous and clinically significant subtypes. Better understanding of metabolic subtypes or metabotypes of ASD can lead to early diagnosis, development and selection of more precise therapeutic intervention, as well as better understand of the efficacy of current interventions within metabotypes.
Objectives:
Enroll a total of 1500 subjects comprised of ASD, development delay (DD) and typically developing (TD) children ages 18-48 months. Employ a robust experimental platform based on orthogonal mass spectrometry methodologies comprised of both targeted and non-targeted metabolomics methods. Identify metabolic perturbations associated with ASD specifically focusing on the identification of metabotypes of ASD through measurement of metabolic differences in patients across the spectrum as compared to DD and TD children.
Methods:
The CAMP is being conducted at 8 locations. Diagnosis is based on DSM-V confirmed by Autism Diagnostic Observation Schedule (ADOS) for ASD and the Mullen scales of early learning for DD. Extensive data is being collected regarding medical history, diet, supplements and family history. Blood and urine samples are being collected for metabolomics and gene expression analysis. The numbers of patients for each group (ASD, TD or DD) were determined by a power analysis study, with the goal of providing a maximum power of 0.9 for pairwise comparisons in univariate and multivariate analyses.
Results:
The experimental platform developed for the CAMP study detects 2.2 times more metabolite related features then the previous results generated from the three smaller banked blood studies. The number of subjects allows for detection of novel, less prevalent metabotypes associated with ASD. The CAMP study metabolomics data will be analyzed in conjunction with cohort information, study demographic data, subject metadata, RNA expression and genotype information to better understand the metabolic profiles associated ASD.
Conclusions:
The CAMP study will provide the largest set of samples collected under procedures designed for metabolomics analysis. Metabolomics will provide a valuable additional perspective on this complex disorder. Collection of blood plasma and urine, as well as RNA and DNA, will allow an integrated evaluation of the metabolic phenotype of ASD. Better understanding of the metabolic phenotype of ASD has the potential to enable earlier diagnosis, identification of biochemical alterations in patients across the spectrum that will provide targets for new treatments as well as better understanding about who benefits from current treatments.

143 **163.143** The Role of Oxidative Stress in Adults with Autism Spectrum Disorders

M. B. Thorsen[1], *N. Bilenberg*[2], *N. Heegaard*[3], *Å. F. Svenningsen*[4] *and T. M. Michel*[5], *(1)Child and Adolescent Psychiatric dept, University of Souther Denmark, Odense, Denmark, (2)Child and Adolescent Psychiatry, Odense C, Denmark, (3)Department of Autoimmunology and Biomarkers, Statens Serum Institut, Copenhagen, Denmark, (4)Department of Neurobiology Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark, (5)Psychiatric Dept, University of Southern Denmark, Odense, Denmark*

Background:
The diagnosis of autism spectrum disorders (ASDs) is currently based on observational and anamnestic data. Despite many years of research into the underlying neurobiology, the etiology of autism is still not fully understood. Oxidative stress could be a key player in the pathogenesis.
Objectives:
As previous studies have focused on children, it is still not known whether oxidative stress is a temporal finding or a persistent key-player in the pathophysiology in ASD. We therefore aimed to investigate the levels of the classical antioxidants superoxide dismutase 1 and 2 in adults with ASD.
Methods:
56 patients with a diagnosis of ASD, along with 56 age- and gender matched healthy controls, had their plasma analyzed for the antioxidants Copper/Zinc superoxide dismutase (SOD1) and Manganese superoxide dismutase (SOD 2) and filled out the autism quotient questionnaire (AQ).
Results:
Increased concentration of SOD1 was found among patients with ASD (268,2 vs. 205,6; p<0,0004), while no difference was found in SOD2 (85,06 vs. 76,21; p=0,5749). Patients with ASD scored higher on AQ (27 vs. 10; p<0,0001). When stratifying into AQ-score ≥ 32 vs. AQ-score < 32 no difference in SOD1 or SOD2 was found. There were baseline differences between case and control group, however none of them showed significant influence on either of the antioxidants.
Conclusions:
Patients with ASD showed higher concentrations of the antioxidant superoxide dismutase 1. This could be the result of an upregulation of the protein synthesis due to increased exposure to oxidative stress. This could be a possible future therapeutic target, although more studies are needed.

144 **163.144** Toward the Development of an ASD Biomarker: Altered Activity of Kinase Signaling Pathways in Blood

E. Argilli[1], *T. Berson*[2], *J. Owen*[1], *S. Thomas*[3] *and E. Sherr*[1], *(1)Neurology, UCSF, San Francisco, CA, (2)Pediatric Neurology, UCSF Brain Development Research Program, San Francisco, CA, (3)Gladstone, UCSF, San Francisco, CA*

Background: A high priority in autism spectrum disorder (ASD) research is the identification of a robust and reliable biomarker. Biomarkers can enable early detection and hence early intervention leading to better outcomes, and may help in the development and stratification of precision therapeutics. Recent progress in the genetics of ASD suggests that the signaling of two key kinase pathways, RAS-MAPK and AKT-PI3K, may be important to ASD pathogenesis. We previously demonstrated that the degree of activation of components of these Ras-MAPK and AKT-PI3K pathways as measured in the brain correlate with social behavior in an ASD-related mouse strain. We also demonstrated that the degree of this kinase activation in the brain correlated with that observed in lymphocytes. These findings motivated our current study, suggesting we can indirectly measure the state of activation of these signaling pathways in the brains of ASD patients and controls from measurements in peripheral blood.
Objectives: The aim of this study is to assess whether there is over and/or under activation of kinase signaling in children with ASD versus controls by using freshly isolated peripheral blood mononuclear cells (PBMCs) as a model. Our initial biopanel measures total expression and activity level (phosphorylated isoforms) of three groups of proteins, p44/42 MAPK (ERK1/2), PTEN and AKT (1-3)
Methods: A cohort of 57 idiopathic ASD children and 66 typically-developing control children (matched for age and gender) were enrolled, clinically assessed and had blood drawn. PBMCs were isolated from whole blood using Ficoll separation. After cell lysis the cytoplasmic fraction was used for Western Blot analysis. Total and phosphorylated form of ERK (ERK and p-ERK), PTEN (PTEN and p-PTEN) and AKT (AKT and p-AKT) were detected and quantified, corrected by Actin levels, and the ratios of the phospho to the total for each protein (p-ERK/ERK, p-AKT/AKT, and p-PTEN/PTEN) were calculated. These values were then z-scored using the mean and standard deviation across the entire cohort to measure the deviation of each individual from a standard value. The absolute value z-scored ratios were separately inserted into a generalized linear model (GLM) with group, age, gender, and gel set as independent variables. A statistically significant p-value ($p<0.05$) associated with the group coefficient was used to determine group differences.
Results: We found that the absolute value of the z-score for the p-ERK/ERK ratio is statistically significantly increased ($p<0.017$) as it is for the p-PTEN/PTEN ratio ($p<0.032$) in ASD children compared to controls, while we found a trend-level increase in p-AKT/AKT in our cohort ($p<0.19$). These comparisons were most significant through the use of |z-score|, demonstrating that both over and under activation of these pathways are found in ASD.
Conclusions: Our results show for the first time that steady state activation levels (both over and under) in the blood of key signaling pathways are significantly altered in idiopathic ASD children compared to controls. Our next steps are to understand how the degree of deviation can predict clinical severity and importantly how these and other measures can serve as a blood-based biomarker for ASD.

145 **163.145** Transcriptome Analysis of Neurons Differentiated from Patient-Specific Blood Derived Induced Pluripotent Stem Cells Reveals Convergent Pathobiology in Idiopathic Autism Spectrum Disorders

J. El Hokayem[1], *B. A. deRosa*[2], *H. N. Cukier*[3], *C. Garcia-Serje*[4], *M. L. Cuccaro*[1], *J. M. Vance*[5], *M. A. Pericak-Vance*[1] *and D. Dykxhoorn*[6], *(1)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (2)Oregon Health and Science University, Portland, OR, (3)John P. Hussman Institute for Human Genomics, Department of Neurology, University of Miami Miller School of Medicine, Miami, FL, (4)John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, (5)Hussman Institute for Human Genomics, Miami, FL, (6)University of Miami Miller School of Medicine, Miami, FL*

Background:
To date, numerous candidate genes have been associated with autism spectrum disorder (ASD) with many of these genes known to have important roles in synaptic function and the development of neural circuits. This suggests that certain neurobiological processes could be commonly altered in ASD. Therefore, although there is a great deal of clinical and genetic heterogeneity in ASDs, there may be convergent deficits in key molecular mechanisms which underlie the disease. Nonetheless, Lack of appropriate human-based models of complex neurodevelopmental disorders has greatly hindered investigations of convergent neurobiology in ASDs. Hence, induced pluripotent stem cells (iPSCs) offer the opportunity to further unravel the complex biology underlying ASD.
Objectives:
This study aims to determine the convergent biological pathways underlying ASD by probing the transcriptome of cortical neurons derived from ASD-specific iPSCs.
Methods:
We derived patient-specific iPSCs from the whole blood of six individuals with idiopathic ASD and of five control individuals as well. Subsequently, each of these stem cell lines were differentiated into cortical neurons for 135 days. RNA was extracted from these neurons at day 35, 85 and 135 of differentiation and whole transcriptome analysis (RNA-Seq) was performed. Significantly differentially expressed genes were identified at each of the time points using edgeR software. Furthermore, gene networks and pathways were analyzed via multiple approaches: Ingenuity Pathway Analysis (IPA), Weighted Correlation Network Analysis (WGCNA), Short Time-series Expression Miner (STEM) and Gene Ontology (GO ontology).
Results:
Analysis of siginificantly differentially expressed genes at each time point highlighted deregulation in brain developmental, cytoskeletal and metabolic processes. Furthermore, analysis of overlapping differentially expressed genes between time points revealed five consistently differentially expressed genes at all three time points: FAR2P1, HS3ST4, MAB21L2, POTEF and TFF3. WGCNA analysis of the RNA Seq data generated a combined total of 52 gene modules and many of these modules presented an enrichment in the deregulation of pathways associated with neuronal differentiation, transcription and DNA and RNA metabolic processes. Finally, the analysis of changes in gene expression over time using the STEM software revealed neuronal cytoskeletal, proliferation and metabolic processes to be deregulated across the whole time course.
Conclusions:
In our study, different analytical approaches revealed multiple pathways and processes that have been previously reported to underlie ASD biology. These mainly consist of brain developmental, neuronal differentiation and cytoskeletal processes. Of particular note, we have found that DNA, RNA and other metabolic processes may be important contributors to ASD pathobiology. We have shown that patient-specific iPSCs can be used to model brain region-specific neuronal development permitting the identification of common molecular mechanisms disrupted in ASD and identifying important candidate targets for therapeutic intervention.

146 **163.146** Transcriptomic Modeling of Phelan-Mcdermid Syndrome Using Glutamatergic Neurons Generated from Patient iPSCs

A. Browne[1], *M. S. Breen*[2], *E. Drapeau*[2] *and J. D. Buxbaum*[3], *(1)Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Autism spectrum disorder (ASD) has high heritability and a prevalence of nearly 1% worldwide, but heterogeneity of patients has made identifying the underlying etiology difficult. By focusing on monogenic disorders with high penetrance for causing ASD, specific pathways might be identified that are common to a broader group of ASD patients with mechanistically related etiology. Phelan-McDermid syndrome (PMS) is one such ASD-associated syndrome that is caused by haploinsufficiency of the gene *SHANK3*, which encodes for a scaffolding protein of the post-synaptic density at glutamatergic synapses. While animal models provide great insight into pathways involved in PMS, induced pluripotent stem cells (iPSCs) generated from patient tissue samples retain the full genetic background of the individual and can be expanded extensively and differentiated into neural progenitor cells (NPCs) and neurons. Since it isn't possible to obtain brain tissue from living ASD patients, having a source of human neural cells in incredibly valuable.
Objectives: The overarching goal of this study is to improve our mechanistic understanding of PMS and identify candidate genes and pathways that can be targeted pharmacologically to alleviate neurological deficits of the syndrome. To accomplish this, we applied a multi-step approach that aimed to: 1) generate high-quality iPSC clones from PMS patients and siblings; 2) differentiate them into NPCs, followed by neurons, to capture the neurodevelopmental phenotype of PMS in patients; 3) identify PMS-associated differential gene expression in iPSC-derived neurons by RNA sequencing; and, 4) identify candidate drug targets and FDA-approved drug compounds for repositioning in PMS.
Methods: Blood samples from patients with PMS and unaffected siblings are collected for 14 PMS patient/sibling pairs and reprogrammed using a modified non-integrating Sendai virus to express reprogramming factors. For each individual, 2-3 clones are expanded for quality control (QC) and banking, and those that pass QC are differentiated into NPCs using a monolayer approach with PSC Neural Induction Media from Fisher. NPC lines are then transfected with doxycycline-inducible Ngn2 lentiviruses with puromycin selection and grown for 3 weeks to allow for maturation. RNA is isolated from NPC and neuron samples and subjected to RNA sequencing, and the PMS-associated changes in gene expression are then compared to known gene expression profiles of FDA-approved drugs and other ASD-associated syndromes.
Results: Twelve PMS patient/sibling pairs have been reprogrammed with 2-3 clones per individual having been used for NPC generation followed by neuronal induction. Initial NPC samples have been subjected to RNA sequencing for preliminary investigation into the early developmental transcriptional profile of PMS. Differentially expressed genes between PMS patient-derived NPCs compared to those from their healthy siblings were found to be enriched for components of the Wnt signaling pathway and were upregulated in the PMS-associated cells.
Conclusions: iPSCs from PMS patients offer a powerful tool for disease characterization, drug identification, and screening. Generating an expression profile for these patient-derived NPCs and neurons will provide a unique perspective on the transcriptional signature of PMS that can be used in conjunction with other models of the disease and known drug expression profiles to identify new therapeutics.

147 **163.147** Whole-Genome Methylation Screen Identifies Enriched Neuronal Pathways in a South African Autism Cohort

S. Stathopoulos[1], *R. Gaujoux*[2] *and C. ORyan*[1], *(1)Molecular and Cell Biology, University of Cape Town, Cape Town, South Africa, (2)Department of Immunology, Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel*

Background:
An increasing number of studies support a role for epigenetic factors in the aetiology of autism. Recent work on monozygotic twin pairs, discordant for autism spectrum disorder (ASD) phenotype, implicated DNA methylation as a contributor to autism. Despite intense research over the past decade, no definitive biological markers for this disorder have been identified given the highly heterogeneous nature of ASD. This highlights the importance of a clearly defined ASD phenotype in molecular research.
Objectives:
We investigate whole-genome methylation patterns in a cohort of South African children. Differentially methylated regions are used to identify biologically relevant pathways. We validate selected genes within these pathways using quantitative methylation assays in both the discovery and replication cohorts.
Methods:
South African boys aged between 6-11 years old (n=32 ASD and n=16 controls) were recruited. All participants were assessed using the Autism Diagnostic Observation Schedule-2, ADOS-2. DNA was extracted from study participants using buccal cells. We performed a whole genome DNA methylation screen using Illumina 450K Human Methylation Array. Differentially methylated loci associated with ASD were used in gene ontology pathway analysis to investigate significant biological pathways. Selected genes from these pathways, both novel and previously associated with ASD, were validated using a quantitative mass spectrophotometry assay(Epityper®).
Results:
We identify over 5000 differentially methylated CPG sites (corrected FDR<0.5) associated with ASD. These sites are distributed across ~4000 different genes and UTRs. Gene ontology analysis identified Nervous System Development and System Development biological processes as being significantly enriched. When comparing ASD endophenotypes, with find significant associations with smaller gene sets. For example, children with severe Repetitive and Restricted behaviours, RRB (ADOS-2 score >8) show significant association for a smaller set of CpG sites across less than 100 genes, and thus we recover more targeted biological processes. We validate differential methylation quantitatively using mass spectrophotometry for two genes: a gene previously associated with ASD (SLC6A4) and a novel signalling gene. The quantitative data supports a role for differential methylation in ASD individuals with high social affect, SA (ADOS-2 SA>8) at both loci.
Conclusions:
This study is the first to investigate whole-epigenome profiles of DNA methylation in a South African cohort of children with ASD. We find that methylation patterns differ significantly between ASD and typically developing children at a large number of genes involved in biologically relevant processes, particularly in nervous system development. When looking at ASD subtypes, we are able to isolate smaller groups of CpG sites that display differential methylation, thus reducing the number of genes and processes involved. We have validated that differential methylation in signaling pathways is associated with ASD subtypes, which is consistent with the central role of neuronal signaling in neuropsychiatric disorders. Our approach of defining ASD subtypes in the search for molecular epigenetic markers is central to the identification of potential ASD biomarkers and effective drug targets.

148 **163.148** Maternal Factors Induces Autism-like Phenotypes in Mice

J. R. Huh*, Department of Medicine, Division of Infectious Diseases and Immunology, University of Massachusetts Medical School, Worcester, MA*

Background:
Â Human epidemiological studies point to a critical role for immune dysregulation in maternal womb as a risk factor in Autism Spectrum Disorder (ASD). This observation, coined maternal immune activation (MIA), has been modeled in mice by inducing inflammation in pregnant dams. However, The immune cell populations critical in the MIA model have not been identified
Objectives:
We tested whether inflammatory T helper cells producing interleukin-17 (Th17 cells) are necessary for MIA-associated phenotypes.
Methods:
We used both genetic mutants and blocking antibodies to investigate the roles of maternal Th17 cell pathway in promoting MIA associated phenotypes.
Â Results:
T cell-specific inactivation of RORγt in mothers (thus selectively removing Th17 cells in pregnant mothers) protected from induction of MIA-dependent behavioral phenotypes in offspring. In addition, we found that MIA leads to abnormal cortical phenotypes in offspring and this malformation is fully rescued by inhibiting the maternal Th17 cell pathway. We also showed that the receptor for IL-17 (IL-17Ra) is expressed in the developing fetal brain and its expression is increased in the cortex upon MIA.
Conclusions:
These observations collectively suggest a hypothesis that uncontrolled activation of IL-17Ra expressed in fetal brain induces abnormal cortical development and these structural abnormalities may be an underlying cause of the MIA-dependent autism-like phenotypes.

149 **163.149** Single-Cell Sequencing Reveals Microglia Population Vulnerability Following Maternal Immune Activation in Mice

T. Hammond *and B. Stevens, Kirby Neurobiology Center, Boston Children's Hospital and Harvard Medical School, Boston, MA*

Background:
Maternal immune activation (MIA) during pregnancy has been linked to increased autism risk in offspring, but the mechanisms that lead to these changes are still largely unknown. Microglia, the resident immune cells in the brain colonize the brain during gestation, are highly sensitive to changes in the brain microenvironment and are altered in the brain's of some individuals with autism. This suggests that microglia could play a role in the disease manifestation and raises the intriguing possibility that their normal role guiding neural network formation during development could be disturbed.
Objectives:
MIA risk in humans and mice has been linked to the first two trimesters of pregnancy, a period when microglia are populating the brain and initiating their normal developmental programs. In order to understand whether and how MIA affects this developmental trajectory - as a whole or in small subsets of cells - we wanted to profile microglia during gestation and in young mice.
Methods: MIA was induced in pregnant mice using Poly I:C. We performed high throughput single cell sequencing (Drop-seq) of microglia at three developmental time points with and without Poly I:C exposure. We also performed immunohistochemistry on brains from littermates to identify different microglia subpopulations based on the markers identified by Drop-seq.
Results:
Based on the sequencing results of several thousand microglia per condition we found that microglia clustered into distinct subpopulations. These different subpopulations expressed markers of cell division, inflammation/phagocytosis, and cell motility. We found that exposure to Poly I:C changed the size of the phagocytic microglia group at the expense of the other subpopulations. These results persisted into early adolescence. Interestingly, this affected a relatively small subset of cells in specific brain regions.
Conclusions:
Our results are the first to create a detailed single cell sequencing map of microglia development in thousands of cells. This power gave us the resolution to detects small subpopulations of interesting microglia in different brain regions. Interestingly, MIA exposure shifted the number of cells occupying each of these states in a region specific manner, suggesting that certain microglia are more vulnerable than others to immune challenge. Further analysis will be needed to figure out potential mechanisms by which these subpopulations might affect neural network formation and behavior

Poster Session
164 - Sensory, Motor, and Repetitive Behaviors and Interests
5:00 PM - 6:30 PM - Golden Gate Ballroom

150 **164.150** A Comparison of Sensory Subtyping Models in Children with Autism Spectrum Disorder

A. E. Lane[1]*, K. K. Ausderau*[2]*, J. C. Bulluck*[3]*, J. Sideris*[4] *and G. T. Baranek*[3]*, (1)University of Newcastle, Callaghan, NSW, Australia, (2)University of Wisconsin-Madison, Madison, WI, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Frank Porter Graham Child Development Institute, Chapel Hill, NC*

Background: Heterogeneity in sensory features in children with ASD is a barrier to the provision of customized and effective therapies (IACC, 2011). To date, two research groups have tested various subtyping models based on different parent-report measures and yielding different numbers of subtypes (range = 3-5 subtypes) across different cohorts (Ausderau et al, 2014; Lane et al, 2014; Lane et al, 2010; Lane et al, 2011).
Objectives: The aims of this study were: (1) test a 3-, 4- and 5-subtype model using the Short Sensory Profile (SSP) questionnaire with an independent and large national sample, and (2) compare the resulting classifications of children on the best-fitting SSP model to the established 4-subtype solution on the Sensory Experiences Questionnaire, version 3.0 (SEQ-3) (Ausderau et al., 2014) using a single cohort. From here, recommendations will be made for a unified model of sensory subtypes.
Methods: Extant data from the SEQ-3 and SSP were analyzed from participants with ASD (n=550), ages 2-12, as part of a national online survey. The SEQ-3.0 has 4 dimensional factors (i.e., hyporesponsiveness; HYPO, hyperresponsiveness; HYPER, sensory interests, repetitions, and seeking behavior; SIRS, and enhanced perception; EP); these factor scores were used in the subtyping analyses (Ausderau et al., 2014). For the SSP, we generated domain z scores (tactile sensitivity, taste/smell sensitivity, movement sensitivity, underresponsive/seeks sensation, auditory filtering, low energy/weak, visual/auditory sensitivity). Then, a latent profile analysis was conducted in MPLUS using the SSP z scores and relevant covariates; statistical fit indices (AIC, BIC, LMR, entropy, BLRT) were analyzed. The similarities and differences between the various subtype models and their theoretical underpinnings were qualitatively evaluated.
Results: Fit indices were mixed for 3-, 4-, and 5-subtype solutions, and we did not find conclusive support for a single subtype solution on the SSP, as was clear with the SEQ-3. The SEQ-3 subtypes included both high and low sensory severity subtypes, as well as two qualitatively different subtypes (one more hypo- and one more hyper-responsive). The SSP subtypes were strongly influenced by two domains: low energy/weak and movement, which are not well represented by items on the SEQ-3. A 3-subtype solution on the SSP was considered, but found to be theoretically less informative (i.e., followed a low, medium, high severity pattern, but no qualitative differences in patterns). The SSP 5-subtype solution showed good fit indices and was more consistent with Lane et al. (2011). Comparison of children's classifications across the two measures within the same cohort of 550 children is in progress.
Conclusions: This study is the first to subtype using two sensory measures within the same cohort of children. A unified model of sensory subtypes in ASD would have significant benefits to the field by clarifying latent constructs and providing guidelines for assessment and targeted interventions; however, theoretical models driving the development of these assessments impact how sensory features are characterized in ASD, and may contribute to inconsistencies in findings across studies. Clinical consensus on the role of various constructs (e.g., sensory modulation vs. motor/praxis) in characterizing sensory subtypes is recommended.

151 **164.151** Acoustic Design and Repetitive Behavior in Children with Autism

***S. Kanakri**, Ball State University, Fishers, IN*

Background: Emerging research in Evidence-Based Design for interiors is considering the unique sensory needs of users with autism spectrum disorders within built environments.
Objectives: The current study observes the impact of the acoustic environment on repetitive behavior in children with autism.
Methods: An observational study was conducted in four school classrooms for children with autism to observe changes in behavior associated with changes in the decibel levels in the room. 42 children, between the ages of 6-9 years old, diagnosed with high functioning autism were observed in classroom settings. Variant decibel levels in the classrooms and variance in the frequency of repetitive behaviors were measured to determine the strength and direction of the correlations between the two. Results were analyzed using Noldus Observer XT software.
Results: The repetitive behavior of children with autism is correlated with the acoustical condition of their environment
Conclusions:
These findings should be considered in the design of classrooms for children with ASD, for the benefit user comfort and educational performance.

152 **164.152** Age Differences in Objects Interesting Autistic Toddlers

***V. Langlois**[1,2], V. Larose[1], J. Degré-Pelletier[2], G. Thermidor[2], S. Mineau[2], C. Jacques[1,2] and L. Mottron, M.D.[2], (1)University of Quebec in Outaouais, Gatineau, QC, Canada, (2)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada*

Background: Â It is well known thatÂ play and interest in objects mediate learning and that cognitive development in young typical children was notably rooted in solitary individuals' sensorimotor interactions with objects (Pellegrini et al., 2007; Piaget, 1983). However, little attention has been paid to young autistic children's use of objects in play situations. Generally, research on autism has focused on restricted interests or restricted use of toys (Klin et al., 2007; Taylor Bruckner & Yoder, 2007). The Montreal Stimulating Play Situation (MSPS; Jacques et al., 2011) is a semi-structured observation schedule where toddlers are exposed to various toys of potential interest to autistic children.
Objectives: To document age differences in autistic toddler's toy exploration while exposed to the MSPS.
Methods: Â 35 young autistic children (24-48 months, mean age = 38.46 months SD= 7.068, MSEL standard score: 63.7 ± 18.5) and 35 older autistic children (49-74 months, mean age = 58.63 months SD= 7.076, MSEL standard score: 68.0 ± 22.4) were exposed to the MSPS. The MSPS is composed of two periods of free play, a semi-free play period and a semi-structured play period and includes 34-40 objects. Object exploration was coded by two research assistants blind to the diagnosis using Observer (K=0.53). First, the Mann-Whitney U test was performed to evaluate the mean rank of the duration and frequency of object exploration in both groups. Then, the proportion of children exploring objects were compared across groups using the Fisher's exact test.
Results:
Three objects were significantly more explored in mean rank frequency and duration by younger children (sound blocks, miniature cars, magnetic letters & numbers, all *p*'s<.05) and one object was significantly more explored in mean rank frequency (visual and sound train, *p*<.05). A marginally higher proportion of younger children explored the visual and sound train (82.9% vs. 60.0%, *p*=0.06) and the sound blocks (71.4% vs. 45.7%, *p*=.05).
Two objects were significantly more explored in mean rank frequency and duration by older children (books and balloons, all p's<.05), while the wheel caterpillar was more explored only in mean rank frequency (*p*<.05). The remote controlled car was marginally more frequently explored (*p*=.06) and this exploration was lasted longer (*p*<.001). A significantly higher proportion of older children explored the books (57.1% vs. 25.7%, *p*< .05).
Conclusions: Â Younger autistic children seem to explore toys which are designed for lower developmental levels and older autistic children explored toys which are designed for higher developmental levels. However, younger autistic children already show an interest for letters and numbers, which is congruent with research showing the precocity of literacy interest in autism (Newman et al., 2007).

153 **164.153** An Analysis of Eating Postures in Adolescents and Young Adults Diagnosed with Autism

***M. E. Parker**[1], M. Weiss[2], M. J. Moran[3], J. T. Foley[4], H. Miller-Kuhaneck[3] and D. McDowell[5], (1)Physical Therapy, Texas State University, San Marcos, TX, (2)Fairfield University, Fairfield, CT, (3)Sacred Heart University, Fairfield, CT, (4)State University of New York at Cortland, Cortland, NY, (5)Texas State University, San Marcos, TX*

Background: Our study sought to look at eating posture in individuals with autism. Most of the studies in autism related to eating are concerning behavior.[1-8] One systematic review looked at interventions to improve eating, but postural analysis was not included.[9] A few studies addressed certain components of motor behavior, posture, and techniques. Brisson et al.[10] performed a retrospective study of infants who were later diagnosed with autism, and found that they demonstrated less anticipatory mouth opening when presented with a spoon than the control group; 4-6 months appeared to be the key period to recognize this delay. Studies with children with autism found that using a flipped spoon improves not only eating behavior, but oral motor processing.[11,12] In addition van den Engel-Hoek et al.[13] analyzed the acquisition of assisted spoon feeding and provided additional data on the components. A cornerstone to understanding how prehension relates to spoon-feeding was supported in the research by Churchill et al.[14] who demonstrated that reaching/grasping and spoon-feeding demonstrate similar kinematics in healthy adult subjects. David et al.[15] sought to identify impairments in precision grip in children and adolescents with high-functioning autism. They found temporal dyscoordination and greater variability in precision grip when the subjects were compared to a group of typically developing age-matched peers. Memari et al.[16] proposed that additional studies are necessary to discern the exact cause and differences in postures between individuals with and without autism. This premise was corroborated in a study assessing individuals with autism with and without speech delay and controls, as they found difference in motor skills.[17]
Objectives: The purpose of this study was to analyze eating postures in a group of individuals with autism spectrum disorders (ASD) who demonstrate expressive language impairment (ELI), and compare their eating postures to a group of age-matched peers. While eating behaviors and techniques have been studied in the autism population,[1-8] to date no research has been generated on the postures of individuals during eating. It was hypothesized that individuals with ELI-ASD would demonstrate different postures and strategies.
Methods: Nine subjects with ELI-ASD (age range 16-22 year; 1 female and 8 males) were recruited for this study. The Childhood Autism Rating Scale (CARS) was used to assess level of autism with all demonstrating "severe autism" with a a mean total score of 51.11 (SD5.54) with significant language impairment. Ten age-matched controls (18-20 year of age; 3 females and 7 males) were also recruited. During the discrete eating events each subject was video taped. Utlilizing a rubric and biomechanical analysis the following data was processed: attention to eating, hand used to hold spoon, grasp, spoon position, trunk posture, and other related movements.
Results: Initial data analysis found significant differences between the ELI-ASD group and the control in eating including attention, grasp, and posture. Additional analysis is ongoing at this time.
Conclusions: Individuals with ELI-ASD demonstrated significantly different eating postures compared to the control group. This new line of analysis provides opportunities for intervention to ameliorate postural deficits, and improve life for individuals with autism in the realm of activities of daily living.

154 **164.154** Auditory Temporal Perception Is Enhanced in Children with ASD

N. E. Foster[1]*, A. Tryfon*[1,2]*, K. A. R. Doyle-Thomas*[3]*, E. Anagnostou*[4]*, K. L. Hyde*[1,2] *and .. NeuroDevNet ASD Imaging Group*[5]*, (1)International Laboratory for Brain Music and Sound Research (BRAMS), University of Montreal, Montreal, QC, Canada, (2)Faculty of Medicine, McGill University, Montreal, QC, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, CANADA, (4)University of Toronto, Toronto, ON, Canada, (5)http://www.neurodevnet.ca/research/asd, Vancouver, BC, Canada*

Background: Pitch and time are two fundamental dimensions of auditory perception. In Autism Spectrum Disorders (ASD), enhanced pitch perception has been reported (Bonnel, 2010), providing support for an auditory basis for the enhanced perceptual functioning (EPF) model of ASD (Mottron, 2006). However, the temporal resolution of auditory perception in ASD has been less studied. Here, we developed a task that allows testing the accuracy of both pitch and time judgments using analogous stimuli within the same participants.
Objectives: The aim of this study was to compare accuracy of fine-grained auditory pitch and time judgments between children with ASD and typically developing (TD) controls.
Methods: Participants were 36 ASD and 27 TD children from the NeuroDevNet project (Zwaigenbaum et al, 2011). Groups were age-matched (mean 12.5 years, range 7-17) and had IQ>70. ASD participants were diagnosed using ADI-R and ADOS. In the Pitch-Time task, reference stimuli consisted of 5 harmonically complex tones (3 harmonics) at 500 Hz, each 100 ms in duration, with an onset-to-onset interval of 350 ms. Participants judged whether the 5 tones were the “same” (reference stimuli) or “different” (pitch or time manipulation). In the Pitch condition, half of the trials had the 4th tone changed in pitch by up to 300 cents. In the Time condition, half of the trials had the 4th tone shifted in time by up to 200 ms. Pitch and Time conditions were presented in separate counterbalanced blocks. Accuracy (percent correct) on the task was calculated by splitting the “different” levels into 4 bins of interest having center values of 3.1, 9.4, 18.8 and 37.5 cents (Pitch), and 14, 35, 49 and 63 ms (Time). Effects of group and level on accuracy were assessed for each condition via ANOVA, and per-level comparisons were made using Student’s t-test with Bonferroni correction across the 4 bins ($p < .0125$).
Results: Â Participants with ASD were more accurate overall compared to the TD group on the Time condition ($F(1,38.9)=5.7$, $p=.02$; Figure 1). Accuracy varied across time levels in both groups ($F(3,106.5)=91.7$, $p<.001$). The greatest group difference was at the 35 ms Time level ($t(23.7)=3.1$, $p=.006$, 95% confidence interval 3.9%-20.2%). In the Pitch condition, accuracy varied significantly across pitch levels ($F(3,142.5)=132.4$, $p<.001$), but there was no group difference on the overall score or for any pitch level (all $p>.15$; Figure 2).
Conclusions: The results provide new evidence for enhanced auditory perception in the time domain in ASD. Accuracy of temporal judgments was greater overall in the ASD group, and this effect was most pronounced for judgments of time manipulations around 35 ms. This enhancement is consistent with and extends our understanding of low-level perceptual advantages under the EPF model in ASD. Further, the study of auditory perception in ASD serves as a complementary lens to more symptom-based studies, and helps to better understand individual differences in ASD.

155 **164.155** Biofeedback-Based Balance Training in Autism Spectrum Disorder

B. G. Travers[1]*, D. C. Dean*[1]*, A. H. Mason*[1]*, A. Ellertson*[2] *and L. A. Mrotek*[3,4]*, (1)University of Wisconsin - Madison, Madison, WI, (2)Boise State University, Boise, ID, (3)Kinesiology, University of Wisconsin-Oshkosh, Oshkosh, WI, (4)BioMedical Engineering, Marquette University, Milwaukee, WI*

Background: Many individuals with autism spectrum disorder (ASD) have difficulties with postural control (for review, see Memari et al., 2014). These postural control difficulties appear to be related to core autism symptom severity (Radonovich et al., 2013; Travers et al., 2013) and may affect adaptive daily living skills, such as dressing and driving. However, there is little published data on whether postural control can be enhanced in ASD through intensive balance training. Examining how balance in ASD changes as a function of training may shed light on the underlying mechanisms involved in poor postural control in ASD and would reveal who on the spectrum may benefit most from this type of training.
Objectives: 1) To examine if substantial balance improvements in ASD can result from a 6-week biofeedback-based balance training, and 2) to examine individual differences in age, cognition, and symptom severity that moderate the effectiveness of the training.
Methods: Twenty-two children and adolescents with ASD (1 female; ages 7-17 years) completed 6 weeks (18 sessions) of biofeedback-based balance training administered through an in-house video game. Each session lasted 60 minutes and consisted of participants playing our *Ninja Training* game that was developed to promote static balance, using a Kinect camera- and Wii balance board. In this game, each participant viewed him/herself on the screen and was asked to match his/her body to a shadow that portrayed one of six desired balance poses. Participants were rewarded for holding the pose as long as possible. We measured the total length of time that the participant was able to correctly hold each pose. Linear mixed-effects models examined balance-related changes over the course of the 18 training sessions in ASD. Pearson R correlations examined whether individual differences in IQ or symptom severity (SRS and RBS-R) were related to balance training outcomes.
Results: Over the 18 sessions of balance training, participants on average increased their balance times by ~2 seconds each session, exhibiting significant gains for both two-footed, β = 2.25, *SE* = .50, $p < .001$, and one-footed standing poses, β = 1.97, *SE* = .58, $p < .001$. Higher performance IQ (but not verbal IQ) related to longer starting balance times, $r = .50$ $p = .02$, and enhanced training-related gains, $r = .41$ $p < .05$. Less severe ritualistic behaviors (but not SRS or other RBS-R domains) related to enhanced training-related gains, $r = -.55$, $p = .008$. Age was not significantly related to starting balance times nor training-related gains (all *p*'s >.08), although the effect sizes were medium (*r*'s from -.36 to -0.38).
Conclusions: Overall, participants exhibited balance improvements, supporting that balance challenges in ASD can be targeted using biofeedback-based balance training. Surprisingly, age was not a strong predictor of training-related changes. However, individuals with ASD who had higher performance IQs and less frequent ritualistic behaviors demonstrated the largest improvements in balance. These data, while preliminary, shed light on why some individuals with ASD may have more persistent difficulties with balance than others.

156 **164.156** Can Timing Tasks Successfully Differentiate Children with ASD from Those with SLI?

A. Gladfelter[1]*, L. Goffman*[2]*, J. Vuolo*[2] *and H. Zelaznik*[3]*, (1)Northern Illinois University, DeKalb, IL, (2)Purdue University, West Lafayette, IN, (3)Health and Kinesiology, Purdue University, West Lafayette, IN*

Background: A perinatal disruption in cerebellar development has been proposed to be a direct cause of autism (ASD; Wang, Kloth, & Badura, 2014). Adults with cerebellar lesions exhibit timing deficits, as indicated by increased timing variability on a finger tapping task (Schlerf, Spencer, Zelaznik, & Ivry, 2007). Much like children with ASD, children with specific language impairment (SLI) show deficits in language and motor development. However, discrete timing is not implicated, because children with SLI do not show deficits in variability during single-effector timing tasks (Zelaznik & Goffman, 2010). Timing tasks that involve coordination of multiple effectors (e.g., clapping) are impaired in SLI (Vuolo, Goffman, & Zelaznik, accepted). Because of the overlap in symptoms, there has been some debate as to whether ASD and SLI are distinct developmental disorders (e.g., Bishop, 2010). We predicted that timing tasks, such as tapping and clapping, might be able to differentiate children with ASD from those with SLI.
Objectives: The goal of our study was to determine whether children with ASD perform more similarly to an individual with cerebellar dysfunction or SLI on timing tasks with one and two-effectors. If children with ASD show impaired single-effector timing, the results would support the hypothesis of cerebellar dysfunction in children with ASD. If children with ASD do not show impaired single-effector timing, but do show bimanual (multi-effector) coordination difficulties on timing, then the results would indicate that ASD is more similar to SLI.
Methods: Eleven children with ASD and 6 age-matched children with SLI (to date) participated in a tapping and a clapping task. Hand movements were recorded. Participants were trained to tap and clap to a 600 ms tone presented by a metronome, and to continue tapping and clapping at the same rate for 32 continuation intervals after the metronome disengaged. Six trials were completed for each task. The within-trial, within-participant variability (CV%) of the interval durations was calculated to provide a measure of timing precision. All children also completed the Movement Assessment Battery for Children – Second Edition to index general gross and fine motor skills.
Results: (Preliminary 11 ASD, 4 SLI) The children with ASD (*M* = 13.29 CV%, *SD* = 8.57) were more variable than their peers with SLI (*M* = 10.83 CV%, *SD* = 3.96) on the single-effector, finger tapping task, but equally variable on the multi-effector clapping task (ASD, *M* = 15.30 CV%, *SD* = 6.21; SLI, *M* = 15.00 CV%, *SD* = 6.07). The children with ASD also performed more poorly on the standardized test of gross and fine motor skills (*M* = 4.73, *SD* = 2.49) than their peers with SLI (*M* = 8.57, *SD* = 2.22).
Conclusions: Â Unlike children with SLI, children with ASD exhibited a decrement in timing precision on the single-effector timing task. This finding lends support to the cerebellar sensitive period hypothesis of ASD put forth by Wang and colleagues (2014). It also highlights the role of timing tasks, and potentially fine and gross motor tasks, in differentiating children with ASD from those with SLI.

157 **164.157** Caregiver Strain Varies By Sensory Subtypes of Children with Autism

B. Hand[1]*, A. E. Lane*[2]*, P. De Boeck*[1] *and A. Darragh*[1]*, (1)The Ohio State University, Columbus, OH, (2)University of Newcastle, Callaghan, NSW, Australia*

Background: Caregivers of children with autism spectrum disorder (ASD) have higher levels of strain than caregivers of children with attention-deficit/hyperactivity disorder, developmental disabilities, or other healthcare needs (Cadman et al., 2012; Dabrowska & Pisula, 2010; Estes et al., 2009). High caregiver strain has been associated with poorer quality of life of the caregiver and negative health behaviors including: decreased physical activity; poor sleep patterns; difficulties with weight maintenance; smoking; and alcohol consumption (Rizk, Pizur-Barnekow, & Darragh, 2014; Gallant & Connell, 1998). Level of strain experienced by caregivers of children with ASD has been shown to be a function of many parent and child characteristics, including the child's difficulty with reacting to everyday environmental sensory stimuli (Kirby, White, & Baranek, 2015; Schaaf, Toth-Cohen, Johnson, Outten, & Benevides, 2011). Recently, researchers have proposed a classification schema for children with ASD based on shared patterns of sensory difficulties that groups children into one of four sensory subtypes using parent responses to the Short Sensory Profile: Sensory Adaptive; Taste/Smell Sensitive; Postural Inattentive; and Generalized Sensory Difference (Lane et al., 2014). As these subtypes have been documented to differ on many behavioral characteristics, it is reasonable to hypothesize that caregivers of children in different subtypes may differ in level of perceived strain (Lane et al., 2010, 2011, 2014). Therefore, sensory subtyping may be a useful mechanism for determining which caregivers of children with ASD may be at risk for the highest levels of strain.
Objectives: We sought to examine the relationship between child sensory subtype and the level of strain reported by the caregiver.
Methods: This study used a non-experimental, cross-sectional design to conduct an online survey of caregivers of children with ASD (n=367). The primary variables of interest were child sensory subtype, as measured by the Short Sensory Profile (McIntosh et al., 1999), and caregiver strain, as measured by the Caregiver Strain Questionnaire (Brannan et al., 1997). Caregiver age, child age, household income, and number of children in the home were included as covariates. A canonical correlation analysis was conducted to examine the relationship between child sensory subtype and caregiver strain.
Results: Caregiver strain was significantly associated with the child's sensory subtype membership, while controlling for demographic variables. Caregivers of children in the Sensory Adaptive subtype reported the lowest levels of caregiver strain, followed by caregivers of children in the Taste/Smell Sensitive subtype. Caregivers of children in the Postural Inattentive and Generalized Sensory Difference subtypes reported the highest levels of strain.
Conclusions: This study demonstrates that strain of caregivers of children with ASD is associated with the child's sensory subtype. Findings from studies using qualitative methods suggest possible mechanisms by which caregiver strain is related to child sensory subtype membership; behaviors consistent with those observed in children in the Postural Inattentive and Generalized Sensory Difference subtypes, for example, were reported to result in disruption of family routines and social activities (Schaaf et al., 2011), which may explain why caregivers of children in these subtypes report the highest levels of strain.

158 **164.158** Characterising the Relationship Between Anxiety, Executive Function, and Restricted and Repetitive Behaviours in Children and Adolescents with Autism Spectrum Disorder

J. Lei[1], *D. G. Sukhodolsky*[1], *S. M. Abdullahi*[1], *M. L. Braconnier*[1], *C. Kautz*[1], *K. A. Pelphrey*[2,3] *and P. E. Ventola*[1], *(1)Yale Child Study Center, New Haven, CT, (2)Yale University, New Haven, CT, (3)Autism and Neurodevelopmental Disorders Institute, The George Washington University, Washington, DC*

Background: Kanner (1943) first hypothesised that anxiety may underlie restrictive and repetitive behaviours (RRBs) observed in children with Autism Spectrum Disorder (ASD), serving as a maladaptive coping mechanism (Rimland, 1964). RRBs may also be associated with poor executive functions (EF), such as poor impulse control, and inflexibility to shift between different tasks (Turner, 1997). However, little is known about the underlying relationship of anxiety with EF and RRBs in children and adolescents with ASD. Better understanding anxiety and EF's roles in RRBs may inform the development of evidence-based treatments to help reduce RRBs.
Objectives: To characterise the relationship between anxiety, EF (impulse control and flexibility), and RRBs in children and adolescents with ASD, and explore possible mediators of RRBs.
Methods: Participants included 41 high-functioning children and adolescents with ASD between the ages of 5 and 17 years (male = 20, female = 21; IQ Mean = 102.24, SD = 19.03; range 74 to 167). Parents completed all behavioural measures. Anxiety subscale of Child and Adolescent Symptom Inventory – 5 (CASI-5) (Sukhodolsky et al., 2007) measured anxiety. The Inhibition and Shift subscales of Behavior Rating Inventory of Executive Function (BRIEF) measured impulse control and flexibility respectively. Repetitive Behavioral Scales-Revised (RBS-R) measured RRBs. First, Pearson's correlation evaluated the relationship between anxiety, flexibility, impulse control, and RRBs. Next, hierarchical linear regression further partitioned the variance associated with anxiety and EF in predicting RRBs. Finally, mediation analyses evaluated possible mediating roles of flexibility and impulse control on the relationship between symptom severity of co-occurring anxiety, and RRBs. Age was controlled in all analyses.
Results: We found significant positive correlation between anxiety (CASI-5 raw) and RRBs (RBS-R total raw) (r =.57, p <.001). Greater difficulties in both impulse control (BRIEF-Inhibit raw), and flexibility (BRIEF-Shift raw) were associated with heightened anxiety (r =.46, p <.01; r =.48, p <.01; respectively), and greater RRBs (r =.64, p <.001; r =.78, p<.001; respectively). Hierarchical Linear regression model (Table 1) showed that flexibility accounted for a significant portion of the variance associated with RRBs, R^2 =.55, F (1,38) = 34.18, p <.001. Adding impulse control did not increase the overall model's ability to account for variances associated with overall RRBs. Adding anxiety accounted for additional variance associated with RRBs, R^2 change =.04, p <.05, and significantly improved model's ability to account for variances associated with RRBs, F change (1,36) = 4.18, p <.05. Mediation analyses revealed that flexibility, and not impulse control, partially mediated the relationship between anxiety and use of RRBs (Figure 1), *Sobel's Z* = 2.93, p<.01. Anxiety did not mediate the relationship between flexibility and RRBs.
Conclusions: Results indicate that children and adolescents with ASD who experience greater levels of anxiety display more RRBs, which was partially mediated by poor flexibility and set-shifting. One clinical implication may be that simultaneously targeting symptoms of anxiety and improving flexibility may help reduce RRBs in young people with ASD. Future research can determine whether findings may hold in a lower-functioning sample, and investigate gender differences.

159 **164.159** Characterization and Clinical Impact of Repetitive Compulsive Behaviors in a Cohort of Psychiatrically Hospitalized Children with ASD

M. Grados[1], *T. Palka*[2], *C. A. Beresford*[3], *F. Barrera*[4], *C. Peura*[5], *P. Kodi*[1], *D. Kaplan*[6], *M. Verdi*[2] *and E. Sannar*[7], *(1)Johns Hopkins University School of Medicine, Baltimore, MD, (2)Developmental Disorders Program, Spring Harbor Hospital, Westbrook, ME, (3)Children's Hospital, Denver Colorado, Aurora, CO, (4)Maine Medical Center, Portland, ME, (5)Developmental Disorders Unit, Spring Harbor Hospital, Westbrook, ME, (6)Child and Adolescent Neuropsychiatry Unit, Sheppard Pratt Health System, Towson, MD, (7)Children's Hospital Colorado, Aurora, CO*

Background: Repetitive compulsive behaviors (RCBs), including stereotypies, self-injurious behaviors and compulsions, are a key clinical feature of autism spectrum disorder (ASD). Diverse RCBs have been reported for patients with different levels of IQ and verbal abilities, but scarce data are available for behaviorally dysregulated patients with ASD requiring hospitalization for acute stabilization.
Objectives: This study aims to characterize RCBs and assess their clinical impact for a sample of youth with ASD hospitalized due to acute behaviors and/or co-morbid psychiatric conditions.
Methods: Youth aged 4-20 years, with an ADOS-confirmed ASD and admitted to a specialized inpatient psychiatry unit, were prospectively enrolled in a six-site study examining patient phenotypes, including RCBs, as part of the Autism Inpatient Collection (AIC). Data regarding the occurrence and nature of RCBs, length of hospital stay, parent stress, and patient community-reported sleep were collected. Caregivers also reported on the following measures at admission: Social Communication Questionnaire (SCQ), Aberrant Behavior Checklist-Community (ABC-C), Self-Injury Subscale of the Repetitive Behaviors Scale-Revised (RBS-R), and the Parent Stress Index-4 –Short Form (PSI-4-SF). They also answered direct questions about patient sleep problems at home, including quality of sleep, awakenings and problems falling asleep. Questions that reflect RCBs from the SCQ (7 items), ABC-C (10 items) and RBS-R (8 items) were chosen and compiled to generate an RCBs composite. Linear regressions estimated the effect of the RCB composite on each of the following outcomes: length of hospital stay, community sleep indicators and parental stress, while controlling for confounders.
Results: Data from 164 patients with ASD who were hospitalized and had complete survey data were analyzed. The mean patient age was 12.8 years (*SD*=3.22). The sample was 23% female and 87% Caucasian. The RCB composite score was significantly associated with higher parental stress level (p=0.002), poor sleep in the community (p=0.01), more frequent awakenings in the community (p=0.04) and longer length of stay (p=0.007). RCB composite scores were then adjusted for IQ and parental income as appropriate, with results continuing to be significant for parental stress (p=0.001), poor community sleep (p=0.02), difficulty falling asleep in the community (p=0.02), and length of stay (p=0.05).
Conclusions: Â RCBs are common and problematic among psychiatrically hospitalized youth with ASD. Results show that RCBs were correlated with clinical outcomes including dysregulated sleep patterns, longer hospitalizations and greater parental stress. These results are independent of the patient's IQ and parental income level, suggesting that RCBs could be a specific target for intervention to improve overall outcome. While causal connections between RCBs sleep patterns are not yet evident, future research could investigate neurobiological connections between these two clinical phenomena.

160 **164.160** Characterizing Restricted and Repetitive Behavior Expression in Minimally Verbal Children and Young Adults with ASD Using Direct Observation and Parent Report

A. M. Yoder[1]*, B. Joseph*[1]*, D. Plesa-Skwerer*[1]*, T. C. Day*[1] *and H. Tager-Flusberg*[2]*, (1)Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA*

Background:
Despite increasing efforts to investigate restricted and repetitive behaviors (RRBs) as one of two core symptoms of autism spectrum disorder (ASD), little is known about their expression in minimally verbal (MV) individuals. Previous research quantifying RRBs in MV individuals with ASD used parent report to supplement routine observations taken during diagnostic testing, but there have been no systematic analyses of RRBs observed during a semi-structured clinical assessment compared with parent report.
Objectives:
First, to quantify the expression of RRBs in MV children and adolescents with ASD using direct observation methods and to compare those results to parent report and, second, to examine the relations been RRBs and age, nonverbal IQ (NVIQ), and receptive vocabulary.
Methods:
Participants
40 individuals, aged 5;3-20;10 years (M=10;5 years), with limited expressive language abilities and a diagnosis of ASD.
Direct Observation
Two raters independently coded ADOS-2 and Adapted ADOS videos for the frequency of RRBs (Kappa=0.81), using a coding scheme based on Repetitive Sensory Motor (RSM) and Insistence on Sameness (IS) subcategories (Bishop et al., 2013) and operational definitions similar to those from the Autism Diagnostic Interview-Revised (ADI-R) and the Repetitive Behavior Scale-Revised (RBS-R). Because administration duration of the ADOS varied across participant (range=45-60 minutes), the frequency of RRBs was translated into rate-per minute of RRBs.
Parent Report
Parents reported the current frequency and intensity of participants' RRBs on the ADI-R and RBS-R. Table 1 shows the percentage of participants who exhibited one or more of the specific RRBs according to parent report.
Other Assessments
The Leiter-3 and Peabody Picture Vocabulary Test (PPVT-4) were administered to assess NVIQ and receptive vocabulary, respectively.
Results:
Almost all participants (97.5%) expressed one or more RSM behavior during the ADOS administration, consistent with parent report. However, only 20% expressed one or more IS behaviors during the ADOS, compared to higher proportions of parent-reported IS behaviors, in daily activities (Table 1).
Observed RSM behaviors were positively correlated with parent-reported RSM behaviors on the ADI-R ($r_s(38)=0.33$, $p=.04$), but were negatively correlated with NVIQ raw scores ($r_s(38)=-.49$, $p=.001$) and PPVT-4 raw scores ($r_s(38)=-0.53$, $p=.00$). There were no correlations between observed RSM behaviors and age, parent-surveyed RSM behaviors (RBS-R), or between any observed or parent reported IS behaviors (Table 2).
Conclusions:
RSM behaviors expressed by MV individuals with ASD are salient enough to be observed in a brief, semi-structured lab setting as well as in the daily activities parents observe. However, format of parent report and method of completion (i.e., interview vs. self-completed questionnaire) could influence correlational results between lab observations and parent report. The lack of correlations between observed and parent-reported IS behaviors are likely a result of their relatively low frequency in a novel laboratory environment.
In addition, the negative correlation between RSM behaviors and receptive word knowledge suggests the need for language and communication interventions to supplement standard behavioral interventions in this population.

161 **164.161** Comparing Severity of Restricted and Repetitive Behaviors Between High Risk Baby Siblings with Different Temperament Profiles

***J. Chen**, J. D. Burke, M. Barton and D. A. Fein, Psychological Sciences, University of Connecticut, Storrs, CT*

Background:
Early self-regulatory behavior is a key component of temperament (Rothbart, Posner, & Kieras, 2006). High risk baby siblings with ASD demonstrate early signs of repetitive behaviors, as well as difficulties with self or other regulation (Bryson et al., 2007). Poor behavior regulation also predicts repetitive behaviors in high functioning school-aged children with ASD (Boyd, et al., 2009). The current study further explores the relationship between early behavior regulation and repetitive behaviors in high risk baby siblings who screened positive for ASD.
Objectives:
To compare severity of restricted and repetitive behaviors (RRBs) in high risk baby siblings with distinctive temperament profiles at age 2.
Methods:
Baby siblings of children with ASD were screened for autism using the M-CHAT(-R) at age 2. Parents of children who screened positive completed the Toddler Temperament Scale (TTS) and Repetitive Behavior Scale – Revised (RBS-R) during a diagnostic evaluation. Mean scores on the Activity, Rhythmicity, Approach, and Distractibility subscales of the TTS (with acceptable internal reliability; i.e., Cronbach's $\alpha \geq 7$; Chen, Barton & Fein, 2016) were dichotomized to contrast the top quartile against the remainder, and entered into a latent class analysis. Model fit indicators suggested a two-class solution as the best model. The two latent classes were subsequently labeled *Poorly Regulated and Attuned* (PRA) and *Well Regulated and Attuned* (WRA; see Figure 1). The PRA group was relatively more likely to endorse high activity, arrhythmicity, and poor approach, and less likely to endorse high distractibility. Chi-square tests were used to compare demographics between the PRA (n = 87) and WRA (n = 40) groups. Logarithmic or square root transformations of RBS-R Total and subscale scores were performed to address skewness in the data. Diagnostic group (ASD, non-ASD) was entered into a hierarchical linear regression before entering the dummy-coded latent classes as predictors of RBS-R scores.
Results:
Chi-square tests indicated no significant differences in age or gender between the PRA and WRA groups. The PRA group had a significantly higher proportion of baby siblings diagnosed with ASD. Logarithmic transformations of the RBS-R Total, Stereotyped Behavior, and Sameness Behavior scores successfully addressed data skewness. Transformations of the other domain scores were unsuccessful due to severe positive skew. Linear regression results indicate a significant improvement in variance predicted by temperament latent class above variance predicted by diagnostic group alone for RBS-R Total Score ($p < .001$, $\Delta R^2 = .118$), Stereotyped Behavior ($p < .001$, $\Delta R^2 = .100$), and Sameness Behavior ($p < .001$, $\Delta R^2 = .083$).
Conclusions:
High risk baby siblings who screen positive for ASD at age 2, and who demonstrate different temperament profiles in early patterns of behavioral regulation and attunement to others, differ significantly in the severity of their RRB symptoms. More severe RRBs were associated with high activity, poor rhythmicity, poor approach, but less distractibility, suggesting that perseverative attention may contribute to RRBs. These differences exist above and beyond having a diagnosis of ASD. Early regulatory behaviors may provide important information about ability to regulate maladaptive repetitive behaviors.

162 **164.162** Comparing fNIRS-Based Cortical Activation Patterns Between Children with and without Autism, during Bilateral Coordination Tasks

***S. Trost**[1], M. Culotta[1], M. Hoffman[1] and A. N. Bhat[2], (1)Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE*

Background: Impairments in motor coordination are often reported in children with Autism Spectrum Disorder (ASD). For example, children with ASD have difficulties with upper-limb, bilateral, and/or visuo-motor coordination using various standardized measures (Bhat, Landa, & Galloway, 2011; Jansiewicz et al., 2006). In the current study, we implemented a novel neuroimaging tool called functional near-infrared spectroscopy (fNIRS) to study the sensori-motor patterns of children with and without ASD during a drumming task.
Objectives: We compared fNIRS-based cortication activation in frontal, parietal, and temporal cortices during drumming between children with and without ASD as well as healthy adults.
Methods: 12 children with and without ASD between 6 and 12 years of age and 12 healthy adults were seated with a tubano drum. The task involved drumming in 3 ways (Srinivasan et al., 2015): a) *Unilateral*: the child hit the drum with one hand only, b) *Alternating*: *the* child hit the drum with both hands alternately, and c) *Complex*: the child hit the drum using a complex quarter-eighth pattern (1:2). 24 trials were collected, 8 per condition using a randomized block design. The oxy hemoglobin response of the fNIRS signal was further analyzed to study differences in activation patterns between tasks, between hemispheres, and between the regions of interest (primary motor, primary somatosensory, auditory).
Results: Our preliminary data suggest that complex drumming led to highest level of cortical activation compared to alternating or unilateral patterns. We also found hemispheric differences depending on the nature of the task. The hemispheric differences were primarily seen in the sensori-motor regions.
Conclusions: We noticed variations in cortical activation patterns based on tasks, hemispheres, and regions. We believe these findings could be used to explain the cortical abnormalities contributing to the motor issues observed in children with ASD. In addition, fNIRS-based activation may be a neurobiomarker to assess treatment-related changes following motor interventions.

163 **164.163** Cross Sectional Associations Between Measures of Social Function, Postural Control and Motor Coordination

***S. L. Morris**, Curtin University, Perth, WA, Australia*

Background: Autism Spectrum Disorders (ASD) are c disorders of social communication and behaviour. Research and treatment focus is on the cognitive, social and behavioural aspects of ASD. Yet motor skill and postural control are significantly different in people with ASD with effect strength of 1.2. Postural control is needed for both social function and motor skill. The pattern of movement of the centre of pressure (COP) during standing represents the control processes underlying postural control. Sample entropy measures the regularity or amount of information in a signal. Less entropy in the COP signal indicates more regular COP fluctuations and more active control of posture. The effective use of visual information is critical to the development of motor function, postural control and social function. The relationship between social function, postural control and motor coordination has not been reported in research literature. The relationship among these factors may inform potential causal pathways in ASD.
Objectives:
To determine the cross sectional associations between measures of social function, postural control and motor coordination.
Methods:
Cross sectional study design. 49 adults selected for their ASD status (n=19) or typically developed (TD) status (n=29) were tested for postural control in quiet stance during eyes open (EO) (30 seconds) and eyes closed (EC) (30 seconds). Only 46 had complete data for postural control (3 TD missing). The sample entropy of each 30 second signal was calculated for the mediolateral (ML) and anterior-posterior (AP) sway. Motor coordination was assessed using the McCarron Assessment of Neuromuscular Development (MAND)-the MAND gross motor (GM) score was used. ASD symptomology was assessed using the Social Responsiveness Scale (SRS-2). All measures were continuous and were compared using Pearson correlation with $p<0.05$ considered as statistically significant. Stepwise linear regression with pin=0.05 and pout=0.10 was undertaken.
Results:
Correlations were statistically significant between the SRS-2 score and the MAND GM score (r=-0.445, p=0.002); the MAND GM score and the sample entropy of the mediolateral sway component during eyes open (r=-0.355, p=0.015). Entropy measures with eyes closed (EC-AP, EC-ML) were not significantly related to the MAND GM score or the SRS-2 (p>0.508). EO-AP sample entropy was not significantly related to the SRS-2 score at p=0.082 (r=-0.259). Stepwise linear regression of SRS-2 against the other variables resulted in a model that explained 23% of the variance (adjusted r square) in the SRS-2 score. SRS-2 = 81.735-0.381 (SE 0.112)(MAND GM) -61.298 (SE 26.992)(sample entropy EO-AP).
Conclusions: Nearly one quarter of variation in social impairment (higher SRS-2) could be explained by poorer gross motor function (lower MAND GM) and more active control of sway in the AP direction with vision. AP sway is generally controlled by the somatosensory system. The findings suggest that these factors are independently related to social impairment. Poor gross motor function was related to a less controlled posture in the mediolateral direction. Mediolateral sway is controlled primarily by visual fixation and the finding supports the hypothesis that poor gross motor function may be related to a lower sensory weighting of vision in postural control.

164 **164.164** Deficits in Taste Identification, in the Context of Intact Taste Sensitivity, in Autism Spectrum Disorder

K. Schauder[1], *P. Allen*[2], *J. M. Keith*[3], *C. J. Zampella*[4,5], *L. N. Soskey*[3], *C. J. Stodgell*[6], *S. L. Hyman*[7] *and L. Bennetto*[3], *(1)University of Rochester, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY, (3)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (4)Clinical & Social Sciences in Psychology, University of Rochester, Rochester, NY, (5)Child and Adolescent Psychiatry and Behavioral Sciences, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of Rochester School of Medicine & Dentistry, Rochester, NY, (7)Developmental and Behavioral Pediatrics, University of Rochester School of Medicine, Rochester, NY*

Background: Atypical sensory processing is widely appreciated as a symptom of autism spectrum disorder (ASD). Experimental data exists across all sensory domains, with a dearth of studies in the domain of gustation (i.e., taste) compared to other sensory domains (e.g., vision, audition). Gustation is important to consider in ASD, not only in the context of sensory processing, but also because atypical taste perception could contribute to the known feeding difficulties associated with ASD (e.g., picky eating). In addition, it remains unknown if taste perception differences exist more broadly across family members with ASD, or if they are specific to individuals with ASD. Taste perception can be evaluated at two levels, taste sensitivity and identification. Taste sensitivity is associated with brainstem functioning whereas taste identification relies on cortical processing networks. Assessing taste at these levels allows us to test for possibly dissociable differences in neural functioning in the context of gustation.
Objectives: Â The purpose of this study was to assess gustation, at the level of both taste sensitivity and taste identification, across three groups: individuals with ASD, unaffected siblings of individuals with ASD, and typically developing (TD) controls.
Methods: Â 81 children, adolescents, and young adults (ages 10-25) with well-characterized ASD, 51 unaffected siblings, and 69 age- and IQ-matched TD controls completed two tasks assessing gustation. Electrogustometry was used to estimate taste sensitivity thresholds on both sides of the tongue using an adaptive staircase procedure. Taste identification was evaluated via "Taste Strips," which assessed identification of sweet, sour, salty, and bitter stimuli, each presented at four concentration levels. A 3 (group) x 2 (side of tongue) mixed-model ANOVA was used to test for differences in taste sensitivity. A 3 (group) x 4 (taste) mixed-model ANOVA investigated differences in taste identification abilities. Follow-up tests were conducted accordingly.
Results: Analyses revealed similar electrogustometry thresholds across groups ($F = 2.46$, $p > .05$). In contrast, there were significant group differences in taste identification accuracy (main effect of group: $F = 14.99$, $p < .001$), with post-hoc Tukey tests indicating that individuals with ASD had significant deficits in overall taste identification compared to both unaffected siblings ($p < .001$) and TD controls ($p < .001$). However, there was no group x taste interaction ($F = .63$, $p > .05$), suggesting consistent impairment in ASD participants across all individual tastes.
Conclusions: This study showed impaired taste identification in the context of intact taste sensitivity in ASD. This suggests that while brainstem functioning seems intact, cortical networks required for taste identification may be selectively disrupted ASD. Unaffected siblings were strikingly similar to TD controls, suggesting that deficits in taste identification is specific to the ASD phenotype and not represented more broadly in family members. Ongoing analyses are exploring gustatory misperceptions (via confusion matrix analyses) and examining how differences in taste perception impact restricted food preferences and vary in the parents of individuals with ASD.

165 **164.165** Defining the 'Autism Motor Signature': Characterisation of Motor Patterns of Children with Autism during Ipad Gameplay

K. Sobota[1,2], *A. Anzulewicz*[1,3], *C. Tachtatzis*[2] *and* ***J. T. Delafield-Butt***[3], *(1)Harimata, Kraków, Poland, (2)Electronic and Electrical Engineering, University of Strathclyde, Glasgow, United Kingdom, (3)Faculty of Humanities and Social Sciences, University of Strathclyde, Glasgow, United Kingdom*

Background:
New evidence indicates disruption to motor timing and integration may underpin autism spectrum disorder (Trevarthen & Delafield-Butt, 2013).Â In previous work, we employed smart tablet computers with touch-sensitive screens and embedded inertial movement sensors to record the movement kinematics and gesture forces made by children with autism and children developing typically. Machine learning analysis of those children's motor patterns identified autism with 93% accuracy, supporting the notion disruption to movement is core feature of autism, and demonstrating autism can be computationally assessed by fun, smart device gameplay (Anzulewicz, Sobota, & Delafield-Butt, 2016). Machine learning analysis is a powerful tool, but it is a 'black box' approach.Â Here, we present new analyses to better define the nature of the motor disruption and therefore to better characterize the 'autism motor signature'.
Objectives:
(1) Determine the kinematic features that characterize the autism motor signature during iPad gameplay.
(2) Define these in terms of motor control properties to better understand its nature.
Methods:
37 children 3-6 years old clinically diagnosed with Childhood Autism and 45 age- gender-matched children developing typically were included. Children with sensory or motor impairment were excluded. iPad mini tablet computers employed two education games: *(1)* 'Sharing' where the main gameplay was to divide a piece of food (e.g. an apple) and distribute it evenly among four children on the screen; and *(2) Creativity* where gameplay was open, unstructured colouring of a toy or animal. Children were seated at a table and the iPad placed in front of them. A five minute unassisted 'experimental' phase was preceded by a two minute assisted 'training' phase.Â Data was collected during 'experimental' gameplay from the tablets' inertial sensors (tri-axial accelerometer, tri-axial gyroscope and magnetometer) and touch screen.Â Raw values and simple kinematic calculations (e.g. gesture duration, amplitude, acceleration, etc.) produced 262 'features' analysed in previous machine learning work with a classification accuracy of 93%.Â These same features were extracted and analysed using standard statistical multivariate analyses.
Results:
Features associated with greater forces made at contact and forces put into the device within a gesture were greater and more variable in children with autism than in children developing typically, respectively.Â Further, gesture kinematics were faster and larger, with more distal use of space in children with autism. And children with autism made faster taps on the screen.
Conclusions:
iPad gameplay stands in agreement to standard measures, providing and accessible new paradigm for autism research. A particular motor pattern characterised by greater impact forces was apparent, supporting the notion that termination of a movement is different, difficult, or disrupted in autism. This finding corroborates data in reach-to-grasp and reach-to-place paradigms that demonstrate greater velocity at the termination of a movement (Crippa et al., 2015). Identification of greater variation in the distribution of forces during a gesture corroborates with reach-to-grasp motion capture data (Cook et al., 2013; Torres et al., 2013). Thus, it appears sub-second regulation of children's intentional movements and timing their termination are two key features of the autism motor signature.

166 **164.166** Determining the Target Postures of Affective Facial Expression in Autism Spectrum Disorder

T. Sorensen[1]*, R. B. Grossman*[2] *and S. Narayanan*[3]*, (1)Linguistics, University of Southern California, Los Angeles, CA, (2)FACE Lab, Emerson College, Boston, MA, (3)University of Southern California, Los Angeles, CA*

Background: The generation of affective facial expressions involves deforming the face to achieve target postures. As a disorder of social communication, Autism Spectrum Disorder (ASD) may involve an atypical inventory of target postures for affective facial expression. Identifying target postures of the face and quantifying the size of target posture inventories may provide insight into how ASD perturbs the motor organization of communicative behavior. These perturbations to affective facial expression may be among the mechanisms which give rise to the perceived atypicality of affective facial expression in ASD.
Objectives: We used a motion capture system in order to identify target postures in the affective facial expressions of children with high-functioning autism (HFA) and typically developing (TD) children. Specifically, we clustered the sampled motion capture marker positions into target postures of the face. We quantified the difference in size of HFA and TD target posture inventories.
Methods: Subjects included 21 children with HFA and 16 TD children, aged 9-14. The experimental task was to watch and mimic the affective facial expressions shown in short video clips. These facial expressions exhibited either Anger, Sadness, Disgust, Surprise, Fear, or Happiness. Each child mimicked 18 expressions. Six motion capture cameras recorded the position of 28 markers and 4 reference sensors on the face at 100 frames per second. Using the reference sensors, a basis was chosen which expressed the position of the 28 markers independently of rigid head motion. The sampled marker positions were clustered into target postures using the k-means algorithm for each recording separately. The number of clusters k was determined as the smallest number for which the clusters explained a threshold percentage of the variance. We varied the threshold over 70%, 80%, and 90% in order to assess the sensitivity of the method. Explained variance was calculated as the ratio of the quantity (1 - within cluster sum of squares) to the total sum of squares. Lower face markers were clustered separately from upper face markers.
Results: In our sample, children with HFA differed from their TD peers in the number of target postures achieved for Anger, Sadness, Disgust, Surprise, Fear, and Happiness. This reflects a quantifiable size difference in the target posture inventories of the HFA and TD groups.
Conclusions: Children with HFA may develop different target posture inventories for affective facial expression than their TD peers. This reflects how ASD perturbs the motor organization of communicative behavior. Further analysis of motor atypicalities will shed light on the mechanisms underlying the perceived atypicality of affective facial expression in ASD.

167 **164.167** Earlier ASD Age of Onset Is Associated with More Amounts and More Severe Restricted and Repetitive Behaviors

H. Root[1]*, P. Hickey*[2]*, S. M. Attar*[2] *and E. Hanson*[3]*, (1)University of Massachussetts at Amherst, Amherst, MA, (2)Boston Children's Hospital, Boston, MA, (3)Children's Hospital Boston, Boston, MA*

Background: Restricted and repetitive behaviors (RRBs) are a core feature of Autism Spectrum Disorders (ASD) (DSM-V, 2013) that can interfere with many aspects of daily functioning (Richler, Heurta, Bishop, & Lord, 2010). For some children, these impairing behaviors are present from as early as 20 months of age (Cox et al, 1999). Moore and Goodson have also shown that the total number of RRBs tend to increase between 2 and 4 years of age (Moore and Goodson, 2003). While research has indicated a relationship between age and RRBs (Richler et al, 2011; Cox et al, 1999; Moore & Goodson, 2003), less is known about the specific relationship between the age of onset of ASD symptomatology and the presence and severity of RRBs.
Objectives: In this study, we explored the role of age of onset of ASD symptoms on the total number of RRBs and the severity of RRBs.
Methods: Â A sample of 473 participants (82% male) aged 36-272 months (SD=48.3, Mean=98.7) were examined for the current study. The Autism Diagnostic Observation Schedule (ADOS) (Lord et al, 2003) and Autism Diagnostic Interview-Revised (ADI-R) (Rutter et al, 1994) was used to verify ASD diagnosis for all participants. The ADI-R was used to evaluate participant's age of onset of symptoms (Question 87). The Behavior and Sensory Interest Questionnaire (BSIQ) (Hanson et al, 2016) was administered to evaluate the total number of RRBs and the severity of those RRBs. Descriptive statistics, a Spearman Rank Test and Mann Whitney U Tests, as the data was not normally distributed, were used to determine the relationship between age of onset and the presence and severity of RRBs. Consistent with prior research, we used norms for early age of ASD onset that have already been set in the field: Early Onset is defined by ASD symptomatology noticed before or at 2 years of age (Baraneck, 1999; Werner et al., 2000), while Late Onset is defined by ASD symptomatology noticed after 2 years of age (Palomo, Belinchon, & Ozonoff, 2006).
Results: Age of Onset was negatively correlated with total amount of RRBs overall ((r(473) = -0.080, p = 0.081) and the total amount of severe RRBs (r(473) = -0.114, p=0.013). Children who experienced Early Onset had significantly more RRB symptoms than children who experienced Late Onset (p=0.019).
Conclusions: Overall, children with Early Onset present with more RRBs overall and more severe RRBs than children with Late Onset. This indicates that there is a relationship between age of onset of ASD symptoms and the presence and severity of RRBs. Additional studies evaluating the effect of services provided to the child may be a potential mediator between age of onset of symptoms and RRBs.

168 **164.168** Evaluating Multimodal Driver Displays of Varying Urgency for Drivers on the Autistic Spectrum

L. S. Shim[1], *P. Liu*[2], *I. Politis*[3], *P. Regener*[4], *S. Brewster*[5] *and F. Pollick*[6], *(1)School of psychology, University of Glasgow, Glasgow, United Kingdom, (2)School of psychology, University of Glasgwo, Glasgow, United Kingdom, (3)University of Cambridge, Cambridge, United Kingdom, (4)Glasgow University, Glasgow, UNITED KINGDOM, (5)School of Computing Science, University of Glasgow, Glasgow, United Kingdom, (6)School of Psychology, University of Glasgow, Glasgow, United Kingdom*

Background: Individuals with ASD demonstrate alterations in sensory processing within different modalities and uncommon responses to sensory stimuli across multiple sensory domains. It is important to note that abnormal sensory processing does not necessarily mean worse performance, as there is evidence of enhanced perceptual functioning in autism. Recent studies show differences of multisensory perception between typically developed and ASD individuals that potentially can lead to difficulties in the integration of multiple sensory signals in everyday situations, such as driving. This is relevant since diverse modes of sensory information can be used to warn a driver and multisensory warnings incorporating two or more modalities show promise in their effectiveness.
Objectives: To evaluate the effectiveness of multisensory warning signals, designed to indicate different levels of urgency, in individuals on the autism spectrum.
Methods: The study involved 20 male (10 typically developed and 10 ASD) participants. The ASD group was defined by having an AQ score over 26 and had an average AQ score of 40.3. Two experiments were conducted: (1) Experiment 1 examined perceive urgency and annoyance with the warnings and (2) Experiment 2 measured recognition accuracy of the level of urgency and the reaction time during a simulated driving task.
Warning design: The warnings used in this study were similar to those of a previous study (Politis, I. et al (2013)). Totally, twenty-one different signals were obtained from the combination of: (1) three levels of designed urgency (LDU) and (2) seven sensory conditions which included unimodal, bimodal and trimodal combinations of audio, visual and tactile.
Results: The results of Experiment 1 revealed that there was no difference between TD and ASD groups in the perceived urgency of the warning signals, though the autism spectrum group reported lower annoyance with the signals than TD group ((*F*(1,58) = 13.22, *r* = 0.43, *p* < 0.01)). Experiment 2 showed that while both groups exhibited high accuracy in correctly reporting urgency level, the autism spectrum group performed better (*Q*(1) = 11.80, *p* < 0.01). Moreover, the fastest overall reaction times obtained were by the autism spectrum group when the warning included a visual component, with vision alone (*F*(1,57) = 5.62, *r* = 0.30, *p* < 0.001) producing the quickest response.
Conclusions: This study compared how typically developed people and individuals with ASD responded to a set of multimodal combinations to alert drivers to events of varying urgency. Two group difference were found in that the ASD group reported the warning signals to be less annoying than the typically developed participants and the ASD group showed an advantage in response time when the warning included a visual modality, in particular for the vision-only condition. These results highlight that while there are similarities, substantial performance differences exist between typical and autism spectrum individuals, suggesting that consideration of these differences can contribute to the design of effective warning signals.

169 **164.169** Exploratory Factor Analysis and Test-Retest Reliability of the Sensory Environment and Participation Questionnaire (SEP-Q)

B. Pfeiffer*, Temple University, Hatfield, PA*

Background: The ability to participate in common daily activities can have a profound impact on the development of young children. One factor identified to impact daily activity for children with Autism Spectrum Disorders (ASD) is the fit between individual sensory processing patterns and the sensory environment (Reynolds, Bendixon, Lawrence, & Lane, 2011). It is estimated that 70-96% of all children with ASD have unusual responses to sensory stimuli in the environment (Ben-Sasson et al., 2009). Unfortunately, there are few instruments that measure the environmental impact on participation in natural environments for children with ASD and even less that measure the sensory characteristics of the environment. The SEP-Q was developed to fill this need, although requires further examination to determine underlying structures of the variable, internal consistency, and test re-test reliability prior to clinical use.
Objectives: The objectives of this study was to examine internal consistency, factor structure, and test-retest reliability of the Sensory Environment and Participation Questionnaire (SEP-Q) in young children with ASD. The SEP-Q measures parents' perspective of the impact of the sensory environment on participation, as well as parent effort to support participation both in home and community environments.
Methods: Â A cross sectional design was used to collect data for psychometric analyses. Participants were 125 parents of children with ASD between the ages of 3 and 5 years old. Recruitment occurred nationally through social media, ASD community/support groups, private preschools, and school districts. Participants completed the SEP-Q, along with the Gilliam Autism Rating Scale (GARS) to confirm diagnosis, and a demographic questionnaire. Participants were emailed a link to collect data through Qualtrics Survey software or were provided with a paper version of the questionnaires based on preference. Cronbach's alpha was used to calculate internal consistency. Canonical correlations and Intra-Class Correlation (ICC) were used to calculate test re-test reliability. An exploratory factor analysis using principle axis factoring was completed using Stata software.
Results: Â The exploratory factor analysis identified the best fit as a two-factor model for both Home and Community scales of the SEP-Q.Â Internal consistency for both subscales representing the two factors was high. Cronbach's alpha for the first factor of the Home scale was .87 and .82 for the second factor.Â Cronbach's alpha for the first factor of the Community scale was .87 and .91 for the second factor. Test re-test reliability for all subscale factors were in ranges considered good (.82-.99).
Conclusions: Â The results of this study identify the underlying factor structure and provide initial reliability for a unique measure to assess the impact of sensory factors within natural environments from the perspective of key stakeholders. The SEP-Q has the potential to support the intervention process within home and community contexts for therapist and families of young children with ASD.

170 **164.170** Gait Analysis and Motor Performance in Children with Autism Spectrum Disorders during Discrete Gait Perturbation

*E. Biffi[1], C. Costantini[2], S. Busti Ceccarelli[1], M. Nobile[1,3], M. Molteni[1] and **A. Crippa**[1,2], (1)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (2)Department of Psychology, University of Milano-Bicocca, Milano, Italy, (3)3Villa San Benedetto Hospital, Hermanas Hospitalarias, FoRiPsi, Albese con Cassano, Italy*

Background: It has been hypothesized that studies on motor function could have significant potential in providing critical insights into the neurobiological basis of Autism Spectrum Disorder (ASD) and in improving its diagnostic characterization (Minshew et al., 2004). On the basis of decades of anatomical and imaging data (Becker & Stoodley, 2013), it has been suggested that the cerebellum could be primarily implicated in ASD. Moreover, the cerebellum has been known to control and adjust gait. Quantitative methods, such as gait analysis, could offer insight on a possible motor signature of ASD that may potentially identify a well-defined motor phenotype within the spectrum.
Objectives: To describe gait patterns and motor performance during discrete gait perturbation in children with ASD compared to typically developing peers.
Methods: Five children with ASD (mean age: 9.2 years) and eight typically developing children (TD) matched by gender and age were enrolled. Gait analysis was carried out in an immersive virtual environment using a 3D motion analysis system with a dual-belt, instrumented treadmill (GRAIL). After 6 min of walking at a comfortable pace, a 20-steps cycle was recorded as baseline. Then, each participant was exposed to 20 trials with a discrete gait perturbation: after a random number of steps, a single perturbation was applied to the dominant side at toe-off, using a split-belt acceleration. Immediately afterwards, a 20-steps cycle was acquired. Finally, at the end of the perturbed trials, we recorded a 20-steps cycle as post perturbation trial. Gait parameters were extracted as previously done (Biffi et al.,2015). Data recorded in perturbation trials were linearly interpolated and R^2 value was used to estimate the goodness of responses to perturbation. Paired and non-paired non-parametric tests were performed within and between groups.
Results: At baseline, children with ASD had significantly increased stance time, reduced range of motion, peak extension, and peak of power at the ankle, increased time of maximum knee flexion with a more negative minimum moment, increased intrarotation of hip and increased pelvic tilt at the initial contact (all $p<0.05$). With respect to perturbation trials, R^2 values for parameters of the perturbed step were significantly higher for TD children ($p<0.001$). Finally, a baseline vs. post perturbation comparison showed in TD children significant increased stance time, maximum extension at hip, abadduction ROM of hip, maximum moment at hip and ROM of pelvic obliquity. In contrast, ASD showed only a reduced time of maximum flexion at hip.
Conclusions: These preliminary findings extend an earlier investigation of our group, depicting gait abnormalities in children with ASD, as stiffer gait and difficulty in balance control (Nobile et al., 2011). With respect to response to discrete perturbation, our results indicate a small but significant adaptation in both groups; however, TD children showed a better rate of adaptation compared to children with ASD. Finally, the observation of greater aftereffects in TD children seems to confirm that they were more able to adapt and store an effective response to perturbation than children with ASD.

171 **164.171** Gender Differences in Autism Spectrum Disorder on Teacher Ratings of the Restricted Behavior Scale-Revised (RBS-R) and the Aberrant Behavior Checklist (ABC)

***A. M. Lipinski**[1], J. A. Toomey[1] and A. K. Jordan[2], (1)The Summit Center, Getzville, NY, (2)Counseling, School, and Educational Psychology, University at Buffalo, SUNY, Buffalo, NY*

Background: Though gender differences in the prevalence rates of autism spectrum disorder (ASD) are widely known and acknowledged, the gender differences in behavioral manifestations of ASD are less known. Some studies claim no differences in profiles between the genders (Andersson, Gillberg, & Miniscalco, 2013), while others report that females show higher levels of functional social behavior and lower levels of and/or different quality repetitive behaviors (Halladay, Bishop, Constantino, Daniels, Koenig, Palmer, Messinger, Pelphrey, Sanders, Singer, Taylor, & Szatmari, 2015; Mandy, Chilvers, Chowdhury, Salter, Seigal, & Skuse, 2012). Given the mixed results and the potential implications for screening, diagnosis, and treatment, it is important to investigate gender differences further.
Objectives: The current study was conducted to investigate gender differences measured on the RBS-R and ABC for children with ASD.
Methods: *Participants.* Teacher ratings on the RBS-R and ABC were collected for 60 children (30 female, 30 male) with ASD. The population was primarily low-functioning based on IQ (mean IQ = 48.97 *sd* =16.54). Female students were matched with male students based on age, IQ, and ethnicity. Average age across the sample was 10.40 (*sd* = 3.37).
Â
Measures. The Aberrant Behavior Checklist (ABC; Aman & Singh, 1986) is a rating scale designed to measure five broad areas of behavior: irritability, lethargy/social withdrawal, stereotypic behavior, hyperactivity/noncompliance, and inappropriate speech. The Repetitive Behaviors Scale – Revised (RBS-R; Bodfish, Symons, Parker, & Lewis, 2000) is a rating scale designed to measure restricted repetitive behavior, a diagnostic feature of autism spectrum disorders (ASD).
Â
Procedures. Teachers completed the RBS-R and ABC as part of a battery of program evaluations collected at the beginning of the school year. Rating forms were scored and entered by research assistants. Data analyses included descriptive statistics, independent samples *t*-test, and Cohen's effect size *d*.
Results: Teacher ratings showed some significant gender differences among children with ASD among the different scales on the RBS-R. On the RBS-R, significant gender differences were found on the restricted behavior subscale ($t(56) = 2.38$, $p = .021$, $d = 0.61$). There were differences found on the subscales of the ABC, but none statistically significant.
Conclusions: Teacher rating on the RBS-R and ABC indicated mixed results regarding gender differences. Similar to prior research, there was some indication of males showing more repetitive behaviors than females with ASD; however, this was only noted on the restricted behavior subscale of the RBS-R (i.e., preoccupation with one subject or activity, attachment to one specific object, preoccupation with parts of objects, and preoccupation with movement).Â Females and males with ASD seem to have similar symptomatology regarding sameness behavior, ritualistic behavior, compulsive behavior, self-injurious behavior, and stereotyped behavior. Additionally, females and males with ASD tend to show the same levels of irritability, lethargy, stereotypic behavior, and hyperactivity. These results can have implications in the diagnosis and treatment of ASD. Further research is needed in the area of gender differences and level and quality of restricted and repetitive behaviors in children with ASD.

172 **164.172** Growth Mixture Modeling of the Repetitive Behavior Scale-Revised in Young Children with ASD

***C. Farmer**, L. Joseph and A. Thurm, National Institute of Mental Health, Bethesda, MD*

Background: There are few data on how restricted and repetitive behaviors (RRB) emerge and change over time in young children with ASD. A handful of longitudinal studies provide some evidence that these patterns may differ based on type of behavior (e.g., higher order versus lower order) and age range.
Objectives: The goal of this analysis was to evaluate the trajectories of subtypes of repetitive behavior, as measured by the Repetitive Behavior Scale-Revised (RBS-R), in a sample of children with ASD and low cognitive and adaptive function. We sought to determine whether the data were best represented by a mixture of trajectory classes, rather than a single, average trajectory, using growth mixture models.
Methods: Data were drawn from a longitudinal natural history study of 106 children with ASD (DSM-IV autistic disorder) assessed at up to five approximately one-year intervals. The age range for the longitudinal data thus spanned 2 to 7 years. We first evaluated the standard growth models for each RBS-R subscale and the total score, followed by growth mixture models of increasing complexity. Where clustering around zero was common, models for censored data were used. Solutions with up to 4 classes were compared on a range of fit indices. Due to sample size constraints, joint trajectories were not modeled, but the joint distributions of most likely class membership across trajectories were calculated. Finally, correlates of class membership, such as level of cognitive impairment, were explored.
Results: For all subscales, the mixture model was better fit to the data than the standard growth model, indicating that the growth model was not adequately accounting for heterogeneity in trajectory. For the purposes of space, we present in this abstract only the best-fitting solution to the Self-Injurious Behavior (SIB) subscale. This was a 4-class model (Figure 1). 41% of the sample was most likely assigned to the No SIB class and 49% to the Mild/Stable class. The remaining classes were small but clinically meaningful, and were therefore retained: Moderate/Valley (6%) and High/Peak (4%). Data on correlates, other subscales, and their joint distributions, will be provided.
Conclusions: These analyses revealed considerable heterogeneity in the developmental trajectories of repetitive behavior in children with autism, as well as across types of repetitive behavior, providing more evidence for the notion that developmental trajectories may be required for ASD phenotyping.

173 **164.173** Higher-Order Repetitive Behaviors in Toddlers Born Preterm

***R. D. Sifre**[1], J. J. Wolff[2], C. Doyle[1], C. Lasch[3], E. Teska[2] and J. T. Elison[2], (1)Education and Human Development, University of Minnesota, Twin Cities, Minneapolis, MN, (2)University of Minnesota, Minneapolis, MN, (3)Institute of Child Development, University of Minnesota, Minneapolis, MN*

Background: Preterm birth is associated with lower IQ, impaired self-regulation, and social communication deficits. Preterm infants are also more likely to receive psychiatric diagnoses including ASD, the prevalence of which is 7% in children born preterm (as compared to 1.5% in the general population) (Johnson et al., 2010). These findings add to the extant literature suggesting the heterogeneous etiology of ASD, and highlight the need for screening tools that capture the dimensionality and heterogeneity in contributing mechanisms and clinical outcomes of ASD.
Objectives: The current study uses the Repetitive Behavior Scale for Early Childhood (RBS-EC; Wolff, Boyd, & Elison, 2016) to compare restricted and repetitive behaviors (RRBs) in preterm (36 weeks gestational age or earlier) and full term toddlers in a community sample of 1,670 participants.
Methods: Parents of toddlers between 17 and 23 months of age were recruited from the Institute of Child Development participant pool registry. Parents were asked to fill out the RBS-EC, an instrument designed to characterize dimensional aspects of RRBs in young children. Of the 1,955 parents who completed the RBS-EC, 285 were excluded for providing responses that suggested invalid data (e.g. time to complete survey was less than 3 minutes) or for missing gestational age data.
Results: Â Data from 1,670 participants were analyzed. Of these participants, 5.9% were born preterm (n=99). The average age at assessment did not significantly differ between groups (Preterm Infants' Mean Age=20.6 months, Fullterm Infants' Mean Age=20.1 months). Overall, parents of preterm toddlers endorsed a greater number of behaviors (t(1666)=2.7, p=.007) and reported a higher frequency of these behaviors (t(1666)=1.9, p=.05). Analyses of the subscales on the RBS-EC indicated no group differences in Self-directed or Repetitive Motor topographies. Group differences emerged in Restricted and Ritual topographies, with parents of preterm toddlers endorsing more items and reporting higher frequencies of these behaviors (**Table 1**). Birthweight, Gestational Age, and Age at Assessment were then entered in a multiple linear regression model. Birthweight significantly predicted the number of Restricted Behaviors Endorsed (t(1666)=-3.3, p=.001), the frequency of Restricted Behaviors (t(1666)=-2.9, p=.003), and the frequency of Ritual and Routine Behaviors (t(1666)=-2.5, p=.01) after controlling for Gestational Age and Age at Assessment. The effect of Birthweight on the number of Ritual and Routine Behaviors endorsed trended towards significance (t(1,666)=-1.7, p=.089).
Conclusions: RBS-EC measures collected from a large community-based sample (n=1,670) indicate that infants born preterm do demonstrate a greater degree of higher-order RRBs as toddlers, as indexed by both topographies endorsed and frequency of these behaviors. Future analyses will expand on these findings by using continuous measures of Age and Gestational Age to better understand the effect of preterm birth on RRBs. Furthermore, data collected on a social-responsiveness measure – the vrRSB – in the same cohort will be analyzed to determine whether these effects are specific to RRBs, or to features of ASD more generally. These data add to the growing body of evidence demonstrating that preterm birth is a risk factor for ASD by identifying elevated RRBs during the second year of life.

174 **164.174** IQ As a Moderator of the Presence, Severity, and Fluctuation Rates of 3 Individual Rrbs: Bouncing, Lining up Objects, and Aversion to Loud Noises

S. M. Attar[1]*, P. Hickey*[1]*, A. Walsh*[1] *and E. Hanson*[2]*, (1)Boston Children's Hospital, Boston, MA, (2)Children's Hospital Boston, Boston, MA*

Background: The presence of restrictive and repetitive behaviors (RRBs) is required for a diagnosis of Autism Spectrum Disorders (ASD) and can have a devastating impact on children and their families (Richler, Heurta, Bishop, & Lord, 2010). Previous researchers observed that IQ moderated the presence of groups of RRBs (insistence on sameness and repetitive sensory motor, Bishop et al, 2006 Bishop et. al 2013). There continues, however, to be a lack of research assessing the characteristics of individual RRBs to help clarify ASD and other syndrome profiles.
Objectives: The current study examined the moderating relationship between NVIQ and VIQ and the presence, severity, and fluctuation of three prevalent, individual RRBs.
Methods: A sample of 458 children were used in analysis. All participants had a research confirmed ASD using ADOS and ADI; Comparison Severity Score (CSS) was used from the ADOS. IQ was assessed using standardized cognitive measures. The prevalence of individual RRBs was analyzed in a previous study that used the Behavior and Sensory Interest Questionnaire (BSIQ, Hanson et. al. 2015). This analysis used three very common RRBs: Bouncing, Lining up Objects and Aversion to Loud Noises (all found in > 50% of the population). We fit logistic regression models to determine the moderating relationship of IQ on presenting RRBs using two interaction variables: a) CSS and VIQ; b) CSS and NVIQ. RRB presence (0-1), severity (0-3) and fluctuation (0-1) were included in separate models as dependent variables. ANOVAs were run to assess the differences between groups. All statistics were run using SPSS.
Results: None of our regression models reached significance. NVIQ, VIQ, and CSS were not associated with a significant increase or decrease in the presence, severity, or fluctuation rates of Bouncing, Lining up Objects, or Aversion to Loud Sounds. While our ANOVAs and T-tests were also not significant, they revealed trends between NVIQ and VIQ and our behaviors. Mean NVIQ decreased approximately ten points between individuals who did not endorse Bouncing and those who did; there was no trend between VIQ and Bouncing. In contrast, mean VIQ decreased 5 points between individuals who did not endorse Lining up objects and those who did; there was no trend between NVIQ and Lining up objects. Finally, mean NVIQ decreased 4 points and mean VIQ decreased 7 points between individuals who did not endorse Aversion to loud noises and those who did.
Conclusions: Our results indicate that continuing to analyze RRBs on an individual basis reveals important information about distinct RRB characteristics that studying them on a grouped basis alone does not, especially in terms of the moderating effect of IQ. While none of our regression models or ANOVAs reached significance, the models assessing the fluctuation rates were the closest. This suggests to us that NVIQ and VIQ may be contributing factors of behavior change over time. Research examining the moderating role of IQ on all 74 RRBs of the BSIQ is in progress.

175 **164.175** Identifying Genetic and Behavioral Correlates of Sensory Issues in Autism Spectrum Disorders

J. Flax[1]*, C. Gwin*[1]*, S. Wilson*[1]*, K. Law*[1]*, B. Patel-Gupta*[1]*, C. W. Bartlett*[2]*, S. Buyske*[3] *and L. Brzustowicz*[1]*, (1)Genetics, Rutgers University, Piscataway, NJ,*

(2)Nationwide Children's Hospital, Columbus, OH, (3)Statistics Dept, Rutgers University, Piscataway, NJ

Background:
Sensory modulation characteristics are now part of the DSM-5 Autism Spectrum (ASD) classification and defined as: “hyper- or hypo-reactivity to sensory input or unusual interest in sensory aspects of the environment” (DSM-5, p.50). Research regarding sensory modulation suggests that upwards of 80% of all individuals on the autism spectrum report some degree of hyper- or hypo-sensory sensitivity. However, there is almost no data on the possible genetic underpinnings that might be involved in sensory sensitivities and only minimal data reported on family members of individuals with ASD.
Objectives: We hypothesize that in addition to sensory modulations issues that affect individuals with ASD, nuclear family members might also present with sensory sensitivity characteristics but to a lesser degree. These behaviors could be considered a characteristic of the Broad Autism Phenotype (BAP) and thus, might be used as a behavioral phenotype in family genetics studies.
Methods: One hundred twenty-seven (127) probands with ASD and 316 of their nuclear family members participated in a family genetics study. All probands received the ADI-R and all family members, including the probands, received the Social Responsiveness Scale (SRS and SRS-2). We used questions 20 (related to hyposensitivity/sensory seeking) and 42 (related to hypersensitivity) to categorize all family members as affected for sensory modulation issues. For ASD probands, we also included ADI questions 71, 72, & 73 to calculate affection rates for sensory issues. We examined the rates of sensory issues in all family members and categorized each member as affected or unaffected for a preliminary linkage analysis.
Results:
Hyposensitivity-Based on a combination of SRS and ADI-R data, parents reported that 86.9% of ASD probands had hyposensitivity issues. Based on SRS data, 16% of fathers, 14% of mothers, and 17% of unaffected siblings (US) also reported hyposensitivity. Group differences were significant when ASD probands were included [X^2 (3, N=443), 261.277, p<.001] but not significant for family member status or sex when probands were excluded from the analysis.
Hypersensitivity- Based on a combination of SRS and ADI-R data, parents reported that 87.9% of ASD probands had hypersensitivity issues. Based on the SRS data regarding hypersensitivity, 26% of fathers, 17% of mothers, and 26% of US reported hypersensitivity. Group differences were significant when ASD probands were included [X^2 (3, N=443) 206.570, p <.001] but not significant for family member status or sex when ASD probands were excluded from the analysis.
Preliminary genetic linkage analysis- Linkage analysis was performed on both variables. We observed evidence of linkage (90% posterior probability) for the hypersensitivity variable on Chromosome 6 while there was no evidence of linkage observed for hyposensitivity.
Conclusions:
As predicted, ASD probands showed high rates of hypo- and hyper- sensitivity supporting the inclusion of sensory modulation in DSM-5 ASD diagnosis. Preliminary exploration of rates in unaffected family members also show some degree of hypo- and hypersensitivity suggesting that these characteristics may be included in the BAP, potentially being beneficial as a behavioral phenotype in family genetics studies such as ours.

176 **164.176** Increased Centre-of-Pressure Regularity during Quiet Stance in Adults with Autism Spectrum Disorder

Y. H. Lim[1], *H. Lee*[1], *T. Falkmer*[1], *T. Tan*[2], *G. Allison*[3] *and S. L. Morris*[4], *(1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)School of Mechanical Engineering, Curtin University, Perth, Australia, (3)Curtin Graduate Research School, Curtin University, Perth, Australia, (4)School of Physiotherapy and Exercise Science, Curtin University, Perth, Australia*

Background: Adults with autism spectrum disorders (ASD) demonstrate atypical postural sway however the underlying processes that cause this are unclear. One hypothesis is that people with ASD rely less on vision and more on somatosensory input when controlling posture. Less use of vision for postural control may put people with ASD at disadvantage in developing complex motor skills and adaptive behaviours. The movement of the centre of pressure (COP) during postural control represents the accumulation of control processes and responses to maintain an upright posture. In general, the mediolateral postural control depends more on visual information whereas the anteroposterior postural control depends more on somatosensory information. Entropy measures the regularity or amount of information in a signal. A larger magnitude of entropy indicates more irregular COP fluctuations and higher automaticity of postural control.
Objectives: The primary aim of this study was to compare the regularity of the COP fluctuations in adults with ASD to their typically developed peers, with and without vision.
Methods: The study used a quasi-experimental case control design with nineteen adults with ASD and twenty-nine typically developed adults. COP position was collected at 100 Hz in two directional dimensions (mediolateral and anteroposterior) during quiet stance on a force platform in visual conditions of eyes open and eye closed. Each condition lasted for 30 seconds. Sample entropy and the Romberg quotient were calculated.
Results: Group differences in entropy were only evident in the eyes open condition in the anteroposterior direction (p=0.038). Mean entropy was smaller in the ASD group by 0.029 (95% CI -0.056 to -0.002). No difference was observed in entropy between the groups in the eyes open condition in the mediolateral direction (p=0.337), and the in the eyes closed condition in either direction (mediolateral p=0.716 and anteroposterior p=0.904, respectively). Additionally, the Romberg quotient of adults with ASD was significantly lower than that of typically developed adults (p=0.032). The Romberg quotient in the ASD group was lesser by 0.217 (95% CI -0.415 to -0.194), indicating a smaller contribution of vision on standing postural control in adults with ASD than typically developed adults.
Conclusions: In the anteroposterior direction, adults with ASD had a smaller magnitude of entropy demonstrating COP fluctuations that were more regular compared with those of TD. Regular COP fluctuations suggest a less adaptable and more attention demanding control of posture. It also indicates a lesser automatic postural control in the anteroposterior for adults with ASD. Cognitive load, disease state, old age, restricted vision and concussion have all been reported to be associated with more regular COP fluctuations. In combination with the smaller contribution of vision on postural control in adults with ASD, the findings are consistent with the previously reported hypothesis that postural control in ASD is biased to somatosensory information. The findings of this study have implication on guiding the development of intervention in areas of motor skills for people with ASD.

177 **164.177** Intact Musical Abilities in Children with Autism Spectrum Disorder

K. Jamey[1], *N. E. Foster*[1], *M. Sharda*[1], *C. Tuerk*[1], *R. Chowdhury*[1], *E. Germain*[1], *A. Nadig*[2] *and K. L. Hyde*[1,2], *(1)University of Montreal, Montreal, QC, Canada, (2)Faculty of Medicine, McGill University, Montreal, QC, Canada*

Background: Autism spectrum disorder (ASD) is a complex neurodevelopmental condition characterized by socio-communication difficulties and atypical sensory perception, particularly in the auditory domain. Despite these impairments, individuals with ASD often have preserved or even enhanced musical skills (Ouimet et al., 2012; Heaton, 2003). Music is therefore insightful for studying auditory processing in ASD. However, music perception on the whole remains poorly understood and underexplored in ASD.
Objectives: The aim of the current study was to evaluate musical perception abilities in school-age children with ASD compared to typical developing (TD) children on a variety of musical tasks including pitch and rhythm discrimination as well as melodic memory. Based on the Enhanced Perceptual Functioning model (Mottron, 2006), we expected children with ASD to perform similar to or better than TD.
Methods: Participants were 28 children with ASD and 24 TD children aged 7-12 years old, matched on age (ASD M=10.5 years, SD=1.6; TD M=9.9 years, SD=1.7; p=.20) and IQ (ASD M=115.6 years, SD=14.6; TD M=119.8, SD=12.9; p=.31). Children with ASD were diagnosed using the Autism Diagnostic Observation Schedule. Exclusion criteria were IQ<85 (measured using the Wechsler Abbreviated Scale of Intelligence) or any hearing impairment. Musical ability was measured using the Montreal Battery for Evaluation of Musical Abilities (MBEMA, Peretz et al, 2013), a music battery with three subtests, 1) melodic pitch, 2) rhythm, and 3) musical memory. Performance accuracy (percent correct) was calculated for all subtests as well as a global score. Participants scoring below chance level (<.55) on the global score (ASD: n=4, TD: n=1) were excluded from analysis. Data was analyzed using repeated-measures ANOVA with group as the between-subjects factor and subtest as the within-subjects factor.
Results: Both ASD and TD performed similarly on the MBEMA. There was no significant main effect of group ($F(44)=.05$, $p=.82$), or group X subtest interaction, ($F(2,88)=.63$, $p=.54$). There was however, a significant main effect of subtest ($F(88)=6.272$, $p<.01$), with both ASD and TD performing better on the rhythm subtest than on the melodic pitch or musical memory subtests. A bonferroni post-hoc analysis yielded a significant difference between rhythm and melody ($p<.01$), as well as rhythm and memory ($p<.05$) but no mean difference between melody and memory ($p=.1.0$; Figure 1).
Conclusions: Children with ASD performed similarly to TD on melodic pitch, rhythm and memory perception tests. TD children in this sample showed a music perception profile similar to the sample the test was normed on (Peretz, 2013). These findings show that music perception abilities are intact in school-age children of average IQ, diagnosed with ASD. These results also provide evidence for preservation of auditory abilities in the musical domain in ASD. This work supports the use of music to improve functioning in other domains in ASD, and can guide future studies of music therapy.

178 **164.178** Interpersonal Sensory-Motor Synchronization in Adults with and without ASD during a Joint Improvisational Mirror Game

R. S. Brezis[1], *Y. Golland*[2], *T. Alony*[2], *L. Noy*[3] *and N. Levit Binnun*[2], *(1)Kanfei Nesharim St. P.O.Box 167, Interdisciplinary Center, Herzliya, Israel, (2)Psychology, Interdisciplinary Center, Herzliya, Herzliya, Israel, (3)Weizmann Institute of Science, Rehovot, Israel*

Background:
Recent research on Autism Spectrum Disorders (ASD) suggests that individuals with autism may have a basic deficit in synchronizing with others, and that this difficulty may lead to more complex social and communicative deficits. The current project aims to conduct an in-depth investigation of interpersonal sensory-motor synchrony in ASD, using an innovative experimental paradigm - the Mirror Game (MG, Fig 1) – that allows high-resolution temporal and spatial motion tracking in an open-ended joint improvisation game (Noy et al., 2011). Using the MG, it has been shown that players can attain moments of highly synchronized *co-confident* (CC) motion, in which the players act as a *coupled unit*.
Objectives:
To investigate the ability of adults with ASD, as compared with typically developing (TD) adults, to synchronize their movements with another person.
Methods:
Participants: data from 27 participants with high-functioning ASD was compared with that of 39 TD adults.
MG procedure: two players face each other holding handles which can move along parallel tracks, and are told to "imitate each other, create synchronized and interesting motions, and enjoy playing together" (Fig 1a,b). All participants played against the same expert improviser. Participants were instructed to first lead the motion (Leader), then follow the experimenter's motions (Follower), and then engage in Joint Improvisation (JI), with no designated leader; in 3-minute trials. The motion of the two handles is sampled at 50 HZ (Fig 1c,d).
Data analysis: Players' synchronization was measured using the mean relative difference in velocity (*dV*) and the timing differences between zero-velocity events (*dT*). Segments of CC motion (Fig 1d) met the following criteria: $dv<0.95$, $dT<0.15$, and no more than one crossing of the acceleration=0 point (i.e., smooth movement, with no corrective jitter).
Results:
We found that individuals with autism *can* attain co-confident (CC) motion when playing the MG with an expert improviser. ASD participants engaged in overall less CC than TD participants (main effect of Group, $F(1,64)=10.6$, $p<.001$), and this was particularly pronounced when *following* an expert improviser (main effect of Role, $F(2,128)=7.11$, $p<.001$; and interaction effect of Role by Group, $F(2,128)=9.2$, $p<.001$; post-hoc between-group analyses in the Following round, $t(64)=6.78$, $p<.001$). Furthermore, ASD participants stayed in CC periods for a shorter duration of time than TD participants ($F(1,61)=8.82$, $p=0.04$).
Conclusions:
These data provide the first evidence, to our knowledge, that individuals with autism can attain highly synchronized, co-confident motion, when playing with another player in an open-ended joint improvisation game. At the same time, they suggest that individuals with ASD have an attenuated ability to engage and *stay* in highly synchronized motion over time. It is possible that individuals with ASD do not detect these periods of CC motions, or do not find them rewarding, hence leading them to disengage earlier from the synchronized motion. Future research should focus on determining the reasons for this attenuated synchronization on both motor and psychological levels.

179 **164.179** Investigating the Association Between Restricted Interests and Language Abilities As Groundwork for Novel Intervention Development

K. Birtwell *and L. Nowinski, Massachusetts General Hospital - Lurie Center, Lexington, MA*

Background: Evidence of restricted interests is a hallmark symptom of autism spectrum disorder (ASD). Current estimates suggest that up to 95% of children with ASD have at least one restricted or circumscribed interest, yet our ability to target or reduce these highly restricted interests and their associated behaviors with traditional pharmacologic and therapeutic/behavioral interventions has been limited to date (Boyd, McDonough, & Bodfish, 2012; Poustka et al., 2014; Turner-Brown, Lam, Holzclaw, Dichter & Bodfish, 2011). Moreover, it may not be clinically beneficial or practically necessary to do so. Rather, clinicians and researchers are increasingly *utilizing*circumscribed interests in the context of various interventions to bolster motivation, rapport, and to ultimately enhance treatment outcomes (e.g., Kryzak & Jones, 2015). Given that ASD is a highly heterogeneous condition, it will be important to identify which patients will be most responsive to such interventions. While the presence of restricted interests in ASD has been associated with higher cognitive functioning (Bishop, Richler & Lord, 2006), few studies have investigated the relationship between specific interests and language skills in this population.
Objectives: The purpose of the present study is to identify specific phenotypic and language traits within individuals with ASD that may make them well-suited for interventions that are designed to utilize circumscribed interests, rather than reduce or eliminate them. Specifically, this investigation seeks to clarify the relationship between language level and intensity of restricted interest in school-aged children with ASD.
Methods: Participants will include approximately thirty children (ages 6 years, 0 months to 10 years, 11 months; including females) with a diagnosis of ASD recruited from a multidisciplinary autism clinic. Each child will be administered various language tasks, including verbal subscales from the Wechsler Abbreviated Scale of Intelligence Scale-2nd Edition (WASI-II; Wechsler, 2011), the Peabody Picture Vocabulary Test, 4th Edition (PPVT-4; Dunn & Dunn, 2007) and the Pragmatics Profile of the Clinical Evaluation of Language Fundamentals, 5thEdition (CELF-5; Wiig, Semel, & Secord, 2013). In addition, parent reporters will be asked to complete the Interest Scale (Bodfish, 2014) and the Affinities Scale, an original measure adapted from the Interests Scale to specifically assess the level of interest in contemporary movies and characters that could be utilized in treatment technologies.
Results: Data collection is ongoing. Results will include sample descriptive data, means and standard deviations of the proposed outcome measures, and Pearson correlation statistics for restricted interest levels and various language abilities.
Conclusions: Results from the present study will help to clarify our understanding of the direction and strength of the relationship between restricted interests and language skills in school-aged children with ASD. These findings will significantly contribute to our limited knowledge of restricted or circumscribed interests and will directly inform subsequent intervention design and implementation. Results will contribute to a small, but emerging body of evidence that a new approach to addressing restricted interests in therapeutic interventions for some individuals with ASD may be warranted.

180 **164.180** Italian Cross-Cultural Adaptation of the Short Sensory Profile in Autism

***G. Valagussa**, E. Grossi, A. Nale and R. Pirovano, Villa Santa Maria scs, Tavernerio, Italy*

Background:
Autism is a neurodevelopmental disorder characterized by widespread abnormalities of reciprocal social interactions and communication, as well as severely restricted interests and highly repetitive behavior. Sensory processing problems are reported in children with autism spectrum disorders and are included in the diagnosis of autism in the latest Diagnostic and Statistical Manual of Mental Disorders (DSM-5). One of the most useful tools to assess sensory characteristics in ASD individuals is the Short Sensory Profile (SSP), but no Italian version of this instrument is currently available.
Objectives:
The aim of this study is to validate an Italian cross-cultural adaptation of the Short Sensory Profile.
Methods:
Following the guidelines for the process of cross-cultural adaptation of self-report measures (Beaton et al., 2000) we did a translation of the process (two independent translators) followed by a back-up translation (two independent translators) and a final review in which full agreement was reached by the study team. We also did a pilot study to apply the SSP in a sample of 46 Italian ASD individuals (7 females; 39 males; mean age 163.5 months – SD 34.3 months, range: 87 – 226 months). The ASD diagnosis was done using the DSM V criteria, and it was confirmed using the ADOS 2. We chose capable special education teachers who carefully and fully reported their behaviors.
Results:
The SSP mean total score of the sample was 147.65 (range 119-176) pointing out the presence of sensory function impairment (the expected value ranges between 155 and 190). Thirty-two percent (N = 15) of the participants obtained a typical performance total score (range 155-190), 30.4% (N = 14) obtained a probable difference score (range 142-154), and 37% (N = 17) obtained a definite difference score (range 38-141). The sensory function impairment resulted particularly severe in two of the Scale sections (table 1): “Underresponsive/Seeks Sensation” (8.7% belonging to typical performance score, 26.1% belonging to probable difference score, 65.2% belonging to definite difference score) and “Auditory Filtering” (17.4% belonging to typical performance score, 39.1% belonging to probable difference score, 43.5% belonging to definite difference score).Â The section “Low energy / Weak” has a total mean score in the range of probable difference (58.7% belonging to typical performance score, 2.2% belonging to probable difference score, 39.1% belonging to definite difference score). The others sections (“Tactile sensitivity”, “Taste/Smell Sensitivity”, “Movement Sensitivity”, and “Visual Auditory Sensitivity”) have a mean score in the range of typical performance (table 1).
Conclusions:
The Short Sensory Profile scale is now validated forÂ use in Italy. The performance of the scales are in line with findings observed in the SSP literature. We confirm the existence of sensory impairments in ASD, particularly expressed as under-responsiveness or seeking stimuli and an increased or decreased response to auditory stimuli.

181 **164.181** Measuring Restricted Interests and Repetitive Behaviors in Infant Siblings at-Risk for ASD: Comparing HOME-Setting Versus Clinic Performance of 12 Month Olds

***M. Lewis**[1], N. Brane[1], J. Bradshaw[2] and A. M. Wetherby[3], (1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)Florida State University Autism Institute, Tallahassee, FL*

Background:
Approximately 20% of younger siblings of children with ASD are at an increased risk for developing ASD (Ozonoff, 2011). According to DSM-5, symptomatology involves restricted, repetitive patterns of behavior (RRB); however, these indicators are only more recently examined in younger siblings. During the second and third year, studies have demonstrated repetitive hand/finger mannerisms become more pronounced among children with ASD and less pronounced among children with developmental delays (DD) and typical development (TD). Zwaigenbaum et al. (2013) summarized prospective studies, in comparison to retrospective studies, more consistently identified RRB as early as 12 months in children with subsequent ASD diagnosis, citing atypical and repetitive behavior with objects and visual exploration of objects. Further, Stronach & Wetherby (2012) examined RRB among toddlers (mean age 20 months) in clinic and home settings, identifying higher presence of RRB in clinic, given the nature of structured probes and repeated presentations of objects.
Objectives:
This study examines the relationship between home observation and clinical assessment of RRB among 53 (projecting 70 by May 2017) 12-month old infants considered at-risk for ASD, given sibling status.
Methods:
High-risk, 12-month infant siblings were seen for communication assessments as part of a federally-funded longitudinal study examining risk and resilience. The assessment battery included two samples of early social-communication behavior: Communication & Symbolic Behavior Scales (CSBS-DP; Wetherby & Prizant, 2002) and a video-recorded home observation. The Systematic Observation of Red Flags of ASD (SORF) is an ASD-specific screening instrument that captures red flags related to social-communication and interaction and RRBs. The SORF was used to rate early symptomatology within clinic (Clinic-SORF) and home (Home-SORF) settings. Pearson's correlation examined linear association between red flags observed in the Clinic-SORF compared to the Home-SORF. Paired t-tests examined differences between number of social-communication and RRB red flags observed using Clinic-SORF and Home-SORF. Further, differences in four specific behaviors of interest from the RRB domain were explored: (1) repetitive movements with objects, (2) repetitive body movements/posturing, (3) sticky attention to objects, and (4) unusual sensory exploration/excessive interest in sensory aspects of environment.
Results:
Pearson's correlation indicated significant association between total observed red flags obtained from home and clinic settings (r= 0.382; $p<0.01$). There was no significant difference between the number of Social-Communication red flags observed in the Home-SORF and Clinic-SORF. However, there were significantly more RRB red flags observed on the Clinic-SORF compared to the Home-SORF. With further analysis at the item level in RRB domain, Clinic-SORF revealed a significantly higher score than Home-SORF for the following items: repetitive movements with objects ($p<0.001$), sticky attention to objects ($p<0.001$), and unusual sensory exploration/excessive interest in sensory aspect of environment ($p<0.001$). There was no difference between Home-SORF and Clinic-SORF for repetitive body movements/posturing.
Conclusions:
Findings suggest home observation and clinic assessment highlight similar social-communication and social-interaction vulnerabilities. Significantly though, while the CSBS is primarily examining communication, structured tasks involving objects and communicative temptations may reveal increased amounts of RRB, therefore exposing earlier symptomatology and providing more quantitative assessment of red flags in this diagnostic domain.

182 **164.182** Motor Behavior As a Qualitative Difference in the Spontaneous Production of Co-Speech Hand Gestures By Adults with Autism Spectrum Disorders

A. Bagdasarov[1], E. S. Kim[2], Y. Zhang[3], Z. M. Dravis[4], M. Cola[3], B. Maddox[5], E. Ferguson[6], L. Adeoye[1], F. Fergusson[1], A. A. Pallathra[7], N. Minyanou[8], L. Bateman[6], A. T. Pomykacz[9], K. Bartley[10], E. S. Brodkin[7], J. Pandey[2], J. Parish-Morris[5], R. T. Schultz[2] and ***A. B. de Marchena****[11,12], (1)University of Pennsylvania, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)The Center for Autism Research/CHOP, Philadelphia, PA, (7)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (10)Center for Autism Research, Malvern, PA, (11)Center for Autism Research, Philadelphia, PA, (12)University of the Sciences, Philadelphia, PA*

Background:
Deficits in nonverbal communication are a required symptom for diagnosis of autism spectrum disorder (ASD). DSM-5 stresses that nonverbal communication in ASD is often characterized by *qualitative* differences, in addition to reduced frequency. These qualitative differences have been inadequately described, in part because qualitative features of behavior are by definition challenging to quantify. Here we examine one qualitative feature of nonverbal communication in ASD: motor behavior during spontaneously produced co-speech hand gestures.
The literature on co-speech gesture in ASD is limited, but suggests that qualitative differences, e.g., in how gesture is formed, used functionally, or integrated with speech, best discriminate ASD from typically developing controls (TDC). Atypical motor behavior is widespread in ASD, both across individuals and across possible motor acts. Reported differences in motor behavior in ASD include low muscle tone, atypical gait, and impairments in praxis/pantomime performance. In typical adults, motor features of gesture (e.g., frequency and size of movements) are associated with empathy, suggesting a relationship between motor behavior during communication and broader social-cognitive deficits associated with ASD.
Objectives:
The primary objective of this study was to determine whether differences in motor features, including movement frequency, size, and complexity, would be observed in co-speech gestures spontaneously produced by adults with ASD.
Methods:
Adults with ASD (n=24) and typically developing controls (n=10) were matched on chronological age, gender, and full scale IQ (all average or above). Data on 14 additional TDCs will be available and analyzed by May 2017. Participants completed a five-trial referential communication task, employed through two networked laptops, in which they described abstract three-dimensional monochromatic figures to a trained confederate. The task was designed to allow for back-and-forth conversational interaction in a controlled setting. All hand gestures produced during the task were tagged and coded for: (1) movement *frequency* (gestures per minute), (2) movement *size* (degree to which hand moved through space), and (3) movement *complexity*(single-handed vs. two-handed gestures).
Results:
Both groups performed very well on the task (96% accuracy across trials in both groups), and all participants in the study gestured at least twice during the 20-minute task (Range: 2-176 total gestures). Overall, participants with ASD produced less movement than those with TDC (p=.04, Cohens d=0.97; Figure 1), evidenced by marginally less frequent gestures (p=.11; Cohen's d=0.72) and significantly smaller movements (p=.005, Cohen's d=0.91) in ASD. There was a significant interaction between hand usage and group with a large effect size (p=.002, Cohen's d=1.23; Figure 2), with participants with ASD using more single-handed gestures and TDC participants using more two-handed gestures.
Conclusions:
During spontaneous interaction, adults with ASD produced fewer, smaller, and less complex co-speech gestures. Motor features of co-speech gesture as a qualitative difference in nonverbal communication in ASD vs. TDCs can be quantified. All features described here can be measured by existing technologies, with potential to increase both the precision and scale of measurement, allowing for larger samples, and possible use as a behavioral biomarker of ASD.

183 **164.183** Natural History of Tiptoe Behavior in ASD

***G. Valagussa**, V. Balatti, L. Trentin and E. Grossi, Villa Santa Maria scs, Tavernerio, Italy*

Background:
The literature confirms that 20-30% of individuals with autism walk on their tiptoes. In a previous study, we found that this behavior transpires not only during walking but also while standing and running, and described three mutually exclusive clinical functional classes. Systematic observations about the natural history of Tiptoe Behavior (TTB) in ASD children in the literature are scarce. Specifically, it is not known if TTB parallels the acquisition of standing, walking and running milestones or appears later on and if these milestones (using the criteria suggested by Dosman and Dedrick) are delayed compared to normally developing peers.
Objectives:
The aims of this retrospective study are: 1) to observe if TTB was exhibited simultaneously or subsequently to the acquisition of standing, walking and running milestones; 2) to describe, in those diagnosed subsequently, when TTB ASD subjects started to stand, walk and run compared to both normal population and non-TTB ASD subjects.
Methods:
Our study sample included 36 ASD subjects (34 males; mean age: 14.3 years) diagnosed with Autism according to the DSM V criteria, confirmed through ADOS 2 and under observation at our Institute. We asked all the subjects' parents to answer a structured interview. We collected information about standing, walking and running milestones. We also asked if and when TTB was observed and when it eventually stopped. Another therapist confirmed the presence of TTB using a standardized method we described in a previous study.
Results:
We found that 18 subjects (50%) never showed TTB, 13 TTB subjects (36%) present TTB at least in one of three previous described situations, while 5 subjects (14%) had TTB in the past but it later stopped. The mean age of standing acquisition of the ASD sample resulted in line with the normative values, without significant differences between TTB and non-TTB subjects (table 1). The mean age of walking acquisition of the ASD sample resulted higher compared to the normative value (16.4 months (9-30 range) vs 12 months (9-18 range) respectively) without significant differences between TTB and non-TTB subjects. The mean age of running acquisition in the ASD sample resulted higher compared to the normative value (26.55 months (12-72 range) vs 15 months (13-20 range)) without significant differences between TTB and non-TTB subjects (absolute difference in favor of non-TTB). We observed that Tip-toe behavior in TTB subjects started significantly later than the acquisition of standing and walking milestone (table 2). Conversely, there was no significant difference between running acquisition and the start of TTB while running.
Conclusions:
TTB subjects exhibit this behavior significantly later to the acquisition of standing and walking milestones while there is no significant difference between running acquisition and the start of TTB while running. No significant difference in the age of acquisition of standing, walking and running milestones between TTB and non-TTB ASD subjects was found. The ASD sample showed a delay in walking and running acquisition compared to the normative values. This finding, if confirmed in other studies, could be included in the clinical abnormalities constellation of autism.

184 **164.184** Noise and Autism Spectrum Disorder in Children: An Exploratory Survey

***S. Kanakri**, Ball State University, Fishers, IN*

Background:
With more students being educated in schools for Autism Spectrum Disorder (ASD) than ever before, architects and interior designers need to consider the environmental features that may be modified to enhance the academic and social success of autistic students in school.
Objectives: This study explored existing empirical research on the impact of noise on children with ASD and provides recommendations regarding design features that can contribute to noise reduction.
Methods: A survey, which addressed the impact of architectural design elements on autism-related behavior, was developed for teachers of children with ASD and distributed to three schools.
Results: Most teachers found noise control to be an important issue for students with autism and many observed children using ear defenders. In terms of managing issues related to noise, most teachers agreed that thick or soundproof walls and carpet in the classroom were the most important issues for children with ASD.
Conclusions: Suggested future research should address architectural considerations for building an acoustically friendly environment for children with autism, identifying patterns of problematic behaviors in response to acoustical features of the built environment of the classroom setting, and ways to manage maladaptive behaviors in acoustically unfriendly environments.

Autism, ASD, Acoustics, Noise, Classroom, Built Environment

185 **164.185** Nonsocial Attentional Bias in Adolescents with ASD Is Not Influenced By the Inversion Effect

K. E. Unruh[1], *N. J. Sasson*[2] *and J. W. Bodfish*[3], *(1)Vanderbilt Brain Institute, Vanderbilt University, Nashville, TN, (2)University of Texas at Dallas, Richardson, TX, (3)Vanderbilt University School of Medicine, Nashville, TN*

Background: Circumscribed interests are a common expression of repetitive behaviors in Autism Spectrum Disorders (ASD); these behaviors tend to be nonsocial in nature and often reflect a disproportionate amount of attention and engagement, compared to social interactions. Our lab previously developed a task to quantify aspects of circumscribed attention for nonsocial information in visual arrays containing both social and nonsocial images (Visual Exploration Task, VET). Using this task, we have previously reported attentional patterns in ASD that are biased toward nonsocial information (e.g., increased number and duration of fixation) and away from social information. However, the mechanism underlying this bias remains unclear.
Objectives: Inverting visual information can lead to attention changes and recognition impairments, most commonly for holistically processed images, such as faces, but extend in some individuals to domains of individual expertise (e.g., cars, birds). The purpose of this task was to assess the influence of inversion on social and nonsocial information in adolescents with ASD, compared to typically developing (TYP) peers.
Methods: Attentional parameters were measured for samples of adolescents with ASD (N = 15; mean age = 13.9 years) and TYP (N = 17; mean age = 13.8 years) for both an upright and an inverted version of the VET eye-tracking task. In this passive viewing task, participants viewed upright and inverted visual arrays, containing both social and nonsocial images. Visual attention was assessed between array types for a) perseveration: average length of time on an item; b) exploration: proportion of items explored; c) detail orientation: average number of discrete fixations; and d) duration: average length of an individual fixation.
Results: For upright arrays, participants with ASD displayed increased nonsocial detail orientation ($F = 7.4$, $p = .008$), a trend for increased nonsocial perseveration ($F = 3.02$, $p = .078$), and decreased social perseveration ($F = 3.7$, $p = .058$), exploration ($F = 17.1$, $p < .0001$), and duration ($F = 10.4$, $p = .002$) compared to TYP participants. For inverted arrays, ASD maintained increased nonsocial perseveration ($F = 4.6$, $p = .042$) and detail orientation ($F = 7.0$, $p = .038$), relative to TYP; however, the groups showed no differences for social variables (all $ps > .05$).
Conclusions: As expected, we found that inversion of images altered attentional patterns to social images in the TYP group but not the ASD group. Further, the nonsocial attentional bias pattern seen in participants with ASD was not impacted by inversion of the images. Overall this pattern of results suggests a robust nonsocial bias in ASD that may reflect enhanced motivation to view nonsocial images, even in a context where doing so is more difficult.

186 **164.186** Novel Methods to Assess the Contribution of Sensorimotor Mechanisms to the Presence of Motor Stereotypy in Autism Spectrum Disorders

R. L. Shafer[1], *K. Wilson*[1], *E. Stroupe*[1] *and J. W. Bodfish*[2], *(1)Vanderbilt University, Nashville, TN, (2)Vanderbilt University School of Medicine, Nashville, TN*

Background: The emergence of motor stereotypy is indicative of neural pathology in several neurodevelopmental and neuropsychiatric disorders including autism spectrum disorders (ASD); however, it is also present early in normative development during the transition from simple, uncontrolled movements to complex, controlled movements. Unlike in ASD, stereotypy in healthy infants begins to decrease within the first year of life and is replaced with goal-directed motor behavior. Research in normative development demonstrates the importance of sensory feedback for the development of motor complexity – as children develop the ability to integrate sensory information from the environment with motor behavior, their behavior becomes less stereotyped and more complex, allowing them to interact adaptively in the environment. This is consistent with our understanding of sensorimotor integration in the brain. Prior studies from our group have found that individuals with ASD who have motor stereotypy also have reduced motor complexity, consistent with the notion that motor stereotypy is a manifestation of low motor complexity. Additionally, individuals with ASD often present with unusual sensory symptoms suggesting that sensory processing deficits may contribute to the development of stereotyped actions.
Objectives: To date, the contribution of motor and sensory factors to the development of stereotyped behavior has only been examined in isolation. There is a need for methods that assess the joint sensory and motor contributions to the emergence of the core features of ASD. The purpose of this study is to develop a method for objectively measuring the role of sensory feedback on motor performance in ASD at the level of both brain and behavior.
Methods: We are adapting methods from studies of normative motor development to assess the effect of sensory feedback on motor complexity in individuals with ASD and relate these metrics to concurrent neural activity. Our method involves the use of virtual reality gloves that monitor hand position in real time and provide sensory feedback in the form of vibro-tactile stimulation. Participants perform a task during which they use their index finger to track a moving stimulus on a screen. For half of the trials, participants receive online vibro-tactile feedback at the fingertip if they deviate from the stimulus, and in the other half of the trials, they do not receive vibro-tactile feedback. Performance is measured using indices of complexity of movement kinematics (via accelerometers embedded in the gloves) and neural complexity (via electroencephalography). Here, we present preliminary results from this novel approach focusing on (a) method feasibility and test-retest reliability and (b) the application of nonlinear dynamic analytic techniques to examine coupling of neural and behavioral output during this sensorimotor task.
Results: N/A
Conclusions: N/A

187 **164.187** Olfactory and Social Impairments in Children with Autism Spectrum Disorders, Sensory Processing Challenges, and Typical Development

J. R. Sweigert[1], *F. Velasquez*[1], *G. Greco*[1], *T. St. John*[2], *K. K. Begay*[2], *G. E. Davis*[3], *A. Estes*[2] *and N. M. Kleinhans*[4], *(1)Radiology, University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA, (3)Otolaryngology, University of Washington, Seattle, WA, (4)University of Washington, Seattle, WA*

Background:
Individuals with autism spectrum disorder (ASD) show atypical sensory processing within the olfactory system. Quantitative measures of olfaction, including detection threshold, identification, and discrimination, have yielded inconsistent results, yet there is mounting evidence that individuals with ASD perform more poorly than typically developing peers on these measures. In addition, the relationship between quantitative olfactory impairments and clinically assessed autism-related behaviors has not been studied, and may help to identify olfaction as a potential biomarker of ASD.
Objectives:
To assess olfactory performance in children with ASD, including smell detection thresholds and odor identification, to determine if olfactory measures can discriminate between ASD and an age and IQ matched clinical comparison group of children with sensory processing challenges (SPC), and to assess the relationship between olfactory performance and autism-related behaviors.
Methods:
14 children with high-functioning ASD (Age=10.36±1.68), 15 children with SPC (Age=10.25±1.62), and 14 typically developing children (TYP; Age=9.40±1.38) participated in this study. Two measures of olfactory processing were assessed. Odor detection thresholdÂ was measured using the phenyl ethyl alcohol version of the Sniffin' Sticks task. Smell identification was measured using the University of Pennsylvania Smell Identification Test (UPSIT). Autism severity was assessed using Module 3 of the Autism Diagnostic Observation Schedule (ADOS-2).
Results:
Children with ASD (M_{ASD}=24.07, SD_{ASD}=5.82) had significantly lower UPSIT scores than TYP children (M_{TYP}= 30.86, SD_{TYP}=3.61; t(26)= -3.71, p<.001), but no differences on the UPSIT were detected between children with ASD and SPC (M_{SPC}=27.73, SD_{SPC} = 5.19; t(27)= -1.79, p=.086) nor between children with SPC and TYP children (t(28)= -0.96, p=0.343). No difference in Sniffin' Sticks detectionÂ threshold was observed between the three groups (M_{ASD}=7.77, SD_{ASD}=4.13; M_{SPC}=8.15, SD_{SPC}=4.64; M_{TYP}=8.66, SD_{TYP}=4.09). UPSIT scores showed a negative correlation with ADOS 2 total score (r(41)= -0.48, p=0.001) and with the Social Affect domain of the ADOS 2 (r(41)= -0.49, p<.001) but no significant relationship was detected between UPSIT scores and the Restricted Repetitive Behavior domain of the ADOS 2 (r(41)= -0.27, p=0.084). Correlation analyses showed no significant relationships between Sniffin' Sticks detection thresholdÂ and ADOS 2 scores.
Conclusions:
Children with ASD showed reduced odor identification compared to typically developing children; however, in this preliminary sample, the two groups had similar odor detection thresholdÂ levels. In comparison to children with SPC, children with ASD showed similar odor identification and detection threshold levels. This finding suggests that the olfactory impairments observed in ASD may be specific to higher order olfactory processing but not unique to ASD. Both autism severity and social impairments were negatively associated with odor identification. The orbital frontal cortex (OFC) mediates odor identification and has also been implicated in social impairments; thus, impaired performance on this odor identification measure may be an especially useful quantitative biomarker of OFC involvement in children with ASD. We aim to validate the current preliminary findings with a larger sample, as data collection for this project is ongoing.

188 **164.188** Postural Control Assessment in Autism Using the Pediatric Balance Scale and the Fall Screen Assessment System: Results from a Pilot Study

G. Valagussa[1,2]*, L. Trentin*[1]*, E. Terragni*[2]*, C. Cerri*[2]*, V. Gariboldi*[2]*, C. Perin*[2]*, D. Mauri*[1] *and E. Grossi*[1]*, (1)Villa Santa Maria scs, Tavernerio, Italy, (2)School of Medicine and Surgery, University of Milano Bicocca, Milano, Italy*

Background: Individuals with ASD have impairments in fine and gross motor skills, motor planning, motor coordination and praxis. A key sensorimotor control process affected by ASD is the management of upright standing. The maintenance of balance depends on the interaction of multiple sensory, motor and integrative systems (i.e. vestibular function, vision, peripheral sensation, muscle force and reaction time). A marked deficit in any one of these factors or a combination of mild impairments in multiple physiological domains may increase the risk of falling. Few studies on this topic are available in the literature and most of them have used just force platform instrumental approaches, neglecting the assessment of different balance components.
Objectives: The aims of this pilot study are: 1) to assess balance in a group of ASD subjects using the Pediatric Balance Scale (PBS), comparing the results with normative values; 2) to assess balance in the same sample, using the Fall Screen Assessment System (FSAS), comparing the results with a control group of normally developing children.
Methods: The study sample included nine ASD individuals and sixteen healthy age matched subjects. The ASD subjects were diagnosed with Autism according to the DSM V criteria, confirmed through ADOS 2 and under observation at our Institute. We employed: a) FSAS, a multi-item scale internationally validated in adult subjects, exploring sensorial and motor performances; b) PBS, a multi-item functional assessment tool exploring functional balance in the context of everyday tasks, commonly used in children and adolescents
Results: The two groups resulted homogeneous as regards age distribution (ASD group mean age 12.2 years - 4.29 SD vs control group mean age 12.8 years - 3.8 SD). We found that five (56%) ASD subjects showed a balance deficit as detected by the PBS (scores below the normality cut-off) and were also positive for the FSAS. Two more subjects were found at risk of falling only by FSAS. FSAS was easily applicable to children and adolescents and showed a statistically significant difference (p = <0.05) between the two groups in the following tests: visual contrast sensitivity, touch sensitivity, ankle dorsiflexion force, knee extension and flexion force, reaction time for hand, and all postural sway tests (table 1), thus evidencing an overall postural control impairment in ASD.
Conclusions:
This study confirms that ASD individuals are at major risk of falling in everyday life. This is attributable to an altered integration and elaboration of sensory and motor information. FSAS integrates the information derived from standard clinical assessment, and can be suggested as a complementary tool in the management of ASD. Moreover, by directly assessing an individual's physiological abilities, intervention strategies can be implemented to target areas of deficit. Further studies are necessary to confirm the results of this pilot study.

189 **164.189** Relationships Between Gross Motor Ability and Social Function in Young Children with Autism Spectrum Disorders

J. M. Holloway[1]*, E. M. Smith*[1]*, A. Cooper*[2] *and F. J. Biasini*[2]*, (1)Physical and Occupational Therapy, University of Alabama at Birmingham, Birmingham, AL, (2)Psychology, University of Alabama at Birmingham, Birmingham, AL*

Background: Autism spectrum disorder (ASD) is characterized primarily by social and communication impairments, however, children with ASD often exhibit additional delays in motor abilities. In children who are typically developing, motor ability is related to social function. However, the extent to which motor ability and social function and participation are related in children with ASD is unknown.
Objectives: The purpose of this study is to examine the relationship between gross motor ability and social function in young children with ASD. We hypothesize that children with ASD who have higher motor ability will also have higher social function.
Methods: Children with ASD between the ages of 48-71 were invited to participate in the study. All children were previously diagnosed with ASD by a physician. Diagnosis was confirmed by study investigators using the *Childhood Autism Rating Scales 2 (CARS2)*. The gross motor subscales of the *Peabody Developmental Motor Scales 2nd Ed (PDMS-2)*were administered to determine each participant's level of gross motor function. The PDMS-2 yielded scaled scores for each of the 3 subscales (Stationary, Locomotion, and Object Manipulation) and a standard score Gross Motor Quotient (GMQ). Social function was measured using the Social Skills Improvement System (SSIS). The SSIS provided an overall standard score for 2 scales: Overall Social Skills and Problem Behaviors.
Results: Six children with ASD have participated in the study thus far.Â We expect to have data from at least 20 participants at the time of the conference in May.Â Participants ranged from 49 to 65 months of age (Mean=56.33 mths). Five children scored in the Mild to Moderate category of the CARS2 while the remaining child scored in the Severe category. Four children demonstrated delayed gross motor skills on the PDMS-2 as indicated by a GMQ <1.5 SD below the mean. Spearman's rank-order correlation revealed a strong, positive relationship between PDMS-2 GMQ and SSIS Overall Social Skills standard scores (r_s=0.829, p=.042). Further analysis revealed significant relationships between the Locomotion (r_s=0.939, p=.005) and Object Manipulation (r_s=0.928, p=.008) subtests of the PDMS-2 with the SSIS Overall Social Skills standard scores. No significant correlations were found for the SSIS Overall Social Skills and PDMS-2 Stationary scales (r_s=.679, p=.138) or the SSIS Problem Behaviors and PDMS-2 GMQ (r_s=-.200, p=.704).
Conclusions: The results thus far support previous findings that suggest that gross motor delays are common in children with ASD. In addition, a positive relationship between gross motor ability and social function was found. Areas of gross motor skills that may be related to social skills are Locomotor skills such as jumping, running, and stair climbing and Object Manipulation skills such as throwing, catching, and kicking a ball. Further research is needed to quantify these relationships and pinpoint exact areas of concern regarding motor skills in young children with ASD.

190 **164.190** Repetitive Behavior and Object Exploration in Young Autistic Children: How Are They Associated?

M. Dawson[1], *V. Courchesne*[2], *S. Mineau*[3], *L. Mottron, M.D.*[3] *and C. Jacques*[4], *(1)Centre d'excellence en Troubles envahissants du développement de, Montréal, QC, CANADA, (2)University of Montreal, Montreal, QC, Canada, (3)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada, (4)University of Quebec in Outaouais, Gatineau, QC, Canada*

Background: An often-repeated but questionable claim about repetitive behaviors in autism is that they interfere with learning. More specifically, increased repetitive behaviors are thought to reduce exploration of the environment in autistic children, thus reducing opportunities for learning (Pierce & Courchesne E., 2001; Sasson et al., 2008, for a review). However, using the Montreal Stimulating Play Situation (MSPS), we found that young autistic children displayed significantly more repetitive behaviors than age-matched typical children, but the two groups of children did not significantly differ in their exploration of objects (Jacques et al., 2016). Our previous findings did not seem to support the prevailing view, but did not address how or whether repetitive behavior is associated with object exploration in autistic and typical young children.
Objectives: Building on our previous findings, and within the same sample of children, to determine whether repetitive behaviors and object explorations (their frequency and duration) are associated in young autistic children; and to determine whether these associations are similar to or different from those found in age-matched typical children.
Methods: 49 autistic (mean age=47.1 months, SD=10.49; mean MSEL=63.7, SD=19.14) and 43 typical (mean age=42.8 months, SD=13.65, p=.09; mean MSEL=110.7, SD=16.9, p<.001) children were assessed with MSPS. Four play periods (one free-play, one semi-free play, one semi-structured play, and a second free-play period) including 34-40 objects of potential interest to autistic children were filmed. Two naïve typical raters coded duration (in seconds) and frequency (number of occurrences) of repetitive behaviors and object explorations on Observer XT 11©. Correlations between repetitive behaviors and object explorations were calculated for autistic and typical groups for the full MSPS (4 correlations), and for each play period (16 correlations).
Results:
For the full MSPS, in typical children, frequency of repetitive behaviors was significantly and positively correlated with frequency of object explorations (r=.336, p=.028), but this was not the case for autistic children, where no significant correlation was found (r=.146, p=.32). Similarly, duration of repetitive behaviors was significantly and positively correlated with duration of object explorations in typical (r=.358, p=.018) but not autistic (r=.058, p=.69) children. The difference between groups was significant for duration (p=.028) but not for frequency (p=.35) correlations.
For the 4 MSPS play periods, correlations were either significantly positive (5 for autistic and 4 for typical children) or not significant (the remaining 7). Significant positive correlations were weak to moderate (r=.296 to .564). There were no significant negative correlations.
Conclusions: Across the full MSPS, we found weak but significant positive correlations between repetitive behaviors and object explorations in young typical children, such that increased repetitive behavior was weakly associated with increased object exploration. No significant correlations were found in age-matched autistic children, who in this sample displayed significantly more repetitive behaviors than their typical controls. Within individual MSPS play periods, some significant positive correlations were found in both groups. However, we found no significant negative correlations. We found no evidence that repetitive behavior reduces or interferes with object exploration in either autistic or typical young children.

191 **164.191** Repetitive Behavior and Restricted Interests of Offspring in Adults with ASD and Other Neuropsychiatric Disorders

D. W. Evans[1,2], *D. B. Hanson*[2] *and M. Uljarevic*[3], *(1)Psychology, Bucknell University, Lewisburg, PA, (2)Bucknell University, Lewisburg, PA, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: The broader autism phenoptype (BAP) is an emerging construct suggesting that first-degree relatives of those diagnosed with autism spectrum disorders (ASD) exhibit behaviors that encompass the ASD spectrum without necessarily reaching diagnostic thresholds for clinical disorder. Generally the BAP refers to behaviors of parents or "unaffected" siblings of children with ASD. Some aspects of the BAP are relevant to other disorders as well. Repetitive Behaviors and Restricted Interests (RBRI) for example not only define ASD (and the BAP) but they also appear in a wide range of other neurodevelopmental and neuropsychiatric disorders, including, but not limited to, obsessive-compulsive disorder (OCD), tic disorders, intellectual and developmental disabilities, and psychotic disorders. What is not well understood is the manifestation of RBRI in the offspring of adults diagnosed with these disorders, as well as (high functioning) ASD. We know virtually nothing, about the trajectory of RBRI in children who are at risk for various neurodevelopmetnal and neuropsychiatric disorders, by virtue of parental diagnostic status.
Objectives: To examine the frequency/intensity, as well as the cross-sectional trajectory, of RBRI in offspring of adults diagnosed with a range of neurodevelopmental and neuropsychiatric disorders who represent a nationally-representative cohort.
Methods: 2897 adults who were ascertained from a representative United States cohort of adults with at least one children ranging in age from 1-17;11 years of age. Families were sent an online battery of surveys indicating demographic status including clinical neurodevelopmental and neuropsychatric diagnostic family history. Parents also completed the Childhood Routines Inventory-Revised (CRI-R) to assess Total RBRI, Repetitive Motor Behaviors/Compulsions (RMBC), and Resistence/Insistence on Sameness (RIS). Parents were grouped into several diagnostic clusters basad on their psychiatric history: ASD (n=38); OCD/tic disorders (n=66); bi-polar/schizophrenia (n=157); no diagnosis (n=1914); "other" diagnosis (n=738). Children were placed into one of three age groups (1-6 years, 7-12 years, 13-17;11 years).
Results: A 4 (parent diagnosis) X 3 (age group) analysis of variance revealed a significant interaction for RMBC ($F(2882,8)= 2.08$, $p= 0.03$), main effects for parent diagnosis for all three CRI-R factors (All $p < 0.0001$), and main effects for age group for Total CRI-R ($p = 0.03$) and RMBC ($p= 0.02$).
Conclusions: The offspring of adults with an ASD demonstrated signficantly higher RBRI relative to all other diagnositic groups, followed by OCD/tic disorders, bi-polar/schizophrenia, any other diagnosis, and no diagnosis. Children of parents with ASD had unique developmental trajectories that indicated progressive age effects across all three age groups, whereas all offspring of all other parental diagnostic groups showed a characteristic increase from agegroup 1 to agegroup 2, with a decrease for age group 3. These data indicate that the frequency/intensity and developmental trajectories of RBRI in children are impacted by parental diagnostic status.

192 **164.192** Repetitive and Restricted Behaviors and Their Sensory Components in Young Children with ASD: Family Quality of Life and Improvement during Intervention.

*K. Strauss[1], **L. Fava**[1], A. Delle Fratte[1], L. Mazzone[2], G. Valeri[3] and S. Vicari[4], (1)Association for Treatment and Research in Autism and Related Conditions, Umbrella Autism, Rome, Italy, (2)University of Catania, Italy, Catania, ITALY, (3)Children Hospital Bambino Gesù - Roma, Roma, ITALY, (4)Children Hospital Bambino Gesù, Rome, ITALY*

Background:
Sensory processing issues (SP) often co-occur with restricted and repetitive behaviors (RRB). Following a developmental account RRBs are defined as developmentally immature responses serving adaptive functions (occupying self versus soothing) to arousal derived from sensory processing issues. Alternative considerations account for sensory processing issues as primary impairment resulting in interaction problems typical for ASD. Comprehensive programs intervene directly on RRBs defined as barriers for learning more mature responses from social experience.
Objectives:
Examine associations of SP and RRB and whether social deficits account for any relationship. Explore their impact on family's Quality of Life and potential change during behavioral treatment.
Methods:
Sixteen parents of preschoolers with ASD who received EIBI intervention provided ratings of Quality of Life (WHOQOL-BREF, WHOQOL Group, 1998) and child characteristics (Restricted and Repetitive Behaviors Scale, Bourreau et al., 2009; Short Sensory Profile, Dunn, 1999). Evaluation of autism core symptoms (ADOS-2, Lord et al., 2012) and developmental cognitive level (GMDS-R, Luis et al., 2006) was provided by external licensed neurodevelopmental psychiatrists.
Results:
Fourteen children (87.5%) demonstrated an probable or definite difference in SP. Strongly associated SP and RRB scores confirmed lower-level clusters of repetitive sensorimotor behaviors and sensorimotor stereotypies ($r=-.639$, $p>.001$ to $r=-.570$, $p>.05$), associated with lower cognitive level ($r=.771$ to $r=.,587$ $p>.05$), and a higher-level cluster of insistence on sameness/modulation insufficiency and sensory seeking /auditory filtering ($r=-.590$ to $r=.508$, $p>.05$). No association was found of ADOS social communication and presence of repetitive behaviors or sensory processing issues. Family QOL was impacted by lower cognitive level ($t=3.695$, $p>.05$) and atypical sensory processing of movement ($t=3.543$, $p>.05$), tactile ($t=5.216$, $p>.01$), visual ($t=4.175$, $p>.05$) stimuli and inattention due to auditory filtering issues. Family QOL was not predicted by age, autism severity or repetitive behavioral representations alone. The full model explained 85% of variability. At six months of intervention SP ($t=-7.001$, $p>.0001$) and RRB ($t=4.759$, $p>.001$) were reduced at a rate of 19% in frequency of case occurrence, with 11 remaining children (68%) demonstrating a difference in SP. Subscale analyses revealed improvement predominantly in under-responsiveness, and distractibility with decline in behavioral representations such as adoption of control, rituals, object attachment, and echolalia. Magnitude of improvement was significantly associated with social communication severity ($p>.01$).
Conclusions:
Results confirm clusters of lower- and higher-order repetitive behaviors, differentially associated with cognitive impairment. This pilot is novel in demonstrating the negative impact of Sensory processing issues on family Quality of Life as well as the efficacy of comprehensive intervention in reducing repetitive behaviors and correlated sensory issues. The present results did not support the assumption of a social-communication dysfunction as a shared mechanism that underlines SP and RRBs. Nevertheless, social-communication deficit was shown to impact the rate of improvement. It is reasonable that decreasing engagement in repetitive behaviors may make the child more amenable to treatment targeting autism core symptoms.

193 **164.193** Restricted Repetitive Behaviors and Interests and the Female Autism Phenotype: An Autism Speaks Autism Treatment Network (AS-ATN) Study.

***J. Knutsen**[1], M. K. Crossman[2], J. M. M. Perrin[2], A. M. Shui[1] and K. Kuhlthau[1], (1)Massachusetts General Hospital, Boston, MA, (2)Harvard Medical School, Boston, MA*

Background: Autism Spectrum Disorder (ASD) continues to be diagnosed at a greater rate in males than in females with current prevalence rates estimated at 4-5:1 (males; CDC, 2016). Although clinical characteristics of ASD manifest differently in males and females (e.g. Bölte et al, 2011; Carter et al, 2007), few studies have investigated sex differences in ASD's two core domains: social–communication and restricted, repetitive behaviors, interests and activities (RRBs). Additionally, compared to the social-communication domain, considerably less is known about the cause, development and impact of RRBs in children with ASD, including possible sex differences.
Objectives: The aim of this study is to examine potential differences in clinically identified (ADOS) RRB symptoms using a large sample of age and IQ-matched females and males with ASD.
Methods: Data were extracted from the Autism Speaks Autism Treatment Network (ATN) registry. The study sample included 513 females and 513 males with **an ASD diagnosis (Autistic Disorder, Asperger's Disorder)** propensity score-matched 1:1 on age in 24mo intervals and IQ (≥70 vs. <70). Age (<6 yrs, 6-<12 yrs), race, ethnicity, IQ, caregiver education, evidence of lost skills, and autism diagnosis were tabulated overall and by sex. Fisher's exact tests evaluated if these characteristics differ by sex. ADOS RRB domain calibrated severity score and its individual items were described overall and by sex in four age-IQ groups: 1. IQ≥70 and < 6 yrs, 2. IQ≥70 and 6-<12 yrs, 3. IQ<70 and <6 yrs, 4. IQ<70 and 6-<12 yrs. T-tests assessed whether RRB differs by sex within each of these groups. Means and standard deviations were reported. RRB individual item scores (1 or 2 vs. 0) were tabulated by sex, and Fisher's exact tests determined if these items differ by sex.
Results: Demographic characteristics, evidence of lost skills, or ASD diagnosis did not differ significantly by sex (see Table 1). RRB total score differed by sex (p=0.022) in the IQ<70-age 6-<12 group, with females reporting lower RRB than males, but no significant sex differences were found for other groups. In the IQ≥70-age<6 group females had a higher percentage of abnormal hand/finger/other complex mannerisms (p=0.038) and abnormal intonation of vocalizations or verbalizations (p=0.049). In the IQ≥70-age 6-<12 group females also had a higher percentage of abnormal hand/finger/other complex mannerisms (p=0.037; see Table 2). No item scores differed significantly by sex in either of the IQ<70 groups.
Conclusions: Â Findings from the largest dataset to date of matched young females and males with ASD indicate that there are sex differences in overall RRBs and in particular sub-domains for selected groups. These differences add to the growing literature regarding the need for sex-specific algorithms in autism diagnostic instruments which may then help improve our ability to identify misdiagnosed and under-diagnosed females with ASD.

194 **164.194** Restricted and Repetitive Behaviors and Interests Differ By Sex and Age in High Functioning Children with ASD

E. J. Libsack[1]*, A. Kresse*[1]*, E. E. Neuhaus*[2]*, R. Bernier*[3]*, K. A. Pelphrey*[4] *and S. J. Webb*[5]*, (1)Seattle Children's Research Institute, Seattle, WA, (2)Seattle Children's Hospital, Seattle, WA, (3)University of Washington Autism Center, Seattle, WA, (4)Yale University, New Haven, CT, (5)University of Washington, Seattle, WA*

Background:
Restricted and repetitive behaviors and interests (RRBs) are a core feature of Autism Spectrum Disorders (ASD) required to meet diagnostic criteria for ASD according to the DSM-5. Research suggests RRBs are a heterogeneous group of behaviors with subtypes having differential developmental trajectories. Patterns of findings across studies are not consistent regarding age-related changes in RRBs. Understanding the developmental trajectory of RRB subtypes in girls and high functioning children and adolescents has implications for better understanding symptom progression across the ASD spectrum.
Objectives:
Data are from a multi-site study focusing on multimodal neurogenetic exploration of girls (and boys) with ASD. In a sample of children with ASD without intellectual impairment, we explore the effects of child age and gender on parent report of RRBs in three domains: stereotyped, ritualistic, and restricted behavior.
Methods:
Preliminary data were analyzed from a sample of children who participated in the NIMH ACE network GENDAAR study, across 4 U.S. research sites. In order to analyze the influence of child gender, we matched a subsample of 40 ASD males and 40 ASD females on age (8-17 years) and IQ (mean IQ=102.95, SD=22.47). Subjects were divided into 2 cross-sectional age groups: 8-12.9 years (children) and 14-17.9 years (adolescents). Parents completed the Repetitive Behavior Scale – Revised (RBS-R) about their child. All subjects met diagnostic criteria for ASD on the ADOS-2 and the ADI Revised. Final analyses will include additional subjects and measures of RRBs.
Results:
On the stereotyped behavior subscale, male children (M=4.55, SD=3.561) scored significantly higher (worse) than male adolescents (M=1.20, SD=1.240) (p=.001), while girls' stereotyped behavior scores did not differ across age groups (p=.106). On the ritualistic behavior subscale, male children (M=5.25, SD=4.587) scored significantly higher (worse) than male adolescents (M=2.50, SD=2.439) (p = .025), however girls' ritualistic behavior scores did not differ across age groups (p=.528). On the restricted behavior subscale, males' scores (M=3.50, SD=3.211) were also significantly higher (worse) than females' scores (M=2.13, SD=2.127), regardless of age group (p=.026).
Conclusions:
In our sample, male children scored higher (worse) than male adolescents on measures of stereotyped and ritualistic behaviors. In contrast, females' scores on stereotyped and ritualistic behaviors did not differ between age groups. Additionally, males scored higher (worse) than females on restricted behaviors. These findings suggest that the level of RRBs in ASD may vary based on age *and*gender, with males showing (overall) higher (worse) scores. Age and gender may be important factors in the developmental trajectory of RRBs in children and adolescents with ASD without intellectual disability.

195 **164.195** Restrictive and Repetitive Behaviors and Interests and Inhibitory Control in Children with Autism Spectrum Disorder

L. J. Nelson *and S. Faja, Boston Children's Hospital, Boston, MA*

Background: Deficits in executive functioning (EF), an ability that encompasses inhibition, planning, attention regulation, set-shifting and working memory, have been observed in children with autism spectrum disorders (ASD) (Ozonoff, Pennington, & Rogers, 1991; Pellicano et al., 2006). Poor inhibitory control has been implicated in the maintenance of the inappropriate (i.e. nonadaptive) thoughts and behaviors distinctive of ASD, termed restrictive and repetitive behaviors and interests (RRBIs) (Turner 1997; 1999). This characteristic can be subdivided into two correlated yet qualitatively different categories: Insistence on Sameness (IS) and Repetitive Sensory Motor (RSM) behaviors (Turner, 1999; Somer et al., 2013) and conceptualized as higher-order (including preoccupations and ritualistic behavior) and sensorimotor, respectively (Mosconi et al, 2011; Turner, 1999). RRBIs generally, and higher-order RRBIs specifically, have been related to inhibitory control in individuals with ASD with mixed results (Lopez et al., 2005; Mosconi et al. 2009). In the present study, inhibitory control and phenotypic variation in RRBIs were examined in 64 high-functioning children with ASD.
Objectives: To determine whether variation in RRBIs relates to impaired inhibitory control in a Stroop task in children with ASD.
Methods: 64 children with ASD between the ages of 7- and 12-years-old were included in analyses. All children had a full-scale IQ above 85. Children participated in the Autism Diagnostic Observation Schedule (ADOS-2) and parents completed survey and interview measures about their child, including the Repetitive Behavior Scale-Revised (RBS-R) and Autism Diagnostic Interview-Revised (ADI-R). Children's behavioral responses were recorded during a computer-based Stroop task. Stroop difference scores were computed from accuracy scores on incongruent and congruent trials, with larger difference scores indicating a failure to inhibit a learned verbal response. Children's inhibitory control in the Stroop task was analyzed with parental reports of RRBIs on the ADI-R and RBS-R, and researcher ratings of RRBIs during the ADOS-2. Higher-order RRBI scores were computed from subscale items on the ADOS-2, ADI-R, and RBS-R.
Results: Correlations between higher-order RRBI scores on the ADI-R and RBS-R and Stroop difference scores were not significant, however higher-order scores on the ADOS-2 were positively correlated with Stroop difference scores ($r = .292$, $p = .019$). A linear regression controlling for age and verbal IQ found a significant relationship between higher-order ADOS-2 RRBIs and Stroop difference scores ($R^2_{change} = .075$, $t(62) = 2.27$, $p = .027$). No relation was found between global RRBI subscales from the ADOS-2, ADI-R, or RBS-R and Stroop performance.
Conclusions: RRBIs were inconsistently related to inhibitory control; however findings suggest readily observable higher-order RRBIs (e.g. via the ADOS-2) may be more indicative of children's current inhibitory skills than parental reports. Analysis of participants' behavioral and electrophysiological responses to a Go-No-Go task is ongoing and will allow further examination of inhibitory control as it relates to RRBIs. Given the significant interference of RRBIs in everyday functioning, computer-based EF training may be an efficacious and desirable intervention for reducing higher-order RRBIs through improved inhibitory control.

196 **164.196** Selective Impairments in Action Understanding and Movement Intentionality in Young Children with Autism When Compared to Williams Syndrome

D. R. Hocking[1]*, P. A. Fanning*[2] *and G. Vivanti*[3]*, (1)Bundoora, Developmental Neuromotor & Cognition Lab, La Trobe University, Melbourne, VIC, Australia, (2)School of Psychology and Public Health, La Trobe University, Melbourne, Australia, (3)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Although previous studies comparing Autism spectrum disorder (ASD) and Williams syndrome (WS) have focused on the social and motor domains separately, recent theoretical perspectives on “motor cognition” have proposed that the motor system is fundamentally intertwined with social functioning. Despite the simplistic view of opposing abnormalities in social behavior, with ASD characterized by hyposociability, and WS exhibiting hypersociability, there are striking similarities in motor dysfunction across these two syndromes. Yet, the extent to which ASD and WS share common deficits in the encoding of others’ motor intentions and movement interference, which are critical motor mechanisms impacting on social functioning, is as yet unexplored. Direct cross-syndrome comparisons of young children with ASD and WS provide a hitherto unprecedented opportunity to examine specificity of motor mechanisms impacting on cognitive and adaptive social functioning.
Objectives: Here we compare the ability to understand and predict others’ intentional actions and movement interference in preschoolers with ASD when compared to a matched sample of children with WS, and typically developing (TD) children. Specifically, we aimed to identify whether deficits in encoding motor intentions and movement execution during incongruent actions are specific to ASD, and explore the extent of association with cognitive and social functioning.
Methods: Using novel experimental behavioral and eye tracking tasks that were video-recorded, we examined childrens’ movement interference when observing a models’ incompatible actions and their understanding of the intended goal of reaching actions across the following conditions: 1) observation of a model performing either congruent or incongruent actions (e.g. placing coins in a moneybox, stacking rings in correct order), 2) coding of childrens’ movement efficiency (time and effective actions) during incongruent versus congruent conditions, and (3 patterns of anticipatory looking to a target during successful or failed attempts by a model to reach over a barrier to retrieve it.
Results: Preliminary findings suggest that children with ASD showed significantly reduced movement interference time during incongruent relative to congruent actions when compared to TD children. Interestingly, reduced movement interference during action observation correlated with greater severity of symptoms in social affect and restricted repetitive behavior in ASD. Although there were no group differences in anticipatory fixations or duration to goal-directed reaching actions, less anticipatory fixations to the target correlated with greater severity of autism symptoms in children with ASD.
Conclusions: Our findings add to the growing evidence base supporting a critical role for motor system dysfunction contributing to difficulties in the social domain in young children with ASD. Direct cross-syndrome comparisions will be important in revealing autism-specific impairments in motor cognition which may lead to new treatment targets for core ASD symptomatology.

197 **164.197** Sensory Experiences of Adults with ASD and Severe and Complex Needs: A Qualitative Study with Practitioner Informants

D. R. Simmons*, H. Marshall and S. Harris, School of Psychology, University of Glasgow, Glasgow, United Kingdom*

Background: It is well established that individuals with Autism Spectrum Disorder (ASD) report unusual sensory experiences (e.g. Smith & Sharp, 2013; Robertson & Simmons, 2015). However, previous research has focused mainly on the sensory experiences of children and verbal adults with ASD and has relied heavily on self-report and parent-report measures: methods with obvious limitations. In this study we focused instead on adults with ASD and severe and complex needs who find it difficult to communicate their own perceptual experiences accurately. In order to access this population, we collected reports from autism practitioners, using semi-structured interviews.
Objectives: To assess whether there are quantitative and/or qualitative differences in the nature and severity of the sensory experiences of adults with ASD and severe and complex needs as opposed to those with typical IQ levels.
Methods: 19 adult autism practitioners were interviewed about their experiences with autistic adults with severe and complex needs. Questions in the interviews used a variant of the Critical Incident Technique (Flanagan, 1954; Dickie et al, 2009) to evoke a more objective analysis of witnessed incidents where there had been clear sensory triggers. Transcripts of the interviews were analysed using Thematic Analysis (Braun & Clarke, 2006).
Results: Many of the responses reported a familiar combination of hyper- and hypo-sensitivities combined with sensory seeking behaviour across all the senses, with a slightly higher frequency of (mainly negative) auditory experiences. Particularly graphic descriptions were given of individuals who maintained pressure on their bodies throughout the day by wearing tight clothing, an individual who was apparently bothered by the humming noise from a fluorescent light, outside the hearing range of the practitioners, and another who was particularly disturbed by visual clutter. Some, however, were less familiar, such as sensory seeking of loud noises like drilling, and of high temperatures by touching hot kettles and toasters. A striking quantitative difference found in these data were the extreme reactions either to avoid or reduce unwanted sensory stimulation or to obtain desired stimulation.Â Examples included “challenging behaviour” like throwing furniture, or running across a busy street to obtainÂ a snack packet, the rustling noise of which was a desired goal.
Conclusions: It appears from our unique and rich data set that the clear sensory features experienced by adults with ASD and severe and complex needs are largely similar in nature to those reported by adults with ASD and typical IQs, with a few fascinating exceptions. However, the most remarkable difference is in the more extreme apparent reactions to both pleasant and unpleasant sensory triggers. Arguably, therefore, sensory “reactivity” is a useful term to have in descriptions of sensory features in ASD. It should also be noted that the combination of experience and relative objectivity on the part of our practitioner participants has provided a valuable extra dimension when investigating the behavioural phenotype of this enigmatic condition, and can be usefully used as an integral part of practitioner training as well as future research.

198 **164.198** Sensory Hypersensitivity and the Predictability of Repetitive Behaviours in Autism Spectrum Disorder

S. E. Schulz[1], *R. A. Stevenson*[2], *M. Segers*[3], *B. L. Ncube*[4] *and J. M. Bebko*[3], *(1)Psychology, University of Western Ontario, London, ON, Canada, (2)Psychology, University of Western Ontario, London, ON, CANADA, (3)York University, Toronto, ON, CANADA, (4)York University, York, ON, CANADA*

Background: Repetitive behaviours (RBs) are a core diagnostic symptom of Autism Spectrum Disorder (ASD) and tremendously impact individuals' day-to-day lives, yet the underlying factors of RBs are not fully understood. Recent work suggests that sensory issues related to ASD, specifically sensory sensitivities, contribute to RBs. While these studies have provided evidence for a relationship between RBs and hypersensitivity in individuals with ASD, these studies have not (1) identified if this relationship is specific to a particular sensory modality, nor (2) included adequate control groups to test if this relationship is specific to ASD.
Objectives: (1) Determine if hypersensitivity in specific sensory modalities contributes to the presence and severity of RBs. (2) Compare the relationship between sensory sensitivity and RBs in children with and without ASD to examine whether this relationship is specific to ASD.
Methods: Parents of 70 children (ASD, n=38; TD, n=32) completed questionnaires reporting on sensory processing (Sensory Profile-2, SP-2), and RBs (Repetitive Behaviours Questionnaire-2; Repetitive Motor Movements subscale). Cognitive ability was tested and matched using the Wechsler Abbreviated Scale of Intelligence–2 (WASI-II). A two-step analysis was employed. First, correlational analyses were conducted to identify relationships between sensitivities in individual sensory modalities in TD and ASD. Second, hierarchical regressions were conducted to examine the unique contributions of sensory sensitivities while controlling for demographic variables.
Results: Correlations confirmed a strong relationship between the RBs and the Sensitivity/Sensory Subscale of the SP-2 not only in ASD ($r^2=0.3133$, $p<0.001$), but also in TD ($r^2=0.1621$, $p=0.022$). The relationship between RBs and processing in individual sensory modalities, however, differed between groups. In ASD, we found that RBs significantly correlated with each individual sensory modality, including audition ($r^2=0.1812$, $p=0.010$), vision ($r^2=0.1698$, $p=0.013$), and touch ($r^2=0.3206$, $p<0.001$). In TD, however, only audition showed a significant correlation ($r^2=0.3154$, $p=0.002$), not vision or touch ($ps>0.05$). Hierarchical regressions revealed that sensory sensitivities were predictive of RBs even when controlling for age, gender, and intelligence in both ASD ($p<0.001$) and TD ($p=0.034$) groups. Similar to the correlation findings, in TD, the main driver of RBs was auditory sensitivity ($p=0.031$). In the ASD group, however, touch was identified being the most predictive of RBs ($p=0.015$).
Conclusions: These data provide evidence that hypersensitivity contributes to RBs in individuals with ASD, but also suggest that this relationship is not restricted to ASD, but is seen in TD as well. Although hypersensitivity relates to RBs in both ASD and TD, exacerbated levels of hypersensitivity in ASD resulted in more severe RBs that surpassed a clinical threshold. While similarities were observed in the overall relationship between sensory sensitivities and RBs, this correlation was apparent across modalities in ASD, but limited to audition in TD. Furthermore, results of the hierarchical regression suggest that in ASD but not TD, sensitivity to touch is particularly predictive of RBs. In sum, these results suggest that (1) sensory sensitivities are strongly related to RBs in individuals with and without ASD, but (2) the pattern of these relationships across sensory modalities diverge between groups.

199 **164.199** Sensory Processing, Repetitive Behaviours and Anxiety in Autism Spectrum Disorder and Williams Syndrome

M. Glod[1], *D. M. Riby*[2], *E. Honey*[3] *and J. Rodgers*[4], *(1)Newcastle University, Institute of Neuroscience, Newcastle Upon Tyne, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, UNITED KINGDOM, (4)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Unusual sensory responses are common in autism spectrum disorder (ASD) and have been included in the diagnostic criteria for the disorder, alongside social communication and interaction difficulties. Sensory difficulties, are also common amongst individuals with other neurodevelopmental disorders, including Williams syndrome (WS). Interestingly, both disorders although with different aetiology and presentations, share not only psychopathology relating to sensory processing, but also repetitive behaviours and anxiety. The associations, however, within and between these features are still not well understood and the degree of the co-occurrence and syndrome-specificity is still not well characterised.
Objectives: The aims of this study were: (a) to examine and compare the features of sensory processing clusters in children with ASD or WS; (b) to investigate whether sensory processing based clusters differed according to levels of anxiety and repetitive behaviours in children with ASD or WS.
Methods: Parents of 17 children with ASD and 16 with WS, aged between 4 and 9 years were recruited. Parents were asked to complete the Sensory Profile to provide information about their children's sensory experiences, the Social Responsiveness Scale (SRS-2) to assess a degree of social impairment, the Spence Children's Anxiety Scale/Preschool Anxiety Scale (SCAS/PAS) and the Anxiety Scale for Children-ASD (ASC-ASD) to assess anxiety symptoms, and the Repetitive Behaviour Questionnaire to evaluate the severity or frequency of repetitive behaviours that the children were engaging in.
Results: Â A hierarchical agglomerative cluster analysis was performed in order to identify subgroups based on sensory characteristics (Low Registration, Sensory Sensitivity, Sensation Seeking, Sensory Avoiding). A two-cluster solution emerged as the best fit to the data when the total sample was entered and also when ASD and WS groups were entered separately. Cluster 1 was represented with a low frequency of sensory behaviours and (2) cluster with a high frequency of sensory behaviours. A MANOVA showed a significant cluster effect for total repetitive behaviour score and both subscales (repetitive sensory motor behaviours and insistence on sameness; $F(3,27)=6.56$, $p=.002$).Â In addition the clusters differed on all total and subscale anxiety scores (SCAS/PAS scores $F(6,24)=4.10$, $p=.006$; ASC-ASD $F(4,23)=3.64$, $p=.019$). Univariate analysis indicated that parents of children in cluster 2 reporting significantly more repetitive behaviours and higher levels of child's anxiety than parents of children in cluster 1. However, when the SRS-2 total score was controlled for only the effect of cluster on anxiety remained significant for the SCAS/PAS scores in the total sample $F(6,23)=2.74$, $p=.037$.
Conclusions: The findings suggest that sensory profiles in children with WS or ASD are similar and that sensory processing atypicalities are associated with higher levels of anxiety and repetitive behaviours in both disorders. However, differences in severity of autistic traits contribute to the higher presentation of repetitive behaviours and anxiety in those children with ASD and WS who have greater sensory difficulties. Further work is needed to explore the role of other possible factors (e.g. intolerance of uncertainty) in the presentation of sensory atypicalities, repetitive behaviours and anxiety in neurodevelopmental disorders.

200 **164.200** Sensory Responsiveness in Siblings of Children with Autism

C. L. Hilton[1] *and D. M. Collins*[2]*, (1)University of Texas Medical Branch, Galveston, TX, (2)University of Texas Medical Branch, League City, TX*

Background:
Although autism spectrum disorder (ASD) is known to be heritable, the patterns of endophenotypic trait occurrences (inherited traits associated with a particular diagnosis that manifest in family members who do not have the diagnosis) are not well understood. Endophenotypes have emerged as an important concept to help clarify genetic underpinnings of complex neuropsychiatric conditions and to provide insight into underlying etiologies. Evidence has identified several endophenotypic traits, including social impairment, Reduced GABA/Cr (Creatine) matter, whole brain functional hypoconnectivity, visual motion perception, atypical frontal activation during visual attention and immunological functions. Children with ASD have been shown to demonstrate unusual sensory responses to stimuli more frequently than do typically developing peers or those with other developmental disorders.
Objectives:
This study examined sensory responsiveness in unaffected siblings of children with ASD and associations between sensory responsiveness and social severity. Questions addressed were: (a) Do unaffected siblings of children with ASD exhibit atypical sensory responsiveness? and (b) Is sensory responsiveness related to social responsiveness in unaffected siblings of children with ASD?
Methods:
185 children between ages 4 and 10.95 years participated in this study, 113 with ASD, 33 unaffected siblings, and 39 controls. Sensory Profile
Caregiver Questionnaires and Social Responsiveness Scales were completed by parents. A Kruskal Wallis ANOVA was used to examine the differences between the sensory response scores. To quantify the size of the variances, we examined the effect sizes in the children with ASD and the unaffected siblings and compared them to the control participants. Because of multiple comparisons, we used a Bonferroni correction to reduce the chances for a Type 1 error. We used a post-hoc Mann Whitney U test with a Bonferroni correction to locate significant differences. Correlations between the severity and the sensory Z scores were examined using the Spearman's rank correlation coefficient test.
Results:
The ASD affected participants had a wide range of sensory scores, while many of the unaffected siblings and controls had a preponderance of scores in the most typical end of the range. This contributed to reduced correlations between sensory and social responsiveness scores among these groups. Significant differences were found betweenÂ participants with ASD and controls, and between participantsÂ with ASD and unaffected siblings for all sensoryÂ quadrants and domains, but not between controls andÂ unaffected siblings. Social responsiveness scores were significantly correlated with scores from most sensory profileÂ categories. Repetitive behaviors were more frequently associated with sensory responsiveness than the other social responsiveness categories.
Conclusions:
Sensory responsiveness as an endophenotype ofÂ ASD is not indicated from these findings; however, studies with larger numbers of unaffected siblings and controls are needed to confirm the null hypothesis. Touch and taste/smell were the domains most frequently associated with social responsiveness, suggesting the possibility that they may bear some responsibility in social responsiveness problems and may be important targets for intervention for these problems. Finding repetitive behaviors to be frequently associated with sensory responsiveness suggests a relationship between the two and the potential for interventions addressing sensory problems to have an impact on repetitive behaviors.

201 **164.201** Sex and IQ As Predictors of Sensory Patterns in ASD

A. A. Alzamel*, L. R. Watson, E. Crais and G. T. Baranek, Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:
Females are underrepresented in ASD, which is possibly influenced by the male-bias in the population. Furthermore, females are diagnosed at a later age preventing them from accessing essential services at earlier stages of development. Little is known about the underlying differences in ASD symptoms between females and males, specifically the manifestation of sensory response patterns. These sensory responses, including hypo-responsiveness (HYPO), hyper-responsiveness (HYPER), and seeking behaviors (SEEK) impact the child's language, adaptive skills, and overall quality of life. Additionally, recent findings suggest that IQ is negatively correlated with increased sensory responses. Previous studies of sensory responses in children with ASD have not included a sufficient number of females to adequately examine potential sex differences.
Objectives:
This study aims to examine sex and IQ as predictors of sensory response patterns in children with ASD.
Methods:
This study used extant data from a large longitudinal study. Caregivers of children with ASD aged 2-12 years old (n=1307) participated in a national online survey examining longitudinal outcomes of sensory behaviors. The national survey study collected data at two time points, but only time point 1 data were analyzed in the current study. The survey included a background questionnaire (including parent report of cognitive functioning converted to a proxy IQ; IQP) and the Sensory Experiences Questionnaire (SEQ.v3). Only children that had a reported IQP were included in the analysis (females n=196 and males n =929). A regression model was employed to examine sex and IQP as predictors of sensory patterns.
Results:
Sex was found to be a significant predictor of HYPO ($p < .025$) and SEEK ($p < .048$), but not HYPER ($p < .40$). Moreover, there was an interaction between sex and IQP ($p < .015$) indicating that females with lower IQP scored higher on HYPO behaviors than males at the same level of IQP. However, with higher IQP levels, males scored higher on HYPO behaviors than females. A similar pattern was found with SEEK ($p < .010$) where females with lower IQP had more seeking behaviors than males, but as IQP increased, males scored higher on SEEK behaviors in comparison to females. IQP had a significant correlation with HYPER ($p < .025$), indicating that children with higher IQP show more sensory hyper-responsiveness, but sex was not significantly associated with HYPER.
Conclusions:
This novel study investigated sex differences in sensory response patterns in children with ASD. These results provide important insight on understanding sensory behaviors in females across different levels of IQP, suggesting that females with lower IQP tend to have more HYPO and/or SEEK behaviors than their counterpart males. In contrast, females with higher IQP show less HYPO and/or SEEK than males with comparable IQP. These findings have implications for diagnosis and intervention that reflect the unique sensory differences between the sexes.

202 **164.202** Standing Balance on Rigid and Unstable Surfaces in Children on the Autism Spectrum: Interaction Between Symptom and Motor Domains

***A. H. Mason**, K. Gruben, D. C. Dean, K. McLaughlin and B. G. Travers, University of Wisconsin - Madison, Madison, WI*

Background:
Difficulty with postural stability during standing on stable surfaces has been reported in people on the autism spectrum (see Memari et al. [2014] for review). However, it is unclear whether unstable surfaces may present even more of a challenge to youth with autism spectrum disorder (ASD). Because much of the ground on which we balance has the potential to be unstable, it is important to understand standing balance on both rigid and unstable surfaces. Further, it is important to understand individual differences that might relate to more severe postural stability challenges in ASD.
Objectives:
1) To examine postural stability in youth on the autism spectrum compared to youth with typical development during standing on a traditional rigid platform compared to a tiltable platform, and 2) to examine whether postural stability measures are related to individual variation in social communication and repetitive behavior symptom severity.
Methods:
Twenty youth on the autism spectrum and 18 youth with typical development (ages 6-16 years, IQ>70, 89% male) stood on both a rigid and tiltable platform that recorded force and center of pressure. Postural sway area and total mean velocity were calculated and served as the primary measures of postural stability. Postural stability was then examined as a correlate of autism symptom severity (RBS-R, SCQ, and SRS). To determine if individuals with ASD exhibited poorer postural stability than individuals with typical development on a rigid versus unstable platform, we conducted a linear mixed-effects analysis to examine the effect of surface condition (rigid versus unstable surface), group status (ASD versus typical development), and FSIQ on postural stability, after controlling for age and repeated measures. Partial spearman rank correlations (regressing out the effects of age) were used to examine the relation between postural stability and autism/autism-like symptom severity.
Results:
There was a main effect for surface, $p < .001$, but not for group status, $p = .86$. Contrary to our hypotheses, there was not a significant surface-by-group interaction, $p = .65$. However, there was a significant three-way interaction between group, surface condition and FSIQ, $p<0.05$. This interaction suggests that those in the ASD group with lower FSIQ had the most difficulty with the unstable surface compared to the rigid surface. FSIQ was not associated with postural sway area in the typically developing group under either surface condition.
Conclusions:
ASD diagnosis alone was not predictive of greater balance challenge on the unstable surface. Instead, only youth on the autism spectrum with lower IQs exhibited differentially more balance challenge on the unstable surface. These results suggest that balance challenge may be related to more severe autism and autism-like symptoms. Further, unstable surfaces, which are common in day-to-day life, may present a particular challenge to the balance of individuals on the autism spectrum with more severe symptom profiles.

203 **164.203** Stereotypies in Autism: An Innovative Mathematical Approach to Depict the Natural Association Scheme of Their Co-Occurrence

***E. Grossi** and E. Caminada, Villa Santa Maria scs, Tavernerio, Italy*

Background:
In autism, stereotypies (stereotypic movement disorders) are frequent and disabling and represent one of the most complex clinical pictures due to a broad spectrum of anomalies.Following the new wave of biology-based research in autism, motor anomalies and other repetitive behaviors are increasingly receiving attention. Indeed, the co-occurrence of many different stereotypies in the same subject theoretically offers the possibility to derive associative patterns useful in developing interpretative models.
Objectives:
The aim of this study is to analyze stereotypies patterns observed in a sample of children and adolescents residing at our Institute and subsequently classify them by means of video-recordings. By using advanced machine learning systems, we are able to develop a semantic connectivity map of the variables under investigation.
Methods:
To define the spectrum of expressions of stereotypies we studied 67 autistic individuals which, as a group, expressed 37 different types of stereotypies defined through standardized video-recording. All individuals but one presented a certain number of stereotypies: average = 11.5; range 0-27. The data were analyzed with a special kind of unsupervised artificial neural network (Auto-CM). Auto-CM is able to a semantic connectivity map in which the matrix of connections, visualized through a minimum spanning tree filter, takes into account nonlinear associations among variables and captures connection schemes among clusters. In this way, the patient state can be viewed as an hyperpoint in a “multimorbidity space” in which each dimension corresponds to a quantitative phenotype.
Results:
The semantic connectivity map showed a meaningful scheme of connections among stereotypies.As far as motor abnormalities are concerned, mouth-trunk-arms movements constitute a central axis of the system from which all other type of movements involving head, legs, shoulder and feet take place. Toe walking is directly linked to other walking abnormalities. Licking, biting, smelling, rubbing and touching body parts form a unique cluster associated to medium ID severity and separate from licking, biting and smelling objects, which is associated to mild ID severity. Severe ID is associated to simple voicing and facial grimacing.
Conclusions:
Machine learning algorithms are able to depict the complex pattern of stereotypies commonly observed in autism, thus allowing for a better definition of major phenotypes that are amenable for future large epidemiological surveys.

204 **164.204** The Importance of Teaching Motor Imitation to Children with Autism: Higher Imitators Can Look to the Face Region More Than Lower Imitators When Observing Motor Gestures.

Y. Ishizuka[1] *and J. Yamamoto*[2,3]*, (1)Keio University, Tama, Tokyo, Japan, (2)Keio University, Tokyo, JAPAN, (3)CREST, Japan Science and Technology Agency, Chiyodaku, Tokyo, Japan*

Background: Imitation can serve two skills, to direct own attention to model stimulus and to do same gestures as model stimulus. However there were few studies to show the association between visual attention and imitation precision (Vivanti, Nadig, Ozonoff, & Rogers, 2008).
Objectives: The purpose of this study is to investigate the relationship between imitation precision and visual attention to face region of motor, object, and oral-facial stimulus.
Methods: 10 children with autism were included in this study. The range of chronological ages was 4 years to 6 years, and developmental age ranged from 1 year to 3 years. We plan to recruit more participants.The experiment was conducted in a testing room at a laboratory. All children participated in the imitation assessment task and eye-tracking assessment task. They received a structured imitation assessment that included 6 object, 6 motor, and 6 vocal imitation tasks. Each child saw symmetric (e.g. touch own head with own hands) and asymmetric gesture (e.g. touch own head with a hand and touch own stomach with the other hand), self (e.g. touch own head with own hands) and other (touch other’s head with own hands) directed gesture on object, and oral (e.g. make noise //a//) and face gestures (e.g. extend tongue). Children also received eye-tracking assessment task.Each child was seated in a chair at a table 30 inches from an 23.5 × 13.3 inch monitor and required to look at experimental stimulus. It was composed of object, motor, oral-facial video clips, which was same as imitation assessment task.
Results: We used Spearman correlations to examine the associations between each imitation precision and fixation durations to face region for each tasks. The result showed that imitation precision was correlated with total time spent looking at face region observing motor stimulus (r=.790, p=.007). The imitation precision wasn’t associated with total time spent looking time at face region observing object and vocal stimulus (object ： r=.419, p=.228; vocal: r=.158, p=.663).
Conclusions: The result demonstrated that higher imitator had more looked at the face region observing motor stimulus. Our findings suggest that teaching motor imitation is one of the most important for early intervention to increase general and selective visual attention to adult. On the other hand, there is no necessity for children with autism who show higher imitation performance to look face when observing object and vocal stimulus, because they have only to look object or hear the vocal stimulus. This study is the first to specifically examine the relationship between imitation precision and visual attention to face region when observing motor, object and vocal stimulus. We plan to collect the data for typically developmental children and compare with these results.

205 **164.205** The Influence of Noise on Autonomic Arousal and Cognitive Performance in Autism Spectrum Disorder

J. M. Keith[1]*, J. P. Jamieson*[1]*, P. Allen*[2] *and L. Bennetto*[1]*, (1)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY*

Background: As many as 95% of individuals with autism spectrum disorder (ASD) experience sensory dysfunction, and the ubiquitous nature of sensory stimuli can present significant challenges to everyday functioning. Although previously unexplored, it is particularly important to understand how sensory stimuli impede an individual's ability to learn and perform cognitive tasks, especially given the overwhelming sensory nature of many education and workplace environments. Additionally, overwhelming sensory input activates the autonomic nervous system's stress response, which may be a key mechanism in the relationship between dysregulated sensory processing and difficulties in cognitive performance.
Objectives: To model the impact of sensory reactivity on cognitive functioning, we investigated the relationship between noise (a pervasive and challenging sensory stimulus) and performance by experimentally manipulating noise levels and task difficulty during measures of working memory. We concurrently collected sympathetic and parasympathetic responses during these tasks to explore the role of autonomic arousal in this relationship.
Methods: Participants included 22 adolescents with ASD (mean age=14.5, range=12-17 yrs) and 18 typically developing (TD) controls (mean age=15.1, range=12-17 yrs). Diagnoses were confirmed using the ADOS and ADI-R in the ASD group and ruled out using the ADOS and SRS in the TD group. Groups were matched on age and Wechsler Verbal Comprehension Index. Participants completed a series of visually presented number span tasks in a 2 x 2 experimental manipulation of noise levels (quiet vs. 75dB gated white noise) and task difficulty (forward span vs. backward span). Electrocardiography, respiratory sinus arrhythmia, and electrodermal activity were collected continuously throughout baseline, cognitive conditions, and recovery periods.
Results: Analyses of cognitive performance data revealed a significant noise (quiet vs. noise) x difficulty level (forward vs. backward) interaction, F=7.25, p=.01, with both groups doing better with the addition of noise in the forward condition, and the ASD group doing marginally worse with the addition of noise in the backward condition. Analyses of heart rate data revealed a significant group x noise x difficulty level interaction, F=7.42, p=.01, with both groups showing increased heart rate with the addition of noise in the forward condition, but only the ASD group showing continued increases in heart rate with the addition of noise in the backward condition, t= -2.10, p<.05. Correlations between the performance and autonomic data revealed an adaptive effect of increased arousal in the forward condition for both groups, r= -.48, p=.004. However, for individuals with ASD, there was a detrimental relationship between increased arousal and performance in the backward condition, r=.60, p=.05.
Conclusions: This study is one of the first to investigate specific adaptive consequences of sensory processing dysfunction in ASD. Findings indicate that simultaneously processing background noise while performing demanding cognitive tasks has both performance and physiological consequences. Importantly, the strongest group differences were in autonomic reactivity, highlighting the importance of monitoring functioning and well-being through multiple methods. These results underscore the importance of minimizing sensory demands in learning contexts for individuals with ASD and suggest that self-regulation interventions may be particularly helpful in minimizing autonomic effects of dysregulated sensory processing.

206 **164.206** The Relation Between Locomotor Dynamics and the Acoustic Startle Response and Its Modulation in Children with Typical Development and Those with Autism Spectrum Disorders

H. Takahashi[1,2], *T. Nakamura*[3], *J. Kim*[3], *H. Kikuchi*[4], *T. Nakahachi*[1], *M. Ishitobi*[1], *K. Yoshiuchi*[5], *T. Ando*[4], *A. Stickley*[1,6], *Y. Yamamoto*[3] *and Y. Kamio*[1], *(1)Department of Child and Adolescent Mental Health, National Institute of Mental Health, National Center of Neurology and Psychiatry, 4-1-1 Ogawahigashicho, Kodaira, Tokyo, Japan, (2)Department of Advanced Neuroimaging, Integrative Brain Imaging Center, National Center of Neurology and Psychiatry, 4-1-1 Ogawahigashicho, Kodaira, Tokyo, Japan, (3)Graduate School of Education, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan, (4)Department of Psychosomatic Research, National Institute of Mental Health, National Center of Neurology and Psychiatry, 4-1-1 Ogawahigashicho, Kodaira, Tokyo, Japan, (5)Department of Stress Sciences and Psychosomatic Medicine, Graduate School of Medicine, University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan, (6)Stockholm Center for Health and Social Change (Scohost), Södertörn University, Huddinge 141 89, Sweden*

Background: Translational research of autism spectrum disorders (ASD), using objective and quantitative behavioral phenotypes and neurobiological endophenotypes, may facilitate a deeper understanding of the underlying mechanisms of ASD.
Objectives: The objective of this study was to investigate the relationship between locomotor dynamics and the profile of the acoustic startle response (ASR) and its modulation in children with ASD and typical development (TD).
Methods: ASR and its modulation, including prepulse inhibition (PPI), was investigated in 14 children with ASD and 13 children with TD. The electromyographic activity of the left orbicularis oculi muscle to acoustic stimuli of 65 to 105 dB sound pressure level, in increments of 10 dB, was measured to evaluate ASR. Average eyeblink magnitude for each acoustic stimuli intensity and average peak startle latency of ASR was evaluated. Locomotor activity i.e. spontaneous physical activity in daily life, was also continuously measured by a watch-type actigraph during a long school vacation. We examined sleep measures, including sleep latency, as well as locomotor activity statistics, including the mean and skewness of all day and daytime activity.
Results: Compared to in the TD group, among ASD children the skewness of all day activity was negative and highly statistically significant, while the skewness of daytime activity was also negative but at a borderline level of statistical significance. For all children combined, actigraph measured sleep latency was significantly related to PPI at the prepulse intensity of 70 dB (PPI70). Increased mean and higher negative skewness values for all day activity were significantly related to reduced PPI70, while for daytime activity these values were associated with a greater ASR magnitude to weak stimuli of 65 dB. Conclusions: Hyper-reactivity, examined as ASR magnitude to weak stimuli was related to locomotor activity, characterized by higher mean and higher negative skewness values during daytime, and reduced sensorimotor gating examined as PPI, to these values occurring all day. PPI was also related to sleep latency. The comprehensive investigation of locomotor activity as well as ASR and its modulation, including PPI, might extend understanding of the neurophysiological basis underlying ASD and other psychiatric problems in children.

207 **164.207** The Relationship Between Audiovisual Statistical Learning and Autistic Traits

R. A. Stevenson[1,2], *J. K. Toulmin*[3], *S. Ferber*[4], *A. Youm*[4], *S. E. Schulz*[5] *and M. D. Barense*[4], *(1)Psychology, University of Western Ontario, London, ON, CANADA, (2)Brain and Mind Institute, University of Western Ontario, London, ON, Canada, (3)University of Toronto, Toronto, ON, Canada, (4)Psychology, University of Toronto, Toronto, ON, Canada, (5)Psychology, University of Western Ontario, London, ON, Canada*

Background:
Sensory issues are a pervasive symptom associated with Autism Spectrum Disorder (ASD). One commonly reported issue is a decreased ability to integrate multisensory information, driven by a reduction in multisensory temporal processing (for review, see Stevenson et al, 2015, Autism Research). The predictive coding hypothesis suggests this is due to a decreased ability to learn statistical relationships between multiple sensory inputs.
Objectives:

1. Directly test statistical learning ability of individuals with and without ASD
2. Determine if there is any relationship between ASD traits and statistical learning abilities

Methods:
To date, participants included 63 typically developed (TD) adults and 11 children with and without ASD. Participants completed a well-characterized statistical learning paradigm. In three counter-balanced runs, participants were presented with three-minute adaptation phases that consisted of repeatedly presenting audiovisual stimulus pairs (flash-beeps) with a consistent temporal relationship, either synchronized, audio-leading by 235ms, or visual-leading by 235ms (**Figure A**). Participants were then presented with flash-beep stimulus pairs with varying temporal offsets (auditory-leading by 400ms to visual-leading by 400ms) and performed a simultaneity judgement task; “Did the flash and beep occur at the same time?”Â (**Figure B**).
Participants mean responses at each offset were fit with a Gaussian curve, and the temporal offset at which they were most likely to perceive stimuli as synchronous was extracted (PSS; **Figure C**). This paradigm typically shifts individuals’ PSS towards the offset to which they were adapted. For example, following visual-leading adaptation, a participant’s PSS shifts to more visual-leading offsets.
Participants also completed the Autism Quotient (AQ), a measure identifying the severity of 5 different traits associated with ASD: social skills; attention switching; communication; imagination; and attention to detail. We correlated shifts in PSS, a measure of statistical learning, with each subscale, with the a priori hypothesis that a relationship would be seen with the *attention to detail* subscale.
Results:
Given the current distribution of participants, data reported here are from our adult TD group. Preliminary results suggest this pattern is consistent with ASD and TD children. Mean PSS were calculated for each adaptation condition (**Figure D**): synchronous (mean=4.1ms, s.e.=6.0ms), audio-leading (mean=4.4ms, s.e.=7.4ms), and visual leading (mean=51.5ms, s.e.=8.9ms). Shifts of PSS in auditory-leading and visual-leading adaptations were then compared to their PSS in the synchronous adaptation with paired t-tests (Auditory-leading p=0.95, t=0.05; Visual-leading p=0.00000008, t=6.23). The significant shift in PSS in the visual-leading adaptation condition was correlated with the attention to detail subscale of the AQ (p=0.0009, r=-0.45;**Figure E**). Thus, less adaptation was related to increased severity of the attention to detail ASD trait.
Conclusions: Â
Results indicate that individuals showing greater severity of the ASD trait “attention to detail” were less able to adapt to the statistics of their sensory environment. This supports the predictive coding hypothesis, suggesting individuals with a greater focus on detailed or local aspects of sensory inputs are less able to learn the statistical temporal relationship between audiovisual inputs, which are likely to impact the ability to integrate multisensory stimuli, as the ability to integrate is in large part driven by the temporal relationships between sensory inputs.

208 **164.208** The Relationship Between Sensory Challenges and Executive Function Differs By Patterns of Sensory Responses in Preschoolers with Autism

K. Carpenter[1], *L. DeMoss*[2], *J. Lorenzi*[3], *K. L. Williams*[4], *L. N. Beyer*[5], *H. Riehl*[3], *E. Glenn*[3], *H. Egger*[6], *G. T. Baranek*[4] *and G. Dawson*[1], *(1)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (2)Social Science Research Institute, Duke University, Durham, NC, (3)Duke Center for Autism and Brain Development, Durham, NC, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Duke Unvierstiy, Durham, NC, (6)Child and Adolescent Psychiatry, NYU Langone Medical Center, New York, NY*

Background: Sensory challenges, including sensory hyperresponsivity (i.e. over-reactivity to sensory input) and sensory hyporesponsivity (i.e. under-reactivity to sensory input), occur in over half of children with autism. Despite the role of executive functions, such as the ability to shift attention and inhibit behavioral responses, in the regulation of behavioral reactions to sensory stimuli, a previous study of high-functioning children with autism did not find a link between overall sensory challenges and executive dysfunction. One potential explanation for this lack of a link is that different patterns of sensory challenges are correlated with distinct executive dysfunctions.
Objectives: To identify the extent to which specific domains of executive functions, namely the abilities to shift attention and to inhibit responses, are correlated with distinct patterns of sensory challenges.
Methods: 29 children (22 Males, 7 Females) with autism between 3 and 6 years old were recruited for a study on sensory over-responsivity and anxiety in autism. Autism diagnoses were confirmed with the Autism Diagnostic Observation Schedule (ADOS-2) and the Autism Diagnostic Interview (ADI-R). Sensory challenges were characterized through parent report with the Sensory Experiences Questionnaire 3.0 (SEQ) and through behavioral observation of the child with the Sensory Processing Assessment (SPA) and the Tactile Defensiveness and Discrimination Test-Revised (TDDT-R). Executive functioning was measured through parent report using the Behavior Rating Inventory of Executive Function – Preschool Version (BRIEF-P). We focused on the three main scales of the BRIEF-P: Shifting, Inhibition, and Emotional Control. The Shifting scale assesses a child’s ability to flexibly switch behaviors in response to external demands, including making transitions, problem-solving, and switching attention. The Inhibition scale assesses a child’s ability to resist impulses and to inhibit their behavior appropriately. Finally, the Emotional Control scale measures the impact of executive dysfunction on a child’s ability to modulate their emotional responses.
Results: Both parent reported and observational measures of sensory hyperresponsivity were associated with worse scores on the Shifting scale of the BRIEF-P. Parent reported sensory hyporesponsivity was also associated with greater dysfunction in the Shifting scale, however this relationship did not remain significant when controlling for age and IQ. Parent reported sensory hyporesponsivity was correlated with higher scores on the Inhibition scale of the BRIEF-P.Â Finally, emotional control was associated with parent reported hyper- and hyporesponsivity. ADOS severity was not associated with degree of sensory challenges or executive dysfunction.
Conclusions: Results suggest that different patterns of sensory challenges are correlated with distinct executive dysfunctions in young children with ASD. Specifically, after controlling for age and IQ, difficulties with flexibly switching behaviors are associated with increased sensory hyperresponsivity, but not sensory hyporesponsivity. On the other hand, difficulties with behavioral inhibition is associated with increased sensory hyporesponsivity, but not sensory hyperresponsivity. Understanding how specific neurocognitive mechanisms may influence children’s ability to regulate sensory challenges may provide more specific targets for early intervention aimed at decreasing the negative impact of sensory challenges, such as decreased adaptive behavior and increased parental stress, in individuals with ASD.

209 **164.209** The Use of Multi-Sensory Environments (MSE) for Children with Autism Spectrum Disorder (ASD): A Qualitative Investigation

K. L. Unwin*, G. Powell and C. R. Jones, Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom*

Background: Multi-Sensory Environments (MSEs; also known as sensory or Snoezelen rooms) are widely used with children with autism spectrum disorder (ASD), particularly in educational settings. MSEs are purpose built rooms equipped with a variety of sensory materials that can be controlled for therapeutic benefit. However, despite the popularity of MSEs, there is limited research and understanding of how these rooms function, their benefits, and their overall efficacy. In addition, most research has looked at users with a range of special educational needs and not focussed on the specific experiences of those with ASD.
Objectives: Using qualitative interviewing, we aimed to establish the practitioner perspective on the use of MSEs for children with ASD. We were particularly interested in: (i) how MSEs were used and (ii) the perceived benefits of MSEs.
Methods: Twelve practitioners (11 female, aged 24-62 years) across 6 special needs schools in the UK participated. The practitioners were either teachers or teaching assistants and had been working with children with ASD in MSE for between 3 and 20 years. Each participant was interviewed using a semi-structured interview, with the data analysed using qualitative thematic analysis (Braun & Clarke, 2006).
Results: Five themes emerged from the interviews: (1) “Child is central”, the belief that the child’s needs, capabilities and preferences defined how and when the MSE should be used, as well as the potential benefits; (2) “Practitioner engagement”, the belief that an active practitioner was necessary for the child to benefit, and that because of this more research and practitioner training was needed; (3) “Positive properties of MSE”, the belief that MSEs had distinct properties, such as flexibility of use and motivational capacity, that contributed to their efficacy. (4) “Benefits for the child”, the MSEs were believed to benefit behaviour, cognition and mood, as well as learning; (5) “Challenges for MSE use”, MSEs were believed to have some drawbacks, including the potential to elicit negative behaviours.
Conclusions: The way in which MSEs were used depended on the needs of the child, and optimal use required an active and trained practitioner. Perceived benefits from MSE use included improvements in behaviour, cognitive ability and mood, with opportunities for teaching and learning within the MSE also possible. Perceived benefits could sometimes have ‘carry over’ effect to outside of the MSE. These findings are currently being used to inform an empirical study on MSEs and ASD within a purpose-built MSE at the Wales Autism Research Centre (WARC), Cardiff University.

210 **164.210** Treatment for Auditory Hyper-Reactivity Behavior in Children with Autism Using Exposure and Response Prevention Principles

T. B. Carson[1], *C. Flores*[2], *K. Ulmer*[2] *and L. Guerrero*[3], *(1)Occupational Therapy, University of Florida, Gainesville, FL, (2)Psychiatry, University of Florida, Gainesville, FL, (3)School Psychology, University of Florida, Gainesville, FL*

Background: Auditory hyper-reactivity is estimated to affect up to 66% of children with autism spectrum disorders (ASD) and has been linked to both child and family mental health factors such as higher levels of stress and anxiety. Although hyper-reactivity to auditory stimuli is a significant problem for these children and their families, there are currently no evidence based treatments available to treat this problem in ASD. Exposure and response prevention (E/RP) is highly effective form of treatment for reducing escape/avoidance behaviors associated with obsessive and compulsive disorders, anxiety and phobias. It has also been shown to be effective for reducing OCD behaviors in children with concurrent ASD suggesting that children with ASD may also respond well to this type of treatment approach being applied to sensory hyper-reactivity behaviors.
Objectives: Case series reporting the feasibility of implementing a modified E/RP approach for reducing auditory sensory over-responsive behaviors in children with ASD.
Methods: A modified E/RP protocol was provided in an outpatient therapy clinic to patients with high functioning ASD who report a strong aversion to specific sounds. Parent and patient report information was collected pre- and post- treatment regarding the level of difficulty tolerating certain sounds as well as a description of types of behavioral responses and level of anxiety experienced when exposed to these sounds. Behavioral responses and self-reported levels of anxiety were collected each treatment session before, during and after exposures. Exposure hierarchies were designed to address specific auditory aversions for each patient. Prior to beginning exposures, patients and parents were educated on how to identify and report levels of anxiety and arousal level through self-regulation treatment strategies such as Zones of Regulation or the ALERT Program.
Results: Preliminary results suggest that patients with high functioning ASD respond well to a modified E/RP protocol as evidenced by decreased avoidance/escape behaviors and decreased self-reported levels of discomfort/anxiety to auditory stimuli that were initially reported to be intolerable.
Conclusions: A modified E/RP approach is feasible to implement for the purpose of reducing avoidance behaviors and anxiety associated with auditory hyper-reactivity in patients with high functioning ASD. This study supports the idea that auditory hyper-reactivity, in some patients, may be the result of a conditioned response and thus, an E/RP based approach may be effective for these patients. Further studies are warranted to further evaluate the efficacy of this approach, generalization and maintenance of treatment outcomes, patient-treatment matching as well as parent education/training on home programs. The results from these studies can potentially: (a) improve children’s abilities to tolerate every day sounds and to engage in activities of daily living and (b) improve evidence-based practice for treating sensory processing difficulties in ASD. This work represents the first step in evaluating the feasibility and efficacy of applying E/RP treatment to reduce auditory hyper-reactivity in children with ASD.

211 **164.211** Unusual Auditory Filtering Behaviors in Minimally Verbal ASD: A Mechanism for Regulating Auditory Input?

S. Schwartz[1], *L. Wang*[2], *B. Shinn-Cunningham*[2] *and H. Tager-Flusberg*[3], *(1)Graduate Program for Neuroscience, Boston University, Boston, MA, (2)Biomedical Engineering, Boston University, Boston, MA, (3)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Many people with ASD exhibit behaviors that suggest irregular responses to auditory inputs and a need to actively regulate their auditory environment. Verbally fluent ASD children with high frequency atypical auditory behaviors and overall repetitive and restricted behaviors (including atypical responses to sounds) demonstrate abnormal sensitivity to sound changes in psychoacoustic experiments and have been described as having average nonverbal IQ and delayed language acquisition (Jones et al., 2009; Kargas et. al., 2015). No research has explored whether minimally verbal ASD individuals with frequent auditory behaviors display atypical sensitivity to sound changes, a necessary mechanism for accurately filtering out irrelevant sounds in the environment. In addition, no research has determined whether regulatory behaviors or filtering issues interfere with receptive language.
Objectives: Our objective was to examine the relationship between atypical auditory behaviors and atypical auditory processing, especially in minimally verbal individuals, and the relationship of these factors to receptive language skills.
Methods: Auditory behaviors were coded from ADOS recordings in individuals with ASD aged 5-21. Individuals were classified as either minimally verbal (ASD-MV: single word or phrase speech) or verbally fluent (ASD-V: complex speech). We coded: 1) Prolonging and/or abnormally manipulating sound-making objects, 2) Humming and/or altering ear shape, 3) Covering the ears with hands or fingers or appearing distressed by noise. Nonverbal intelligence and receptive language were measured with the Leiter and PPVT, respectively. Event-related potentials (ERPs) were measured in a passive, single-stream oddball mismatch negativity paradigm designed to quantify automatic detection of sound input change.
Results: ASD-MV individuals displayed a greater incidence of auditory behaviors than ASD-V individuals ($\chi^2(1)=19.66$, $p<0.01$), with the greatest difference in humming and ear shaping ($t(10)=-2.24$, $p=0.04$). Significant differences between groups were not observed for the other two behavioral categories (object manipulation ($t(10)=-1.83$, $p=0.09$); avoidance/ear covering ($t(10)=-1.43$, $p=0.18$)). Because we observed a large range in the frequency of auditory behaviors in the ASD-MV group, we did further within-group analyses. We found that time spent engaging in auditory behaviors significantly correlated with receptive language raw scores (Rho=-0.575, $p=0.003$; Figure 1A), but not with nonverbal intelligence (Rho=-0.256, $p=0.23$). Increases in time spent engaging in these behaviors was also associated with reduced early ERP responses to sound change (Rho=0.54, $p=0.08$; Figure 1B).
Conclusions: This work finds that auditory behaviors like humming and ear shaping are more common in ASD-MV than ASD-V. Within ASD-MV, there is a subset of individuals engaging in auditory behaviors at least 10% of the time. Individuals in this subgroup exhibit extremely low receptive language skills, but within-range nonverbal intellectual functioning, relative to others who are also minimally verbal. There is evidence that this subgroup is less efficient at detecting sound input change and consequently may be less efficient at separating and filtering sounds. Past experience with under-filtered sounds may increase auditory behaviors to serve as a mechanism for regulating auditory input; however, this regulatory activity may also inadvertently block sounds that are important. Future work should continue to investigate the clinical implications of how these behaviors affect receptive language processing.

212 **164.212** Videogames for Children and Adolescents with Autism Spectrum Disorders: Users Perspectives

C. D'Agostino *and M. Admiraal, Yoenfoco, Buenos Aires, Argentina*

Background:
Typical children and adolescent spend their free time with videogames. Individuals with autism are no exceptions and videogames might be very good tools for socialization and interactions though many prejudices still exist and limits the use and potential of them for interventions.
Objectives:
The aim is to report results of an ongoing descriptive study of the preferences and use of videogames of an argentinian sample of children and adolescents with ASD for improving social interventions with videogames.
Methods:
We design and adapt a questionnaire of videogames based on previous experiences for children and adolescents that assess key areas such as preferred device they play with more often, preferred consoles, who they play with more often, and with whom they enjoy to play with more, amount of hours playing a day, preferred games, and preference for violent videogames. All participants (N= 30, 25 male, 5 females) where assessed individually to complete the questionnaire and was adapted in some cases to make sure they understand the questions. They all have a previous reliable diagnosis of ASD and were assisting to social skills groups in the same setting during the research period 2015-2016. All individuals had verbal with IQ from mild ID to normal IQ with ages from 9 to 18. Statistical descriptive data was analyzed.
Results:
All children were able to complete and understand the questionnaire. The distribution of devices used for play was even with consoles (36%) tablets (29%) computers (29%) and a small part with smartphones (6%). At home individuals played with Wii® (47%) and Play Station® (44%) and very few XBOX®(9%).Individual reported playing more often alone (57%) and less frequently with peers (21%)friends (11%)and online (11%) they also reported than then enjoyed more playing alone (66%) rather than with friends (17%) or siblings(7%) or online(10%). Half of the sample reported not liking videogames with blood, guns, and violence (50%) and some report to like them sometimes (29%) and smaller part reported to enjoyed them always (21%). Almost half of the sample did not know how much time they spend playing during school days (41%) or weekends (46%) and some others reported playing one hour (31%) or two (32/23%) a day. Data of favorite games was collected but was related to special interests and was very heterogeneous and more than 200 games in were identified without finding statistical significance in them.
Conclusions:
Though limitations on sample size, preliminary results might suggest that children with ASD enjoyed playing with videogames in different devices. Structuring and measuring time of play of videogames is evident and necessary. The fact they like and play more often alone is an interesting focus on intervention considering most of them have one console at home. Violent videogames, a general concern of parents and professionals, might not be the most popular ones for people with ASD unlike the typical peers and their preferences might be tied to their special interest, and might be useful to foster social motivation and interactions if videogames are played with others.

213 **164.213** Visual Integration of Direction and Orientation Information in Autistic Children

C. Manning[1]*, M. S. Tibber*[2] *and S. C. Dakin*[3]*, (1)Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom, (2)Camden and Islington NHS Foundation Trust, London, United Kingdom, (3)Department of Optometry and Vision Science, University of Auckland, Auckland, New Zealand*

Background: Theoretical accounts propose that autistic visual perception is characterised by a focus on details, and a disinclination or reduced ability to integrate information across parts of the scene in order to perceive the overall whole. In contrast to these theories, we recently demonstrated *enhanced* integration of visual motion signals in autistic children compared to typically developing children (Manning et al., 2015, *J Neurosci, 35*(18), 6979-6986).
Objectives: Here, we had two main aims: 1) to investigate the robustness of our finding of increased motion integration within a new sample of autistic and typically developing children, and 2) to determine whether increased integration in autistic children would extend to a static, orientation task.
Methods: We presented motion and orientation equivalent noise and coherence tasks to 46 autistic children aged 6 to 14 years and 45 typically developing children matched in age and non-verbal IQ. The equivalent noise tasks consisted of two interleaved conditions: a high-noise condition in which children judged the average direction or orientation of elements while the external noise (standard deviation of direction or orientations) was manipulated, and a no-noise condition in which children were required to judge the direction or orientation of elements sharing the same direction or orientation. The thresholds from this task were subjected to equivalent noise modelling to yield measures of local internal noise and global sampling. In the coherence tasks, the proportion of signal elements sharing the same direction or orientation amidst otherwise random noise elements was manipulated. We assessed group differences using a combination of frequentist and Bayesian statistical approaches.
Results: When combining data from the motion tasks of the original and replication experiments, autistic children had increased integration of direction information compared to typically developing children in the high-noise condition (indexed by higher maximum tolerable noise values), yet similar no-noise and coherence thresholds as typically developing children. Equivalent noise modelling revealed increased sampling in autistic children for motion information but no conclusive evidence for atypical levels of internal noise. Yet, analysis of the data in the replication sample alone did not provide sufficient evidence either in favour or against the hypothesis of increased integration in autism. There was no evidence of differences between autistic and typically developing children in the orientation equivalent noise and coherence tasks.
Conclusions: Overall, autistic children integrated motion information better than typically developing children. However, the groups overlapped considerably and there was substantial individual variability. Therefore, the effect may not always be detected in small samples due to sampling error. There was no indication of atypical integration of orientation information in the current study, although larger samples will be required in order to provide conclusive evidence. These results help characterise the nature of sensory processing in autism, which is of high import and relevance given the recent inclusion of sensory symptoms in diagnostic criteria. If increased integration is specific to motion information, domain-specific accounts of autistic perception will be required.

214 **164.214** Visual Spatial Channel Bandwidth Varies with Autistic Trait Level

M. H. Laurie[1] *and D. R. Simmons*[2]*, (1)College of Medicine & Veterinary Medicine, University of Edinburgh, Edinburgh, United Kingdom, (2)University of Glasgow, Glasgow, UNITED KINGDOM*

Background:
Visual processing in autism is the topic of ongoing debate (Simmons et al, 2009). One of the most basic measures of visual performance is contrast sensitivity - the detectability of small changes in light intensity. Previous studies have reported lower, higher and equal sensitivities in autistics, relative to controls, depending on the stimulus used (Adams et al, 2010; Koh et al, 2010). Stimulus complexity potentially also affects contrast sensitivity differentially (Bertone et al, 2005), and autistics have greater difficulties when perceiving “masked” stimuli (Greenaway, Davis & Plaisted-Grant, 2013). These difficulties are potentially linked to neural noise theories of autism (Simmons et al. 2009; Dinstein et al, 2015), given physiological research that relates increased noise to increased channel bandwidths (i.e. information taken in) in neural processors, which is in turn a suggested explanation for sensory filtering difficulties in autism (Plaisted et al. 2003). Furthermore, sensory difficulties vary with autistic trait level, as measured by the Autism Spectrum Quotient (AQ; Baron-Cohen et al. 2001; Robertson & Simmons, 2013).
Objectives:
To investigate the potential link between autistic trait level and the bandwidth of visual spatial channels.
Methods:
38 participants completed the study, which involved two visual tasks and completing the AQ. Both tasks were presented in a standard two-interval forced choice paradigm. Task 1 was a contrast detection task, which measured the thresholds (i.e. minimum contrast) for detecting a sinusoidal variation in luminance (Gabor patch) centred at three spatial frequencies (SFs): 0.5, 1, and 2 cycles per degree(cpd). In task 2, participants were asked to detect a 1-cpd target stimulus in the presence of three different masks (0.5-, 1-, and 2-cpd) – whilst the mask contrast was held constant (10x detection), the target stimulus contrast was adjusted to measure thresholds. The size of the mask varied with SF to counteract stimulus spatial bandwidth differences. A ratio of the thresholds (masked vs. unmasked) for the target stimulus was calculated to estimate the SF processing bandwidth at 1-cpd.
Results:
Groups of individuals with high (N = 18; mean AQ = 24) and low (N = 20; mean AQ = 9) levels of autistic traits were formed by a median split. Bootstrapped t-tests (iterations = 1,000) revealed group differences in both tasks. For unmasked stimuli, participants with higher levels of autistic traits had significantly higher contrast sensitivities (lower thresholds) at 0.5-cpd (t=-47.65,p<.001) and 1-cpd (t=-8.28,p<.001) and lower sensitivity (higher thresholds) at 2-cpd (t=53.87p<.001). Additionally, the threshold ratio (estimation of SF bandwidth at 1-cpd) was significantly higher for those with higher levels of autistic traits at all SFs (t=-34.62;-11.43;-58.66,p<.001).
Conclusions:
These data suggest that (1) contrast sensitivity varies with autistic trait level, and (2) those with higher levels of autistic traits have broader spatial frequency channels, in line with theoretical predictions (Plaisted et al. 2003; Simmons et al. 2009), thereby lending support to neural noise theories of altered perception in autism, and meriting further testing in the autistic population.

Poster Session
165 - Social Cognition and Social Behavior II
5:00 PM - 6:30 PM - Golden Gate Ballroom

215 **165.215** A Meta-Analysis on Local and Global Face Perception in Individuals with ASD

K. Evers[1,2]*, R. Van der Hallen*[1,2] *and J. Wagemans*[1,2]*, (1)KU Leuven, Leuven, Belgium, (2)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium*

Background: Atypical global and local visual processing is often reported in individuals with ASD. However, findings on global and local face processing are inconsistent: Some studies have, for instance, revealed reduced face inversion effects in ASD, whereas others did not, leaving the field inconclusive. Factors such as stimulus, paradigm and participant characteristics could contribute to the large inconsistencies both within and across tasks.
Objectives: Instead of yet another empirical study evaluating a specific aspect of holistic face processing in individuals with ASD, the field is in need of a systematical and quantitative overview of the available evidence. We therefore wanted to systematically examine and combine all empirical data on this topic by means of a meta-analysis, in which the effect size across different studies was calculated, evaluating the overall evidence for differences in local and global face processing in individuals with and without ASD.
Methods: We have performed a formal meta-analysis, which incorporated the empirical data of 27 articles and several moderator variables in our analysis.
Results: Overall, results provided evidence for a general deficit in face processing in individuals with ASD ((Hedges' *g* effect size = -0.70). The ASD group performed significantly worse on both global (*g* = -.67) and local face processing tasks (*g*= -.76). However, no moderating effects of task or stimulus characteristics were found.
Conclusions: This meta-analysis showed an overall face perception problem in individuals with ASD. However, current analyses did not provide evidence for atypical local or global face processing. In addition, the impact of several moderating variables is discussed.

216 **165.216** A Pilot Investigation of the Relationship Between Parasympathetic Arousal, Stress, and Social Functioning in Youth with ASD before and after a Peer-Mediated, Theatre-Based Intervention

R. A. Muscatello[1], *S. Ioannou*[2] *and B. A. Corbett*[3], *(1)Neuroscience Graduate Program, Vanderbilt University, Nashville, TN, (2)Lipscomb University, Nashville, TN, (3)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*

Background: Many individuals with autism spectrum disorder (ASD) experience significant physiological arousal and stress during social interaction. Dysregulation of the autonomic nervous system (ANS) has also been reported in ASD. Respiratory sinus arrhythmia (RSA) is an indicator of parasympathetic regulation and theorized as a marker of behavioral flexibility. Parasympathetic dysregulation in ASD may be associated with impaired social functioning, but a peer-mediated theatre intervention might help alleviate this altered ANS arousal during play.
Objectives: To investigate associations between RSA, stress, and social functioning before and after a theatre intervention. RSA was hypothesized to correlate with stress, social symptoms, and amount of cooperative play. Further, differences in RSA were expected following the 10-week intervention.
Methods: The pilot investigation consisted of two preliminary studies. Study 1 included 21 children with ASD, ages 8 to 16. Children participated in the Peer Interaction Paradigm (PIP), a 20-minute playground interaction consisting of four 5-min. periods of independent (T1, T3) and cooperative play (T2, T4). RSA was collected at baseline and throughout the interaction. Parents reported stress, social functioning, and internalizing symptoms via the Stress Survey Schedule (SSS), Social Responsiveness Scale (SRS), and Child Behavior Checklist (CBCL). Pilot Study 2 assessed changes in RSA following a 10-week theatre intervention, with participants randomly assigned to the experimental group (n=12) or wait list control (n=9). Statistical analyses included ANCOVA for group differences and Pearson correlations for associations. Baseline RSA was subtracted from RSA during play to create difference scores representing RSA suppression, with more negative scores indicative of greater suppression.
Results: In Study 1, RSA during cooperative play T4 was negatively associated with total stress at trend (r=-.42, p=0.06) and significantly negatively correlated with the Changes domain of the SSS (r=-.51, p=0.02). Regarding ANS arousal and play, self-play during T2 was negatively associated at trend-level with RSA suppression (r=-.42, p=0.06), such that more self-play was correlated with a larger decrease in RSA. Amount of self-play at T2 positively correlated with social problems (r=.47, p=0.04) and internalizing symptoms (r=.51, p=0.02) on the CBCL and SRS total T-score (r=.44, p=0.05). In Study 2, no treatment effects were observed for baseline RSA or during the PIP (all p>0.05). RSA suppression was not associated with cooperative play (all p>0.05) either before or after the intervention.
Conclusions: Decrease in RSA during a stressor is considered a mobilization response. For youth with ASD, more stress, especially from changes throughout the day, was associated with greater decreases in RSA. This suggests children with higher stress perceive social interaction as more threat-inducing, indicated by greater suppression of the parasympathetic system. Those with lower RSA during play also engaged in more self-play, providing evidence that greater RSA suppression is associated with less social engagement. Increased self-play was related to social symptom severity, suggesting potentially important relationships between autonomic and social functioning that warrant further investigation. Though no treatment effects were observed, conclusions are limited due to the very small sample size and require future studies of a larger cohort to assess for significant changes following intervention.

217 **165.217** A Systematic Review of the Eye Tracking and Electroencephalography Correlates of Facial Emotion Recognition in Individuals on the Autism Spectrum

M. H. Black[1,2], *N. T. Chen*[2,3,4], *K. Iyer*[2,5], *O. V. Lipp*[2,3], *S. Bolte*[2,6,7,8], *M. Falkmer*[1,2,9], *T. Tan*[2,5] *and S. J. Girdler*[1,2], *(1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Psychology and Speech Pathology, Curtin University, Perth, Australia, (4)School of Psychology, University of Western Australia, Perth, Australia, (5)School of Mechanical Engineering, Curtin University, Perth, Australia, (6)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (7)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Dept. Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (8)Stockholm County Council, Center for Psychiatry Research, Stockholm, Sweden, (9)School of Education and Communication, CHILD programme, Institute of Disability Research, Jönköping University, Jönköping, Jönköping County, Sweden*

Background: While difficulties in facial emotion recognition (FER) are quite consistently reported in Autism Spectrum Disorders (ASD), behavioural studies alone cannot elucidate the specific nature of this impairment. Eye tracking (ET) and electroencephalography (EEG) provide insight in to the underlying attentional and neurological correlates underlying performance, allowing for a greater understanding of the processing of FER in ASD. Given that these processes change and develop along the developmental trajectory, there is a need to synthesise these findings in relation to developmental stages in order to investigate how the maturation of these systems impact FER in ASD.
Objectives: This systematic review evaluates the research examining the ET and EEG outcomes of individuals with ASD during FER in order to provide an overview of the current state-of-the-art in the area.
Methods: A systematic review was conducted in accordance with PRISMA guidelines. Six electronic databases were searched for articles examining either ET or EEG in individuals with ASD while completing FER tasks. This review examines 54 articles examining ET or EEG in individuals with ASD during FER meeting inclusion criteria.
Results: Both atypical gaze and cortical activation were found in articles included in this review. Reduced gaze to the eyes of emotionally expressive faces were consistently found in adult studies, however, were less consistently found in child studies, indicating an effect of developmental processes on these functions. Atypical cortical activation was evident across the developmental trajectory with effects being particularly evident for the N170 event related potential. Studies examining quantified EEG suggest that across the frequency spectra, individuals with ASD have atypical cognitive processing of FER, possibly indicating impairment in the pathways involved in the automatic processing of FER.
Conclusions: ET and EEG findings indicate divergent development of the neurocognitive mechanisms of FER in individuals with ASD, which may further be modulated by certain self-regulatory or compensatory strategies. Implications for understanding the social brain in ASD, as well as future directions for the integration of ET and EEG methods are discussed.

218 **165.218** ADOS and IQ As Predictors of Success on a Social Skills Intervention

A. D. Haendel[1], *A. McVey*[1], *B. Dolan*[1], *H. K. Schiltz*[1], *K. A. Willar*[2], *F. Mata-Greve*[1], *A. M. Carson*[3], *E. Vogt*[1], *S. Stevens*[4] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Children's Hospital Colorado, Aurora, CO, (3)Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (4)University of Minnesota Medical School, Blaine, MN*

Background: Research has found that higher IQ scores are associated with lower frequency and severity of challenging behaviors in people with Autism Spectrum Disorder (ASD) (McTiernan, Leader, Healy, & Mannion, 2011). There is a paucity of research in the area of looking at IQ and ASD severity in relation to success on social skills intervention programs.
Objectives: The primary objective of the current study was to examine the relationship between Autism Diagnostic Observation Schedule- Generic (ADOS-G: Lord et al., 2000) Total scores and Full Scale IQ (FSIQ) scores on the Kaufman Brief Intelligence Test (K-BIT: Kaufman & Kaufman, 2004), and how they predict response to a social skills intervention.
Methods: Following consent, 42 adolescents between the ages of 11-16 years, with FS IQ greater than 70 (confirmed by the KBIT) and ASD (confirmed by the ADOS-G), participated in the 14-week PEERS®intervention program (Laugeson & Frankel, 2010). PEERS® is a manualized, social skills/friendship training intervention for youth with social challenges that has a strong evidence-base for use with adolescents with autism spectrum disorder (Laugeson et al., 2012). Upon completion of PEERS, adolescents completed self-report surveys: the Quality of Socialization Questionnaire (QSQ: Laugeson & Frankel, 2010), the Friendship Quality Scale (FQS), and the Test of Adolescent Social Skills Knowledge (TASSK: Laugeson & Frankel, 2010). A composite outcome score was then generated from those three measures.
Results: There were significant correlations between FSIQ and ADOS (r (40) = .40, p < .01), FS IQ and outcome (r (40) = -.42, p < .01), and ADOS and outcome (r (40) = -.52, p < .01). A multivariateÂ linear regression indicated that the full model significantly predicted outcome,Â F (2, 39) =Â 9.46,Â pÂ < .01,Â explainingÂ 33% of the variance. However, with both ADOS and FSIQ in the model, onlyÂ ADOS scoresÂ (β=Â -0.422,Â pÂ < .01)Â were a significantÂ predictor of averageÂ outcome, whereas FSIQ was not.Â
Conclusions: Â Our results demonstrateÂ a relationship between ADOS scores and FSIQ scores in adolescents with ASD. However, when considered together, only ADOS scores were a significant predictor of outcome in a social skills intervention. Adolescents with higher ADOS scores, indicating more symptoms of ASD, were more likely to have lower PEERS outcome scores.Â These findings will be examined further by comparing additional participants as well as looking at these outcome measures at pre- and post-PEERS treatment to see if any changes were made due to the intervention. This study has the potential to add literature linking success on social skills intervention programs to FSIQ and ASD severity scores.

219 **165.219** Abnormal Use of Facial Expressions in ASD: A Meta-Analysis

D. A. Trevisan[1], *E. Shin*[2] *and E. Birmingham*[1], *(1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, University of British Columbia, Vancouver, BC, Canada*

Background: The abnormal use of facial expressions is a noticeable clinical feature of ASD (APA, 2013), yet this specific aspect of nonverbal communication has received little empirical attention. The existing research on this topic has yielded an inconsistent pattern of results. Some studies show that individuals with ASD are less expressive (Loveland et al., 1994; Snow et al., 1987), are less likely to naturally attend to and imitate others' expressions (McIntosh et al., 2006), and may display confusing, ambiguous or inappropriate facial expressions in which it is difficult to interpret what emotion they are expressing (Brewer et al., 2016; Reddy et al., 2002). However, other studies fail to find group differences in imitative expression (Press et al., 2010) and even show heightened expression in ASD in some circumstances (Capps et al., 1993). Clearly, research is needed to untangle this puzzling pattern of results.
Objectives: The goal of this study is to review and make sense of the existing literature on abnormal facial expressions in ASD. Of special interest is to identify the moderating variables that may be accounting for inconsistent findings in this literature.
Methods: We use meta-analytic techniques to summarize existing effect sizes that compare facial expressions in ASD with matched control participants. We will also examine the influence of several potential moderating variables including study setting (experimental vs. natural), social context of facial expressions (e.g., social vs. nonsocial), task demands (e.g., spontaneous vs. voluntary expression production), and outcome measure (salience vs. quality of expression). More than 30 articles have been retrieved for potential inclusion, although literature searches and data analysis are still in progress.
Results: Thus far, 9 studies have been coded and analyzed yielding 15 separate effect sizes. Across all effect sizes, participants' facial expressions differed significantly from matched comparison groups, cohen's d = .230, 95% CI[0.04, 0.42], p = .018. A few interesting patterns are emerging. First, effect sizes appear to be influenced by the specific dependent measure of interest across studies. For example, large group differences were found in *quality* of expression, cohen's d = .931, p < .001, k = 5, but not for *salience* of expression, Cohen's d = -.104, p = .210, k = 9. Second, the context in which expressions were used influenced the strength of the effect sizes. For example, in naturalistic settings, *social smiles* (expressions directed towards another person) were much less frequent in the ASD participants, Cohen's d = 1.14, p < .001, k = 3, compared to *non-social* expressions which were only marginally different, Cohen's d = .318, p = .077, k = 5.
Conclusions: Initial results suggest that, compared to neurotypicals, people with ASD may not be particularly *less* expressive, but are significantly more likely to convey confusing facial expressions that are difficult for others to interpret. Additionally, in naturalistic settings, children with ASD may not be less expressive overall, but are less likely to use facial expressions with communicative intent or to reciprocate others' expressions. These findings may have important clinical and research implications.

220 **165.220** Adolescent Social Competence in Autism Spectrum Disorder: Associations with Perceptions and Metaperceptions of Peers

L. Usher[1]*, C. A. Burrows*[2]*, D. S. Messinger*[3] *and H. A. Henderson*[4]*, (1)Waisman Center, University of Wisconsin-Madison, Madison, WI, (2)University of Miami, Coral Gables, FL, (3)Psychology, University of Miami, Miami, FL, (4)University of Waterloo, Waterloo, ON, CANADA*

Background: During social interactions with peers, individuals form perceptions of their peers and impressions of what peers think about them -- metaperceptions (Laing et al., 1966). These abilities are important for social success during adolescence when self-identity formation, social transitions, sensitivity to peer evaluations, and perspective-taking skills increase rapidly. Research on perception and metaperception in those with ASD is limited, and may offer insight into mechanisms underlying heterogeneity in social competence observed in adolescents with ASD.
Objectives: We examined associations between perceptions/metaperceptions and observed social behavior during a dyadic interaction using the Perceptions and Metaperceptions Questionnaire (PAMQ).
Methods: Fifty adolescents interacted in pairs consisting of one adolescent with ASD (M_{age}=14.66, SD=1.43; $M_{VerbalIQ}$=105.00, SD=14.79) and a gender-, age-, and verbal IQ-matched unfamiliar adolescent without ASD (M_{age}=14.21, SD=1.34; $M_{VerbalIQ}$=108.48, SD=13.83). Dyads were instructed to get to know each other for five minutes. During the interaction, participants were coded for Social Reciprocity (seeking, eye contact, conversational efficacy, and social ease) and Social Initiative (proportion of time talking, reversed latency to first utterance, reversed latency to first spontaneous utterance, and sharing). Immediately following the interaction, each participant completed the Perceptions and Metaperceptions Questionnaire (PAMQ) indexing perceptions of the peer (e.g., "How cool is ___?") and predictions of peer's impressions (e.g., "How cool does ___ think you are?"). Positively-valenced words indicating liking (e.g., happy) and negatively-valenced words indicating disliking (e.g., boring) were analyzed separately.
Separate Actor-Partner Interdependence Models (APIMs) were used to estimate effects of a peer's perceptions on an adolescent's social behavior, as well as the effect of the adolescent's metaperception on his/her own social behavior.
Results: Path coefficients for all four models are listed in Table 1. Regardless of diagnostic group, adolescents who predicted higher liking ratings from peers displayed more Social Reciprocity, b=.03, t(33)=3.13, p=.004. Adolescents whose peers reported liking them more tended to display more Social Reciprocity, b=.02, t(32)=1.77, p=.09. The more adolescents predicted their peer to dislike them, the less Social Reciprocity adolescents displayed, b=-.03, t(34)=-2.40, p=.02.
Across both groups, adolescents who predicted higher liking ratings from peers displayed significantly more Social Initiative, b=.03, t(37)=3.09, p<.01. Adolescents whose partners disliked them more displayed significantly less Social Initiative, b=-.05, t(36)=-.02, p<.01.
Conclusions: Findings suggest that the way that adolescents believes they are perceived as well as the way that they are actually perceived are important factors relating to social competence. Adolescents with positive beliefs about how they are perceived by peers may subsequently have more reciprocal social interactions. Conversely, adolescents who have reciprocal social interactions with peers may develop positive ideas of how they are perceived by peers. Directionality of effects involving perceptions, metaperceptions, and social competence should be further investigated in future longitudinal studies.

221 **165.221** Affective Sharing and Friendship Reciprocity Among School-Aged Boys with ASD

J. Mendelson[1] *and R. O. Nelson-Gray*[2]*, (1)Duke University, Durham, NC, (2)UNC Greensboro, Greensboro, NC*

Background: Affective sharing plays a defining role in the friendships of typically developing (TD) school-aged boys (e.g., Newcomb & Bagwell, 1995), distinguishing both friends from non-friends and reciprocal from unilateral friendships. Although some research suggests that children with ASD engage in lower levels of affective sharing while interacting with friends (Bauminger-Zviely & Agam Ben-Artzi, 2014), whether it plays a comparably definitive role in the friendship of school-aged boys with ASD remains unseen.
Objectives: This study examined the role of affective sharing in the friendships of boys with ASD aged 8-12, as compared to TD boys.
Methods: 13 boys with ASD and 17 TD boys participated in a 12-minute behavioral observation with a self-nominated friend. Members of each friend dyad were asked to list their top 5 best friends while out of earshot of the other member of the dyad. The behavioral observation was then coded using the Social Interaction Observation System (SIOS; Bauminger, 2002).
Results: Six boys' nominated friends did not spontaneously reciprocate their friendship nomination. Two were from TD-TD dyads (Dyad Group 1), two were ASD-TD (Dyad Group 2) dyads, and two were from ASD-ASD dyads (Dyad Group 3). Dyad Group 3 also had a significantly higher rate of unreciprocated friendships based on the more direct friend nomination procedure than did Dyad Group 1 ($t(18)$=2.39, p=.03). Friendships of boys with ASD demonstrated lower mean levels of time spent in synchronous behavior, responsiveness, and positive social engagement than did those of TD boys at a rate that fell below significance (time spent in synchronous behavior=(t(28)=1.39, p=.14; responsiveness=(t(28)=.27, p=.79; positive social engagement (t(28)=1.77, p=.088; see Table 1). Behavioral observations of unilateral friendships were comparable to those of reciprocated friendships in terms of time spent in synchronous behavior (t(28)=.-1.06, p=.30) and responsiveness (t(28)=-.10, p=.33). However, unilateral friendships demonstrated lower levels of positive social engagement (t(28)=-2.05, p=.05) than reciprocated friendships, regardless of dyad diagnostic status. Specifically, friends who did not spontaneously reciprocate the friendship nomination demonstrated significantly lower levels of positive social engagement during the observed interaction (t(28)=-2.27, p=.03), whereas target children did not (t(28)=-1.66, p=.11), regardless of the diagnostic status of the target child.
Conclusions: Boys with ASD demonstrated lower mean levels of affective sharing in a pattern comparable to what has been previously found in the literature (Bauminger et al., 2008b; Bauminger-Zviely & Agam Ben-Artzi, 2014; See Figure 1). However, differences in affective sharing behavior fell below significance, suggesting that boys with ASD *were* able to engage to a sufficient degree to maintain reciprocal friendships. Additionally, among the four boys with ASD in unilateral friendships, lower rates of positive social engagement than in reciprocated friendships were found among their *friends*, suggesting that the lower rates of affective sharing in unilateral friendships were driven at least as much by the friend's lack of engagement in the friendship as by lower levels of affective sharing on the part of the boy with ASD. Findings suggest that affective sharing plays a comparably central role in the friendships of boys with ASD.

222 **165.222** Are Communication and Social Skills Associated with Emotional Expressions during a Stimulating Play Situation in Young Autistic Children?

D. Girard[1]*, V. Courchesne*[2]*, C. Cimon-Paquet*[2]*, E. Danis*[1]*, I. Soulières*[3] *and C. Jacques*[4]*, (1)University of Quebec in Montreal, Montreal, QC, Canada, (2)University of Montreal, Montreal, QC, Canada, (3)University of Quebec in Montreal, Montréal, QC, Canada, (4)University of Quebec in Outaouais, Gatineau, QC, Canada*

Background: Â Recent work suggests that we are better at interpreting facial emotions of typically developing (TD) individuals than those of individuals on the Autism Spectrum (AS) (Brewer et al., 2015). Also, preliminary findings using the Montreal Stimulating Play Situation (MSPS), showed that AS children, who have similar number of both positive and negative emotions compared to TD children, express emotions coded as "unknown" by typical raters (Jacques et al., 2015). Therefore, it is possible that the failure of TD individuals to infer the accurate mental state in AS individuals have a direct impact on the assessment of socialization and communication domains.
Objectives: To document whether the frequency of emotional expressions observed during periods of free and semi-free play in the MSPS is associated with communication and socialization skills as perceived by parents within each group.
Methods: 37 AS and 39 TD children aged between 24 and 72 months were exposed to the MSPS and filmed. Using the Noldus Observer software, two naïve raters coded the 76 videos and defined emotional expressions (positive, negative and unknown). Positive emotions were coded when the child smiled. Negative emotions were coded when the child cried or frowned. Unknown emotions were coded when there was a clear facial expression, but the rater was not able to categorize it as a positive or negative expression. 29% of the videos were double coded (K=0.33). Communication and socialization skills were assessed through parent interview using the second edition of the Vineland Adaptive Behavior Scale. Both groups were paired on age (p=.124).
Results: The variable "emotional expressions" represents the total number of times the child expressed each type of emotions (positive, negative, unknown) during the MSPS. There was no significant association between socialization skills, and emotional expressions in the TD group. In the AS group, results indicated a negative association between socialization skills and the frequency of unknown emotions (r=-.57, p<.05), explaining 32.9% of variance. No main effect emerged regarding the association between communication skills and emotional expressions, though there was a trend for a negative association with the frequency of unknown emotions (r=-.49, p=.074), explaining 24.2% of variance in the AS group. We conducted additional exploratory analyses to document whether each subscale of the socialization scale (interpersonal relationship, play and leisure, coping skills) was associated with emotional expressions within each group. The linear regressions revealed that there was only a significant association between the interpersonal relationship scale and the frequency of unknown emotions in the AS group (r=-.57, p<.05).
Conclusions: These preliminary results suggest that in this sample of AS children, greater deficits in socialization skills as perceived by parents, more particularly in interpersonal relationships, could be associated with higher frequency of unknown emotions during the MSPS. Our findings indicate that AS children may express emotions atypically which might, in turn, lead to a difficulty of TD individuals to correctly identify them. This association between atypical expression of emotions and incorrect identification of emotions by peers and/or parents may reduce the quality of social interactions.

223 **165.223** Autistic Traits Predict Weaker Sensitivity to Reward in Emotion Perception

H. Thaler[1]*, A. Fiskaali*[1]*, P. K. Mistry*[2]*, J. Hohwy*[3] *and J. Skewes*[4]*, (1)Interacting Minds Center, Aarhus University, Aarhus, Denmark, (2)University of California Irvine, Irvine, CA, (3)Philosophy & Cognition Lab, Monash University, Melbourne, Australia, (4)Interacting Minds Centre, Aarhus University, Aarhus, Denmark*

Background:
When we look at a person's face and try to infer what she is feeling, our interpretation is usually influenced by context (Barrett et al., 2011). One contextual factor that plays a significant role is utility, i.e. how useful it is to us to detect emotional changes. Recent advances in perception research indicate that individuals with autism spectrum disorder (ASD) show basic differences in how they process sensory cues. A common Bayesian explanation for these differences is that those with ASD rely more on immediate sensory information, while they appear to be less influenced by prior perceptual expectations (Pellicano & Burr, 2014). The forming of prior perceptual expectations could also be the psychological mechanism through which context modulates emotion perception. Yet it is unclear whether ASD is associated with a lower tendency to integrate context into emotion judgments.
Objectives:
The purpose of this study is to examine whether ASD-like traits affect how much individuals rely on personal utility when making emotion judgments. Using computational modeling we estimate how changes in facial cues and utility contribute to response bias in emotion judgments, and how these estimates are represented in brain activation.
Methods:
Forty-five healthy adults completed an emotional signal detection task while undergoing functional magnetic resonance imaging (FMRI). Participants were told a fictional background story in which the protagonist was just saying goodbye to his girlfriend for a day (neutral outcome) or for a year (sad outcome). Their task was to guess the emotional outcome based on facial expressions of the protagonist, morphed to convey varying degrees of emotional intensity. Utility was manipulated by offering rewarding and punishing payoffs for different response strategies, incentivizing in turn more liberal or more conservative response biases. After each trial, participants received feedback on their performance and the amount of money they gained or lost. We developed a computational model that extends a neural network model of criterion learning (Helie, 2014) with signal detection theory and prospect theory. This model estimates individuals' sensitivity to perceptual information, sensitivity to reward, and reward bias. We regressed participants' autistic traits as assessed by the autism spectrum quotient (AQ) against these parameter estimates. For FMRI analysis we entered them as parametric modulators into FMRI analysis.
Results:
Autistic traits predicted sensitivity to reward and reward bias, but not sensitivity to perceptual information. This effect was negative, with increasing autistic traits leading to a weaker role of reward. Reward sensitivity modulated brain activation in the striatal region. Stimulus sensitivity modulated brain activation in ventromedial prefrontal regions, striatal regions, and posterior midcingulate cortex.
Conclusions:
In line with our assumptions, ASD-like traits were associated with a lower reliance on utility. This could be a potential route to explaining why individuals with ASD often experience difficulties with perceiving emotional expressions. A weaker integration of reward context could signify that their interpretation of emotional faces is less flexibly adapted to situational needs. Emotional expressions are often embedded into a complex environment, which may make their interpretation particularly challenging for those with ASD.

224 **165.224** Autistic Traits and Symptoms of Social Anxety Related to Different Phases of Attention to Others' Eyes in Social Anxiety Disorder

J. L. Kleberg[1]*, J. Högström*[2]*, M. Nordh*[2]*, S. Bolte*[3]*, E. Serlachius*[4,5] *and T. Falck-Ytter*[6]*, (1)Uppsala University, Uppsala, Sweden, (2)Centre for Psychiatry Research, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, (3)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (4)Centre for Psychiatry Research, Department of Clinical Neuroscience, Karolinska Institutet Stockholm, Sweden, Karolinska Institutet, Stockholm, Sweden, (5)Stockholm Health Care Services, Stockholm County Council, Stockholm, Sweden, (6)Dept of Psychology, Uppsala University, Uppsala, Sweden*

Background:
Autism spectrum disorder (ASD) and Social Anxiety Disorder (SAD) have partly overlapping symptoms. It is also increasingly acknowledged that both SAD and ASD can be understood as the extreme ends of continuous phenotypes. Elevated autistic traits are common in SAD, and people with ASD often have high levels of social anxiety. Studies relating symptom dimensions to cognitive mechanisms can therefore be informative about similarities and differences between the two conditions. Gaze avoidance has been linked to both SAD and ASD, but little is known about differences between the two conditions.
Objectives:
We examined the relationship between SAD and ASD symptoms and different stages of visual attention to human eyes.
Methods:
Participants: 25 treatment-seeking adolescents diagnosed with Social Anxiety Disorder (21 female). Social anxiety levels and autistic traits were assessed dimensionally. All participants were diagnosed by an experienced clinical psychologist. Data was first analyzed in females only, and then in the full sample.
Stimuli consisted of images of human eyes among non-social distractors. Images were presented in horizontal arrays. The position of the eyes were counterbalanced across trials. Gaze was recorded with a corneal reflection eye tracker.
Measures: Latency to first fixation at the eyes, and latency to orient from the eyes once they were fixated. Social anxiety was measured with the SPAI-C [2]. Autistic traits were measured with the SRS [2].
Results:
Controlling for social anxiety, elevated autistic traits were associated with delayed *orienting to* eyes presented among distractors ($p < .05$; see Figure 1A). In contrast, elevated social anxiety levels were associated with faster *orienting away* from the eyes, when controlling for autistic traits ($p < .01$; see Figure 1B). Both mechanisms typically operated within less than 1000 milliseconds.
Conclusions:
We found evidence of independent contributions by two aspects of social attention – orienting to and orienting away from eyes, to autistic traits and SAD symptoms, respectively. With regards to ASD, this study suggests that autistic traits are related to a reduced bottom-up driven salience of human eyes. In contrast, social anxiety mainly had an effect at later stages of processing, possibly reflecting anxiety-driven avoidance.
Â

225 **165.225** Autistic Vulnerability in Police Interviews: Compliance Vs. Suggestibility

K. L. Maras*, Claverton Down, University of Bath, Bath, England, United Kingdom*

Background: People with autism spectrum disorder (ASD) display a characteristic pattern of social communication impairments that may make them more vulnerable to encountering the Criminal Justice System as a victim, witness or suspect. However it has been suggested memory and cognitive impairments may result in heightened *suggestibility* in ASD, while impaired social cognition together with issues such as self-esteem, anxiety and fear of negative evaluation may result in an increased tendency to be overly *compliant* with requests.
Objectives: To examine whether adults with ASD exhibt heightened suggestibiliy and compliance.
Methods: We report a series of studies utiising both experimental and self-report methods examining suggestibility and compliance in autistic adults and their age- and IQ-matched typically developed (TD) comparisons.
Results: Findings across two experiments indicated that autistic adults (with IQ in the normal range) are not more suggestible than TD adults. Findings regarding compliance were mixed: in Study 1, we found no difference in self-reported compliance between ASD and TD groups. Study 2 however found increased (informant-reported) compliance in ASD participants from a clinical sample referred for psychiatric evaluation, and Study 3 found increased ASD compliance in an experimental task testing compliance with an unreasonable request for participants' time.
Conclusions: Â It is important to consder the role of individual differences and psychological vulnerabilities to suggestibility and compliance in ASD.Â Findings have both theoretical and practical implications.Â Not only could a tendency towards over-compliance leave individuals with autism at increased risk of exploitation to enter the criminal justice system in the first instance, it also has a number of direct implications for obtaining evidence from them using different interview techniques. Leading or cued questions might result in heightened acquiescence, and interrogative, leading or coercive suspect interviewing techniques may result in false confessions.

226 **165.226** Brain Correlates of Self-Other Distinction Centred on Touch and Actions in Adults with High-Functioning Autism

E. Deschrijver[1]*, J. R. Wiersema*[2] *and M. Brass*[1]*, (1)Ghent University, Ghent, Belgium, (2)Ghent University, Ghent, BELGIUM*

Background: Â It has been argued that patients with autism spectrum disorder (ASD) have problems to distinguish self from other when observing other people's behavior (Spengler et al., 2010). While there is some behavioral evidence that ASD patients slow down more strongly when performing an action while observing an incongruent action, this evidence is however far from being conclusive. When centred onÂ *tactile*Â *consequences*Â *of*Â observed actions and felt touch, neural evidence for self-other distinction problems in ASD was recently provided (Deschrijver et al., 2016a). So far however, neural evidence for self-other distinction problems centred on actions per se does not exists in ASD.
Objectives: By means of EEG, we assessed whether self-other distinction centred on actions was neurally disturbed in the group of adults with ASD that had shown impaired self-other distinction centred on tactile consequences of observed actions and felt touch in an earlier study (Deschrijver et al., 2016a). If so, we reasoned that their brain should not adequately signal when an observed action does not match an own action.
Methods: We employed the imitation-inhibition paradigm (Brass et al., 2000), in which participants observe a human hand lifting the index or middle finger while they are instructed to perform the same (congruent) or the opposite (incongruent) movement. Following our earlier EEG-studies (Deschrijver et al., 2016ab), we hypothesized that if self-other distinction centred on actions is impaired in ASD, we should observe a smaller congruency difference within the P3 in adults with ASD as compared to a matched control group.
Results: The ASD group did not show diminished neural signaling of observed actions that do not match own actions, as reflected in an intact P3- congruency effect within the imitation-inhibition task. As such, we did not find evidence for disturbed self-other distinction centred on actions in our group with ASD. Instead, we found evidence for disturbed motor preparation processes within the readiness potential.
Conclusions: Self-other distinction centred on actions may be preserved in individuals with ASD, while self-other distinction centred on tactile consequences of observed actions and own touch may not. The sense of touch and motor preparation processes may play a more crucial role for social cognition in ASD than previously thought.

227 **165.227** Changes over Age in Eye-Gaze Pattern in ASD from Childhood to Adolescence: A Cross-Sectional Eye-Tracking Study

A. Vincon-Leite[1]*, E. Rechtman*[1]*, E. Douard*[1]*, A. Philippe*[2]*, N. Chabane*[3]*, H. Lemaître*[4]*, J. M. Tacchella*[1]*, F. Brunelle*[1]*, N. Boddaert*[1]*, A. Saitovitch*[1] *and M. Zilbovicius*[1]*,*

(1)INSERM U1000, Institut Imagine, Paris, France, (2)UMR 1163, Institut Imagine, Paris, France, (3)INSERM U1000, Paris, France, (4)INSERM U1000, Institut Imagine, Université Paris Sud, Paris, France

Background: Deficits in social interaction, notably difficulties to establish a direct eye-contact, are a core characteristic in ASD. Thanks to eye-tracking methodology, eye-gaze behavior, crucial for human interaction, can be measured objectively. It is now well documented that persons with ASD, adults and children, met a specific eye-tracking pattern when they passively view a dynamic social scene. Indeed, compared to individuals with typical development (TD), persons with ASD present less interest for facial cues conveying social indices useful to understand the main running social scene and they present more interest to background non-social details. To our knowledge, no study has demonstrated changes linked to age of this eye-gaze pattern in ASD and TD children using the same stimuli and across a large and representative cohort extending from infancy to adolescence.
Objectives: In this context, the current study sought to investigate (i) whether individuals with ASD exhibit differences in eye-tracking pattern compared to TD children; and (ii) how this eye-gaze pattern could change with age during the childhood and adolescence period in ASD and TD children.
Methods: Forty-four children with ASD (age = 8.7 ± 3.7, range: 2.3-16) and forty-six TD children (age = 9.5 ± 3.5 range: 2.6 -17.9) participated in this study. ASD diagnosis was based on DSM IV-R and ADI-R criteria. Tobii-T120 eye-tracker was used to measure eye-gaze processing during passive visualization of social movies displaying characters engaged in peer to peer social interactions (Saitovitch et al., 2016). Viewing time was measured in areas with strong social contents (face-region) and in non-social areas (background-region). Firstly, viewing time was compared between ASD and TD children. Subsequently, a correlation analysis was performed between age and viewing time to the face or background-region. For both analyses we used linear regression model.
Results: Compared with TD children, children with ASD had significantly reduced viewing time to the face-region ($p<0.001$) and significantly increased viewing time to the background non-social region ($p<0.001$). Moreover, for children with ASD, we described a significant positive correlation between viewing time to face-region and age ($p<0.001$) as well as a significant negative correlation between viewing time to the background non-social region and age ($p<0.001$). For TD children, viewing time toward facial and background non-social regions remains stable and invariant across the period studied (*interaction group: age* $p<0.05$). Actually, quasi all TD children, independently of their age and since the early infancy, fixed the face-region more than 80% of the social movie duration and the background-region less than 20%.
Conclusions: The present cross-sectional study confirmed differences in viewing time to face and background non-social region between ASD and TD children. Furthermore, we present for the first time a correlation between age and viewing time to face and background-region in children with ASD that could reflect an adaptation and learning process. We can suppose that fixation to face is innate in TD children whereas for children with ASD it constitutes a learned behavior that change with age. Longitudinal studies are needed to confirm these results.

228 **165.228** Children with ASD and Their Siblings: A Detailed Analysis of Sibling Interactions Using a Micro-Analytic Computerized Methodology

Y. Rum[1]*, D. A. Zachor*[2] *and E. Dromi*[3]*, (1)Tel-Aviv University, Tel Aviv, ISRAEL, (2)Tel Aviv University / Assaf Harofeh Medical Center, Zerifin, ISRAEL, (3)Tel Aviv University, Tel Aviv, ISRAEL*

Background: Sibling relationships are often the longest and most significant relationships a person has in life, with the potential to deeply influence personality, social and cognitive skills (Boer, Dunn, & Dunn, 2013; Gass, Jenkins, & Dunn, 2007). Research on the development of typically developing (TD) young children highlight the significant role of sibling interaction as one of the most enhancing contexts for acquiring communicative and social skills (Brody, 2004; Dunn, 1992). Considering the fact that communicative-social impairments are fundamentalÂ in ASD, and the role that TD siblings of children with ASD play on their sibling's development (Ben-Yitzhak & Zachor, 2016) the paucity of research on these children's interaction with their siblings is striking.
Few studies compared sibling interaction where one sibling has ASD with interaction between TD siblings, or pairs where one sibling has a disability other than ASD (Kaminsky & Dewey, 2001; Knott, Lewis, & Williams, 1995; 2007). Rather than compare groups on the basis of average data, in the current study we aim to examine in detail the characteristics of sibling interaction in a within-subject design.
Objectives: Frame by frame analysis of sibling interactions in which one sibling is diagnosed with ASD.
Methods: The primary participants were 10 children with ASD (ages 5-10). Each child was visited at home and video-recorded for about an hour during interactions with: 1) an older TD sibling; 2) the mother, and with each partner data was collected in three activities: 1) a collaborative construction game; 2) while reading a book together; and 3) during play with a familiar toy. The order of tasks and partners were counterbalanced.
Twenty-four video recordings were systematically analyzed utilizing *Interact* software (a total of 12 hours) according to a set of categories for analysis. In addition, for each partner we coded whether he\she was on or off task, and qualitative remarks regarding joint engagement were noted.
Results: Sibling interactions were mostly positive, and consisted of pro-social, play-related, and discourse actions. Interactions of ASD children with their siblings were more reciprocal balanced and less agonistic than the interactions with their mothers. Episodes of joint engagement were demonstrated in all dyads: More and longer joint engagement episodes were recorded for children with ASD in sibling interactions than with mothers. In some cases of sibling interaction, joint engagement was demonstrated for almost all of the observation period.
Conclusions: The frame-by-frame analysis revealed indices of better social skills in children with ASD during sibling interaction. This finding is important mainly due to the need to evaluate the social-communicative potential of children with ASD, who often fail to interact with unfamiliar examiners, and do not always fully cooperate with standardized testing. Results have also implications for social intervention programs for children with ASD. Detailed description of siblings' interaction highlight strategies for enhancing communicative skills of children with ASD.

229 **165.229** Clinician-Derived Social Profiles Predict Play and Friendships with Peers in Children with Autism Spectrum Disorder

E. Fox[1]*, A. Wolken*[2]*, C. M. Hudac*[3]*, M. Frye*[1]*, R. K. Earl*[4]*, S. Trinh*[1] *and R. Bernier*[5]*, (1)University of Washington, Seattle, WA, (2)University of Washington Medical Center, Seattle, WA, (3)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)University of Washington Autism Center, Seattle, WA*

Background:
Children with autism exhibit deficits in peer play and social relationships, but there is great variability across individual children's abilities in these areas. The severity and presentation of restricted/repetitive behaviors also vary across individuals, and there is a lack of information on the direct impact of these behaviors on peer interactions (McConnell, 2002). The heterogeneity in social skills and atypical behaviors makes it difficult to develop targeted treatments that address the challenges children with autism experience in peer play and friendships.
Objectives:
To examine the social profiles of children with autism based on clinician-child interactions in a large, well-characterized sample in order to predict parent-reported quality of peer play and friendship.
Methods:
Utilizing data from the Simons Simplex Collection (SSC), our participants included 1571 children (11.2% female) with ASD between the ages of 4 years and 17 years 11 months (M = 9.75 years, SD = 3.14 years) who completed the Autism Diagnostic Observation Schedule (ADOS) Module 3. We created five social profile composites based on select ADOS items: (1) Social Approach, (2) Social Response, (3) Reciprocity, (4) Nonverbal Behaviors, and (5) Atypical Behaviors. Quality of peer play and friendship was assessed using items from parent-reported responses on the Autism Diagnostic Interview-Revised (ADI-R). We conducted a series of simple linear regressions to determine whether social profile related to peer play and friendship. Second, we added socioeconomic status (SES), Full-Scale IQ, and age to the regressions to account for individual predictors. Finally, we converted each continuous outcome to a binary outcome and ran binary logistic regressions to determine how well our social profiles predicted the quality of peer play and friendship.
Results:
Out of the five social profiles, Social Approach was significantly related to quality of peer play (ß=.08, p=.030), and Atypical Behaviors was significantly related to quality of friendships (ß=.097, p<.001). When considering individual predictors, SES was significantly related to quality of peer play (ß=.08, p=.030), and both FSIQ (ß=-.087, p=.001) and age (ß=.060, p=.020) were significantly related to quality of friendships. A binary logistic regression showed Social Approach was marginally significant in predicting aberrant behaviors in peer play (ß=-.364, p=.064), and Atypical Behaviors significantly predicted aberrant behavior in friendship (ß=-.301, p<.001). Adding individual predictors strengthened the model ($\chi(3)=23.28$, p<001).
Conclusions:
These findings suggest that aspects of social functioning observed in clinician-child encounters may predict quality of peer interactions. Of the five social profile composites, social approach predicted quality of peer play and atypical behaviors predicted quality of friendships. Because initiating interactions is the first step in engaging in peer play, increased difficulties with social approach may impact play negatively. The repetitive behaviors, restricted interests, and sensory needs common in children with autism may inhibit social engagement and, subsequently, interfere with the formation of friendships. Using a large sample and information from a widely-utilized diagnostic assessment, this study provides insight into which specific aspects of social competence should be targeted in ASD interventions.

230 **165.230** Comparing How Autistic and Non-Autistic Adolescents Describe Their Relationships with Friends, Family Members and Teachers: Less Need to Pretend but More Superficial Evaluations of Friendship

Y. Nishio[1]*, A. Riccio*[2]*, K. Bottema-Beutel*[3] *and K. Gillespie-Lynch*[2]*, (1)Graduate School of Human Development and Environment, Kobe University, Kobe, JAPAN, (2)Department of Psychology, College of Staten Island and The Graduate Center, CUNY, New York, NY, (3)Lynch School of Education, Boston College, Boston, MA*

Background: Autism-related social difficulties worsen in adolescence (Locke et al., 2010). Autistic adolescents encounter changes in peer culture and relationships with adults (Carter et al., 2013). Studies showing that autistic adolescents have fewer and qualitatively different friendships have not examined the broader context of their relationships with other significant people (Sedgewick et al, 2015). This study extends our work demonstrating that autistic adolescents in Japan report less closeness with friends and greater reliance on adults by administering similar measures to a sample in NYC.
Objectives: Examine how adolescents with and without ASD perceive their relationships with friends, family and teachers.
Methods: Thirty-two adolescents completed an online survey: typically developing (TD)= 14 (5 girls); ASD= 18 (5 girls); (TD age: *M*=13.64; ASD age: *M*=13.28, *p*=.59). Measures included the Friendship Qualities Scale (FQS; Bukowski et al.1994), the Japanese Friendship Scale (Otani, 2007), The Inventory of Parent and Peer Attachment-Revised (Gullone et al., 2005), the Intolerance of Uncertainty Scale (Carleton et al., 2007) and a ranking of how likely they were to seek advice from their father, mother, brother/sister, teacher, friend and "other". Open-ended responses to "How do you know when someone is your friend?" were scored into non-mutually exclusive categories: companionship, intimacy, and affection (Bauminger & Kasari, 2000), superficial explanations, and shared interests.
Results: No group differences on the FQS were observed (*p*=.65), The Japanese Friendship Scale revealed that autistic adolescents more often *disagreed* that they could *not* express their true selves with friends (*p*=.006). They also reported higher uncertainty avoidance (*p*<.05). Less need to hide one's true self and heightened uncertainty avoidance were dimensionally associated with autistic traits (*p*<.001). Attachment to parents did not differ (*p*=.96).Â Autistic participants reported seeking help from teachers more and from siblings less than TD participants (*ps*<.04). Chi square tests revealed no differences in how often autistic and non-autistic participants included companionship, intimacy, affection, or interests as friendship indicators. However, 10 autistic participants provided superficial indicators of friendship (e.g., "when they help me in school") while none of the TD participants did (*p*<.001). Length of these explanations did not differ (*p*=.37).
Conclusions: Like autistic adolescents in Japan (Nishio & Torii, 2016), autistic adolescents in NYC sought advice from teachers more than non-autistic youth. Autistic adolescents may compensate for challenges with peers by remaining closer to adults.Â Unlike Japanese adolescents, autistic adolescents in NYC did *not* report more attachment to parents or friendship difficulties relative to non-autistic peers. The latter may be attributable to how autistic and non-autistic people decide if someone is a friend. Autistic people may use more superficial indicators (Whitehouse et al., 2008). Autistic people and those with heightened autistic traits reported less need to hide their true selves from friends. Trainings to encourage youth to befriend autistic people could emphasize their honesty. Interventions for autistic adolescents should provide opportunities to practice evaluating the depth of friendship and the degree of self-disclosure that is likely to be effective, and practice communicating with siblings.

231 **165.231** Comparing Mother-Child and Father-Child Emotion Co-Regulation Processes in Relation to Adaptive Functioning in Children with ASD

W. A. Goldberg[1], *D. R. Garfin*[2] *and Y. Guo*[3], *(1)Psychology and Social Behavior, University of California, Irvine, Irvine, CA, (2)Psychology & Social Behavior, Univ Cal Irvine, Irvine, CA, (3)University of California Irvine, Irvine, CA*

Background: Emotion regulation plays a crucial role in the development of adaptive skills. Emotional dysregulation, while not a core deficit of ASD, is frequently observed among children with ASD and contributes to problems in social interaction. Emotion regulation abilities facilitate the development of emotional functioning and long-term adaptive skills (Gross, 1998, 2007). Parent-child co-regulation lays the foundation for future self-regulation in children although more is known about mother-child than father-child interaction. The current study compared micro-level positive and negative emotion co-regulation processes between mother-child and father-child dyads in relation to the adaptive functioning of children with ASD.
Objectives: To compare mother-child and father-child emotion co-regulation processes, examined using a dynamic systems approach, in relation to children's adaptive social functioning.
Methods: Forty-four mother-child and father-child dyads [(75% boys; *M*age = 5.37, *SD*=1.42 years) were videotaped during a semi-structured, 10-minute Three Boxes (Vandell, 1979; NICHD, 1999) play procedure at home. The children were 44% European American, 15% Asian/Asian American, 24% Hispanic/Latino, and 17% multiethnic or other. Clinical reports, the Social Communication Questionnaire (Rutter, Bailey, & Lord, 2003), and ADOS-2 (Lord et al., 2012) were used to screen and diagnose ASD. Positive and negative emotion regulation processes in dyadic mother-child and father-child interaction were coded in 5-second intervals using INTERACT 9.47 software (Mangold, 2007). Intercoder agreement exceeded .90. The observation data were imported into the State Space Grid (SSG) software (Lamey, Hollenstein, Lewis, & Granic, 2004) to operationalize the structure of emotion co-regulation indicated by *dispersion* (an index of spread of emotional states) and the content of emotion co-regulation indicated by *mutual positive interaction* and *mutual negative interaction*. The dependent variable was the *adaptive composite* scale from parent reports on the Vineland Adaptive Behavior Scales-II (Sparrow et al., 2005). OLS regressions were used to analyze the data with age of child controlled.
Results: Children were reported to have higher adaptive functioning when they were observed to have less dispersion in their emotion states with their mothers (beta=-.42, *p*<.05) and fewer mutually negative emotion states with their mothers (beta=-.66, *p*<.01); the corresponding father-child variable were not significant. Children with ASD showed greater adaptive functioning when they had proportionally more mutually positive emotion states with their fathers (beta=.32, p<.05). Children's adaptive functioning was lower when parent-child states were mismatched such that children were in negative emotion states while either parent was in positive ones (mother-child dyads- beta=-.30, p<.05; father-child dyads- beta=-.26, p<.10, marginal).
Conclusions: To our knowledge, the current study is the first to compare the emotional structure and content of interaction in dyads of children with ASD and their mothers and fathers using the State Space Grid method. Mother-child emotion regulation processes were more frequently associated with children's Vineland scores than were father-child processes. However, valences differed in their importance for children: Negative interactions with mothers and positive interactions with fathers were most salient for children's adaptive functioning.

232 **165.232** Conditional Probabilities of Dynamic Visual Scanning Quantify Altered Pathways of Learning in Toddlers with Autism Spectrum Disorder

E. Coben[1], *A. Khan*[1], *A. Klin*[2], *W. Jones*[2] *and S. Shultz*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA*

Background: Perceived stimulus salience and learning are tightly linked: attending to a particular stimulus at a given moment may result in learning that impacts where one chooses to look in the future. Likewise, *not* attending to that stimulus may lead to a different pathway of learning, resulting in different future fixations. Despite reports that children with Autism Spectrum Disorders (ASD) attend to social scenes differently than typically-developing (TD) children (Shultz et al., 2011), studies have not examined conditional probabilities of dynamic visual scanning, that is, the probability that viewers will fixate a particular location given viewers' previous fixation locations. Investigating the conditional probability of fixations may reveal what is learned and what is missed by children with ASD.
Objectives: This study characterizes learning pathways in toddlers with and without ASD by identifying on-screen fixation locations that predict future fixation locations.
Methods: Eye-tracking data were collected from 81 toddlers with ASD (mean age=24.1(1.7) months) and 75 TD toddlers (mean age=24.6(0.9) months) while viewing clips of naturalistic peer interactions. Fixation targets were defined as characters or objects perceived as highly salient (indexed by timepoints when most viewers looked at the same location; Figure 1a-b). Targets were identified separately for TD and ASD groups ('TD targets' and 'ASD targets'). Conditional probability ratios were calculated for all target pairs as the proportion of viewers who fixated on initial target X *and* later target Y relative to those who fixated on Y but *not* X (Figure 1c). *Conditionally dependent* target pairs had conditional probabilities above 1.0, indicating targets were *more* likely to be fixated on had viewers looked at specific locations, and were *less* likely to be fixated on had viewers *not* looked at those earlier locations. Conditionally dependent target pairs were identified for TD viewers fixating on TD and ASD targets, and for ASD viewers fixating on ASD and TD targets.
Results: Conditionally dependent target pairs were identified for TD and ASD viewers, indicating that viewing patterns of both groups are influenced by past viewing experience. Interestingly, TD fixations on TD targets appeared to be more strongly influenced by previous viewing experience compared to ASD fixations on ASD targets: a greater number of conditionally dependent target pairs were identified for TD viewers and the conditional probabilities of identified pairs were higher for TD (mean=5.33(10.40)) than for ASD viewers (mean=3.17(3.15)). When TD toddlers fixated on ASD targets, conditional probabilities were lower than when fixating on TD targets (mean=2.66(2.60)), suggesting that TD fixations are less strongly influenced by fixation locations perceived as salient by ASD viewers. By contrast, conditional probabilities were comparable when ASD viewers fixated on ASD compared with TD targets (mean=3.17(3.15), mean=3.19(3.63), respectively), suggesting ASD fixations are similarly influenced by TD and ASD targets.
Conclusions: In navigating the social world, current understanding depends on past experiences, as information conveyed in past fixation locations may influence future viewing. Calculating conditional probabilities of dynamic visual scanning provides a novel means of quantifying how learning shapes and is shaped by altered patterns of visual engagement in ASD.

233 **165.233** Culture-Specificity and Generalisability of Factors That Affect Vocal Modulation during Conversation: The Role of Autistic Traits

N. Singh[1]*, O. Spinola*[2,3]*, T. A. Sumathi*[4] *and B. Chakrabarti*[3]*, (1)National Brain Research Centre, Manesar, Haryana, INDIA, (2)National Brain Research Centre, Manesar, India, (3)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (4)Language, Literacy and Music Laboratory, National Brain Research Centre, Manesar, Gurgaon, India*

Background:
Vocal modulation is a critical component of interpersonal communication. It not only serves as a dynamic and flexible tool for self-expression and linguistic information but also functions as a social tool. Autism Spectrum Disorders is often associated with a lack of appropriate vocal modulation, with several reports of a 'monotonic' style of speaking. Vocal modulation can also be affected by the relationship between the two interactants, such as interpersonal closeness. We speak differently with our friends vs strangers. Cultures across the world are associated with established differences in display rules for facial and vocal expressions. The extent of culture-specificity in the impact of these factors on vocal modulation remains largely unknown, and can contribute to differential manifestation of autism-related symptoms.
Objectives:
To investigate the impact of autistic traits and interpersonal closeness on vocal modulation during a real two-person conversation, in three countries (India, UK, and Italy).
Methods:
85 same-sex pairs of participants were tested in all, by being recorded during a conversation about an abstract painting. The articulation area of the speech modulation spectrum was extracted using the method developed by Singh and Singh (2008). This area for each speaker was correlated with the self-reported perceived closeness to the other member of the pair and with the individual Autistic Quotient (AQ).
Results:
Results indicated a significant positive correlation between interpersonal closeness and articulation area in all three countries (India: $r=0.43$, $p<0.01$; United Kingdom: $r=0.35$, $p<0.01$; Italy: r=034, $p<0.05$). A significant negative correlation between AQ and articulation area was observed only in the UK sample only($r=-0.23$, $p<0.05$), but not seen in the other countries.
Conclusions:
The positive relationship between interpersonal closeness and vocal modulation was observed in all three countries, suggesting cultural generalisability of this result. In contrast, autistic traits were negatively associated with vocal modulation only in the UK sample. This observation could be driven by differences in baseline levels of vocal modulation in different cultures, which can lead to potential culture-specificity in the manifestation of autistic traits.

234 **165.234** Deficit in Emotion Recognition in High Functioning Autism Spectrum Disorder

N. Mazzoni*, Y. Ozturk, A. Bentenuto and P. Venuti, University of Trento, Rovereto, Italy*

Background: The ability to recognize emotions is a core deficit of ASD, and difficulty in understanding other people in everyday interaction is widely reported in the individuals with this syndrome. However, the exact nature of the emotional deficits in ASD remains unclear. To date, probably due to the different matching criteria for control group, stimulus type and task demands, no agreement in the investigation of the deficits in recognizing emotional expression in ASD has emerged. Also, the comprehension of social meaning across different communicative channels is still widely unexplored.
Objectives: The aim was to investigate the ability of individuals with high-functioning (HF) ASD in recognizing emotions across a range of different social signals.
Methods: Participants were 20 adults with HF ASD and 20 controls matched for non-verbal IQ, age and gender. They were asked to categorize 24 images of faces, 24 images of whole body, and 30 video clips of Full-light (FLDs) and 30 Point-light display (PLDs) of whole body movements depicting emotional expressions (fearful and happy) or neutral actions. Accuracy and response times (RT) were recorded.
Results: Within group logistic regression analysis showed that, in participants with ASD , the accuracy relative to fearful stimuli was significantly lower in PLDs than in FLDs (p = .01), body images (p = .002) and marginally face (p = .05). Regarding the recognition of happiness, the accuracy in face was higher than that of body images (p = .03), FLDs and PLDs (p = .001). In TD group there was not any difference across emotion neither for face nor for body images recognition. When the two groups were compared, no significant group difference emerged in accuracy in all the classes of stimuli (all p > .2). Repeated measures ANOVAs for the RTs revealed an interaction effect between class of stimuli and emotions (F(2,38) = 4.14, p = .02): fearful faces were recognized by ASD subjects faster than fearful bodies (p = .003) and neutral faces were recognized faster than neutral bodies (p = .001). In TD subjects, no effect of display or emotions were found. Between group comparison showed no group difference in static stimuli (face and body images) (F(1,38) = 0.100, p = .753), while participants with ASD were slower than TD in recognizing dynamic body movements (FLDs and PLDs) (F(1,38) = 5.202, p = .028).
Conclusions: The findings show that individuals with HF ASD are as accurate as TD in recognizing the emotional content of faces and body movements, both static and dynamic. On the contrary, HF ASD were slower than TD in recognizing dynamic body movements, but not static stimuli. Our results are in contrast with prior studies highlighting deficit in face perception in ASD population. Besides, our data reveal a specific difficulty in processing the body movement from dynamic stimuli. Accuracy and RTs did not vary according to the emotional content, in any of display conditions. The ASD impairment in social interaction could be related to the processing of human movement rather than to the recognition of emotion.

235 **165.235** Deficits in Emotion Processing Ability Predict Autistic Traits in Children: Eye Tracking Results from a Retrodictive Mindreading Task

***D. J. Walker**, S. A. Cassidy and L. Taylor, Psychology, Coventry University, Coventry, United Kingdom*

Background: Â Research presents conflicting results regarding whether autistic traits are associated with emotion processing abilities (Harms, Martin and Wallace, 2010), or reduced attention to the eyes of faces (Cassidy *et* al. 2014; Jones and Klin, 2013; Jones, Carr and Klin, 2008). Inconsistent findings highlight the need to revisit experimental procedures; including the use of stimuli with more naturalistic responses.
Objectives: Â 1) To establish whether retrodictive mindreading (RM) ability predicts autistic traits; and 2) To establish whether visual perusal patterns predict autistic traits.
Methods: Â 38 children without ASC (18 males, 20 females; mean age (8.99 years), SD=19.24, range 72 months – 153 months) took part in a RM emotion task. This involved participants observing short video clips of people reacting to one of four prompts (being asked a difficult maths question, being given monopoly money, being given negative feedback and being given positive feedback), and subsequently guessing which prompt caused the reaction, and how the person felt. Participants' visual perusal patterns were recorded via the Tobii eye tracker, and participants' parents completed the Autism Spectrum Quotient child version (AQ).
Results: Â A one way ANOVA showed that certain prompt types were more accurately recognised than others (F(2.40, 79.26)= 28.202, p<0.001). Post hoc Bonferroni corrected t-tests showed that responses to the maths question and monopoly money were significantly more accurately recognised than the negative and positive feedback prompts (p<0.001). There were no significant differences in the recognition rates between maths question and monopoly money (p=1), or negative and positive feedback (p=1). Recognition rates did not significantly predict AQ scores for any of the prompts (p>0.05). A multiple regression analysis was conducted with AQ scores as the outcome variable and RM ability, eye-mouth ratio and face-body ratio as predictors. The model was a significant predictor of AQ scores (F(3,28)=3.562, p = 0.027, adj. R^2 = .20), with total correct RM (p=0.02) a significant predictor. Looking to the face of the body (p=0.058) and eyes of the face (p=0.058) were borderline significant predictors.
Conclusions: There were significant differences in the recognition rates of the different expressions, but this did not independently predict AQ scores. Results of the multiple regressions suggest that RM ability is associated with autistic traits. More time spent looking at the body also approached significance as a predictor of autism traits. Contrary to some claims the more time spent viewing the eyes relative to the mouth was suggestive of higher autistic traits, however this result was borderline significant. These results suggest autistic traits are related to difficulties in RM and by extension emotion processing, and do present with altered viewing patterns. There are implications for future research considering the stimuli used and if this accurately replicates naturalistic social responses allowing valid recognition testing and visual perusal. These results need to be replicated in a sample with confirmed ASC diagnosis.

236 **165.236** Deficits in Social Awareness & Social Motivation Associated with Increase in Aggression in ASD

***S. M. Attar**[1], A. Walsh[1], P. Hickey[1] and E. Hanson[2], (1)Boston Children's Hospital, Boston, MA, (2)Children's Hospital Boston, Boston, MA*

Background: Â Aggressive behaviors, directed either toward the self or others, can cause severe psychological and physical damage to an affected individual, family, and others in the affected individual's environment (De Giacomo et al 2016).Â Prior research has shown that, in individuals with ASD, language skills and cognitive functioning are associated with these behaviors (Dominick et al, 2007).Â Research has also noted that individuals with ASD show deficits in their ability to notice and act on social cues (Vivanti et al, 2011) and that they engage in reduced social interactions. No study to date has looked at the relationship between aggressive behaviors in children with ASD and these two social domains.v
Objectives: Â We used two scales of the Social Responsiveness Scale (SRS): Social Awareness, which measures the ability to pick up on social cues, and Social Motivation, which measures the extent to which an individual is motivated to engage in social-interpersonal behavior (Constantino and Gruber, 2005), to assess whether deficits in either of these areas are associated with increased presence and level of aggressive behavior. We hypothesize that children with higher Social Awareness scores will present with increased aggressive behaviors, and that Social Motivation is not necessarily associated with aggressive behaviors.
Methods: A sample of 307 children (53.7% male) with research confirmed ASD diagnosis using ADOS and ADI-R were examined. Participant ages ranged from 46 months to 224 months (Mean= 124.38, SD= 40.481). IQ was measured with the Differential Ability Scales. Pearson correlations between Social Motivation, Social Awareness (SRS) and Aggressive Behaviors (Child Behavior Checklist, CBCL) were examined. We fit a regression model to examine the relationship between Social Motivation, Social Awareness, and Aggressive behaviors controlling for NVIQ and Age.
Results: Both Social Awareness and Social Motivation were correlated with Aggressive Behaviors (Social Awareness r=.364, p<.000; Social Motivation r=.304, p<.00). There was a significant, positive relationship between Aggressive Behaviors and Social Awareness (p<0.000) but not between Aggressive Behaviors and Social Motivation (p>0.05), after controlling for age and IQ. Specifically, for every additional point on the Social Awareness scale on the SRS, there is, on average, a .26 increase in the CBCL Aggressive total (Awareness Beta = .267, p<.000), after controlling for Age, NVIQ, and Social Motivation. Social Motivation, Social Awareness, Age, and IQ, taken together, account for approximately 21% of the variation in Aggressive behaviors (Adjusted R Square =.209). Age has a negative relationship with the Aggressive Behaviors total of the CBCL, indicating that for each additional month of age, an individual's aggression level decreases by .067 points, on average, after taking into account our other variables.
Conclusions: Our findings indicate that it may be the reduced capacity to notice social cues and not the lack of motivation to engage in reciprocal social motivation that is associated with increased aggressive behaviors. We believe that future research is needed to discover additional variables that account for the remaining variation in aggression.

237 **165.237** Defining Domains of Social Functioning in Adults with Autism Spectrum Disorder As Targets for Treatment

A. A. Pallathra[1], *M. E. Calkins*[2], *B. Maddox*[3], *L. Perez*[4], *J. Miller*[5], *J. Parish-Morris*[3], *W. Bilker*[4], *D. S. Mandell*[4], *R. T. Schultz*[5] *and E. S. Brodkin*[1], *(1)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (2)Psychiatry, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA, (4)University of Pennsylvania, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: There is increasing recognition of the need to develop treatments for adults with autism spectrum disorder (ASD) to improve their social functioning, a key factor in adults' employment, relationships, and overall quality of life (Howlin et al., 2013; Shattuck et al., 2012).Â However, little is known about the relative level of impairment in various behavioral domains underlying social functioning, or about the relationship among these behavioral domains in adults with ASD.Â To our knowledge, previous studies have not measured these social behavior domains in the same sample of adults with ASD, which makes it difficult to know which domains should be targeted by treatments and how to best track treatment response. In this study, adults with ASD completed multiple measures in each of four domains underlying social functioning: social motivation, social anxiety, social cognition, & social skills. We hypothesized there would be a high degree of correlation among measures within the same domain (i.e. convergent validity), and more modest degrees of correlation among measures across domains, indicating only a modest relationship among these domains, and the need for multidimensional treatment approaches.
Objectives: To assess behavioral domains underlying social functioning in adults with ASD, and measure correlations among measures within and between these behavioral domains. This analysis will help determine whether multidimensional treatment approaches are warranted, and will provide a baseline profile of these domains in adults that can be used for tracking treatment response.
Methods: Participants were enrolled in a pilot study of a new cognitive behavioral treatment program, TUNE In, Training to Understand and Navigate Emotions and Interactions. At baseline, twenty-nine adult participants with ASD (Table 1) completed multiple measures in each of four behavioral domains, as well as measures of overall ASD phenotype and measures of community social functioning. The raw scores of some measures were inverted so that higher scores indicated greater impairment in all measures. Then, raw scores for each measure were converted into standard scores, and bivariate correlations between scores were analyzed using SPSS. To correct for multiple comparisons, significance thresholds were set at a false discovery rate of 10%.
Results: There were statistically significant, robust correlations among measures within each domain, with the exception of social cognition and community functioning (Figure 1). Measures of social motivation were significantly correlated with measures of all other domains, except for social cognition. Additional significantly strong cross-domain correlations were found between measures of anxiety & ASD phenotype; measures of social skills & community functioning; and measures social skills & ASD phenotype.
Conclusions: There are significant correlations among measures within and between behavioral domains underlying social functioning in adults with ASD. Social motivation, in particular, is highly correlated with all domains, except social cognition. However, the variability among the participants in each measure and the lack of robust correlations between all domains suggest a need for multidimensional service strategies that can target the particular domains of social functioning most in need of improvement in each individual with ASD.

238 **165.238** Developmental Trajectories of the Attunement of Visual Salience in Infants at High-Risk for ASD with Varying Levels of Affectedness at Outcome

A. Kreuzman[1], *M. E. Micheletti*[1], *J. D. Jones*[2], *A. Klin*[3], *S. Shultz*[4] *and W. Jones*[3], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, & Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta & Emory School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Infants actively shape their environment by directing their attention towards content that they perceive to be most salient. From birth, typically developing (TD) infants are already remarkably attuned to the social world, displaying preferential attention to people. By selectively attending to socially adaptive signals, TD infants create opportunities for social learning that further refine their attention towards those stimuli with greatest relevance to their developmental goals. In contrast, reduced interest in the social world—a hallmark of Autism Spectrum Disorders (ASD), observed already by the second month of life—may lead to increasingly atypical development and schemas of salience. By dynamically assessing group agreement in allocation of visual resources within particular contexts over the first two years of life, this study examines how deviation from typical norms may yield increasingly divergent schemas of salience during infancy. Analyses were performed in infants at high-risk for ASD to examine the impact of deviations from typical norms dimensionally across the full spectrum of social ability to disability.
Objectives: To map developmental trajectories of attunement of visual salience in infants with varying levels of social disability.
Methods: Longitudinal eye-tracking data were collected from children at high-risk for ASD at 10 time points between 2 and 24 months of age. Participants watched naturalistic videos of caregivers and toddler interactions. Diagnostic evaluations at 24 and 36 months identified high-risk infants who: were clinically unaffected (HR-UA; N=33), exhibited subthreshold symptoms of ASD (BAP; N=19), or received a diagnosis of ASD (N=24). Allocation of visual resources was quantified by kernel density analysis at each movie frame in a sample of 24-month-old TD toddlers (N=79) to create a moment-by-moment map of normative salience in relation to movie content. This process was then repeated for HR-UA, BAP, and ASD infants at each longitudinal time point. The salience maps of TD 24-month-olds were used as a baseline for comparison of salience maps generated in HR-UA, BAP, and ASD infants.
Results: Results showed graded effects by outcome, with HR-UA infants displaying the greatest attunement to features perceived as salient by TD 24-month-olds and infants with ASD showing the least attunement to such features. Preliminary results indicate that HR-UA infants' moment-by-moment deployment of dyadic attention to eyes and mouths is synchronized with that of TD 24-month-olds by as early as 7 and 9 months of age, respectively. By contrast, BAP infants showed delays in reaching these milestones for dyadic eyes and mouth (and never reached baseline levels for attention to peer faces), while ASD infants failed to reach all milestones except for dyadic attention to mouths (delayed by 3 months).
Conclusions: This research demonstrates that deviations from typical trajectories of visual attention are associated with greater social disability at outcome in infants at high-risk for ASD. By failing to deploy attention in a manner that provides experiences that are important for social learning, BAP and ASD infants are learning about the world in very different ways, leading to increasingly atypical trajectories of learning and development.

239 **165.239** Developmental Trajectory of Theory of Mind Abilities in Children with Autism Spectrum Disorder

E. Hilvert[1] *and D. Davidson*[2]*, (1)Loyola University, Chicago, IL, (2)Loyola University Chicago, Chicago, IL*

Background: Â Although theory of mind (ToM) impairments in children with Autism Spectrum Disorder (ASD) have been widely researched, the developmental trajectory of these skills is unclear. Research has indicated that ToM ability in children with ASD may follow a similar course of development, but at a slower rate compared to neurotypical (NT) children (Steel et al., 2003). However, there is evidence that children with ASD may have a unique trajectory where skills progress in a different sequence (Peterson et al., 2012) or even plateau (Ozonoff & McEvoy, 1994).Â These conflicting findings may be due to variance in children's linguistic abilities and task complexity.
Objectives: Â Using the Developmental Trajectory approach (Thomas et al., 2009), we sought to understand (1) whether differences in performance on a range of ToM skills (first-order to higher-order) between children with and without ASD are due to a delay in onset and/or a difference in the rate of development, and (2) whether these mentalizing abilities are better explained by age or language ability.
Methods: This study compared the ToM ability of 19 children with ASD to 26 NT children (7-12 years of age). Children completed a battery of ToM measures, including: (1) the Unexpected Contents Task (first-order false belief; Perner et al., 1989), (2) Birthday Puppy Story (second-order false belief; Sullivan et al., 1994), (3) Strange Stories (higher-order ToM; Happé, 1994), and (4) the Frith-Happé animations (higher-order ToM; White et al., 2011). Children were matched on age, nonverbal-reasoning, and receptive language (Table 1).
Results: Â Across all ToM measures, children with ASD scored lower than NT children, indicating greater challenges with ToM (Table 1). Using the Developmental Trajectory Approach, we contrasted comparisons between groups' ToM trajectories, plotted according to chronological age (CA) with those plotted according to verbal mental age (VMA).Â Looking at the relations between VMA and ToM, children with ASD had a delay in onset of ToM development compared to NT children across all ToM measures. VMA was predictive of performance on all ToM tasks in children with ASD, but only predicted the rate of growth on the Strange Stories Test for NT children. Overall, CA predicted performance on the Unexpected Contents Task and the Frith-Happé animations. However, children with ASD showed growth on these ToM measures whereas NT children's performance did not change with their CA. CA was not related to performance on the Strange Stories Test or the Birthday Puppy Story in either group.
Conclusions: Â In line with past research (Steel et al., 2003), children with ASD showed significant improvement in ToM ability with increasing VMA, and in some instances CA. CA appeared to play a greater role in performance on tasks that required less language comprehension (e.g., Unexpected Contents) in children with ASD.Â However, the rate of growth in ToM ability differed between groups (i.e., ToM ability in NT children was less affected by CA and VMA). Taken together, these findings provide evidence that the development of ToM in children with ASD may be both delayed *and* deviant compared to NT children.

240 **165.240** Do Adolescents with Autism Use Task-Irrelevant Facial Expressions of Threat to Adapt Their Behaviour?

C. Ioannou[1]*, E. Vilarem*[1]*, M. El Zein*[1]*, V. Wyart*[1]*, I. Scheid*[2]*, F. Amsellem*[3]*, R. Delorme*[3]*, C. Chevallier*[1] *and J. Grèzes*[1]*, (1)Ecole Normale Supérieure, Paris, France, (2)Robert Debre University Hospital, Paris, France, (3)Institut Pasteur, Paris, France*

Background:
Autism spectrum disorders (ASD) are characterised by significant atypicalities in the affective domain and research suggests that they process or react to social cues differently from typically developing (TD) individuals. The roots of such difficulties are still debated but it has been suggested that either difficulties in processing the emotional cues themselves or/and dysfunctions in the mechanisms underlying the preparation of appropriate response behaviour to perceived social signals, could play an important role in these social deficits. Recently, we demonstrated that adolescents with ASD can accurately process emotional displays (Ioannou et al. under review) while taking into account contextual information (gaze direction). These results suggest the possibility that significant difficulties in social interaction and communication seen in ASD may exist independently of their ability to process the social signals themselves.
Objectives:
The present study moves a step further by addressing whether, when decoding skills appear preserved, adolescents with ASD can exploit social cues adequately during real-life social interactions to adapt their behaviour.
Methods:
To address the question of how emotional signals impact action decisions, we use ecological stimuli developed by Vilarem et al. (in preparation) reproducing a complex social environment, i.e. a waiting room with four seats, two of which are occupied by two task-irrelevant individuals, one with a neutral expression and the other with either a neutral, angry or fearful expression of varying intensity. Fearful and angry displays, while both indicating the presence of a potential threat in their environment, differ in their social functions, and, as research suggests, are associated with different approach or avoidance tendencies. Of interest here, neuro-typical adult participants, when requested to make spontaneous, free action choices between non-emotional targets (empty seats), they choose more often to avoid individuals with an angry expression, by selecting the chair on the opposite side of the scene, next to the neutral face and to approach individuals with a fearful expression, by selecting to sit next to the fearful person.
In the present study, 25 adolescents (12-17 yrs old) with ASD and 25 age-, gender-, IQ- matched TD controls will be tested using an adapted version of the above spontaneous-decision of action task in order to test whether adolescents with ASD can exploit task-irrelevant emotional displays to select their subsequent course of action. To date 20 ASD and 18 TD adolescents have been tested and recruitment will be completed in November 2016.
Results:
Preliminary results reveal a trend for choice tendencies (interaction emotion by tendency) similar to adults, in both groups. TD and ASD adolescents avoided anger significantly more than fear but to date only the TD group, and not the ASD, approached fear significantly more than anger. Complementary analyses on movement kinematics and pupil dilation will be performed.
Conclusions:
Preliminary results suggest that while ASD adolescents appear to be able to exploit anger cues to adapt their behaviour (avoidance - defence behaviour system), they may not perceive fearful expression as an affiliative cue leading to approach behaviour.

241 **165.241** Do You See What I See? the Recognition of Bullying in Male Adolescents with Autism Spectrum Disorder

E. A. Kelley[1]*, Z. Hodgins*[2]*, R. Furlano*[1]*, L. Hall*[1] *and C. C. Hudson*[1]*, (1)Queen's University, Kingston, ON, CANADA, (2)Queen's University, Kingston, ON, Canada*

Background: Youth with ASD have repeatedly been found to be victimized by their peers at a higher rate than typically-developing youth, but few studies have investigated whether youth with ASD are able to recognize and describe bullying situations. The few studies that have focused on these youth's ability to recognize bullying have merely asked the youth whether or not an instance of bullying had occured in the scenario.
Objectives: The current study was designed to investigate not only whether adolescents with ASD were able to recognize bullying when it occured, but also whether they were able to accurately describe the situation, identify the bully/bullies and victim(s), and discuss why the bullying occurred.
Methods: Male adolescents with ASD and typically-developing (TD) controls (M_{age} = 14.62, *SD* = 1.91), matched on full-scale IQ, watched six videos portraying various bullying scenarios and were interviewed after each video. The interviews were coded for the participants' ability to accurately describe the bullying situations.Â We also collected information about the adolescents' own experiences with victimization using self-report questionnaires.
Results: Â Results indicated that adolescents with ASD had significantly lower bullying perception scores compared to TD adolescents *F*(1, 65)= 11.86, *p*= .001, eta squared =.15. Self-report measures of victimization were significantly correlated with bullying perception scores in TD adolescents (*r*(36)= .34, *p*= .034)Â but not in adolescents with ASD *r*(25)= .02, *p*= .917.
Conclusions: Despite receiving a definition of what bullying entails at the beginning of the study, male adolescents with ASD were less able to identify bullying and less able to describe what was occuring in bullying videos than their age- and IQ-matched peers.Â The fact that understanding of bullying was related to experiences with victimization in TD youth but not in youth with ASD raises questions about how youth with ASD understand when they themselves are being bullied. Future research to explore this question will be discussed.

242 **165.242** Does Hot Executive Function Predict Theory of Mind in Children with Autism Spectrum Disorder?

S. Tsermentseli[1]*, E. C. Kouklari*[2] *and C. Monks*[2]*, (1)University of Greenwich, London, United Kingdom, (2)Psychology, Social Work, and Counselling, University of Greenwich, London, United Kingdom*

Background: Previous research has clearly demonstrated that Autism Spectrum Disorder (ASD) involves deficits in multiple neuropsychological functions, such as executive functioning and theory of mind. A conceptual distinction is commonly made between cool (cognitive) and hot (affective) Executive Function (EF). In ASD, continued attention has been paid to the cool areas of executive dysfunction. Cool EF has been strongly related to Theory of Mind (ToM) but research has not taken into account the association between hot EF and ToM in ASD.
Objectives: The current study aimed to investigate group differences in hot and cool EF in school-aged children with ASD relative to typically developing peers by employing a more extensive battery of both cool and hot EF tasks in comparison to previous studies. The second aim was to explore the association between hot and cool EF and ToM abilities in school-aged children with ASD. Traditionally, research on the EF-ToM relationship has mainly employed cool EF tasks. The distinction between cool and hot EF proposes that ToM may be more strongly related to hot EF than cool EF. We thus attempted to specifically examine whether ToM performance could be predicted by hot EF performance after controlling for potential co-variates and cool EF.
Methods: Sixty children with an official diagnosis of ASD (55 males) (M=9.98 years, SD=1.9) and sixty nine (69) controls (M=9.64 years, SD=1.58) (60 males) aged 7-12 years old matched for mental and chronological age completed tasks tapping cool EF (i.e. working memory, inhibition, planning), hot EF (i.e. affective decision making, delay discounting), and ToM (i.e. emotion understanding and false/no false belief).
Results: Significant group differences in each EF measure supported a global executive dysfunction in ASD. Correlational analysis showed several significant associations between EF and ToM measures. Specifically, ToM false/no false belief performance was significantly correlated to Go/No-Go and Tower of London scores, whereas performance on the Eyes Test was related to all EF measures, both cool and hot. Regression analysis revealed that the ASD group demonstrated deficits in emotional understanding relative to controls that were predicted by hot EF delay discounting, over and above cool EF and control variables.
Conclusions: Our findings replicated the well-established relationship between cool EF and ToM but also demonstrated a predictive relationship between hot EF and ToM emotion understanding, prompting questions of how these seemingly distinct constructs are related. This study improves understanding of the profile of higher-order cognitive deficits in children with ASD, which may inform diagnosis and intervention.

243 **165.243** Does Preferential Looking at Social and Non-Social Aspects of Naturalistic Scenes Differ Between Individuals with ASD with and without Intellectual Disabilities?

A. San Jose Caceres[1], *L. Mason*[2], *H. L. Hayward*[3], *D. V. Crawley*[4], *J. E. Tillmann*[5], *T. Charman*[6], *J. K. Buitelaar*[7], *D. G. Murphy*[8] *and E. Loth*[9], *(1)Denmark Hill, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, England, United Kingdom, (2)CBCD, Birkbeck, University of London, Gravesend, UNITED KINGDOM, (3)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)King's College London, London, England, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (8)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Â The social motivation theory of autism spectrum disorders (Klin et al., 2002; Chevallier et al., 2012) suggests that core social-communicative deficits may stem from diminished social motivation. One indicator of social motivation deficits is reduced spontaneous attention to faces (notably eyes), people and social actions (Falck-Ytter & von Hofsten, 2010). While abnormalities have been reported across the life span, most studies were conducted with ASD participants with IQ in the normal range. Although IQ is considered the best predictor of outcome (Howlin et al., 2004) little is known about the effect of IQ on social attention, or whether preferential looking patterns differ between individuals with ASD with and without intellectual disabilities.
Objectives: Â The present study aimed to 1) examine group differences in looking patterns on social and non-social aspects of naturalistic social scenes, 2) to explore the role of IQ/intellectual disability (ID) in viewing patterns, and 3) the relationship between looking patterns and level of social impairments/adaptive functioning in individuals with high-functioning ASD and those with ASD+ID.
Methods: 231 individuals with ASD and 186 controls with typical development (TD) or mild intellectual disabilities (IQ 40-148), aged 12-30 years were recruited as part of the multi-center EU-AIMS Longitudinal European Autism Project. In all centers, gaze patterns during viewing of six static images were recorded via using Tobii eye-trackers. Areas of interest (AOIs) were defined as face, eyes, mouth, and objects that were relevant (i.e., part of a social interaction). Preliminary analyses focused on % gaze time. IQ was measured with the Wechsler scales, social-communicative impairments using the Social Responsiveness Scales (SRS-2) and social adaptive behaviour using the social-subdomain of the Vineland scales (VABSsoc). Individuals were divided into intellectual ability groups (i.e. above and below IQ 70).
Results: We found a significant main effect of IQ group on % gaze time on faces ($p < .001$) as well as an IQ group x diagnosis interaction ($p = .017$). Whereas those with mild ID (without ASD) looked on average less at faces than the TD group ($p < .001$), among the ASD group, intellectual ability level did not affect looking times on faces. In line with previous findings, among individuals with IQ >70, the TD group showed looked longer at faces than the ASD group ($p < .001$; see Fig.1 for an example of viewing times by group during a highly social scene). In the ASD+ID group, higher % gaze time to eyes was significantly correlated with higher symptom severity (SRS-2 scores) ($n = 46$, $r = .41$, $p = .007$). Figure 2 shows the percentage for composite looking times (i.e. all 6 images) for each AOI by group.
Conclusions: Individuals with ASD with/without ID showed similar rates of social attention to faces, while IQ affected viewing patterns in the ID group. This finding is inconsistent with the notion that social motivation may be less influenced by cognitive development in ASD. However, unexpectedly looking times to social features were not linked to level of social impairment/adaptive behaviour. We plan to further investigate fixation patterns (e.g., first looks, average fixation times) in static and dynamic social scenes.

244 **165.244** Dynamic Eyetracking As a Measure of Treatment Response for an ASD Social Skills Intervention

R. K. Greene[1], *M. Sullivan*[1], *E. S. Brodkin*[2], *A. A. Pallathra*[2], *J. K. Kinard*[3], *M. G. Mosner*[1], *J. Parish-Morris*[4], *R. T. Schultz*[5] *and G. S. Dichter*[1], *(1)University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (3)Carolina Institute for Developmental Disabilities, University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The development and evaluation of novel ASD treatments currently relies on clinical observations and parent-report questionnaires to examine response to treatment. However, most commonly used measures of ASD symptoms lack sensitivity to change. Therefore, unbiased ASD treatment outcome measures are urgently needed to accurately evaluate novel ASD interventions. Eyetracking-based measures of social attention have the potential to be a reliable measure of response to ASD treatments that target social communication and social cognition skills.
Objectives: This preliminary study aimed to examine the extent to which time spent looking at faces in a dynamic social eyetracking paradigm reflected treatment-related changes in social communication skills due to a social skills intervention for adolescents and young adults with ASD. Changes in clinical report measures of social communication were also evaluated across time points.
Methods: Fourteen adolescents and young adults with ASD (Age: M=16.28 years, SD=2.19) completed a dynamic eyetracking task prior to and immediately following Social Cognitive and Interaction Training for Autism (SCIT-A; Turner-Brown et al., 2008) an 8-week social skills group intervention. Data were collected using a Tobii TX300, which sampled at 300Hz. Participants viewed a silent 8-minute video eyetracking paradigm, which showed children participating in both joint and parallel play (Chevallier et al., 2015). Stimuli include 22 semi-naturalistic, 15-second silent video clips, in which two school-age siblings play together (joint condition) or independently (parallel condition). Tobii software produced a Total Fixation Duration (TFD) outcome measure, which represents the summed length of all fixations within each area-of-interest (AOI). This TFD measure for faces was used as an index of the degree to which participants prioritized faces in joint conditions relative to parallel conditions. The Social Responsiveness Scale, Second Edition (SRS-2) was also collected before and after the intervention.
Results: Paired t-tests were used to examine the change in visual preference for social stimuli and SRS-2 scores before and after the social skills intervention. Results from the eyetracking task showed an increase in visual prioritization of social stimuli following the intervention, t=2.09, p=0.057. This change in visual preference reflects a large effect size, d=0.82. Additionally, SRS-2 scores declined significantly following the social skills intervention, t=6.46, p=<.0001, reflecting a large effect size, d=2.53.
Conclusions: Eyetracking and SRS-2 measures of social communication showed improvement in visual social preference and social communication skills, respectively, in adolescents and young adults with ASD following an 8-week social skills group intervention. These preliminary results suggest that this eyetracking-based measure of social attention may be sensitive to change in the context of an ASD intervention. Further research is needed to examine the reliability and generalizability of these findings to other interventions with appropriate controls for practice effects.

245 **165.245** Dynamic Facial Information Processing in Autism Spectrum Disorders and Typical Development: Social Attention Paradigms

C. Wardak[1], *N. Hernandez*[1], *Y. Mofid*[1], *L. Roché*[1], *C. Barthélémy*[1], *J. C. Elian*[2], *E. Houy-Durand*[3], *M. Lemaire*[4], *A. Saby*[5], *J. Malvy*[3], *M. Guimard-Brunault*[5], *J. Martineau*[1] *and F. Bonnet-Brilhault*[3], *(1)UMR INSERM U 930 – Université François-Rabelais de Tours, Tours, France, (2)Centre pédiatrique de Paris Nord, Sarcelles, France, (3)UMR930, INSERM, Université François –Rabelais de Tours, Tours, France, (4)Centre Universitaire de Pédopsychiatrie, TOURS, FRANCE, (5)CRA Centre Val de Loire, CHRU de Tours, Tours, France*

Background: Autism Spectrum Disorders (ASD) are characterized by atypical patterns of behaviors and impairments in social communication possibly related to an alteration of face processing. Faces bring many social information through their configuration but also through head and facial muscles movements. Human faces have varying degrees of animation: 1/ Micromovements (with only postural adjustments of the head and tone facial muscles); 2/ Macromovements (with facial expressions and eye and head movements).
Objectives: The aims of this study was to characterize, thanks to eye behavioral indices (gaze focus), and eye physiological indices (pupil diameter), responses to facial micromovements and to facial macromovements in typical development and in ASD development.
Methods: Gaze focus (gaze patterns on whole faces and eyes and mouth region, scan time, fixation duration) and pupil responses were recorded with an eye tracking system in 100 typical and 90 ASD children (3-12 years old) during 3 paradigm: *i/ Micromovement paradigm*: presentation of statics and dynamics neutral faces; *ii/ Emotional macromovement paradigm*: presentation of dynamics neutral and emotional faces (happy and sad faces); *iii/ Socio-attentional macromovement paradigm*: presentation of dynamics faces orienting their gaze towards an object.
Results: In both groups, micromovements and emotional macromovements enhance gaze focus in response to faces, but the gaze focus is decreased in ASD group compared to control. Concerning pupil responses, micromovements and emotional macromovements enhance pupil dilation in response to faces only in control group. Socio-attentional macromovements induce gaze orientation towards the object congruent with the gaze of the face presented mainly in control group. Maturation of gaze focus and pupil response was found in both group.
Conclusions: These results underlie atypical processing of emotional and social facial motion perception which could in turn result in impaired social interaction in autistic pathology.

246 **165.246** Effect of ASD Traits on Young Adults' Romantic Relationship Experience

J. Zhou[1], *E. G. Keenan*[2], *L. Zinn*[2], *A. Burns*[3] *and M. D. Lerner*[2], *(1)Stony Brook University, Port Jefferson, NY, (2)Stony Brook University, Stony Brook, NY, (3)Stony Brook University, Massapequa, NY*

Background:
While Autism Spectrum Disorder (ASD) is characterized by social communication deficits and challenges in forming close relationships (American Psychiatric Association, 2013), little is known empirically about how these features manifest in adult romantic relationships. Prior literature that explored sexual well-being among adults with ASD has suggested that adults with ASD tend to have less sexual experience and lower sexual satisfaction (Byer & Nichols, 2014; Dewinter et al., 2016). However, no study to date has assessed the effect of ASD traits on other aspects of romantic experience (e.g., breakup) that can lead to negative emotional consequences. This effect may be subject to potential gender differences, given their importance in romantic relationship functioning (for a review, see Miller, 2014).
Objectives:
This study explored whether ASD traits are associated with less and poorer romantic experience among college students, and whether gender moderates these associations.
Methods:
One hundred and ninety-eight typically-developing adults (138 females, 59 males, 1 other) completed the Autism Quotient (AQ; Baron-Cohen et al., 2001) and Romantic Experience Questionnaire (Greene, 2006). Additional questions regarding romantic experience included the total number of romantic relationships and the length of the longest romantic relationship (LRR, if applicable).
Results:
Higher AQ scores predicted fewer total number of romantic relationships (b=-.031, p<.01), and no gender difference was found (p > .29). AQ did not predict LRR, but gender moderated the association between AQ and LRR ($b_{gender*AQ}$=-.029, p =.05), such that the association between AQ and LRR was positive in men but absent in women. Among the participants with prior romantic relationship experience, AQ did not predict any negative romantic experiences (e.g., breakup, being cheated on, etc.) across both genders after controlling for lifetime number of relationships (p > .29). However, gender moderated the relationship between AQ and number of times being left by a partner for someone else ($b_{gender*AQ}$=-.036, p<.05), such that the association between AQ and the number of times being left by a partner for someone else was positive in men but absent in women.
Conclusions:
Adults with greater ASD traits tended to report less romantic experience in general, suggesting that ASD traits may prevent individuals from engaging in romantic relationships. Stronger associations between AQ and LRR as well as the number of times being left by a partner in men than in women suggest a gendered effect of ASD traits on romantic competence. Specifically, the association between ASD traits and LRR may reflect low romantic competence (e.g. an unwillingness to end a relationship due to the difficulty of forming one to begin with, and/or inability to end a relationship). Similarly, an association between ASD traits and the number of times being left by a partner may be a result of subjective distortions of breakup experiences or deficits in romantic relationship functioning. Given the invariance of romantic competence across gender among typically-developing emerging adults (Davila et al., in press), the gendered effect of ASD traits in our findings may result from different manifestations of ASD traits in romantic relationship functioning across genders.

247 **165.247** Engagement Across School Contexts: How Children Interact with Peers on the Playground and in the Classroom

A. Osuna[1], *C. Kasari*[1], *S. Y. Shire*[2] *and K. Krolik*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA*

Background: Children with autism spectrum disorder (ASD) have difficulty in social communication functioning that often negatively impacts their social functioning, especially at school. Children with ASD are often unengaged on the playground and report fewer friends than typically developing peers (Bauminger and Kasari, 2000). On the playground, children with ASD spend about one third of their recess periods unengaged or isolated from peers (Kasari et al., 2011), which can negatively impact their social experience at school. Although previous studies have looked at engagement of children with ASD on the playground, it is uncertain if this level of engagement translates to engagement inside the classroom.
Objectives: The present study sought to explore the social engagement states of elementary school-aged children with ASD during recess play times and during classroom small group activities.
Methods: The data were drawn from a larger pilot study that sought to understand an adaptive playground intervention for children with ASD. Participants included 26 children with ASD (80.6% male) aged 5-12 years who were ethnically diverse (51.6% Hispanic or Latino) and from eight different elementary schools from a large urban school district in the USA. Children were included in general education classrooms for a portion of their day and fell within the typical range of intellectual functioning (≥ 70). Each child's playground engagement with peers was rated by a reliable observer blinded to treatment condition using the Playground Observation of Peer Engagement (POPE; Kasari, Rotheram-Fuller, & Locke, 2005), a measure of children's peer engagement during a ten-minute period. Children's peer engagement was also observed in the classroom during a small group activity and coded using the same interval engagement coding system as the POPE. Both measures categorize the child's behavior into four engagement states: solitary, parallel, parallel aware, and jointly engaged or in games with rules.
Results: Â Descriptive statistics were analyzed to explore the engagement states of children with ASD across playground and classroom observations. Within the classroom, children were solitary 10.5%, parallel 52%, parallel aware 33.3%, and jointly engaged 4.2% of the time. Fifteen classroom observations occurred during small group activities, usually arts and crafts and math, in which the children were mostly parallel aware. On the playground, children spent 30% of their time solitary, 18.2% parallel, 25.3% parallel aware, and 26.5% jointly engaged with peers. Qualitative notes from the POPEs detailed that jointly engagement with peers occurred during structured games with rules, usually facilitated by a paraprofessional aide.
Conclusions: Results highlight that the engagement level with peers vary across school contexts for children with ASD. Although studies have measured social skills engagement within the classroom (Sparapani et al., 2015) and on the playground (Kretzmann et al., 2015), it is important to consider engagement across both settings since they both offer critical information about the child's social functioning. Results may inform school-based social skills treatment interventions.

248 **165.248** Experimental Risk-Taking in Teens with an Autism Spectrum Disorder.

L. M. Olde Dubbelink[1]*, S. van der Oord*[2] *and H. M. Geurts*[1]*, (1)University of Amsterdam, Amsterdam, NETHERLANDS, (2)Clinical Psychology, University of Leuven (KU Leuven), Leuven, Belgium*

Background: Puberty is the hallmark of increased real-life risk-taking in typically developing (TD) teens. As teens with an autism spectrum disorder (ASD) develop non-typically, they might take fewer risks than their TD peers. One study investigated risk-taking in teens with and without ASD with an adjusted version of the Balloon Analogue Risk Task for youth (BART-Y; South, Dana, White, & Crowley, 2011), and found no group differences. This study needs replication with the original BART-Y.
Objectives: We will examine whether ASD teens show less risk-taking than TD teens on the BART-Y. In line with South et al.(2011), we will explore IQ and anxiety as predictors of experimental risk-taking. Additionally, we will include pubertal stage as a predictor, and explore whether parent-reported real-life risk-taking is positively associated with BART-Y performance.
Methods: 34 teens with a clinical DSM-IV-TR/DSM-5 ASD diagnosis and 34 age- and gender-matched TD teens (age:12-16, IQ>80) performed the BART-Y. They were assessed on ASD symptoms (SRS [and 3Di diagnostic interview for ASD group]), IQ (WISC-III-NL Block Design and Vocabulary), anxiety (SCARED-71, parent-report), pubertal stage (PDS, self-report), and risk-taking (CAMEL, parent-report).
Results: Groups did not differ on age, gender, and IQ. As intended, ASD teens had higher SRS scores than TD teens (p<.0001). Group significantly predicted BART-Y performance (ASD<TD;β=-5.54,p=.04) and explained 6.1% of its variance. However, Bayesian regression indicated only anecdotal evidence for the hypothesis that groups differed on the BART-Y, BF_{01}=1.47. All other predictors were non-significant. None of their Bayes factors showed substantial evidence for the hypothesis that these factors predicted BART-Y performance. Real-life risk-taking was higher in ASD as compared to TD teens (p=.008, BF_{01}=5.1). BART-Y performance did hardly correlate with CAMEL scores (r=.089. p=.473).
Conclusions: Although preliminary analyses indicated less risk-taking in ASD as compared to TD teens, Bayesian statistics showed that evidence for this group difference was only anecdotal. It is, therefore, more valid to conclude that teens with ASD do not differ from TD teens in experimental risk-taking, in line with South et al.(2011). IQ, anxiety, as well as pubertal stage did not impact experimental risk-taking. Surprisingly, parents reported that ASD teens take more risks in real-life than their TD peers. The next step is to determine whether this is also supported by self-report. Understanding the origin of the contrast between subjective and objective measures of risk-taking during puberty is important to fully grasp risk-taking in ASD teens in this crucial developmental stage.

249 **165.249** Exploring Self-Conscious Emotion Processing in Adolescents with High Functioning Autism

K. F. Jankowski*, D. Cosme and J. H. Pfeifer, Psychology, University of Oregon, Eugene, OR*

Background: Autism is commonly associated with atypical emotion processing and perspective-taking abilities. These atypicalities can impose challenges in inferring and appropriately responding to others' thoughts/feelings, which can negatively impact social interactions. While most autism research has explored basic, nonsocial emotion-processing in young children, little is known about advanced, social emotion processing in older youths.
Objectives: Using dynamic, more ecologically valid and salient stimuli, we investigated self-conscious emotion processing in adolescents with high functioning autism (ASD) and neurotypical peers (NT). Specifically, we explored adolescents' ability to infer their peers' level of embarrassment and pride, while manipulating perspective-taking demands.
Methods: Adolescent males ages 11-17 (21 ASD, 11 NT; recruitment ongoing) completed a novel, self-conscious emotion task, consisting of videos of peers singing in a competition. The task included 24 videos representing two factors: emotion (embarrassment, pride) and perspective-taking demands (low, high). In videos requiring low perspective-taking, singers' emotions were congruent with their performance (sing poorly, look embarrassed; sing well, look proud); in videos requiring high perspective-taking, they were incongruent (sing poorly, look proud; sing well, look embarrassed). Participants used a 4-point Likert scale (0=none to 3=high) to rate how intensely singers felt embarrassed and proud. To investigate the fixed effects of group, emotion, and perspective-taking demands on inferred emotion ratings, we ran multilevel modeling in R.
Results: First, we ran a model with emotion, perspective-taking demands, and their interaction as fixed effects. There was a significant effect of perspective-taking demands [$t(733)=-3.89$, $p<0.001$] such that participants gave higher ratings during videos requiring low perspective-taking, and a significant interaction effect of emotion x perspective-taking demands [$t(733)=-3.89$, $p<0.001$]. Second, we ran the same model and included group as a fixed effect. There was no significant effect of group nor its interaction. Furthermore, adding the fixed effect of group did not significantly improve model fit (Model 1: AIC=1424.4, BIC=1452.2; -2 log Likelihood=-706.18; Model 2: AIC=1424.7, BIC=1471.2; -2 log Likelihood=-702.36; χ^2 (4)=7.647, *ns*).
Conclusions: Collapsed across groups, adolescents report lower emotion intensity ratings during conditions requiring higher perspective-taking, suggesting that they perceive their peers as feeling less embarrassed and proud when their performance is incongruent with their emotions. Interestingly, adolescents with ASD make similar inferences about their peers' emotions as NT adolescents. Furthermore, heightened perspective-taking demands similarly reduce the intensity ratings of adolescents with and without ASD. These findings suggest that adolescents with ASD may be able to accurately infer others' emotions, especially in the context of multiple facial/postural cues using more salient and ecologically-valid stimuli. These findings contrast with previous reports of impaired emotion processing in younger children, which may reflect developmental differences or differences in paradigm design. Broadly, these findings suggest that adolescents with high functioning ASD may have relatively intact emotion recognition abilities, but impairments in real world social interactions may be driven by difficulties in applying this information and/or responding in socially appropriate ways.

250 **165.250** Exploring the Effect of Social Anxiety on Eye Gaze in Adolescents with ASD Across Emotion Recognition Paradigms

A. T. Wieckowski[1], *N. N. Capriola*[1], *S. M. Roldan*[1] *and S. W. White*[2], *(1)Virginia Tech, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Social anxiety is highly prevalent among adolescents with autism spectrum disorder (ASD) and research suggests that anxiety symptoms might heighten the social impairment often seen in this population. Although not entirely consistent, the extant research generally shows a pattern of diminished gaze to social features in the context of heightened gaze to non-social stimuli in people with ASD, relative to controls. Very little research has considered the potential influence of co-occurring social anxiety, diagnostically or dimensionally, on gaze patterns in youth with ASD. Understanding the possible influence of social anxiety on gaze, and other indicators of social cognition, is important given that social anxiety – like ASD, has been robustly associated with atypical social gaze.
Objectives: The goal of the current study is to explore the role of social anxiety on gaze patterns across two separate samples of adolescents with ASD. Additionally, we explore the influence of stimulus type (static, dynamic) and task instructions (free viewing, directed emotion recognition).
Methods: Participants with ASD (n = 28) and age-matched typically developing (TD) adolescents (n = 32) were drawn from two separate studies and included adolescents aged 12 and 17 years, inclusive. In both studies (emotion recognition and free viewing), participants completed one session in which they completed a computerized task where they viewed a single face expressing an emotion and completed a measure of social anxiety: Screen for Child Anxiety Related Disorders (SCARED; Birmaher et al., 1997) or Social Worries Questionnaire (SWQ; Spence, 1995). The Social Responsiveness Scale (Constantino, 2012) was also gathered for all participants. In the emotion recognition study, participants viewed a video of an adult expressing an emotion. In the free viewing study, participants viewed static stimuli of emotions from the NimStim Set of Facial Expressions.
Results: Internal consistency was high for both SCARED (α = .922) and SWQ (α = .816). For the participants with ASD, partial correlation indicated that accounting for ASD severity, self-reported social anxiety symptoms were negatively associated with gaze duration to eye region of the face across presented emotion type (r = -.474, p = .043). This effect was found for stimuli depicting anger (r = -.458, p = .050), surprise (r = -.507, p = .032), and disgust (r = -.533, p = .025). However, this effect was only found for the free viewing paradigm. For the emotion recognition study, self-reported social anxiety symptoms were positively associated with gaze duration to eye region only for the stimuli depicting sadness (r = .656, p = .039).
Conclusions: Results support prior research suggesting that co-occurring social anxiety influences social gaze in youth with ASD. However, this study promotes further examination of the influence of methodological factors (specifically stimulus type and task instruction) on the role of social anxiety on how individuals with ASD view facial emotion stimuli. We will further explore these factors and their likely influence, as well as the relationships among ASD features, social anxiety, and other gaze metrics within both TD and ASD samples.

251 **165.251** Eye Gaze Characteristics of Adults on the Autism Spectrum during Complex Dynamic Facial Emotion Recognition

M. H. Black[1,2], *N. T. Chen*[1,3,4], *S. Bolte*[1,5,6,7] *and S. J. Girdler*[1,2], *(1)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (2)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (3)School of Psychology and Speech Pathology, Curtin University, Perth, Australia, (4)School of Psychology, University of Western Australia, Perth, Australia, (5)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (6)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Dept. Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (7)Stockholm County Council, Center for Psychiatry Research, Stockholm, Sweden*

Background: Impairment in facial emotion recognition (FER) is regularly associated with Autism Spectrum Disorders (ASD), and possibly underlies aspects of the social communicative difficulties of ASD. Research has sought to examine the contributing mechanisms of this FER difficulty through eye tracking. However, to date, much of the existing literature examining eye gaze during FER has focused on examining the processing of static images of basic emotions (happy, sad, anger, fear, disgust, and surprise). Such stimuli may be inadequate in providing an accurate representation of the extent of FER deficits in ASD. It is arguable that individuals with ASD (particularly higher functioning individuals or adults) have greater difficulty in understanding complex nuanced emotions during social interaction. As such, the investigation of FER of complex emotion may have greater direct practical relevance to the difficulties experienced by people with ASD. To date, no study has examined the eye gaze patterns of adults with ASD during FER of complex, dynamic stimuli. The investigation of eye gaze during the FER of complex, dynamic stimuli may provide more extensive insights in to the cognitive processes underlying FER in ASD.
Objectives: To examine the eye gaze characteristics of adults with high functioning ASD while viewing complex, dynamic facial emotions to investigate the underlying attentional and cognitive processes underlying complex FER in ASD.
Methods: Eye tracking data was recorded while 20 adults with high functioning ASD and 20 IQ and gender matched typically developing adults completed a labelling FER task. Participants were required to complete subset of the Cambridge Mind Reading Face-Voice battery, a battery which consists of videos of complex emotions.
Results: Adults with ASD were significantly less accurate at identifying positive complex emotions (vibrant, empathic, exonerated, and intimate) compared to typically developing counterparts. Adults with ASD also fixated longer to the mouths of complex, dynamic emotions regardless of emotional valence.
Conclusions: Findings suggest that the processing of positive affect is particularly impaired in ASD when viewing complex, dynamic stimuli. Excessive focus to the mouths of complex emotions during FER may hinder the extraction of pertinent information from other core face regions, which may cause particularly pronounced deficits when viewing positively valanced emotions. The findings provide useful insights into the mechanisms of emotion recognition impairments in ASD during the processing of complex social information.

252 **165.252** Eye Gaze and Pupillary Response in Angelman Syndrome

*M. P. Hong[1], J. L. Guilfoyle[1], L. N. Mooney[1], L. K. Wink[2], R. Shaffer[3], E. Pedapati[4] and **C. A. Erickson**[2], (1)Psychiatry, Cincinnati Childrens Hospital, Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Cincinnati Children's Hospital Medical Center, Harrison, OH, (4)INSAR Cincinnati Children's Hospital Medical Center, Anderson, OH*

Background:
Angelman syndrome (AS) is a rare neurological disorder characterized by severe developmental disability, communication impairment, elevated seizure risk, and motor system abnormalities caused by disruption of maternally inherited E3 ubiquitin protein ligase gene (UBE3A) located in chromosome region 15 (15q11-q13) (Kishino, Lalande et al. 1997, Clayton-Smith and Laan 2003). Eye tracking measures, such as the evaluation of gaze points and pupil size, provide promising strategies to quantify the severity of symptoms and resolve subgroup heterogeneity across developmental disabilities (Sweeney, Takarae et al. 2004, Boraston and Blakemore 2007). Several eye tracking studies have reported that individual preference for geometric patterns over social scenes can predict diagnosis of ASD (Pierce, Conant et al. 2011, Gaietto 2014).
Objectives:
The aims of this study were to both determine the feasibility of social scene eye tracking and pupillometry measures in individuals with AS and to compare the performance of AS participants to individuals with idiopathic Autism Spectrum Disorder (ASD) and typically developing controls (TDC).
Methods:
Individuals with AS and age- and gender- matched controls completed a social eye tracking paradigm. Neurobehavioral characterization of AS participants was completed via a battery of psychological testing and caregiver behavioral evaluations such as the Bayley Scales of Infant and Toddler Development (BSID-III) (Bayley and Reuner 2006), Aberrant Behavior Checklist (ABC), Social Responsiveness Scale (SRS), and Vineland Adaptive Behavior Scales (VABS-II) (Sparrow, Balla et al. 1984).
Results:
Forty-seven percent of recruited AS participants completed the eye tracking paradigm.
Compared to TDC, AS subjects demonstrated significantly less preference for social scenes than geometric shapes. Additionally, AS subjects did not show increased pupil dilation, compared to TDC, when viewing social scenes versus geometric shapes. There was no significant difference found between AS and ASD subjects in either social eye tracking or pupillometry.
Conclusions:
This study is the first to demonstrate the feasibility of successful eye tracking in AS. Individuals with AS demonstrated both a lower preference for social stimuli than TDC. The use of eye tracking and pupillometry may represent an innovative measure for quantifying AS-associated impairments in social salience.

253 **165.253** Eye- Versus Mouth-Looking Patterns in Emotional Contexts in Children with ASD

***M. Kim**[1], C. Foster[2], Q. Wang[3], C. A. Wall[4], B. Li[3], E. Barney[5], Y. A. Ahn[1], L. Booth[2], M. C. Lyons[6], C. Paisley[6], S. M. Abdullahi[2], M. L. Braconnier[2], J. Lei[2], C. Kautz[2], P. E. Ventola[2] and F. Shic[7], (1)Seattle Children's, Seattle, WA, (2)Yale Child Study Center, New Haven, CT, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (4)University of South Carolina, Columbia, SC, (5)Child Study Center, Yale University, New Haven, CT, (6)Yale University, New Haven, CT, (7)Seattle Children's Research Institute, Seattle, WA*

Background: Previous literature reports that toddlers with ASD show increased looking at mouths compared to typically developing (TD) toddlers (Jones, Carr & Klin, 2008). However, other studies have found no between-group differences in eyes/mouth attention, though associations between attention to the mouth and language skills have been noted (Guillon, Hadjikhani, Baduel & Roge, 2014). Additional work suggests an important role of context, e.g. Hutchings & Brien (2016) report that children with ASD look more at the mouth when discussing feelings but not actions, with higher mouth gazing associated with poorer verbal ability. The evidence remains unclear as to whether eye- versus mouth-looking patterns can be differentiated between children with and without ASD, and whether the discrepancies are generally moderated by emotional context.
Objectives: To examine looking at the eye versus mouth in children with ASD versus non-ASD during a social-information-seeking task depicting escalating emotional expression.
Methods: Thirty-six 4 to 8 year-olds, ASD n = 14 (MDQ= 88, SD = 20) and non-ASD n = 22 (MDQ= 109, SD=12), watched a video of an actress involved in a stressful activity (e.g. blowing up a balloon until it pops) that ends in a Resolution (e.g. actress sighs in relief after balloon pops). Previous eye tracking analyses had shown that children with ASD spent significantly less time looking at the face (Face%) during the Resolution than non-ASD children ($p < .05$) (Foster et al., unpublished). We examined the components of %Face to examine between-group differences in eye- and mouth-looking (%Eyes and %Mouth) within this escalating emotional context.
Results: Immediately prior to the Resolution, there was no difference in face, eye or mouth gaze allocations between ASD and non-ASD children (see Figure 1). During the Resolution, there was a main effect of diagnosis on %Mouth ($F(1,36)$, $p < .05$, $\eta p2 = .157$) with children with ASD spending less time on the mouth ($M = .76$, $SD = .42$) than non-ASD children ($M = .13$, $SD = .06$). No diagnosis effect on %Eyes was observed between non-ASD and ASD (Ms = .22 and .17, SDs = .03 and .03, respectively). Across all participants, there was a positive correlation between %Mouth and DAS-II Verbal Reasoning Standard Scores ($r = .381$, $p < .05$).
Conclusions: Children with ASD spend less time viewing the face than do non-ASD children in Emotional Contexts but the difference is driven by lower mouth- as opposed to eye-scanning. Given that the Resolution sets up the expectation of an emotional context, it could be that non-ASD children look to the mouth for additional input during periods of emotional expectation, a tendency that may not be developed in children with ASD. If so, then the results support studies that find mouth gazing to be a functional and adaptive behavior that can supplement other communicative visual cues, especially in situations that warrant context deduction (i.e. how is the actress feeling now). However, the correlation between %Mouth and verbal scores suggests an alternative interpretation which links insensitivity to cues during Resolution to communicative competence rather than social disability, specifically.

254 **165.254** Face Engagement in Preschoolers As It Relates to Characteristics of the Broader Autism Phenotype

***J. B. Wagner**, 2800 Victory Blvd, 4S-209, College of Staten Island, CUNY, Staten Island, NY*

Background:
A large body of work has examined visual attention to social images in individuals with ASD to understand how scanning patterns might reflect autism-specific characteristics (for a review, see Guillon et al., 2014). This work has recently been extended to the study of social attention as it relates to autism-related traits found in the general population, or the 'broader autism phenotype' (BAP). For example, Vabalas and Freeth (2016) found that neurotypical adults with higher BAP scores showed less active visual exploration during social situations.
Objectives:
Few studies have looked at relations between BAP and social attention in typically-developing children, and the present study aims to assess how individual variability in BAP during early childhood could relate to attention to social and non-social images.
Methods:
The current sample consisted of 18 preschool-aged children (M_{age} = 46 months, SD = 9.8 months). Each child was shown eight 12-second trials displaying arrays of five items (face, bird, car, phone, color-matched scrambled face, see Elsabbagh et al., 2013), and looking patterns were recorded with an SMI RED 120Hz eye-tracker. After the eye-tracking task, the child's primary caregiver completed the Social Responsiveness Scale, Second Edition (SRS-2, Constantino & Gruber, 2012), a measure used to assess autism-related characteristics, with higher scores reflecting increased levels of BAP. The present participants had SRS-2 scores in a range not typically associated with ASD (T scores below 60). Eye-tracking measures focused on two aspects of face attention: 1) face engagement (time spent on the face out of time spent on all five items); and 2) face fixation bias (difference between average fixation duration to the face and average fixation duration to the other four items). SRS-2 T scores were calculated for Total score, Restricted Interests and Repetitive Behaviors (RRB) and the Social Communication and Interaction composite (SCI).
Results:
For face engagement, a significant negative association was found with SRS-2 Total scores, $r(16) = -.56$, $p = .016$, and SCI scores, $r(16) = -.56$, $p = .016$ (Figure 1), but not RRB ($p = .25$). This suggests that children with more BAP traits of social and communication difficulties show less attention to faces within the array of items. For face fixation bias, a significant negative association was found with SRS-2 Total scores, $r(16) = -.52$, $p = .026$, and RRB scores, $r(16) = -.58$, $p = .011$ (Figure 2), but not SCI ($p = .08$). This suggests that children with fewer BAP characteristics, especially in the RRB domain, showed longer average fixations to the face as compared to the other items.
Conclusions:
Consistent with past work in adults and older children, the present study found that characteristics of the BAP predicted social attention in preschoolers. Different BAP domains predicted differential aspects of social attention, with increased BAP SCI characteristics relating to a smaller proportion of time on the face, and increased BAP RRB characteristics relating to less fixation-specific face biases. Future work is needed to explore the mechanisms by which these different BAP domains might influence social attention across development.

255 **165.255** From Milliseconds to Months: Long-Term Developmental Change in Moment-By-Moment Attention to Social Stimuli in Infants with ASD

***M. E. Micheletti**[1], A. Kreuzman[1], J. D. Jones[2], A. Klin[3], S. Shultz[4] and W. Jones[3], (1)Marcus Autism Center, Children's Healthcare of Atlanta, & Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta & Emory School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Attention bridges the gap between the environment and an individual's subjective experience: on a moment-by-moment basis, and throughout development, children devote attention to features of the environment perceived to be most relevant. Existing research suggests that children with autism spectrum disorder (ASD) look less at other's eyes and faces than typically developing (TD) peers. However, little is known about how these looking patterns differ on a moment-by-moment basis, or how these differences emerge or change over time. One way to examine the longitudinal development of these looking patterns is to compare the way that younger infants dynamically scan social scenes to how older infants scan the same content, measuring developmental attunement of time-varying visual salience. By 24 months, TD children are remarkably consistent in fixating on the same social content at the same time. This consistency provides a developmental benchmark against which to compare the results of younger infants with and without ASD.
Objectives: Quantify the developmental attunement of time-varying visual salience between 2 and 24 months in infants with and without ASD.
Methods: From 2-24 months of age, children at low- and high-risk for ASD viewed video scenes of naturalistic social interaction (actresses portraying the role of caregiver and scenes of peer children at play) while eye-tracking data were collected. TD and ASD outcome groups were identified by diagnostic evaluations at 24 and 36 months. Analyses focused on low-risk TD males (n = 79) and males with ASD (n = 24). For both groups, time-varying kernel density estimation was used to quantify moment-by-moment visual scanning to eyes, mouth, face, body, and object regions, quantifying the extent to which younger infants looked at the same social content at the same moments in time.
Results: By 7 months, TD infants time their eye and mouth fixations in a manner that is not significantly different from that of TD 24-month-olds (Figure 1, statistical comparisons by bootstrap 95% confidence intervals). Likewise, by 12 months, TD infants time their face fixations in a manner that is not significantly different from that of 24-month-olds. Similar TD milestones are attained at 18 months for body and object regions. In contrast, ASD infants do not time their fixations in a typical manner for eye, face, or body and object looking at any time in the first 24 months of life. Only fixations on the mouth are timed in a manner similar to TD infants, and this similarity occurs 5-6 months later than is typical.
Conclusions: During the first two years of life, TD infants time their fixations in a manner that is increasingly similar to that of older TD children, reflecting a clear developmental progression in attention to dyadic eye and mouth cues, peer faces, bodies and objects. These moments of visual experience lay the foundation for developmental learning and future social functioning. In contrast, children with ASD deploy their attention differently across timescales short and long, creating a uniquely different experience, one which is likely to have cascading effects on future social and cognitive development.

256 **165.256** Gaze Glasses for Outcome Assessment in ASD

*K. Zhou, B. Gutierrez, V. Minces, J. Townsend and **L. Chukoskie**, University of California, San Diego, La Jolla, CA*

Background: Successful social interaction skills require the marshaling of visual attention and gaze in a fast and accurate manner. However, fast shifts of visual attention (Townsend, et al., 1996) and accurate shifts of gaze are deficient in individuals with ASD (Miller, et al., 2014). In fact, disordered visual orienting is among the earliest signs of ASD identified in prospective studies of infant siblings (Zwaigenbaum, et al. 2005) and it persists across the lifespan (Miller, et al., 2014). However, gaze timing and accuracy are malleable through intervention (Chukoskie, et al., 2013, 2015). Although we have tools to assess changes in gaze on a computer screen, we lack similar objective and reliable tools that can measure changes in gaze behavior in natural social interactions. We need novel outcome measures that will enable us to test the efficacy of interventions that aim to improve social interaction.
Objectives: We evaluated a novel glasses-based eye-tracking tool for the objective assessment of social interactions with one or more partners.Â We also evaluated a suite of computer vision-based tools for analyzing gaze behavior during these interactions.
Methods: We have tested inexpensive eye-tracking glasses in a structured interaction based on a social game with the research participant and two other players. The analysis suite includes tools for face- and object-recognition in the video that enables the analysis of gaze with respect to facial features and objects, as well as trigger events, such as the onset of a sound or object movement.
Results: Twelve children and adolescents with ASD wore the glasses while engaged in a game and social conversation. The glasses were comfortable, quick to don and doff, and involved minimal calibration time. Using computer vision tools, we identified looks to facial features and other objects in the scene, streamlining analysis of the data, which would otherwise have required labor-intensive "hand coding". Using these tools we were able to quantify the number of looks to particular objects or people, the duration of these looks, and the time it took to initiate a look based on a trigger event.
Conclusions: We recommend this novel glasses-based eye-tracking tool and accompanying software suite as a strong candidate for creating objective outcome assessments of social engagement in ASD at a range of ages.

257 **165.257** Gaze Perception, Superior Temporal Sulcus and Autism: An rTMS Study

***A. Saitovitch**[1], J. C. Lamy[2], E. Rechtman[1], T. Popa[2], S. Medhi[2], N. Chabane[3], A. Philippe[4], F. Bonnet-Brilhault[5], G. Martinez[6], H. Lemaître[7], J. M. Tacchella[1], R. Calmon[1], D. Grevent[1], F. Brunelle[1], N. Boddaert[1] and M. Zilbovicius[1], (1)INSERM U1000, Institut Imagine, Paris, France, (2)Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06 UMR S 1127, ICM, CENIR, F-75013, Paris, France, (3)INSERM U1000, Paris, France, (4)UMR 1163, Institut Imagine, Paris, France, (5)UMR930, INSERM, Université François –Rabelais de Tours, Tours, France, (6)Centre Hospitalier Sainte-Anne, Paris, France, (7)INSERM U1000, Institut Imagine, Université Paris Sud, Paris, France*

Background: The superior temporal sulcus (STS) is known to be implicated in social perception and social cognition processes, mainly the process of eye gaze information. Previous brain imaging studies have suggested that abnormalities within the STS would be related to social impairments in autism. In a recent study with healthy volunteers, we have shown that it is possible to change gaze pattern by transitory inhibition of the neural activity of the STS using repetitive transcranial magnetic stimulation (rTMS). Indeed, inhibition of the right STS reduced fixations to the eyes of characters during visualization of social movies, as measured with eye-tracking (Saitovitch et al. 2016).
Objectives: In this study in adults with ASD, we investigated changes using eye-tracking changes in gaze perception induced by rTMS stimulation of the right STS.
Methods: Seventeen adults with ASD (mean age = 22.4 ± 2.3) participated in the study. ASD diagnosis was based on DSM IV-R and ADI-R criteria. All subjects underwent a structural MRI for a precise localization of the stimulation target for each individual. Subjects underwent both sham stimulation and excitatory rTMS delivered over the right posterior STS (mean Talairach coordinates: 50 -53 15). The rTMS stimulation was delivered following protocol described by Huang et al., 2005. Stimulation was delivered in 2sec trains every 10sec, a total of 190sec (600 pulses), with an intensity of 90% of the active motor threshold. Fixations to the eyes were measured with a Tobii-120 eye-tracker during passive visualization of social movies at baseline, at 3 time-points (1min, 6min and 12min) after sham and at 3 time-points after TMS (1min, 6min and 12min). Eye-tracking data was processed with Tobii-Studio® software. Individual analysis was performed a posteriori in order to detect individual patterns of response, with a threshold of 12% increase or decrease.
Results: At the group level, no significant results were found in fixations to the eyes after stimulation of the STS. Qualitative analysis of data indicates strong heterogeneity in the response. Therefore, individual analysis of data has allowed to identify three different groups within participants: 3 subjects respond to the stimulation by increasing fixations to the eyes (>12%); 8 participants respond to the stimulation by reducing fixations to the eyes (>12%); 6 participants presented no changes in gaze pattern.
Conclusions: This study shows the feasibility of a TMS protocol in participants with ASD. Preliminary results show that, in line with the heterogeneity of autism itself, response to the TMS varies among individuals. Such heterogeneity could be linked to differences in the lasting effects of the TMS in ASD, as described in previous research (Oberman et al, 2012). A further study will address this issue in the perspective to use TMS as new therapeutic strategy in autism.

258 **165.258** Gender Differences in Adaptive Functioning in High-Functioning Youth with ASD

S. Huberty[1], *H. Bowman*[2], *C. DiStefano*[1], *P. Renno*[3], *M. Dapretto*[4] *and S. S. Jeste*[5], *(1)University of California Los Angeles, Los Angeles, CA, (2)NPI Psychiatry, UCLA, Los Angeles, CA, (3)University of California Los Angeles, Santa Monica, CA, (4)University of California, Los Angeles, Los Angeles, CA, (5)UCLA, Los Angeles, CA*

Background: Autism spectrum disorder (ASD) is overwhelmingly more prevalent in boys than girls (Lai, Lombardo, & Baron-Cohen, 2014), and thus most research to date has primarily focused on males with ASD. However, several studies suggest that females with ASD may show better social communication skills (Mandy et al., 2012) and better adaptive functioning (Howe et al., 2015) than male counterparts, with age and level of cognitive functioning modulating these differences.
Objectives: The current study aimed to investigate gender differences in the adaptive functioning and clinical presentation of high-functioning youth with ASD. Further, we examined whether the relationship between social skills in the diagnostic setting and parental reports of social functioning in daily life differed between genders.
Methods: We examined adaptive behavior and social skills in a cohort of 75 females and 87 males with ASD, matched by age and IQ (ages 8-17 years, IQ>70). ASD diagnosis was confirmed using the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2; Lord et al., 2012), Autism Diagnostic Interview-Revised (ADI-R; Rutter, LeCouteur, & Lord, 2003), and clinical judgment. Parents completed the Vineland Adaptive Behavior Scales-Second Edition (VABS-II) Survey Interview Form (Sparrow et al., 2005).
Results: Results from independent samples t-tests using domain standard scores on the VABS-II indicated that females with ASD had significantly higher scores on the Communication ($t(159) = 2.037$, $p = .043$) and Daily Living Skills ($t(160) = 2.075$, $p = .04$) domains, but males and females did not differ on the Socialization domain ($t(160) = .073$, $p = .942$). These findings suggest that, while females have stronger language and daily living skills, they experience similar levels of social difficulty as males. On the ADOS-2, Restricted and Repetitive Behavior scores did not differ between males and females ($t(159) = .427$, $p = .670$), but females had significantly lower Social Affect scores ($t(159) = -3.397$, $p = .001$). In males, ADOS-2 Social Affect scores were negatively correlated with VABS-II Socialization standard scores ($r(85) = -.276$, $p = .01$), such that boys who exhibited greater social impairments during the ADOS-2 were also reported to have greater social difficulties in their daily lives (based on the VABS-II) . However, in girls with ASD, these indices of social functioning were not significantly correlated ($r(72) = -.018$, $p = .876$).
Conclusions: While both boys and girls with ASD encounter similar levels of social difficulties in their daily lives as reported by parents, fewer social impairments were detected in girls within the diagnostic setting. Furthermore, parent report was strongly associated with diagnostic assessment of social skills in males, but this relationship was not present in females. Our findings suggest that, while girls might appear to have stronger social skills in the structured context of a diagnostic assessment, they may nevertheless struggle in applying those skills in real world settings. Future research should further explore possible gender differences in how social skills displayed during a one-on-one assessment might relate to overall social functioning.

259 **165.259** Gender Identity in People with Autism

K. Cooper[1], *A. J. Russell*[1] *and L. Smith*[2], *(1)University of Bath, Bath, UNITED KINGDOM, (2)University of Bath, Bath, United Kingdom*

Background:
Females have traditionally been under-represented in autism research, and recently there has been increased interest in sex differences in autism. A related area of significance is *gender identity*, defined as the label an individual gives their gender, and *gender identification*, defined as social affiliation with members of one's gender group. There is evidence that people with autism are more gender variant compared to typically developing people, and they may therefore have lower gender identification. Further, autism identification (sense of affiliation with others with autism) may be lower in women with autism who are in the minority compared to men with autism. Social identification is frequently associated with psychological well-being, and so differences in autism and gender identification could have implications for mental health outcomes.
Objectives:
This study used well-validated measures which have not yet been applied to the autism population to investigate sex differences in autism identification, gender identity and gender identification, as well as comparisons to controls. A further aim was to investigate the relationship between autism and gender identification and psychological well-being.
Methods:
A total of 539 adults participated, including participants with autism (129 women and 143 men) and typically developing controls (143 women and 114 men).Â Participants reported having been diagnosed with an Autism Spectrum Disorder. Participants completed a survey online that included demographic information and self-report measures of gender identity, gender identification, autism identification and psychological well-being (self-esteem, depression and anxiety measures). Data was analysed using Chi-square, Pearson's correlation and 2x2 MANOVAs (sex by autism).
Results:
People with autism were significantly less likely to be gender congruent (have a gender identity congruent with sex assigned at birth; χ^2=45.98, p<.001), and significantly more likely to be gender dysphoric (have intent to change from their sex assigned at birth; χ^2=12.40, p<.001) than controls. Women with autism had lower gender congruence χ^2=150.24, p<.001 and higher gender dysphoria χ^2=11.85, p=.001 compared to men with autism. As predicted, people with autism had lower gender identification than controls F(1,535)=149.49, p<.001. Contrary to the predicted outcome men and women with autism had equivalent scores in gender and autism identification. People with autism had significantly lower self-esteem F(4,527)=29.34, p<.001 and higher depression F(4,527)=38.77, p<.001 and anxiety F(4,527)=46.20, p<.001 scores compared to controls. Gender identification was positively associated with self-esteem R=.195, p=.001 and negatively associated with depression R=-.311, p<.001 and anxiety R=-.240, p<.001. Autism identification was positively associated with self-esteem R=.174, p<.01.
Conclusions:
People with autism experience differences in their gender identity and gender identification as compared to the typically developing population. Women with autism have more varied gender identities compared to men with autism, although both groups had equivalent levels of gender and autism identification. Poor gender identification is associated with poor mental health outcomes, with females at most risk due to their increased gender variance. However, while autistic participants reported poorer mental health than average, having a positive autism social identity appeared to offer a protective mechanism and is therefore a potential target for intervention.

260 **165.260** Heartfelt Emotion: Heightened Sympathetic Arousal and Reduced Changes in Parasympathetic Arousal during Empathy for Pain in Autism

M. Hoogenhout[1]*, S. Schulz*[2]*, P. Weyers*[2] *and S. Malcolm-Smith*[1]*, (1)Department of Psychology, University of Cape Town, Cape Town, South Africa, (2)Department of Psychology, University of Würzburg, Würzburg, Germany*

Background:
The ability to respond appropriately to social cues depends on autonomic flexibility – the capacity to regulate parasympathetic and sympathetic responses to stimuli. It has been proposed that autonomic dysregulation is a contributing pathway to reduced social reciprocity in autism spectrum disorder (ASD), and that parasympathetic regulation is reduced in ASD. However, most studies have focused on resting state arousal in ASD, and have not measured parasympathetic responses to social stimuli. Furthermore, the interaction between parasympathetic and sympathetic responses to social stimuli remains unexamined in ASD. In the case of empathy, it is thought that autonomic responses may either prime an individual for prosocial behaviour, or lead to feelings of personal distress, which are associated with reduced helping and consolation. Typically, heightened parasympathetic arousal and reduced sympathetic arousal to perceiving others' pain are associated with greater empathic concern, increased prosocial behaviour and decreased distress. This pattern of autonomic arousal may be altered in ASD, impeding capacity for social engagement.
Objectives:
We investigated whether sympathetic and parasympathetic arousal during pain observation is correlated with amount of autism traits, as well as with subjective empathic concern and personal distress.Â
Methods:
Individuals with varying levels of autism traits, as measured on the Autism Diagnostic Observation Schedule 2 and Autism-Spectrum Quotient, participated (N = 96, n_{ASD} = 27; ages 14 – 45). Participants watched two cycles of videos depicting facial pain. The stimuli featured male and female actors initially showing a neutral expression (1-3 s), followed by an expression of pain (3 s). We measured pre-ejection period (PEP) and skin conductance levels, indicators of sympathetic arousal, and respiratory sinus arrhythmia (RSA), a measure of parasympathetic arousal, over a 2-minute baseline period and during the videos. The autonomic measures were correlated with Likert-scale ratings of empathic concern for the actors and personal distress in response to the videos.
Results:
Pain observation elicited co-activation of the sympathetic and parasympathetic nervous systems to the first cycle of pain videos, followed by a synergistic decrease to resting state arousal levels. There was a significant interaction between amount of autism traits and video cycle in RSA, heart rate, and skin conductance: Participants with high amounts of autism traits had heightened sympathetic arousal (SCL) in cycle 1. Parasympathetic arousal (RSA) in cycle 1 was not associated with amount of autism traits. However, individuals with lower autism traits showed greater decreases in parasympathetic arousal from cycle 1 to cycle 2, indicating better regulation of arousal. PEP was not associated with amount of autism traits. Participants reported greater empathic concern than personal distress during pain observation. Empathic concern was not correlated with amount of autism traits.
Conclusions:
The subjective and physiological data suggest that empathic concern for others' distress is not diminished in ASD. However, reduced regulation of autonomic threat responses may contribute to reduced social reciprocity in ASD. The findings highlight the importance of including physiological and cognitive emotion regulation strategies in social interventions.

261 **165.261** Helpful or Harmful? a Scoping Review of Autism Spectrum Disorder Diagnostic Disclosure

C. Labonte[1]*, S. Hodgetts*[2]*, J. Frison*[1] *and S. Phelan*[2]*, (1)Department of Educational Psychology, University of Alberta, Edmonton, AB, Canada, (2)Department of Occupational Therapy, University of Alberta, Edmonton, AB, Canada*

Background: Â People with autism spectrum disorder (ASD) often experience stigma, bullying, and social exclusion, perhaps due to the 'invisibility' and social deficits of ASD (Broady, Stroyle, & Morse, 2015; Chambres, Auxiette, Vansingle, & Gil, 2008; Humphrey & Lewis, 2008; Nowicki & Sandieson, 2002). For these reasons, deciding to disclose a diagnosis of ASD to others represents an important life decision for persons with ASD and their families. Diagnostic disclosure may affect stigma and social inclusion, as well as other aspects of everyday life, yet little is known about diagnostic disclosure for individuals with ASD. Research investigating the positive and/or negative implications of disclosure or non-disclosure can help inform the decision-making processes for people with ASD and/or their families, and benefit professionals to whom parents and people with ASD often turn for advice and support.
Objectives: To identify, describe and summarize existing literature on outcomes and perceptions of disclosure or non-disclosure of an ASD diagnosis to others (e.g., teachers, peers, employers).
Methods: A scoping review of scientific literature using Arksey's and O'Malley's (2005) methodological framework was conducted. Relevant English-language databases (PsycInfo, ERIC, CINAHL, Medline, and SocINDEX) and reference lists were searched using terms related to ASD (e.g., autis*, ASD, pervasive develop* dis*), disclosure (e.g., reveal*, divulge*), and perspective (e.g., attitude*, accept*). Studies that focused on disclosure to the person with ASD and/or his parents were excluded. Search was limited to studies available in English published between 2004 and the present. Thematic analysis was conducted using mind mapping (Davies, 2011) procedures.
Results: Â Twenty-seven articles met the inclusion criteria. These articles focused on outcomes for children (n=9), adolescents (n=5), and adults (n=13) diagnosed with ASD. Perspectives of disclosure from two standpoints were presented: from persons diagnosed with ASD (n=15), and from the perspective of others (n=14) (two articles included both perspectives). Knowing one's diagnosis appeared to alter views of persons with ASD. However, there was disconnect in perspectives between others (e.g., peers, general public without ASD) and persons with ASD. Results suggest that others perceive that diagnostic disclosure has positive effects on social acceptance and perceptions of disability (e.g., decreases negative behavioral attributions) for children and adolescents with ASD, especially when explanatory information about ASD was provided with the ASD label. Existing research also supports an assumption by others that diagnosis should and will be disclosed. Studies on the perspective of persons with ASD (most of whom were adults) indicated that they were generally reluctant to disclose their diagnosis due to perceived stigma. Disclosing their diagnosis was perceived to lead to negative outcomes.
Conclusions: Existing research suggests that disclosing a diagnosis of ASD will positively impact social acceptance by others, at least for children or adolescents with ASD. However, adults with ASD perceive stigma related to an ASD label. Professionals and the general public should be aware of their assumptions related to ASD and diagnostic disclosure. More research on the processes and outcomes of diagnostic disclosure in ASD, across the lifespan, is warranted.

262 **165.262** Hostile Attributions of Intent and Comorbid Behavior Problems in Children with ASD

R. M. Fenning[1]*, J. M. Moffitt*[2]*, J. K. Baker*[1] *and A. Partida*[2]*, (1)Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (2)Center for Autism, California State University, Fullerton, Fullerton, CA*

Background: The tendency to attribute hostile intent in social situations has been linked robustly to aggressive behavior and poor peer status in children with neurotypical development (e.g., Orobio de Castro et al., 2002). Related research on children with ASD has been limited and characterized predominantly by a focus on group differences. Of the studies that have addressed associations between attributional processes and social and behavioral functioning in this population, findings are decidedly mixed. Some studies have revealed expected relations between greater hostile attributions and poorer outcomes (Meyer et al., 2006) whereas others have not detected significant associations (Flood et al., 2011; Ziv et al., 2014).
Objectives: This pilot study sought to clarify and extend prior research by: 1) further examining the role of hostile attributions of intent in relation to parent-reported social problems and challenging behaviors in children with ASD, and 2) investigating processes in children with more diverse developmental profiles than have typically been included in prior research.
Methods: Participants included families of 21 children (71% male; 48% Caucasian/Non-Hispanic) with ASD between the ages of 5 and 11 years (*M*=8.43, *SD*=1.63). Mean child IQ fell within the low-average range, but significant variation was present (SB-5 ABIQ: *M*=85.19, *SD*=19.83, 43% IQ<76). Children's attributions of hostile intent were coded from the *Home Interview with Child* (CPPRG, 1991). The total number of hostile attributions generated, number of hostile attributions produced for minor harm scenarios, and number of hostile attributions generated for unsuccessful peer entry situations were considered (K=.94). Children's social problems and challenging behaviors were indexed by parent report on the *Child Behavior Checklist* (*T*-scores for Social Problems, Rule-Breaking Behavior, and Aggressive Behavior) and the *Social Skills Improvement System Rating Scales* (scores for Problem Behaviors, Externalizing Behavior, and Bullying).
Results: Child age, gender, IQ, and family income were not significantly related to hostile attributions. Given sample size considerations, emphasis was placed on statistical significance as well as effect sizes. Trends were observed for associations between total number of hostile attributions and parent-reported rule-breaking behavior, *r*=.45, *p*=.06, and aggression, *r*=.43, *p*=.05. Associations with social problems, r=.34, *ns*, and general problem behaviors, *r*=.30, *ns*, were in the same direction and moderate in strength, but non-significant. Hostile attributions generated for unsuccessful peer entry vignettes were more consistently associated with parent-reported outcomes than were attributions for minor harm scenarios. Hostile attributions for peer entry events were significantly positively associated with parent-reported social problems, *r*=.53, *p*<.05, rule-breaking behavior, *r*=.58, *p*<.01, and aggression, *r*=.53, *p*<.05. In contrast, hostile attributions in minor harm scenarios appeared more important for understanding parent-reported bullying behavior. Total number of hostile attributions of intent (B=.52, *p*<.05, OR=1.69) and hostile attributions for minor harm (B=1.05, *p*<.05, OR=2.85) were predictive of increased likelihood of elevated bullying behavior. The more general SSiS Externalizing Behavior score was not significantly associated with attributions.
Conclusions: Hostile attributions of intent may represent an important individual difference factor for children with ASD. Improved understanding of mechanisms underlying comorbid behavior problems may provide valuable insight into avenues for targeted intervention.

263 **165.263** How Adolescents with Autism Spectrum Disorders (ASD) Spontaneously Attend to Real-Life Scenes: Use of a "Change Blindness" Paradigm

M. Hochhauser[1] *and O. Grynszpan*[2]*, (1)University of Haifa, Haifa, ISRAEL, (2)CNRS UMR 7222, Institute of Intelligent Systems and Robotics, University Pierre et Marie Curie, Paris, FRANCE*

Background: Current behavioral research in Autism Spectrum Disorders (ASD) argues in favor of a dissociation between superior abilities in detecting visual details and deficient visual attention towards relevant social signals. The component of visual attention was assessed through "change blindness", a perceptual occurrence that transpires when a change in a visual stimulus is introduced and the observer does not notice it straightaway.
Objectives: To compare the visual attention of adolescents with and without (ASD) when viewing real-life stimuli by measuring the response times between the time observers were asked to search for a change in a visual stimulus task and the time they detected the change.
Methods: Twenty-eight adolescents with high-functioning ASD aged 12- 18 years and 25 matched TD adolescents viewed 36 pairs of digitized photographs. Each pair was identical apart from a single difference in the presence or absence of a particular item. This item was either a central component of the scene depicted on the photograph or was a marginal detail. The images were displayed in a 'flicker paradigm' whereby the item alternately appeared and disappeared.Â
Results: As expected marginal details were harder to detect than central components of the scenes. However, the pattern of response times did not differ significantly between the two groups of participants.
Conclusions: Adolescents with ASD did not demonstrate different change blindness behavior compared with TD. These results, although supported by previous findings using a similar paradigm, challenge the hypothesis of superior visual detection abilities in ASD and warrant further analysis

264 **165.264** How Do Typically Developing Undergraduate Students Reason about Including Peers with ASD?

K. Bottema-Beutel[1]*, S. Y. Kim*[1]*, S. Crowley*[2] *and D. B. Miele*[2]*, (1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Applied Developmental Psychology, Boston College, Chestnut Hill, MA*

Background: Increasing numbers of students with ASD are entering post-secondary education, but there is little research to support meaningful inclusion in these environments (Newman et al., 2011). This study explores how undergraduate students evaluate and reason about hypothetical scenarios in which a protagonist does not invite a target student to a social event based on the target's disability status. When reasoning about exclusion, individuals often rely on moral justifications, which pertain to welfare, justice, and rights. How different justifications are prioritized influence individual's ultimate evaluations as to whether exclusion is right or wrong. Evaluations and reasoning about social issues can vary by the context in which the social event occurs, and the characteristics of the person being excluded (see Smetana, 2006 for a review).
Objectives: To determine if the probability that:

- Participants' evaluations regarding the permissibility of the protagonist's decision varies according to the social context and the target's disability (ASD vs Learning Disability [LD]).
- Participants' use of moral justifications to explain why failing to include is permissible varies by context and the target's disability.

Methods: One-hundred fifty undergraduate students were administered two versions of three different vignettes in which a protagonist chooses not to invite an individual with a disability (the target) to a social gathering. The target is identified as having ASD in one version of the vignettes, and LD in the second version. The social scenarios in each vignette varied from private (a party in one's dorm) to public (a school cafeteria and admission to a university). Participants were asked to evaluate whether the protagonist's decision is acceptable or unacceptable (evaluation) and indicate their reasoning (justification). Mixed-effects logistic regression was used to account for the nesting of responses within participants.
Results: Preliminary findings from 55 participants indicated that, for participants' evaluations, there was a main effect for disability but not context. Participants were more likely to consider the protagonist's decision acceptable when the target had ASD as compared to LD (OR = 6.28, p= .006). Moral justifications for why failing to include was acceptable were more likely to be given when the character had an ASD as compared to LD (OR = 8.48, p < .001) and in the university as compared to the party context (OR = 3.21, p < .001).Â Finally, there was an interaction between the university context and disability (p= .01). The odds of using moral justifications to indicate why it was permissible not to include a student with a disability at a university was 27.18 if the target had ASD, and 8.67 if the target had LD. In non-university contexts, odds were .85 for ASD and 2.62 for LD.
Conclusions: These findings show that university students find it more acceptable not to include students with ASD as compared to LD, and use moral justifications to support their evaluation. Students may feel that, in certain contexts, including students with ASD may inhibit their well-being. University students may need information regarding the value of including students with ASD in contexts related to university life.

265 **165.265** Humor Responses and Social Referencing in Children with ASD: The Role of Social Cognitive Complexity

E. Ferguson[1]*, J. Brown*[2]*, N. Minyanou*[3]*, L. Bateman*[1]*, Z. M. Dravis*[2]*, M. Cola*[4]*, A. T. Pomykacz*[5]*, A. B. de Marchena*[6]*, K. Bartley*[7]*, E. S. Kim*[8]*, J. Pandey*[8]*, R. T. Schultz*[8] *and J. Parish-Morris*[2]*, (1)The Center for Autism Research/CHOP, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (6)Center for Autism Research, Philadelphia, PA, (7)Center for Autism Research, Malvern, PA, (8)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Humor is a universal experience, but some kinds of humor are more complex than others. Slapstick humor and social humor, for example, rely on two different types of cognitive processes and levels of social understanding. Prior research suggests that individuals with ASD may prefer slapstick comedy and simple jokes over humor that hinges on social cognitive inferences about beliefs or feelings (Ricks & Wing, 1975; Samson & Hegenloh, 2009). Additionally, research suggests that audible laughter may be an area of relative social strength for individuals with ASD, as the laughter of children with ASD has been found to be pleasant to naïve raters (Hudenko & Magenheimer, 2011). Given that expressions of positive affect and shared humor experiences can form a foundation for peer friendships, it is important to understand how children with ASD respond to different kinds of humor stimuli.
Objectives: Assess how children with ASD respond to humorous videos that contain different levels of social-cognitive complexity.
Methods: Participants were 43 children (28 male, mean age: 10.46 years; ASD N=20, TDC N=12, non-ASD mixed clinical or first-degree relative with ASD N=11; matched on age and sex ratio). Children watched two short videos that showed: 1) a baby laughing hysterically at a dog chasing bubbles (Figure 1a), and 2) a father giving his baby a lemon wedge to taste for the first time (Figure 1b). Children's responses were coded for the presence or absence of smiling, laughing or giggling, speaking over the video, and social referencing (i.e., looking at the task administrator during the video to share affect or seek nonverbal information).
Results: Â Smiling was the most frequently observed response, with 93% of participants exhibiting at least one smile during the videos. Nearly half of participants engaged in social referencing at least once (49%), while only about 30% laughed out loud or spoke during the video. We examined diagnostic group differences in the two most frequent responses (smiling and social referencing) via repeated measures ANOVA. A three-way interaction emerged between video (Bubbles, Lemon), response (Smiling, Social referencing), and diagnosis [ASD, non-ASD, TDC; F(2,40)=2.97, p=.06; Figure 2]. Planned t-tests revealed that fewer children with ASD smiled during the lemon video than the bubbles video, and more children with ASD engaged in social referencing during the lemon video than the bubbles video (ps<.05).
Conclusions: These preliminary data suggest that when videos depict more social-cognitive complexity, children with ASD smile less and engage in more social referencing. One explanation for this finding is that the lemon video is ambiguous, leading to greater uncertainty in how to respond. Whereas the baby's laughter in the bubbles video provides a clear clue to the video's intent, the lemon video requires perspective-taking; the viewer may smile in response to the father's humorous tone, or sympathize with the baby's disgust. To understand individual response patterns more fully, we will transcribe children's verbal descriptions of the videos. Future studies will identify characteristics of the perceiver that predict humor responses to videos with varying levels of social-cognitive complexity.

266 **165.266** I Think We'Re Alone Now: Solitary Social Behaviors in ASD

E. Zane*, K. Neumeyer, A. Chugg, J. Mertens and R. B. Grossman, FACE Lab, Emerson College, Boston, MA*

Background: For years, individuals with Autism Spectrum Disorder (ASD) were described as producing uniform, emotionless, and flat facial expressions (Review in Begeer et al., 2008). But recent studies have found facial expressions among individuals with ASD to be more variable and sometimes more intense than those of TD participants (Faso et al., 2015; Grossman et al., 2015).
These mixed findings may be due to the different social settings within which facial expressions are monitored (Rinn, 1984; Namba et al., 2016). We hypothesize that modulation of facial expressions based on social context is impaired in ASD.
Objectives: To investigate spontaneous expressions in a context designed to be relatively free of social demands.
Methods: We presented four minutes of YouTube clips to twenty adolescents with ASD (ages 10 - 17, 3 females) and twenty TD adolescents (ages 10 - 16, 7 females) who were not significantly different on IQ (ASD *M* = 115, TD *M*= 109), age, and gender. We told participants that they should watch these clips to keep themselves entertained while the researchers set up the next study. Researchers remained in the room but were hidden by a partition, so that participants watched the videos without a social partner.
We coded video-recordings of participants watching the YouTube clips for facial responsiveness ("High", "Low", or "None") based on the intensity and variety of facial expressions. We also coded for laughter and vocalizations (e.g., "Gross!", "Eww!").
Results: Â A higher proportion of participants with ASD (55%) were "high responders" than TD participants (5%), $p < 0.001$. Conversely, all "Non-responders" were TD individuals. All participants with ASD laughed at the videos, 50% of TD participants laughed, $p = 0.001$. More participants with ASD vocalized in response to the videos (79% versus 21%), $p = 0.001$.
Conclusions: Â During (pseudo)-solitary video-watching, adolescents with ASD produced a greater variety and intensity of facial and vocal expressions than TD peers. In fact, all "flat" and "emotionless" participants were TD. They may have suppressed their expressions because the RA was still present in the room (Robbins & Vandree, 2009). Also, TD participants may not have amplified their expressions because of the lack of social reciprocity of the situation (Rinn, 1984; Chapman, 1973; Robbins & Vandree, 2009).
The fact that the ASD group was so much more expressive was unexpected. Perhaps, once they were "alone," they felt unencumbered by social pressures, and reacted spontaneously to the videos. But it is also possible that the ASD group interpreted the social context of the experiment differently from their TD peers. Although the RAs couldn't see the videos from behind the partition, participants with ASD may still have considered them social partners and used their exaggerated expressions, comments and laughter as social overtures. This study sheds light on the impact of perceived social context on the facial and vocal expressions of adolescents with ASD.

267 **165.267** Implicit Action Anticipation in Children with and without ASD and Varying Intellectual and Language Impairments: Testing the Application of a Non-Verbal Eye-Tracking Paradigm in a Heterogeneous Sample

S. Anns[1] *and S. B. Gaigg*[2]*, (1)Autism Research Group, School of Psychology, City, University of London, London, United Kingdom, (2)Psychology, City, University of London, London, United Kingdom*

Background: Â
Explicit theory of mind has mostly been measured using verbal false belief paradigms and findings have been complicated by both the verbal nature of the tests and also by the pragmatic and structural language ability of the populations in question. To counteract this, Senju et al., (2010) built on Onishi & Baillargeon's (2005) study of implicit false belief attribution and found that children with ASD (aged 6-8 years; n = 12) had difficulties with action anticipation (AA) compared to their typically developing (TD) counterparts matched on age and fluid intelligence.
Objectives:
The primary aim of the current study was to replicate Senju et al's (2010) experiment with a larger cohort of children with ASD; including both low (**ALI**) and high (**ALN**) verbal abilities as well as those with idiopathic (no known cause) intellectual disabilities (**ID**) in comparison to **TD** children. A secondary objective was to test any associations of AA ability with VIQ and conceptual semantic knowledge.
Methods:
Four groups were recruited in a between measures design: **ALI** (*n*=11;12-18 years; VIQ < 75 on WASI verbal subtests); **ALN** (*n*=15; 6-11 years; VIQ > 90); **ID** (*n*=11; 12-18 years; VIQ < 75; and **TD** (*n*=18; 6-11 years; VIQ > 90). Fluid intelligence (Ravens Coloured Progressive Matrices) and conceptual semantic knowledge (The Pyramids and Palm Trees Test; PPT) were also assessed.
Eye tracking data was collected using the same methodology as Senju et al., (2010) and Southgate et al., (2007). A video was presented of an actor watching a ball being hidden in one of two boxes. The object was then displaced when the actor was looking away.Â Total looking time to the correct versus incorrect location was then coded which represented children's anticipation of the actor's behaviour. This was only possible if children had attributed a false belief. Success at the fourth familiarisation stage was necessary for inclusion. Surprisingly 27 out of a total 55 participants (49%) were excluded (ALI = 5/11; ALN = 9/15; ID = 4/11 & TD = 10/18). Additional tests of false belief attribution included an explicit question from the experimenter at the end of the video and a 'Hidden Contents' standard false belief task (SFB).
Results:
Due to the unexpectedly high participant exclusion rate analyses were conducted on the dataset before and after exclusion to explore the possibility that children may have taken longer than the 4 trials to familiarise. This was not the case. In both analyses there were no significant differences between any of the groups on implicit action anticipation (IAA), nor on the explicit AA question. This was also the case when combined **ASD** (ALI +ALN) versus **Non-ASD** (ID + TD) groups were taken into account. In addition there were no significant associations found between AA and other theory of mind measures (SFB and explicit question), as well as VIQ and PPT.
Conclusions:
These findings call into question the validity and reliability of this experimental paradigm and invite further discussion as to how this may be remedied. Several explanations are offered.

268 **165.268** Implicit Attitudes Towards Individuals with Autism By College Students and the General Population

J. Burk[1]*, C. L. Dickter*[2] *and J. Zeman*[1]*, (1)College of William and Mary, Williamsburg, VA, (2)College of William & Mary, Williamsburg, VA*

Background: Individuals with autism spectrum disorder (ASD) demonstrate strengths and challenges. Thus, it is not surprising that some studies demonstrate that individuals with ASD are perceived negatively, whereas other research suggests positive perceptions (Swaim & Morgan, 2001). Most research has relied on self-report which is effective at evaluating explicit attitudes but is susceptible to social desirability biases. To more completely characterize the attitudes towards members of social groups, it is also important to assess implicit measures because each method predicts different types of behavior. Furthermore, measuring these attitudes in diverse samples of individuals is vital.
Objectives: The goal of these studies was to address gaps in the literature by designing a measure of implicit bias and assessing implicit attitudes towards people with ASD. Study 1 measured implicit attitudes of college students and Study 2 focused on implicit attitudes of the general United States population. In addition, we sought to determine whether individuals who report more autistic behaviors would show less implicit bias towards persons with autism than those who report fewer autistic behaviors.
Methods: Participants in Study 1 were 178 non-ASD college students (65 male; *M* = 19.15 years, 50.0% White). In Study 2, participants were 94 non-ASD individuals (50 male; *M* = 31.3 years, 66.0% White) who were recruited through Amazon MTurk. All participants completed a modified version of the Implicit Attitudes Test (IAT, Nosek et al., 2002) which we developed to assess attitudes towards autistic and neurotypical individuals. The Autism Quotient questionnaire (AQ; Baron-Cohen et al., 2001) measured self-reported autistic traits.
Results: In Study 1, there was an overall implicit bias against individuals with autism (*d* = 0.83, *SD* = 0.41)*;* this mean was significantly different from 0, *t*(177) = 27.09, *p* < .001. These findings demonstrate that participants had more positive implicit associations with neurotypical compared to autistic individuals. The IAT was significantly negatively correlated with the total AQ score, *r* = -.18, *p* = .02, such that individuals who reportedh more autistic behaviors had less implicit bias. The results of Study 2indicated implicit bias against individuals with autism (*d* = 0.63, *SD* = 0.47). This bias score was significantly different from 0*, t*(93) = 12.94, *p* < .001. As in Study 1, there was a significant negative correlation between AQ score and IAT score, *r* = -.45, *p* < .001. Thus, both college students and adults who report more autistic behaviors held less implicit bias toward those with autism.
Conclusions: Â We created the first IAT to measure students' implicit associations with neurotypical and neurodiverse individuals. In both studies, our samples generally held an implicit bias against individuals with autism. In addition, this bias was weaker for individuals who reported higher numbers of autistic behaviors. This latter finding suggests that individuals with autistic traits may be more sympathetic to individuals with autism because they have experience with and understand the behaviors displayed by those with autism.

269 **165.269** Increased Synchronous and Sustained Social Interactions Following a Social Skills Intervention for Adults with ASD

M. Murray[1]*, A. Pearl*[2]*, S. L. Brown*[3]*, Z. Soulliard*[4] *and K. C. Durica*[1]*, (1)Psychiatry, Penn State College of Medicine, Hershey, PA, (2)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hummesltown, PA, (3)Penn State College of Medicine, Hershey, PA, (4)Psychology, Saint Louis University, St. Louis, MO*

Background: Despite increases in research examining the efficacy of social skills interventions for individuals with Autism Spectrum Disorder (ASD), few studies have targeted adults. This is problematic as peer relationships during adulthood demand interactions that display complex social behaviors (i.e. behaviors occurring at the same time as each other) for optimal impact and efficiency.
Objectives: This study examined the effectiveness of a social skills intervention for adults with ASD as evidenced by an increase of synchronized behaviors (i.e., eye contact, affect, and verbalization) at post-intervention of the social skills project compared to pre-intervention.
Methods: Twenty-five adults between the ages of 18- and 30-years-old (*M* = 23.47, SD = 4.13) completed a 5-minute unstructured conversation with a same-age peer confederate pre- and post-intervention. The adolescents (84% male, 88% Caucasian) were diagnosed with ASD, confirmed by collateral reports on the Social Responsiveness Scale, Second Edition (SRS 2; *M* = 67.96, SD = 9.22). Additionally, verbal IQ was estimated using the Kaufman Brief Intelligence Scale, Second Edition (KBIT-2; *M* = 99.28, SD = 16.48). The target participants' behaviors were coded using Noldus Information Technology software. The 5-minute dyad conversations were coded for seconds of eye contact and positive affect. Verbal activity was also coded, including the number of questions, validating statements, commenting statements, topic changes, run-on statements, and social niceties.
Results: Â *T*-tests were conducted to compare the participants' use of synchronized behaviors at pre- and post-intervention. The duration of synchronized behaviors increased greatly at post-intervention. Following the intervention, when the participants were verbalizing they displayed an increase in synchronous eye contact (*t* = -3.55, *p* < .01), as well as positive affect (*t* = -3.23, *p* < .01). Additionally, when the participant was verbalizing and displaying positive affect simultaneously, they also displayed a significant increase in eye contact following the intervention (*t* = -4.20, *p* < .001).
Conclusions: Â Presently, there is little research regarding the efficacy of social skills interventions for adults with ASD. Results of the current study show an overall increase in adults' use of complex social behaviors following a social skills intervention. These skills can be an indicator of quality conversations, though the skills often need to be explicitly taught to individuals with ASD to increase social functioning. The study shows preliminary evidence that an intervention targeted specifically to adults is successful in increasing these complex social behaviors.

270 **165.270** Increased Value of Biological Motion in Individuals with Few Autistic Traits

E. H. Williams *and E. S. Cross, Psychology, Bangor University, Bangor, United Kingdom*

Background: Individuals with a diagnosis of Autism Spectrum Disorder (ASD) characteristically demonstrate impaired eye-contact during social interactions, and from an early age, look less towards faces than typically developing (TD) individuals. The Social Motivation Theory of Autism posits that this is due to a reduced sensitivity to the reward value of social stimuli, specifically faces, in ASD. Research has also demonstrated that TD individuals preferentially orient towards another type of salient social stimulus, namely biological motion. Individuals with ASD, however, do not show the aforementioned behaviours. Although the reward value of faces to TD and ASD individuals has been investigated, it remains unknown how rewarding both populations find biological motion.
Objectives: The present study investigated the value assigned to biological and non-biological motion by typically developing participants, and further examined whether reward values differed in individuals with more autistic traits. Videos of a human performing smooth, natural movements were used as a proxy for biological motion, and videos of a human performing rigid, robotic movements were used as a proxy for non-biological motion.
Methods: Autistic traits were measured in typically developing adults who then completed an innovative behavioural paradigm that measures stimuli preference.
Results: The results suggest that typically developing participants prefer biological, or human-like, motion, and exert more effort to view this type of stimuli in comparison to non-human-like motion or control stimuli. However, this preference appears to be weaker in individuals with more autistic traits.
Conclusions: This study is the first to investigate the reward value of biological motion in adult participants in the same way as has previously been investigated for faces. These results thus provide novel findings that TD individuals show a preference for biological motion, and that this preference is reduced in individuals with more autistic traits. Furthermore, this study helps us to begin to understand whether individuals with ASD assign a reduced reward value to faces alone, or whether these individuals find a broader conceptualisation of social stimuli less rewarding compared to TD individuals.

271 **165.271** Influence of Parental Emotion Scaffolding on Children's Emotion Regulation, Social Functioning, and Behavior Problems

L. Berkovits[1,2], *B. Caplan*[2], *A. Eisenhower*[3] *and J. Blacher*[4], *(1)UCEDD, Children's Hospital Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)University of Massachusetts Boston, Boston, MA, (4)University of California - Riverside, Riverside, CA*

Background: The development of emotion regulation remains understudied among children with autism spectrum disorder (ASD). In particular, little inquiry has been made into how parents influence children's emotion regulation development, despite strong evidence for parents' role in this area for typically developing children (Morales et al., 2005; Grolnick, Bridges & Connell, 1996).Â Furthermore, emotion dysregulation is closely related to social difficulties for children with typical development (e.g., Blandon, Calkins, & Keane, 2010; Brophy-Herb et al., 2013; Eisenberg et al., 1993) and children with ASD (e.g., Berkovits et al., 2016), suggesting that strategies that reduce dysregulation might lead to improvements in social functioning.
Objectives: Specific research questions addressed are: To what extent does parental scaffolding of children's emotion understanding predict change in teacher ratings of children's (1) emotion dysregulation, (2) behavioral difficulties, and (3) social skills?
Methods: This study examined emotion dysregulation in 4- to 7-year-old children with ASD (N=59) using data obtained from a multi-site longitudinal study collected at two timepoints, 10 months apart. Children's ASD diagnoses were confirmed using the ADOS-2 and all children exhibited IQ ≥ 50. Parental scaffolding of children's emotion understanding was observed and coded during an 8-minute parent-child shared reading task (with wordless picture books) at the first of two visits. A summary code captured the frequency and depth of parents' emotion-related comments during the task. Children's emotion regulation abilities were measured using teacher report on the Emotion Dysregulation Index of the Teacher Report Form (TRF-EDI; Achenbach & Rescorla, 2000, 2001; Samson et al., 2014) at both timepoints. Teachers also reported on children's internalizing and externalizing behaviors on the TRF and social skills on the SSIS (Gresham & Elliott, 2008) at both timepoints.
Results: Hierarchical regressions showed that higher parental emotion scaffolding predicted improvement in teacher ratings of children's emotion dysregulation across the two timepoints. Parental emotion scaffolding explained an additional 5.9% in variance in later ratings of children's emotion dysregulation, after accounting for prior level of dysregulation (ΔR^2=.059, p<.05). Higher parental emotion scaffolding also predicted significant improvement in teacher ratings of children's internalizing behaviors, explaining an additional 5.7% of the variance in later ratings (ΔR^2=.057, p<.05). Prediction of change in children's externalizing behaviors was marginally significant (ΔR^2=.045, p<.10). Parental emotion scaffolding did not directly predict change in children's social skills across the two timepoints. However, mediation analyses (i.e., utilizing SPSS PROCESS macro with bootstrapping) found a significant indirect effect of parental emotion scaffolding on teacher ratings of social skills, whereby higher emotion scaffolding predicted improvement in child emotion dysregulation which, in turn, predicted improvement in social skills.
Conclusions: Parental emotion scaffolding predicted improvement across time in teacher ratings of child emotion dysregulation and behavior problems and indirectly predicted improvement in child social skills. Of note, this study used teacher measures to validate the influence of parental emotion scaffolding, reducing shared method variance in determining the effects of parenting on child behavior. These findings could inform interventions to teach parents how to support their children's emotion regulation development and social and behavioral functioning.

272 **165.272** Influences of Others' Speech on Gaze Behavior during Activity Monitoring in Children with and without ASD

Y. A. Ahn[1], *C. Foster*[2], *E. Barney*[3], *Q. Wang*[4], *C. A. Wall*[5], *B. Li*[4], *L. Booth*[2], *M. C. Lyons*[6], *C. A. Paisley*[7], *S. M. Abdullahi*[2], *M. L. Braconnier*[2], *J. Lei*[2], *M. Kim*[8], *C. Kautz*[2], *P. E. Ventola*[2] *and F. Shic*[9], *(1)Seattle Children's, Seattle, WA, (2)Yale Child Study Center, New Haven, CT, (3)Child Study Center, Yale University, New Haven, CT, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (5)University of South Carolina, Columbia, SC, (6)Yale University, New Haven, CT, (7)University of Alabama, Tuscaloosa, AL, (8)Center for Child Health, Behavior and Development, Seattle Children's, Seattle, WA, (9)Seattle Children's Research Institute, Seattle, WA*

Background: Â Monitoring of the activities of others is a crucial component of social learning in young children. Recent work has highlighted that atypical attention patterns in toddlers with autism spectrum disorder (ASD) during activity monitoring may be associated with cognitive deficits and greater autism severity (Shic, Bradshaw, Klin, Scassellati, & Chawarska, 2011; Shic et al., 2014). While toddlers with ASD exhibited looked less towards socially-relevant information and showed insensitivity to others' gaze information, high-functioning adults with ASD appeared to attend to actresses' gaze cues during activity monitoring (Foster et al., 2016). Although others' gaze cues may not be salient to toddlers with ASD, the presence of others' speech may encourage them to direct their attention towards people in the scene (Ahn et al., 2016). As sensitivity to social information in ASD individuals varies across development, it is important to understand the developmental trajectory of sensitivity to others' speech during activity monitoring in ASD.
Objectives: Â To explore the extent to which the presence or absence of others' speech influences attention allocations in children with and without ASD during activity monitoring.
Methods: Â Thirty-eight children aged 4-8 years (ASD n=16, TD n=22) viewed 12 10s video clips of two actresses interacting over a shared task (e.g., cutting toy vegetables). The video clips varied by the actress pair, type of activity, background, gaze behavior of the actresses (mutual towards each other or towards the activity), and presence of distractors (many distractors or no distractors). Eye-tracking methodology was employed to examine participants' gaze patterns. Analyses were conducted to examine between-group differences during the presence and absence of speech in the proportion of time participants spent looking at the actresses' heads (%Head), the area of shared central activity between the two actresses (%Activity), and the background elements including distractors (%Background).
Results: Consistent with previous work with toddlers, school-age children with ASD attended significantly less to the actresses' heads (p<.05, ηp2=.04) and activity (p<.01, ηp2=.07) and looked significantly more at the background elements (p<.01, ηp2=.07) regardless of the presence of speech. Both ASD and TD children exhibited a larger %Head during mutual gaze between the actresses (p<.01, ηp2=.11) and during the presence of speech (p<.05, ηp2=.03), as well as a larger %Activity during activity gaze between the actresses (p<.01, ηp2=.33). They oriented their attention towards the background during the absence of speech (p<.05, ηp2=.03).
Conclusions: These results support previous findings that children with ASD demonstrate diminished attention towards people and activities. Similar to the toddler work, the current results indicate that both ASD and TD school-age children demonstrate sensitivity to others' speech. However, the gaze cues of the speakers seem to be more salient to 4-8 year-old ASD children than to the toddlers, which is a similar pattern exhibited by adults with ASD. Thus, the attention allocation during activity monitoring in individual appear to alter around school-age. Further research should investigate the effects of others' speech on attention patterns in adults with ASD in order to fully understand the development trajectory of attention to social information in ASD population.

273 **165.273** Innovations in Theory of Mind Assessment: The Theory of Mind Inventory-2

T. L. Hutchins[1] *and P. A. Prelock*[2], *(1)Communication Sciences & Disorders, University of Vermont, Charlotte, VT, (2)College of Nursing and Health Sciences, University of Vermont, Burlington, VT*

Background: Traditional assessments of Theory of Mind (ToM) utilize direct measures of child performance and are plagued by ceiling effects (when mentalizing is relatively good), test-practice effects, and a child performance factors including language, motivation, attention, and memory. To complicate matters, significant disagreements and confusion in science are arising, not because people hold incommensurable world views, but because of the variable methodology and vague terminology that surround the construct of ToM.
Objectives: Develop two resources that can be used in research and clinical practice. These are 1) the Theory of Mind Inventory (ToMI-2; a reliable and valid caregiver broadband measure of ToM) and 2) the Theory of Mind Atlas (or encyclopedia) which is intended to map the broad and multifaceted construct of ToM.
Methods: Traditional norming and psychometric analyses were conducted to evaluate the reliability and validity of the ToMI-2. The development of the Theory of Mind Atlas was guided by a comprehensive review of of the vast theory of mind literature. The goal is to summarize the state of the knowledge for each ToM domain identified in typical development as well as ASD, ADHD, and oral or late-signing children with hearing loss.
Results: The ToMI-2 was normed on children ages 2-13 and performed extremely well on all tests of psychometric rigor (reliability, validity). The Theory of Mind Atlas is now available for free to all registered users of Theoryofmindinventory.com. By design, the atlas is constantly being updated to add content and reflect the most up-to-date evidence.
Conclusions: The ToMI-2 and the Theory of Mind Atlas represent important contributions in our efforts to improve the range of tools available for assessing and for understanding (and communicating about) theory of mind.

274 **165.274** Internet Use in Individuals with Autism Spectrum Disorders: Content, Behaviors, and Correlations with Parent Reports

M. E. Quinn[1], *E. Ramos*[2], *C. McCormick*[3] *and T. P. Levine*[1], *(1)Brown University, Providence, RI, (2)Boston University, Boston, MA, (3)Department of Psychiatry and Human Behavior, Brown University, Providence, RI*

Background: How children, adolescents, and adults with Autism Spectrum Disorders (ASDs) engage with content on the Internet has been of growing interest to families and clinicians and may be an area of concern for mental health. People with ASD may be at high risk for compulsive internet use and negative interactions with other users while communicating online.
Objectives: This study sought to identify how children, adolescents, and adults with ASDs are using the Internet, as well as the degree to which parents are aware of this use.
Methods: 33 parent and participant pairs were enrolled through an outpatient psychiatric clinic setting (average participant age: 14.3 years old) in which participants were diagnosed with ASDs. Parents and participants were recruited if they were able to answer our written questionnaire on Internet use. This included questions regarding average time spent daily on the Internet, categories of Internet usage (gaming, social media, shopping, watching videos, etc.), social Internet activities performed (picture sharing, discussion boards, write a contribution, etc.), use of the Internet for ASD information, compulsive Internet Usage (using Young's Internet Addiction Test (1999)), Internet safety. Parents also filled out the Social Responsiveness Scale (SRS). Participant use of internet was examined and compared with parent reports of internet use. Correlations were used to examine relationships between compulsive internet use and ASD symptoms.
Results: Average Total SRS scores for participants was 80 (SD 8.1). Parents reported an average of 2 to 4 hours of Internet use with their children, while participant estimates were slightly higher at 3 to 5 hours of daily Internet use (S.D. 1.7 and 2.1, respectively). There was a statistical association between child and parent responses (p=0.00), with a correlation of 0.75 from parent to child. The most popular categories of Internet use were Video Gaming and Watching videos. This was followed by Social Media, Watching TV series/anime/Movies, and Listening to Music. Parents and children indicated the same ranking of categories by total response, demonstrating a high degree of knowledge on the parents' part of the preferred and most used types of Internet use. The most popular social Internet activities reported by participants were viewing other people's videos and pictures as well as looking for new information (81.82%). The majority of parents (69.7%) answered that they use the Internet to find information about autism, in comparison to only 27.27% of children who said they did the same. Results for Young's Internet Addiction Test were suggestive of relatively low average compulsive Internet behavior among participants with ASDs. Both parents and children indicated mostly low levels of unsafe internet behavior, such as giving out personal information or encountering unwanted requests to engage in sexual activities or talk.
Conclusions: Internet use in individuals with ASDs does not appear to have significant compulsive qualities and parents are aware of their use. Further studies are needed to elucidate more on differences in Internet use between those who have ASDs and those who do not.

275 **165.275** Investigating Developmental Relations Between Social Reward, Social Cognition, and Symptom Severity in ASD.

E. Sadikova[1], *L. C. Anderson*[2], *M. G. Pecukonis*[2], *K. R. Warnell*[3] *and E. Redcay*[2], *(1)University of Maryland, College Pa, MD, (2)Department of Psychology, University of Maryland, College Park, MD, (3)Department of Psychology, Texas State University, San Marcos, TX*

Background: The social motivation theory of autism posits that individuals with autism spectrum disorder (ASD) derive less reward from social interactions, which may result in a cascade of developmental deficits, including those of social cognition (Chevallier et al., 2012a; Dawson et al. 2005). However, while previous literature has linked increased social reward to decreased autistic-like traits (Chevallier et al., 2012b, Foulkes et al., 2015), few studies have examined developmental changes in social reward and in relations between social reward and social cognition from childhood through adulthood.
Objectives: We investigated age-related differences in social reward and explored relations between social reward and social cognition in participants with ASD between middle childhood and adulthood.
Methods: To date, participants include 35 individuals diagnosed with ASD, aged 7-30 years (5 females, *Mean Age* =15.19, *SD*= 5.90). We administered five subscales from the self-report Social Reward Questionnaire (SRQ) (Foulkes, Viding, McCrory & Newman, 2014): Admiration (e.g., "I enjoy it if others look up to me"); Negative Social Potency (e.g., "I enjoy tricking someone out of something"); Passivity (e.g., "I enjoy following someone else's rules"); Pro-social Interactions (e.g., "I enjoy treating others fairly"); Sociability (e.g., "I enjoy going to parties") The ADOS-2 was administered to confirm clinical cut-off and estimate symptom severity. Finally, social cognitive measures Reading the Mind in the Eyes task (RMET) and Strange Stories were given.
We used correlation analyses to examine the relation between symptom severity and social reward. To investigate age-related changes in social reward, we conducted correlations between age and social reward subscales, separately, while controlling for symptom severity (ADOS Symptom Severity Index). To examine age-related changes in the relation between social reward and social cognition, we ran regressions with age and social reward as predictors of social cognitive measures, separately.
Results: We found a negative correlation between the Pro-Social Interactions subscale of the SRQ and ADOS total severity scores (r = -.404, p = .032), even when controlling for age (r = -.424, p = .034). There was a positive correlation between age and the Pro-Social Interactions (r = .459, p = .021) subscale of the SRQ, and a negative correlation between age and the Negative Social Potency subscale (r = -.425, p= .034). These correlations remained significant when controlling for ADOS total severity scores. Further, there was no significant relation between social reward and the social cognition measures.
Conclusions: Our results are consistent with the literature in that enjoyment of socially positive interactions negatively correlates with symptom severity. Further, our results indicate potential changes in social reward with age; specifically enjoyment of pro-social interactions may increase with age, and enjoyment of negative potency interactions may decrease with age, even when taking symptom severity into account. Finally, our results indicate that social reward may not be related to social-cognition within this age range. It is possible that the relation between these two factors plays a larger role earlier in development.

276 **165.276** Is Participation in Family Role-Play in Second Life Associated with Improved Social and Emotional Support and Well-Being Among Adults with Autism Spectrum Disorders?

L. L. Gilmour[1] *and V. R. Smith*[2]*, (1)University of Alberta, Edmonton, AB, Canada, (2)Educational Psychology, University of Alberta, Edmonton, AB, CANADA*

Background: Virtual worlds, such as Second Life (SL), may provide a venue to overcome social barriers and allow for the formation of meaningful relationships for some adults with Autism Spectrum Disorders (ASD) that have difficulty achieving these relationships in offline settings.
Objectives: This mixed methods study examines whether participation in SL among adults with ASD is associated with positive perceptions of emotional support and wellbeing.
Methods: A total of 91 participants were included in the study: 13 had ASD and used SL, 12 had ASD and did not use SL, 44 did not have ASD and were SL users, and 22 did not have ASD and did not use SL. Questionnaires and interviews with participants were used to collect the data.
Results: Individuals with ASD who participated in SL rated themselves significantly higher on measures of social fun, emotional support, and flourishing in SL than they did for real life (RL). In contrast, individuals with ASD who participated in SL reported lower social fun in RL than those who did not participate in SL.
Conclusions: While the results of the questionnaire data suggest that individuals who are attracted to SL report poorer social and emotional support and well-being offline, interviews with SL users revealed a more complex story. Participants described that the quality of social and emotional support in online situations is similar to social support received in SL among individuals without ASD. In addition participants described learning communication skills in SL that they were later able to apply to RL. This suggests that SL may create an environment where adults with and without ASD can perform equally.

277 **165.277** Joint Attention Difficulties in Autistic Adults: An Interactive Eye-Tracking Study

J. Brock[1]*, N. J. Caruana*[2]*, G. McArthur*[3]*, A. Woolgar*[4]*, H. Stieglitz Ham*[5]*, N. Kloth*[6] *and R. Palermo*[6]*, (1)Macquarie University, Sydney, NSW, Australia, (2)Department of Cognitive Science, Macquarie University, Sydney, AUSTRALIA, (3)Cognitive Science, Macquarie University, Sydney, Australia, (4)Macquarie University, Sydney, Australia, (5)Curtin University, St. Lucia, AUSTRALIA, (6)University of Western Australia, Perth, Australia*

Background: Joint attention – the ability to coordinate attention with a social partner – is critical for social communication, learning, and the regulation of interpersonal relationships. Infants and young children with autism demonstrate impairments in both initiating and responding to joint attention bids in naturalistic settings. However, little is known about joint attention abilities in adults with autism.
Objectives: In the current study we investigated joint attention abilities of autistic adults using a novel “virtual reality” task.
Methods: We tested 17 autistic adults and 17 age- and nonverbal IQ-matched controls. During testing, participants interacted via an eye-tracker with an on-screen avatar whom they were led to believe was controlled by another participant but was in fact programmed to respond dynamically to the participant’s own eye-movements. Together, the participant and avatar completed a “Catch the Burglar” task that required them both to initiate and respond to joint attention bids. Participants also completed a non-social control task that required the same pattern of eye-movements to be made in response to arrow rather than eye gaze cues.
Results: Compared to control participants, autistic adults completed significantly fewer trials successfully. They were also significantly slower to respond to joint attention bids in the first block of testing but performed as well as controls in the second block. Importantly, there were no group differences in the non-social task. In interviews conducted after the study, autistic participants commented that they initially found it challenging to communicate using eye gaze, but were able to develop strategies that allowed them to achieve joint attention.
Conclusions: This study provides the first evidence that subtle difficulties in joint attention persist into adulthood, at least for some autistic adults. The results contrast with previous studies of autism that find little evidence of impairment on computer-based gaze-cueing tasks. This, we argue, highlights the importance of embedding joint attention episodes in realistically complex social interactions in which participants have to determine the relevance of multiple social cues. Our study also demonstrates the potential and feasibility of virtual reality paradigms for studying social interaction difficulties within a controlled yet ecologically valid experimental context.

278 **165.278** Joint Attention, Social Referencing, and Theory of Mind in ASD and Non-ASD Children

S. Taraben[1]*, K. Vogt*[1] *and R. Lajiness-O'Neill*[2]*, (1)Eastern Michigan University, Ann Arbor, MI, (2)Eastern Michigan University, Ypsilanti, MI*

Background: Joint attention and theory of mind are both integral parts of a core social-communicative system that begins developing in infancy. While joint attention begins emerging between 6 and 15 months in typically-developing children, theory of mind begins emerging at around 4 years. Although longitudinal data suggests a relationship between joint attention and theory of mind, little is known about the extent of the relationship and variables that mediate the relationship. Because joint attention emerges before theory of mind, it is possible that joint attention deficits contribute to theory of mind deficits in children with autism spectrum disorder (ASD). Moreover, information regarding the development of joint attention beyond infancy in typically developed children is limited and may facilitate a better understanding of typical vs. atypical socio-cognitive development.
Objectives: The purpose of this study was to explore differences between children with ASD and typically developing children in theory of mind and rates of joint attention and social referencing and to examine the relationships between all three variables. In addition, the study examines the effect of age and joint attention and the effect of age and social referencing on theory of mind in both groups.
Methods: A sample of 20 children with ASD between the ages of 6 and 12 years were compared to a sample of 19 typically-developing children in the same age range. With the exception of one control, who was matched within 1-year, all controls were matched by gender and age within 6-months to children in the ASD group. The groups were assessed at the Eastern Michigan University Psychology Clinic on tests of intelligence and social functioning, including communication, social awareness, social affect, and theory of mind.
Results: The ASD group had lower overall levels of theory of mind and more specifically, verbal theory of mind, than the non-ASD group. In addition, in comparison to the non-ASD group, they had lower instances of initiated joint attention and social referencing. Age was shown to be positively related to theory of mind. In addition, bivariate relationships between language measures and theory of mind measures were found. Joint attention was found to predict theory of mind, with greater attention predicting greater theory of mind. Moreover, verbal language was also found to be related to theory of mind. No relationship between age and theory of mind, even as moderated by joint attention, was found for ASD and non-ASD participants.
Conclusions: Results suggest lower social functioning in the ASD group, as demonstrated by poorer theory of mind and lower rates of joint attention and social referencing. A relationship between language measures and theory of mind measures suggest that children may develop compensatory behaviors which allow them to achieve greater scores in theory of mind. Lastly, the findings suggest that joint attention and verbal language can be used as indicators of theory of mind abilities and deficits in those areas may perhaps be addressed to improve or prevent theory of mind deficits.

279 **165.279** Less Sensitive Face-Selective Responses in ASD Measured with Fast Periodic Visual Stimulation EEG

S. Vettori[1]*, S. Van der Donck*[2]*, M. Dzhelyova*[3]*, B. Rossion*[3] *and B. Boets*[4]*, (1)Onderzoeksgroep Psychiatrie UZ Herestraat 49 - bus 7003 64, K U Leuven, Leuven, Flemish Brabant, Belgium, (2)KU Leuven, 3000 Leuven, BELGIUM, (3)Psychological Sciences Research Institute and Institute of Neuroscience, UCL, Louvain-la-neuve, Belgium, (4)Katholieke Universiteit Leuven, Leuven, BELGIUM*

Background:
Fluently recognizing faces and facial expressions is highly important for our social interactions. Impaired and atypical face processing have often been postulated as a key deficit in autism spectrum disorders (ASD). Despite the great amount of research on face identity and facial expression recognition in ASD, results are mixed. This is partly due to the widely used tasks tapping explicit face processing, which may give an incomplete estimate of face processing abilities in ASD.
Objectives:
Therefore, we wish to examine these face processing impairments in ASD with an innovative EEG approach. This method combines fast periodic visual stimulation (FPVS) with scalp electroencephalography (EEG). The main advantage of this new and highly versatile FPVS EEG approach is that it offers an objective, quantifiable and robust index of implicit face processing abilities, reliable at the individual level, within a few minutes of time and without any complex data analysis. The core idea of FPVS is that the periodicity of the electrophysiological response on the human scalp corresponds exactly with the periodicity (frequency) of the visual stimulation. Hence, it can be used for efficiently measuring categorization responses of complex visual stimuli in the human brain.
Methods: In this study, the ability to rapid categorization of natural face images was assessed. 25 high-functioning young boys with ASD (age 8-12) and 25 typically developing (TD) boys without any psychiatric disorder completed the FPVS EEG paradigm. In this paradigm, images of objects in their natural background are presented at a baseline frequency rate of 6 Hz. Every fifth image, widely variable face images appear in the sequence. If participants detect the periodic appearance of the face stimuli, a face-selective response is observed in the EEG at exactly 1.2 Hz (6/5). Further, participants completed computerized versions of the Benton Facial Recognition Test (BFRT) and the Cambridge Face Memory Test (CFMT). In addition to verbal, performal and total IQ, clinical assessments included questionnaires assessing quantitative autism characteristics (Social Responsiveness Scale), symptoms of depression (Child Depression Inventory), symptoms of anxiety (SCARED), symptoms of congenital prosopagnosia (adapted version of the 20-item prosopagnosia index), and the Child Behavior Checklist.
Results:
Results show that the paradigm seems to be able to discriminate between children with and without ASD. We observe that boys with ASD are at least as sensitive as TD boys to the periodic flickering of the stimuli at the base rate (6 Hz), indicating that they pay equal attention to the images presented on the screen. However, they are far less sensitive to the periodic appearance of the face stimuli at oddball rate (1.2 Hz). We will further expand these results by showing correlations between the FPVS paradigm and symptom severity and IQ scores.
Conclusions:
These results suggest that for boys with ASD, their neural system is less tuned to the socially relevant information on the screen, as their face-selective response is less sensitive compared to TD boys. Furthermore, the results indicate the strength of our technique as a powerful and sensitive tool to measure socio-communicative difficulties in ASD.

280 **165.280** Living with Autism As a University Student: An Irish University Experience

M. R. Sweeney*, Dublin City University, Glasnevin, Ireland*

Background: Â A recent autism prevalence study conducted in Ireland has shown Autism rates of 1%. The National Council for Special Education in Ireland recently published new policy advice on the education of people with Autism. One of the findings, underpinning the Council's advice, is that 1 in 65 or 14,000 students in National and Secondary school in Ireland have a diagnosis of Autism. This means that more people with Autism are attending education in Ireland than ever before.
Objectives:
The aim of our research project is to explore the college related experiences of students with autism attending an Irish University. Of particular interest is

- Their interactions with staff and other students
- Their teaching and learning experiences
- Their integration into the University community
- The physical campus environment
- Travel to and from campus

Methods:
Methods: There are three parts to this study
1) An online survey with students with autism attending university (n=50)
2) Semi-structured interviews or focus groups (n = 3 groups of 6-8) with key campus staff who regularly engage with students with autism
3) An online survey of the entire student body at the University to explore their attitudes and knowledge of autism (n= 16,000) pre an post a high profile awareness campaign
Results: Â Data from the 3 arms of the study above will be presented to give a picture of the issues arising for students attending university as well as the supports being put in place. Additional supports needed will be identified.
Conclusions: Â This study will identify what is currently working well for students with Autism in the University and where improvements could be made to make the University more "Autism-Friendly". It is hoped that a model will be developed which can be replicated in other HEIs.

281 **165.281** Mindfulness Training with Children on the Autism Spectrum: A Pilot Study Evaluating the Impact of Mindfulness on Social and Cognitive Outcomes

A. Sande[1]*, D. Gagnon*[1] *and J. M. Montgomery*[2]*, (1)University of Manitoba, Winnipeg, MB, Canada, (2)Psychology, University of Manitoba, Winnipeg, MB, CANADA*

Background: People with Autism Spectrum Disorder (ASD) face difficulties with social and emotional skills, including troubles understanding and managing emotions and succeeding in social interactions (Bellini, Peters, Benner, & Hopf, 2007). Many different interventions have been designed to improve social, emotional, and adaptive outcomes for people with ASD; however many of these programs do not create long lasting or generalizable change (Bellini et al. 2007). Mindfulness-based interventions aim to increase self-awareness and self-management skills. These therapies are growing in popularity and have shown positive results for improving social skills and executive functioning (higher-order thinking processes), and decreasing problem behaviours (Beauchemin, Hutchins, & Patterson, 2008; Khoury et al. 2013) in both typical and clinical populations. Since mindfulness has only recently emerged as a therapy for ASD, existing research is limited to evaluating adolescents and adults with ASD and typical children, rather than directly investigating approaches for children with ASD directly.
Objectives: To evaluate the effectiveness of Paws b, a recently developed mindfulness program (MiSP, 2015) specifically for children ages 7-11 years, to improve social skills, self-concept, executive functioning, and problem behaviours in children with ASDs.
Methods: Five children with ASD participated in the 7 week Paws b program (6 lessons and 1 booster class). The participants of this study were all boys with ASD (M = 8 years, 3. 4 months, Range = 6 years 10 months- 10 years). Two of the five children had comorbid diagnoses and were the only two participants on medication. Children completed the Beck Youth Inventory as a measure of Self-Concept. Parents completed the parent versions of both the Social Skills Improvement System (SSIS), which assesses Social Skills and Problem Behaviours, and the Behaviour Rating Inventory of Executive Function (BRIEF), which assesses Executive Functioning Skills. All data was compared using paired sample t-tests, and effect sizes were calculated for all results to indicate practical significance.
Results: Parent reports for Social Skills showed a significant increase following Paws b training, and children reported a significant increase in their Self-Concept following Paws b. While not statistically significant, improvement trends were noted in the areas of Executive Functioning or Problem Behaviours.
Conclusions: The results of this study indicate that Paws b shows promise to improve social skills and self-concept in children with ASD. Though there were no statistically significant improvements in the other measured variables, the subscales trended in the expected direction will be valuable resources for informing future research directions. The results of this study indicate that improvement trends may have been affected by the short program duration, which suggests that a longer program may result in noticeable improvements in more areas. However, effect size calculations indicate that some of the changes, while not statistically significant, were practically significant changes for the participants.

282 **165.282** Moderating Effects of Verbal IQ on Social Competence Intervention Outcomes

J. Stichter[1], *E. Malugen*[1], *M. Herzog*[2], *R. M. O'Donnell*[3,4] *and S. Kilgus*[1], *(1)University of Missouri, Columbia, MO, (2)Special Education, University of Missouri, Columbia, MO, (3)Educational, School, and Counseling Psychology, University of Missouri Columbia, Columbia, MO, (4)Health Psychology, Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO*

Background: Students with autism spectrum disorders (and similar social challenges) often struggle social interactions with both peers and adults. Despite increased efforts to identify effective interventions to address these social competence challenges, few intervention studies examine characteristics that may be associated with higher or lower treatment response. Research implicates the role of verbal abilities on a variety of social functioning indicators of youth with ASD or similar social/behavioral challenges.
Objectives: The objective of the current study is to examine the moderating effect of student verbal IQ (VIQ) on treatment response, as measured by teachers' reports of social functioning, to a specified social competence curriculum.
Methods: This study utilizes data from a four-year cluster-randomized trial examining the efficacy of the Social Competence Intervention for Adolescents (SCI-A, *n* = 146) versus school-designated business as usual social programming (BAU, *n* = 128) for a range of middle-school students identified with social challenges (e.g., ASD, emotional behavior disorders, ADHD). The SCI-A curriculum is grounded in cognitive behavior intervention and includes specific social content and instructional strategies across all lessons. BAU settings varied considerably in their scope and delivery.Â Students across both conditions were primarily male (>84%) and mean full-scale IQ (FSIQ) scores in the average range. The majority of students had eligibility for special education services, with over 75% under the categories of autism or emotional/behavioral disturbance. For each student, one general education teacher completed the Social Responsiveness Scale, 2nd edition (SRS-2) at pre and post intervention.
Results: Â Controlling for relevant behavioral covariates and FSIQ, we conducted multilevel models testing moderating effects of VIQ and of VIQ/nonverbal IQ discrepancy on SCI-A's efficacy in improving teacher' reports of social outcomes. We examined the effect sizes simple slopes at lower (85) versus higher (115) levels of VIQ and at lower (-11) versus higher (+11) levels of VIQ to NVIQ discrepancy. Results indicated significant interactions between condition (SCI-A versus BAU) and students' VIQ (see Table 1) and the VIQ to NVIQ discrepancy (see Table 2). SCI-A had more positive impact than BAU on students' social awareness (*d* = .38), social communication (*d* = .50), and social motivation (*d* = .35) at lower levels of VIQ; these patterns were more pronounced when students had discrepantly lower VIQ than NVIQ (awareness *d* = .97, communication *d* = .97, motivation *d* = 1.34). For those at higher levels of VIQ and with discrepantly higher VIQ than NVIQ, SCI-A was less effective than BAU in improving students' social outcomes (*d*s > .47).
Conclusions: SCI-A demonstrated small to moderate effects on social awareness, communication, and motivation to be social for students with lower verbal abilities. SCI-A's consistency of concept language, cognitive strategies for social interpretation, and scaffolded opportunities to learn and practice skills may better address the needs and challenges of students who have lower verbal abilities than their higher ability peers. These findings have implications for understanding the role of VIQ in intervention response and determining what intervention features may be more impactful for students with lower versus higher verbal abilities.

283 **165.283** Music and Autism: Understanding the Role of Music in Everyday Life

D. M. Greenberg[1,2], *S. Baron-Cohen*[3] *and P. J. Rentfrow*[4], *(1)Department of Psychiatry, Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (2)Clinical Psychology, City University of New York, New York, NY, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)Psychology, University of Cambridge, Cambridge, United Kingdom*

Background: In children and adults with autism, musical savantism occurs at elevated rates in autism. Indeed adults with autism perform better on some music performance tasks, including pitch perception. However, little is known about the role of music in their everyday life and why they engage and prefer music in unique ways.
Objectives: To map the role of music in the everyday lives of adults with higher functioning autism. Specifically, (1) to gain a broad picture of the uses and effects of music in autism, and (2) to investigate the cognitive factors that underlie differences between autism and control groups on musical consumption, engagement, preferences, evoked emotions, and peak experiences.
Methods: A range of musical assessments were administered online to multiple autism and control groups. These included measures of musical importance and consumption (n = 156 in the autism group and 142 in the control group); music engagement (n = 152 and 146), musical preferences (n = 97 and 135), music use and evoked emotions (158 and 271) and peak experiences (n = 89 and 127). The Empathizing Quotient (EQ), Systemizing Quotient-Revised (SQ-R), and Autism Spectrum Quotient (AQ) were administered to subsets of all the samples.
Results: Adults with autism showed clear differences from controls in how they use and are affected by music in everyday life. The autism group scored higher on cognitive/intellectual engagement with music, and preferred music with more intense and complex features. They scored higher on using music to get through difficult times and to be relieved of worries. They also scored higher on feeling wonder, transcendence, and tension from music. And responses on peak experiences demonstrated that music with patterns and repetition facilitated strong and intense reactions to music. The individual differences found in musical behavior were in part underpinned by cognitive 'brain type' classifications (as assessed through the EQ and SQ-R) and scores on the AQ.
Conclusions: This is one of the first comprehensive studies on music and everyday life in autism. The findings shed light on the link between autism and music and provide evidence for the cognitive factors that underlie this relationship by extending the empathizing-systemizing (E-S) theory to music. The findings also have the potential to inform treatments in music therapy and clinical settings.

284 **165.284** Naturalistic Assessment of Empathy and Social Cognition in Adolescent ASD – Eye-Tracking As Predictor of Performance and Behavioral Phenotypes in Clinical and General Populations

N. Muller[1,2], *L. Poustka*[3] *and T. Banaschewski*[4], *(1)Department of Child and Adolescent Psychiatry and Psychotherapy, Central Institute of Mental Health, Mannheim, Germany, (2)University of Heidelberg, Heidelberg, Germany, (3)Clinic for Child and Adolescent Psychiatry, Medical University Vienna, Vienna, Austria, (4)Central Institute of Mental Health, University of Heidelberg, Heidelberg, GERMANY*

Background: Empathy and social cognition are the basis of our social functioning and they are deviating in autism spectrum disorders (ASD; Harms et al., 2010; Bons et al., 2013; Senju, 2013). Questionnaire measures or abstract tests often fail to capture deviating empathy and social cognition in adolescent ASD, which can be attributed to compensating strategies in lab experiments that are revealed by eye-tracking methodology (Senju et al., 2009; Chevallier et al., 2015). Aberrant empathy in ASD may also reflect the endpoint of a trait continuum in the normal population that is different to aberrant empathy in conduct disorder
Objectives: The Multifaceted Empathy Test – Junior Revised (MET-JR) and the Movie for the Assessment of Social Cognition (MASC) were adapted for adolescent age ranges and investigated in three independent samples (MET-JR clinical sample: n = 57, MASC clinical sample: n = 56, MET-JR community sample: n = 215).
Methods: The original MET is a picture-based measure of cognitive and emotional empathy (Dziobek et al., 2007), while the MASC is a video-based behavioral test of inferring others' mental and emotional states (Dziobek et al., 2006). The MASC was assessed with concurrent eye-tracking. We conducted factor and psychometric analysis of our naturalistic measures in comparison to common questionnaires and tests (MASC vs. SRS, RMET, and EQ; MET-JR vs. SRS, GEM, and ICU).
Results: The MET-JR and the MASC were validated as ecologically-valid estimate of empathy (α = .71-.96) or social cognition (α = .74-.84) as they correlated significantly with related measures (r = .39 - .53) and associated constructs (r = -.37 - .59), but not significantly with cognitive ability or age. Both measures were able to differentiate ASD from clinical control groups, with AUC = .87 and AUC = .75, and delivered large effects by comparing ASD and non-ASD groups, with d = 1.1 – 2.4 and d = 0.9. Concerning the MET-JR, distinct clinical empathy profiles found for ASD and conduct disorder were replicated as disjoint empathy continua in the community sample. Concerning the MASC, smaller pupil sizes were observed for ASD (d = 0.6) and fixation on eyes positively predicted performance (f^2 = 0.15). However, exploratory factor analysis retrieved a single-factor solution for the MASC with R^2 = .36, while confirmatory factor analysis of the MET-JR partially delivered insufficient fit indices (RMSEA = .066).
Conclusions: We delivered naturalistic assessment tools of the interrelated constructs of empathy (MET-JR) and social cognition (MASC). We showed aberrant performance in both measures for adolescent ASD that can be related to empathy trait continua in the normal population and be predicted by gaze behavior. Nonetheless, factor analyses revealed that we have not sufficiently understood the latent construct structure of empathy and social cognition that also show conceptual overlap (Schaafsma et al., 2015). This could be overcome by a replication with a larger sample assessed with both naturalistic measures, the MET-JR and the MASC.

285 **165.285** Offending, Social Vulnerability and Compliance in Autism: The Moderating Effect of Theory of Mind

K. L. Payne[1], *A. J. Russell*[2], *M. Brosnan*[2] *and K. L. Maras*[2], *(1)Psychology, University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, UNITED KINGDOM*

Background: People with a diagnosis of Autism Spectrum Disorder (ASD) are reported to be disproportionately highly represented within the prison population. In a survey of 1,344 individuals with ASD from the general population, 37% reported that they had been forced or manipulated to do something that they did not want to do by someone they thought of as a friend - including criminal behaviours (National Autistic Society, 2014). Beyond this, little is known about the ASD offender profile and why they may offend. Wider literature suggests that social vulnerability and compliance may be factors relevant to ASD and related to offending, especially co-offending with others. In addition, Theory of Mind (ToM) abilities are theorised to be a core deficit in ASD and have been found to be impaired in criminal offenders (without ASD). This is pertinent as ToM has been suggested to have a moderating effect on social vulnerability, however, there is no data on the moderating effect of ToM upon compliance. To date, only one paper has examined ToM in criminal offenders with ASD and reported that the ASD offenders had better ToM than ASD non-offenders – but these differences were non-significant. To date, no single research paper has looked at social vulnerability, compliance and ToM in ASD populations with a focus upon criminal offenders.
Objectives: The study had two objectives: 1) to investigate whether ASD offenders typically offend alone or with other people; 2) to identify the extent to which social vulnerability and compliance distinguish criminal offenders with and without ASD, and to what extent does ToM moderate these relationships.
Methods: Seventy-nine participants with ASD (39 offenders; 40 non-offenders) and 78 typically developed (TD) participants (39 offenders; 39 non-offenders) completed the two sub-test version (vocabulary and matrix reasoning) of the Wechsler Abbreviated Scale of Intelligence (Wechsler, 1999), the Social Vulnerability Scale (Pinsker et al., 2006), the Gudjonsson Compliance Scale (Gudjonsson, 1989) and the solo/co-offending questionnaire designed for this study.
Results: Results indicated ASD offenders were significantly more likely to commit crimes alone than with other people. Initial findings indicated increased social vulnerability and compliance within both ASD groups (offenders; non-offenders) and also the TD offender group when compared to TD non-offenders (controlling for IQ). However, when both ToM and IQ were controlled for, the results indicate that ToM moderated the differences observed between the groups.
Conclusions: Convicted offenders with ASD typically commit crimes alone as opposed to with others. The expected finding of increased social vulnerability and compliance in the ASD groups (offenders; non-offenders) and in the TD offenders when compared to TD non-offenders was removed when accounting for ToM. The findings are therefore consistent with the broader literature identifying deficits in ToM in both ASD populations and criminal offenders, which may explain the higher-than-expected prison population of people with ASD. Understanding more about the moderating effect of ToM will allow not only interventions to help increase awareness and reduce manipulation (into both offending and non-offending behaviours) but also could be used to design intervention/strategies for reducing recidivism.

286 **165.286** Parent-Child Interaction and Peer Relationships in School-Age Children with ASD

A. Rodda[1], *A. Estes*[2], *T. St. John*[2], *J. Munson*[1] *and S. Dager*[3], *(1)University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA, (3)University of Washington School of Medicine, Seattle, WA*

Background: Peer competence and friendships are important achievements for school-age children. However, peer relationships and contributors to success in this domain among children with ASD are not well understood. Better language ability has been associated with better peer competence in children with ASD. Parent-child interaction patterns characterized by shared control are associated with increased peer competence and higher-quality friendships in children with typical development, but this has yet to be demonstrated in children with ASD.

Objectives: 1) Compare peer competence and friendships in school-aged children with ASD and TD. 2) Examine the relationship between communication ability and parent-child shared control in preschool to peer competence and friendships in school-age.

Methods: This study included 26 children with ASD (20 male) assessed at preschool-age (*M*=4.3 years) and school-age (*M*=11.7 years) and 25 peers with TD assessed at school-age (18 male; *M*=10.45 years). School-age IQ ranged from 30-128 in the ASD group. Preschool parent-child interaction in the ASD group was microanalytically coded (Relationship Affect Coding System; Peterson et al., 2010) to quantify shared control during play. Higher values of Shared Control (ratio of parent questions + directives to child questions + directives) indicated more parental control. Preschool and school-age communication was measured with the Vineland. School-age peer competence (Social Skills Responsiveness Scale) and friendship quality (Friendship Qualities Scale, FQS; Bukowski et al., 1994) were measured via parent report.
Results: Children with ASD had lower Peer Competence and Friendship Quality than children with TD (2-tailed *t*-tests, *p*s<.001). Almost 70% of children with ASD (18/26) and all children with TD had one or more friends. Two hierarchical multiple regression analyses were performed. For Peer Competence: Block 1, (NVIQ and age), was significant, R^2=.33, *p*<.001. Block 2, (Group and school-age Communication), was significant, R^2_{change}=.30, *p*<.001. For Friendship Quality: Block 1, (NVIQ and age) was significant, R^2=.11, *p*<.05. Block 2, (Group and school-age Communication) was significant, R^2_{change}=.25, *p*<.01. Shared Control correlated with Peer Competence, (*r*=-.44, *p*<.05), but not Friendship Quality. To examine the relationship between Shared Control and Peer Competence, a multiple linear regression was performed. Block 1, (preschool Communication) was at trend level, R^2=.135, *p*=.08, f^2=.26. Block 2, (Shared Control), was at trend level, R^2_{change}=.07, *p*=.08. This study is ongoing, and the final analyses will include four in-process subjects who have not yet completed the study.

Conclusions: Many school-age children with ASD have at least one friend, indicating that children with a range of communication abilities and intellectual functioning can develop reciprocal friendships. However, most children with ASD and poorer communication had lower peer competence and friendship quality. A trend level association between shared parent-child control of interactions was detected, but future studies are needed to further elucidate the potential relations between parent-child interaction and later peer relationships. Better understanding of precursors to peer competence and friendships is needed to build evidence-based interventions for improving outcomes for school-aged children with ASD.

Oral Session -
172 - Welcome Address & Sponsor Update
8:45 AM - 9:00 AM - Yerba Buena 8-9

8:45 Welcome Address & Sponsor Update (Sat)

Keynote Address
173 - Developmental Endophenotypes to Quantify the Emergence of Autism in Infancy
9:00 AM - 10:00 AM - Yerba Buena 8-9

Speaker: A. Klin and W. Jones, Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA

Reciprocal social engagement is a fundamental platform for infant brain development, fueling the emergence and refinement of social and communicative skills and facilitating a cascade of key neurodevelopmental milestones. In particular, the immediate postnatal state is marked by neoteny and extreme neuroplasticity: because human infants enter the world in such a fragile state, their survival depends upon a parent or caregiver's near-constant care. As a result, the fast pace of infant brain growth and specialization is typically enacted within a very specific context: reciprocal social engagement. This presentation focuses on the quantification of *social visual engagement* – the way in which infants visually explore, engage with, and ultimately learn from and adapt to their surrounding world. We focus on a series of experimental studies probing the first 2 years of life. Results indicate that social visual engagement is under stringent genetic control, is highly conserved across human and non-human primate species, and is pathognomonically impaired in infants later diagnosed with autism. Together, these findings implicate social visual engagement as a neurodevelopmental endophenotype for autism and also augur a new generation of human and cross-species gene-brain-behavior studies to advance understanding of the pathobiology of autism.

9:00 Developmental Endophenotypes to Quantify the Emergence of Autism in Infancy

A. Klin *and W. Jones, Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA*

Reciprocal social engagement is a fundamental platform for infant brain development, fueling the emergence and refinement of social and communicative skills and facilitating a cascade of key neurodevelopmental milestones. In particular, the immediate postnatal state is marked by neoteny and extreme neuroplasticity: because human infants enter the world in such a fragile state, their survival depends upon a parent or caregiver's near-constant care. As a result, the fast pace of infant brain growth and specialization is typically enacted within a very specific context: reciprocal social engagement. Together, these findings implicate social visual engagement as a neurodevelopmental endophenotype for autism and also augur a new generation of human and cross-species gene-brain-behavior studies to advance understanding of the pathobiology of autism.

Panel Session

174 - Building a Phenotype: Discoveries of Genetically Distinct Subtypes of ASD

10:30 AM - 12:00 PM - Yerba Buena 3-6

Panel Chair: Caitlin Hudac, *Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA*

Discussant: Raphael Bernier, *University of Washington Autism Center, Seattle, WA*

The significant etiologic and phenotypic heterogeneity of autism spectrum disorder (ASD) has made it challenging to target underlying mechanisms of ASD pathology and identify replicable biomarkers. A burgeoning "genetics-first" approach has been proposed to reduce heterogeneity and enable identification of subtypes of individuals with ASD across multiple physiological and behavioral systems. To make progress in the development of ASD biomarkers, we must establish the connection between behavior and the underlying physiology associated with etiologically defined subgroups. In this panel, we will focus on recent discoveries spanning multiple units of analysis to describe ASD phenotypes of children and individuals with genetic variants. We will begin by identifying behavioral patterns of syndromic ASD associated with de novo mutations and copy number variations (Stessman). We will then present data connecting behavior and physiology for specific genetic subtypes, including eye gaze phenotypes in PTEN carriers (Frazier), EEG resting state phenotypes in 15q11.2-13 duplication carriers (Jeste), and EEG dynamic patterns of attention in SCN2A carriers (Hudac). We will discuss common strategies and underlying mechanisms across these topics and the relevance of genetically distinct subtypes for the identification of biomarkers in ASD.

10:30 **174.001** Targeted Sequencing Identifies 90 Neurodevelopmental Disorder Risk Genes with Autism and Developmental Disability Biases

Background: *De novo* and rare, gene-disruptive mutations are known to contribute to the biology of neurodevelopmental disorders (NDDs), including autism spectrum disorders (ASD) and intellectual disability/developmental disability (ID/DD), but the pathogenicity of several hundred candidate genes that have emerged from whole-exome sequencing studies has yet to be established. Advances in next-generation sequencing technology have enabled systematic screening of tens of thousands of individuals to identify individually rare *de novo* events in the most important risk genes. Phenotypic follow-up of probands broadly drawn from NDDs has allowed us to explore specific clinical phenotypes in a genotype-first manner.

Objectives: Using a targeted sequencing approach, we aimed to screen over 10,000 NDD probands for disruptive variation in high-impact genes curated from published exome sequencing studies to identify individuals carrying novel *de novo* events, proving the statistical significance of specific genes. While disruptive genetic events may be individually rare, by leveraging samples and data from multiple comorbid conditions (e.g., ASD and ID/DD), we increase our sensitivity to identify the most important risk genes.

Methods: We applied single-molecule molecular inversion probes to sequence 208 candidate genes from an international cohort of 13,475 NDD probands (n=6,410 with a primary diagnosis of ASD and n=7,065 with ID/DD) and 2,867 unaffected sibling controls. Samples were collected as part of an international consortium termed the ASID (Autism Spectrum/Intellectual Disability) network that involved 15 centers across seven countries and four continents where patients were largely consented for clinical follow-up.

Results:

We report 90 genes that show an excess of *de novo* mutations or an overall burden of private, disruptive mutations in 5.4% of patients screened in the study compared to unaffected controls. We identify 44 novel NDD genes that reach locus-specific significance (e.g., *NAA15*, *KMT5B*, *ASH1L*, *KATNAL2* and *NCKAP1*) and confirm the importance of previously reported high-impact genes (e.g., *SCN2A*, *ARID1B*, *ADNP*, *CHD8* and *POGZ*). Neuronal-based assays for a subset of genes in *Drosophila* as a model system add further evidence to bolster their involvement in NDDs, including genes at the cusp of statistical significance. While many genes are clearly risk factors for NDD broadly, secondary analyses of both the genetic burden and subsequent patient follow-up for 25 genes in 303 patients highlights genes with a statistical bias toward ASD versus ID/DD diagnosis. We find that patients with mutations in genes enriched for ASD show significantly lower rates of seizures ($p = 1.20x10^{-4}$), congenital abnormalities ($p = 1.88x10^{-2}$), and microcephaly ($p = 1.79x10^{-7}$) but higher rates of macrocephaly ($p = 5.25x10^{-3}$) compared to comorbid ASD and ID/DD genes and strong ID/DD genes. Clinical follow-up for specific genes—*NAA15*, *KMT5B* and *ASH1L*—reveals novel syndromic and non-syndromic forms of disease with variable penetrance.

Conclusions: In total, 43% (90/208) of our candidate genes reach locus-specific significance for disruptive mutations, closely matching empirical expectations based on the mutational differential between probands and unaffected siblings. We observe evidence of phenotypic bias (ASD versus ID/DD) for severe mutations in 25 genes, specifically highlighting a gene network associated with high-functioning autism (FSIQ > 100).

10:50 **174.002** Cognitive, Behavioral, and Eye Gaze Patterns in Patients with Germline Heterozygous PTEN Mutations and Autism Spectrum Disorder

T. W. Frazier[1], *E. W. Klingemier*[1], *E. E. Zetzer*[1] *and C. Eng*[2], *(1)Cleveland Clinic Center for Autism, Cleveland, OH, (2)Genomic Medicine Institute, Cleveland Clinic, Celeveland, OH*

Background: A growing body of literature has identified a relationship between the tumor suppressor gene *PTEN* and autism spectrum disorder (ASD) with macrocephaly (PTEN-ASD). Our initial cohort study found that PTEN-ASD patients had lower PTEN protein levels, abnormal brain white matter, and reduced cognitive function (IQ, working memory, and processing speed) relative to other macro- and normo-cephalic ASD patients and healthy controls. Yet, beyond this initial study, there is limited data on specific neurobehavioral phenotypes associated with PTEN-ASD.
Objectives: Our primary aim was to leverage detailed cognitive and symptom data collected in our initial cohort to compare the neurobehavioral characteristics of PTEN-ASD cases relative to other ASD and control cases. The secondary aim was to conduct a preliminary analysis of eye gaze data to social stimuli collected from a new cohort of PTEN cases.
Methods: In our initial cohort (17 PTEN-ASD, 16 macro-ASD, 38 normo-ASD, and 14 controls), measures of autism symptoms, other psychopathology domains, child and family quality of life, attention, motor, and affective processing were collected. In our new cohort, remote eye gaze tracking was conducted from 8 PTEN patients and 18 age- and sex-matched healthy controls while they viewed brief videos depicting side-by-side faces, natural interactions, joint attention bids, and social versus abstract stimuli. Fixation duration was computed to specific regions-of-interest within each stimulus. In both samples, generalized estimating equation analyses examined group differences across neurobehavioral and eye gaze measures.
Results: Consistent with our previous findings, parent-reported and clinician-observed autism symptoms were highly similar across PTEN-ASD patients and other ASD groups. However, gross motor, and to a lesser extent, fine motor problems were more substantial in PTEN-ASD patients than other ASD groups (Figure 1a). PTEN-ASD patients were also rated as showing less emotion dysregulation (Figure 1b), anxiety/fear, aggression, and self-injury than other ASD groups. On cognitive testing, PTEN-ASD patients had problems with sustaining attention (Figure 1c), but were not impulsive. Affect and prosody recognition was impaired in PTEN-ASD relative to other ASD groups, but this was no longer significant after adjusting for IQ. The IQ reductions observed in PTEN-ASD patients were completely accounted for by impaired sustained attention, processing speed, and working memory. Quality of life, communication skills, and other psychopathology measurements were comparable across all ASD groups. In our new cohort, PTEN-ASD patients showed significant and dramatic reductions in eye gaze to socially-relevant regions-of-interest across 3 of the 4 stimuli (Figure 1d).
Conclusions: A PTEN-specific phenotype of ASD is emerging. The profile is characterized by generally reduced, but still variable, IQ - resulting from impairments in sustained attention, processing speed, and working memory. Also present is decreased fine and gross motor function, but PTEN-ASD patients ascertained to date had fewer behaviors suggestive of emotional dysregulation. Intriguingly, PTEN-ASD patients show highly similar autism symptom and eye gaze patterns to other ASD cases. These data support early referral of PTEN-ASD cases to occupational and physical therapy and suggest specific behavioral approaches to maximize sustained attention and reduce the impact of impaired processing speed and working memory.

11:10 **174.003** Electrophysiological Biomarkers of Dup15q Syndrome: From Mechanism to Clinical Implications of Functional Biomarkers in Autism Genetics

S. S. Jeste[1], *J. Frohlich*[2], *P. Golshani*[3], *L. Reiter*[4], *E. H. Cook*[5], *R. Sankar*[3] *and D. Senturk*[6], *(1)UCLA, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Center for Autism Research and Treatment, University of California, Los Angeles, Los Angeles, CA, (4)University of Tennessee Health Science Center, Memphis, TN, (5)Psychiatry, University of Illinos at Chicago, Chicago, IL, (6)University of California Los Angeles, Los Angeles, CA*

Background: The surge in genetic testing for children with Autism Spectrum Disorder (ASD) has facilitated the identification of causative rare genetic variants and the recognition of clinically meaningful genetic syndromes (Jeste and Geschwind, 2014). Insights into specific neurobiological mechanisms of disease also pave the way for the identification of genetically informed, brain based biomarkers that can enhance translational studies and clinical trials. Duplications of 15q11.2-q13.1 (Dup15q syndrome) are highly penetrant for autism spectrum disorder (ASD), with the duplicated 15q region containing several genes critical for brain development and excitatory/inhibitory balance (UBE3A and $GABA_A$ receptor genes). An electrophysiological (EEG) pattern characterized by excessive activity in the beta (15-30 Hz) band has been noted in clinical reports (Urraca, 2013), likely rooted in disruption of GABAergic tone.
Objectives: We asked whether spontaneous EEG oscillatory power distinguished children with Dup15q syndrome from those with non-syndromic ASD and then examined the clinical correlates of this electrophysiological biomarker in Dup15q syndrome (Frohlich et al, under review).
Methods: In the first study, we recorded spontaneous EEG from children with Dup15q syndrome (n = 11), age-and-IQ-matched children with ASD (n = 10) and age-matched typically developing (TD) children (n = 9) and computed relative power in 6 frequency bands for 9 regions of interest (ROIs). Group comparisons were made using a repeated measures analysis of variance. In the second study, we partnered with the national Dup15q Alliance and recorded spontaneous EEG from a larger cohort at the biannual Dup15q Family Meeting (n=27). We then examined age, epilepsy, and duplication type as predictors of beta power using linear regressions.
Results: Spontaneous beta1 (12 – 20 Hz) and beta2 (20 – 30 Hz) power were significantly higher in Dup15q syndrome compared with both comparison groups, while delta power (1 – 4 Hz) was significantly lower than both comparison groups. Effect sizes in all three frequency bands were large ($|d| > 1$, $|d|>1.7$ in beta2). Beta2 power was significantly related to epilepsy diagnosis in Dup15q syndrome. In a subset of participants with longitudinal data, beta power remained stable over time.
Conclusions:
Our findings have laid the foundation for a larger scale study of the functional and clinical implications of electrophysiological biomarkers in this syndrome. We are examining the stability of beta power and whether it is modulated with cognitive or perceptual tasks, or during sleep. One might hypothesize that persistent beta oscillations in sleep could disrupt sleep architecture enough to impact cognition and behavior in these children. A lack of modulation of EEG oscillations during cognitive tasks also could directly hinder learning. We also are quantifying EEG oscillations in several pre-clinical models of Dup15q syndrome in order to elucidate the specific role of UBE3A and $GABA_A$ receptor gene expression on this biomarker. We consider this study in the context of larger scale efforts in autism genetics to identify biomarkers that may facilitate clinical stratification, treatment monitoring, and measurement of target engagement for future clinical trials that target the putative effects of genes implicated in neurodevelopmental disorders.

11:30 **174.004** Dynamic Patterns of Attention in Children with Rare SCN2A Genetic Variants

C. M. Hudac[1], *T. DesChamps*[2], *B. E. Cairney*[3], *R. Ma*[4], *A. Wallace*[2], *V. Troiani*[5], *A. S. DiCriscio*[6], *C. M. Taylor*[7] *and R. Bernier*[3], *(1)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA, (3)University of Washington Autism Center, Seattle, WA, (4)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, MA, (5)Geisinger-Bucknell Autism & Developmental Medicine Institute, Lewisburg, PA, (6)Geisinger ADMI, Lewisburg, PA, (7)Geisinger Health System, Lewisburg, PA*

Background: As described by Stessman in this panel, *SCN2A* is one of 87 genes that show an overall burden of private disruptive mutations in neurodevelopmental disorders, including ASD. Research in animal models highlights the critical role of SCN2A in controlling voltage-gated ion channels essential for the propagation of action potentials and neurotransmission. Despite extensive knowledge of molecular and cellular disruption, little is known about the neural phenotype associated with *SCN2A* mutations in humans, including domain general areas of cognition, such as attention.
Objectives:
We aimed to characterize dynamic patterns of attention associated with the *SCN2A* genetic variant. Targeted recruitment focused on children with ASD who had completed genetic testing in priori studies and had a gene disrupting mutation to *SCN2A*. Prior studies have found that children with ASD exhibit overall attenuation of the P3 component in response to standard and deviant stimuli (e.g., Salmond et al., 2007; Donkers et al., 2013). However, we hypothesized that children with ASD and a SCN2A mutation may showcase differences in functioning and ongoing changes throughout the duration of the experiment.
Methods: To date, participants (*N*=30) included children with *de novo SCN2A*, non-carrier biological siblings, and non-carrier biological parents (see Table 1 for participant demographic data). During EEG acquisition, children watched a video while passively listening to tones that varied in pitch (1000 or 1200 Hz) and duration (50 or 100 ms). In this way, we generated a standard condition (83%) and three possible deviant conditions (e.g., frequency only, duration only, frequency and duration; 5.5% each). A single-trial approach tracked dynamic patterns of attention (i.e., the variability of the P3a over the course of the experiment).
Results:
Preliminary analyses targeted peak latency across frontocentral scalp electrode clusters for the P3a component (180-350 ms). Multilevel models (SAS 9.4) tested habituation differences (i.e., the rate of decreasing P3a latency) in the dynamic context of time related to condition and group. A three way interaction between condition, group, and time was significant, $F(2,32000)=4.98$, $p=.0069$ and patterns are illustrated in Figure 1. Pairwise comparisons of habituation patterns show that *SCN2A* carrier P3a latencies were becoming increasingly faster for both deviant and standard tones. This pattern was significantly different than the slowing P3a latencies exhibited by parents (deviant diff.=-.33, $p=.038$; standard diff. = -.023, $p<.0001$) and siblings (standard diff =-.03, $p<.0001$).
Conclusions: Children with *SCN2A* mutations exhibit distinct dynamic patterns of attention in comparison to unaffected non-carrier biological relatives. These patterns were consistent, regardless of development, for continuous exposure to standard tones, suggesting an underlying genetically distinct subtype. Specifically, the response is increasing in efficiency for *SCN2A* carriers, which may suggest a delay in low-level sensory processing. In contrast, in response to deviant tones (i.e., novel stimuli), this pattern of habituation is common to both *SCN2A* carriers and siblings, but not parents, which may highlight underlying developmental changes. We will discuss implications for the *SCN2A* neural phenotype at the intersection of dynamic attention, sensory-seeking behaviors, and ASD symptomology.

Panel Session
175 - Mental Health Crises in Youth with Autism Spectrum Disorder
10:30 AM - 12:00 PM - Yerba Buena 7

Panel Chair: Luther Kalb, *Johns Hopkins School of Public Health, Baltimore, MD, Johns Hopkins School of Public Health, Baltimore, MD*

A mental health crisis occurs when an individual experiences an acute disturbance of thought, mood, or behavior and the resources available to manage the situation are not available at the time and place of occurrence. Clinical experience suggests such crises occur frequently among individuals with an Autism Spectrum Disorder (ASD) and that they have serious negative consequences for child and family functioning. Despite the scope and impact of this issue, there is no systematic research on the measurement or management of mental health crises in individuals with ASD. This panel addresses this gap from several perspectives. Mr. Kalb will present on the development and psychometric analysis of the first mental health crisis measure designed for youth with ASD. Dr. Vasa will describe results from the first national survey of child and adolescent psychiatrists examining management of mental health crises among youth with ASD. Dr. Righi will report on the factors related to inpatient psychiatric hospitalization among youth with ASD, an important setting for treatment of mental health crises. Dr. Siegel will conclude the panel by discussing the prevalence and correlates of suicidal expression, a critical and life-threatening symptom of crisis, among children and adolescents with ASD admitted to an inpatient psychiatric setting.

10:30 **175.001** Psychometric Analysis of the Mental Health Crisis Assessment Scale in Youth with Autism Spectrum Disorder

L. Kalb[1], *L. Hagopian*[2,3] *and R. A. Vasa*[2], *(1)Johns Hopkins School of Public Health, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD, (3)Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Population-based research has shown that three quarters of youth with autism spectrum disorder (ASD) suffer from a co-occurring psychiatric disorder (Simonoff et al., 2008) and data from a clinic-based sample indicated that over 90% of referred youth with ASD have 3 or more psychiatric disorders (Joshi et al., 2010). Despite this burden, outpatient mental health providers who are available to work with this this population are scarce (Brookman-Frazee et al., 2012). This gap in care, along with clinical experience, suggests youth with ASD are risk for experiencing a mental health crisis. However, no measures of mental health crisis exist for this population.
Objectives: To examine the reliability and validity of a novel measure, the Mental Health Crisis Assessment Scale (MCAS).
Methods: Data used for this study were gathered from the Interactive Autism Network (IAN), an online US based research registry. Prior studies have established the validity of the ASD diagnosis in IAN (Daniels et al., 2011; Lee et al., 2010). For this study, parents had to report that their child was between 3-24 years of age and met the cutoff on the Social Communication Questionnaire (Rutter et al., 2003). A mental health crisis was defined as “an acute disturbance of though, mood, or behavior that requires immediate intervention” (APA, 2002). Mental health crisis was measured by the MCAS, a 28-item parent reported crisis measure made up of three sections, including a 14-item list of mental health symptoms, 7 items measuring acuity of symptoms, and 5 items assessing parental management of symptoms. Data were collected in three waves. The first wave (n = 121) were gathered to establish criterion validity by examining the association between the MCAS and a custom, semi-structured clinician interview. Construct validity was established through exploratory factor analysis (EFA; n = 229), in the first two waves of data collection, and independently corroborated through confirmatory factor analysis (CFA; n = 352) in the third wave of data collection. Convergent validity was determined by assessing the association between the MCAS and family distress (Weiss & Lunsky, 2010), parental stress (Macomber et al., 2006), and use of emergency psychiatric services in the third wave of data collection.
Results: Results from the EFA and parallel analysis identified a two-factor structure (Factor 1: behavioral acuity and Factor 2: behavioral management) of the MCAS. The CFA confirmed that the two factor model fit the third wave of data well (RMSEA = 0.10, CFI = 0.96, TLI = 0.95). The measure also demonstrated strong internal consistency values across all study waves (α ranged from 0.80-0.90). Results from the clinician interview analyses suggested a strong association between the MCAS and clinician opinion (ROC = 0.85). Lastly, positive associations were found between the MCAS and family distress (r = 0.57), parental stress (r = 0.48), and use of emergency psychiatric services (r = 0.67; all p<.05).
Conclusions: Results from this study support the MCAS as a psychometrically robust tool that can characterize a unique, important, and heavily understudied dimension of mental health among youth with ASD.

10:50 **175.002** Management of Mental Health Crises in Youth with and without Autism Spectrum Disorder: A National Survey of Child Psychiatrists

R. A. Vasa[1], *L. Kalb*[2], *E. Stuart*[3], *D. S. Mandell*[4] *and M. Olfson*[5], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins University, Baltimore, MD, (3)Johns Hopkins School of Public Health, Baltimore, MD, (4)University of Pennsylvania, Philadelphia, PA, (5)Columbia University Medical Center, New York, NY*

Background: Â Youth with autism spectrum disorders (ASD) exhibit a host of dangerous behaviors, such as aggression, self-injury, and elopement (Simonoff et. al., 2008; Anderson et al., 2012). It is critical to understand if child and adolescent psychiatrists are equipped to manage these challenging behaviors. It is also important to investigate whether child and adolescent psychiatrists believe the resources available to manage mental health crises are accessible and useful. Gathering the perspective of these clinicians is particularly relevant since they are front line service providers for youth with serious mental health problems and key stake holders in the mental health system. To date, no study has examined child psychiatrists' management of mental health crises among youth with ASD.
Objectives: To examine: 1) whether child psychiatrists differed in their management of mental health crises between youth with and without ASD, and 2) whether there are differences in access to external resources to manage crisis-related events among youth with ASD compared to youth without ASD.
Methods: A 10-item custom online survey was administered to members of the American Academy of Child and Adolescent Psychiatry. The psychiatrists were divided into two groups based on the number of youth with ASD they cared for in their practice. Clinicians who routinely saw youth with ASD (n = 374) responded to questions pertaining to the ASD population only, while clinicians who did not see children with ASD (n = 492) responded to identical questions in reference to children without ASD. Weights were calculated to account for non-response and demographic differences between the ASD and non-ASD psychiatrist groups. Doubly robust linear regression models that employed the combined survey weights were used to examine differences in item means between psychiatrists treating youth with and without ASD.
Results: Both groups of psychiatrists were equally willing to accept youth with a mental health crisis into their practice, although 25% of all psychiatrists were not accepting any new patients with a history of mental health crises into their practice. Psychiatrists who cared for youth with ASD reported less access to other consulting mental health professionals ($p<0.05$) and less access to psychiatric crisis evaluation centers that could facilitate inpatient admission ($p<.05$). Psychiatrists who were providing services to youth with ASD were also less likely to recommend that parents take their child to the ED during a mental health crisis and reported less confidence in ED professionals ($p<.05$) and police ($p<.05$) to manage youth with ASD during a crisis, compared to those without ASD, in a safe and developmentally appropriate manner.
Conclusions: Child psychiatrists caring for youth with ASD need access to more resources to manage these patients during crises. In addition to developing best practice guidelines to manage youth with ASD in crises, the field is also in need of more child adolescent psychiatrists who are comfortable accepting and treating these young people.

11:10 **175.003** Predictors of Inpatient Psychiatric Hospitalization for Children and Adolescents with Autism Spectrum Disorder

G. Righi[1], *J. M. Benevides*[2], *C. A. Mazefsky*[3], *M. Siegel*[4], *S. J. Sheinkopf*[5] *and E. M. Morrow*[6], *(1)Alpert Medical School of Brown University, Rumford, RI, (2)RI-CART and ADDIRC, Somerset, MA, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (4)Maine Medical Center - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME, (5)Brown Center for the Study of Children at Risk, Women and Infants Hospital, Providence, RI, (6)Department of Molecular Biology, Cell Biology and Biochemistry and Institute for Brain Science, Brown University, Providence, RI*

Background:
The presence of Autism Spectrum Disorder (ASD) has been associated with significant health care expenditures (Barrett et al. 2015; Hamdani and Lunsky, 2016; Mandell et al. 2006), due to greater utilization of a variety of medical and psychiatric health services including both inpatient and outpatient care, compared to individuals without ASD (Croen et al. 2006). There is reason to believe that service utilization is not evenly distributed across individuals with ASD and that there are certain risk factors that place individuals at a greater risk of requiring more services.
Objectives:
To determine factors that can identify children and adolescents with ASD at risk of psychiatric hospitalization.
Methods: Participants were selected from the Autism Inpatient Collection (AIC; n =218, 77% male, Mean age = 12.8y), and the Rhode Island Consortium for Autism Research and Treatment (RI-CART; n = 255, 80% male, Mean age = 12.3y,). Selected RI-CART participants had never been hospitalized for psychiatric reasons. Participants were frequency-matched on age and gender. All participants had: 1) a confirmed diagnosis of ASD, 2) a demographic questionnaire, 3) Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) with scores above the ASD cut-off, and 4) Vineland Adaptive Behavior Scales, Second Edition (VABS-2). Chi-square and independent sample t-tests were utilized to identify variables more prominent in the hospitalized sample. Significant predictors were entered in a multiple logistic regression model to examine their relative contribution to the likelihood of being psychiatrically hospitalized.
Results:
The AIC sample presented with higher rates of intellectual disability and nonverbal status ($\chi^2 = 67.1$, $p<0.0001$; $\chi^2 = 11.8$, $p = 0.001$, respectively), lower VABS-2 adaptive behavior composite score and communication, daily living skills, and socialization domain standard scores ($t(471) = 7.8$, $p<0.0001$; $t(471) = 7.5$, $p<0.0001$; $t(471) = 6.6$, $p<0.0001$; $t(471) = 7.9$, $p<0.0001$), higher ADOS-2 overall calibrated severity score ($t(435) = 3.5$, $p = 0.001$) and Social Affect severity score ($t(325) = 4.1$, $p <0.0001$), higher number of psychiatric diagnoses per individual ($t(471) = 5.2$, $p <0.0001$), higher rates of mood disorders diagnoses ($\chi^2= 62.7$, $p <0.0001$), and sleep problems ($\chi^2 = 36.6$, $p <0.0001$). More caregivers in the AIC sample reported being unmarried or without domestic partnerships ($\chi^2 = 15.2$, $p < 0.0001$). In the multivariate analyses, presence of a mood disorder (OR = 7.011, $p < 0.0001$), followed by the presence of current sleep problems (OR = 2.367, $p < 0.001$), and higher SA severity score (OR = 1.131, $p = 0.001$) predicted inpatient status. Having a higher VABS-2 adaptive behavior composite score (OR = 0.951, $p <0.0001$), and having a married or domestic-partnered primary caregiver (OR= 0.395, $p = 0.001$) decreased the likelihood of hospitalization.
Conclusions:
Findings reveal indicators that may identify children and adolescents at greater risk of psychiatric hospitalization. Our results underscore the importance of a multi-disciplinary approach to the assessment and treatment of children and adolescents with ASD that addresses behavioral, psychological/psychiatric, adaptive, medical, and family functioning in order to decrease the utilization of inpatient psychiatric services.

11:30 **175.004** Talking about Death or Suicide: Prevalence and Clinical Correlates in Youth with Autism Spectrum Disorder

M. Siegel[1], *A. Thurm*[2], *C. Farmer*[2], *J. A. Bridge*[3,4], *E. Lanzillo*[5], *R. Greenbaum*[6], *M. Pao*[5], *C. A. Mazefsky*[7] *and L. Horowitz*[5], *(1)Maine Medical Center - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME, (2)National Institute of Mental Health, Bethesda, MD, (3)The Ohio State University, Columbus, OH, (4)The Research Institute, Nationwide Children's Hospital, Columbus, OH, (5)Intramural Research Program, National Institute of Mental Health, National Institutes of Health, Bethesda, MD, (6)Children's Mental Health Team, Surrey Place Centre, Toronto, ON, Canada, (7)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Recent studies suggest that youth with Autism Spectrum Disorder (ASD) are at heightened risk for suicide, but these symptoms often go undetected (Bennett, 2016; Ludi et al., 2012). A significant barrier to accurately detecting suicide risk in ASD is a gap in knowledge about how suicidal thoughts are expressed in youth with ASD. Filling this gap is critical to inform suicide prevention strategies.
Objectives: To describe the prevalence of thoughts about death or suicide in a psychiatric inpatient sample of children and adolescents with ASD, with a range of intellectual ability and co-occurring psychiatric diagnoses, in order to inform suicide prevention strategies.
Methods: A parent reported item from the Child and Adolescent Symptom Inventory-5 (CASI-5), inquiring whether the youth recently "has periods lasting at least several days where he/she talks about death or suicide," was used to estimate prevalence of thoughts about death or suicide for 107 verbally fluent youth (nonverbal IQ >55, ages 10-18 years) with ADOS-confirmed ASD admitted a specialized psychiatric hospital unit (the Autism Inpatient Collection (AIC)). Consensus diagnoses for co-occurring psychiatric disorders were made by a child psychiatrist and unit clinician with expertise in assessment of co-occuring psychopathology in ASD.
Results: Per parent report, 23% of youth with ASD talked about death or suicide "often" or "very often." Clinical correlates included the presence of co-occurring depression (OR=2.71, 95% CI 1.12-6.55) or anxiety disorders (OR = 2.32, 95% CI 1.10-4.93). Demographic factors, including NVIQ, sex, race, and age, were not significantly associated with talking about death or suicide (p>.05).
Conclusions: Talking about death or suicide was a common occurrence in verbally fluent youth with ASD admitted to inpatient psychiatric units. The principal factors related to talking about death or suicide were depressive and anxiety disorders. This was particularly notable because youth with ASD are most frequently admitted to psychiatric hospital units due to externalizing behaviors, such as aggression toward others and property destruction, rather than internalizing problems (Siegel et al., 2011). As prior research has highlighted the under-reporting of suicidal thoughts in typically developing youth, our results may also be an underestimate. Screening for suicidal thoughts in this population can be confounded by some of the challenges inherent to ASD. This includes, but is not limited to, difficulty in identifying self-states, having restricted interests in morbid or negative topics, and displaying deficits in social pragmatics when making suicidal statements to gain attention or escape demands. These challenges and the high prevalence reported here suggest an urgent need for developmentally appropriate suicide risk screening measures for youth with ASD to inform suicide prevention strategies.

Panel Session
176 - The Continuum of ASD Across the Lifespan: Stability and Change in Symptoms, Cognitive Skills and Adaptive Functioning Based on Four Independent Cohorts
10:30 AM - 12:00 PM - Yerba Buena 8

Panel Chair: So Hyun Kim, *Center for Autism and the Developing Brain, White Plains, NY*

Discussant: Vanessa Hus Bal, *STAR Center for ASD & NDD; Dept of Psychiatry, University of California, San Francisco, San Francisco, CA*

As ASD is a lifelong developmental disorder, there is a need to examine behavioral trajectories from the emergence of symptoms to long-term outcomes. This panel aims to shed light on the developmental continuum of ASD based on data from four independent cohorts followed during different developmental stages from infancy to middle adulthood. The first presentation examines trajectories of directly observed ASD symptoms in a cohort of infants and toddlers seen approximately every 1-6 months from 1-3 years. The second presents ASD symptom trajectories based on parent interviews repeated on five occasions between 2-18 years and their relation to parent-reported language. The third uses multiple assessment modalities to demonstrate changes in ASD and mental health symptoms, as well as cognitive and adaptive functioning from 12-16 years in a population-based sample. The last compares child and middle-adulthood ASD symptoms, IQ and adaptive behavior in a 30-year follow up study of individuals initially assessed between 2-16 years. By providing insight into stability and change across different developmental periods, these studies highlight methodological challenges to assessment of individuals with ASD. Taken together, findings underscore the need for careful diagnostic, behavioral and intellectual assessment capturing variability in trajectories and outcomes over time.

10:30 **176.001** Patterns of ASD Symptom Trajectories in Infants and Toddlers Followed from 12 to 36 Months of Age

S. H. Kim[1] *and C. Lord*[2]*, (1)Center for Autism and the Developing Brain, White Plains, NY, (2)Psychiatry, Weill Cornell Medical College, White Plains, NY*

Background: Studies of children with ASD have demonstrated significant variability in 2-year trajectories in ASD between 12–18 months. Examining varying trajectories that characterize early development in ASD will aid in better understanding of the prognosis as well as phenotypic markers for different neurobiological subgroups.
Objectives: This study examined symptom trajectories in infants and toddlers referred for possible ASD and other developmental disorders as well as typical controls using a high-density of observations from 12-36 months of age.
Methods: A total of 153 children (103 ASD) with baseline assessments at the mean age 18 months (*SD*=4.2) and final assessments at 31 months (*SD*=5.7) were administered the Autism Diagnostic Observation Schedule (ADOS) for every 1-6 months. All children initially received the Toddler Module and 58 children transitioned to Module 2 at the average age of 30 months (*SD*=3.53). Symptom trajectories were examined based on Proc Traj using the calibrated severity scores. Changes in NVIQ and VIQ scores as well as each item score on the ADOS Toddler Module were examined using the Generalized Linear Mixed Model (GLMM).
Results: Using the minimum BIC as the selection criterion, the best trajectory typology was a model with four classes (Figure 1; nonspectrum ~ 24%; worsening ~27%; moderately persistent~24%; severely persistent ~25%). Children with ASD were more likely to belong to the worsening, moderately persistent and severely persistent groups (71%, 97% and 97% respectively) than the nonspectrum group (8%), $\chi^2(3)=417.816$, $p<0.001$. Most children who developed phrase speech by age 3 were more likely to belong to the nonspectrum and worsening groups (50%) than the other two groups (17-28%), $\chi^2(3)=228.692$, $p<0.001$. Trajectory groups showed significant differences in baseline ADOS calibrated severity scores (Table 1) (F=46.705, social affect; F=10.287, repetitive behaviors; p's<0.001). At both the baseline and final evaluations, the four groups varied significantly in their NVIQ and VIQ scores (p's<0.001). NVIQ was stable for all groups whereas group by age interaction emerged for VIQ (F=1.423, $p<0.05$) as VIQ improved for the nonspectrum and worsening groups but was stable for the other two groups. At the item level, children showed either an improvement (e.g., frequency of vocalization, use of gestures) or stability (e.g., eye contact, facial expression) on a majority of items although a few symptoms worsened (e.g., response to name).
Conclusions: Trajectories of ASD symptoms were most strongly predicted from initial levels of social communication impairments. Symptom levels for most children within the moderate to severe ranges initially were stable over the first and second year of life. A subset of children with ASD (20%) showed mild symptom levels during the first year, which worsened gradually over time, consistent with the past findings (e.g., Ozonoff et al., 2015). The initially lower symptom level may delay the ASD diagnosis in these children. The severely persistent group showed the most impairment in language and cognitive skills across time. Initially mild symptom levels predicted better language outcomes. More variability in trajectories was observed at the item level, suggesting that item trajectories do not necessarily follow the overall symptom trajectories.

10:50 **176.002** Stability and Change in ASD Symptoms from Childhood to Young Adulthood: Associations with Spoken Language Development

V. Hus Bal[1]*, M. Fok*[2] *and C. Lord*[3]*, (1)STAR Center for ASD & NDD; Dept of Psychiatry, University of California, San Francisco, San Francisco, CA, (2)University of California, San Francisco, San Francisco, CA, (3)Psychiatry, Weill Cornell Medical College, White Plains, NY*

Background: Â Previous studies suggest improvements in autism symptoms across child- and adulthood (McGovern & Sigman, 2005; Gillespie-Lynch et al., 2012). It is unclear, however, if all symptoms are improving or if specific behaviors show different trajectories. Although symptom manifestation is known to vary across language levels (e.g., Dilavore et al., 1992), the extent to which reported "improvements" reflect social-communicative development attributable to improvements in language has not yet been explored.
Objectives: Â To explore trajectories of social-communicative (S-C) symptoms from ages 2 to 18 in children exhibiting different language development patterns.
Methods: Â S-C symptoms of 132 children with ASD referred before 2 years were assessed using the Autism Diagnostic Interview-Revised (ADI-R) at five ages (approximately 2, 3, 5, 9, 18). Ten items from Current Behavior Algorithm S-C domain were summed to yield three subdomains (Nonverbal Behaviors, Shared Enjoyment, Socioemotional Reciprocity) and an overall S-C score. Because most children were language-delayed at 2, the sample was divided by language level at 3 and 18: verbal at 3 and 18 (V-V), delayed at 3/verbal at 18 (D-V), delayed at 3/minimally verbal at 18 (D-MV). Generalized Linear Mixed Models were used to explore trajectories of S-C symptoms; main effects of time and language group and time*language interactions were assessed.
Results: Overall S-C scores decreased across time (Fig1; p<.001). The D-MV group exhibited the most impaired S-C at all ages (p<.001). D-V and V-V differed only at T3 (p<.001). From 2-18, the D-MV group showed less improvement (Mdiff=2.65) than D-V (Mdiff=6.47) and V-V (5.91). Trajectories of Shared Enjoyment and Socioemotional Reciprocity showed similar patterns, with V-V and D-V groups demonstrating the greatest reduction in symptoms. Notably, the V-V group showed significant improvements in Shared Enjoyment from 2-3 and 3-5, whereas Socioemotional symptoms declined the most between 2-3. S-C items provided evidence for improvement, stability and, worsening of individual symptoms (Fig.2). While some items showed improvement across language levels, reduction of most symptoms seemed to be related to language development. Items relating to nonverbal communicative behaviors (inappropriate facial expressions and social smiling) showed stable or worsening trajectories.
Conclusions: Consistent with prior studies, overall social-communicative symptoms declined across childhood. These data suggest, however, that apparent improvements in some symptoms may be attributable to language gains, whereas others show improvement or stability across language levels. These findings underscore the difficulty in separating social and language abilities and the need to consider language skills when interpreting estimates of social-communicative behaviors, particularly in longitudinal or treatment studies monitoring changes over time. It is also important to highlight that ADI-R diagnostic classifications are based upon past behaviors; declines in symptoms (regardless of relation to language) demonstrate why current behaviors cannot be used in place of past symptoms for diagnostic purposes. Finally, differences in symptom presentation by both language and age highlight the need to develop new tools to assess current symptoms, particularly in adults with more developed language. Tools developed for use with younger children may not include items that capture the full manifestation of ASD in adulthood.

11:10 **176.003** Developmental Trajectories from Mid-Childhood to Early Adulthood in a Population Sample

T. Charman[1]*, R. Kent*[2]*, S. Lukito*[3]*, D. Stringer*[4]*, G. Baird*[5]*, A. Pickles*[6] *and E. A. Simonoff*[7]*, (1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Institute of Psychiatry, Psychology, and Neuroscience, King's College London., London, UNITED KINGDOM, (4)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (5)Newcomen Children's Neurosciences Centre, Evelina London Children's Hospital at Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM, (6)King's College London, London, UNITED KINGDOM, (7)Institute of Psychiatry, London, UNITED KINGDOM*

Background: An increasing number of studies have examined outcomes from childhood into adulthood in individuals with autism spectrum disorder (ASD). However, most samples have been clinically ascertained and few, if any, population-based.
Objectives: To examine early adult outcomes in the population-based Special Needs and Autism Project (SNAP) cohort (Baird et al., 2006).
Methods: From 158 children with ASD seen in the SNAP prevalence cohort at age 12 years a subsample were re-assessed in adolescence (age ~16 years, *n* = 90, excluding lowest IQ subsample) and young adulthood (age ~23 years, *n*= 126, full IQ range). We collected data on IQ (WISC, WASI), adaptive functioning (Vineland Adaptive Behavior Scale (VABS), Adaptive Behavior Assessment Scale (ABAS)) and mental health problems (Strengths and Difficulties Questionnaire (SDQ)). One-way repeated measures ANOVAs and post-hocs were run to determine if there were differences in scores across time.
Results: There were statistically significant differences over time for IQ, $F(2,146) = 43.4$, $p<0.001$; follow up t-tests found IQ at 23 years to be significantly higher than at 12 years ($p<0.001$) or 16 years ($p<0.001$). General adaptive behaviour composite scores were significantly higher at 23 years as measured using the ABAS than at 12 years as measured using the VABS ($t(110) = 15.28$, $p<0.001$). Total SDQ scores also varied significantly over time $F(2,146) = 31.3$, $p<0.001$; follow up t-tests found total SDQ score at 16 years ($p<0.001$) and 23 years ($p<0.001$) to be significantly lower than at 12 years. We are currently conducting multivariate analyses to examine the following questions: (1) using latent growth models to test the childhood predictors of young adult outcomes; and (2) using latent class analysis (LCA) approaches to examine individual trajectories over time. Finally, we will use a statistical weighting procedure to report estimates weighted back to the epidemiological sample from which the cohort was drawn.
Conclusions: In common with previously reported clinically-ascertained samples followed into adulthood, in the SNAP prevalence sample we found some evidence of improvements over time in intellectual ability and adaptive functioning and a reduction in mental health problems, at least as assessed by the SDQ screener. Some caution is required, in part because of the different measures used to assess IQ and adaptive behaviour over time and the developmental appropriateness of the SDQ in young adults. Adult outcomes in the population of individuals with ASD are highly variable and understanding more about mid-childhood predictors of young adult outcomes may help us clarify appropriate targets for intervention and support.

11:30 **176.004** Autism 30 Years Later: A Follow up Study of Children Diagnosed with ASD from 1970-1999

M. R. Klinger[1]*, N. Bagatell*[2]*, A. T. Meyer*[2]*, W. T. Brooks*[3] *and L. G. Klinger*[1]*, (1)UNC TEACCH Autism Program, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)TEACCH Autism Program, Carrboro, NC*

Background: While there is a developing literature on ASD in adulthood, few longitudinal studies from childhood to adulthood have been conducted. The majority of these studies have focused on the transition years from adolescence to young adulthood. Thus, there is little research on autism in middle adulthood.
Objectives: This research capitalizes on a unique data set of individuals who were diagnosed with ASD as children by the University of North Carolina TEACCH Autism Program from 1970-1999. Participants were reevaluated an average of 30 years after their initial diagnosis in order characterize changes in symptom severity, IQ, and adaptive behavior from childhood to mid-adulthood. Specific objectives included: (1) Measure the stability of ASD characteristics from childhood into middle adulthood; (2) Measure the relative increase or decrease in ASD characteristics from childhood into mid-adulthood.
Methods: Participants were 55 adults with ASD in mid-adulthood (27-57 years of age, M = 37 years) who had previously participated in a larger study of adult outcomes. All adults were diagnosed with an ASD during childhood (initial evaluations at 29 months to 16 years, M=6 years, 4 months). Participants participated in comprehensive assessments in adulthood including diagnostic (ADOS-2 and CARS-2), intellectual functioning (Stanford-Binet-5), and adaptive behavior (VABS-II) assessments. Additionally, childhood assessment data were also used from the CARS, IQ scores from a wide variety of tests, and Vineland Adaptive Behavior Scale (VABS).
Results: 54 out of 55 adults met diagnostic criteria across clinical judgment, CARS-2 and ADOS-2. CARS-2 scores during adulthood were modestly related to childhood CARS scores (r=+.34, p=.01), with little overall change in total CARS score (Childhood M=33.5, Adulthood M=33.1; t(54)=.45, p=.66). Intellectual functioning was remarkably stable across 30 years with adult IQ being strongly correlated to childhood IQ (r=+.71, p<.001). However, IQ scores showed a marginally significant drop over time (Childhood M=71.4, Adulthood M=66.9; t(52)=1.65, p=.10). Adaptive behavior was also quite stable across 30 years with adult VABS-II Standard Scores being strongly correlated to childhood VABS Standard Scores (r=+.52, p<.001). However, these scores showed a substantial decrease over time (Childhood M=61.1, Adulthood M=45.2; t(49)=5.29, p<.001).
Conclusions: In spite of a 30-year delay, ASD diagnoses were stable over time. Of the 55 participants in this study, only 1 did not receive a current ASD diagnosis. ASD symptoms, intellectual functioning, and adaptive behavior during adulthood were highly correlated with scores from childhood. This is especially impressive given the wide variety of IQ tests given during the childhood assessments. Both intellectual functioning and adaptive behavior showed decreased scores in adulthood indicating a decreased rate of development compared to the normative sample. This decrease was especially large for adaptive behavior indicating that adaptive behavior is a crucial area where individuals with ASD are at great risk to fall even further behind their peers as they move into adulthood. These adaptive behavior skills ought to be a primary target for interventions with children and adults with ASD as research suggests that adaptive behavior is the primary predictor of adult employment and quality of life.

Panel Session
177 - Altered Sensory Processing and Social Functioning in ASD: Examining Associations and Mechanisms through Multiple Methods and Populations.
10:30 AM - 12:00 PM - Yerba Buena 9

Panel Chair: Mirella Dapretto, *University of California, Los Angeles, Los Angeles, CA*

Discussant: Kevin Pelphrey, *Yale University, New Haven, CT*

Individuals with ASD have extremely high rates of sensory processing atypicalities, including over-responsivity, under-responsivity, and sensory seeking (Ben-Sasson et al., 2008). However, sensory symptoms have been understudied until recently, when they were added to the DSM-5 diagnostic criteria for ASD. Since then, sensory processing abnormalities have been increasingly recognized to be associated with greater impairment, including more social deficits (Glod et al., 2015). However, there has been little research examining how and why sensory processing difficulties are associated with social impairment. This panel addresses possible mechanisms underlying the association between atypical sensory processing and social symptomatology while highlighting recent advances in behavioral, physiological, and imaging methods for studying sensory processing from infancy through adolescence. Teresa Tavassoli will present data examining whether sensory and social symptoms are differentially associated across children with ASD, Sensory Processing Disorder, and typical development. Blythe Corbett will discuss the association between sensory symptoms, social difficulties, and accumulated stress (as indexed by evening cortisol). Shulamite Green will address neurobiological mechanisms underlying the effect of distracting sensory stimuli on social cognition. Finally, Carissa Cascio will present on sensory seeking and frontal alpha asymmetry as longitudinal predictors of social functioning in infants at high and low risk for ASD.

10:30 **177.001** Exploring the Relationship Between Sensory and Social Symptoms of Autism

T. Tavassoli[1], *L. J. Miller*[2], *S. A. Schoen*[3], *J. Brout*[4], *J. C. Sullivan*[5] *and S. Baron-Cohen*[6], *(1)Seaver Autism Center, New York, NY, (2)STAR Institute for SPD, Greenwood Village, CO, (3)Sensory Processing Disorder Foundation, Greenwood, CO, (4)Duke University Medical Center, Durham, NC, (5)Northeastern University, Boston, MA, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Children with autism spectrum conditions (ASC) often show atypical sensory reactivity symptoms in addition to social difficulties compared to typically developing (TD) children. It is unknown, however, whether sensory and social symptoms in ASC might be related to one another. To test this relationship we compared children with ASC to children who exhibit similar sensory symptomatology but do not have ASC, that is, children with the suggested diagnostic term 'sensory processing disorder' (SPD).
Objectives: Â The goals of this study were to determine if a) sensory and social symptoms are related, and b) if children with ASC could be distinguished from children with SPD based on sensory and/or social features. Specifically, we sought to differentiate children with ASC and SPD on sensory subtypes (e.g. over-reactive, under-reactive and sensory craving) and amount of sensory symptoms and/or on social features, specifically empathy using parent questionnaires.
Methods: The study included 210 participants: 68 children with ASC, 79 children with SPD and 63 typically developing (TD) children. We used the Sensory Processing Scale Inventory to measure sensory symptoms (over-reactivity, under-reactivity and sensory craving); the Autism Spectrum Quotient (AQ) to measure autistic traits, and the Empathy Quotient (EQ) to measure social skills.
Results: Children with ASC and SPD showed more sensory symptomatology than TD children (p< .01). Furthermore, even though children with SPD had higher empathy scores compared to children with ASC, they had lower empathy scores compared to TD children (p< .01). Last, sensory symptomatology and social features showed a negative correlation with each other, across groups.
Conclusions: Taken together, our findings suggest that there is a relationship between sensory symptomatology and social aspects of ASC. Children with ASC are most affected by sensory symptoms, and show lowest empathy. Children with SPD lie in between children with ASC and typical developing children on these measures. Future longitudinal studies are needed to explore if children with ASC and SPD both start with the same amount or type of sensory symptoms in early childhood and whether there is a difference in the type of sensory symptoms they display. This study also sheds light on the similarities and differences between children with ASC and SPD. Improved sensory and social phenotyping is an essential first step towards reducing diagnostic confusion between ASC and SPD.

10:50 **177.002** Examining Tactile Sensitivity and Associations with Physiological Arousal and Social Functioning in Youth with Autism Spectrum Disorder.

B. A. Corbett[1] *and R. A. Muscatello*[2]*, (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Neuroscience Graduate Program, Vanderbilt University, Nashville, TN*

Background: Autism spectrum disorder (ASD) is characterized by significant difficulties in social cognition and communication, as well as impairments in sensory processing. Previous findings have consistently shown elevated evening cortisol in youth with ASD compared to typically developing (TD) peers (Tomarken et al., 2015), suggesting increased accumulation of stress throughout the day (Corbett et al., 2009). Various factors may underlie this increased arousal, to include significant stress from social interaction, changes throughout the days, or heightened sensory sensitivity to internal or external stimuli.
Objectives: The current study examined potential associations between sensory processing, physiological arousal, and social responsiveness in ASD. It was hypothesized that underlying sensory defensiveness would be associated with increased arousal and reduced social functioning in youth ASD.
Methods: A large sample (N=113) of youth with ASD (N=64) or TD (N=49) between 8 and 17 years of age were recruited. Evening cortisol was collected as part of a larger study, which collected diurnal salivary samples over 3 days at home, 4 times per day (Immediate Waking, 30-min post-waking, afternoon, and evening). Sensory sensitivity was reported using the Short Sensory Profile (SSP). Social functioning was assessed by three parent-report measures including the Social Communication Questionnaire (SCQ), Social Responsiveness Scale (SRS), and the Child Behavior Checklist (CBCL). Pearson product correlations were conducted to measure levels of association between dependent variables.
Results: Sensory functioning (SSP) was negatively correlated with evening cortisol at trend-level ($r=-.18$, $p=0.08$). When individual subscales of the SSP were explored, a significant negative correlation was observed for the Tactile domain and evening cortisol ($r=-.28$, $p=0.007$). Moreover, the SSP Tactile domain was also negatively associated with measures of social functioning, including the SCQ ($r=-.64$, $p<0.001$), the SRS total score ($r=-.69$, $p<0.001$), and the social problems subscale on the CBCL ($r=-.69$, $p<0.001$). Within group comparison for the ASD group, corroborated relationships between tactile sensitivity and physiological and social functioning: SSP Tactile showed negative associations with evening cortisol ($r=-.31$, $p=0.03$), SCQ ($r=-.33$, $p=0.02$), SRS ($r=-.43$, $p<0.001$), and social problems on the CBCL ($r=-.61$, $p<0.001$). In the TD group, tactile sensitivity was only correlated with total SRS ($r=-.36$, $p=0.01$).
Conclusions: The study reveals significant associations between evening cortisol, sensory processing, and social functioning. Tactile sensitivity was related to physiological regulation and social responsiveness, such that impaired tactile processing corresponded with elevated evening cortisol and greater impairment in social functioning. Findings suggest sensory processing, especially tactile defensiveness, may underlie a number of symptoms in ASD, including accumulated stress, social responsiveness, and social symptom severity. The lack of significant findings in the TD group further suggest this underlying role of sensory processing may be unique to ASD. Tactile responsiveness may serve as a marker of more significant impairment in other core symptom domains, and future research should be directed towards understanding the directionality of these relationships, such that treating one symptom may directly or indirectly improve the others.

11:10 **177.003** Sensory over-Responsivity and Social Cognition in ASD: Effects of Aversive Sensory Stimuli and Attentional Modulation on Neural Responses to Social Cues

S. A. Green[1]*, L. M. Hernandez*[2]*, H. Bowman*[3]*, S. Y. Bookheimer*[4] *and M. Dapretto*[4]*, (1)Ahmanson-Lovelace Brain Mapping Center, UCLA, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)NPI Psychiatry, UCLA, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA*

Background: Sensory over-responsivity (SOR) is an impairing condition manifested as extreme sensitivity to stimuli such as unexpected loud noises or being touched. SOR is particularly common (rates of 56-70%) in autism spectrum disorders (ASD) and, notably, it is associated with higher impairment including greater deficits in social and adaptive behavior (Ben-Sasson et al., 2008). Although SOR is strongly linked to impairment, the mechanisms through which it disrupts social functioning are not well understood. Previous research from our lab suggests that SOR may be related to an overattribution of salience to extraneous sensory information. Individuals with ASD and SOR show hyperactivation and reduced habituation in the amygdala and sensory cortices in response to mildly aversive sensory stimuli (Green et al., 2015), as well as increased salience network connectivity with amygdala and somatosensory cortex (Green et al., 2016). Taken together, these studies suggest that SOR is associated with atypical allocation of attention to extraneous sensory stimuli rather than relevant social stimuli. Yet, the effect of sensory distracters on the brain's ability to process social information has not been tested directly.
Objectives: To examine the effect of a tactile sensory distracter on brain responses during a social cognition task, and to test whether explicitly directing attention to relevant social cues can mitigate the effect of the sensory distracter.
Methods: Participants were 15 children and adolescents with ASD and 16 TD matched controls, between 8-17 years of age. While undergoing fMRI, children completed a social cognition task, which involved determining whether a speaker was sarcastic or sincere. They completed the task with/without a tactile sensory distracter, and with/without instructions directing their attention to relevant social cues. Parents completed the tactile scales of the Short Sensory Profile (Dunn, 1999) and SenSOR Inventory (Schoen et al., 2008); scores were combined into a tactile SOR composite.
Results: When completing the task in the presence of the sensory distracter, TD youth showed increased activity in auditory language and frontal regions whereas ASD youth showed decreased activation in these areas. Instructions mitigated this effect such that ASD youth no longer showed decreased activation during tactile stimulation; instead, the ASD group showed increased medial prefrontal (mPFC) activity. With attentional instructions, higher SOR was associated with greater activity in primary auditory and visual cortex as well as higher-level language and face processing regions, whereas lower SOR was associated with greater activity in temporal pole and mPFC, regions associated with integrative social cognition such as inference and theory of mind.
Conclusions: Results demonstrate for the first time a neural mechanism through which sensory stimuli may disrupt social cognition, and that attentional modulation can restore neural processing of social cues through prefrontal regulation. Attentional modulation may work through different mechanisms depending on level of SOR: youth with high SOR may rely on processing individual visual and auditory stimuli whereas youth with low SOR may be better able to integrate and interpret multiple social cues. Findings have implications for novel, integrative interventions that incorporate attentional directives to target both sensory and social symptoms.

11:30 **177.004** Neurophysiological Substrates and Developmental Sequelae of Sensory Seeking in Infants at High Risk for Autism Spectrum Disorder

T. Woynaroski[1]*, C. Damiano*[2]*, D. M. Simon*[3]*, L. V. Ibanez*[4]*, C. R. Newsom*[5]*, M. Murias*[6]*, M. T. Wallace*[7]*, W. L. Stone*[8] *and* ***C. J. Cascio***[9]*, (1)Hearing and Speech Sciences, Vanderbilt University Medical Center, Thompsons Stn, TN, (2)University of North Carolina, Durham, NC, (3)Program in Neuroscience, Vanderbilt University, Nashville, TN, (4)UW READi Lab, Seattle, WA, (5)Pediatrics, Vandetbilt University Medical Center, Nashville, TN, (6)Duke University, Durham, NC, (7)Vanderbilt University, Nashville, TN, (8)Psychology, University of Washington, Seattle, WA, (9)Vanderbilt University School of Medicine, Nashville, TN*

Background:
Children with autism spectrum disorder (ASD) show a broad range of unusual responses to sensory stimuli and experiences. It has been proposed that early differences in sensory responsiveness may arise from atypical neural function and produce “cascading effects” on development across a number of domains. A primary challenge to confirming these hypotheses is that ASD cannot always be definitely diagnosed in the earliest stages of development (i.e., infancy). A potential solution is to prospectively follow infants at heightened risk for ASD based on their status as infant siblings of children who are diagnosed. The present study examined the developmental sequelae and possible neurophysiological substrates of a specific sensory response pattern: unusually intense interest in nonsocial sensory stimuli or “sensory seeking.” Infants at high risk (HR) for ASD were compared to a control group of infants at relatively lower risk for ASD (LR; siblings of children with typical developmental histories).
Objectives:
Research questions included: a) Do HR infants differ from LR infants in sensory seeking behavior?, b) Does sensory seeking predict concurrent social orienting and future socialization?, and c) Is sensory seeking predicted by early frontal alpha asymmetry?
Methods:
To answer these research questions, we carried out a longitudinal correlational investigation in which 20 HR infants and 20 LR controls were followed over 18 months. At entry to the study, sensory seeking and social orienting were measured in 18-month-old infants using the Sensory Processing Assessment, and alpha asymmetry was measured via resting state EEG. Eighteen months later, social symptomatology was evaluated in a comprehensive diagnostic evaluation.
Results:
HR infants showed elevated sensory seeking relative to LR controls ($t_{(38)}$=2.26, p = .029), and increased sensory seeking predicted reduced social orienting across groups, concurrently (β=.570, t=2.822, p < .0001) at eighteen months. Seeking behavior additionally predicted future social symptomatology across groups (β=.376, t = 2.78, p = .008), but this effect varied by group (seeking*risk group interaction β=.672, t=4.448, p =.008), such that higher seeking at 18 months predicted increased social symptoms in the HR group, but decreased social symptoms in the LR group.Â A mediation analysis indicated that social orienting mediates the relation between sensory seeking and social deficits, and that this effect is moderated by risk group. The relation between frontal asymmetry and sensory seeking at 18 months also varied according to risk group (seeking*risk group interaction β=-2.458, t=-3.38, p = .002), such that increased sensory seeking was associated with greater right asymmetry in the HR group, but with greater left asymmetry in the LR group.
Conclusions:
Findings suggest that sensory seeking may produce cascading effects on social development in infants at heightened risk for ASD by impeding social orienting early in life. Atypical frontal alpha asymmetry may underlie this atypical behavioral pattern of sensory responsiveness.

Poster Session
178 - Early Development (< 48 months)
12:00 PM - 1:40 PM - Golden Gate Ballroom

1 **178.001** Early Social Communication Predictors of Emergent Literacy Skills in Preschool Children with Autism Spectrum Disorder

V. P. Reinhardt[1,2] *and A. M. Wetherby*[2]*, (1)MIND Institute, University of California Davis, Davis, CA, (2)Florida State University Autism Institute, Tallahassee, FL*

Background:
Reading proficiency is pivotal for academic success, with wide ranging societal, educational, and economic costs associated with low literacy attainment (Baer, Kutner, Sabatini, & White, 2009). The core social communication features and associated language difficulties frequently observed in children with Autism Spectrum Disorder (ASD) place them at risk for developing reading difficulties (Ricketts, Jones, Happé, & Charman, 2013). Reading difficulties (RD) are among the most common and persistent areas of learning challenges in students with ASD (Huemer & Mann, 2010; Randi, Newman, & Grigorenko, 2010). Preschool emergent literacy (EL) skills are developmental precursors to school-age literacy and academic skills and provide the means to identify children at risk for RD early. The literature examining EL skills in children with ASD is limited, and few investigations have examined predictors of EL skills.
Objectives:
To examine the relations between early social communication (18-24 months) and preschool emergent literacy skills in a longitudinal sample of children with ASD.
Methods:
Children in the current study (n=45; 38 male) were recruited from the FIRST WORDS®Project (Wetherby et al., 2004), a prospective longitudinal study of children at the Florida State University Autism Institute. Children in the current study completed the Communication and Symbolic Behavior Scales (CSBS) Behavior Sample between 18-24 months (M= 21.45, SD= 1.37) and a comprehensive language and literacy battery around 4-5 years of age (M= 60.34, SD= 4.57). To confirm ASD diagnosis, all children participated in a comprehensive ASD evaluation battery that included the Autism Diagnostic Observation Schedule, Mullen Scales of Early Learning and Vineland Adaptive Behavior Scales and received a best-estimate diagnosis of ASD. EL skills including print knowledge and phonological awareness were measured using the development version of the Test of Preschool Early Literacy (Lonigan, Wagner, Torgesen, & Rashotte, 2007). Oral language was evaluated using the Clinical Evaluation of Language Fundamentals- Preschool (Wiig, Secord & Semel, 1992), Peabody Picture Vocabulary Test-III (Dunn & Dunn, 1997), and the Expressive One-Word Picture Vocabulary Test-Revised (Brownell, 2000). Nonverbal cognitive functioning was measured using three subtests of the Stanford-Binet Intelligence Scale, Fourth Edition (SB-IV; Thorndike, Hagen, & Sattler, 1986).
Results:
Predictive relations between CSBS cluster scores and latent preschool Oral Language, Phonological Awareness, and Print Knowledge variables were examined using multiple regression. Findings indicated moderate, significant relations between the CSBS Emotion and Eye Gaze cluster and preschool oral language (r = 0.49, p = 0.001) and between the CSBS Understanding Cluster and preschool oral language (r = 0.50, p < 0.001). In addition, there was a moderate, significant predictive relation between the CSBS Understanding cluster and preschool phonological awareness (r = 0.31, p< 0.05).
Conclusions:
These findings provide preliminary evidence that early social communication skills in the second year of life may offer a useful strategy to predict later language and reading difficulties. Delineating predictors of EL has important implications for understanding how early social communication deficits impact the development of reading in children with ASD.

2 **178.002** "The Phenomenon of Loss." Early Development and Functional Outcome in Children with Autism Spectrum Disorder and Reported Developmental Regression.

S. D. Boterberg[1]*, R. Van Coster*[2] *and H. Roeyers*[1]*, (1)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Department of Pediatric Neurology & Metabolism, Ghent University Hospital, Ghent, Belgium*

Background: Although in most children with ASD an *early onset* of symptoms can be observed, about one-third appears to show a loss of previously established skills somewhere in the second year of life, a phenomenon called *regression*. Recently, additional patterns of onset have been described such as *early onset+regression* and *plateau*. However, due to methodological issues and different views on the definition of regression, still little is known about early pathways, causes, predictors and prognosis.
Objectives: The first purpose is to explore the trajectories of different onset patterns in ASD. Second, we want to examine if pre-regression development is really typical. Third, outcomes in terms of severity of ASD-symptoms, language and behavioural functioning will be investigated.
Methods: Participants are 100 children (4-10y) with a diagnosis of ASD. Parent report is used to measure early ASD-symptoms, classification to onset groups (EDQ, ADI-R, RSQ) and current behavioural problems (CBCL). Non-verbal intelligence is measured through the WNV. Current severity of ASD-symptoms is both reported by parents (SCQ, SRS) and clinically evaluated (ADOS-2). Outcomes in language reception and production are measured through the CELF-4 and by parent report (NCDI).
Results: Preliminary results based on 54 children revealed an *early onset* (*n*=23), a *later onset* (*n*=15) and an *early onset+regression* group (*n*=6). Other children had a typical development followed by *regression* (*n*=8) or *plateau* (*n*=3). Regression involved in 92% of the children loss of language skills, in most cases combined with loss of other skills such as social skills. In 38% of the children loss or a stagnation in motor skills (mean onset: 18m) was reported to precede loss in other skills (mean onset: 24m).
Analysis of early development shows similar scores of social and stereotyped behaviours in the first 18 months of life in both the regression (ASD-R) and non-regression group (ASD-NR). Further, ASD-R showed even less early communicative behaviours ($U(50)=105.5; p<.01$) and received the clinical diagnosis of ASD at a younger age than ASD-NR (38m vs 67m; $t(52)=4.2; p<.001$).
Analysis of current functioning shows lower non-verbal intelligence scores (67 vs 92; $U(54)=83.5; p<.001$) in ASD-R. Examination of current severity of ASD-symptoms and behavioural problems based on parent report shows no significant differences. However, on the ADOS-2 there are significantly more restricted and repetitive behaviours ($U(54)=486; p<.001$) in ASD-R, especially more sensory interests ($\chi^2(1)=14.6; p<.001$) and mannerisms ($\chi^2(1)=27.6; p<.001$). Analysis of current language outcome shows both an increased delay in receptive and expressive language (37m vs 11m; $t(51)=3.3; p<.01$ and 32m vs. no delay; $t(51)=3.6; p<.01$, respectively) in ASD-R.
Conclusions: We found support for different onset patterns previously described in the literature. Since some parents report motor atypicalities preceding loss of other skills, some evidence is provided for the over-pruning hypothesis as a neuropathological mechanism of regression. Further, the majority of ASD-R appears to have pre-existing social-communicative difficulties and received their clinical diagnosis earlier than ASD-NR, supporting that regression may provide a useful “red flag” in identifying children who are at risk for ASD. Furthermore, ASD-R display more severe impairments later in life as measured by non-verbal IQ, clinical evaluation of ASD-symptomatology and language abilities.

3 **178.003** 'Sticky Attention' and the Development of Impaired Social Orienting and Atypical Arousal Regulation in Infants at High Risk for ASD

B. Keehn[1], *J. B. Wagner*[2], *H. Tager-Flusberg*[3] *and C. A. Nelson*[4], *(1)Purdue University, West Lafeyette, IN, (2)College of Staten Island, CUNY, Staten Island, NY, (3)Psychological and Brain Sciences, Boston University, Boston, MA, (4)Boston Children's Hospital, Boston, MA*

Background: Flexibly shifting attention – disengaging from a current locus and shifting attention to a new object or event within the environment – plays an important role in the development of both social orienting and arousal regulation. In infants at high risk for autism (HRA), slowed attentional disengagement is one of the earliest impairments reported, and is associated with a later diagnosis of the autism spectrum disorder (ASD). Thus, early deficits in disengagement may contribute to the atypical development of social orienting and/or arousal regulation, and play an important role in the emergence of ASD.
Objectives: To investigate the association between attentional disengagement, measured at 6 months, and development of social orienting and arousal modulation, measured at 12, 18, and 24 months, in HRA (with and without a later diagnosis of ASD) and low-risk comparison (LRC) infants.
Methods: Infants completed visits at 6, 12, 18, and 24 months of age. An eye-tracking paradigm was used to assess the speed of attentional disengagement at 6 months (n=35 HRA; n=42 LRC). Latency to disengage attention was measured as the time necessary to shift attention from a central fixation (i.e., a face) to a peripheral target. Social orienting abilities were assessed using three observational measures, the Communication and Symbolic Behavior Scales (CSBS) and the Autism Observation Scales for Infants at 12 months, and the Autism Diagnostic Observation Schedule at 18 and 24 months, as well as the CSBS parent-report questionnaire at 12 and 18 months. Arousal regulation was measured using a series of parent-report questionnaires: the Infant Behavior Questionnaire at 12 months, the Toddler Behavior Assessment Questionnaire at 18 and 24 months, and the Infant Toddler Social Emotional Assessment at 12, 18, and 24 months. Items and subscales from these measures were standardized and averaged to create social orienting and arousal regulation composite scores at 12, 18, and 24 months.
Results: Latency to disengage attention at 6 months did not differ significantly between HRA and LRC groups. For the LRC group, but not the HRA group, faster disengagement latency at 6 months was associated with better social orienting abilities at 12 months, $r(31) = .53$, $p<.01$ (see Figure 1). For the HRA group, but not the LRC group, slower attentional disengagement was related to poorer arousal regulation at 12 months, $r(33) = .59$, $p<.01$, 18 months, $r(28) = .54$, $p<.01$, and 24 months, $r(26) = .47$, $p<.05$.
Conclusions: Efficient attentional disengagement is vital for the adaptive allocation of attention (e.g., sharing attention with a communicative partner) and facilitates early arousal regulation (e.g., shifting attention away from an over-arousing stimulus). Preliminary results suggest that faster attentional disengagement is associated with more skillful social orienting abilities at 12 months in LRC but not HRA infants. In contrast, for the HRA group, increased latency to disengage attention was associated with greater aversion to novelty and difficulties in regulating arousal. Our findings suggest that atypical attentional disengagement may have sequelae that, in combination with other primary disturbances, contribute to the emergence of the ASD phenotype.

4 **178.004** A Results Driven Approach to Evaluating Progress for Toddlers with ASD Participating in a State Early Intervention Program

D. M. Noyes-Grosser[1], *K. M. Siegenthaler*[1], *Y. Wu*[1], *B. Elbaum*[2] *and R. G. Romanczyk*[3], *(1)New York State Department of Health, Bureau of Early Intervention, Albany, NY, (2)University of Miami, Coral Gables, FL, (3)State University of New York at Binghamton, Binghamton, NY*

Background: States must report annually to the U.S. Department of Education on child outcome indicators for toddlers exiting Part C Early Intervention (EI) Programs. Data are aggregated across the heterogeneous group of children in EI for reporting purposes. In New York State, children with ASD represent approximately 11% of children receiving EI. However, outcomes are not reported separately for this group.
Objectives: To evaluate outcomes of Part C EI services, using federal outcome indicators, for toddlers with ASD in New York State's EI Program (NYSEIP).
Methods: Early intervention and preschool special education evaluation records were obtained for 160 children with ASD in the NYSEIP. Trained reviewers completed the Child Outcome Summary (COS) rating (National Early Childhood Outcomes Center, 2005) in three federal outcome areas:Â social emotional development, including positive social relationships; acquisition and use of knowledge and skills, including early language and literacy; and use of appropriate behaviors to meet needs. Ratings within each outcome area were derived from evaluations conducted on entry to EI and exit to preschool special education. Standardized test scores in all developmental areas were used to determine COS ratings, except in a few instances where scores were not available and descriptive developmental information was used instead. Based on entry and exit ratings, children were classified into 3 groups: (a) received the same score at both time points (consistent delay compared to typically developing [TD] peers), (b) had a higher score on exit than on entry (moved closer to TD peers), or (c) had a lower score on exit than on entry (lost ground compared to TD peers).
Results: In the area of social-emotional development, 42% of toddlers with ASD moved closer to TD peers, 25% maintained a consistent delay, and 31% lost ground compared to TD peers. In the area of acquisition and use of knowledge and skills, 55% moved closer to TD peers, 29% maintained a consistent delay, and 16% lost ground. In the area of using appropriate behaviors to meet needs, 23% moved closer to TD peers, 30% maintained a consistent delay, and 48% lost ground compared to TD peers.
Conclusions: Most studies examining the effect of EI on young children with ASD can be characterized as efficacy studies conducted in controlled research environments (Weitlauf et. al.,2014). This study is unique in evaluating outcomes for children with ASD participating in community-based services delivered through a state Part C EI program. The majority of toddlers with ASD participating in the NYSEIP moved closer to the skill level of TD peers in the area of acquisition and use of knowledge and skills (55%). A smaller percentage showed acceleration of skill development in social-emotional development (42%) and using appropriate behavior to meet their needs (23%). These findings are consistent with those from controlled studies, suggesting EI services delivered through state Part C programs are effective in improving outcomes for children with ASD. Examination of service delivery characteristics associated with positive outcomes can inform development of more effective services for toddlers with ASD and their families.

5 **178.005** Are Longitudinal Associations Between Joint Attention and Language Attributable to Nonsocial Attention in Infancy? an Infant Sibling Study

M. Del Rosario[1]*, S. Singh*[2]*, N. Pham*[2] *and K. Gillespie-Lynch*[3]*, (1)Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Department of Psychology, College of Staten Island and The Graduate Center, CUNY, New York, NY*

Background:
Longitudinal associations between joint attention (JA) and language commonly documented among children with and without autism (Brooks & Meltzoff, 2005; Sigman and Ruskin, 1999) are often interpreted as evidence that both JA and language reflect social understanding (Charman et al., 2000). Keehn and colleagues (2013) hypothesized that atypical non-social attention may underlie impaired JA and contribute to language difficulties among autistic children. Positive associations between the duration of non-social attention in infancy and later language have been demonstrated among typically developing (TD) children (Kannass & Oakes, 2008). Longitudinal associations between social attention, JA, and language have also been documented among TD children (Salley et al., 2013).
Objectives:
To investigate if 12-month nonsocial or social attention is associated with 18-month JA and examine if nonsocial attention accounts for associations between JA and language.
Methods:
Participants with (n = 65) or without (n = 41) an autistic sibling were classified as autistic (n = 9), other concerns (n =17), or TD (n = 80) by a clinician at 36 months or later. At 12 and 18 months, RJA and IJA were assessed with the ESCS. Examiners also caught participants' attention and shook two rattles for approximately 15 seconds. The rate of gaze shifts between rattles (nonsocial attention) and the duration of attention to the examiner (social attention) were coded. The MSEL were administered at 18, 24, and 36 months.
Results:
Nonsocial and social attention at 12 and 18 months were not correlated with 18-month IJA or RJA (ps > .07). We ran repeated measures general linear models with raw expressive and receptive language at 18, 24 and 36 months as dependent variables and outcome, 18-month RJA and IJA as predictors. We then added nonsocial and social attention at 12 and then 18-months to each model. IJA, RJA and outcome were associated with overall expressive language (ps< .05). Outcome predicted changes in expressive language (p< .001). When 12-month attention was entered, nonsocial attention (fewer gaze shifts), IJA and outcome were associated with overall expressive language (ps< .05) while RJA and social attention were not (ps> .12). When 18-month attention replaced 12-month attention, only nonsocial attention and outcome were associated with overall expressive language (ps < .01); RJA, IJA, and social attention were unrelated (ps> .12). RJA, IJA and outcome were initially associated with overall receptive language (ps< .02). When 12-month attention was entered, nonsocial attention, IJA, and RJA (ps< .02) were associated with overall receptive language; social attention and outcome were unrelated (p> .06). When 18-month attention was entered, RJA, nonsocial attention and outcome were associated with overall receptive language (ps < .05) while IJA and social attention were not (ps > .06).
Conclusions:
These findings demonstrate that reduced distractibility contributes to commonly observed associations between JA and language among children with and without autism. However, nonsocial attention was unrelated to JA and some associations between JA and language remained apparent when nonsocial attention was accounted for. Nonsocial attention is not a clear precursor for JA but both contribute to language development.

6 **178.006** Atypical Visual Attention in Infants at High Genetic Risk for Autism Spectrum Disorder

D. Reisinger*, A. Brewe, K. Smith, A. Vittes and J. Roberts, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Evidence indicates that developmental changes in visual attention between 6 to 12 months-of-age predict later autism spectrum diagnoses (ASD; Ibanez et al., 2008). Infants with fragile X syndrome (FXS) are at high risk for developing ASD, as are infants with an older sibling diagnosed with ASD (ASIBs). Abnormal attention to objects have been documented as early as two months of age and extending into preschool years in ASIBs (Jones & Klin, 2013). Similar findings have been identified in FXS (Roberts et al., 2012). To date, no groups have investigated how these two high-risk groups differ in their attention to objects. Investigating early deficits in visual attention in infants at high risk for ASD can refine the infant phenotype of FXS and ASIBs and serve as a potential prognostic indicator of ASD risk.
Objectives: Our aim was a cross-syndrome characterization of the relationship of object attention in high risk samples at 9, 12 and 24 months of age and its predictive value to ASD severity at 24 months.
Methods: Participants included infant males with FXS (n=18), ASIBs (n=26), and typically developing infants (TD; n=28) assessed at 9, 12 and 24 months of age. Proportion of time looking at toy keys was the dependent variable (LabTAB; Goldsmith & Rothbart, 1996) with visual attention coded offline (κ=0.85). The Mullen controlled for developmental level, and the Autism Diagnostic Observation Schedule-2 reflected autism severity at the 24-month outcome.
Results: Developmental level was included in all models. ANCOVAs suggest no groups differences at 9 or 12 months of age (*p*s>0.05) in attention to objects. However, at 24 months of age there were group differences ($F(2,54)=3.09$, $p=0.05$, *partial* $\eta^2= 0.10$). TD infants spent more time looking at the object in comparison to ASIBs. Regression models examined object attention predicting later ASD severity. At 9 months, increased object attention was predicative of decreased ASD severity at 24 months in ASIBs (*B*=-11.43, *SE*=2.96, *p*=0.01), but not in FXS (*B*=-11.66, *SE*=5.84, *p*=0.11). At 12 months, increased object attention was associated with increased ASD severity at 24 months in infants with FXS (*B*=20.46, *SE*=8.96, *p*=0.04), but not in ASIBs (*B*=-5.11, *SE*=4.23, *p*=0.25). At 24 months, object attention was not predictive of ASD severity at 24 months in FXS (*B*=2.75, *SE*=3.86, *p*=0.49) or ASIBs (*B*=5.42, *SE*=3.02, *p*=0.09).
Conclusions: Our results suggest infants with FXS, ASIBs, and TD infants display similar profiles in their attention to objects during the first two years of life, with differences emerging at 24 months of age between infant ASIBs and TD infants. Object attention appears to be related to ASD outcomes differentially in these two high-risk groups. Decreased object attention in ASIBs at 9 months was associated with increased ASD symptoms, whereas increased object attention at 12 months in FXS was related to increased ASD symptoms. These findings suggest that, although object attention may manifest differently in these two groups, they both are associated with ASD outcomes. It appears different mechanisms specific to these two phenotypes impacting object attention may produce similar outcomes relative to ASD.

7 **178.007** Birth Order and Sibling Status Impacts Psychometrics of M-CHAT-R with Follow-up (M-CHAT-R/F)

K. R. Bradbury[1], *D. L. Robins*[2], *M. Barton*[1], *W. L. Stone*[3], *Z. Warren*[4] *and D. A. Fein*[1], *(1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (3)Psychology, University of Washington, Seattle, WA, (4)Vanderbilt University, Nashville, TN*

Background:
The M-CHAT-R/F is a parent-completed, screening instrument to detect autism spectrum disorder (ASD) in toddlers. When a child screens positive on the initial items, the structured follow-up interview confirms responses and reduces false positives. The presence of older siblings as a comparison can impact parent's perception of development in later-born children. Previous research suggests that parents report developmental concerns about their first-born child significantly later than concerns about later-born children. Furthermore, concerns for later-born children are reported even earlier when there are older ASD-affected siblings. The current study proposes to explore how birth order (first-born vs. later-born) and sibling status (ASD-Sibs vs. NonASD-Sibs) affect performance on the M-CHAT-R/F.
Objectives:
To compare M-CHAT-R/F performance in first-born children (No-Sibs) and later-born children with an older sibling with ASD (ASD-Sibs) or an older sibling without ASD (NonASD-Sibs).
Methods:
Toddlers (*n*=321; *M* = 21.4 mos, *SD* = 3.6) were evaluated after screening positive on the 2-stage M-CHAT-R/F. Diagnostic outcome (ASD vs. non-ASD) was compared across groups using chi square. In a subset of children who received an ASD diagnosis (*n*=126), total scores and item performance at initial and follow-up screen were compared for first-born children (*n*=50) and two groups of later-born children (ASD-Sibs, *n*=30; NonASD-Sibs, *n* = 46). ASD severity, measured by CARS total scores and ADOS severity scores, was compared across groups using one-way ANOVA.
Results:
Samples did not differ on most demographic variables, although the ASD-Sibs group included fewer minority children than the other groups. Findings held when the confound of race was removed from the model. Children in the ASD-Sibs group were more likely to be diagnosed with ASD ($PPV_{ASD\text{-}Sibs}$ = .64; $PPV_{No\text{-}Sibs}$= .55; $PPV_{NonASD\text{-}Sibs}$ = .35, p = .001). In the subset of children with ASD, initial screener scores did not differ between groups ($F(2,123) = 1.396$, p = .251); however, scores after follow-up differed significantly ($F(2,123) = 3.684$, p = .028). Post-hoc comparisons using the Tukey HSD test indicated that the No-Sibs group (*M*=4.47, *SD*=2.89) scored significantly lower after follow-up compared to the ASD-Sibs group (*M*=6.73, *SD*=3.01), whereas the NonASD-Sibs group's (*M*=5.8, *SD*=3.72) scores did not differ from either group. Failed items that were more likely to change to pass with further questioning represented subtle social developmental milestones (e.g., showing to share, following gaze, social referencing) as determined by chi square (*p*'s<.02). No differences were observed between groups on CARS scores and ADOS calibrated severity scores (*p*'s >.5).
Conclusions:
Birth order may impact parents' responses on screening measures, such as the M-CHAT-R, particularly when an ASD-affected child is in the household. Parents of first-born children are more likely to change their responses at follow-up, suggesting a decreased awareness of subtle developmental milestones, especially compared to parents of ASD-Sibs. Diminished change between screener and follow-up for the ASD-Sibs group may suggest accurate reporting, although hypervigilance might also play a role. As ASD severity was comparable across groups, these findings are likely representative of differences in parent experience as opposed to differences in ASD symptomatology.

8 **178.008** Bridging Early Diagnosis and Intervention: Racial Differences in Accessing Early Intervention

B. A. Brooks[1], *L. Armistead*[2], *L. B. Adamson*[2] *and D. L. Robins*[3], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Georgia State University, Atlanta, GA, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: It is important to facilitate the transition to treatment after an early diagnosis of ASD. Delays entering Early Intervention (EI) may occur for many reasons, including how parents perceive the diagnosis (Abrams & Goodman, 1998) and coordination of intervention services (Bailey et al., 2004). Minority families may have additional barriers to access ASD-specific EI. Research indicates that racial minorities, lower income families, and parents with less education report more difficulty entering EI services than families that are more affluent, educated, or those that do not identify as a racial minority (Carr et al., 2015; Zwaigenbaum, 2015).
Objectives: This exploratory study investigated racial differences in accessing EI services following toddler diagnosis of ASD or other developmental delays.
Methods: Parents were recruited as part of a feasibility study of the transitional period following a diagnosis of ASD (*n*=13), Global Developmental Delay (*n*=14), or language disorder (*n*=9). Thirty-six mothers of toddlers (M_{age} =22.72 months *SD*=3.70) were contacted approximately 12 weeks following diagnosis (*M*=87.28 days, *Median*=78.50 days, *SD*=27.56). Majority (*n*=14non-Hispanic Caucasian) and Minority mothers (*n*=21 African American, 1 Latino) answered open-ended questions about accessing EI services. Responses were coded on a continuous scale (0 = "I have not contacted EI services", 4 = "My child is currently receiving therapy." "Child is receiving *more* than 10 hours of services per week."). Two coders reliably rated responses (*Kappa* =.89, *p*<.001).
Results: Majority mothers (M_{EIcode}=2.93, SD=.27; e.g., "My child is receiving therapy") were further along in the EI process than minority mothers (M_{EIcode}=1.91, SD=1.27; eg., "I have contacted several providers/I am on the waitlist to receive services"), *r*(35)=-.46, *p*=.01. Race (*β*=-..42, *p*=.01) predicted access to EI above and beyond maternal education, R^2 =.22, *F*(2, 35)=4.53 *p*=.02. Total hours of therapy between majority (*M*=1.39, *SD*=.1.42 and minority children did not differ significantly (*M*=.89 *SD*=1.44) *t*(34)=.04, *p*=.84, *d*=.35, small effect, range 0-6 hours). There was not a significant main effect of diagnosis on access to EI and there were no significant race x diagnosis interactions.
Conclusions: Parental race significantly predicted access to EI three months after receiving a diagnosis, even after accounting for maternal education. Minority mothers (predominantly African American) were less likely to be as far along in the EI process as majority mothers at follow-up. On average, minority mothers had contacted several EI providers but were not yet receiving therapy, whereas majority mothers already accessed therapy at follow-up. Although the number of therapy hours did not significantly differ between majority and minority toddlers, a similar trend is observed with minority mothers reporting fewer therapeutic hours. Additionally, toddlers within this sample are only receiving approximately one hour of therapy (*M*=1.08, *SD*=1.43) per week, far less than what is recommended. Given the low number of total EI hours across both groups, all families may benefit from additional support in accessing necessary EI services. Systemic improvements may be necessary to improve the availability and accessibility of EI services for families, immediately following diagnosis.

9 **178.009** Can Early Vocalizations Predict Later ASD Symptom Severity?

D. Garrido[1], *L. R. Watson*[2], *R. Garcia-Retamero*[1], *G. Carballo*[1] *and E. Crais*[2], *(1)Psychology, University of Granada, Granada, Spain, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:
Varied infant risk markers predict later diagnoses of autism spectrum disorder (ASD). Limited findings are available, however, on predicting continuous measures of ASD symptoms from behaviors of infants at-risk for ASD (Macari et al., 2012; Northrup & Iverson, 2015). This approach is consistent with the current conceptualization of ASD as a dimensional disorder (Lord & Jones, 2012), and clinically important because of the possibility that infants at highest risk for severe ASD symptoms (and most in need of early intervention) can be identified earlier than reliable diagnoses can be made. Pursuing this idea, we examined the utility of one infant ASD risk marker, a low frequency of vocalizations directed to others (Ozonoff et al., 2010; Winder et al., 2013), in predicting later ASD symptom severity.
Objectives:
To investigate to what extent infant vocalizations (directed/non-directed) predict later ASD symptom severity in social-affective (SA) and repetitive and restricted behaviors and interests (RRBI) domains among community-identified infants at-risk for ASD.
Methods:
Our sample comprised 82 infants, identified as at-risk for ASD via community screening with the First Year Inventory (Baranek et al., 2007). Thirty-minute video samples were coded for directed and non-directed speech-like vocalizations at 14 months (range 13-15). "Directed" vocalizations were those accompanied with gestures and/or eye contact, used within an interactive context, or imitating an adult's vocalization. We used the frequency of directed and non-directed vocalizations to predict the severity of SA and RRBI symptoms at 23 months (range 20-25), based on the calibrated severity scores derived from Autism Diagnostic Observation Schedule-2 algorithm scores (Hus et al., 2014).
Results:
First order correlations showed a non-significant negative correlation between directed vocalizations and SA severity, *r* = -.143, *p* =.199, and a significant negative correlation with RRBI severity, *r* = -.421, *p* < .001).Â In contrast, non-directed vocalizations correlated significantly and positively with SA (*r* = .287, *p* = .009), but minimally and non-significantly with RRBI (*r* = .092, *p* = .412). Despite patterns in the first order correlations, multiple regression analysis showed that both directed (*β* =-.478, *t*(80) =-4.65, *p* < .001) and non-directed (*β* =.217, *t*(80) = 2.11, *p* =.038) vocalizations contributed significantly to predicting RRBI at 23 months, accounting for 22.1% of the variance in RRBI severity. Similarly, both directed (β = -.235, t(80) = -2.16, p =.034) and non-directed vocalizations (*β* = .348, *t*(80) = 3.21, *p* =.002) made significant contributions to accounting for a total of 13.4% of the variance in SA severity.
Conclusions:
The finding that directed and non-directed vocalizations combined to account for more variance in later RRBI severity than SA severity was partially inconsistent with our predictions, especially given the relatively strong role for directed vocalizations in predicting RRBI severity. Nevertheless, particularly if combined with other infant risk markers, vocalizations may have utility in identifying infants whose functioning will be most severely impacted by ASD. Future research should be directed at explaining the associations between directed/non-directed vocalizations and RRBI and SA severity.

10 **178.010** Cascading Effects of Attention Disengagement and Sensory Seeking on Social Symptoms in a Community Sample of Infants at-Risk for a Future Diagnosis of ASD

G. T. Baranek[1], *T. Woynaroski*[2], *S. Nowell*[1], *L. Turner-Brown*[3], *M. DuBay*[1], *E. Crais*[4] *and L. R. Watson*[5], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Hearing and Speech Sciences, Vanderbilt University Medical Center, Thompsons Stn, TN, (3)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)University of North Carolina- Chapel Hill, Chapel Hill, NC*

Background: Sensory seeking behaviors are prevalent across development in children with ASD and are associated with greater autism severity and lower social adaptive skills (Ausderau et al., 2016; Watson et al., 2010). These features are also correlated with attention disengagement difficulties (Sabatos-Devito et al., 2016). Preliminary work with infants at familial risk for ASD (i.e., infants sibs) suggests that sensory seeking may predict later social symptomatology, mediated through reduced social orienting (Woynaroski et al., under review).
Objectives: We aimed to systematically replicate and extend earlier findings, drawing on extant longitudinal data from a *community sample* of one year-olds at-risk for a later diagnosis of ASD.
Our specific research questions were (1) Is increased sensory seeking late in the second year of life (i.e., 20-24 months) related to social symptom severity at 3-5 years of age, via social orienting? (2) Is increased sensory seeking *as measured earlier in the second year of life* (i.e., 13-15 months) similarly predictive and mediated by social orienting?
Methods: 55 infants were identified at 12 months of age using the two-domain cut-off on the First Year Inventory (Turner-Brown et al., 2013) as part of recruitment into an intervention study, and assessed at three time points (T1: 13-15 mos.; T2: 20-24 mos.; T3: 3-5 yrs.). Intervention and control groups were merged for these analyses since no main effects of treatment on child outcomes were found in the parent study. Two mediation models were conducted testing the extent to which observed sensory seeking behavior, tested at T1 & T2 using the Sensory Processing Assessment (SPA; Baranek, 1999), predicted ADOS social-affective calibrated severity scores (T3), mediated through social orienting, which was also measured using the SPA (T2). Post-hoc analyses investigated attention disengagement as a precursor of seeking behaviors in early development.
.
Results: We replicated findings that a) high-risk children who go on to be diagnosed with ASD show heightened sensory seeking in the 2nd year of life relative to those who do not receive a diagnosis, and b) increased sensory seeking indirectly related to later social symptomatology via reduced social orienting. Sensory seeking appears to have more clinical utility later in the second year of life (20-24 mos.) than earlier (13-15 mos.) in the present sample. Post hoc analyses suggested diminished attention disengagement at 12-15 mos. preceded and predicted increased sensory seeking at 20-24 mos.
Conclusions: Findings added support for the notion that sensory features produce cascading effects on social development in infants at risk for ASD and suggest that reduced attention disengagement early in life may set off this cascade.

11 **178.011** Characterization of Infants at High-Risk and Ultra High-Risk for Autism

N. M. McDonald[1], *L. P. Jackson*[1], *C. Ponting*[2], *M. Dapretto*[3] *and S. S. Jeste*[4], *(1)Semel Institute, UCLA, Los Angeles, CA, (2)Clinical Psychology, UCLA, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)UCLA, Los Angeles, CA*

Background: Converging evidence suggests that there are multiple genetic pathways to autism spectrum disorder (ASD). One genetically high-risk group that has been studied widely includes infants with older siblings with ASD, with risk modulated by the number of affected individuals in a family (multiple affected: multiplex, one affected: simplex). These younger siblings (*high-risk [HR] siblings*) have a recurrence rate of 18.7%, whereas siblings from multiplex families (i.e., *ultra high-risk [UHR] siblings*) carry an additional twofold increase in risk. While it is expected that a larger proportion of UHR siblings will present with atypical development by age three, the timing and quality of the divergence in development between UHR and HR siblings is unclear. Investigation of UHR siblings offers a unique opportunity to determine whether there are observable differences in early development associated with a heightened genetic load for ASD.
Objectives: To contrast cognitive abilities, language skills, and early autism symptoms in UHR and HR siblings from ages 6-18 months.
Methods: Participants included 25 HR and 9 UHR siblings enrolled in a longitudinal study. HR siblings had one older sibling with ASD (no other family history) and UHR siblings had at least two older siblings with ASD. *Cognitive abilities* were measured by the Mullen Scales of Early Learning (MSEL) at 6, 12, and 18 months. *Language skills* were measured with the MacArthur Communication Development Inventory (CDI; parent report) at 9, 12, and 18 months. Early *ASD symptoms* were measured by the Autism Observation Scale for Infants (AOSI) at 12 months and Autism Diagnostic Observation Schedule-Toddler Module (ADOS-T) at 18 months.
Results: Initial results (see Table 1) indicate no apparent differences in cognitive and language abilities between HR and UHR siblings prior to one year, nor were there differences in gross motor skills at any age. However, differences were observed in cognitive abilities at 12 and 18 months. Group differences were most prominent in the MSEL nonverbal domains at 12 months, while global cognitive delays, particularly in language, characterized the UHR siblings' MSEL performance at 18 months. Differences in language skills were also reported by parents on the CDI, most notably in the number of words produced at 12 and 18 months. There were no differences in early autism symptoms at 12 or 18 months.
Conclusions: This study found clinically significant differences in cognitive and language abilities between HR and UHR siblings emerging by 12 months. Children from multiplex families had lower cognitive scores, with a higher incidence of scores indicating developmental delays at 18 months. Although preliminary, results suggest that the impact of increased genetic load associated with multiplex family status may first become evident in general developmental delays, rather than early ASD symptomatology. This may reflect an increased incidence of inherited risk variants in UHR siblings that, while increasing disease burden, may also be less specific to ASD. Given the high incidence of developmental delays, UHR siblings should be monitored closely to assess the need for early intervention. Longitudinal data will continue to be collected in this sample.

12 **178.012** Characterizing Head Motion in Diffusion Magnetic Resonance Imaging (MRI) of Infants in the First Six Months of Life

M. Zeydabadinezhad[1], *S. Shultz*[2], *W. Jones*[3], *A. Klin*[3] *and L. Li*[2], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Decatur, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA*

Background:
Diffusion MRI (dMRI) is a powerful and noninvasive tool for quantifying the development of brain white matter, potentially playing a critical role in understanding normal brain development and the neuropathology of related brain disorders, such as Autism Spectrum Disorders (ASD). However, the technique is susceptible to head movement as it essentially measures the movement of water molecules in the brain. Although head motion in infants is commonly considered to be more extensive than in adults, patterns of infant head motion, especially in the first six months of life and in dMRI data, have never been systematically characterized.
Objectives:
To systematically characterize head movement in infants from birth to 6 months of age and its impact on dMRI data.
Methods:
27 typically developing (TD) infants (corrected gestational age: 22-195 days, 7 females) were enrolled in the study. A group of 13 healthy adults (age: 23-42 years, 7 females) were also included as a comparison group. All data were collected on a Siemens 3T Tim Trio scanner with 32-channel head coil and multiband sequences. DTI parameters are: TR/TE of 6200/74ms, a multiband factor of 2 combined with a GRAPPA of 2, FOV of 184×184, spatial resolution of 2mm isotropic, b=0/700 s/mm^2, 61 diffusion directions, extra 6 of b0s in both phase encoding directions. FSL and in-house Matlab codes were used to preprocess all MRI data. The output of FSL/mcflirt with 6DOF and mutual information as cost function was used to derive the alignment parameters and motion indices. We also modified a comprehensive measure of head motion, Total Motion Index (TMI), to objectively define signal drop out in developing brains.
Results:
Means of the modified TMI, Framewise displacement (FD), and motion RMS were all higher for infants compared to adults (p=0.003, p< 0.001 and p=0.024, two samples T-test). There was an inverse correlation between motion indices and age in infants. Consistent with studies of older populations, fractional anisotropy (FA) decreased with head motion (p=0.011). We tested several postprocessing techniques to minimize the impact of motion on estimating FA and selected 'eddy' in FSL (5.0.9) because it assumes no models in recovering signal dropout and rotates diffusion gradient table due to head motion. After motion correction, the slope characterizing the relationship between FA changes and age decreased from 0.87 to 0.84,Â suggesting that FA in younger infants may be more corrupted by higher levels of head motion.
Conclusions:
Head motion in 0- to 6-month-old infants was systematically investigated and characterized. In addition, an improved, comprehensive measure of infant motion that quantifies unbiased signal dropout in diffusion MRI was developed. Given the prevalence of head motion in pediatric and clinical populations, a thorough understanding of the impact of head motion on infant neuroimaging data may serve as a critical step in the use of the tool for identifying the neuropathology of ASD.

13 **178.013** Community Screening at 12 Months with the First Year Inventory: Stability of Diagnostic Clinical Impressions over Time

L. Turner-Brown[1], *S. Nowell*[2], *N. B. Leezenbaum*[3], *A. T. Meyer*[2], *G. T. Baranek*[4], *E. Crais*[4] *and L. R. Watson*[4], *(1)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)TEACCH, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Research on emergence of autism (ASD) symptoms and stability of diagnosis in very young children has focused primarily on children at high-genetic-risk for ASD (Ozonoff, et al., 2015). The current study follows up a community sample of children identified as at-risk for ASD on the First Year Inventory (FYI) at age 12 months. Previous research found that approximately 31% of children who screened positive on the FYI at 12 months met diagnostic criteria for ASD at age 3 years (Turner-Brown et al., 2013). However, no research has examined whether a diagnosis would be reliable or stable under 18 months in community screened samples. A subsample of children returned for follow-up diagnostic evaluations between 3 and 5 years.
Objectives: Our aim was to examine stability of clinical impressions of the at-risk children at 13 months (mean age = 13.2 months, s.d. = 2.5) with diagnosis established at 4 years (mean age = 47.4 months, s.d. = 7.4), and to examine characteristics at 13 months that distinguished children who were diagnosed with ASD from those that were not. We also aimed to examine clinician confidence about clinical impressions at 13 months.
Methods: Participants in this study represent a subsample of 87 children who screened positive on the FYI and participated in a 6-month RCT of Adapted Responsive Teaching intervention; this subsample (n = 32) participated in a follow-up study with independent raters at age 4 years. At 13 months, participants completed comprehensive evaluations with skilled clinical examiners that included assessment of developmental skills (Mullen Scales of Early Learning) and ASD symptoms (Autism Observation Scale for Infants). Assessors rated their clinical impression of the child (e.g., ASD/not ASD) and their confidence in this rating (Not at all confident (1) to Very Confident (5)). Diagnoses were not made at 13 months, though concerns were shared with families. At follow-up, a comprehensive diagnostic evaluation was completed.
Results: At 4-year outcome, 11 children (34%) were diagnosed with ASD, and 21 (66%) did not meet diagnostic criteria for ASD. Sensitivity (.73), specificity (.81), and positive predictive value (.67) of 13 month clinical impressions with diagnostic outcomes are presented in Table 1. Examiners expressed low confidence in their clinical impressions at 13 months (M=1.9, s.d. = .94) regardless of whether their impression was ASD or not. There were no significant differences in confidence for children whose impression was stable over time compared to those that changed (e.g., false positive/negative), p = .5. Furthermore, there were no significant differences between outcome groups in 13 month AOSI scores, p = .7. On the Mullen at 13 months, children with an outcome diagnosis of ASD had lower expressive language than those who did not develop ASD, t(30) = 2.7, p= .01.
Conclusions: Stability of clinical impressions was lower from 13 months to 4 years than prior research with older children (e.g., 18 -35 months). Clinician confidence was low at 13 months regardless of whether the impression was stable over time. Implications for very early ASD screening will be discussed.

14 **178.014** Comparison of Mullen Profiles Among Children with DS, ASD, and Comorbid Presentation of DS and ASD

M. Udhnani[1], *T. Hamner*[1], *D. Fidler*[2], *S. Hepburn*[3], *C. Robinson Rosenberg*[4] *and N. R. Lee*[1], *(1)Drexel University, Philadelphia, PA, (2)Colorado State University, Fort Collins, CO, (3)University of Colorado / JFK Partners, Aurora, CO, (4)University of Colorado, Aurora, CO*

Background: While there is a sizeable body of research on developmental profiles for children with Down syndrome (DS) and children with Autism Spectrum Disorder (ASD), little is known about the profile of children with both (DS+ASD). Although some studies have reported that children with comorbid DS+ASD have lower developmental quotients than those with DS (DiGuiseppi et al., 2010), the profile of relative strengths and weaknesses on developmental tests, such as the Mullen Scales of Early Learning (MSEL), is not firmly established, particularly relative to groups with DS or ASD in isolation. As early intervention has been shown to alter developmental trajectories and improve lifetime outcomes for children with ASD (Orinstein et al., 2014; Zwaigenbaum et al., 2015), elucidating the cognitive profiles of children with comorbid DS+ASD early in development is critical to informing early intervention for this group.
Objectives: The goal of this study is to assess developmental profiles within and between clinical samples of children with ASD, DS, and DS+ASD.
Methods: Participants included 165 children (112 males; Mean age=51.54+23) with ASD (n=111), DS (n=31), and DS+ASD (n=23). Data were compiled from a larger study completed at the University of Colorado School of Medicine (DiGuiseppi et al., 2010) and from the National Database for Autism Research. Children with ASD were matched to the two DS groups on age and sex. Developmental functioning was assessed using the MSEL. Developmental quotients ([mental age/chronological age]*100) were calculated for the Visual Reception (VR), Fine Motor (FM), Receptive Language (RL), and Expressive Language (EL) scales of the MSEL.
Results: A 3x4 repeated measures ANOVA with one between-subjects factor (Group: ASD vs. DS vs. DAS+ASD) and one within-subjects factor (MSEL Scale) was completed to evaluate whether the profile of scores differed as a function of group. A significant group x scale interaction was revealed (F [6,486]=5.7, p<.001), such that the ASD groups had a more variable MSEL scale profile than the DS only group. Specifically, when each group's individual scale DQs were compared to mean DQ (averaged across the 4 scales), a pattern emerged differentiating the DS only group from the two ASD groups. For DS only, VR was significantly higher than mean DQ, while EL was significantly lower (ps<.003).Â In contrast, all scales differed from mean DQ in the ASD and DS+ASD group (all ps<.02); VR and FM were significantly higher, while RL and EL were significantly lower.
Conclusions: Â Results of this preliminary study suggest MSEL profiles for children with DS+ASD are more similar to those with ASD than DS.Â While MSEL absolute scores differed between DS+ASD and ASD overall, the pattern of scores was similar. Moreover, individual scale scores were more variable for the two ASD groups than for the DS group alone. Thus, identifying a comorbid ASD diagnosis in youth with DS appears to not only be important for treatment targeting social-communication skills but also for educational planning.

15 **178.015** Comparison of Parent Report and Direct Assessment of Child Ability in Toddlers

K. A. Perkins[1], *L. E. Miller*[2], *Y. G. Dai*[3] *and D. A. Fein*[4], *(1)Rhode Island Consortium for Autism Research and Treatment, East Providence, RI, (2)University of Connecticut, Mansfield Center, CT, (3)University of Connecticut, Storrs, CT, (4)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Parents observe child skills across settings and functional domains. Therefore, parent report may play a key role in the identification of developmental delays. However, recent research has raised concerns about the accuracy of parent report.
Objectives: The current study assessed agreement on receptive language (RL), expressive language (EL), and fine motor (FM) skills, as measured by parent report and direct assessment, in toddlers.
Methods: Participants were 109 children (66 males; mean age 24.0 ± 4.6 months) recruited through a larger study on the early detection of autism spectrum disorder (ASD). Children were divided into three groups (ASD, *n* = 28; Other Developmental Delay (DD), *n* = 57; Typical Development (TD), *n* = 24) according to DSM-IV-TR clinical best estimate diagnosis, using observation, history, and testing data, including Autism Diagnostic Observation Schedule (ADOS) scores. Parent report was obtained using the Vineland Adaptive Behavior Scales, Second Edition (VABS-II). Child ability was directly measured using the Mullen Scales of Early Learning (MSEL). The current study used correlation and mixed-design ANOVAs, with method as a within-subjects factor and diagnostic group as a between-subjects factor, to assess agreement.
Results: Â RL scores on the VABS-II and MSEL were strongly correlated in the DD group ($r(57) = .702$, $p < .001$) and moderately correlated in the ASD ($r(28) = .525$, $p = .004$) and TD ($r(24) = .404$, $p = .05$) groups. On ANOVA, a main effect of method was not significant ($F(1, 106) = .765$, $p = .384$, $\eta_p^2 = .007$). EL scores were strongly correlated in the DD ($r(57) = .675$, $p < .001$) and TD ($r(24) = .732$, $p < .001$) groups, but were not significantly correlated for children in the ASD group ($r(28) = .232$, $p = .418$). On ANOVA, a main effect of method was not significant ($F(1, 106) = .067$, $p = .796$, $\eta_p^2 = .001$). FM scores were strongly correlated in the TD group ($r(24) = .693$, $p < .001$) and moderately correlated in the ASD ($r(28) = .491$, $p = .008$) and DD ($r(57) = .555$, $p < .001$) groups. On ANOVA, a main effect of method trended toward significance, with parents reporting slightly higher FM abilities than seen on direct assessment ($F(1, 106) = 3.880$, $p = .051$, $\eta_p^2 = .035$).
Conclusions: Â Overall, parent report of child ability level did not differ significantly from direct assessment, across functional domains and diagnostic groups. Although ASD group EL scores were not significantly correlated, no effect of method was found on ANOVA; this may be due to limited EL abilities in the ASD group. A trend-level effect of method was found for FM scores, possibly due to child unwillingness to perform tasks on direct assessment or inaccurate parent reporting. Taken together, results suggest that parents are reliable reporters of child ability in toddlerhood, but, given moderate correlations between reported and measured behaviors, the fullest picture may be obtained by using both methods. Future research should examine specific skills that are under- or over-reported.

16 **178.016** Construct and Predictive Validity of Modified Checklist for Autism in Toddlers, Revised with Follow-up (M-CHAT-R/F) Taiwan Version for Toddlers in Taiwan

Y. T. Wu, ***J. M. Tsai*** *and Y. C. Yang, School and Graduate Institute of Physical Therapy, National Taiwan University College of Medicine, Taipei, Taiwan*

Background: Â Identification of ASD at an earliest age allows for provision of early intervention to facilitate the development of affected children. The M-CHAT-R/F is one of the screening tools which refers to the widespread screening of a population at risk for ASD and can be administered to all children in primary care settings. The M-CHAT-R/F is designed as a two-stage screener that consists of parent-report items and clinician-initiated follow-up questions. Our research group has translated the M-CHAT-R/F to Mandarin Chinese as a Taiwan Version. Preliminary results showed that the M-CHAT-R/F Taiwan version had acceptable reliability and discriminative validity for developmental screening in Taiwanese toddlers. However, no previous factor analysis of the M-CHAT-R/F has yet been published in the literature and little is known about the predictive validity for child's developmental outcome.
Objectives: Â The objectives are to 1) explore the factor structure of the M-CHAT-R/F Taiwan version, and to 2) examine predictive validity of the M-CHAT-R/F total score on developmental scores of theÂ MullenÂ ScalesÂ ofÂ EarlyÂ LearningÂ (MSEL)Â at child's 30 and 36 months of age.
Methods: Â Toddlers aged 16-30 months were prospectively enrolled in this study. Children with major sensory, motor or neurological impairment/disorder were excluded. Parents filled out the M-CHAT-R/F at the beginning of the study and received developmental assessments by using the MSEL when child approached 30 and 36 months of age. Exploratory Factor Analysis (EFA) was conducted to investigate the factor structure of the M-CHAT-R/F Taiwan version. Linear regression analysis was used to examine the association between the M-CHAT-R/F total scores and MSEL developmental scores.
Results: Â One hundreds and seven toddlers were recruited in this study. An Initial analysis showed the Kaiser-Meyer-Olkin statistic was 0.87 (above the threshold of 0.5) and the Bartlett's Test of Sphericity was significant ($p < .0001$), indicating that the M-CHAT-R/F data were suitable for EFA. Five factors were derived accounting for 55.6% of the variance (Figure 1): (1) social attention and play (9 items); (2) communication (3 items); (3) interest and imitation (3 items); (4) behavior (3 items); and (5) motor (2 items). All the factor loadings of each item were > 0.3 on the derived factors (ranging 0.45 – 0.84). The results of predictive validity showed the M-CHAT-R/F total scores at child's early ages were significantly associated with the MSEL scores at child's 30 and 36 months of ages (β= 112.9, R^2=0.209, $p<0.001$). Children who were classified as high risk or median risk for ASD in the M-CHAT-R/F scores were found to have significantly lower MSEL developmental scores at 30 and 36 months of age ($p<0.05$).
Conclusions: Â This study showed a five-factor structure for the M-CHAT-R/F Taiwan Version. The finding of factor structure reflects the DSM-5's diagnostic criteria for ASD, providing some evidence towards a similar factor structure of autistic traits and related symptoms for toddlers in Taiwan. Furthermore,Â the associations between the M-CHAT-R/F and MSEL suggests an acceptable predictive validity that the M-CHAT-R/F is predictive of child's developmental outcome on the MSEL scales.

17 **178.017** Decision Factors in Referrals for Autism Spectrum Disorder Evaluations

M. A. Cannon *and T. P. Gabrielsen, Brigham Young University, Provo, UT*

Background: Children with autism spectrum disorder (ASD) have better outcomes with early identification and early intervention. Early screening and diagnosis can help identify children with ASD. Professionals have the responsibility to refer children, of any age, for early identification in the presence of concerns or positive screening results. Currently, however, less than half of children with ASD received their first comprehensive evaluation by a professional before age 3, which is late, given the stability of diagnoses at age 2. If signs are evident in many children at age 2, it is unknown why more children are not referred at earlier ages.
Objectives: This study looked at the factors that professionals may use in order to make referral decisions.
Methods: Over 360 interdisciplinary clinicians and educators attended a professional development workshop, where they watched brief clips of children with typical development, language delays, or ASD. Professions included in the sample were health care, speech language and hearing, early intervention, educators, therapists and family service professionals. Professionals were also asked to make a decision about referral, as well as state the factors they used to make this decision.
Results: Â The most commonly used factors to make referral decisions were interactions/engagement, verbal/non-verbal cutes, and appropriate play. Across disciplines, referral accuracy was consistent (75%). A Chi-square test showed no significant effect of profession on accuracy of referral decision (χ^2=0.719). A more detailed analysis of the Chi-square residuals for the collapsed professional categories revealed that speech and hearing professionals were less likely to refer children for autism evaluations in our sample. All other professions showed similar and higher rates of referral. The sensitivity and specificity in referral decisions for this group of professionals was fairly well balanced at .74 and .75 respectively. In our sample, although professionals were accurate in their referrals for a majority of children, they still missed 26% of children with subtle early signs.
Conclusions: Â This result is encouraging, because it tells us that the broad range of disciplines represented in "frontline" early childhood personnel can notice early signs of autism and refer for further evaluation equally, but that this method alone is not foolproof and that referrals are not happening at the same level as shown in this demonstration, suggesting further exploration into factors affecting actual referrals and follow through. These findings also support the need for adding universal screening for autism to detect early signs that might be missed in brief observations.

18 **178.018** Describing a Methodology for Evaluating Robot-Assisted Intervention Using Eye-Tracking

R. L. Beights*, A. M. Mastergeorge, V. Jain and W. H. Dotson, Texas Tech University, Lubbock, TX*

Background: Robots, similar to other new forms of interactive technology, are used in clinical intervention for children with ASD at an increasing rate (Cabibihan et al. 2013; Diehl et al., 2012; Scassellati et al., 2012). However, understanding effective components of child response to robot-assisted intervention (RAI) is largely unknown aside from initial reports of engagement and interest in robots as a novel technology (e.g., Begum et al., 2016). The majority of published research provides little quantitative assessment (e.g., eye-tracking for visual attention assessment) or experimental manipulation that could establish a strong foundation for using robots in early intervention (Coeckelbergh et al., 2015).
Objectives: The purpose of the current study is to describe methodology for evaluating the utility of RAI for young children with ASD using eye-tracking metrics as a primary measure of attention and response to instruction. The primary aim is to describe how to identify relevant factors for treatment effectiveness based on visual attention to instructional targets of imitative motor actions and verbal fill-in statements. Understanding targeted attentional factors related to viewing RAI will guide design and selection of effective technology-facilitated EI strategies.
Methods: A task analysis for assessment of visual attention was completed prior to implementing the protocol with participants 2 to 5 years of age. This task analysis provided detailed steps of stimuli design and experimental session preparation. Six-minute experimental sessions examined visual attention for 28, 10-second robot (RDI) and human-delivered (HDI) instructional stimuli measured directly through eye-tracking. Pilot participants included two male children diagnosed with ASD. Areas of interest (AOI) were defined a priori based on salient features of the instruction. Data collection involved multiple gaze metrics, including gaze fixation and duration.
Results: Pilot data focused on gaze fixation and visualization of fixation points within AOI. Gaze fixation data for motor actions revealed greater visual attention to salient instructional features when viewing RDI versus HDI (Figure 1). Participants showed a greater number of fixation points following the pattern of movement in the RDI condition, as compared to fixation that was more localized to the face in the HDI condition. Gaze fixation data for verbal fill-ins showed visual attention within the AOI (head/mouth) in both RDI and HDI conditions (Figure 2). Gaze duration data indicated that sustained visual attention was greater in the HDI conditions as compared to RDI conditions. Additional data for up to 20 participants will be analyzed and discussed..
Conclusions: Differential patterns of visual attention within pre-defined AOI were observed across RDI and HDI conditions. Participants showed increased gaze fixation when viewing RDI for motor actions, suggesting the robot stimuli promoted increased attention to multiple salient features of instruction as opposed to more selective attention to a specific feature. Conclusions regarding utility of this methodology for evaluating RAI and implications for intervention will be discussed.

19 **178.019** Developmental Trajectories of ADHD Symptoms in Infants at Risk for ASD

L. Bell[1]*, M. Miller*[2]*, A. Farquhar-Leicester*[1]*, C. Ferguson*[1]*, G. S. Young*[3] *and S. Ozonoff*[3]*, (1)UC Davis MIND Institute, Sacramento, CA, (2)University of California, Davis, MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA*

Background: Comorbidity rates between ASD and attention-deficit/hyperactivity disorder (ADHD) are as high as 40-70% (Antshel et al., 2016), making it important to better understand the presentation of ADHD symptoms in ASD. This is especially critical since the presence of ADHD symptoms in young children can delay a diagnosis of ASD by several years (Miodovnik et al., 2015). Very little research has focused on the early development of ADHD symptoms in infants developing ASD, despite the fact that a better understanding of the onset and early course of ADHD symptoms among infants at risk for ASD could improve early diagnostic and classification efforts and have implications for early intervention.
Objectives: We examined when differences in ADHD-related behaviors emerged among participants with either ASD or typical development (TD) outcomes.
Methods: Participants were drawn from a larger longitudinal study of infants at high- and low-risk for ASD (infant siblings); a subset of those with 36-month outcomes of either ASD (n = 14) or TD (n = 36) was included in the present investigation. We conducted second-by-second behavioral coding of videos from the 12-, 18-, 24-, and 36-month visits, examining four coded behaviors (Table 1) related to ADHD symptomatology (inattention, hyperactivity, out-of-seat behavior, and grabbing). Behaviors were coded from 5-minute video segments of structured testing. Group differences in ADHD-related behaviors from 12 to 36 months were examined via a Generalized Estimating Equations approach, using a negative binomial distribution with log link for each coded behavior.
Results: Â Estimated marginal means of each coded behavior are displayed in Figure 1. The interaction between inattention, visit, and outcome was significant (Wald χ^2 = 13.71, df = 3, p = .003). The ASD group significantly increased in the frequency of inattentive behavior over time, and significantly differed from the TD group at 36 months of age; there was also a trend toward more frequent bouts of inattention in the ASD group at 24 months. The interaction between out-of-seat behavior, visit, and outcome was also significant (Wald χ^2 = 10.44, df = 3, p = .015). The ASD group decreased over time and engaged in significantly fewer bouts of out-of-seat behavior at 36 months of age compared to the TD group. The interaction between hyperactive behavior, visit, and outcome was not significant (Wald χ^2 = 4.28, df = 3, p = .233), nor was the 3-way interaction for grabbing behavior (Wald χ^2 = .95, df = 3, p = .813).
Conclusions: Â Infants developing ASD showed more frequent bouts of inattention than infants developing typically by 36 months of age, as well as less frequent bouts of out-of-seat behavior by 36 months. Our findings contribute to the growing literature implicating early attentional processes in ASD (reviewed in Johnson et al., 2014) and is consistent with prior research documenting elevated rates of ADHD-related inattention symptoms in older children with ASD (Leyfer et al., 2006). Coding of the full sample is ongoing and may help clarify the unexpected finding of minimal group differences in hyperactive-impulsive behaviors.

20 **178.020** Developmental Trajectories of Sex Differences in Negative Affect in Infants with FXS and at ASD Risk

C. A. Wall *and J. Roberts, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Research in Autism Spectrum Disorder (ASD) and fragile x syndrome (FXS) has predominantly focused on males due to sex differences in prevalence rates and increased phenotypic variability in females. Because temperament is relatively stable and accurately measured in infancy, it is a useful approach to understanding early developmental trajectories. Temperament has been linked to psycholobiological processes and systems, and thus may help identify early phenotypic markers of ASD that are tied to neurological or biological underpinnings. For example, a temperamental profile including higher negative affect has been shown to predict ASD in infant siblings (Garon et al., 2009).
There are reported sex differences in temperament in typically developing (TD) infants with girls rated higher on effortful control and boys higher on surgency, but no sex differences are observed in negative affect (Else-Quest, Hyde, & Goldsmith, 2006). However, no studies have examined sex differences in negative affect in infants at risk for FXS, and few have explored these questions in ASD. Because FXS is an X-chromosome linked, single-gene disorder associated with autism, it offers unique insight into the neurobiological sex differences in both disorders.
Objectives: To assess the differences in initial level and change of negative affect from 12- to 18- and 24-months by sex and risk group.
Methods: Participants included 109 infants assessed at 12, 18, and 24 months-of-age: 30 TD males, 25 ASIB males, 25 males with FXS, 9 TD females, 9 ASIB females, and 11 females with FXS. Most infants (n=94) had at least two data points. Parents completed the Infant Behavior Questionnaire at 12 months (IBQ; Rothbart, 1978) and the Early Childhood Behavior Questionnaire at 18-24 months (ECBQ; Putnam, Gartstein, & Rothbart, 2006).
Results: A growth model using hierarchical linear modeling (HLM) centered at 12 months was performed. Results demonstrated a significant effect of age, with groups showing less parent-reported negative affect over time t(171) = -12.65, p <. 0001, d = 1.66. There was a marginal effect of risk group t(100) = -1.82, p = .07, suggesting that the FXS group had less negative affect than the ASIB and TD groups (ds > .3) who were not different from each other (d = .07). No sex differences were found.
Conclusions: This study was the first to examine sex differences in negative affect in infants with FXS and those with an older sibling with ASD. Consistent with earlier reports of these relationships TD infants, we found no sex differences in any risk group. This work suggests that existing conceptualizations about negative affect and its relation to ASD may be applicable to both males and females with these disorders. Further, the marginal effect risk group points to the possibility that profiles for predicting ASD may differ by etiological group, especially considering other work suggesting that negative affect is related to ASD symptoms in ASIB infants but anxiety in infants with FXS (Tonnsen, Malone, Hatton, & Roberts, 2013). Given the impact of early detection and intervention, it is important that early phenotypic characterizations of these disorders consider the impact of sex differences.

21 **178.021** Do Toddlers at Familial Risk for ASD Differ in Their Electrophysiological Responses to Known and Unknown Words?

K. H. Finch[1]*, A. Seery*[2]*, H. Tager-Flusberg*[1] *and C. A. Nelson*[3]*, (1)Psychological and Brain Sciences, Boston University, Boston, MA, (2)New York University School of Medicine, New York, NY, (3)Boston Children's Hospital, Boston, MA*

Background:
Language is often impaired in individuals with autism spectrum disorder (ASD). Additionally, subtle atypicalities in language processing have been found in unaffected individuals at familial risk for ASD. In typically developing toddlers, neural responses, measured by event-related potentials (ERPs), vary depending on word familiarity and language ability (Mills et al., 2005). Kuhl and colleagues (2013) found atypical ERPs to words in toddlers with ASD. However, they did not control for language, so it is difficult to interpret whether these ERP differences were driven by ASD or the children's language abilities.
Objectives:
Our study investigates electrophysiological responses to words in 24-month-old toddlers with and without ASD, including those at familial risk, while controlling for language abilities.
Methods:
Participants
59 monolingual, English-speaking 24-month-olds were divided into three groups: low-risk control (LRC; N=34), high-risk for ASD (HRA; older sibling with ASD) without ASD (HRA-, N=21), and HRA children with ASD (ASD; N=4).Â
Procedure
ERPs were recorded while children passively listened to a stream of words playing from bilateral loudspeakers. Forty nouns were presented up to three times across two categories: 'known' words, confirmed through parent report, and 'unknown' words.
Analysis
Analysis focused on the mean amplitude of the N200-500 (negative component from 200-500ms post-stimulus onset) as its distribution varies depending on word familiarity (Mills et al., 2005). To analyze group differences, we used a mixed-model ANOVA with two conditions (known, unknown), two regions (parietal, occipital), and two hemispheres (left, right) as repeated measures and group (LRC, HRA-, ASD) as a between-subjects factor. We controlled for language abilities in our analyses using the verbal developmental quotient (VDQ) from the Mullen Scales of Early Learning (Table 1). We also investigated relationships between the N200-500 and language abilities and ADOS severity scores.
Results:
The results of the ANOVA found that there was a main effect of condition ($F(1,55)=4.34$, $p=0.042$) with a more negative amplitude for known words than for unknown words. There was also a significant group by condition by hemisphere interaction ($F(2,55)=3.86$, $p=0.027$). This was driven by a significant difference between groups in the left hemisphere in response to the known words ($p=0.037$). However, follow up on this revealed LRC, HRA-, and ASD groups were not significantly different from each other (all $p>0.10$; Figure 1). There were no other significant effects.
There was a significant relationship between the N200-500 in the right hemisphere sites and VDQ ($r_S=0.328$, $p=0.011$), such that toddlers with a less negative response in the right hemisphere had better language abilities. There were no significant relationships with ADOS severity scores.
Conclusions:
When controlling for language abilities, toddlers with ASD and unaffected familial members of ASD showed similar lateralization patterns in response to known words as their typically developing peers. Moreover, there was a significant relationship between the lateralization pattern of the N200-500 and language abilities but not with ASD severity. Thus, any differences in ERPs in response to language within these groups may be a result of varying language abilities as opposed to an ASD diagnosis or familial risk of ASD.

22 **178.022** Does Dyadic Synchrony and Responsiveness in the First Year Inform Later Autism Diagnoses?

A. J. Schwichtenberg[1]*, A. M. Kellerman*[1]*, R. Abu-Zhaya*[2]*, M. Miller*[3]*, G. S. Young*[3] *and S. Ozonoff*[3]*, (1)Purdue University, West Lafayette, IN, (2)Speech-Language and Hearing Sciences, Purdue University, West Lafayette, IN, (3)University of California, Davis, MIND Institute, Sacramento, CA*

Background: Within dyadic play interactions, infants and their partners create temporal responsiveness and synchrony (Feldman, 2007). In the first year of life, the ability to engage in sustained synchronous interactions develops as infants learn to match play partner behaviors and sequentially regulate their behaviors in response to others (Feldman, 2007; Fogel, 1993; Tronick, 1989). Difficulty developing competence in these early social building blocks can inform later difficulties with language, joint attention, and emotion regulation (e.g., Granat et al., 2016). For children at elevated risk for autism (i.e., infant siblings of children with autism), it is unclear if early synchrony could inform later autism diagnoses and/or developmental progress/concerns.
Objectives: The present study explored if dyadic synchrony and responsiveness observed within the first year could inform autism diagnoses and other developmental progress/concerns at 36 months of age.
Methods: As part of a prospective study, 151 infants and their mothers (high-risk group n = 105, low-risk group n = 46) completed a standardized mother-infant play task when infants were 6, 9, and 12 months of age. These interactions were recorded and micro-coded for infant and mother gaze, affect, and vocalizations. Using these micro-codes, we created theory-driven composites for dyadic synchrony, responsiveness, and responsiveness timing (Table 1). At 36 months, infants/toddlers completed an assessment that included developmental functioning (via the Mullen Scales of Early Learning; MSEL) and were assigned diagnostic outcome classifications (i.e., autism, other developmental concerns, or typical development).
Results: Using linear and multinomial regression models, we assessed each composite at 6, 9, and 12 months as predictors of 36-month diagnostic outcomes and MSEL scores (with terms for infant sex, maternal education, and family income). Overall, the tested synchrony and responsiveness composites did not predict which children received an autism diagnosis. However, these composites did inform 36-month language development for all assessed infants, particularly when considering synchrony and responsiveness at 12 months of age (Table 1). For children who received an autism diagnosis, dyads coded as more synchronous and responsive in the first year had higher language scores at 36 months (Table 2). However, this finding was not consistent across the 6-, 9-, and 12-month assessments.
Conclusions: Dyadic synchrony and responsiveness, within the first year of life, did not inform which children would receive an autism diagnosis at 36 months. However, consistent with previous research (Northrup & Iverson, 2015), dyadic behaviors during the first year informed language progress for children with and without autism. The findings of the present study highlight mother-infant synchrony and responsiveness as a mechanism through which interventions may promote optimal development in children at elevated risk for autism.

23 **178.023** Does Eye-Tracking during Dynamic Videos Relate to Social Interactions in High-Risk Infants?

A. M. Kellerman*, D. S. Robinson, B. A. Jameyfield and A. J. Schwichtenberg, Purdue University, West Lafayette, IN*

Background: Poorly modulated eye contact is an early behavioral risk marker for autism spectrum disorder (ASD), facial processing difficulties, and joint attention development (e.g., Dawson et al., 2004). Quantifying eye contact within on-going social interactions can be difficult, and many researchers often use eye-tracking technology to assess where and for how long individuals look to the eyes (or mouth) of a speaker or perceived social partner (e.g., Chevallier, et al., 2015; Chawarska & Shic, 2009). However, we know relatively little about how these behaviors with 2D faces/partners relate to on-going live social interactions.
Objectives: We aim to replicate previous studies (e.g., Jones et al., 2008) by assessing the prospective associations between eye-tracking indexed look to eyes or mouth with elevated autism risk and later developmental concerns. Our novel contribution includes assessing how eye-tracking is associated with concurrent eye-contact modulation/competence within on-going social interactions.
Methods: Â As part of an ongoing prospective study, 21 infant siblings of children with autism (high-risk group; *n* = 12) or typical development (low-risk group; *n* = 9) completed an eye-tracking task and the Early Social Communication Skills (ESCS; Mundy et al., 2003) when siblings were 18 months of age. A dynamic video task was administered with *iMotions* software and a Tobii X2-60 eye-tracker. The coded video stimuli included three trials of a woman speaking to the observer with happy, neutral, and sad expressions and tones.Â Eye-tracking summary data included fixations and the amount of time infant spent attending to the speaker's eyes and mouth. For the ESCS, initiations of joint attention (IJA) were totaled for frequencies of lower-level, higher-level, and overall bids.Â By 36 months of age, infants/toddlers completed a developmental evaluation and the outcome groups of ASD, other, and typical development were assigned.Â Due to the limited sample size in the current study, outcome group was dichotomized into typical (TYP; *n* = 11) and non-typical (Non-TYP; *n* = 10).
Results: Â Risk and outcome group differences across the dynamic video task were assessed using general linear models with gender as a covariate.Â The high-risk group spent significantly less time looking to speaker's eyes during the happy trials (Table 1).Â When assessing by outcome, the Non-TYP group spent less time attending to speaker's eyes during the neutral trials, and Non-TYP group IJA scores were positively correlated with time spent looking to speaker's eyes during happy and sad trials and looking to the speaker's mouth during neutral trials (Table 2).Â These associations were not present in the TYP group.
Conclusions: Â These findings partially replicate previous research (e.g., Dawson et al., 2005) and demonstrate that (even in small samples) time spent looking to a 2D speaker's eyes can serve as a risk marker of later developmental concerns in children at elevated risk for autism. Additionally, time spent assessing eyes in emotionally salient videos (happy or sad) may serve as a proxy for eye contact modulation/competence within on-going social interactions. With replication, this quantification could serve as an intervention metric and/or research tool.

24 **178.024** Early Adaptive Functioning Trajectories in Preschoolers with Autism Spectrum Disorders

M. Franchini[1,2], *E. Gentaz*[2], *N. Kojovic*[1], *H. Wood de Wilde*[1], *S. Eliez*[3] *and M. Schaer*[1], *(1)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland, (2)Sensorimotor, Affective and Social Development Unit, University of Geneva, Geneva, Switzerland, (3)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland, University of Geneva, Geneva, Switzerland*

Background: In preschoolers with Autism Spectrum Disorders (ASD), symptom severity has a negative impact on the development of adaptive functioning (Szatmari et al., 2015). Adaptive functioning impairments (e.g. dependency in activity as personal hygiene) critically impact the quality of life of those children and their family. Developmental features such as reduced social interest or the presence of behavioral problems can further impede daily life learning experiences (e.g. Chevallier et al., 2012, Fulton et al., 2014). However, so far, the development of adaptive functioning in young children with ASD remains speculative and has to be tested in a longitudinal multiple visits design.
Objectives: The first aim of the current study is to confirm the impact of high symptom severity on adaptive functioning trajectories in a sample of preschoolers with autism spectrum disorder. The second objective intends to explore whether reduced social interest and severe behavioral problems negatively affect developmental trajectories of adaptive functioning in young children with ASD.
Methods: Fifty-eight children with ASD (141 visits in total) and 29 age and gender matched typical developing (TD) children (64 visits in total) were longitudinally followed between 1.8 and 5.0 years old. At the baseline, diagnosis of ASD was confirmed with the Autism Diagnostic Observation Schedule (ADOS, Lord et al., 2000), which also allows defining symptom severity. Behavioral problems and social interest were also measured, using respectively, the Child Behavior Checklist for Ages 1.5-5 (CBCL/1.5-5, Achenbach & Rescorla, 2001) and a validated eye-tracking paradigm of visual preference for biological and non-biological motion (Pierce et al., 2012; Franchini et al., 2016). Besides baseline assessment, data on adaptive functioning were collected with the Vineland Adaptive Behavior Scales, 2nd edition (standard scores; Sparrow et al., 2005) every 6 months (for a maximum of two years).
Results: Using mixed models regression analyses we first demonstrated that children with ASD showed parallel developmental trajectories but significantly lower performance of adaptive functioning as compared to TD children ($p<0.0001$). Second, within ASD children, our results demonstrated that those with: 1) higher symptom severity ($p<0.0001$); 2) reduced social interest ($p=0.03$) and; 3) higher scores of behavioral problems ($p=0.01$) exhibited especially lower trajectories of adaptive functioning. However, the group by diagnosis interaction (i.e. slope of the trajectories) did not differ between these groups.
Conclusions: Our results support that, beyond high symptom severity, both reduced social interest and higher behavioral problems are also associated with lower adaptive functioning in young children with ASD. These findings further bolster the idea that social interest and behavioral problems are crucial for the early adaptive functioning development of children with autism. The current study has clinical implication in pointing out relevant targets for early intervention in ASD children.

25 **178.025** Early Detection for Risk of Autism Spectrum Disorder Using the Infant-Toddler Social and Emotional Assessment (ITSEA): A Prospective High-Risk Cohort Study

S. Raza[1], *L. A. Sacrey*[2], *L. Zwaigenbaum*[3], *S. E. Bryson*[4], *J. A. Brian*[5], *I. M. Smith*[6], *W. Roberts*[7], *P. Szatmari*[8], *T. Vaillancourt*[9], *C. Roncadin*[10] *and N. Garon*[11], *(1)University of Alberta, Edmonton, AB, Canada, (2)Autism Research Centre, Edmonton, AB, CANADA, (3)University of Alberta, Edmonton, AB, CANADA, (4)Dalhousie University, Halifax, NS, CANADA, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (7)University of Toronto, Toronto, ON, CANADA, (8)Centre for Addiction and Mental Health, Toronto, ON, CANADA, (9)University of Ottawa, Ottawa, ON, CANADA, (10)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, CANADA, (11)Mount Allison University, Sackville, NB, CANADA*

Background: Characterizing the early development of children later diagnosed with Autism Spectrum Disorder (ASD) is crucial in order to identify early risk markers and potential targets for early intervention to improve functional outcomes. Recent evidence suggests that early social-emotional difficulties may predict later ASD symptomatology and developmental problems. This study examines whether scores on a parent-reported questionnaire, the Infant-Toddler Social Emotional Assessment (ITSEA), may be informative for early risk detection of ASD in a high-risk sibling population.
Objectives: The objective of the present study was to examine the relationship between parent-reported ITSEA scores at 18 months, and ASD symptomatology and diagnostic outcomes at 36 months in a cohort of toddlers at high-risk of developing ASD (HR; have older sibling diagnosed with ASD).
Methods: Three groups of toddlers participated: (1) HR siblings who did not receive an ASD diagnosis at 36 months (HR-N; n=238), (2) HR siblings who did receive an ASD diagnosis at 36 months (HR-ASD; n=93), and (3) low-risk toddlers with no family history of ASD (LR; n=133). Parents completed the ITSEA at 18 months. ITSEA domain scores (Externalizing, Internalizing, Dysregulation, and Competence domains), subdomain scores, and indices (Maladaptive, Social Relatedness, and Atypical indices) were calculated. At 36 months, an independent blinded diagnostic ASD assessment was conducted for all toddlers using the ADI-R and the ADOS. ITSEA scores were compared using a series of one-way ANOVAs with Group (HR-ASD, HR-N, LR) as the independent measure and Domain scores and Indices as the dependent measures. Group effects were explored using Benjamini & Hochberg (1995) corrections for multiple comparisons. Predictive contributions of the ITSEA were assessed using correlations between domain scores and indices at 18 months, and ADI-R and ADOS scores at 36 months.
Results: Parents of HR-ASD toddlers reported higher ITSEA scores on the Internalizing ($q \leq 0.001$) and Dysregulation ($q \leq 0.025$) domains, and Maladaptive ($q \leq 0.024$) and Atypical ($q \leq 0.001$) indices, as well as lower scores on the Competency ($q \leq 0.001$) domain and Social Relatedness ($q \leq 0.001$) index compared to parents of HR-N and LR groups. These results indicate greater impairment in social-emotional functioning at 18 months among HR toddlers later diagnosed with ASD. With respect to prediction, all ITSEA domain scores (with the exception of Externalizing in the HR-ASD group) and indices were significantly correlated with ASD symptomatology in both HR groups on the ADI-R (p's < 0.05). The Externalizing, Internalizing, and Dysregulation domains were correlated with the ADOS in the HR-ASD group (p's < 0.01), but not in the HR-N group.
Conclusions: Parental ratings on the ITSEA provide valuable information about the relation between early social-emotional functioning and later developmental outcomes in children who will and will not receive an ASD diagnosis. Specifically, HR siblings with ASD displayed marked social-emotional difficulties at 18 months, which predicted later ASD symptomatology and diagnostic outcomes at 36 months. These findings highlight the importance of considering social-emotional regulation when assessing the risk for ASD.

26 **178.026** Early Gesturing As a Screener of Subsequent Language Ability in Infants at Risk for Autism Spectrum Disorder

D. Tagavi[1,2]*, H. Tager-Flusberg*[2] *and C. A. Nelson*[3]*, (1)Clinical Psychology, University of California, Santa Barbara, Santa Barbara, CA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background: Siblings of children with autism spectrum disorder (ASD) are at a heightened risk for displaying ASD-like traits in early childhood and have an increased likelihood of developing this disorder (Constantino, Zhang, Frazier, Abbacchi, & Law, 2010; Ozonoff et al., 2010). Research on high-risk infants has found delays in understanding speech, producing vocalizations, or communicating through gestures at as early as 12 months (Mitchell, et al., 2006; Ozonoff, et al., 2010; Paul, Fuerst, Ramsay, Chawarska, & Klin, 2011).
Objectives: We examined parent report of infant gesturing at 12 months and its ability to predict language ability at 36 months for at-risk and typically developing (TD) siblings. We aim to determine if an easily accessible, cost-effective parent measure of gesturing is significantly associated with later language ability in at-risk infants.
Methods: The 126 participants included in this analysis were part of a longitudinal study of infants with an older sibling either with ASD (HRA; n=68) or without (LRC; n=58). Twelve siblings were diagnosed with ASD at 36 months based on the Autism Diagnostic Observation Schedule (ADOS) and clinical confirmation and were excluded from group difference analyses. We conducted an independent samples t-test to examine the differences between HRA and LRC on scores of gesture usage at 12 months using parent report scores from the MacArthur-Bates Communicative Development Inventories (MB-CDI), and receptive and expressive language at 18, 24, and 36 months using the Mullen Scales of Early Learning (MSEL). A partial correlational analysis was conducted to examine the association between parent-reported 12-month infant gesture, and 36-month language ability, controlling for 36-month nonverbal intelligence.
Results: Results were significant for early, late, and total gestures at 12 months (Early: $t(112)=3.82$, $p<.001$; Late: $t(112)=2.55$, $p=.01$; Total $t(112)=3.29$, $p=.001$). Results were also significant for expressive language at 24 and 36 months (24 months: $t(88)=3.32$, $p=.001$; 36 months: $t(60)=2.20$, $p<.05$), and receptive language at 18 and 24 months (18 months: $t(106)=4.10$, $p<.001$; 24 months: $t(88)=3.64$, $p<.001$). This indicates that HRA produced fewer gestures than LRC at 12 months, produced fewer sounds, words, and phrases at 24 and 36 months, and understood fewer words throughout the first two years of life. Additionally, we found that 12-month gesturing ability was associated with subsequent language ability at 36 months ($r=.40$, $p=.02$) in HRA infants, but not LRC ($r=.10$, $p=.53$).
Conclusions: We concluded that in at-risk infants, 12-month gesturing ability is associated with 36-month language ability, even when controlling for nonverbal intelligence. When examining TD infants, gesturing was not significantly associated with later language. This finding is inconsistent with previous research on TD siblings and could be due to LRC parents not being as cognizant of their child's gesturing ability. It is now clear that parent report measures of infant gesturing are associated with language ability at up to three years in high-risk populations. These results indicate that delayed gesturing may be easily identified through parent report measures. Clinicians should screen parents for these delays within the first year of life so that interventions can be implemented before symptoms manifest fully.

27 **178.027** Early Predictors of Social Anxiety in 12-Month-Old Infant Siblings of Children with Autism Spectrum Disorder

A. L. Hogan*, S. L. O'Connor, N. S. Poupore, B. Tonnsen and J. Roberts, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Siblings of children with autism spectrum disorder (ASIBs) are at elevated risk for anxiety later in life. In typically-developing infants, heightened social fear and atypical heart activity (e.g., respiratory sinus arrhythmia, RSA) have been shown to predict later social anxiety. However, very few studies have focused on the early risk markers of anxiety in ASIBs.
Objectives: Investigate fear and RSA in 12-month-old ASIBs and low-risk controls (LRCs) to determine if early risk markers of anxiety are present.
Methods:
Participants included 28 ASIBs (*M* = 12.94 months, *SD* = 1.33 months, 75% male) and 19 LRCs (*M* = 12.34 months, *SD* = 0.72 months, 74% male). Parent-reported fear was measured via the Fear Subscale from the Infant Behavior Questionnaire-Revised (IBQ-R; Gartstein & Rothbart, 2003). Observed social fear was measured by gaze behavior during a Stranger Approach paradigm. The proportion of time spent directing gaze toward the stranger served as an index of attention to threat. The proportions of time directing gaze to the parent and time averting gaze (i.e., looking away from the stranger and the parent) were also computed. Heart activity was recorded during a baseline period and during Stranger Approach. RSA was derived for both periods and RSA Change was calculated as Baseline RSA minus Stranger Approach RSA.
Results:
Independent samples *t*-tests were used to examine differences in parent-reported fear, observed social fear, and RSA. The ASIBs had higher parent-reported fear, $t(45) = -1.71$, $p = .09$, with Cohen's $d = .52$, indicating a medium effect size. During Stranger Approach, ASIBs and LRCs demonstrated similar gaze behavior, ts < ± 1.32, ps > .20. Groups did not differ on baseline RSA or Stranger Approach RSA, ts < ± .85, ps > .40. However, the LRCs demonstrated a greater RSA Change, $t(25) = 2.58$, $p = .02$. In ASIBs, baseline RSA was correlated with time averting gaze, $r = -.51$, $p = .04$, and RSA Change was correlated with time averting gaze, $r = -.69$, $p = .001$, and time gazing at the stranger, $r = -.50$, $p = .08$. No significant correlations between fear and RSA were observed in LRCs.
Conclusions:
Results suggest that behavioral markers observed in an experimental paradigm (i.e., behavioral fear) may not distinguish ASIBs at 12 months of age. However, parents of ASIBs did rate their children marginally more fearful than did parents of LRCs. Furthermore, ASIBs demonstrated suboptimal RSA Change in response to a stranger approach, a physiological profile associated with later social anxiety in community samples. Interesting correlations between heart activity and behavioral fear were observed in the ASIBs, but not the LRCs, supporting theories that poor physiological regulation contributes to disrupted modulation of attention and may be linked to anxiety later in development. In all, these findings suggest that individual differences in physiology and fear may be interacting in ASIBs to confer later risk for anxiety. Future studies should examine the longitudinal effects of such factors as they relate to anxiety outcomes in ASIBs.

28 **178.028** Elevated Levels of Glutamate in 4-6-Month-Old Infants at High Familial Risk of Autism Spectrum Disorders

I. Pote[1,2], *R. Dimitrova*[1,2], *J. Ciarrusta*[1,2], *E. Perry*[2], *J. Kangas*[2], *J. M. Allsop*[1], *E. Hughes*[1], *M. Fox*[1], *D. G. Murphy*[2], *G. M. McAlonan*[2] *and M. A. Rutherford*[1], *(1)Division of Imaging Sciences and Biomedical Engineering, Centre for the Developing Brain, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: There is now compelling evidence to suggest that abnormalities in excitatory and inhibitory neurotransmission may underpin 'atypical' development, including neurodevelopmental disorders such as autism spectrum disorder (ASD). Proton magnetic resonance spectroscopy (^{1}HMRS) provides an invaluable tool for studying brain metabolites *in vivo*. However, there have been no studies thus far examining the neurochemistry of ASD in early infancy; and so, we do not know if there are any neurochemical differences in infants-at-risk of developing the condition. This is an important omission, especially when considering that brain metabolite changes often precede structural abnormalities.
Objectives: In this study, ^{1}HMRS was used to investigate whether 4-6-month-old infants at high familial risk of ASD showed differences in brain metabolite ratios, when compared to low-risk controls. Infants were considered to be at 'high-risk' if they had at least one sibling with a diagnosis of ASD, and at 'low-risk' if they had no family (first-degree relative) history of ASD.
Methods: We acquired ^{1}HMRS at 3T from the basal ganglia of 33 infants (n=14 'high-risk' and n=19 'low-risk'), scanned between 4-6 months of age. Using a single voxel point resolved spectroscopy sequence (PRESS), set at an echo time of 55ms, glutamate measures comprised of glutamate plus glutamine (Glx) were obtained, and expressed relative to Choline (Cho) and Creatine (Cr) - i.e. Glx/Cho and Glx/Cr, respectively. Then, an analysis of covariance was used to test for group differences in these brain metabolite ratios. Infant risk group (low-risk versus high-risk) was input as a fixed factor, and the dependent variables of interest included: Glx/Cho and Glx/TCr. Infant age and sex were controlled for.
Results: Infants in the high-risk group had significantly higher levels of Glx/TCho [$F(1,21)=6.04$, $p=0.023$] and Glx/TCr [$F(1,21)=4.86$, $p=0.039$], when compared to those in the low-risk group, suggesting that absolute levels of Glx are elevated in 4-6-month-old infants at high-risk of ASD.
Conclusions: We emphasize that these results are preliminary and that data acquisition is still ongoing. Nevertheless, the findings presented in this study suggest that an imbalance in excitatory/inhibitory neurotransmission may be present in young infants genetically predisposed to developing ASD, and supports the notion that such an imbalance may partially underpin the pathophysiology of the disorder. Further proof that the glutamatergic pathway may be altered in infants-at-risk of ASD is required. However, the current findings should incentivize the ongoing search for pharmacological interventions targeting both glutamatergic and GABAergic systems.

29 **178.029** Examination of Developmental Sensitivity of Items on the Revised First Years Inventory Screener for Infants at Risk for a Later Diagnosis of ASD

Y. J. Chen[1], *V. L. Davis*[2], *L. R. Watson*[1], *E. Crais*[1], *L. Turner-Brown*[3], *J. C. Bulluck*[1], *W. Zhang*[1], *R. A. Faldowski*[1] *and G. T. Baranek*[1], *(1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Department of Psychology, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Â The First Years Inventory (FYI) v3.1 is a newly revised parent-report questionnaire designed to identify infants at risk for a later diagnosis of ASD, expanding the target age from 12 months to 8-16 months. Each item on the FYI uses 5-point Likert scales (never to always) on items across two original domains (i.e., social communication; sensory-regulatory functions) and typical milestones. Due to potential maturational changes across this age range, the FYI items need to be assessed with respect to age norms and developmental sensitivity in order to develop a clinically useful scoring algorithm in the future. That is, a given screening item may be highly sensitive to ASD risk in a 15-month-old, but relatively insensitive to ASD risk in a 9-month-old. There is currently no "ASD-specific" parent-report screening tool for early risk markers in this age range that considers the effects of developmental sensitivity of individual items, which is a critical issue to address.
Objectives: The current study aimed to analyze a community sample of 5,960 infants aged 8-16 months to consider norms and developmental sensitivity of each FYI item across the domains of interest as a first step in creating a clinically more useful tool.
Methods: The FYI 3.1 was sent to ~40,000 families across North Carolina through the state birth registry. Each family received either an A or B version of the questionnaire to reduce time burden. There were 48 questions in each version with 27 core questions across the two versions, and thus 69 different items in total. We received 6,657 valid FYIs (response rate: 17%) and 5,960 were analyzed after excluding pre-term infants. Ordinal logistic regression analyses were conducted by item to examine the association between age and the 5-level ordinal response categories.
Results: Â There were 10 items showing statistically significant associations with age and Cox & Snell's pseudo R-square values ranging from 0.15-0.35, and all these items were in the domain of "social communication". Among them, two core items within the construct of "social initiation" had the largest R-square values (above 0.30).
Conclusions: The results showed that the developmental factor should be taken into consideration for ASD screening items related to social communication, but less so for sensory-regulatory functions. The statistically significant associations between age and item responses indicated that age explained a relatively large proportion of the variability in these item responses. The current results are supported by a longitudinal research indicating that social engagement increases linearly within the first 5 years of life, with major strides during the first year (Feldman & Eidelman, 2009). Accounting for developmental sensitivity when scoring specific items on ASD screening tools may help decrease false-positive screens for those of younger age within a wider age window. Follow-up studies are being conducted to optimize risk scoring algorithms and maximize prediction to ASD outcomes at age 3.

30 **178.030** Examining Sex Differences in Adaptive Behavioral Development in High Risk Infants with ASD, Social Communicative Delay, and Typical Development

E. Sharer[1]*, J. N. Constantino*[2]*, K. Botteron*[3]*, A. Estes*[4]*, H. C. Hazlett*[5]*, J. Piven*[6]*, R. T. Schultz*[7] *and J. T. Elison*[1]*, (1)University of Minnesota, Minneapolis, MN, (2)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO, (3)Washington University School of Medicine, St Louis, MO, (4)University of Washington Autism Center, Seattle, WA, (5)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Carolina Institute for Developmental Disabilities, Carrboro, NC, (7)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: There is notable phenotypic heterogeneity among high-risk (HR) siblings of children with autism who do not meet ASD diagnostic criteria. A substantial proportion of non-ASD HR siblings manifest a profile of subthreshold ASD symptoms and/or low developmental level compared to low-risk (LR) children (Messinger et al., 2013). More work is needed to understand heterogeneity in HR siblings and to potentially elucidate sex-specific differences, if present. Under-representation of females in research may obfuscate female protective effects or sex-specific ASD and subclinical social-communicative development.
Objectives: To determine whether sex differentially influences behavioral trajectories in ASD, social-communicative concern, and typical outcomes in a sample of HR infant siblings while controlling for genetic loading in families.
Methods: We examined 334(137F) HR and 123(55F) LR infant siblings, assessed at 6, 12, and 24-months. ASD classification at 24 months was based on CBE using DSM-IV criteria and by meeting ADOS criteria (HR-ASD, N=72(15F)). HR siblings with 24-month receptive or expressive language Mullen Scales of Early Learning scores one SD below the mean and/or ADOS social affect subscale score >5 were classified as HR-SocCom (N=87(36F)) to capture subthreshold, yet concerning social-communicative development. The remaining HR infants (N=175(86F)) are referenced as HR-TD. No LR infants had an ASD diagnosis. Experimentally controlling for genetic loading, the HR sample was restricted to participants with male probands, except HR-ASD females (as a female containing family may reflect different inheritance pattern). Five LME models were fit to each Vineland Adaptive Behavioral Scale (VABS) subscale and summary score. Predictors of interest include age, group, sex, and interactions. Benjamini-Hochberg correction was applied to pairwise group comparisons.
Results: Infants are more likely to be male in the HR-ASD group as compared to the HR-TD (RR=1.56, p=.00005) and the HR-SocCom (RR=1.35, p=.006). We observe equal sex proportion in the HR-SocCom and HR-TD groups (RR=1.15, p=0.241). All best-fit LME models of VABS subscales and composite score, except motor skills, include age, group, sex, and group-by-age effects. The motor skills best-fit LME model included age and group. Group-by-sex interactions did not improve fit in any model. 6-month ABC scores revealed the following pattern of group differences (LR-TD>HR-TD>HR-ASD, whereas the HR-SocCom group did not differ from the HR-TD or the HR-ASD group). 6-month motor scores revealed the following pattern of group differences (LR-TD>HR-TD=HR-SocCom>HR-ASD). Trajectories across the interval differentiated the groups in a consistent manner in the ABC, communication, and socialization domain, such that LR-TD=HR-TD>HR-SocCom>HR-ASD.
Conclusions: Experimentally controlling for proband sex, we did not observe specific sex effects on group trajectories of adaptive behavior from 6-24 months of age. Pairwise group differences revealed a gradient of attenuated adaptive behavioral development across groups. Relative risk discrepancy between HR males and females is maintained in ASD but not social-communicative concern, indicating sex may protect from diagnostic, but not subthreshold levels of concern. These data are consistent with previous reports (Constantino & Todd, 2003; 2005) suggesting that the M:F sex ratio differs by degree of affectation.

31 **178.031** Exploring Positive Affect in a Randomized Control Trial of the Social ABCs Parent-Mediated Intervention for Toddlers with Confirmed or Suspected ASD

J. A. Brian[1]*, **E. M. Dowds***[2]*, T. McCormick*[3]*, S. Macwilliam*[4]*, K. Lynch*[5] *and S. E. Bryson*[6]*, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Burlington, ON, Canada, (3)IWK Health Centre, Halifax, NS, CANADA, (4)IWK HEALTH CENTRE, HALIFAX, NS, CANADA, (5)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, CANADA, (6)Dalhousie University, Halifax, NS, CANADA*

Keywords: ASD, early intervention, toddlers, parent-mediated intervention, communication, positive affect, smiling, social orienting
Background : The *Social ABCs* is a parent-mediated intervention (Brian et al., 2016) based on empirically supported Pivotal Response Treatment (PRT; Koegel & Koegel, 2006). The main targets of the *Social ABCs* are functional early (vocal/verbal) communication and positive affect sharing between child and caregiver among infants/toddlers who have suspected or diagnosed Autism Spectrum Disorder (ASD). Our positive affect target is motivated by evidence of reduced or declining positive affect, in high-risk infants, predictive of ASD outcomes (e.g., Bryson et al., 2007; Filliter et al., 2015; Landa et al., 2013; Ozonoff et al., 2010); this highlights the importance of positive affect as an early intervention target for toddlers with ASD, particularly given its importance in developing social relationships and learning generally.
Objectives : Bolstered by evidence of increased shared smiling between child and caregiver following participation in the*Social ABCs* intervention (p =.017; Brian et al., under revision; Bryson et al., IMFAR, 2015), we sought to further explore the impact of our intervention on person- vs. object-oriented smiling.
Methods : 62 parent-toddler dyads were randomized into the *Social ABCs* (treatment) group or received treatment as usual (control) across 2 Canadian research sites (Toronto and Halifax). Parents of toddlers aged 16 to 30 months received 12weeks of in-home, live coaching, followed by 12-week parent implementation. Here, we compare groups (treatment vs. control) on changes from baseline to post-training (week 12) in three key video-coded behaviours: (1) child smiling to caregiver, (2) parent smiling to child, and (3) child smiling at objects/activities.

Results : Paired samples t-tests (with Bonferroni correction) revealed: (1) parents in the *Social ABCs* group (but not controls) smiled significantly more to their children post-training relative to baseline (p=.002); (2) children in the *Social ABCs* group (but not controls) smiled significantly more to their caregivers following intervention (p=.02); and (3) children in the control (but not treatment) condition smiled significantly more to objects at the end of the 12-week period (p=.007) compared to baseline.

Conclusions: Significant gains were observed, only for the treatment group, in person-oriented smiling. Conversely, controls spent increasingly more time smiling at objects/activities, with no change in person-oriented smiling, over the same time period. In order to further investigate the role of positive affect, we will explore relationships between smiling and child communication, parent self-efficacy, fidelity, and stress. Next steps involve further elucidating the relevance of smiling as a treatment target in ASD, with discussion about the importance of positive affect in the development of social relationships and in learning more generally. Finally, we consider whether child smiling increased because the behaviour (smiling) itself was reinforced by caregivers, or whether it is better understood as an index of 'feeling good' in the context of the intervention.

32 **178.032** Exploring Sex Differences in Autism Spectrum Disorder in the Charge Study

M. White[1]*, C. W. Nordahl*[2]*, K. Angkustsiri*[3]*, R. Hansen*[4]*, D. Harvey*[5]*, I. Hertz-Picciotto*[6] *and D. J. Tancredi*[7]*, (1)Pediatrics, UC Davis, Sacramento, CA, (2)Department of Psychiatry & Behavioral Sciences, University of California-Davis, Sacramento, CA, (3)University of California at Davis, Sacramento, CA, (4)UCD MIND Institute, Sacramento, CA, (5)Public Health Sciences, Division of Biostatistics, UC Davis, Davis, CA, (6)University of California at Davis, Davis, CA, (7)UC Davis School of Medicine, Sacramento, CA*

Background: Â Autism spectrum disorder (ASD) is more prevalent in males than females.Â Understanding the phenotypic differences between males and females may allow for insight into the etiology of ASD, which could guide sex specific screening, diagnostic and treatment pathways.
Objectives: Â To evaluate sex differences in developmental and adaptive function of young children with autism spectrum disorder (ASD)
Methods: The Childhood Autism Risk from Genetics and the Environment (CHARGE) study is an ongoing, population-based case-control study.Â Participants include children ages 2-5 years old with ASD and typically developing (TD) controls.Â TD children were age and location matched using birth certificate data.
For this analysis, all children who met criteria for ASD based on the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2) and Autism Diagnostic Interview – Revised (ADI-R) were included. Any child with a known genetic syndrome was excluded.
We evaluated developmental and adaptive function in 724 children with ASD (612 M, 112 F) and 482 TD controls (397 M, 85 F) with a mean age of 44.1 months. Chi-square tests, ANOVA or logistic regression were used to evaluate differences in baseline demographics. T-tests, ANOVA, or Chi-square tests were used to assess differences in autism characteristics, including age at diagnosis, ADOS-2 comparison score, ADI-R scores and percentage of children enrolled in services. A 2X2 factorial ANOVA was used to estimate the interaction between diagnosis and sex for developmental and adaptive measures.
Results: There were no significant sex by diagnosis interactions in demographics. However, age at clinic visit and maternal education were both approaching significance. On further analysis, there was a main effect of diagnosis on both age (TDs younger, p=.005) and maternal education (TDs with more educated mothers, p=.01). Autism characteristics did not differ between males and females. As the outcome measures are standardized for age, only maternal education was used as a covariate in the following analyses. On the MSEL, there was a main effect of sex on visual reception (p=.01), receptive language (p=.02), expressive language (p=.02), fine motor (p=.003), and the early learning composite (p=.04) with females scoring higher than males in both ASD and TD groups. There were no significant sex by diagnosis interactions on the MSEL. On the VABS, there was a main effect of sex on communication (p=.02), daily living skills (p=.01), socialization (p=.03), and the composite (p=.02). There were also significant sex by diagnosis interactions in daily living skills (p=.001), socialization (p=.04), and the composite (p=.009). TD females tended to score higher than TD males, while males and females with ASD had similar adaptive skills.
Conclusions: Females scored higher than males in all aspects of developmental functioning in this sample, regardless of whether they were ASD or TD. However, only TD females outscored their male counterparts in adaptive skills. Therefore, a developmental advantage does not translate into superior adaptive functioning in females with ASD in this sample.

33 **178.033** Gender Differences in CSBS Scores

S. James[1]*, E. C. Bacon*[2]*, C. J. Smith*[1] *and K. Pierce*[3]*, (1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)University of California San Diego, La Jolla, CA, (3)University of California, San Diego, San Diego, CA*

Background: Â The prevalence of autism is reported to be higher among males than females, although the exact mechanism underlying this gender difference is unknown. Evidence suggests that phenotypic gender differences may account for some of this male bias in prevalence (Gould & Ashton-Smith, 2011). Specifically, differences in the manifestation of symptoms (e.g. females exhibiting fewer stereotypies) may result in females being underdiagnosed (Werling & Geschwind, 2013). The implications of gender differences in phenotypic presentation are diverse, starting with a need to re-examine, and potentially amend screening and diagnostic tools.
Objectives: Â This study's objective was to assess if gender differences exist in screening and diagnostic methods for autism.Â Specifically, we examined if Communication and Symbolic Behavior Scales Developmental Profile Infant-Toddler Checklist (CSBS) scores varied between male and female toddlers. The CSBS is a broadband screening tool used to detect various disorders, including autism (Wetherby et al., 2008). The CSBS comprises three composite scores (social, speech, and symbolic) and a total score.
Methods: Data were collected as part of a larger study, in collaboration with UCSD, that is testing a model called Get S.E.T. Early (S=Screen, E=Evaluate, T=Treat), designed to detect, evaluate, and treat autism within the first 2 years of life. Children from the general Phoenix and San Diego population are screened using the CSBS at 12-, 18-, and 24-month well-baby checkups. Children who fail the CSBS are referred for free developmental evaluations. Analyses for this study focused on two groups of children from the Phoenix cohort: (1) 7504 toddlers (3874 females and 3630 males) who passed all sections of the CSBS, and (2) 324 toddlers (82 females and 242 males) who failed at least one section of the CSBS and who received a developmental evaluation. Mean scores for males and females were compared using Bonferroni-corrected Mann-Whitney U tests.
Results: For toddlers who passed the CSBS, females scored significantly higher than males for the social (*MD*=0.36, *r*=.07), speech (*MD*=0.41, *r*=.09), and symbolic (*MD*=0.40, *r*=.07) composites, and for the total score (*MD*=1.17, *r*=.08). For toddlers who failed the CSBS and who received a developmental evaluation, no significant differences between males and females emerged for any composite score or the total score. Approximately 56% of the 242 evaluated males were at-risk for ASD, while only 38% of the 82 evaluated females were at-risk for ASD.
Conclusions: Although females who passed the CSBS had significantly higher composite scores, and total scores, than males who passed the CSBS, mean differences were negligible with small effect sizes, and statistical significance was likely achieved as a result of the large sample size. No gender differences emerged for children who failed the CSBS and who received a developmental evaluation. Despite this, approximately 3 times as many males than females failed the CSBS and received a developmental evaluation, and among those who received the developmental evaluation the odds of being at-risk for ASD were 2 times higher for males than females. This suggests that increased sensitivity on screening and diagnostic assessments for ASD is needed to better reflect the autism phenotype expressed by females.

34 **178.034** How Frequent Is Loss of Skills in ASD Associated with Genetic Abnormalities?

A. Thurm[1], *S. L. Bishop*[2], *C. Farmer*[1], *S. J. Sanders*[3], *L. Soorya*[4], *L. Berry*[5], *C. P. Schaaf*[6], *M. A. Gillentine*[7], *A. Simon*[5] *and R. P. Goin-Kochel*[8], *(1)National Institute of Mental Health, Bethesda, MD, (2)Psychiatry, University of California San Francisco, San Francisco, CA, (3)UCSF, San Francisco, CA, (4)Rush University Medical Center, Chicago, IL, (5)Baylor College of Medicine, Houston, TX, (6)Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, (7)Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, (8)Pediatrics, Baylor College of Medicine, Houston, TX*

Background: Â The rate of identification of genetic abnormalities in individuals diagnosed with ASD is rising. Functions of the involved genes include brain development and metabolic processes (de la Torre-Ubieta, Won, Stein, & Geschwind, 2016). The majority of extant literature on regression, or loss of skills, in ASD included samples considered "idiopathic," and thus has not explored if and how genetic abnormality association relates to specific patterns of symptom onset or loss. While we do know that regression may be associated with specific genetic vulnerabilities related to ASD and/or intellectual disability (Molloy, Keddache, & Martin, 2005; Neul et al., 2014), full exploration requires both large data sets as well as data from cohorts of specific genetic disorders associated with ASD.
Objectives: Â The purpose of this study was to investigate milestone attainment and loss of skills in individuals with genetic findings known to be associated with ASD, and in other specific genetic conditions.
Methods: First, we explored findings from the Simons Simplex Collection (SSC), including 112 probands with at least one *de novo* loss of function mutation copy number variants in, or including, a high confidence (*HC*) ASD gene or locus (an age, IQ, and sex-matched control group was selected from the remaining non-HC [*None*] group). Second, we report data from several natural history studies of genetic disorders, including Phelan-McDermid Syndrome (22q13 deletion or mutation; N=39; mean age 7.5+4.5 years), 15q13.3 deletion/duplication syndromes (Ndel=18; mean age 14.5+1.7 years; Ndup=18; mean age 9.9+3.0 years respectively), 16p11.2 CNVs, and 1q21.1 CNVs. The ADI-R was used to determine rates and pattern of skill attainment and loss.
Results: In the SSC cohort, the HC group had a significantly later mean age of walking than the None group. Both language and other skill loss were more common in the None group than in the HC group. Table 1 shows loss of language and other skills from preliminary data in the SSC cohort, as well as other genetic conditions. A fuller description of onset patterns, areas of loss, and current functioning in these cohorts will be provided, including the 16p11.2 and 1q21.1 cases.
Conclusions: While skill loss was more common in the SSC cohort when no genetic abnormality was present, it was present, along with a significant attainment lag in motor skills, in the HC group as well. Skill loss was relatively common in several other genetic conditions associated with ASD. These findings challenge the notion that regression is specifically associated with idiopathic or specific genetic conditions associated with ASD.

35 **178.035** IQ-Based Developmental Phenotypes of ASD Between Ages 2 and 7 Years and Their Correlates

M. Solomon[1], *A. M. Iosif*[2], *L. Libero*[3], *D. D. Li*[4], *L. Deprey*[5], *S. Ozonoff*[3], *S. J. Rogers*[6], *C. W. Nordahl*[7], *S. Ghetti*[8] *and D. G. Amaral*[7], *(1)MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (4)UC Davis MIND Institute, Rancho Cordova, CA, (5)University of California at Davis MIND Institute, Sacramento, CA, (6)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (7)Department of Psychiatry & Behavioral Sciences, University of California-Davis, Sacramento, CA, (8)Department of Psychology, University of California-Davis, Davis, CA*

Background: Longitudinal Investigation of the developmental phenotypes of ASD offers a promising strategy for of identifying homogeneous pathophysiology-based subgroups. Here, we investigate cognitive phenotypes defined by IQ trajectory change between ages 2 and 7 in the Autism Phenome Project (APP) longitudinal cohort.
Objectives: To: (1) examine cognitive development between ages 2 and 7; (2) define ASD phenotypes derived from IQ-based developmental trajectories during this period; and (3) investigate associations between trajectory membership, and adaptive functioning, problem behaviors, and autism severity.
Methods: Latent class modeling using adjusted DQ scores derived from the Mullen Scales of Early Learning and the Differential Abilities Scale-II at ages 2 and 7 was implemented in 97 individuals with ASD. After classifying the ASD participants into trajectory groups, we examined changes in IQ, adaptive functioning, problem behaviors, and autism severity using a repeated measures approach with multiple comparison correction. All models included fixed effects for time, trajectory group, and their interaction. Problem behaviors, autism severity, and adaptive functioning were assessed using the CBCL, ADOS-2, and VABS-2, respectively.
Results: Three distinct IQ trajectory groups were identified. The first had IQs ≤ 77 at both times (**Greater challenges**: n=36; 37%). The second had IQs ≥ 75 at both times (**Lesser challenges**: n=23; 24%). A third group exhibited IQs < 82 at age 2, and had scores of ≥ 70 at age 7 with increases of ≥ 1 standard deviation (**Changers**: n=38; 39%). Repeated measures analyses revealed that the **Lesser challenges** group had significantly higher IQ scores than the **Changers** (31 points) and the **Greater challenges** groups (39 points) at age 2 (both p < .001). The 60% of the sample that was in either the **Changers** or **Lesser challenge**s groups had significant improvements in IQ from age 2 to 7 (30 and 10 points, respectively, both p<.001). On the VABS-2, at age 2, there were significant differences across trajectory groups, driven mainly by differences between the **Greater challenges** and the **Lesser challenges** groups (t=4.23, p<.001). On the VABS-2, between ages 2 and 7, the **Lesser challenges** group showed no change, while the **Changers** improved by 6 points (t=2.43, p=.02), and the **Greater challenges** group declined by 9.4 points (t=-4.5, p<.001). On the Externalizing scales of the CBCL, there was no group difference at age 2, however the **Changers** experienced a significant 8-point decline in Externalizing (t=4.32, p <.001), while the other groups did not. Autism severity changed significantly only in the **Lesser Challenges** group (t=4.88, p<.001).
Conclusions: A significant proportion of children with low early cognitive abilities will undergo significant intellectual development by age 7. This **Changers group** also exhibited significant reductions in externalizing symptoms by age 7, suggesting that reducing these symptoms by middle childhood is related to positive changes in cognitive development and adaptive functioning. Only the **Lesser Challenges** group showed a significant reduction in autism symptom severity during this period. A follow-up study of the APP at ages 8-12 is ongoing.

36 **178.036** Infant Gaze to Faces Across Interactive Contexts

D. N. Gangi[1]*, A. J. Schwichtenberg*[2]*, A. M. Iosif*[3]*, G. S. Young*[4] *and S. Ozonoff*[4]*, (1)UC Davis MIND Institute, Sacramento, CA, (2)Purdue University, West Lafayette, IN, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA*

Background: Infant gaze is an important social-communicative behavior and is particularly relevant among infants at risk for autism spectrum disorder (ASD), who have been shown to exhibit atypicalities in gaze-related behavior in the first year of life. A common scenario in research settings, in which conditions need to be standardized across participants, is to measure infant social-communication behavior with an unfamiliar examiner, including during diagnostic assessments such as the Autism Diagnostic Observation Schedule. It is important to understand how infant behavior in structured contexts with novel social partners relates to behavior during interaction in a more familiar context (i.e., play) with a caregiver to assess whether skills in such structured settings generalize to other contexts.
Objectives: To investigate the relationship between gaze behavior during two different interactive contexts: structured testing with an unfamiliar examiner and unstructured play with a parent, in infants without and with a sibling with ASD.
Methods: Â Participants were classified into one of three groups based on diagnostic assessment at 36 months: low-risk non-ASD (*n*=53), high-risk non-ASD (*n*=66), or ASD group (*n*=17; 16 high-risk, 1 low-risk). At 6, 9, and 12 months, infants participated in two interactive contexts: 1) an unfamiliar examiner administered the Mullen Scales of Early Learning, a standardized developmental test, and 2) a play interaction with a parent, during which infants (in a high chair with a tray) and their parents (seated across from their infants) were provided a set of age-appropriate toys and instructed to play as they would at home. Infant social-communicative behavior was coded during the first 6 minutes of the examiner-administered Mullen Visual Reception subtest and during the 3-minute parent-child play interaction at each visit. The frequency of gaze to an adult's face was coded following procedures in Ozonoff et al. (2010). Frequency counts were then divided by the total duration coded to create rates of gaze per minute in each context.
Results: Â Regression analyses were conducted to examine the associations between infant gaze to face behavior in the two interactive contexts at each age, controlling for potential effects of familial risk or diagnostic classification. At 6 months, infant gaze to faces during Mullen testing approached significance in predicting infant gaze to face during parent-child play, β=0.25, standard error=0.14, p=.08. At 9 months, infant gaze to faces during Mullen testing significantly predicted infant gaze to face during parent-child play, β=0.34, standard error=0.10, p<.001. At 12 months, infant gaze to faces during Mullen testing significantly predicted infant gaze to face during parent-child play, β=0.46, standard error=0.14, p<.01.
Conclusions: Â Infant gaze behavior, a potential early marker of ASD, was significantly associated between two interactive contexts by 9 months of age, controlling for outcome group. Infants with higher levels of gaze to the face of an examiner during structured testing were likely to have higher levels of gaze to the face of a parent during unstructured play. This supports the validity of observing gaze behavior within laboratory settings, which appears to provide a representative measurement of an infant's skills in more naturalistic settings.

37 **178.037** Insecure-Resistant Attachment Classification (and behaviors) in Infants Later Diagnosed with Autism Spectrum Disorder

K. B. Martin[1]*, E. B. Prince*[1]*, J. D. Haltigan*[2]*, N. Ekas*[3] *and D. S. Messinger*[4]*, (1)Psychology, University of Miami, Coral Gables, FL, (2)Psychology, Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Psychology, Texas Christian University, Fort Worth, TX, (4)Psychology, University of Miami, Miami, FL*

Background:
Attachment security, assessed between 12-15 months using the gold-standard Strange Situation Procedure (SSP), is an index of early social-emotional functioning. Autism spectrum disorder (ASD) involves impairments in social-emotional functioning, including difficulties forming and maintaining relationships. Researchers have found that children with ASD are less likely to have secure attachments to their parent (Rutgers et al., 2004), largely using modified versions of the SSP at later ages and retrospectively after a child is diagnosed. Few studies have examined attachment security prospectively in infant siblings of children with ASD using the original SSP. In a previous study of infant siblings of children with ASD, we found that these high-risk infant siblings were not more likely to evince insecure attachment to their parent than infant siblings of typically-developing children (Haltigan et al., 2011).
Objectives:
To determine whether attachment security at 15 months differs by later diagnostic outcome at 36 months (ASD or no ASD diagnosis).
Methods:
Infant-parent dyads (*n*=95) completed the SSP at 15 months. Infants were reliably classified by expert raters as secure (*n*=72), avoidant (*n*=10), or resistant (*n*=13). Attachment was also examined as a continuous score along two dimensions: approach/avoidance behaviors and resistance/disorganization behaviors (Spieker & Fraley, 2003). The sample included infants without (low-risk) and with (high-risk) an older sibling with ASD. At 36 months, a diagnosis of ASD was determined for low- and high-risk children by an experienced clinician informed by the Autism Diagnostic Observation Schedule. We assessed differences in attachment security in low-risk children (Low-Risk/No-ASD, *n*=39), high-risk children with no ASD diagnosis (High-Risk/No-ASD, *n*=40) and high-risk children with an ASD diagnosis (High-Risk/ASD, *n*=16).
Results:
The frequencies of secure and insecure attachment classifications differed between the three outcome groups, $p<.005$, as children with ASD were disproportionately more likely to be classified as insecure than children without ASD (**Figure 1**). The frequencies of secure, resistant, and avoidant attachment differed between the three outcome groups, $p<.02$, as children with ASD were more likely to be classified as insecure-resistant than children without ASD (**Figure 2**). High-Risk/ASD infants had higher resistance/disorganization scores than both Low-Risk/No-ASD and High-Risk/No-ASD infants, $F(2, 92)=3.469$, $p=.035$, but did not differ along the approach/avoidance dimension, $F(2,92)=.786$, $p>.05$.
Conclusions:
Using a prospective design, we found that high-risk infant siblings *who are later diagnosed with ASD* are able to form attachment relationships with their caregivers, but are more likely to display insecure attachment patterns compared to children without ASD. High-Risk/ASD infants exhibited more resistant and disorganized strategies when interacting with their parents. These prospective findings suggest that half of infants who go on to develop ASD have early social difficulties that interfere with their ability to establish a secure attachment with their caregiver. Alternatively, the increased resistant/disorganized scores in the ASD group may be indicative of underlying neurological impairment rather than an indicator of a problematic attachment relationship (Pipp-Siegel et al., 1999). It is also possible that High-Risk/ASD infants, because of temperamental variables or the early emergence of ASD symptoms, may tax caregivers' ability to be sensitively responsive to their infants.

38 **178.038** Interactions Between Young Children with Autism Spectrum Disorder and Their Caregivers

J. Obitko[1]*, C. Wong*[2] *and K. C. Gallagher*[3]*, (1)FPG Child Development Institute, UNC Chapel Hill, Chapel Hill, NC, (2)University of North Carolina, Chapel Hill, Chapel Hill, NC, (3)FPG Child Development Institute, UNC - Chapel Hill, Chapel Hill, NC*

Background:
In research with young children with autism spectrum disorder (ASD), observing caregiver-child interactions provides an opportunity to assess children's social-communication behaviors and caregivers' parenting styles. One assessment used, the Indicator of Parent Child Interaction (IPCI), an Individual Growth and Development indicator (IGDI) has been used frequently in educational assessment with infants and toddlers, but less so in research with young children with ASD. The current study examined parent-child interactions with the IPCI with a group of toddlers with ASD.
Objectives:
Our specific aims include:

1. To examine caregiver interaction behaviors as measured by the IPCI.
2. To examine child interaction behaviors as measured by the IPCI.
3. To identify caregiver and child characteristics that may affect their interaction behaviors.

Methods:
Thirty-three young children with or at risk for ASD, as determined by the Modified Checklist for Autism in Toddlers (M-CHAT), participated in the IPCI with a primary caregiver as part of a larger intervention study. Children ranged in age from 17 to 42 months old, with a mean of 24 months. Primary caregivers were mostly female and ranged in age from 25 to 52 years, with a mean of 35 years old. The IPCI consists of four semi-structured parent-child activities (free play, looking at books, distraction task, and dressing), similar to those that might be observed in daily family routines. Episodes were videorecorded for a total of ten minutes and coded in 30-second intervals on 6 caregiver interaction behaviors (warmth and acceptance, descriptive language, follows lead, maintaining/extending, harsh/critical, and restrictions) and 6 child interaction behaviors (positive feedback, sustained engagement, follow through, irritable/fuss/cry, external distress, and frozen/watchful). Children were also assessed on the Mullen Scales of Early Learning from which a mental age score was calculated.
Results:
Caregivers engaged in descriptive language with their children in over half of the intervals (M=10.42, SD=5.20). In almost half of intervals, caregivers were observed following the child's lead (M=8.06, SD=4.39). No harsh or critical caregiving behaviors were observed. Children demonstrated sustained engagement in play with a toy for approximately half of the intervals (M=10.36, SD=3.87); however, children displayed positive affect such as smiling at their caregiver in only about 5% of the intervals (M=1.15, SD=2.25). No children demonstrated frozen/watchful behavior. Parents' use of descriptive language and children's engagement were positively correlated with children's mental age scores (r=.417, p<.05; r=.375, p<.05, respectively).
Conclusions:
Findings from this descriptive study provide valuable information about caregivers' and children's behaviors during interactions across several different activities. In particular, caregivers used descriptive language over half of the time with their toddlers, and more so when toddlers had higher cognitive skills. Furthermore, children with higher cognitive scores demonstrated more engagement in activities with caregivers than children with lower scores. Future research will examine how aspects of caregiver-child interactions may change over time as related to an intervention to enhance interaction quality.

39 **178.039** Investigating the Construct Validity of the Social Communication Schedule for Young Children with Severe Visual Impairment 'at Risk' of ASD: Relations with the Child Behaviour Checklist

N. Dale[1], *E. Sakkalou*[1], *M. O'Reilly*[2] *and A. Salt*[3], *(1)Clinical Neurosciences, UCL Great Ormond Street Institute of Child Health, London, United Kingdom, (2)UCL Institute of Child Health, London, UNITED KINGDOM, (3)Great Ormond Street Hospital for Children, London, UNITED KINGDOM*

Background:
Children with congenital profound or severe visual impairment (VI) are at high risk of ASD and social communication difficulties. Studies report a much higher prevalence of ASD in children with VI (~30%) compared to rates in the sighted population (Jure et al., 2016). Socio-communicative difficulties in children with VI become evident from around 2 years of age (Dale & Sonksen, 2002). Existing tools used to measure early socio-communicative development are highly vision-dependent and not valid for children with VI. We developed the Social Communication Schedule (SCS) to examine social-communicative difficulties in 2-year-olds with VI. SCS is based on the Visual Impairment and Social Communication Schedule (VISS - Absoud et al., 2010), which had preliminary validation with children with VI and was highly reliable in predicting a later diagnosis of ASD. The SCS was developed further to include standard behavioural items and social 'presses' to elicit social and communicative behaviours that allow for reliable behavioural coding. We also developed the Negative Behavioural Screener (NBS) to examine ASD related difficulties including repetitive behaviours. To begin to establish construct validity parents completed the Children's Behavior Checklist (CBCL 1.5 – 5 years), a standardized parental questionnaire which measures behavioural difficulties and problems in preschool children. It includes the subscale PDP (Pervasive Developmental Problems) which has consistently provided predictive relations with existing ASD screening tools (Muratori et al., 2011; Sikora, et al, 2008).
Objectives:
To examine the construct validity of the SCS and NBS at 2 and 3 years of age by cross-sectional and longitudinal comparisons to the CBCL PDP subscale.
Methods:
Preliminary data from 50 children at 2 years (M=26.10, SD=2.30) and 39 at 3 years (M=38.28, SD=2.91), with 'simple' congenital disorders of the peripheral visual system from the longitudinal OPTIMUM project (Dale et al.) were rated using the SCS (high scores indicated better social communicative abilities) and a negative behaviour screener (NBS – higher scores indicated more negative behaviours), whilst engaging in social and independent play tasks. Parents rated the CBCL when children were 2 and 3 years of age and the PDP subscale was extracted for analyses.
Results:
Strong negative relations between SCS scores and NBS scores (**ρ** =-.73, p<.001), suggested that children who scored higher on socio-communicative abilities on SCS had lower negative behaviour scores on NBS. At 2 years of age, a negative correlation was found between PDP and SCS (**ρ** =-.45, p<.01) and a positive correlation between PDP and NBS (**ρ** =.37, p<.01). Similar patterns were found at 3 years on the same scales (**ρ** =-.41, p<.01, **ρ** =.48, p<.01). Children with lower SCS scores and higher NBS scores were rated higher on PDP by parents at both time points.
Conclusions:
The SCS, which is newly developed for young children with VI, and NBS showed moderate relations with the CBCL PDP subscale at 2 and 3 years. Findings suggest that this 'early stage' tool may provide a useful means of differentiating behaviours, which may be early signs of autism.
Â

40 **178.040** Preschool Peer Relationships in Younger Siblings of Children with ASD

A. Estes[1], *J. Munson*[2], *T. St. John*[3], *M. J. Guralnick*[4], *S. Dager*[5], *A. Rodda*[2], *H. C. Hazlett*[6], *K. Botteron*[7], *R. T. Schultz*[8], *J. Piven*[9] *and T. The IBIS Network*[10], *(1)Speech and Hearing Sciences, University of Washington Autism Center, Seattle, WA, (2)University of Washington, Seattle, WA, (3)University of Washington Autism Center, Seattle, WA, (4)Psychology and Pediatrics, University of Washington, Seattle, WA, (5)University of Washington School of Medicine, Seattle, WA, (6)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (7)Washington University School of Medicine, St Louis, MO, (8)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Carolina Institute for Developmental Disabilities, Carrboro, NC, (10)University of NC, Chapel Hill, NC*

Background: Peer competence and friendships are major developmental achievements in middle-childhood and are related to emotional well-being and academic skills. Peer relationships in preschool provide opportunities to develop the skills required for these achievements. By school-age, children with ASD demonstrate fewer reciprocal friendships and poorer peer competence than same-age peers. However, little is known about peer relationships in preschool-age children with ASD. Younger siblings of children with ASD may be at risk for poor peer competence and friendships due to higher rates of ASD (~20%) and other developmental and psychiatric conditions (~25%), but no empiric studies have yet described peer relationships in this high-risk (HR) population. Caregivers play an important role in promoting peer competence during preschool, but it is not yet known to what extent having an older sibling with ASD may impact early peer relationship development in this high-risk group.
Objectives: We examined 1) peer relationships in preschool-aged HR vs low-risk (LR) younger siblings, 2) factors associated with poorer peer relationships, and 3) peer relationship support activities among caregivers with an older child with ASD (HR) vs typical development (LR).
Methods: Data include 70 HR (16 ASD-pos; 54 ASD-neg) and 36 LR participants enrolled in the Infant Brain Imaging Study at 6 or 12 months with peer relationships measured during preschool (age 3-5). Diagnosis (based on DSM-IV-TR) and language ability (Expressive and Receptive Language, Mullen Scales) were directly assessed by research reliable clinicians across 4 sites at age 3-5 or at 24 months for 20 HR-ASD-neg children assessed only by questionnaire at age 3-5. Peer relationships (Peer Social Contact Questionnaire; Guralnick, 1997), and problem behavior (Internalizing and Externalizing scales, CBCL) were assessed through parent-report at preschool age.
Results: The HR-ASD-pos group had significantly fewer peer playmates than the HR-ASD-neg and LR-neg groups (F(2,103)=7.80, p<.001) and lower quality peer interactions than HR-ASD-neg group (F(2,79)=4.66, p<.05). Half of ASD-pos preschoolers had no playmates vs 20% of HR-ASD-neg and 20% of LR. HR-ASD-pos children with no peers had higher internalizing and externalizing behavior than those with peers, and HR-ASD-neg and LR groups. Caregivers of HR-ASD-pos children reported significantly greater stress while monitoring play (F(2,77)=4.82, p<.05) and greater need to directly facilitate peer play interactions (F(2,76)=4.20, p<.05). HR-ASD-neg and LR caregivers did not differ regarding stress while monitoring or facilitating.
Conclusions: Children with ASD already demonstrate precursors to poor peer competence and friendship outcomes by preschool, with fewer playmates and lower quality peer relationships. Having an older sibling with ASD does not increase caregiver stress or monitoring demands during younger sibling playdates. Importantly, arranging playdates is no more difficult for caregivers of preschoolers with ASD, caregivers with an older sibling with ASD (HR-ASD-neg) or caregivers with only typically developing children (LR). However, caregivers of preschoolers with ASD report increased stress while monitoring playdates as compared with HR-neg and LR caregivers. The preschool years may be well-suited for implementing parent-delivered interventions to support the development of peer competence in younger siblings of children with ASD and to reduce caregiver stress while monitoring play.

41 **178.041** Motor Delays in Infants and Toddlers with ASD and Social Communication Delay

R. Landa[1] *and M. Tahseen*[2], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

Background: Infants having an older sibling with an autism spectrum disorder (ASD) are at heightened risk (HR sibs) for ASD and other delays. Differences in HR sibs' postural control, grasping, and anticipatory action responses have been reported but little is known about how these manifest in children later identified as exhibiting ASD, non-ASD social or communication delay, or no delays.
Objectives: Examine motor development between ages 6-24 months in children at heightened risk for ASD and other social communication delays, and the relation between these and developmental status between 24-36 months.
Methods: HR sibs (N=150, 95 males) and LR controls (N=60, 27 males) in this prospective, longitudinal study were assessed with the Peabody Developmental Motor Scales-2 (PDMS; Folio & Fewell, 2000) at ages 6, 10, 14, 18, and 24 months. Dependent variables were PDMS raw scores on the (1) Stationary, (2) Object Manipulation, (3) Grasping, and (4) Visual-Motor Integration subscales. Between ages 24-36 months, children were classified as No Delay (N= 134, 66 males, 79 HR, 55 LR), Social or Communication Delay (Other Delay, N= 45, 32 males, 39 HR) or ASD (N= 32, 24 males, 32 HR) using Mullen Scales of Early Learning (for No Delay and Other Delay groups), and ADOS scores and clinical judgment (for all three groups).
Results: LR and HR children in the No Delay and Other Delay groups performed similarly, so were combined for analyses to maximize sample size. Multiple one-way ANOVAs (with Bonferroni corrections) revealed significant group differences across the three groups defined by outcome classification (No Delay, Other Delay, and ASD) within each age (6, 10, 14, 18 and 24 months; e.g., Figures 1, 2). Children in the ASD group scored significantly lower on Stationary and Object Manipulation subscales than the No Delay group at 18 months and 24 months. On the Visual-Motor Integration subscale, the ASD group scored significantly lower than the No Delay group at an early age (6, 10, and 14 months). On the Grasping subscale, the ASD group scored lower than both No Delay and Other Delay groups only at age 24 months. Interestingly, the Other Delay group differed from the No Delay group on Stationary skills at 24 months and from the ASD group on Object Manipulation and Grasping subscales at 24 months.
Conclusions:
Children with ASD exhibited delay in motor development from mid-infancy into early toddlerhood. The earliest distinguishing delay was observed in visual-motor integration. This has implication for development of perception-action coupling, and could deter efficient and timely anticipatory responses and interpersonal synchrony in children with ASD. Later in the second year, toddlers with ASD exhibited slowing in fine motor development in areas integral to play development. Gross motor delays were identified in toddlers with social and communication delays at age 24 months, when more complex gross motor skills are expected to emerge. Research examining the association between these early delays and concurrent and later play and social communication in children with ASD and social communication disorders is needed.

42 **178.042** Mouse Model of Chd8 Haploinsufficiency Results in Altered Neuronal Proliferation and Megalencephaly

A. Gompers[1], *L. Su-Feher*[2], *J. Ellegood*[3], *T. W. Stradleigh*[2], *I. Zdilar*[2], *N. A. Copping*[4], *M. C. Pride*[4], *M. A. Riyadh*[5], *G. Kaushik*[6], *J. P. Lerch*[7], *B. Mannion*[8], *V. Azal*[8], *A. Visel*[8], *L. A. Pennacchio*[8], *D. Dickel*[8], *J. Crawley*[9], *K. Zarbalis*[10], *J. L. Silverman*[11] *and A. S. Nord*[2], *(1)University of California, Davis, Davis, CA, (2)Center for Neuroscience, Department of Neurobiology, Physiology, & Behavior, University of California, Davis, Davis, CA, (3)Hospital for Sick Children, Toronto, ON, CANADA, (4)UC Davis, Sacramento, CA, (5)University of California-Davis, sacramento, CA, (6)University of California-Davis, Sacrameto, CA, (7)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (8)Lawrence Berkley Laboratories, Berkley, CA, (9)University of California, Sacramento, CA, (10)University of California Davis, Davis, CA, (11)MIND Institute and Department of Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA*

Background: Efforts to uncover the genetic basic of Autism Spectrum Disorder (ASD) via exome sequencing of autism patients have identified the chromodomain helicase binding protein (*CHD8*) as a candidate gene. Patients with de novo mutations in *CHD8,* resulting in loss of function and haploinsufficiency, show a clinical presentation of autism comorbid with cognitive impairment, macrocephaly, craniofacial dysmorphology, and gastrointestinal issues.
Objectives: To uncover neurodevelopmental pathology associated with *CHD8* haploinsufficiency driving in autism, macrocephaly, and impaired cognition utilizing a mouse model
Methods: We generated a mouse model harboring a germline mutation in *Chd8* using the CRISPR/Cas9 system. We performed RNA-sequencing across development to analyze changes in gene expression in *Chd8* heterozygous (*Chd8*$^{+/-}$) forebrain. We used EdU labeling to measure neuronal proliferation at embryonic day 13.5. We utilized a battery of behavioral tests to assess social, repetitive and cognitive behaviors in adult *Chd8*$^{+/-}$ mice.
Results: Consistent with previous publications, homozygous deletion of *Chd8* in our mouse model is embryonic lethal. We found altered expression of early neurodevelopmental and differentiation genes in *Chd8*$^{+/-}$ forebrain, including sets of genes critical for RNA processing (including RNA splicing, mRNA stability, and transport) and chromatin structure and organization. *Chd8*$^{+/-}$ mice have increased neuronal proliferation in the ventricular zone at embryonic day 13.5, the peak of neurogenesis. We observed increased cortical length and cortical thickness at postnatal day 7. Cursory examination of cortical lamination revealed no obvious differences in layer specification in at postnatal day 1. Our behavioral assays did not reveal social or anxiety phenotypes in assays that have face value validity for autism. Preliminary analysis in a fear-based learning task suggested impaired cue and correlative learning in *Chd8*$^{+/-}$ mice.
Conclusions: Our mouse model recapitulates human macrocephaly phenotype, reveals elevated neuronal proliferation as a possible root for brain size increase, and provides insight into the gene expression networks altered by mutation of one copy of the *Chd8* gene.

43 **178.043** Neurodevelopmental Consequences of Fetal Androgen Exposure Depend on Sex

B. McKenna *and J. Michaelson, Department of Psychiatry, University of Iowa, Iowa City, IA*

Background: Autism spectrum disorder (ASD) displays a striking sex bias, which has fueled research around the hypothesis that aberrant sex hormone exposure may be a contributing factor to the condition. Previous studies utilized morphological features that are known to reflect androgen exposure – e.g. digit ratio or facial features – to explore the biological mechanisms behind ASD. However, few studies have compared these measures to the specific traits prevalent in the disorder. Even fewer have broadened their sample to include not only individuals with ASD, but also typically developing individuals and those with other neurodevelopmental conditions such as language impairment or intellectual disability. With a diagnostically diverse cohort, determining the influence of prenatal androgen exposure on clinically relevant traits will further our understanding of the role of sex in neurodevelopment.
Objectives: Â This study investigated the relationship between prenatal androgen exposure and behavioral traits that exist to varying degrees in the general population but are particularly pronounced in individuals diagnosed with ASD.
Methods: Â 642 individuals spanning a spectrum of social, behavioral, communication, and cognitive capabilities were recruited from hospitals and clinics across the state of Iowa. Two morphological features – digit ratio and facial masculinity – were used as proxy measures for prenatal androgen exposure. 2D:4D ratios were calculated from finger length measures obtained from subjects' hand scans; facial masculinity was determined through computational analyses of subjects' photographs. Self- and parent-reports were corroborated by examination of medical records to determine medical history and comorbidities. Scores for 'Social Deficit', 'Sensory Sensitivity', 'Restricted/Repetitive Behaviors', 'Anger/Aggression', and 'Cognitive Deficit' were calculated from these responses.
Results: The two morphological features used to reflect prenatal androgen exposure – 2D:4D ratio and facial masculinity – were significantly correlated. Both measures were associated with ASD-related characteristics, in a sex-dependent manner.Â In male subjects, greater prenatal androgen exposure correlated with fewer restricted/repetitive behaviors, lower aggression, fewer sensory sensitivities, and less severe cognitive deficits.Â In female subjects, greater prenatal androgen exposure resulted in more severe behaviors and deficits. Overall, neurodevelopmental symptomatology was more severe when prenatal androgen exposure was discordant with biological sex.
Conclusions: The influence of prenatal androgen exposure on ASD-related behaviors, social abilities, and cognitive deficits is mediated by sex. These effects are not limited to individuals with ASD or other neurodevelopmental conditions, as they were detectable in both clinical and subclinical populations.

44 **178.044** Parent-Child Co-Regulation in Toddlers with ASD

A. M. Dimachkie[1], *A. Gulsrud*[2], *W. I. Shih*[3] *and C. Kasari*[3], *(1)Human Development and Psychology, UCLA, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background:
Individuals with ASD have been known to exhibit deficits in emotion regulation (ER) capabilities (Konstantareas and Stewart, 2006). These deficits, in combination with impairments in social and emotional development that are characteristic of ASD, may compound negative outcomes and even moderate children's response to intervention and treatment (Jahromi et al, 2012). In addition, parents, more specifically mothers, of children with ASD may serve a crucial role in facilitating and fostering their children's ER development (Morris et al., 2011). In a sample of toddlers with ASD, mothers were found to use a range of strategies to co-regulate their child's negativity in a free play interaction (Gulsrud et al., 2012).
Objectives:
This study aims to identify potential ER and co-regulation strategies used by toddlers with ASD and their parents during a distress task.
Methods:
77 toddlers with ASD (24 – 36 months) completed a 3-minute distress task based upon the Lab-TAB distress task used with typically developing preschoolers (Goldsmith, Reilly, Lemery, Longley, & Prescott, 1999). Toddlers were given a locked toy box and a ring of keys and encouraged by parents to open the box. VideosÂ of the task were codedÂ for child negativity and then in 10-second intervals for presence of nine measures of child emotion regulation ER strategies and five parent co-regulation strategies. Descriptive statistics were collected on the types and frequencies of parent and child ER strategies, and the frequency of children's expressed negativity. Chi-squared tests of independence were conducted to determine whether a relationship existed between strategy use and children's expressed negativity. Finally, a bivariate correlation was conducted to discover whether a relationship exists between child's ER strategy use and ADOS (ADOS; Lord et al., 1989) severity score.
Results:
Findings showed that children most frequently used "distraction" as a strategy, appearing in 57.1% of sessions. The least used child strategy was "physical self-soothing", coded in 5.2% of sessions. Children used ER strategies on average 17.84 times (SD=8.80) per session. Parents were found to most frequently use "following" as a co-regulation strategy, utilized in 41.6% of the sessions. The least employed parental strategy was "active game-like engagement", appearing in 1.3% of sessions. Parents used co-regulation strategies on average 2.32 times (SD=2.80) per session. Findings revealed that children used significantly more "tension release" ($p=0.000$) and "other-directed assistance seeking" ($p=0.013$) during sessions with negativity, and significantly more "idiosyncratic behaviors" ($p=0.014$) during sessions with no negativity. One parent strategy, "physical comfort" approached significance, appearing more in the presence of no negativity ($p=0.054$). A bivariate correlation revealed a significant correlation between child's ADOS severity score and the frequency of their ER strategy use ($r = 0.491$, $p < 0.01$).
Conclusions:
Results revealed that parents rely on a variety of strategies when attempting to co-regulate their toddlers with ASD, especially during distressing tasks. Children with ASD also attempt to regulate their own negative emotions, relying most heavily upon "tension release" and "other-directed assistance seeking". Findings also suggest that ER strategy use increases in frequency in correlation with the severity of the child's ASD.

45 **178.045** Perceptions of the Parenting Experience Among Caregivers of Toddlers: Comparison of ASD Risk and Non-Risk Groups

R. A. Lindsey[1], *L. K. Hansen*[2], *T. D. Barry*[1], *R. Sturner*[3,4] *and B. Howard*[3,4,5], *(1)Washington State University, Pullman, WA, (2)University of Southern Mississippi, Hattiesburg, MS, (3)Center for Promotion of Child Development through Primary Care, Baltimore, MD, (4)Johns Hopkins University School of Medicine, Baltimore, MD, (5)Total Child Health, Baltimore, MD*

Background: Parenting a child with autism spectrum disorder (ASD) may be especially challenging due to symptoms of ASD and the associated problems (e.g., regulation during daily living tasks; externalizing behaviors; Davis & Carter, 2008; Ming et al., 2008). Whereas much research on children with ASD assesses deficits, relatively fewer studies have examined strengths. Nevertheless, including an assessment of strengths is important, as they may protect against parental stress (Carter et al., 2003) and can provide a broader picture for intervention planning (Oswald et al., 2001).
Objectives: The present study compares perceptions of parenting among caregivers of two groups of children—those above and those below the cut-score consistent with an ASD diagnosis on the Modified Checklist for Autism in Toddlers (M-CHAT). Understanding more about parents' perceptions of both difficulties and strengths can inform interventions to ameliorate difficulties and build upon strengths with a goal of reducing parenting stress.
Methods: Data were drawn from a national primary care sample who completed online questionnaires prior to children's health supervision visits. Caregivers of 5,690 children, aged 16-30 months (*M* = 1.30 years; *SD* = 1.85; 67.8% European-American, 30.2% African-American) completed the M-CHAT (Robins, Fein, Barton, Green, 2001), a validated parent-report for screening toddlersÂ for ASD. These caregivers were also asked to choose one or two items from 22 choices representing the best parts of parenting and one or two items from 23 choices representing the hardest parts of parenting. Best and hardest choices were theoretically and clinically derived.
Results: Consistent with the general population base rate (APA, 2013), 1.14% (*n* = 65) scored 7 or higher on the M-CHAT (indicating a possible diagnosis of ASD). Group comparisons (M-CHAT <7 and >7) for items most frequently endorsed as the best parts of parenting and the hardest parts of parenting are presented in Figures 1 and 2, respectively. Overall, caregivers most frequently endorsed playing with him/her, the way he/she smiles, and watching him/her with siblings among the best parts of parenting. Caregivers most frequently endorsed crying/fussing/tantrums and managing other stress among the hardest parts of parenting. Chi-square analyses indicated the same pattern regardless of M-CHAT scores for most choices. However, there were statistically significant differences for wondering if I am a good enough parent (*p* = .04; endorsed more in the M-CHAT <7 group) and too much/not enough help/advice (*p* = .03; endorsed more in the M-CHAT >7 group).
Conclusions: Even among caregivers of children with a significant M-CHAT score, the parts of parenting identified as best included social (i.e., interactions with family) and early communicative (i.e., smiling) behaviors. Likewise, these caregivers endorsed struggling with the same child behavior problems and other stress as other caregivers, with a few significant differences. These results underscore the commonalities in the experience of caregivers of toddlers, regardless of level of child ASD symptoms. These findings highlight the importance of targeting social skills and communication in early interventions with at-risk children as well as assisting caregivers to build skills to address behavior problems and reduce stress.

46 **178.046** Physiological Measurements of Voice Quality in Children with Autism Using Electroglottography in Relation to Clinical Assessment Outcome

S. Ghai *and G. Ramsay, Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA*

Background:
Atypical voice quality has been a characteristic trait in individuals with autism. Many standard clinical assessment tools include subjective evaluation of voice characteristics and social communication skills for clinical diagnosis of autism. However, a means of statistically quantifying atypicality in voice production in individuals with autism that can also contribute to reliable prediction of clinical diagnosis is still lacking. In previous research, we showed that longitudinal acoustic measures of infant vocal behavior including the fundamental frequency contour, duration and timing of dyadic interactions with caregivers within the first two years of life have potential as biomarkers for early detection of autism. However, acoustic measures of prosody do not directly quantify the actual mechanism of voice production. Electroglottography (EGG) provides non-invasive physiological measures of vocal fold function, and voice source parameters obtained through EGG signal processing may therefore provide us with better information about the origin of voice disorders in autism.
Objectives:
The goal of this study is to explore the potential of physiological measures of voice quality to capture information relevant to diagnostic characterization by correlating acoustic measures of voice quality obtained using EGG with standard measures used for clinical assessment of language and social communication in autism spectrum disorders (ASD). We test the hypothesis that objective measures of abnormal voice quality characteristics are predictive of clinical outcome.
Methods:
As part of our initial pilot study, we recruited in total 8 low-risk children with no history of autism and high-risk children with older siblings diagnosed with ASD. We collected high-quality EGG and microphone recordings of each child at 2-3 years of age. We also collected a battery of clinical assessment measures from each child at the same age. From the EGG recordings, we hand-labeled and extracted sequences of utterances containing clean child vocalizations and calculated the mean and standard deviations for four measures of voice quality across all speech frames for each child: the fundamental frequency (F0), the open quotient (OQ), the return quotient (RQ), and the speed quotient (SQ). We then compared the correlation between physiological measures of voice quality with clinical outcome measures corresponding to social communication and motor control.
Results:
Our final sample consisted of 4 TD children and 4 children diagnosed with ASD. Group differences in all of the four acoustic measures of voice quality showed significant correlation with each other and may have potential to aid prediction of diagnostic characterization. Group-level categorizations based on these physiological measurements of voice quality were consistent with categorizations based on the ADOS summary scores.
Conclusions:
Preliminary results suggest that typically developing children and children with ASD differ according to physiological measures of atypical voice quality which may be related to clinical outcome measures. However, these observations and results are currently being further verified on a larger cohort.

47 **178.047** Positive Affect in Infants at High Risk for ASD: A Multimethod Longitudinal Analysis

F. E. Kane-Grade*, S. Macari, A. Milgramm, E. Hilton, P. Heymann and K. Chawarska, Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Temperament refers to relatively consistent dispositions present early in life underlying the expression of activity, reactivity, and emotionality (Goldsmith et al., 1987). Surgency reflects positive affectivity and sociability (Putnam, Gartstein, & Rothbart, 2006). Children at high risk (HR) for autism are reported to exhibit reduced Surgency at 7 and 14 months of age (Clifford et al., 2013), and those later diagnosed with ASD show lower positive anticipation at 24 months (Garon et al., 2009; Zwaigenbaum et al., 2005). Little is known about laboratory-based measures of positive affectivity in infants at risk for ASD or how they compare with parent-reported Surgency.
Objectives: (1) To examine positive affect and Surgency at 6 and 12 months among HR siblings who later develop ASD (HR-ASD), HR siblings without ASD (HR-nASD), and typically-developing LR children (LR-TD); 2) To examine concurrent relationships between lab-based and parent report measures of positive affectivity/Surgency at 6 and 12 months; and 3) To examine group differences on parent-reported Surgency at 18 months.
Methods: 184 infants (HR-ASD, *n*=21; HR-nASD, *n*=104; LR-TD, *n*=59) completed a lab-based measure of positive affectivity at 6 and 12 months and were evaluated for ASD at 24 or 36 months. Parents provided information about their infant's Surgency by completing the Infant Behavior Questionnaire (IBQ; Gartstein, & Rothbart, 2003) at 6 and 12 months and the Early Childhood Behavior Questionnaire (ECBQ; Putnam, Gartstein, & Rothbart, 2006) at 18 months. Examiners administered a series of brief standardized probes (Social Orienting Probes; SOP) designed to elicit positive affect, including speaking in motherese, singing a nursery rhyme, tickling, playing peek-a-boo, and demonstrating a toy. Videotaped sessions were coded offline by blinded coders for the duration of the infants' display of positive affect, standardized over the length of each probe (%PosAffect). Linear mixed models were used to examine the effects of age and diagnostic group on %PosAffect and Surgency at 6 and 12 months. ANOVA was used to examine differences between diagnostic groups on Surgency at 18 months. Pearson correlations were employed to examine concurrent relationships between %PosAffect and Surgency at 6 and 12 months.
Results: Analyses of %PosAffect ($F(1, 313)=20.7$, $p<.001$) and Surgency ($F(1, 260)=19.6$, $p<.001$) both revealed only a main effect of age (6<12months). Diagnostic groups differed significantly on Surgency at 18 months, $F(2, 124)=4.8$, $p=.009$; LR-TD>HR-ASD). Positive affect displayed during the SOP at 12 months was significantly correlated with concurrent Surgency, $r=.20$, $p=.02$, with a trend toward a significant correlation between measures at 6 months, $r=.16$, $p=.09$.
Conclusions: Results indicate that neither positive affect during a live social interaction nor Surgency as reported by parents differed across the three groups at 6 or 12 months, but at 18 months of age, HR-ASD infants displayed lower Surgency than LR-TD infants. Results are largely consistent with the previous literature. We extend this work by showing congruency between parent report of Surgency and an observational measure of positive affectivity. Future research should examine additional aspects of temperament using a multimethod approach.

48 **178.048** Positive and Negative Affective Vocalizations in 2-Year-Olds with ASD

S. Plate[1], *J. Parish-Morris*[2], *J. Migliaccio*[3], *L. Bateman*[4], *J. L. Wood*[2], *R. F. Slomowitz*[5], *J. E. Maldarelli*[5], *S. Paterson*[6], *J. Pandey*[5], *N. Marrus*[7], *A. Estes*[8], *H. C. Hazlett*[9], *L. Zwaigenbaum*[10], *K. Botteron*[11], *S. Dager*[12], *J. Piven*[13] *and R. T. Schultz*[5], *(1)Bryn Mawr College, Bryn Mawr, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)James Madison University, Harrisonburg, VA, (4)The Center for Autism Research/CHOP, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Children's Hospital of Philadelphia, Philadelphia, PA, (7)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO, (8)University of Washington Autism Center, Seattle, WA, (9)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (10)University of Alberta, Edmonton, AB, CANADA, (11)Washington University School of Medicine, St Louis, MO, (12)University of Washington School of Medicine, Seattle, WA, (13)Carolina Institute for Developmental Disabilities, Carrboro, NC*

Background: Research on affect in young children with ASD suggests that they are less socially reactive, smile less, and show more distress reactions than typical peers (Cassel et al., 2011; Zwaigenbaum et al., 2005). Child temperament is particularly important to study because children with difficult temperaments are at increased risk of child abuse and neglect (Fisher, Hodapp, and Dykens, 2008). Plumb and Wetherby (2012) found that infants later diagnosed with ASD produced more non-speech distress vocalizations than developmentally delayed children and typically developing controls. However, the field has yet to conclusively determine whether diagnostic group differences exist in delight and distress sounds (Sheinkopf et al., 2000; Paul et al., 2011; Schoen, Paul, & Chawarska, 2011).
Objectives: Assess whether patterns of non-speech affective vocalization distinguish children in three groups: children who have an older sibling with ASD and are also diagnosed with ASD (ASD); children at high-familial risk for ASD by virtue of having an older sibling with ASD, but not currently diagnosed with ASD themselves (HR-), and children at low-familial risk for ASD with no ASD diagnosis themselves (TDC).
Methods: The Communication and Symbolic Behavior Scales (CSBS; Shumway & Wetherby, 2009) was administered to 33 2-year-olds (ASD: 9, TDC: 12, HR-: 12) participating in the Infant Brain Imaging Study (IBIS; Estes et al., 2015). Two individuals coded child non-speech vocalizations into four categories: (1) delight (laugh), (2) distress (cry, whine, fuss), (3) atypical (squeal, growl, yell, grunt), or (4) other (sound effect, uncodable); ("vegetative" vocalizations like coughs were excluded from the current analyses). For this study, we calculated the percentage of time occupied by distress and delight vocalizations relative to total amount of non-speech vocalization produced by each child.
Results: Â A repeated measures ANOVA with group (ASD/TDC/HR-) as a factor and affective vocalization type (delight/distress) as a repeated measure revealed a trend toward an interaction between group and type, $F(2,29)=3.01$, $p=.065$, $\eta_p^2= .17$ (see Figure 1). Planned paired contrasts revealed that the ASD group produced significantly more distress than delight vocalizations ($p<.05$), the TDC group produced marginally more delight vocalizations than distress vocalizations ($p<.08$), and the HR- group produced equal amounts of each type (p=n.s.). Independent samples t-tests showed the ASD group produced a significantly higher percentage of distress vocalizations (39%) than the TDC group (14%, $p<.05$). In contrast, the TDC group produced a significantly higher percentage of delight vocalizations (43%) as compared to the ASD group (12%, $p<.05$). The HR- group was not significantly different from the other two groups on either variable.
Conclusions: Â Emotion regulation difficulties in ASD are common and impairing (Mazefsky et al., 2013) and dysregulation in toddlers is associated with increased parenting stress (Davis & Carter, 2008). Fine-grained identification of distress vs. delight vocalizations in children's natural communication, demonstrated here, could serve as a way to monitor progress as clinicians and parents help children learn to regulate their emotions. We plan to code distress/delight vocalizations at 6 and 12 months as well, to understand developmental continuity and deviation in this domain (anticipated complete, May 2017).

49 **178.049** Potential Neonatal Neurobehavioral Signs of ASD Risk in Premature Infants

E. Tenenbaum[1,2], *S. J. Sheinkopf*[2,3,4,5], *A. L. Salisbury*[1,4,5], *K. Hawes*[1,4,5], *L. M. Dansereau*[1,5], *R. Bigsby*[1,4,5], *A. Laptook*[4,5], *M. Taub*[5], *L. L. LaGasse*[1,4,5], *B. Vohr*[4,5], *J. Padbury*[4,5] *and B. M. Lester*[1,2,4,5], *(1)Brown Center for the Study of Children at Risk, The Warren Alpert Medical School of Brown University, Providence, RI, (2)Department of Psychiatry and Human Behavior, The Warren Alpert Medical School of Brown University, Providence, RI, (3)Brown Center for the Study of Children at Risk, Women and Infants Hospital, Providence, RI, (4)Pediatrics, The Warren Alpert Medical School of Brown University, Providence, RI, (5)Pediatrics, Women and Infants Hospital, Providence, RI*

Background: The prevalence of autism spectrum disorders (ASD) among premature infants is approximately five times greater than the general population. Current assessments have not identified reliable behavioral predictors of ASD risk in early infancy. It is hypothesized that early differences in social attention and responses may be diminished in infants at risk for ASD. Such early indicators of risk for ASD have not yet been investigated in premature infants.
Objectives: To explore the NICU Network Neurobehavioral Scale (NNNS; Lester & Tronick, 2004) as a potential predictor of ASD symptomatology in toddlerhood. The NNNS is a standardized neonatal neurobehavioral assessment that includes specific responses to animate and inanimate stimuli and more general summary scores.
Methods: Participants included 211 families from an 18 month follow-up study of associations between a single family room neonatal intensive care unit (NICU) model of care and infant neurodevelopmental outcome (Lester et al., 2016).Â Infants were all born <36 weeks gestational age (*M* = 27.59, *SD* = 2.27) and <1500 g (*M* = 967.39, *SD* = 240.73). Fifteen percent were from very low SES families. The NNNS was administered prior to NICU discharge (*M* gestational age = 37.75 weeks, *SD* = 4.60). The NNNS includes procedures in which the infant attends to animate (examiner's voice and/or face) and inanimate (rattle/ball) stimuli. The NNNS also includes summary scales describing infants' neurobehavioral status. Participants were seen in our follow-up clinic at 18 months (*M* = 22.44 months (uncorrected), *SD* =1 .68). Follow-up measures included the Pervasive Developmental Disorders Screening Test, a parent-report screening measure of ASD symptoms (PDD-ST; Siegel, 2004), and the Response to Name and Response to Joint Attention items adapted from the Autism Diagnostic Observation Schedule (Lord et al., 2000), a method reported on previously (Stephens et al., 2012). Logistic and linear regressions were used to explore relations between scores on the NNNS and ASD outcome measures with gestational age as a covariate.
Results: Â Logistic regression showed that diminished orientation to voice on the NNNS was related to lack of response to name, $\chi^2 = 10.14$, $p = .04$, OR = 1.48, 95%CI 1.12-1.96, $p = .006$. Analysis of the NNNS summary scores using linear regression showed more non-optimal reflexes were associated with elevated risk scores on the PDD-ST scores, $F(3, 177) = 4.74$, $p = .003$, $\beta = 3.39$, $p = .001$.
Conclusions: Â Results suggest that the NNNS may be related to signs of ASD symptomatology at 18 months in infants born <36 weeks gestational age. The relation between the infant's response to voice on the NNNS and response to name at 18 months could suggest developmental continuity in response to voice, which is often diminished in ASD. The finding that infants with higher scores on the PDD-ST had less optimal reflexes is consistent with atypical motor behaviors in infants later diagnosed with ASD (Bryson et al., 2007). Although this study was limited by use of ASD symptom counts rather than diagnosis, results suggest potential neurobehavioral signs of risk for ASD in early infancy.

50 **178.050** Predictors of Expressive Language Outcome over a Two Year Period in Very Young Pre-Verbal Children with ASD

D. Oosting *and A. S. Carter, University of Massachusetts Boston, Boston, MA*

Background: Extant research suggests that up to two-thirds of children with ASD who are pre-verbal, or have significantly impaired expressive language in toddlerhood, will develop some degree of functional expressive language by age five (Tager-Flusberg & Kasari, 2013; Thurm et al., 2014). Nonverbal cognitive ability, autism symptom severity, adaptive social functioning, and use of specific social skills such as joint attention in toddlerhood have been associated with expressive language outcomes (i.e., remaining pre-verbal or exhibiting improved expressive language; Thurm et al., 2007).
Objectives: We examined associations between nonverbal cognitive ability, adaptive social functioning, autism symptom severity, and use of joint attention skills in toddlerhood and expressive language ability two years later in a sample of very young pre-verbal children with ASD. We sought to identify baseline indices of child functioning that predicted stability in expressive language impairment versus improved expressive language.
Methods: Participants were 56 children (13 girls) with ASD first assessed at 20 to 33 months (T1; M = 28 ± 4 months) and again two years later (T2; M = 52.8 ± 5 months, range = 43-66). Participants were pre-verbal at first assessment, defined by *t*-scores on the Mullen Scales of Early Learning (Mullen) expressive language scale below 30, which corresponds to the "Very Low" descriptive category. Nonverbal cognitive ability was operationalized with a composite of the Mullen Visual Reception and Fine Motor subscales. Social functioning was assessed by mother-reported Vineland Adaptive Behavior Scales Socialization standard scores. Autism symptom severity was assessed with the Autism Diagnostic Observation Schedule algorithm total score. The Early Social Communication Scales measured joint attention skills, which included response to and initiation of requests, reciprocal social play, and shared attention. Children were assigned to outcome group based on their T2 Expressive Language *t*-score. Children whose scores remained in the Very Low range (*t*-scores ≤30) were assigned to the "remained pre-verbal" group (*N* = 38), and children with Below Average or Average range scores were assigned to the "improved" group (*N* = 18). T1 age was included in analyses as a covariate.
Results: In bivariate analyses, baseline nonverbal cognitive ability, autism symptom severity, social functioning, and T1 age differed significantly by outcome group (*p*s < .05). The "improved" group was younger at T1 and demonstrated higher baseline nonverbal cognitive ability and social functioning and less severe autism symptoms than the "remained pre-verbal" group. Subsequent logistic regression revealed that T1 autism symptom severity significantly predicted group membership ($\beta = -.35$, $p = .002$; OR: .70, CI: .56–.88), as did T1 age ($\beta = -.27$, $p = .007$; OR: .77, CI: .63 –.93).
Conclusions: Â Our results support the role of autism symptom severity in toddlerhood in predicting expressive language outcomes later in childhood (Weismer & Kover, 2015). Contrary to expectations, nonverbal cognitive ability and parent-reported social functioning were unrelated to expressive language outcome, though our power was limited (Thurm et al., 2014). Identifying early predictors of expressive language outcomes can inform much-needed additional research that focuses specifically on individuals with ASD who have limited expressive language.

51 **178.051** Preferential Attention to Audiovisual Synchrony Predicts Language Ability in Toddlers with ASD

G. Ramsay[1]*, A. Abraham*[2]*, J. B. Northrup*[3]*, D. Lin*[4]*, A. Klin*[1] *and W. Jones*[1]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (2)Vanderbilt University School of Medicine, Nashville, TN, (3)University of Pittsburgh, Pittsburgh, PA, (4)Brigham and Women's Hospital & Massachusetts General Hospital, Boston, MA*

Background: Children with ASD exhibit atypical patterns of visual attention to the social world, responding differently to physical and social contingencies relative to non-autistic peers. In studies examining preferential attention to audiovisual synchrony, we showed that ASD infants are relatively insensitive to social contingencies afforded by talking faces, focusing instead on physical contingencies between light and sound. By manipulating audiovisual stimuli comprising faces and shapes synchronized with speech and tones, we found that TD controls exhibited a preference for synchronous faces and speech, lacking in ASD participants, even though groups did not differ in baseline sensitivity to audiovisual synchrony. In early studies, significant differences were found based on simple measures of visual attention derived from mean relative fixation durations. More recently, we applied techniques from information theory to quantify differences between full probability distributions of eye-tracking trajectories across groups, and derived optimal classifiers based on a generalized likelihood ratio test that achieved sensitivity 79.5% and specificity 97.4% in discriminating ASD infants from TD controls. In evaluating our classifier performance, we noticed that ASD infants with eye-tracking likelihood-ratio scores closer to the typical range appeared to have better language ability, suggesting a potential relationship between sensitivity to audiovisual synchrony and the emergence of spoken language.
Objectives: Our goal was to test whether information-theoretic measures of differences in visual attention to audiovisual synchrony that discriminate between TD and ASD toddlers predict language ability in those children.
Methods: Toddlers with autism (N=34) and typically developing controls (N=20) participated in a simple preferential-looking paradigm based on split-screen presentation of video stimuli (faces and shapes) paired with audio stimuli (speech and tones). Using different combinations of video and audio stimuli, and manipulating audiovisual synchrony between the two, we tested for differences in attention to social and physical contingencies. Eye tracking was used to quantify response. Using machine-learning techniques, we derived optimal measures of overall attention and attention to social target across all stimulus combinations, focusing on responses to speech and non-speech. An optimal classifier was derived using a generalized likelihood ratio test calculated from the entire joint distribution of our measures across groups. Receiver operating characteristics were further used to quantify classification performance, using leave-one-out cross-validation with the log likelihood ratio as the test statistic. To determine the relationship between preferential attention to audiovisual synchrony and language ability, we calculated the correlation between the log likelihood ratio scores and the receptive and expressive language scores determined from clinical assessments using the Mullen Scales of Early Learning.
Results: We found significant correlations ($P<0.05$) between the log likelihood ratio scores (speech/non-speech conditions) and both receptive ($r=-0.332/-0.394$) and expressive ($r=-0.413/-0.409$) language scores.
Conclusions: Patterns of preferential attention to audiovisual synchrony that discriminate between ASD and TD children are also predictive of language ability in those children, suggesting that differential sensitivity to social and physical contingencies in talking faces is a pathway to spoken language in autism.

52 **178.052** Prelinguistic Predictors of 24-Month Expressive Language for Infants at High-Risk for ASD

J. Bradshaw[1]*, S. Gillespie*[2]*, N. Brane*[3]*, M. Lewis*[3]*, C. Klaiman*[1] *and C. A. Saulnier*[4]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Children's Healthcare of Atlanta, Emory University, Marcus Autism Center, Atlanta, GA*

Background: Language development for typically developing children occurs in the context of rich social interactions. Precursors of expressive language comprise a repertoire of nonverbal communicative behaviors, including gestures and facial expressions (Bates et al., 1987). Most children with autism spectrum disorder (ASD) experience difficulty with the acquisition and use of language, which has a significant impact on overall level of functioning. Moreover, the majority of high-risk infant siblings of children with ASD also exhibit language atypicalities, presumably indicative of the broader autism phenotype (e.g., Messinger et al., 2013). Identification of prelinguistic predictors of 24-month expressive language outcome could improve early detection of language delays and inform early intervention practices for high-risk siblings.
Objectives: The goals of this study are to: 1) identify prelinguistic predictors of 24-month expressive language outcome for high-risk and low-risk infants, and 2) compare linear regression and random forest methods for identification of predictor variables.
Methods: Participants include 39 high-risk and 56 low-risk infants seen for developmental and social-communication assessments at 12- and 24-months as part of a large, federally-funded longitudinal study examining risk and resilience in the first two years of life. The Communication and Symbolic Behavior Scales (CSBS-DP; Wetherby & Prizant, 2002) is a standardized assessment tool that examines communicative, social-affective, and symbolic abilities, resulting in seven clusters that make up three composites: Social (Emotion/Eye Gaze, Communication, Gestures), Speech (Sounds, Words), and Symbolic (Understanding, Object Use). The CSBS and Mullen Scales of Early Learning were administered at 12- and 24-months for each participant. Univariable and multivariable linear regressions were conducted using the 24-month Mullen Expressive Language T-score as the outcome. Possible predictor variables included: risk status, 12-month Mullen Expressive (EL) and Receptive (RL) Language subdomains, and all CSBS clusters. These results were compared to a random forest approach (a machine learning tool for regression) using the same predictor and outcome variables.
Results: High-risk infants scored significantly lower than low-risk infants on Mullen expressive language at 24-months ($p<.001$). The four most significant predictors resulting from the univariable regression were risk status ($R^2=.19, p<.001$), CSBS Gestures ($R^2=.14, p<.001$), CSBS Communication ($R^2=.11, p<.001$), and CSBS Speech ($R^2=.11, p<.001$). The multivariable regression revealed risk status, CSBS Speech, and CSBS Understanding as most predictive of expressive language ($R^2=.31$, RMSE=11.36). Using random forests, the four most significant predictors were risk status, CSBS Speech, Mullen EL, and Mullen RL, (RMSE=10.96). A Spearman correlation indicated moderate agreement between the regression and random forest approach with regard to significant predictors ($r_s=.53$).
Conclusions: Results suggest several prelinguistic factors that significantly predict 24-month expressive language in high-risk and low-risk infants. There was moderate agreement between the linear regression and random forest approaches. Risk status was by far the most predictive of expressive language at 2-years. Additional significant predictors included gesture use, receptive language, very early speech (i.e., first words), and the overall frequency and function of communication. These results have significant implications for the development of very early intervention strategies that target all forms of communication, including gestures, first words, and receptive language, to promote language development in high-risk infants.

53 **178.053** Longitudinal Examination of Head Control in Infants at High- and Low-Risk for Autism Spectrum Disorder from Two to Six Months

S. Carpenter[1]*, L. Evans*[1]*, C. Beacham*[1]*, C. Klaiman*[2] *and J. Bradshaw*[2]*, (1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Toddlers with autism spectrum disorder (ASD) show atypical motor and cognitive development in the first two years of life (Landa et al., 2013). Recently, motor delays have been documented in infants at high-risk for ASD as young as 6-months of age, specifically highlighting head control as an area of concern (Bhat et al., 2012, Flanagan et al., 2012). Prospective, longitudinal measurement of motor milestones, beginning as early as 2-months, will inform early detection methods and support the development of novel interventions for ASD.
Objectives: The goal of this study is to explore differences in the emergence of head control abilities, coordinated with visual and auditory attention, in 2- to 6-month-old infants at high- and low-risk for ASD.
Methods: The *Bayley Scales of Infant and Toddler Development* was administered monthly to infants enrolled in a large, longitudinal, federally funded study at high-risk (HR, N=23) and low-risk (LR, N=15) for ASD at five time points between 2- and 6-months of age. Four items specifically measuring head control were selected from the Bayley and included in the current analysis: follows-ring, turns-to-sound, shifts-attention, and follows-ball. Each item was administered with the infant sitting in the caregiver's lap and required head control in conjunction with visual and/or auditory attention. Chi-square analyses were used to identify differences in reaching each of these milestones at monthly time points from 2- to 6-months of age. Data collection for this study is ongoing and we anticipate an additional 25 participants to be added to the current sample before May, 2017.
Results: Overall, HR infants appeared to meet each milestone later than LR infants. Milestones were considered to be met when 100% of infants within a group demonstrated the behavior. LR infants met the follows-ring milestone at 3-months while HR infants met this milestone at 5-months. There was a marginally significant between-group difference at 3-months ($p=0.07$). The turns-to-sound milestone was achieved at 4-months for LR infants and 5-months for HR infants. No significant differences were observed at a single time point for this item. The shifts-attention milestone was achieved at 4-months for LR infants and 5-months for HR infants, with no observed significant differences between groups at any time point. Finally, results revealed that LR infants met the follows-ball milestone at 4-months, while HR infants met this milestone at 5-months. A marginally significant between-group difference for this item was observed at 2-months ($p=0.1$) and a significant difference was observed at 4-months ($p=0.01$).
Conclusions: This preliminary study is one of the first to provide evidence for very early delays (starting at 2-months) in HR infants' use of head control while attending to visual and auditory stimuli. Identification of early differences in head control, especially when paired with measures of attention, can contribute to our understanding of motor ability within the cascade of developmental and social abnormalities observed in children with ASD. These results could have significant implications for early detection of ASD and the development of early intervention.

54 **178.054** Self-Regulation and Attention from 1-Week to 2-Months of Age in Infants at High- and Low-Risk for ASD

L. Evans[1]*, S. Carpenter*[1]*, C. Beacham*[1]*, S. Gillespie*[2] *and J. Bradshaw*[3]*, (1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Infant self-regulation, in the face of highly stimulating or distressing events, emerges in the first months of life. This ability is critical for maintaining alertness, interacting with a caregiver, and attending to the environment. Toddlers with autism spectrum disorder (ASD) experience difficulty with self-regulation, which could interfere with social interaction, communication, and learning (Dodge, 1989; Gomez & Baird, 2005). Previous studies suggest a link between decreased self-regulatory capacities in early infancy and later medical and behavioral problems, including ASD (Liu et al., 2016; Gomez & Baird, 2005). For this reason, high-risk infant siblings of children with ASD may demonstrate a decreased ability to self-regulate in the first few months of life compared to low-risk infants.
Objectives: This exploratory study compared abnormalities in self-regulatory abilities in the first months of life for infants at high- and low-risk for ASD. Specifically, we investigated very early developmental trajectories of 1) excitability, 2) self-regulation, and 3) attention in high-risk and low-risk infants between 1-week and 2-months of age.
Methods: As part of a large, longitudinal, federally funded study, participants included low-risk (LR, N=20) and high-risk (HR, N=19) infants seen at 1-week, 1-month, and 2-months of age. Measures of excitability, regulation, and attention (response to visual and auditory stimuli) were obtained from the *NICU Network Neurobehavioral Scale* (NNNS; Lester & Tronick, 2004) and differences between HR and LR infants were explored. Given the documented relationship between regulation and learning, the *Bayley Scales of Infant and Toddler Development* was administered and associations between Bayley cognitive scores and NNNS regulation scores were also investigated.
Results: Repeated measures two-way ANOVAs were used to analyze trajectories of excitability, self-regulation, and attention across HR and LR infants. There were no differences in excitability between groups at any time point. However, there was a marginally significant interaction ($p=.125$, see Fig 1a) in which LR infants showed a significant decrease in excitability across time ($p=.05$), while HR infants remained stable. In regard to self-regulation, both HR and LR infants made very little change from 1-week to 2-months, however there was a marginally significant difference across groups at 1-month: HR infants demonstrated fewer self-regulatory abilities compared to LR infants ($p=.09$). In contrast to HR infants, LR infants showed steadily increasing attention scores from 1-week to 2-months, resulting in a marginally significant interaction across time and risk group ($p=.122$, see Fig 1b). HR infants showed significantly lower attention scores at 2-months ($p=.010$). Finally, Pearson correlations revealed a positive association between self-regulation ability and Bayley cognitive standard scores at 2-months ($r= .421$, $p<.05$).
Conclusions: Very few studies to date have investigated neurobehavioral differences in HR and LR infants as young as 1-week-old. These preliminary findings provide novel evidence suggesting differences in trajectories of excitability, self-regulation, and attention. Further, these results suggest that self-regulation could be important for early cognitive development. Finally, results reveal that HR infants as a group may be more vulnerable to difficulties in self-regulation and attention when compared to LR infants.

55 **178.055** Prevalence of Four Types of Feeding Problems in Children Under Three with ASD Compared to Children with Language Delay

P. Towle[1]*, L. Seiverling*[2]*, H. Hendy*[3] *and J. Pantelides*[4]*, (1)Westchester Insitute for Human Development, Valhalla, NY, (2)Psychology, St Mary's Hospital for Children, Bayside, NY, (3)Penn State University, Schuylkill, PA, (4)Penn State University, State College, PA*

Background:
Feeding problems such as selective eating in children with autism spectrum disorder (ASD) have been shown to be higher in prevalence compared to typically developing children and children with other developmental delays (prevalence estimates 46% - 89%, Ledford & Gast (2006)). The majority of studies investigating this have had samples of children over the age of three years. There are some studies that suggest that feeding problems start very early in ASD, but they are either very general in description (Dominick et al., 2007; Olsson et al., 2013), spanned large age ranges without separate analyses for infants and toddlers (Field et al., 2003; Williams et al., 2005), or used children referred specifically to feeding clinics (Williams, Gibbons, & Schreck, 2005). The issue of a comparison group is important, as well, since it will be important to know if children with ASD differ from other children who might be also prone to feeding problems (e.g., children with other disabilities such as language delay). More specific information is available for older children with ASD, showing that children with ASD are selective by a variety of dimensions including food texture, taste or smell, foods mixed together, brands, or food shape (Hubbard et al., 2014).
Objectives: To compare the prevalence of four types of feeding problems for children with ASD under the age of three years, compared to children with non-ASD language delay (LD). Goal 2: To explore demographic variables (gender, age of first evaluation, and neighborhood income) for their associations with the four feeding problems.
Methods: Chart review study of 78 children with ASD and 85 children with Language Delay (LD). Each early intervention chart contained a full psychological and speech-language report. Inter-rater reliability (30% of charts) was found to be excellent, ranging from .62 to .85, for the following feeding problems: food selectivity by texture, food selectivity by food type, refusal to eat new foods, and food over-stuffing.
Results: For each problem, a 2X2 Chi-square analysis showed that children with ASD showed significantly higher prevalence rates than children with LD.Â A 2X2 ANCOVA compared number of children's four feeding problems across diagnosis group (ASD, LD), gender (male, female), with age of first evaluation and neighborhood income serving as covariates. There was a significant gender effect, with male children showing more of the four feeding problems than did female children (male mean = .59, SD = .89; female mean = .16, SD = .43). No significant effects were found for age of first evaluation or neighborhood income.
Conclusions: Results suggest that children with ASD are at significantly greater risk during their first three years of life for each of four types of feeding problems: problems with food texture, and food type, new food refusal, and food over-stuffing. Prevalence rates for feeding problems found for the children with ASD in the present study were similar to those of previous estimates with various types of comparison groups.

56 **178.056** Re-Examining Measures of Risk in the Study of Autism Spectrum Disorder in Infancy

R. Burger-Caplan[1,2]*, A. Klin*[3] *and W. Jones*[3]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Psychology, Emory University, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA*

Background: Autism Spectrum Disorder (ASD) is one of the most highly heritable of all psychiatric disorders, and presents phenotypically with enormous heterogeneity of social, cognitive, adaptive, and behavioral symptoms and levels of functioning. While ASD likely has a genetic etiology, the state of the field limits the ability to prospectively identify genetic risk for the disorder experienced by a given individual. The current study aims to assess the predictive ability of seven factors of birth and early development that have been suggested across the ASD literature to index risk. To assess these factors, the current study adapts a framework outlined by Kraemer et al (1997), identifying ideal attributes of a risk factor to include (1) measurability—the factor's ability to be quantified, (2) precedence—the presence of the factor prior to ASD outcome, (3) usability—the ability of the factor to differentiate among diagnostic outcomes, and (4) potency—the extent to which the factor meaningfully predicts outcome. The present study assesses a range of markers, as they each predict outcome at multiple levels of resolution (*dichotomized* into ASD and non-ASD groups; *categorical,* including Typically-Developing (TD), Broader Autism Phenotype (BAP), and ASD groups; and *dimensional*across level of social disability).
Objectives: The present study will assess the **usability** (binary) and **potency** (continuous) of objective and measurable factors—demonstrating varying levels of precedence—identified as potential markers of infant-experienced risk for the development of autistic social disability.
Methods: Participants were 187 24-month-old infants (113 male, 74 female). The sample was enriched for ASD (96 younger siblings of a child with ASD), and represents a range of gestational age, birthweight, developmental abilities, and diagnostic outcomes (135 TD, 22 BAP, 30 ASD). The Mullen Scales of Early Learning (Mullen), the Vineland Adaptive Behavior Scales (Vineland-II) and the Autism Diagnostic Observation Schedule (ADOS-2) were administered. Diagnostic characterization occurred at 36-months-old.
Results: Multiple of the tested risk factors "failed" the test of usability (Figure 1), not differentiating among diagnostic outcomes (i.e., gestational age and birthweight). Some factors "passed" the test of usability, though demonstrated relatively low potency (Figure 2; i.e., sex and cognitive ability). Sibling Status (presence of an older sibling with ASD), and adaptive ability both demonstrated usability with varying degrees of potency across levels of outcome, though it is of note that Adaptive ability "fails" the test of precedence, emerging alongside symptoms of ASD.
Conclusions: These analyses suggest that there is enormous variability in the degree to which quantifiable factors of infancy and early development are meaningfully predictive of ASD. Further, the current study demonstrates use of a new framework for assessing and understanding such variability, so as to better select and identify risk factors that have predictive utility across multiple levels of diagnostic resolution. While sibling status demonstrates usability and potency across resolutions of diagnostic outcome, 50% of younger siblings of children with ASD go on to develop typically. Thus, there continues to be room for a factor that might index risk experienced by a given child with higher specificity.

57 **178.057** Removal of Electronic Screen Media Viewing in Young Children with ASD: Case Reports

K. F. Heffler[1]*, L. R. Frome*[2] *and D. F. Gullo*[3]*, (1)Ophthalmology, Drexel University, Philadelphia, PA, (2)INVO, York, PA, (3)Drexel University School of Education, Philadelphia, PA*

Background: Higher amounts of television viewing by young children is associated with language, social and cognitive delays. Screen viewing interferes with social interactions that predict positive child development. Many children with ASD watch high amounts of TV and video.
Objectives: To describe the developmental trajectory of three young children with ASD with a history of high amounts of electronic screen media (ESM) viewing, who underwent an ESM fast based on the recommendation of a community provider.
Methods: Review of health and early intervention records of three boys with ASD who decreased ESM viewing beginning at ages 20 to 42 months of age.
Results: Child #1 viewed an average of 4 hours of TV daily, received early intervention at 15 months for language delay, but progressed poorly. Diagnosed with ASD as a 43-month-old, he demonstrated poor eye contact, repetitive spinning and solitary play. After screen removal, eye contact improved, followed by increased social interaction and diminished spinning. He no longer met ASD criteria 9 months after screen reduction with language delay resolving 9 months later. Child #2 viewed 11 hours of children's TV daily since birth. In early intervention since a 17-month-old, he was diagnosed with ASD at 21 months with poor eye contact, no awareness of others, no response to name, sensory avoidance and spun wheels on cars rather than engaging in functional play. Batelle Developmental Inventory (BDI) documented > 2 SD delays in cognitive, communication, and social/emotional development. Two months post screen removal, he acknowledged people, had good eye contact, and used gestures. Two months later, goals of sharing joint attention and following 1-step directions were mastered and he added vocabulary words daily.Â Child #3 was exposed to TV/video 3½ hours daily from age 2 months, increasing to 7 hours daily as a 6-month-old. Early intervention began at 20 months of age for “red flags” of autism with ASD diagnosed at 29 months, with ADOS-2 score of 12. He used few words, avoided eye contact, threw toys instead of functional play, viewed objects of interest in an unusual way, inconsistently responded to name and pulled on parents without eye contact for his needs. Worsening global developmental delay was documented by BDI at age 31 months and goal progress was poor. Over a 4-month period post screen removal, beginning at 36 months of age, he consistently improved his expression of needs and wants from 1.4 to 3.5 out of 4 (rating of 0 to 4 with 0 full prompt and 4 fully initiates). Six months after screen reduction, he has excellent eye contact, fully expresses himself in phrases and and engages in functional and imaginative play with peers. His support services have been reduced.
Conclusions: These cases suggest positive developmental changes related to reduction of ESM exposure in three young children with ASD. Reduction or removal of ESM is unlikely to provide significant risk to a young child. Further research is needed to clarify the relationship between ESM viewing and developmental trajectory in young children with ASD.

58 **178.058** Preserved Play in Females at High Risk for ASD Across the Range of Symptom Severity

E. Hilton[1]*, P. Heymann*[2]*, S. Macari*[2]*, A. Milgramm*[2]*, F. E. Kane-Grade*[3] *and K. Chawarska*[2]*, (1)Yale Child Study Center, New Haven, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Yale child Study Center, New Haven, CT*

Background: Previous research indicates that the ratio of autism spectrum disorder (ASD) in males to females is 4.3:1 across the full range of intellectual functioning and is even more skewed, 5.5:1, in individuals without comorbid intellectual disability (Fombonne, 2005). Females with similar levels of autism symptomatology as their male counterparts are less likely to receive an ASD diagnosis (Dworzynski et al., 2012). Explanations of this gender disparity include hypotheses about the roles of genetic and biological factors, but their empirical support is inconsistent (Kreiser & White, 2014). Recent work has discussed a potential bias in our conceptualization of ASD as consistent with the symptom profile common in males, while females with ASD may have a different constellation of symptoms. Therefore, further investigation of the bias of the “male autism phenotype” is warranted (Robinson et al, 2013). Symbolic play (i.e. use of imagination to pretend that an object is something else) has previously been implicated in ASD (Lam & Yeung, 2012). However, gender differences in symbolic play in infants and toddlers at high and low risk for ASD have not been sufficiently explored.
Objectives: To examine symbolic play skills in male and female infants and toddlers between 12 and 24 months who are at high risk (HR) and low risk (LR) for developing ASD.
Methods: All children (n= 207, 62.3% males) were administered the Autism Diagnostic Observation Schedule (ADOS-T) by psychologists at 12, 18, and 24 months. ADOS item C2 (Imagination/Creativity) indexed symbolic play; scores range from zero to three, zero indicating well-developed imaginative play skills and three indicating none. HR children were divided into two groups based on their 24-month ADOS calibrated severity score (CSS): HR-Elevated (HR-E; CSS 4-10; n=51) and HR-Non-elevated (HR-NE; CSS 1-3; n=87). LR children all had non-elevated CSS (LR-NE; n=69).
Results: A linear mixed model for item C2 indicated a main effect of ASD severity group ($F(2, 565) = 3.457$, $p = .032$), a main effect of age ($F(2, 565) = 90.061$, $p < .001$), and a main effect of gender ($F(1, 565) = 21.709$, $p < .001$). Pairwise planned contrasts revealed that the LR-NE group had significantly better play skills than the HR-E group ($p = .009$); symbolic play skills improved over time (12-18mo, 18-24mo, 12-24mo) ($ps < .01$), and females displayed more advanced symbolic play than males ($p< .001$).
Conclusions: This study is unique in longitudinally investigating play in infants as young as 12 months and found that females across all ages with both high and low ASD symptom severity showed significantly stronger symbolic play skills than males. Stronger play abilities in females, regardless of ASD symptomatology, may be a factor in the clinical presentation of females with increased autism symptoms. In other words, play skills appear to be relatively preserved in females with elevated ASD symptoms. Future studies should examine the possibility that intact play skills are part of a female autism phenotype.

59 **178.059** Sex Differences in Parental First Concerns for Children Screened at-Risk for ASD

R. K. Ramsey[1]*, L. Nichols*[1]*, N. N. Ludwig*[1]*, D. A. Fein*[2]*, L. B. Adamson*[1] *and D. L. Robins*[3]*, (1)Georgia State University, Atlanta, GA, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Â Autism spectrum disorders (ASD) are more prevalent in males than females, with a ratio of approximately 4:1. Furthermore, research suggests that there may be sex differences in early ASD symptomology, with boys exhibiting more readily observable non-verbal impairments and restrictive and repetitive behaviors than girls (Hiller et al., 2015). Due to this more obvious presentation of behaviors in males, ASD may be perceived by parents as being a "boys' diagnosis," which may affect parent report of ASD concerns.
Objectives: Â This study examines whether there are differences in the timing and type of parent report of first concerns between boys and girls who are at-risk for ASD based on the Modified Checklist for Autism in Toddlers (-Revised), with Follow-Up (M-CHAT(-R)/F).
Methods: Â The sample included 532 (N_{male}=373) toddlers considered at-risk for ASD based on the M-CHAT(-R)/F administered during 18- and 24-month well-child visits at pediatricians' offices in metro-Atlanta and Connecticut. Upon comprehensive diagnostic evaluation, 274 (N_{male}=205) were diagnosed with ASD, 226 (N_{male}=150) were diagnosed with a developmental delay, and 32 (N_{male}=18) did not meet criteria for any DSM-IV/5 disorder. Prior to evaluation, parents completed a history questionnaire that included open-ended questions regarding concerns about their child. Parent concerns were coded using a scheme adapted from Ozonoff et al. (2009) into ASD-related concerns (Speech/Communication, Repetitive/Restrictive Behaviors (RRBs), Social, and specific mention of "autism/ASD") and Non-ASD concerns (Motor, Behavior/Temperament, Medical/Regulatory, Feeding/Eating, Disruptive Behavior, and Unspecified). Age and type of first concerns were compared between all boys and girls who were at-risk (i.e., ASD and non-ASD). These were also compared within the ASD group only.
Results: Â For the entire at-risk sample, there was no difference in age of first concern between boys (M=13.76, SD=6.75) and girls (M=13.83, SD=5.57; t(163)=-.057, p=.96); however, parents reported more overall ASD-related concerns in boys (M=1.23, SD=.80) than girls (M=1.05, SD=.72; t(327)=-2.46, p=.014). Parents also expressed concern about RRBs more often for boys (13.7%) than for girls (7.5%; X^2(1, N=532)=4.01, p=.029). Furthermore, parents specifically named "autism/ASD" as a concern more often for boys (5.6%) compared to girls (1.3%; X^2(1, N=532)=5.15, p=.014). In the subsample of children diagnosed with ASD, parents also specifically named "autism/ASD" as a concern more often for boys (7.3%) than girls (0%; X^2(1, N=274)=5.34, p=.011); no other sex differences emerged.
Conclusions: Parents of male toddlers at risk for ASD expressed more ASD-related concerns than parents of female toddlers. Parents of boys reported concern about RRBs and specifically named "autism/ASD" more often than parents of girls. It was notable that no parents of girls who were diagnosed with ASD had named autism/ASD as a specific concern. Thus, parents may not recognize or report concerns about ASD in girls, even though symptoms are clinically significant and warrant diagnosis. In an effort to reduce missed or later diagnosis of ASD in girls, future research should focus on assisting parents in recognizing ASD symptoms in girls to improve the utility of parent-reported ASD concerns in the early diagnosis of ASD, and revising the diagnostic process to account for potential sex differences.

60 **178.060** Sex Differences in Young Children Referred for Autism Spectrum Disorder

C. C. Bradley[1], *L. A. Carpenter*[1], *Z. Warren*[2], *C. Lajonchere*[3], *J. Park*[1], *A. D. Boan*[1] *and S. M. Kanne*[4], *(1)Medical University of South Carolina, Charleston, SC, (2)Vanderbilt University, Nashville, TN, (3)UCLA Institute for Precision Health, Los Angeles, CA, (4)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Research has consistently found a sex difference in Autism Spectrum Disorder (ASD), such that boys are 2-5 times more likely to be diagnosed with ASD than girls. Previous studies have suggested that girls, particularly those without comorbid behavior problems or developmental delays, may be less likely to be diagnosed with ASD compared to boys with similar levels of ASD-related symptoms, although this relationship is less clear in toddler and preschool-aged children referred for ASD.
Objectives: (1) To evaluate sex differences in age of referral and age of diagnosis for children under 6 years of age referred due to concerns for ASD; (2) To examine sex differences in cognitive, developmental, and adaptive functioning for young children referred for concerns for ASD and those ultimately diagnosed with ASD; (3) To compare the severity of ASD-symptomology and behavior problems in males and females referred for and diagnosed with ASD.
Methods: Data for the present study comes from a multisite study examining the sensitivity and specificity of a novel smartphone screening tool for ASD. Participants included 230 children between the ages of 18 and 72 months who were referred for evaluation due to concerns for ASD (mean = 40.34 months; SD = 14.88 months). All participants received thorough ASD diagnostic evaluations including clinical interview, demographics, and measures of cognitive/developmental abilities (Mullen or DAS-II), adaptive functioning (Vineland-2), behavior problems (CBCL/TRF), and ASD symptomology via the SRS-2 and ADOS-2. Participants were 80% male, 77% White, 17% Black, 6% Other/Unknown, and 4% Hispanic. Seventy-one percent of participants (164/230) were diagnosed with ASD following the evaluation.
Results: Of the 230 children referred for concerns for ASD, 20% (n = 47) were female. Sixty four percent met DSM-5 criteria for ASD (n = 31), compared to 73% of referred boys who received an ASD diagnosis. Among the full sample of those referred for ASD concerns, girls had equal concerns for ASD on ASD-screening instruments (M-CHAT or SCQ). On average, girls were older at the time of referral than boys (43.18 vs. 39.46 months) and this difference was more pronounced among those subsequently diagnosed with ASD (44.19 vs 38.01 months; $p < 0.05$). Among those who met criteria for ASD, girls had less cognitive impairment ($p < 0.05$), but poorer average adaptive functioning when compared to boys. Among those diagnosed with ASD, boys and girls had similar rates of restricted repetitive behaviors, although there was a non-significant trend for girls to be less likely to have difficulty with transitions and changes in routine ($p = 0.07$).
Conclusions: Few studies have evaluated sex differences in young children referred for concerns of ASD. Although girls and boys presented with similar ASD-related concerns at referral, girls in this study were both referred and diagnosed at later ages compared to boys. There also appear to be a number of differences with respect to cognitive and adaptive behaviors between girls and boys diagnosed with ASD and additional analyses focused on clarifying the differences between boys and girls meeting DSM-5 criteria for ASD are ongoing.

61 **178.061** Social Responsiveness at 12 and 15 Months Predicts Severity of Social Deficits at 4 Years in Infant Siblings

A. C. Dowd[1], *B. G. Davidson*[2] *and A. R. Neal-Beevers*[1], *(1)University of Texas at Austin, Austin, TX, (2)Pediatrics, University of Miami Miller School of Medicine, Miami, FL*

Background:
Social skills deficits (e.g. joint attention and empathy) that are characteristic of Autism Spectrum Disorder (ASD) emerge early in infancy and are evident before children receive formal diagnoses (Dawson et al., 2004). These early deficits may impact subsequent social skills development (Mundy & Neal, 2001). Therefore, it is important to identify which early deficits, at what age, are related to subsequent social functioning. Understanding if these early social skills deficits predict later social deficits is crucial for building a developmental model of ASD, identifying target areas for intervention, and establishing a timeframe for beginning early interventions.
Objectives:
Identify the extent to which social responses (joint attention skills and responses to examiner's distress) at 12 and 15 months predict the severity of social deficits at four years.
Methods:
Eleven high-risk and 19 low-risk infant siblings were assessed longitudinally at 12 and 15 months of age for: 1) Attention and Affect responses to a standard empathy paradigm (Hutman et al., 2010), 2) Responding to and Initiating Joint Attention (RJA and IJA, respectively; Early Social Communication Scales; Mundy et al., 2003). Additionally, mothers later completed the Social Responsiveness Scale (SRS-2; Constantino, 2012) when infants were 4 years old (mean age= 49.0 months). Linear regressions, with the SRS-2 total severity score (SRS_Total) as the outcome, were conducted separately for RJA, IJA, Attention, and Affect as predictors at each age (12 and 15 months). Risk status was included as an additional predictor in each model to determine if early deficits were predictive of social deficits, beyond known risk effects.
Results:
At 12 months, significant negative effects of Attention ($p<0.001$) and Affect ($p=0.048$) on SRS-2 Total scores were observed. At 15 months, significant negative effects of Attention ($p=0.005$) and RJA ($p=0.046$) and a marginally significant effect of Affect ($p=0.056$) on SRS-2 Total scores were observed. These findings suggest that infants who paid less attention to the examiner in distress at 12 and/or 15 months, who displayed less affect towards the examiner in distress at 12 and/or 15 months, and/or who failed to respond to the examiner's request for joint attention at 15 months were reportedly exhibiting greater social deficits at 4 years.
Conclusions:
Consistent with theory, the results of our study indicate that observed social deficits in infancy predicted parent report of social deficits in early childhood. Specifically, we found that failing to respond to either a social partner's: (1) distress, or (2) attention significantly predicted greater social impairment 3 years later. Our data would suggest that any early failures to respond to social partner may be important markers of social developmental risk that should be closely monitored and/or be considered intervention targets.

62 **178.062** Stability of Temperament in Children with Autism Spectrum Disorder, Developmental Delays, and Typical Development: A Brief Longitudinal Study

N. M. Reyes[1]*, C. E. Walsh*[2]*, G. N. Soke*[3] *and S. Hepburn*[4]*, (1)Box C-234, University of Colorado - Denver, Aurora, CO, (2)Developmental Pediatrics, University of Colorado School of Medicine, Aurora, CO, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)University of Colorado / JFK Partners, Aurora, CO*

Background: Previous research suggests that children with Autism Spectrum Disorder (ASD) demonstrate differences in temperament development when compared to typically-developing children (TD). To date, no study has examined temperament development over time in children with ASD.
Objectives: To examine temperament changes in preschool children with ASD, developmental delays (DD), and TD, using parent report during two assessments.
Methods: We included children with ASD (n=37), DD (n=29), and TD (n=27). Children were administered the Mullen Scales of Early Learning (MSEL), and the Autism Diagnostic Observation Schedule (ADOS) at time 1. Parents completed the Carey Temperament Scales (CTS) at time1 and time 2. We compared parents rating of different temperament items on the CTS between time 1 and time 2.
Results: At time 1, children with ASD were rated as less distractible ($F(2.00, 89.00)=27.039$, $p<0.001$), and adaptable ($F(2.00, 89.00)=9.073$, $p<0.001$), as well as more emotionally negative ($F(2.00, 89.00)=10.213$, $p<0.001$) when compared to their TD and DD peers. Children with ASD were also perceived as more withdrawn (i.e., approach) and intense than their TD peers only, respectively ($F(2.00, 89.00)=7.217$, $p=0.001$; $F(2.00, 89.00)=5.131$, $p<0.005$). At time 2, the ASD group was rated differently on all dimensions, except intensity. Specifically, children with ASD were perceived as more active ($F(2.00, 65.00)=12.791$, $p=0.001$), less biologically rhythmic ($F(2.00, 65.00)=7.889$, $p<0.001$), more withdrawn ($F(2.00, 65.00)=13.765$, $p<0.001$), less adaptable ($F(2.00, 65.00)=13.625$, $p=0.051$), more emotionally negative ($F(2.00, 65.00)=5.391$, $p<0.050$), less persistent ($F(2.00, 65.00)=8.591$, $p<0.001$), and less distractible ($F(2.00, 65.00)=11.424$, $p<0.001$), than the TD and DD groups. They were also described as less reactive to their environment than their TD peers only ($F(2.00, 65.00)=4.983$, $p=0.010$). Additionally, the DD group was rated less active ($F(2.00, 65.00)=12.791$, $p=0.001$), adaptable ($F(2.00, 65.00)=13.625$, $p=0.051$), and reactive ($F(2.00, 65.00)=4.983$, $p=0.010$) than the TD group. Regarding temperament development overtime, parent ratings did not change between time 1 and time 2 in the TD group, but ratings varied substantially in the ASD or DD groups. Specifically, at time 1, results showed that in the ASD group only activity ($r=.60$, $p<.001$) and approach ($r=.53$, $p<.001$) were significantly associated to their corresponding dimensions at time 2. However, in the TD group, rhythmicity ($r=.51$, $p<.050$), approach ($r=.75$, $p<.001$), intensity ($r=.81$, $p<.001$), and mood ($r=.60$, $p<.050$) at time 1 were significantly associated to their corresponding dimensions at time 2. No associations were found in the DD group.
Conclusions: Overall, children with ASD were often viewed as having more temperamental difficulties than their typically developing peers, as well as their developmentally delayed peers. Unlike children with ASD, the TD group showed less cross-time variability in their temperament. These findings indicate that children with ASD and developmental delays might have a different developmental trajectory than children with typical development as it relates to temperament. Results of this study are also informative to clinicians and researchers and suggest the need to assess and provide interventions related to temperament problems in children with ASD.

63 **178.063** Studying Heart Rate Differences during Social Stimuli in Infants at Risk for ASD and ADHD

T. Bazelmans[1]*, S. Greve*[1]*, T. Charman*[2]*, E. Jones*[3] *and M. H. Johnson*[4]*, (1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Birkbeck, University of London, London, UNITED KINGDOM, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: Behavioural difficulties in Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) have been linked to atypical functioning of the autonomic nervous system (ANS). Hyper-arousal in ASD during social situations has been proposed to underlie the differences found in attention to faces. Conversely, inattention and hyperactivity in ADHD have been related to hypo-arousal in response to stimuli. The influence of the ANS during the emergence of behavioural differences in early childhood is unclear.
Objectives: The aim of this study is to see if 5-month-old infants at risk for ASD and ADHD show differences in their heart rate to social and non-social videos compared to low-risk infants. Additionally, we were interested if there are group differences in heart rate changes during the separate videos.
Methods: This preliminary data is part of BASIS (British Autism Study of Infant Siblings – www.basisnetwork.org), a longitudinal study following 5- month old infants at high familial risk for ASD (*N* = 34) and ADHD (*N* = 10) due to having an older sibling with ASD or sibling or parent with ADHD. They are compared to low-risk infants that have an older sibling but no first-degree relatives with ASD or ADHD (*N* = 18). Heart rate was measured continuously during an eye-tracking paradigm, starting and ending with a non-social video (*NS1* and *NS2*). In between, two social videos were presented (*Happy* and *Sad*), counterbalanced in order. Average heart rate and changes throughout the duration of the videos were compared between groups using repeated measures ANOVAs.
Results: There is a significant effect of video type ($F(2.44, 109.57) = 5.15$, $p = .004$, $\eta_p^2 = .10$). Average heart rate is lower during *NS1* compared to *Happy*, *Sad* and *NS2*. The other three videos did not differ from each other. There are no group differences or interaction effects. For the *NS1*, *Happy* and *Sad* videos there is a significant effect of time (*NS1*: $F(3.89, 229.28) = 5.88$, $p < .001$, $\eta_p^2 = .09$; *Happy*: $F(3.09, 151.24) = 3.33$, $p = .020$, $\eta_p^2 = .06$; *Sad*: $F(3.76, 195.67) = 4.09$, $p = .004$, $\eta_p^2 = .07$). Within-subject contrasts show that heart rate decelerates in the first 5 seconds and accelerates between 15-25 seconds. There is no significant effect of group or interaction effects.
Conclusions: This preliminary data shows that infants at low and high risk for ASD and ADHD are comparable in average heart rate and heart rate changes in response to social and non-social videos. All groups show an initial deceleration in heart rate during three of the videos, consistent with literature on deceleration in response to orienting and attention. The acceleration in heart rate can be interpreted as the termination of attention or an increase in stress. Later time points need to be considered to see if and when physiological differences emerge in development and whether they relate to later-emerging behavioural atypicalities.

64 **178.064** Studying Symptom Onset and Intervention for Infant Siblings of Children Diagnosed with Autism

T. D. Graupner *and G. Sallows, Wisconsin Early Autism Project, Madison, WI*

Background**:**
About 20 percent of infant siblings of ASD children will be diagnosed with ASD by age three. (Brian et al., 2014; Ozonoff et al., 2011). Symptoms of ASD are present during the first two years of life, and reflect aberrant brain activation (Brian et al., 2014; Jones and Klin, 2013; Landa et al., 2012), which may be normalized by learning new responses to environmental stimulation, including human interaction (e.g., Helt, et al., 2008; Xu et al., 2009). By intervening before the full syndrome is present, at risk children may avoid being diagnosed (Rogers et al., 2008). Using ABA, ESDM or other strategies, several studies have found improvement in at risk children under two years old (MacDonald et al., 2004; Rogers et al., 2010, 2014**).**
Objectives:
1. Determine the earliest signs of symptomatic behavior including delays and loss of skills during the first six months of life in infant siblings.
2. Describe the response to intensive intervention with symptomatic infants and their parents.
Methods:
Parents of infant siblings gave informed consent. Infants were assessed using the AOSI (Bryson et al., 2000), Bayley III, the Mullen, the PLS-5, and the Vineland. Development was followed weekly throughout intervention. Intervention followed developmental, ABA and ESDM strategies, coupled with family counseling and training for parents. Intervention ranged from 15 to 40 hours weekly. Parents attended with their infants, which allowed us to do direct coaching. Staffing of the intervention room was 1:1.
Results:
1. Of the 75 infants, ranging in initial age from 6 days to 7.5 mos (mean 2.5 mos), 13 were identified as showing symptoms of ASD (20.3%), and 11 were typical developing (TD). Symptoms included poor eye contact, reactivity, fleeting attention and engagement with us, flat affect with no smiling, low response to physical interaction, staring off, preferring objects to human interaction, repetitive toy play, poor self-soothing, and rigidity/ fear of novelty, e.g., new toys or people.
2. TD infants showed no losses of raw score points during the first six months. By comparison, symptomatic infants showed delays beginning at 16 days to 2 mos (mean 1.2 mos), and losses of raw score points beginning at 16 days to 5 months (mean 2.6 mos). Most children with losses had 3-4 during the first 6 months, while 2 had 20 losses. The duration of losses was 1 to 2.5 weeks. Losses represented all areas: motor, language, cognitive and social skills.
3. Parents needed coaching to become more attentive, interactive, positive and sensitive to their infant's cues (Wan et al., 2013).
Conclusions:
Early symptoms including loss of skills in all areas occurred during the first one or two months of age. In spite of showing early delays and loss of skill, all infants responded well to intervention.Â Progress was somewhat uneven, with periods of rapid learning followed by plateaus for a week or so, followed by resumption of gains. So far, the 13 infants who showed ASD symptoms, no longer do so. However, since only two are now 2 years old, these results are preliminary.

65 **178.065** Systematic Review of Comorbid Symptomatology and Challenging Behaviors in Infants and Toddlers with Autism Spectrum Disorder

T. L. Benninger[1] *and A. N. Witwer*[2]*, (1)Psychology, The Ohio State University, Columbus, OH, (2)Nisonger Center, The Ohio State University, Columbus, OH*

Background:
Children with Autism Spectrum Disorder have high rates of co-occurring emotional and behavioral disorders, often contributing to impairments in learning and development. As the field moves toward earlier diagnosis, many of these co-occurring behaviors appear and require treatment in toddlers and very young children. Clinicians often refer to these as co-occurring psychiatric disorders, challenging behaviors, or both interchangeably due to inconsistencies in theories on comorbidities in children this young. It is important to have a clearer picture of the composition of these concerning behaviors in order to successfully intervene.
Objectives:
This study will examine the utility of comorbid diagnoses in very young children with ASD to determine if this is an appropriate term for a toddler and the validity and efficacy of labeling challenging behaviors. In addition, this study will categorize and summarize the prevalence data of comorbid symptomatology and challenging behaviors in multiple samples of toddlers with ASD.Â
Methods:
A range of medical, educational and scientific databases were searched to identify studies of comorbidity and challenging behaviors in toddlers with ASD (i.e., Medline, PSYCHinfo and Education Research Complete). The search was limited to peer-review articles published in English from 1990 to 2016. We searched with the following terms: Psychopathology OR challenging behavior OR problem behavior –AND Infants OR toddlers OR young children –AND Autism OR ASD. Additional searches were performed including terms for each comorbid symptom and group of challenging behaviors (including 'ADHD' 'Hyperactivity' 'Anxiety' 'Aggression' 'Self-Injury' and 'Stereotypy') to attempt to identify all possible studies.Â A combined 415 results were found through these three search engines. References of identified studies were searched and relevant studies included.A total of 34 articles met criteria and were included in this review.Â
Results:
Studies reporting total prevalence of challenging behaviors and/or comorbid symptoms of psychopathology estimate between 15.9% and 46.2% of infants and toddlers with ASD have at least one clinically significant area (Eisenhower, Baker & Blacher, 2005; Hartley, Sikora & McCoy, 2008; Rojahn et al., 2009;. Matson, Fodstad, Mahan & Sevin, 2009). Most frequently reported behaviors include externalizing symptoms such as physical aggression, disruptive/tantrum behaviors and ADHD symptoms such as inattention and impulsivity. Much less data is available on internalizing symptoms in toddlers such as depression/withdrawal symptoms. Additionally, demographic differences were reported regarding race, age and sex.
Conclusions:
Challenging behaviors in toddlers with ASD present in a wide variety of ways. Evidence is mixed for making a formal psychiatric diagnosis in toddlers as co-morbidities in very young children are often unstable. Despite this, it is clear from this review that many that toddlers with ASD present with significant amounts of challenging behavior which could likely benefit from intervention. Implications for diagnostic practices are discussed along with needed areas of future research.

66 **178.066** Tactile Sensory Gating in Infant Siblings of Children with ASD or ADHD and Age-Matched Controls

***E. S. Piccardi**, M. H. Johnson and T. Gliga, Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: Atypical responses to sensory stimuli, in the forms of hypersensitivity and hyposensitivity, are commonly observed in individuals diagnosed with ASD and ADHD (Schauder & Bennetto, 2016) but have rarely been contrasted in experimental studies. Given the genetic overlap between the two diagnoses, investigating similarities and differences in early sensory symptomatology may help in unraveling shared/unshared developmental pathways (Johnson & al., 2015). Inefficient filtering of environmental stimulation ("sensory gating") has been proposed as a cause of the sensory abnormalities observed in children with ASD/ADHD, and previously measured by employing ERP auditory gating paradigms (Orekhova et al., 2008; Orekhova & Stroganova, 2014).
Objectives: This study investigated behavioral and neural mechanisms mediating tactile sensory gating in three groups of 10-month-olds: infants at familial risk of ASD (*N*=49), infants at familial risk of ADHD (*N*=17) and age-matched controls (*N*=22). We expected to observe greater variability in contingent behavioral responses and reduced habituation to tactile stimulation in at-risk infants. These results would support research indicating that both hypersensitivity and hyposensitivity occur in individuals diagnosed with ASD and ADHD. Additionally, they would point to impairments in habituation mechanisms occurring in these disorders. From a neural perspective, we predicted to observe sensory gating deficits in at-risk infants. These results would extend previous research employing ERP auditory paradigms indicating that sensory gating abnormalities are indexed by neural aberrations in atypical cohorts.
Methods: 10-month-old infants were tested with a paired-stimulus paradigm: 100 ms pairs of vibro-tactile stimuli (S1-S2) with 700 ms ISI within the pair and 8 seconds ISI between the pairs. Stimuli were delivered through headphones placed to the infants' feet: 38 pairs were administered during 2 blocks lasting 4 minutes each. Infants' behavior (looking, moving) was scored during the "anticipation phase" (4 seconds before S1) and the "reactive phase" (4 seconds after S2). Continuous scalp EEG was recorded, the mean amplitude of ERPs time-locked to vibrotactile stimulation was extracted from four electrode pools.
Results: Analysis of behavioral data revealed a main effect of stimulation time (p<.0001) in all groups, indicating that infants' mean behavioral reactivity was higher during the "reactive phase" as compared to the "anticipation phase". Moreover, all groups exhibited habituation effects (1st half vs. 2nd half, p<.001). Analysis of ERPs mean amplitude revealed a main effect of stimulus (S1 vs. S2, p<.05) in the central and inferior parietal pools, indicating that efficient sensory gating occurred in the three groups.
Conclusions: Our findings suggest that behavioral and neural mechanisms mediating tactile sensory gating in infants at familial risk of ASD and ADHD are not significantly different from those observed in age-matched controls. In spite of typical behavioral reactivity and decrease amplitude of ERPs with stimulus repetition, other neural indexes may be atypical in at-risk cohorts (i.e., lateralization of responses, ongoing EEG power). Future analyses will be implemented to compare these indexes and characterize possible risk markers across the three groups.

67 **178.067** Temperament As a Predictor of Anxiety in High-Risk Infants

***J. Ezell**[1], S. M. Matherly[1], K. E. Caravella[1] and J. Roberts[2], (1)University of South Carolina, Columbia, SC, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background: Fragile X syndrome (FXS) is a monogenetic disorder characterized by intellectual disability and is the leading known heritable genetic cause of autism spectrum disorder (ASD), which makes it an ideal model for studying ASD. High rates of anxiety have been reported in both FXS and ASD with features of anxiety and ASD overlapping. Specific infant temperament profiles characterized by elevated negative affect have been associated with later emerging anxiety in typically developing and FXS samples and may be predictive of later anxiety in ASD (Tonnsen et al 2013). Despite the high association of anxiety in these disorders, no studies have examined relationships of temperament to anxiety using a cross-syndrome approach. Understanding early features and the trajectory of anxiety symptoms is critical to direct early, targeted treatments to reduce or prevent the occurrence of anxiety in these populations.
Objectives: The purpose of this study is to characterize the emergence of anxiety disorders in high risk infant populations; infants with FXS or ASD siblings contrasted to low-risk controls with two primary questions:

1. What is the prevalence of anxiety symptoms in 24-month-olds with FXS, ASD siblings, and TD controls?Â
2. Does negative affect at 12 months predict anxiety symptoms at 24-months in FXS contrasted to ASD siblings and low risk infants covarying for developmental level?

Methods: We used a prospective longitudinal design. Participants included 31 infants with FXS, 31 ASD siblings, and 37 low-risk controls. The Negative Affect cluster of the Rothbart-Infant Behavioral Questionnaire (IBQ), a parent measure of infant temperament, was completed at 12-months. The Child Behavior Checklist (CBCL) 1.5 – 5 years old Anxiety Problems Subscale, a DSM oriented scale of anxiety, was completed at 24 months. The Early Learning Composite (ELC) of the Mullen Scales of Early Learning, a measure of broad development, was completed at both age points.
Results: A one-way ANOVA showed that the CBCL Anxiety scores for the FXS group were significantly higher than both the ASD siblings (p=.006) and low risk controls (p=.004). A linear regression showed a significant main effect for group and Negative Affect predicting anxiety at 24 months when ELC is covaried (F(2, 62)=2.25, p=.049). Correlations for each group showed a moderate, positive relationship between Negative Affect and anxiety symptoms for infants with FXS (r(18) = .40, p=.086).
Conclusions: This is the first study to compare anxiety symptomatology across infants at high and low risk for anxiety and ASD. Further, this is also the first study to use temperament as a predictor of anxiety symptoms at 24 months of age. Results suggest that the FXS group has elevated anxiety symptomology strongly correlated with negative affect that is distinct from the ASIB group, which indicates potential etiologically distinct profiles of the relationship of early temperament to anxiety or ASD in high-risk groups.Â Temperament characterized by negative affect may impair infants' responses to the environment, reducing positive interaction and resulting in greater emergence of anxiety.

68 **178.068** The Guided Participation Relationship and Parental Tutoring Strategies in Preschoolers with Autism.

J. A. Hobson[1], *E. Kirk*[2], *F. Larkin*[3], *L. Hollaway*[4], *M. Garlington*[5] *and J. A. Moore*[6], *(1)Sonoma State University, Santa Rosa, CA, (2)Department of Psychology, University of York, York, United Kingdom, (3)Department of Psychology, University of York, York, UNITED KINGDOM, (4)Pediatrics Plus, Little Rock, AR, (5)Pediatrics Plus, Conway, AR, (6)University of Central Arkansas, Conway, AR*

Background:
In a Guided Participation Relationship, parents scaffold children's performance during instructional activity to promote feelings of competence and autonomy (Rogoff, Ellis, & Gardner, 1984). Parents provide such support within their children's Zone of Proximal Development (Vygotsky, 1978). However, not all parents are equally effective as tutors. Mothers of securely attached preschool children are more effective tutors, in that they provide more positive feedback, are less likely to intervene physically, provide help when asked, and pitch their help at an appropriate level for the child's needs (Meins, 1997).Â Feedback and responsiveness from their children help parents provide appropriate levels of scaffolding, encourage motivation, and support transfer of responsibility. Children with autism and their caregivers show difficulties negotiating the Guided Participation Relationship (Beurkens, Hobson, & Hobson, 2013).
Objectives:
The first aim of this study was to compare matched groups of young children with and without autism on a parental tutoring task. Our second aim was to ascertain whether the parental tutoring task revealed patterns of change in a subset of the children with autism, those who (with their parents) received an intervention designed to foster the Guided Participation Relationship (Relationship Development Intervention, RDI).
Methods:
The study included 32 children, between the ages of 3 - 6 years, and their parents. There were 16 children (8 girls) who were diagnosed with developmental disabilities but did not show features of autism, and a matched group of 16 children (7 girls) with a previous diagnosis of autism. At the beginning of the school-year, children were administered the ADOS, a parental tutoring task, and a language assessment. The children with autism were in two separate classes (each class n = 8) in the same preschool. One of the classes added RDI to the daily curriculum. RDI was delivered within the classroom, and via parent sessions provided on site throughout the school year. At the end of the school year, all of the children with autism (and their parents) were assessed again, with the ADOS, tutoring task, and a language assessment.
Parental scaffolding on the tutoring task was coded using Meins (1997) coding scheme (i.e. type and specificity of parent intervention, child sensitivity to feedback, child success, parent response).
Results:
By way of illustration, parents of children with ASD used more spontaneous non-verbal intrusions (ASD=14.85 (2.78), DD=8.30 (0.51), Mann Whitney U=28, p=.021), and more verbal utterances with a physical component (U=23.00, p=.009). Parents in both groups were similar in their sensitivity to the child's success (i.e. adjusted their feedback accordingly). We will provide additional data on child sensitivity to feedback, and changes over time.
Conclusions:
Results of the present study suggest that parents of children with autism do appear to be sensitive to their child's ability level and adjust their interventions accordingly. On the other hand, physical intervention may be required more often for children with ASD, which is consistent with previous literature. Further results may reveal improvements in the guided participation relationship when this is a treatment focus.

69 **178.069** The Quantitative Checklist for Autism in Toddlers (QCHAT): Validation of a Screening Instrument in Italy.

L. Ruta[1,2], *G. M. Arduino*[3], *F. Apicella*[2], *E. Leonardi*[4], *R. Maggio*[4], *N. Chericoni*[2], *V. Costanzo*[2], *N. Turco*[3], *A. Gagliano*[4], *F. Chiarotti*[5], *G. Pioggia*[1], *C. Allison*[6], *S. Baron-Cohen*[6] *and F. Muratori*[2], *(1)Institute of Applied Sciences and Intelligent Systems, "Eduardo Caianiello", National Research Council of Italy, Messina, Italy, (2)IRCCS Stella Maris Scientific Institute, Pisa, Italy, (3)Centro Autismo e Sindrome di Asperger ASLCN1, Mondovì, Italy, (4)University of Messina, Messina, Italy, (5)Department of Cell Biology and Neuroscience, National Institute of Health, Rome, Italy, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:
Early screening and detection of autism spectrum disorders (ASD) is crucial to enable early effective interventions and to improve long-term outcomes. Several studies in the past two decades have focused on the development of early ASD screening tools that have been tested in both the general population and at-risk children, in population-based and clinically-referred samples. The Quantitative CHecklist for Autism in Toddlers (QCHAT) is a parent-report questionnaire that quantifies autistic traits along a continuum at 18-30 months (Allison et al., J Autism Dev Disord 2008). The QCHAT discriminated between a group of unselected children and those having a diagnosis of ASD. Furthermore it showed that autistic traits are continuously distributed in the general population of toddlers.
Objectives:
To examine the distribution of Q-CHAT scores in (a) an unselected sample of toddlers (TD), (b) in a sample of toddlers and young children with Developmental Delay (DD), and (c) in a sample of young children already diagnosed with an ASD, in three regions (Piemonte, Toscana and Sicilia), representative of the North, Centre and South of Italy.
Methods:
A group of n=318 children took part in the study and the QCHAT was administered. These comprised n=129 TD children (mean age=32.9, SD=9.4 months), n=50 DD children (mean age=27.6, SD=8.3 months), and n=139 ASD children (mean age=31.6, SD=8 months). TD children were recruited in mainstream nursery schools in the three regions involved in the study. ASD and DD children were tested at the clinical facilities within the Autism Centre of the NHS in the province of Cuneo (Piemonte), the Scientific Foundation "Stella Maris" in Pisa (Toscana) and the University Hospital "G. Martino" in Messina (Sicilia) respectively. The Autism Diagnostic Observation Schedule - Second Edition (ADOS-2) and the Griffith's Mental Development Scale (GMDS) were used as part of the diagnostic assessment in the DD and ASD groups. The three groups were matched for age and no region differences were found for age, gender, and QCHAT total scores. A between group analysis of variance was conducted to assess group differences in the QCHAT total scores, accounting for gender effects and gender by group interaction. No differences in Developmental Quotient scores were found in the ASD and DD groups ($F(2,196)=1.66$, $p<0.2$).
Results:
A main effect of group was observed on the QCHAT scores, with the ASD group (mean = 39.4 (SD = 13.1)) scoring significantly higher than the DD (mean = 27.1 (SD = 6.3) and TD (mean = 21.1 (SD = 6.6) group respectively ($F(2,312) = 76.4$, $p<0.001$). No gender and group by gender interaction was found ($F(1,312)=0.62$, $p=0.4$ and $F(2,312)=0.01$, $p=0.99$).
Conclusions:
The QCHAT was able to discriminate between a group of young children with a diagnosis of an ASD and unselected children, as well as between children with developmental delay. This replicates previous findings in a different cultural setting. A large-scale population-based screening study in different regions of Italy is underway to assess the validity of the Q-CHAT as a screening instrument for ASD.

70 **178.070** The Relationship of Early Childhood Characteristics to Autism Severity at School Age

P. Towle[1] *and N. Turygin*[2]*, (1)Westchester Insitute for Human Development, Valhalla, NY, (2)Behavioral Psychology, Westchester Institute for Human Development, Valhalla, NY*

Background: Children with autism spectrum disorder (ASD) are diagnosed at increasingly early ages (prior to age 3). It is widely known that outcomes vary widely; some toddlers diagnosed with ASD improve greatly as they age, while others continue to experience severe challenges. However, the symptoms most predictive of the future presence and severity of the disorder in later childhood are not well understood. The present longitudinal study explored early predictors of later autism severity and adaptive behavior.
Objectives: The present study explored the relationship of early symptoms and developmental level to the later presentation of the disorder. Specifically, we examined the relationship of ASD symptom severity and adaptive behavior scores at diagnosis (prior to age 3), gender, and age of diagnosis, to symptom severity and adaptive behavior scores at follow-up (school age).
Methods: This longitudinal study examined 70 children who were diagnosed with ASD prior to age 3 (Time 1) and who were 7 years or older (Time 2) (range 7-16 years). The participants were identified from review of early intervention clinical charts at a University Center for Excellence in Disabilities. Approximately half the children were diagnosed before age 24 months. Time 1 data were extracted from early intervention charts, and included: age at diagnosis, sex, and scores from the Vineland Adaptive Behavior Scales (VABS I & II) and the Childhood Autism Rating Scale (CARS). Parents who agreed to participate were mailed a packet containing a consent form, the Gilliam Autism Rating Scale (GARS-3), the Social Communication Questionnaire-Current (SCQ-C) and an extensive parent questionnaire. Once the packet was returned, a phone call was made to administer the VABS- II. Based on the parental responses, GARS-3, SCQ-C, and the VABS-II Daily Living Skills score, participants were divided into one of the three diagnostic/disability categories: ASD with moderate to severe disability, ASD with mild disability, and no ASD diagnosis (but may have had other diagnoses such as learning disabilities and ADHD).
Results: Data were analyzed using ANOVA, ANCOVA, and correlations. In terms of the three diagnostic categories at school-age, 52.2% retained a diagnosis of ASD with moderate to severe developmental disability, 29.0% continued to exhibit ASD with milder disability, and 18.8% no longer met diagnostic criteria for ASD. Autism symptoms at Time 1 were significantly associated symptoms at Time 2 for measures of core ASD symptoms and adaptive behavior. However, early socialization scores were most predictive of both later adaptive behavior scores (Adaptive Behavior Composite, Communication, Socialization Vineland Subscales) as well as later autism severity (GARS total, GARS social, and GARS RRB). As well, the CARS Hyperactivity item was differentially strongly associated with later symptom severity.
Conclusions: Several variables predict later functioning in children with early diagnoses of ASD. Socialization scores were predictive of both later adaptive functioning and autism severity at follow up, as was the single CARS item of hyperactivity, demonstrating continuity in child functioning features over several years. The significant relationships and continuity is striking, given that in this data set, from 4 to over ten years have lapsed since the measurements were taken.

71 **178.071** To Help or Not to Help: Prosocial Motivation in Children at Risk for Autism Spectrum Disorder

E. Demurie*, P. Warreyn, C. Bontinck and H. Roeyers, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: The social motivation hypothesis of autism spectrum disorder (ASD) posits that decreased social motivation in ASD may result in less attention to and thus fewer experiences with social sources of information, negatively influencing the development of social cognition and social-communicative abilities (Chevallier et al., 2012). As this reduction in social motivation is considered to be an etiological factor in ASD, we should be able to observe this difference early in life. However, the diagnosis of ASD can only be reliably made around the age of 2 to 3 years (Charman & Baird, 2008).
Younger siblings of children with an ASD have a 10 to 20 times higher risk of developing ASD themselves and are likely to share some behavioral characteristics with their older sibling (Szatmari et al., 2004). Therefore, the current study focused on intrinsically socially motivated behavior of these 'high-risk (HR) siblings', by administering helping tasks.
Objectives: The current study aims to extend our understanding of (pro)social motivation in HR siblings. Two research questions were formulated:
1. Is there a difference in helping behavior between high-risk and low-risk infants?
2. Is helping behavior associated with social-communicative abilities?
Methods: 24 HR siblings and 34 siblings of typically developing children (low-risk (LR) siblings), participating in a prospective study design, were tested in six helping tasks (Warneken & Tomasello, 2006, 2007) at 24 months of age. In the *experimental condition* (3 tasks) the researcher accidentally encountered a problem that she could not solve herself without the help of the child. In the *control condition* (the other 3 tasks, counterbalanced) a similar situation was created intentionally by the researcher and thus no help was needed. All sessions were videotaped and coded with regard to helping behavior and eye contact to the parent and researcher. Furthermore, the Autism Diagnostic Observation Schedule, Toddler module (ADOS-T; Lord et al., 2013) was administered.
Results: All participants helped more frequently in the experimental compared to the control condition, which suggests that the experimental manipulation was successful.
Second, a significant condition x group interaction showed that HR siblings helped less in the experimental condition than the LR infants. Their helping reactions were also slower. Furthermore, LR siblings made more eye contact with the researcher and parent in the control condition compared to the experimental condition, while there was no effect of condition on eye contact of HR siblings.
Finally, within the total sample, more frequent and faster helping behavior in the experimental condition was associated with lower ADOS-T social affect and total scores.
Conclusions: Given the less frequent and slower helping reactions of HR siblings, it is possible that also children at risk for ASD show lower levels of (pro)social motivation. Furthermore, we found evidence for less social referencing in the ambiguous control conditions in the HR group. LR infants checked more often with the parent and researcher during this strange social situation. Finally, frequency and speed of helping behavior was clearly related with social-communicative abilities in early development.

72 **178.072** To Test or Not to Test: Parents' Perspectives on Infant Sibling Studies in Autism Spectrum Disorders

S. Achermann[1], *S. Bolte*[2] *and T. Falck-Ytter*[3], *(1)Psychology, Uppsala University, Uppsala, Sweden, (2)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (3)Dept of Psychology, Uppsala University, Uppsala, Sweden*

Background:
Longitudinal studies of younger siblings of children on the autism spectrum are important as they may point to potentially malleable behavioral and brain processes associated with the later emergence of symptoms. Yet, ethical discussions around such sibling studies are not well-developed. In particular, a better understanding of the potential risks and disadvantages for participating families is needed in order to accurately evaluate the benefit-risk ratio.
Objectives:
We investigated parents' perspectives on participating in an infant siblings study in order to assess possible risks, disadvantages and concerns for participating families. This study builds on previous findings using a larger sample.
Methods:
Questionnaire data was obtained from a total of 79 parents (65% participation) after completion of at least three visits. The data collection was part of an ongoing longitudinal study following infant siblings from 5 months of age to 72 months. Infant siblings had either an older sibling on the autism spectrum or an older neurotypical sibling. During the visits families underwent multiple measures and assessments including eye-tracking, motion-tracking, parent-child-interaction, EEG and MRI. Families typically spent 4-5 h in the lab. The questionnaire examined parents' attitudes towards participating in an infant sibling study, assessed parents' satisfaction and motivation, and explored how parents perceived the child's satisfaction with the study.
Results:
The responses from parents indicated a high level of satisfaction with study participation, both from their own (87%), and the envisaged child perspective (72%). In open comments, parents emphasized the importance and meaningfulness of studying early trajectories in atypical development and a majority strongly recommended other families to participate (89%). No parent expressed complaints about experimental measures or growing concerns for the child's development due to study participation, rather parents expressed appreciation of getting early feedback and advice concerning their child's development. However, the many questionnaires used in the study and long testing days were perceived as a burden for the parents.
Conclusions:
Studying infant siblings of children on the autism spectrum provides important scientific knowledge about the early development of neurodevelopmental disorders. Assessing early precursors and illuminating differential pathways on the autism spectrum is likely to facilitate early diagnosis and intervention. Although our data are based on participating parents only, they suggest that infant sibling studies have a favorable benefit-risk ratio, which is informative for future ethical discussions.

73 **178.073** Trajectories of Cognitive Development in Toddlers at-Risk for Autism Due to Language Delays

L. Henry[1], *C. Farmer*[1], *L. B. Swineford*[2], *S. S. Manwaring*[3] *and A. Thurm*[1], *(1)National Institute of Mental Health, Bethesda, MD, (2)Washington State University, Spokane, WA, (3)University of Utah, Salt Lake City, UT*

Background: Toddlers with early language delays (LD) demonstrate variable outcomes, with some improving enough to “catch up,” and others developing a variety of disorders, including autism spectrum disorder (ASD; Miniscalco et al., 2006). Cognitive growth in other at-risk infants (siblings of children with ASD) is variable, but is often delayed (Brian, et al., 2014; Landa, & Garrett-Mayer, 2006; Landa et al., 2012; Estes et al., 2015). Less is known about cognitive development in toddlers at-risk for ASD due to early LD.
Objectives: Â The aim of the present study was to examine the trajectories of both nonverbal and verbal cognitive development in toddlers with significant LD compared to TD, and investigate patterns of cognitive development in relation to outcome classification.
Methods: Data were combined from two longitudinal studies of language delay conducted at the National Institute of Mental Health and the University of Utah (n=91). Cognitive assessment included administration of the Mullen Scales of Early Learning (MSEL) at approximately 18 months of age. Dependent on MSEL language scores and history of delay, toddlers were categorized in to two groups: At-risk for ASD due to significant LD (N=30), or TD (N=61). Follow-up visits occurred at approximately 24 and 36 months. Growth mixture models (GMM) explored heterogeneity in cognitive development. In the full sample, a series of increasingly complex GMM were fitted and up to five classes were enumerated. Based on several fit indices and interpretability, the best solution was selected, and class membership was evaluated as a predictor of outcome grouping: No delays, non-spectrum delay, or ASD.
Results: The best-fitting models for nonverbal mental age (NVMA) and verbal mental age (VMA) are shown in Figure 1. The three-class solution was selected for NVMA (Age Appropriate, 78%, Delayed, 20%, and Significantly Delayed, 2%). Despite its small size, the Significantly Delayed trajectory was empirically supported and clinically meaningful. Unsurprisingly, NVMA class assignment was related to outcome (Figure 2; Fisher’s Exact Test, p<.001); there was no significant difference in assignment for toddlers with non-spectrum delay compared to ASD, though the sample size reduced power. The best-fitting model for VMA consisted of four classes: Age Appropriate (67%), Delay Catch-Up (9%), Delayed (17%), and Significantly Delayed (7%). VMA class assignment was also related to outcome (Figure 2; Fisher’s Exact Test, p<.001); toddlers with no delay outcomes comprised the Age Appropriate and Delay Catch-Up classes, while toddlers with non-spectrum delay and ASD predominantly formed the Delayed and Significantly Delayed classes, with no significant difference in assignment in toddlers with non-spectrum delay compared to ASD.
Conclusions: Results demonstrate significant heterogeneity in the cognitive development of toddlers with LD. Given that study recruitment was based on LD, the increased heterogeneity in trajectory observed for VMA compared to NVMA is unsurprising. Further, the four VMA classes were predictive of outcome classification, revealing variability in the development of toddlers with no delays, non-spectrum delay, and ASD outcomes, and demonstrating the link between impaired cognition and ASD in toddlers. We plan to extend these analyses to explore individual subscales of the MSEL.

74 **178.074** Trajectories of Focused Attention in Infancy Predict ASD and ADHD Symptoms at Age 3 Years.

A. Hendry[1], *E. Jones*[2], *T. Charman*[3], *M. H. Johnson*[4] *and T. B. Team*[5], *(1)King's College London, London, UNITED KINGDOM, (2)Birkbeck, University of London, London, UNITED KINGDOM, (3)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (4)School of Psychology, Birkbeck College, London, United Kingdom, (5)Birkbeck College London, London, United Kingdom*

Background: The tendency to selectively sustain attention for longer durations correlates with better concurrent learning and better cognitive outcomes later in development. Whilst individuals with Autism Spectrum Disorder (ASD) are commonly observed to show high levels of focused attention once engaged, they may struggle with *selectively* applying this ability across a range of tasks and contexts. Indeed, ASD is highly comorbid with Attentional Deficit Hyperactivity Disorder (ADHD) and autism symptom severity has been found to associate with difficulties with selective maintenance of attention from the third year of life and beyond. Moreover, difficulties with selectively engaging and maintaining attention may underlie the difficulties with joint attention that are characteristic of ASD. It is not yet known however whether attentional difficulties are primary or secondary to the development of ASD and ADHD symptoms.
Objectives: To observe patterns of change in the tendency to selectively maintain attention across contexts in the first 3 years of life amongst infants at high risk for ASD. To relate these differences to ASD and ADHD symptoms at age 3 in order to better understand the etiology of ASD and ADHD comorbidity.
Methods: Tendencies in behaviour across contexts are most effectively and efficiently measured with parent report, particularly for infants where moment-by-moment fluctuations in state can be extreme. We therefore collected parent report of the tendency to exhibit focused attention using the Infant Behaviour Questionnaire–Revised at 10 and 14 months, the Early Childhood Behavior Questionnaire at 24 months and the Children’s Behavior Questionnaire at 36 months. This data was collected in a sample of 116 infants at high familial risk for ASD, and 27 low-risk controls. Parent report of autism and ADHD symptom severity at 36 months was captured using the Autism Diagnostic Interview and Child Behavior Checklist-Preschool Assessment respectively. Latent Growth Curve Models were used to examine inter- and intra-individual change over time. By the time of presentation this analysis will be extended to a further sample of 100 infants at high familial risk for ASD and 50 low-risk controls.
Results: Infant levels of focused attention are negatively associated with parent-reported symptoms of autism-related social difficulties (standardised β = -0.638, p<0.05) and ADHD symptoms (standardised β = -1.059, p<0.001) at age 3. Within the same model, growth in focused attention is also associated with parent-reported autism-related social difficulties (standardised β = -3.634, p<0.001) and ADHD symptoms (standardised β = -3.844 p<0.001), and parent-reported symptoms of ASD and ADHD are positively correlated (standardised β = 6.960 p<0.001).
Conclusions: High ASD and ADHD symptoms at age 3 are associated both with low infant levels of focused attention and with slow growth in focused attention. These data highlight the need for longitudinal models when investigating cognitive mechanisms implicated in developmental disorders and lend support to the theory that control of attention is implicated in the etiology of both ASD and ADHD. Further work is underway to validate these findings against observational measures of focused attention and ASD and ADHD symptoms.

75 **178.075** Treating Autism Symptoms in Infancy through Parent-Mediated Intervention

A. Tanner*, Education, Queen's University Belfast, Vancouver, BC, Canada*

Background: Recent research suggests autism symptoms can emerge as early as 6 months of age and are reliably detected as early as 12 months of age. Early Intensive Behavioral Intervention is the most established intervention for preschool aged children with autism, however best practices for intervention to treat autism symptoms in infancy are still being established.
Objectives: The present study uses behavior skills training to teach parents how to implement parent-mediated behavioral intervention strategies with their infants who are showing signs of Autism Spectrum Disorders (ASD).
Methods: Ten parent/infant dyads participated in the 12-week intervention, which consisted of1-hour weekly parent-coaching sessions, focusing on using daily routines such as mealtimes and play, to teach imitation, joint-attention and verbal behavior to their infants who ranged in age from 7-18 months. Five-minute videos were recorded at the start of every session and scored using partial interval recording for the presence of target behaviors. Three parent and three infant target behaviors were targeting throughout the twelve sessions
Results: Results will be discussed in terms of acquisition of target behaviors, reductions in autism symptoms using a low-intensity parent-mediated behavioral treatment model and the social validity of the intervention. All infant participants showed a significant decrease in autism symptoms after 12-weeks of parent-mediated intervention. Symptom reduction and acquisition of target behaviors maintained at 1 and 3 month follow-ups.
Conclusions: Behavior Skills Training was effective at teaching parent-mediated intervention to reduce autism symptoms in infants and young toddlers who were showing signs of autism.

76 **178.076** Utilising Technology for the Early Detection of Autism: Introducing Asdetect, an Early Detection Mobile Application for Caregivers

J. Barbaro *and N. Kolivas, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Early detection of autism is vital as it provides access to early intervention, facilitating children's developmental outcomes and reducing family stress (Crane et al. 2016; Dawson et al., 2008; 2010; Howlin, 1997). Over the past 11 years, two community-based studies on the early detection of autism (Social Attention and Communication Study; SACS & SACS-Revised; Barbaro & Dissanayake, 2010; 2013) have been conducted within the Victorian Maternal and Child Health system, Australia. The SACS program is currently the most accurate and sensitive method for identifying autism in children under 24-months, but its use has been limited to universal services.
ASDetect (released February 2016) is a free mobile application that incorporates a modified version of the SACS training, and allows caregivers to monitor the signs of autism in children aged 11-30 months. Assessments at 12-, 18-, and 24-months contain 12-15 short videos demonstrating key social-communication behaviours, followed by 'mostly'/'rarely' questions. Behaviours found to be most predictive of autism by 24-months (Barbaro & Dissanayake, 2013) are used to determine a child's 'likelihood' for autism ('high vs 'low'), and caregivers are encouraged to share their child's results with their doctor.
Objectives: This study's objectives were to compare the responses for children at 'high' and 'low' likelihood for autism on each of the behavioural items, and qualitatively explore the experiences of, and actions taken by, caregivers following use of ASDetect.
Methods: 3452 assessments (with caregivers "opting in" for research) were undertaken at 12 (n=848), 18 (n=966), and 24-months (n=1638). Percentage of 'mostly/rarely' responses for each item was compared between children with a 'high' and 'low' likelihood of autism at each assessment using Fisher's exact probability test. A brief email survey was also sent out to all caregivers who opted into research.
Results: 932 children retuned a 'high-likelihood' result (73% male, 27% female), with 71% of caregivers reporting they already had prior concerns. All items at each age significantly differed between 'high' and 'low' likelihood groups; the strongest associations across each assessment involved *use of gestures, eye contact, pointing,* and *showing* (phi coefficient range = .63-.75), with 81-94% of 'high-likelihood' children rarely engaging in these behaviours, compared to 7-11% of 'low-likelihood' children. The survey (n= 122) indicated that 60% of parents whose children returned a 'high-likelihood' result arranged a follow-up appointment with their doctor, with 24% subsequently receiving a diagnosis (43% autism, 53% developmental/language delay, 14% "other"). Caregivers agreed/strongly agreed that ASDetect was "easy to use" (98%), the videos were helpful in illustrating the questions (97%), they knew more about social-communication milestones following its use (90%), and that they would recommend it to other parents (96%).
Conclusions: ASDetect has facilitated hundreds of families in seeking professional support following a 'high-likelihood' result for their child. Items that differentiated children at 'high' and 'low' likelihood for autism are strongly consistent with previous work identifying the predictors of autism in 12-24-month-old children. Projects are now underway to determine the psychometric properties of ASDetect in identifying children with autism, and translating the content into other major languages.

77 **178.077** Visual Attention Patterns in Toddlers with and without Autism

S. Zheng[1]*, K. Hume*[2] *and L. Turner-Brown*[3]*, (1)University of North Carolina at Chapel Hill, Carrboro, NC, (2)University of North Carolina, Chapel HIll, Carrboro, NC, (3)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Eye-tracking studies have found that children with ASD show unique patterns of exploration, detail orientation, and perseveration in the Visual Exploration Task (VET), when compared to typically developing children. It is essential to use developmentally appropriate images and stimuli when designing the visual exploration task, as circumscribed interests may differ across different age groups. A toddler adaptation of VET (VET_T) was developed to capture the visual attention patterns of toddlers with ASD. However, VET_T needs to be validated as a reliable tool in capturing the differences in visual attention patterns between toddlers with and without ASD.
Objectives: This study compared the visual attention patterns of toddlers with and without ASD on the VET and VET_T, in an effort to: 1) examine differences in visual attention patterns of toddlers on the VET-T and on the original VET; and 2) compare differences in visual attention patterns between toddlers with and without ASD.
Methods: Thirty-nine toddlers with a diagnosis of ASD (17-35 months of age) and 21 without ASD (14-34 months of age) participated in this study. Each participant completed the VET and VET_T, which includes 12 VET arrays and 7 VET_T arrays. Randomized Arrays were organized to include high autism interest (HAI), low autism interest (LAI) and social items. Three major outcome variables representing visual exploration patterns were calculated: 1) Exploration: Number of images viewed per second onscreen, 2) Perseveration: Duration of fixation per image explored, and 3) Detail Orientation (DO): Number of discrete fixations per image explored. A series of repeated measures ANOVAs were conducted to test the differences in visual patterns of toddlers with and without ASD on the VET and VET_T.
Results: Toddlers with and without ASD showed different visual exploration patterns in the two tasks:
1) Both groups of toddlers were significantly more detail oriented in the VET_T (p<.05) and also showed significantly higher DO towards HAI items (p<.05) than toward social items and LAI items, especially in the VET_T (significant interaction effect, p<.001). There were no significant differences between toddlers with and without ASD;
2) No significant differences in exploration were found between tasks. However, both groups explored significantly more social items than LAI items. Also, the ASD group showed higher exploration during the tasks than the group without ASD (p<.05).
3) Toddlers showed significantly higher perseveration in VET_T (p<.05). No significant differences were found in stimulus types or between groups.
Conclusions: VET_T, which includes developmentally appropriate stimuli, is more effective at capturing the visual attention of when compared to the original VET. Thus, researchers should consider using this task when examining visual patterns in young children. Toddlers with ASD demonstrated different visual attention patterns across both tasks with higher exploration than toddlers without ASD. This finding indicated toddlers with ASD had visual exploration differences and this could be taken into consideration for intervention design. Further analysis will be done to explore the effects of autism symptoms and severity on toddler's visual attention patterns towards different items in the ASD group.

78 **178.078** Visual Local - Global Processing in 3 - Year Old at Risk Siblings with and without Diagnosis and Typically Developing Children

E. Nilsson Jobs[1], *T. Falck-Ytter*[2,3] *and S. Bolte*[4], *(1)Uppsala University, Uppsala, SWEDEN, (2)Psychology, Uppsala Universitet, Box 1225, Uppsala, SWEDEN, (3)KIND (Center of Neurodevelopmental Disorders), Karolinska Institutet, Stockholm, Sweden, (4)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden*

Background:
Visual processing has been extensively investigated in individuals with autism spectrum disorder (ASD) aged 6 years and older. In brief, the literature suggests superiority in local processing, but also slower global processing than local processing in individuals with ASD. Little is known about local vs. global visual processing in young children with ASD.
Objectives:
The aim of this study was to investigate local and global processing in 3-year old high risk (HR) siblings with an ASD diagnosis (HR+), without ASD diagnosis (HR-), and in low risk (LR) siblings. We expected a local-over-global advantage in the HR+ compared to HR- and LR groups in terms of accuracy and/or response latency.
Methods:
Participants Thirty-two children (age M = 39.6 months, SD = 4.2) from the longitudinal Early Autism Sweden (EASE) study participated: eight LR (3 girls, 5 boys, age M 38.21 months, SD = 3.03), 16 HR- (11 girls, 5 boys, age M 39.64 months, SD = 4.33) and 8 HR+ (6 girls, 2 boys, age M 41.10 months, SD = 5.05).
Diagnostic assessment ASD diagnosis was based on clinical consensus and DSM-5 criteria, and supported by assessment with ADOS-2, ADI-R, Vineland II, and the Mullen Scales of Early Learning.
Local/Global tasks Established measures of local and global processing such as the Embedded Figures Test and the Fragmented Picture Test (modified to suit 3-year olds) were collected. In addition, the local measures Hidden Figures and Figure-Ground were applied as well as the global measure Closure. Accuracy, latency and local/global discrepancy of task performance were evaluated

Results:
A series of one-way ANOVAs with post hoc tests (Bonferroni corrected) were conducted for all visual processing measures. We found a significant between group effect for the local measure Hidden Figures [F (2, 29) = 5.28; p = .011], in which the HR+ group performed more accurately (M = 14.13; SD = 1.46) than both HR-and LR groups (M = 10.81; SD = 3.47, p = .013; M = 10.00; SD = 1.93, p = .016, respectively). No other group differences were found.
Conclusions:
In line with our hypothesis and with previous findings of a local processing bias in older individuals with ASD, three year olds with autism spectrum disorder showed superior performance on the local processing measure Hidden figures compared to both other groups. Although implications are limited due to small sample size and the fact that only one measure yielded significant results, the findings nevertheless extend earlier evidence of enhanced local processing in ASD to early childhood.

79 **178.079** Visual Search Cancellation and Autism Symptoms: What Young Children Search for and Co-Occurring ADHD Matter

B. R. Doherty[1], *T. Charman*[2], *M. H. Johnson*[3], *G. Scerif*[1] *and T. Gliga*[3], *(1)University of Oxford, Oxford, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: Enhanced visual search is one of the most replicated findings in the autism spectrum disorder (ASD) literature and has been documented as young as in infancy and toddlerhood. Visual search in this context often refers to locating one target amongst distracters—less research has investigated search strategies when there are multiple targets amongst distracters, and no studies to our knowledge have manipulated targets and distracters to investigate varying search strategies based on task requirements. It is possible that in ASD performance will be poorer in a multiple target cancellation task, in particular when targets represent a conceptual category as opposed to an exemplar and thus require conceptual knowledge. Alternatively, poor search organization might be associated with attention deficit/hyperactivity disorder (ADHD) symptoms. In contrast, it is possible that performance will be enhanced when exemplar targets are perceptually similar to distracters, thus requiring perceptual abilities known to be enhanced in ASD.
Objectives: This study sought to investigate cancellation performance in 36-month-olds at high and low familial risk for autism, as well as associations with ASD and ADHD symptoms.
Methods: One-hundred and thirty-one 36-month-olds at high (n = 106) and low (n = 25) familial risk for ASD participated in the visual search cancellation task on a touchscreen monitor as a part of a battery of cognitive tasks. In this task, children were asked to search for and touch a) cats among inanimate objects (baseline, "exemplar search"), b) animals amongst inanimate objects (to test categorization, such that higher autistic symptoms were hypothesized to relate to worse performance, "conceptual search"), and c) dogs amongst furniture (to test for the ability to discriminate between perceptually similar objects, such that higher autistic symptoms were hypothesized to relate to better performance, "perceptual search"). The Autism Diagnostic Observation Scale (ADOS) was used to assess severity of autism symptoms and the Child Behavior Checklist (CBCL) was used to assess ADHD symptoms.
Results: While controlling for motor and language abilities, we found that ASD symptom severity did not associate with general enhanced performance in search, but did associate with poorer categorical search in particular, consistent with literature describing impairments in categorical knowledge in ASD. Furthermore, ASD and ADHD symptoms were both independently associated with more disorganized search paths across all conditions
Conclusions: ASD traits therefore do not always convey an advantage in visual search—this depends upon the nature of the stimuli (e.g., exemplar vs. categorical) and the presence of co-occurring ADHD symptoms.

80 **178.080** When High-Risk 2-Year-Olds without ASD Talk the Most

J. Migliaccio[1], *J. Parish-Morris*[2], *S. Plate*[3], *L. Bateman*[4], *J. L. Wood*[2], *R. F. Slomowitz*[5], *J. E. Maldarelli*[5], *J. Pandey*[5], *M. R. Swanson*[6], *S. Paterson*[7], *N. Marrus*[8], *A. Estes*[9], *H. C. Hazlett*[10], *L. Zwaigenbaum*[11], *K. Botteron*[12], *S. Dager*[13], *J. Piven*[14] *and R. T. Schultz*[5], *(1)James Madison University, Harrisonburg, VA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Bryn Mawr College, Bryn Mawr, PA, (4)The Center for Autism Research/CHOP, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Carrboro, NC, (7)Children's Hospital of Philadelphia, Philadelphia, PA, (8)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO, (9)University of Washington Autism Center, Seattle, WA, (10)Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC, (11)University of Alberta, Edmonton, AB, CANADA, (12)Washington University School of Medicine, St Louis, MO, (13)University of Washington School of Medicine, Seattle, WA, (14)Carolina Institute for Developmental Disabilities, Carrboro, NC*

Background: Â Recent research using home-based digital audio recordings at 9 months of age suggests that some children at high-familial risk for ASD are "hyper-vocalizers," producing more vocalizations than low-risk peers (Swanson et al., in press). More vocalizations are associated with higher rates of conversational turn-taking, potentially contributing to a "social feedback loop" that is beneficial to children's social development (Warlaumont, 2014). It is not yet known whether increased vocalization rates remain characteristic of high-risk children as they age, or whether these patterns differ in children ultimately diagnosed with ASD. In this study, we test "hyper-vocalization" in a new setting (clinical assessment) with older children (2-year-olds) and gold standard human coding to identify speech and non-speech vocalization.
Objectives: Determine whether vocalization patterns distinguish 2-year-olds: (1) at high-familial risk for ASD by virtue of having an older sibling with ASD, but not currently diagnosed with ASD themselves (HR-), (2) at low-familial risk for ASD with no ASD diagnosis themselves (TDC), and (3) children who have an older sibling with ASD and are also diagnosed with ASD (ASD).
Methods: Â Thirty-three 2-year-olds (9 ASD, 12 TDC, 12 HR-) were administered the Communication and Symbolic Behavior Scales (CSBS; Shumway & Wetherby, 2009) as part of a longitudinal study (IBIS; Estes et al., 2015). Vocalizations were coded as "speech" or "non-speech" by two blind reliable transcribers ("vegetative" vocalizations were excluded from the current analyses). T-tests compared the percentage of total recording duration occupied by child vocalizations of any type, percentage of speech and non-speech vocalizations relative to total recording length, and number of speech and non-speech vocalizations produced per 10 minutes.
Results: HR- children vocalized for a significantly greater percentage of time (21.5%) than ASD children (13.5%; $p<.05$), with TDCs falling between (16.7%). All groups produced a significantly higher percentage of speech vocalizations than non-speech vocalizations (all ps<.05). The HR- group produced the highest percentage of speech sounds, with a significantly higher percentage (17%) than the ASD group (11.6%; $p=.05$), but not statistically more than the TDC group (14.5%), which was also not different from the ASD group. HR- children produced a greater *number* of speech vocalizations per 10 minutes (Mean=6.56, SD=2.38) than ASD children (Mean=4.07, SD=1.92), suggesting more frequent speech vocalizations. The TDC group mean (5.81, SD=2.71) did not differ from either risk group. Non-speech vocalization rates did not differ by group.
Conclusions: Our data, using gold standard human coders and standardized assessment, are consistent with recent research using home-based recordings to capture vocalizations in 9-month-old infants at high- and low-risk for ASD. Our convergent data suggest that some children at high risk for ASD may possess characteristics that lead to increased vocalization. These same characteristics may simultaneously confer protection against developing ASD, in part by contributing to an active "social feedback loop" that supports social development by providing enriched opportunities for conversational turn-taking (Warlaumont et al., 2014). We anticipate coding 6- and 12-month-old assessments for each child prior to May 2017, to model developmental trajectories in speech and non-speech vocalization across risk groups.

81 **178.081** Variation in Social Visual Engagement - a Putative Autism Endophenotype - Reflects Stringent Genetic Control in Early Childhood

S. Kennon-McGill[1], *N. Marrus*[1,2], *C. Weichselbaum*[3], *A. Klin*[4,5,6], *W. Jones*[4,5,6] *and J. N. Constantino*[1,2,7], *(1)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO, (2)Intellectual and Developmental Disabilities Research Center, Washington University, St. Louis, MO, (3)Psychiatry and Genetics, Washington University School of Medicine, St. Louis, MO, (4)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (5)Center for Translational Social Neuroscience, Emory University, Atlanta, GA, (6)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA, (7)Department of Pediatrics, Washington University School of Medicine, St. Louis, MO*

Background: Â Diminished eye contact—and more specifically, atypical development of social visual engagement (SVE)—has been shown to predict autism spectrum disorder (ASD) by as early as 6 months-of-age among infants at elevated familial risk for ASD. Deviations in visual orientation to socially-salient cues in the course of moment-to-moment life experience are a target of early intervention for ASD, but the nature of causal influence on variation in SVE in early childhood , as well as the genetic structure, is unknown.
Objectives: Â This study aims to examine the genetic structure of early SVE in an epidemiologically-ascertained sample of normal, like-sex toddler twins.
Methods: Â We examined patterns of concordance in how children visually engage a caregiver's face and how they observe and seek information in the actions and reactions of peers. By collecting eye-tracking data from 338 toddlers, we first examined pairwise concordance in social visual engagement as a function of genetic and environmental variation in 82 monozygotic twins (MZ, 41 pairs), 84 dizygotic twins (DZ, 42 pairs), and 84 non-biologically-related toddlers (42 randomized pairs, matched by age and sex). Our experiments measured both macro-level indices of SVE (e.g. percentage of time spent looking at eye regions), as well as micro-level indices (e.g. timing of individual eye movements, direction of eye movements, etc.).
Results: Â For concordance in eye- and mouth-looking, MZ twin-twin intraclass correlations (ICCs) were remarkably high: 0.91 for eyes (95% CI: 0.85-0.95) and 0.86 for mouth (95% CI: 0.76-0.92). This markedly contrasted with correlations for DZ twins: eyes, 0.35 (95% CI: 0.07-0.59) and mouth, 0.44 (95% CI: 0.16-0.65). We also found similar striking concordance among MZ twins compared to DZ twins for micro-level, moment-by-moment SVE. MZ twins demonstrated greater probability of moving their eyes at the same times: for each movement made by twin 1, within 350 milliseconds, there was an 18.6% increase in twin 2's probability of *also* making an eye movement. When analyses were restricted to moments of motor *initiation*of the saccade, we observed a 21.1% increase in probability of time-locked eye movements: within +/-16.7 msec, MZ twins, but not DZ twins, initiated saccades at the same moments.
Conclusions: MZ twins exhibit strikingly high concordance in overall levels of eye-looking; greater probability of shifting their eyes at the same moments in time; greater probability of shifting their eyes in the same subsequent directions; and greater probability of contemporaneously fixating on the same semantic content. These high levels of MZ concordance, observed at both macro- and micro-levels, indicate strong biological basis for variation in social visual engagement, with a substantial amount of that variation accounted for by genetic influence.

Poster Session
179 - Family Issues and Stakeholder Experiences II
12:00 PM - 1:40 PM - Golden Gate Ballroom

82 **179.082** "Luchando Por Ellos:" Understanding Beliefs about ASD from First Generation, Mexican Parents

S. R. Cohen[1], *J. Miguel*[2] *and M. Shaner*[2], *(1)University of California - San Diego, La Jolla, CA, (2)UC San Diego, La Jolla, CA*

Background:
Beliefs about ASD relate to parents' treatment decisions (Blacher, et al., 2014). Parents' beliefs about ASD shape parents' reports of symptoms, the time they take to seek treatment, and the treatment they select (Ravindran et al., 2014). Some Latino parents make religious attributions about their child's disability that may shape treatment decisions. For example, some Latino parents believed that their child with disabilities was a punishment from God, others believed that the child was a gift from God, still others believed that God sent this child to test them (Bailey, et. al., 1999). Beliefs may cause parents to delay seeking treatment or to seek alternative treatment. In a study examining Latino families and their children with ASD, parents were found to endorse non evidence-based treatments that did not meet efficacy standards (Levy et al., 2003).
Objectives:
Understanding parents' beliefs about ASD may shape treatment of ASD for Mexican-heritage (MH) children, whom are diagnosed at 50 percent below the national average and have low treatment participation rates (CDC, 2014, Lopez, et. al., 2013). The objective of this study was to understand MH parents' beliefs about ASD and its causes.
Methods:
Participants were 28 MH parents (22 first generation; *M* age= 37; *SD* = 5.8) of children with ASD (*R* = 2 to 15 yrs old). Researchers employed cultural consensus modeling (Weller, 2007) in audiotaped focus groups to assess parents' beliefs about two questions: "Please tell me what words or phrases you think of when you think about children with autism;" and "What do you think causes autism?" Participants ranked their responses in order of importance. Researchers compiled free lists and determined the total number of distinct responses for each question. Saliency scores for ranked items were calculated and an average score was determined for each response among those included in the participant's rankings. Participants rationalized each step of the process.
Results:
Preliminary results indicated 62 distinct responses for Question One and 31 distinct responses for Question Two. When tabulating the free-list items across the focus groups, responses that described similar concepts were grouped together. For example, "falta de aceptacíon de otros niños o personas" (*lack of acceptance from other children or people*) was grouped with a similar response in a different focus group: "*discriminacíon*" (discrimination). The three most salient responses for Question One were "Que necesitan mucha ayuda." (*That they need a lot of help*);Â "muy cariñosos" (*very affectionate*); and "se necesita más informacíon." (*One needs more information*). The three most salient responses for Question Two were "La alimentacíon," *(what you eat)* "La genetica," (*genetics)* and "Vacunas" *(vaccinations)*.
Conclusions:
Parents' responses to Question One identified stigma – a negative evaluation of the child and family - as a theme. Saliency scores for Question One showed parents' beliefs as child-centered, even identifying the child's strengths (i.e., affectionate). Saliency scores for Question Two identified several beliefs, one of which is not supported by empirical evidence (i.e., vaccines) (DeStefano, et. al., 2013). Future analyses will utilize the transcribed interviews to rationalize parents' beliefs.

83 **179.083** A Peer-Support Group for Typically Developing Siblings of Individuals with ASD in India

D. Taneja *and S. P. K. Jena, Applied Psychology, Delhi University, New Delhi, India*

Background: Having a person with autism in the family, can be challenging for all members, including the typically developing siblings of the person with autism. In most communities, parents of children with similar conditions have the opportunities to interact while availing services for their child or by participating in parent support groups. However, it is very common for typically developing siblings to not get an opportunity to share their experiences with other siblings. They go through life feeling 'alone', often resenting their sibling with disability, and not fully understanding the implications of having a brother or a sister with autism. This is especially of great concern in low and middle income countries like India, where no state support is as yet available, and the unspoken cultural expectation is that the typical sibling will care for the autistic sibling once the parents are no more. To understand the experiences of typically developing siblings of individuals with autism, we conducted Awesome Sibling Meetups (ASM) a peer support programme based on US based sibling support model *Sibshops.*
Objectives: The study evaluates the impact of a peer support programme on a typical sibling's knowledge of autism; behaviours towards the autistic sibling; their individual strengths and difficulties; quality of friendships and coping styles. It also evaluates the impact of the programme on the relationship between the two siblings.
Methods: Nine typically developing siblings participated in a peer-support programme at Action for Autism, the National Centre for Autism in India. Twelve sessions of 3-4 hours each were conducted over a period of four months. The sibling support model *SibshopsÂ* was adapted for the Indian culture and was a mix of fun activities with primary focus on peer support. The programme was a safe place for siblings to share their feelings with other sibling participants. The typically developing siblings were assessed at the beginning and at the end of the programme. Additionally, parents were interviewed about relationship between the two siblings; typical sibling's strengths, difficulties and behaviours towards the autistic sibling; their parenting and coping styles.
Results: Findings from sibling measures indicate an increase in the knowledge of autism; decrease in anger/resentful feelings towards autistic siblings; and use of more positive coping styles. Parents reported decrease in negative behaviours towards the autistic siblings by the typically developing siblings. Results also indicate a decrease in typical siblings emotional, conduct, and peer problems; and an increase in their prosocial activities.
Conclusions: This is one of the few studies in a low resource country like India, which focusses on typically developing siblings of children with autism. Results support the need for such group interventions and controlled evaluation of sibling support groups to improve mental health and functioning of typically developing sibling. It has implications for running sibling support groups in low resource countries.

84 **179.084** AIRB3: Measuring Collaborative Networks Among Parents and Autism Intervention Providers during the Pre-Transition Period.

E. McGhee Hassrick[1]*, K. M. Carley*[2]*, N. R. Tomy*[1]*, J. Chow*[3]*, L. Hauptman*[3]*, B. Bronstein*[4]*, D. S. Mandell*[4]*, A. C. Stahmer*[5] *and C. Kasari*[6]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Carnegie Mellon University, Pittsburgh, PA, (3)University of California Los Angeles, Los Angeles, CA, (4)University of Pennsylvania, Philadelphia, PA, (5)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (6)University of California, Los Angeles, Los Angeles, CA*

Background: Finding and arranging interventions for children with ASD and coordinating them across the life course presents many challenges for people with autism, their parents and providers. Collaboration is particularly challenging during transitions, such as when moving from preschool to kindergarten or middle school to high school.
Objectives: To use social networks techniques to measure collaboration for children with ASD.
Methods: Participants were 6 children with ASD from families with incomes below the poverty line who were transitioning to a new school: 3 children transitioning from middle to high school, 2 from elementary to middle and 1 from pre-school to kindergarten. We used a three stage snowball process to identify individuals involved during the pre-transition period. This process yielded 59 key people, from which we recruited 42. The Social Dynamics of Intervention (SoDI) survey tool was conducted at the end of the school year before the transition to the new school.
Results: Â Child team size varied from 15 to 30, with a mean of 12 people identified as “key” and 10 identified as “not key”. Most school and district staff identified were from the pre-transition school (mean = 76%). Fewer were identified as district staff (mean = 17%). Only 2 teams identified people from the post-transition school.Â Participants often named people as team members that parents did not identify.Â On average, 52% of relied on providers that were not named by the parent. About half of identified team members were considered “inner circle” providers (mean = 47%) and 1/3 (mean = 38%) were “outer circle” providers. The majority of team members were school and district providers (mean = 61%). Fewer healthcare providers (mean = 10%), community members (mean = 10%) and family members (mean = 14%) were identified. Parents were identified as essential inner/outer participants team members by a small number of people per team (mean = 3.5 participants). Meanwhile, parents identified more team members as essential (mean = 9.3 participants). See Table 1 for summary of results. **Social network analysis indicated thatÂ** an average of 3.50 team members (per team) reported that they relied on the primary parent for essential support with the child’s interventions and primary parents reported that they relied on an average of 4.80 team members (per team) for essential support with the child’s interventions. Parents varied in the degree of leadership they had within each team (eigenvector centrality). Only one parent had a high eigenvector score (.85 SD above random mean).Â See Figure 1 for sociograms.
Conclusions: On average, parents did not identify 52% of the people identified as essential. This suggests that parents did not rely on many of their child’s everyday providers. With the exception of one team, none or few people from the post transition context were involved with the child’s team during the pre-transition period. Network findings suggest that parents relied on other team members more than other team members relied on them for support of the child’s everyday interventions. Only one parent emerged as a leader among team members.

85 **179.085** ASD Symptom Severity Moderates the Relationship Between Child Externalizing Behavior and Maternal Stress

D. Janvier[1]*, M. O'Brien*[1]*, E. Kang*[2]*, M. D. Lerner*[2] *and M. Tudor*[3]*, (1)Psychology, Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Stony Brook, NY, (3)Yale Child Study Center, New Haven, CT*

Background: Children with autism spectrum disorders (ASD) present a greater number of externalizing behaviors than typically-developing (TD) children (Mahan & Matson 2011). These behaviors present unique stressors to mothers of children with ASD (Peters-Scheffer et al. 2012). Mothers have also reported experiencing elevated levels of stress when raising children with severe ASD symptoms compared to mothers of children with low ASD symptomatology (Konstantareas & Papageorgiou 2006). Similar studies suggest that externalizing behaviors in youth with ASD are stronger predictors of maternal stress than ASD symptoms (Peters-Scheffer et al. 2012, Lecavelier & Wiltz 2006). Previous research also suggests that externalizing behavior is more likely to predict maternal stress even when holding the severity of ASD symptoms constant, and that it remains a stronger predictor even when measured alongside other stressful ASD related symptoms (Peters-Scheffer et al. 2012). It is not known, however, whether degree of ASD symptomatology and child externalizing behaviors interact in relation to maternal stress. Objectives: The present study analyzes whether ASD symptomatology moderates the relationship between child externalizing behaviors and maternal stress. Methods: Mothers (N = 223) with exactly one child with ASD (ageÂ *M*Â = 6.74,Â *SD*= 2.99; 84% male) completed the Behavioral Assessment System for Children (BASC-2; Reynolds & Kamphaus, 2004) as a measure of externalizing behaviors and the Social Responsiveness Scale-2 (SRS-2; Constantino et al., 2012) to identify the presence and extent of autistic social impairment in the child. Mothers self-reported stress indices via the Parental Stress Index (PSI-4-SF; Abidin 2012). Results: Total child externalizing behaviors were found to predict maternal stress, particularly in the Difficult Child Subscale of the PSI (*β=Â* -.57,Â *p*<.001). Moderation analyses revealed that SRS-2 total scores moderated the relationship between child externalizing behaviors and maternal stress (*B=Â* -.01,Â *p*<.001), such that the relation was strongest when child ASD symptoms were low (*B*= .66,Â *p*<.001; Figure 1). Post-hoc probing indicated that the same pattern of effects was found in all subdomains of externalizing behaviors (hyperactivity, aggression, and conduct problems allÂ *B*=-.01, p<.02) and with all SRS-2 subscales (allÂ *B*Â < -.01,Â *p*< .007). Conclusions: Externalizing behavior in ASD youth was found to predict maternal stress, with a stronger effect seen in children with lower ASD symptomatology. Essentially, the relationship between externalizing behavior and maternal stress was strongest at low levels of ASD symptomatology. It may be that mothers of children with fewer ASD symptoms may attribute parenting stress to child externalizing behaviors, whereas mothers of those with high ASD symptoms may attribute stress to ASD symptoms. Specifically, mothers’ behavioral expectations may differ when perceiving their child’s social ability as greater than other children with ASD (Mori et. al 2009).Â Subsequently, these expectations may affect mothers’ sense of parenting efficacy, leading to increased stress. The poignant relationship found between externalizing behavior, maternal stress and ASD symptomatology demonstrates a significant need in providing relevant and comprehensive interventions that address all three elements of this model, thereby ameliorating stress levels in mothers and improving family quality of life for families of youth with ASD.

86 **179.086** Acceptance or Forever Seeking Answers ? Adaptive and Maladaptive Responses to Having a Child with ASD

N. S. Da Paz[1]*, B. Siegel*[2] *and E. Epel*[1]*, (1)Psychiatry, University of California, San Francisco, San Francisco, CA, (2)Autism Center of Northern California, San Francisco, CA*

Background:
Parenting a child diagnosed with an autism spectrum disorder (ASD) is often associated with chronic stress, elevated anxiety, and depressive symptomology. While this might be true for some, there are caregivers who show psychological resilience as indicated by low levels of reported stress and decreased symptomology. This healthy adaptation might be explained by the caregiver's ability to accept the child's ASD diagnosis. Previous studies have shown that caregivers who had resolved their negative emotions toward their child's diagnosis reported lower stress, while parents who had not experienced emotional resolve reported stress in clinically significant levels. To date, only one instrument, the Reaction to Diagnosis Interview (RDI) (Marvin & Pianta, 1996), has been extensively used to capture caregiver reaction to their child's diagnosis of a chronic illness or disability, categorizing parents as either resolved or unresolved. No measures have examined reactions to having a child with an ASD. Here we examine a new measure of adaptation.
Objectives:
We examined a novel 30-item questionnaire, Adjustment to the Diagnosis of Autism (ADA) developed by Bryna Siegel. This scale was designed to assess the range of parent emotional and attitudinal reactions to their child's diagnosis of autism.
Methods:
We administered the scale to a sample of 77 mothers of children with ASD. We conducted a factor analysis to identify constructs illustrative of acceptance or non-acceptance of the ASD diagnosis. Principal components analysis was performed using direct oblimin rotations with Kaiser normalization to allow for correlations between the extracted components.
Results:
The Bartlett's test of sphericity was significant ($\chi 2$ (435) = 1417.63, $p < .01$). The three factor solution, which explained a cumulative 32.47% of the variance, identified three subscales with primary loadings that ranged from .3 to.75. Factor 1: Externalizing Blame (unresolved/non-acceptance), included "A parent never really gets over a diagnosis of autism in their child." Factor 2: Self-Blame (unresolved/worry), included "There are things I did that make me worry that I contributed to my child's difficulties." Factor 3: Acceptance (resolved/acceptance), included "I have a greater acceptance of my child's autism than I used to." Only one item "I wish we lived in a time or place where parents were expected to leave children like this in a home or hospital" was eliminated because it failed to meet a minimum factor loading criteria of 0.3 or above and did not contribute meaningful information to the three proposed constructs.
Conclusions:
The autism research community knows anecdotally the wide range of coping responses to the diagnosis, but these have not been easily measureable. This novel instrument offers a way to measure caregivers' acceptance or non-acceptance of the autism diagnosis. This could have implications for parental mental health, selection of therapeutic options, and ability to participate in behavioral therapy. Future studies can utilize the instrument to determine the predictive ability of acceptance with family and child behavioral and mental health outcomes.

87 **179.087** Acceptance or Forever Seeking Answers? Adaptive and Maladaptive Reactions to Your Child with ASD

N. S. Da Paz[1] *and E. Epel*[2]*, (1)University of California, San Francisco, San Francisco, CA, (2)Psychiatry, University of California, San Francisco, San Francisco, CA*

Background: Parenting a child diagnosed with an autism spectrum disorder (ASD) is often associated with chronic stress, elevated anxiety, and depressive symptomology. While this might be true for some, there are caregivers who show a certain degree of resilience as indicated by low levels of reported stress and decreased psychological symptomology. This adaptation might be explained by the caregiver's resolve to accept the child's ASD diagnosis or not. Previous studies have shown that caregivers who had resolved their negative emotions toward their child's diagnosis reported lower stress, while parents who had not experienced emotional resolve reported stress in clinically significant levels. To date, only one instrument, the Reaction to Diagnosis Interview (RDI) ((Marvin & Pianta, 1996), has been extensively used to capture caregiver reaction to their child's diagnosis of a chronic illness or disability. The instrument categorizes parent responses to six open-ended questions into two constructs, resolved or unresolved. Being resolved represents acceptance of the child's diagnosis and is equated with adaptive coping, a mechanism that contributes to better health and psychological well-being. A majority of studies have utilized the RDI for child diagnoses such as cerebral palsy, epilepsy, and phenylketonuria (PKU). However, only two have used the RDI to assess parent reaction to their child's diagnosis of autism. In both instances, the open-ended interview captured data cross-sectionally and not over time.
Objectives: We evaluated a novel 30-item questionnaire, Living with Autism (LWA) (Siegel, 2010), designed to specifically address parent reactions to their child's diagnosis of autism with a sample of 77 maternal caregivers of children with ASD.
Methods: We conducted a factor analysis to identify constructs illustrative of acceptance or non-acceptance of the ASD diagnosis. Principal components analysis identified a solution for three factors, each examined using direct oblimin rotations with Kaiser normalization to allow for correlations between the extracted components.
Results: The Bartlett's test of sphericity was significant ($\chi 2$ (435) = 1417.63, $p < .01$). The three factor solution, which explained a cumulative 32.47% of the variance, identified three subscales with primary loadings that ranged from .3 to a high of .75. Factor 1: Externalizing Blame (unresolved/non-acceptance), included "*A parent never really gets over a diagnosis of autism in their child.*" Factor 2: Self-Blame (unresolved/worry), included "*There are things I did that make me worry that I contributed to my child's difficulties*." Factor 3: Acceptance (resolved/acceptance), included "*I have a greater acceptance of my child's autism than I used to.*" Only one item "*I wish we lived in a time or place where parents were expected to leave children like this in a home or hospital*" was eliminated because it failed to meet a minimum factor loading criteria of 0.3 or above and did not contribute meaningful information to the three proposed constructs.
Conclusions: This novel instrument offers promising insight to caregivers' acceptance or non-acceptance of the autism diagnosis. Future directions could utilize the instrument to determine the predictive ability of acceptance with psychological outcomes, such as perceived stress and/or depressive symptomology.

88 **179.088** Access to Autism Information and Services for Korean American Families of Children with ASD

H. S. Lee[1]*, E. Cho*[2]*, A. C. Stahmer*[3] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)California State University, Sacramento, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background:
Koreans are the fifth largest Asian group in the U.S., but are still underrepresented in autism studies examining service disparities. Often, Koreans are not included in these studies (Liptak et al., 2008) or collapsed into "others" or "Asian Americans" (Thomas et al., 2007; Mandell et al., 2009). These umbrella terms mask cultural differences within Asian Americans and their unique needs in accessing autism services.
The Korean culture is highly collectivistic and tends to stigmatize mental health issues, discouraging families from accessing appropriate services (Papadopoulos, Foster, & Caldwell, 2013). A large-scale study found Korea's ASD prevalence to be a staggering 1 in 38 children, but many were untreated or misdiagnosed due to stigma (Kim et al., 2011).
Limited English proficiency is associated with underutilization of services and reliance on online help (Spencer & Chen, 2004). Grinker et al. (2015) found that Korean mothers consulted Korean websites as their primary ASD information source due to language barrier.
Experiences of Korean families of children with ASD need to be examined in order to address service barriers and underrepresentation of Koreans in autism research.
Objectives:
The goal of this study was to explore barriers in accessing autism services and potential solutions for Korean American families.
Methods:
Semi-structured focus groups were conducted with 13 Korean mothers of children with ASD recruited in Los Angeles and Sacramento, CA. Participants were first generation immigrants, whose length of time lived in the U.S. ranged from 10 months to 27 years. Focus group sessions were scribed, audio-recorded, and transcribed. Dedoose software was used for qualitative coding of the transcripts. Coders were trained until interrater reliability was established. Discrepancies in the codes between the coder and a second reviewer were reconciled through consensus.
Results:
Language barrier and lack of social support were common themes. Even the most acculturated parents preferred bilingual therapists but had minimal success in finding them. Pediatricians' and parents' lack of autism knowledge, and elders in the family and professionals reassuring parents to "wait and see" were barriers to receiving a diagnosis. Other challenges included long waiting lists for services and being unfamiliar with the system. Some parents mistrusted Korean pediatricians, but still resorted to going to them due to language barrier.
Parents found other parents of children with ASD and Korean websites helpful. However, these websites were discussion forums where information is not monitored for accuracy. Parents agreed that autism education for pediatrician and parents is needed. Many wanted a website containing information about local bilingual providers, services organized by child's age, and other autism resources in Korean.
Conclusions:
As all participants were first generation immigrants, their biggest challenges were language barrier and lack of social support. In particular, language affected multiple domains directly related to service access, such as obtaining knowledge, selecting providers, and advocating for themselves. As a potential solution to mitigate these issues, parents recommended development of a Korean website with detailed information about services.

89 **179.089** An Exploratory Study of the Impact of Autism Traits on Parenting

C. Dissanayake[1], *A. L. Richdale*[2], *N. Kolivas*[2] *and L. Pamment*[3], *(1)Olga Tennison Autism Research Centre, Bundoora, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia*

Background: Despite a rich general literature on parenting typically developing children (TD), there is a paucity of research examining the influence of autism traits on parenting. Given that autism traits are believed to be normally distributed and are associated with traits such as anxiety and depression, they may have a negative impact on parenting. However, no studies to date have examined whether such traits are related to parenting TD children. Such information is important to establish the need, if any, for parenting supports for parents with high autism traits.
Objectives: Our overall aim was to investigate the influence of autism traits on self-reported parent's sense of competence to establish whether they influence the parenting of TD children. We also investigated whether autism traits contribute to the self-reported parent-child relationship, and whether parenting needs differ between parents with high and low traits of autism.
Methods: Fifty-eight (58) parents (50 mothers) with either a child/ren or a first degree relative with autism *and*a TD child under 18 years (target child) completed the Autism Quotient (AQ). In addition to a set of control measures (e.g., SES, Depression, Anxiety and Stress etc.), parents completed questionnaires on Parenting Sense of Competence, the Parent-Child Relationship, Parenting Difficulties and Family Quality of Life (QoL). They also completed the Child-AQ and the Strengths and Difficulties Questionnaire (SDQ) with regard to their target TD child.
Results: Parent AQ scores were moderately correlated with the Child-AQ (r= .34), but not with the SDQ. Regression analyses examined the unique contribution of parental autism traits to parenting and quality of life (QoL) variables, and the parent-child relationship (after controlling for the DASS). Autism traits did not uniquely contribute to parenting satisfaction and efficacy (competence), QoL, or the parent-child relationship, with the exception that parents with high autism traits reported less involvement with their TD child.
Parents with high (>26; n = 20) and low (<20; n = 32) AQ scores were compared on reported parenting difficulties/needs; parent with high autism traits reported significantly more parenting difficulties/needs compared to parents with low traits.
Conclusions: The wealth of available parenting resources may not address the specific needs of parents on the autism spectrum. Although autism traits did not impact on parenting sense of competence, QoL or the parent-child relationship, they impacted on parent-reported levels of involvement with their TD child, and parenting difficulties. Thus, supports should be built around these specific aspects of parenting to assist parents on the autism spectrum prosper in their parenting role.

90 **179.090** Anxiety and Depression in Chinese Parents of Children with Autism Spectrum Disorder (ASD)

M. Uljarevic[1], ***X. Su***[2] *and R. Y. Cai*[3], *(1)Bundora Campus, La Trobe University, Melbourne, VIC, Australia, (2)Department of Special Education, East China Normal University, Shanghai, China, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background:
Anxiety and depression are very prevalent in parents of children with autism spectrum disorder (ASD). However, reasons behind such high prevalence of affective problems iare currently unknown. Research to date has mainly considered the impact that children with autism have on parental levels of affective disorders, suggesting that behavioural and emotional problems in children can have more significant impact than the core ASD symptoms. However, it is clear that some of the parental own traits can on one hand buffer against the negative effects of stress and thus serve as resilience factors, and on the other hand increase risk for negative outcomes. Two of parental traits that have been previously identified as risk factors for anxiety in both general population, and in population of mothers of children with ASD are Intolerance of Uncertainty (IoU) and Hypersensitivity. However, the relative contribution of children's and parental own traits to parental well-being haven't been explored before.
Objectives:
(1) explore levels of anxiety and depression in a population of Chinese parents of children with ASD; (2) explore the impact of children's behavioural problems, parental traits of IoU and Hypersensitivity on parental anxiety and depression.
Methods:
One hunder twenty seven parents (108 mothers) of children with ASD (106 males) completed Depression Anxiety and Stress Scale-21 (DASS-21), Intolerance of Uncertainty-12 scale (IoU-12), Highly Sensitive Person Scale (HSP) and Strengths and Difficulties Questionnaire (SDQ) as measures of parental anxiety and depression, IoU, Hypersensitivity and children's behavioural problems respectively. Mean age of parents was 35.73 years (SD= 4.11) and mean age of children was 5 years (SD= 2.78).
Results:
Fifty nine percent of parents met the DASS-21 cut-off criteria for elevated anxiety (mild: 19.7%, moderate: 11%, severe: 10.2%, extremely severe: 17.3%) and fifty one percent for elevated depression (mild: 14.2%, moderate: 21.3%, severe: 12.6%, extremely severe: 2.4%). Parental anxiety and depression were associated with their children's emotional problems (r= .324, p <.001; r= .267, p =.002 respectively), and their own levels of IoU (r= .624, p <.001; r= .656, p <.001) and Hypersensitivity (r= .412, p <.001; r= .362, p <.001). In addition, parental anxiety was associated with their children's hyperactivity problems (r= .187, p= .035). When entered into the regression models, these variables accounted for 44.6% of variance for anxiety (F= 24.557, p <.001; IoU and emotional problems being unique, independent predictors, t = 6.53, p < .001, β = .237; t = 3.15, p = .002, β = .497 respectively) and 46% of variance for depression (F= 34.908, p <.001; IoU and emotional problems being unique, independent predictors, t = 7.98, p < .001, β = .281; t = 2.512, p = .013, β = .378 respectively).
Conclusions:
This is the first study to explore the contribution of children's behavioural problems, and parental levels of IoU and Hypersensitivity in predicting parental anxiety and depression. Implications for designing efficacious parental support programs will be discussed.

91 **179.091** Assessing Predictors of Perceived Utility of Biological Testing Among Parents of a Child with Autism

A. Yusuf[1], *I. Peltekova*[1], *R. Bruno*[2], *J. Frei*[3] *and M. Elsabbagh*[4], *(1)McGill University, Montreal, QC, CANADA, (2)Research Institute of the McGill University Health Centre, Montreal, QC, CANADA, (3)McGill University, Montreal, QC, Canada, (4)McGill University, Montreal, CANADA*

Background: The development of biological testing for autism from identifying autism biomarkers has the potential to facilitate identification and allow for tailored and targeted treatments. In ensuring that future biological testing would address the needs of affected families, it is crucial to anticipate potential benefits and challenges posed by biological testing by assessing family's perceived utility of biological testing. Previous research, predominantly qualitative, has suggested some parents found biological testing beneficial to improve care while others questioned its value. However, there is no consistent definition of perceived utility and no previous studies have examined its potential predictors.
Objectives: We defined perceived utility of biological testing as the potential benefits and risks for families considered by families to be possible as a result of biological testing. Our aim is to examine the extent to which a new measure of perceived utility of biological testing among parents of a child with autism is associated with level of knowledge of autism, time since diagnosis, and symptom severity.
Methods: Data were drawn from an ongoing prospective study, *ASD Genome to Outcome*. Children were enrolled when being referred for an autism evaluation or have a confirmed diagnosis of autism for which genetic testing is recommended or has already been performed. A systematic process was used to develop two questionnaires to assess perceived utility and knowledge with input from the target population to establish content validity. The perceived utility questionnaire consists of 23 items with a 4-point Likert scale. The knowledge questionnaire consists of 19 items with a true or false response option. Potential confounds, namely age of respondent, household income, and education, were assessed and would be controlled for statistically if they are associated with perceived utility.
Respondents (n=20) had a mean age of 40.7 years old (*SD*=9.15) and were mostly mothers (90%). Their child with autism (n=15 males) had a mean age of 6.7 years old (*SD*=3.60).
Results: Age of respondent, household income, and education were not associated with perceived utility. Clinician-rated symptom severity was associated with perceived utility of biological testing. Parents of a child with high social communication severity reported significantly higher perceived utility (*M*=89.9, *SD*=5.02) compared to those of a child with moderate social communication severity (*M*=80.4, *SD*=4.56), $t(7)$= 2.84, p=0.025. Contrary to our prediction, knowledge of autism and time since diagnosis were not significantly correlated with perceived utility of biological testing ($r(18)$ = -0.20, p = .40, $r(11)$ = -0.26, p = .40 respectively). However, the two predictors were correlated: longer time since diagnosis was associated with higher levels of knowledge of autism, $r(11)$ = 0.57, p= .03.
Conclusions: Ongoing administration of the questionnaire in the target sample size of n=150 would clarify possible determinants for family engagement in biomarker discovery. The study allows for future work to address specific determinants to improve family engagement in biomarker discovery.

92 **179.092** Assessment of Community Participation and Self-Determination As Outcomes of Transition for Youth and Young Adults with ASD

J. Boloor[1], *W. H. Wong*[2], *M. W. Jackson*[3], *J. A. Findley*[2] *and L. A. Ruble*[2], *(1)Educational, School and Counseling Psychology, University of Kentucky, Lexington, KY, (2)University of Kentucky, Lexington, KY, (3)University of Kentucky, Winchester, KY*

Background:
The Individuals with Disabilities Education Act (2004) mandates transition planning for all students with Individual Education Programs. But research suggests that the transition planning process need improvement (Cameto, Levine, & Wagner, 2004). National data of transition outcomes indicate adults with ASD have the lowest rate of employment, and the highest rate of no activities (Shattuck et al., 2012). As part of a larger study that used focus group methodology to identify issues of transition planning, two transition outcomes emerged as important to key stakeholders. Participants suggested that student self-determination and participation in the community are important in relation to transition and could indicate the quality of transition planning outcomes. Thus, two constructs – self-determination and community involvement – are critical skills that, if targeted during transition planning, have promise for improving post-school outcomes. Self-determination refers to self-advocacy that can be operationalized as setting goals reflecting personal interests and making choices (Wehmeyer & Field, 2007). Community involvement considers participation in structured activities (e.g., work), unstructured activities (e.g. leisure), and memberships. However, rarely are these aspects of transition planning considered (Carter et al., 2013).
Objectives:
To describe (a) student's self-determination associated with transition planning and (ii) community involvement.
Methods:
A review of literature using the words "measurement of self-determination, measurement of community integration, transition, adolescence, and autism" was conducted to find instruments that captured these aspects of transition. Because no measures captured the constructs based on our needs, a measure of self-determination was developed that was comprised of 12 items (4-pt scale, 1 = strongly disagree to 4 = strongly agree) and covers three broad areas of transition meeting participation, goal setting and attainment skills and choice-making The transition participation consisted of 4 items (α = .84), goal settings and attainment skills consisted of 4 items (α = .88), and the choice making consisted of 4 items (α =.94). For community involvement, a survey of 33 items was developed that covered seven types of activities (leisure, daily life, social media, etc) and was assessed based on frequency of participation (rarely/never to several times each day). Data from 7 parents of children with ASD completed the survey. Frequency tables were generated for self-determination and community participation. Data are currently being collected on 18 additional youth as part of a randomized controlled trial (RCT).
Results:
Preliminary results indicate low self-determination skills for transition age youth with ASD for participating in the transition planning process (M = 2.33, SD = .72), for goal setting and attainment skills (M = 2.29, SD = .96), and for choice making (M = 2.37, SD = .95). For community participation, parents reported highest participation for watching TV (about daily) and lowest for participating in activities such as team sports. Only one parent reported involvement in extracurricular activities.
Conclusions:
Results from parent reports indicate moderately low levels of self-determination among their adolescents with ASD and low levels of community participation. We will have more data as part of a RCT by May.

93 **179.093** Associations Between Understanding of ASD and Perceptions of the Sibling Relationship

M. Coffman[1], *N. Kelso*[2], *L. Antezana*[1], *M. L. Braconnier*[3], *J. A. Richey*[4] *and J. Wolf*[3], *(1)Virginia Tech, Blacksburg, VA, (2)William Patterson University, Wayne, NJ, (3)Yale Child Study Center, New Haven, CT, (4)Virginia Tech, Blackbsurg, VA*

Background:
Autism Spectrum Disorder (ASD) is a condition that impacts not only the affected child, but also parents and unaffected siblings (UAS). Families in which a child has ASD report higher levels of stress (Eisenhower et al., 2005; Quintero & McIntyer, 2010), less frequent use of adaptive coping strategies (Hastings et al., 2005) and are at greater risk for psychological difficulties (Glasberg, 2000; Dunn et al., 2001). In particular, UAS face unique stressors. In an estimated 73% of ASD cases, the UAS becomes the caregiver after the death of the parents (Gidden, 2007). These sibling relationships have been described as less close, less reciprocal, and more stressful than other sibling relationships (Orsmond & Seltzer, 2007; Stoneman, 2007). In addition, siblings within affected families spend less time together compared to typical sibling pairs (Knott et al, 1995).
Objectives:
The present study aims to examine what UAS understand about autism and how their understanding affects the sibling relationship. We predicted that increased understanding of ASD would lead to improved ratings of the sibling relationship.
Methods:
The sample included 46 UAS (Mean age = 9.93). UAS completed an interview on their understanding of ASD (Glasberg, 2000) and self-report measures regarding the sibling relationship. Parents completed questionnaires on the their observations of the sibling relationship. To test our hypotheses that understanding of ASD would affect the sibling relationship, we conducted linear regressions with understanding of ASD predicting the sibling relationship.
Results:
For child-report, we found that understanding of ASD significantly predicted decreased overall satisfaction with the sibling relationship (p = 0.027, R^2 = 0.12; Fig 1) and decreased satisfaction with time spent with one's sibling (p = 0.047, R^2 = 0.087). Additionally, as understanding of ASD increased, perceptions of positive sibling behaviors decreased (p = 0.034, R^2 = 0.088) and perceptions of supportive behavior towards their sibling with ASD decreased (p = 0.033, R^2 = 0.112). Parent-report did not reveal a significant association between understanding of autism and sibling relationship.
Conclusions:
In contrast to our hypothesis, we found, across multiple measures of the sibling relationship, that as understanding of ASD increased, satisfaction with the quality of the sibling relationship decreased. There are many potential reasons for this unexpected finding. For example, knowledgeable parents may spend more time advocating for their child with ASD, which could result in less time with the UAS, or more pressure on the UAS. This interaction may cause UAS to feel frustrated with their sibling with ASD. This hypothesis is somewhat consistent with literature indicating that UAS often feel negative feelings (e.g., guilt, jealousy) about their sibling with ASD (Gray, 1998). Alternatively, UAS who have more knowledge of ASD may feel dissatisfied with the amount of time they get to spend with their sibling (e.g., they may wish to spend more time with their sibling with ASD). It is also possible that UAS with more knowledge are overly critical of their behavior towards their sibling with ASD. Our findings have wide-reaching implications for improving the sibling relationship and family dynamic.

94 **179.094** Autism Spectrum Disorder Traits and Parental Stress: The Moderating Role of Parental Self-Efficacy

R. S. Factor[1,2], *D. Swain*[1,2] *and A. Scarpa*[1,2], *(1)Virginia Tech, Blacksburg, VA, (2)Virginia Tech Center for Autism Research, Blacksburg, VA*

Background: The relationship between parenting stress and child behavior is a complex bi-directional process (Baker et al., 2003). Previous research has established that caregivers of children with Autism Spectrum Disorder (ASD) experience increased parenting stress as a result of unique parenting demands and child problem behavior (Davis & Carter, 2008; Estes et al., 2013). Positive self-concepts, specifically parental self-efficacy (PSE), may buffer stress in a number of contexts (Cieslak, Benight, & Lehman, 2008). While many studies examine parenting stress in relation to ASD, they often use parent self-report rather than objective measures in a laboratory setting. High-frequency heart rate variability (HRV) is a measure of autonomic functioning that is mediated by parasympathetic nervous system activity (Berntson, Cacioppo, Quigley, & Fabro, 1994), and has been used to indicate flexible emotional responding and psychopathological processes (Thayer & Lane, 2000; Kreibig, 2010).
Objectives: The present study aims to further explore the role of PSE as a moderator in the relationship between parental stress and ASD traits, utilizing a biological, unbiased measure of stress (HRV) within a controlled laboratory environment. Findings may have implications for parent training and intervention targets. It is predicted that PSE will act as a "buffer," decreasing the effect of ASD traits on parental stress that is measured physiologically with HRV.
Methods: The present study examined the stress parents of children with ASD experience and the way in which PSE may moderate the impact ASD traits have on this stress by using a physiological measure of stress. The sample included 41 mother-child dyads (32% ASD; 61% male, 7-12 years). ASD traits were determined by The Autism Spectrum Quotient-Child Version (AQ-Child; Auyeung, Baron-Cohn, Wheelwright, & Allison, 2007), parental stress was measured by baseline HRV using Polar Pro software, and PSE was measured by the Parental Sense of Competence scale (PSOC; Johnston & Mash, 1989). HRV was measured during a 3-minute baseline video to achieve a "vanilla" baseline (Jennings, Kamarck, Stewart, Eddy, & Johnson, 1992).
Results: Regression analyses indicated main effects for both ASD traits and PSE on maternal baseline HRV, such that increased HRV (i.e., reduced physiological stress) was related to higher ASD trait scores (β =1.40, p = .001) and reduced PSE scores (β = -.974, p = .003). However, the interaction term (i.e., PSExAQ) was not significant (β =.064, p = .12). Therefore, PSE did not significantly moderate the relationship between ASD traits and parental stress.
Conclusions: Â These findings suggest relationships of parental physiological stress with ASD trait severity and PSE. Specifically, heightened ASD trait severity and lower PSE were both associated with increased HRV. These results may illustrate the fact that parents whose children have more severe ASD and therefore, higher AQ scores, might have developed more adaptive coping mechanisms. However, the relationship indicating low PSE and increased HRV is unexpected. One potential explanation is that there may be some discrepancy in what HRV is truly measuring, and it might not be a truly accurate indicator of parental stress.

95 **179.095** Barriers and Facilitators to Physical Activity in Families Who Have a Child with ASD

J. Blagrave[1] *and M. Foester*[2]*, (1)California State University, Chico, Chico, CA, (2)Kinesiology, California State University, Chico, Chico, CA*

Background: Parents and caregivers of children with ASD's have been shown to have high levels of stress. Recent research has shown the benefits of physical activity for individuals with ASD's, but limited research has focused on the physical activity and leisure activity of families with ASD's.
Objectives: The purpose of this study was to explore barriers and facilitators families who have children with ASD's experience in accessing physical activity (PA).
Methods: This qualitative phenomenological study used semi-Structured interviews with 13 parents and/or caregivers to explore barriers and facilitators to participation in PA. Participants were recruited through local agencies who serve children with ASD's using a criterion-sampling approach. Interview questions focused around physical activity experiences of the family members individually and as a whole. Data were transcribed and coded deductively for themes within each data set and then between participants to find overarching themes to barriers and facilitators to PA for families who have a child with ASD.
Results: To be presented.
Conclusions: To be presented.

96 **179.096** Barriers to Technology Inclusion: Teens with ASD and Typically-Developing Peers

C. A. Cohen *and A. R. Marvin, Kennedy Krieger Institute, Baltimore, MD*

Background:
Current standards and guidelines for creating accessible web and information technology have focused on people with visual, auditory, and motor differences. Some attention is now being paid to cognitive differences, but little attention has been paid to creating evidence-based guidelines for people with autism spectrum disorder (ASD). With the nearly ubiquitous use of technology among teens with autism and a desire to enter technology-involved careers, little research has been done to understand what programs (applications) are being used, whether teens with ASD can use them, and whether current design guidelines adequately address the diverse needs of people with ASD.
Objectives:
The purpose of this research was to understand which commonly-used applications are difficult for teens with ASD to use and to identify avenues for improvement.
Methods:
An anonymous 80-question survey was administered online to parents/guardians of ASD and typically developing (TD) children ages 13-17 living in the US with and without ASD. Participants were recruited through the Interactive Autism Network (IAN) and social media. The survey was administered during October and November 2015.
Results:
348 survey instances were completed: ASD=264 (76%); TD=84(24%). Male-to-female gender ratios for TD (1:1) and ASD (5.87:1) were in the expected range.
Three groups were used for analysis: ASD with normal-or-above intellectual ability (ASD-Average); ASD with lower-than-normal intellectual ability (ASD-Low); and TD. No TD teens were attributed with lower-than-normal intellectual ability. Logistic regression was used to compare program use and difficulty across groups, controlling for the child's age, gender, race (white/non-white), and ethnicity (Hispanic/Non-Hispanic).
In general, teens were using a wide variety of applications, with ASD-Low teens using fewer office/productivity applications and having more difficulty when using them than ASD-Average and TD groups. For entertainment applications, fewer ASD-Low teens were using and they had greater difficulty than the other groups. There was no significant difference between the groups in the use or difficulty of educational applications, which tend to be tailored for different skill levels. See Table 1.
We asked the parents of teens with ASD the open-ended question: *What advice do you have for people who design computers and other digital devices, computer applications, and web pages so that they could improve these technologies for your child?* A thematic content analysis revealed the following themes for the ASD groups, in order of frequency: interfaces should be simple, predictable, error free, accommodate motor differences, and be respectful and age-appropriate regardless of level of functioning. These themes are very much in line with the guidelines for people with cognitive and motor differences.
Conclusions:
Most of the teens in this study with ASD were active technology users. When programs were tailored to the needs of the ASD-Low teens, they are able to use them. People who design office/productivity and entertainment applications should provide simplified versions so that people with lower intellectual ability and cognitive differences can have equal access to occupational and entertainment opportunities. Adherence to current accessibility guidelines for people with cognitive and motor differences will help increase technology access for people with ASD.

97 **179.097** Behaviour Problems and ASD Characteristics Predict Parent Competency and Caregiver Strain

B. Thompson[1], *M. Moretti*[2] *and G. Iarocci*[3], *(1)Autism Developmental Disorder Lab, Burnaby, BC, CANADA, (2)Simon Fraser University, Burnaby, BC, Canada, (3)Simon Fraser University, Burnaby, BC, CANADA*

Background: Research investigating factors that predict parenting stress show mixed findings. Some researchers suggest that autism spectrum disorder (ASD) characteristics are an important determinant of parenting stress (Huang et al., 2014); however, others suggest that behaviour problems may impact parenting stress more than ASD characteristics (Zaidman et al., 2014). Behaviour problems associated with ASD are common and heterogeneous; many children with ASD have a co-occurring diagnosis of a disruptive behaviour disorder, such as conduct disorder or oppositional defiant disorder (Kaat & Lecavalier, 2013). As a result, it can be difficult to determine the degree to which ASD characteristics or behaviour problems contribute to perceived levels of parent competency and caregiver strain.
Objectives: 1) To investigate whether behaviour problems and ASD characteristics predict significant impairments in parent sense of competency and caregiver strain; and 2) investigate the interaction between behaviour problems and ASD characteristics; and 3) investigate the interaction between behaviour problems and ASD characteristics with child's sex.
Methods: Two hundred and forty six caregivers (*M*=44.05; SD=8.24), rated their child's ASD symptoms on the Autism Spectrum Quotient adolescent short form (AQ-10), and behaviour problems on the Brief Child Family Phone Interview (BCFPI). Parents reported levels of their own Parent Sense of Competence (PSOC) and Caregiver Strain (CGSQ).
Results: Hierarchical multiple linear regression analyses indicated that high levels of behaviour problems and ASD characteristics each contributed significantly to low levels of PSOC and high levels of CGSQ. ASD characteristics significantly accounted for an additional 2.1% of the variance in PSOC and 5.8% of the variance in CGSQ.
Further, the interaction between behaviour problems and ASD characteristics was significant for CGSQ, accounting for an additional 1.4 % of the variance in CGSQ scores. When ASD characteristics are low, parents report increasing levels of caregiver strain as their children's behaviour problems increase ($p < .001$). When ASD characteristics are high, parents report elevated levels of caregiving stress even when behaviour problems are low ($p < .001$); caregiving stress then steadily rises as a behaviour problems increase in this population.
The sex by behaviour problems interaction term was significant. Results showed that caregiver strain increases as behaviour problems increased among males and females ($p < .001$); however, the rate of increase in caregiver strain in relation to behaviour problems was steeper for females ($p < .001$).
Conclusions: Â Behaviour problems and ASD characteristics predict both parent sense of competency and caregiver strain. However, ASD characteristics appear to be a better predictor of parent competency and caregiver strain than behaviour problems. An interaction between behaviour problems and ASD characteristics was found for caregiver strain suggesting that the rate of increase in caregivers' strain in relation to behaviour problems was steeper when ASD characteristics were low as compared to high, yet parent sense of competency was unaffected. In addition, the rate of increase in caregiver strain in relation to behaviour problems was steeper for females as compared to male children, yet parent sense of competency was unaffected.

98 **179.098** Being a Spectrum Mother: A Mixed Methods Study

C. Stewart[1], *J. J. Long*[1], *C. Tait*[1] *and* ***B. Auyeung***[2,3], *(1)Scottish Autism, Dunfermline KY12 7TL, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom, (3)Autism Research Centre, Cambridge, United Kingdom*

Background: Parenting a child with autism can be challenging for both parents. Previous work in this area has highlighted quality of life issues for parents of children with Asperger's syndrome and autism. Mothers in particular have been found to experience significantly more stress with a reduced quality of life. However, little to no work to date far has established the specific needs and the challenges of women who are on the spectrum themselves.
Objectives: In this study, we examine specific experiences and key needs of spectrum mothers in negotiating social expectations, childbirth, everyday parenting, and in accessing health and education services.
Methods: This study included 35 spectrum mothers (with an autism diagnosis or self identified) and 23 non-spectrum mothers. In order to explore issues in open dialogue, varied qualitative methodology featuring focus groups, interviews and questionnaires were used to obtain information on particular issues that each mother faces. Quantitative data were also collected and will be discussed. Key areas of questioning included issues related to pregnancy, being a new mother, development of the child and a discussion on the kind of assistance that would be most helpful.
Results: Qualitative and quantitative data analysis methods were employed.
In the area of pregnancy, key issues identified in the spectrum mothers included:

- Lack of clarity in communication between mothers and healthcare professionals.
- Difficulty with unfamiliar and changing environments.
- The necessity of having to interact with other people, including other mothers, health practitioners and hospital staff.

For spectrum mothers, the challenges of being a new mother included:

- Difficulties in accessing mother and toddler groups.
- Health visitor and other medical checks.
- Confidence in parenting skills in both the practical and emotional aspects of being a parent.

As children grow, spectrum mothers reported:

- Lack of confidence in parenting skills, particularly in the area of emotional responsiveness.
- Difficulties when interacting with teachers, other parents and accessing groups for extracurricular activities for their children.
- Extreme exhaustion.
- Feelings of isolation.
- Fears and realities of being judged, both with and without disclosure of autism status.

Spectrum mothers report that the following would help:

- Autistic-specific advice on pregnancy and childbirth; guidance as a new parent.
- Support for being a good social role model for children, despite individual difficulties.
- Ideas for a daily routine.

Conclusions: The findings from this study underline the specific challenges faced by spectrum mothers. These challenges not only affect spectrum mothers, but also have implications for outcome in children as the spectrum mothers underline worries about how their autism affects their children, such as access to group activities, interactions with other families, real or perceived judgemental attitudes from others and management of the parent-teacher relationship.
Additionally, potential strategies for improving the service provision, proposed by spectrum mothers, are described. It is hoped this study will provide a framework of specific areas of difficulty for spectrum mothers, and that future work will lead to the development and identification of specific support mechanisms for spectrum parents and their children.

99 **179.099** Beliefs about Causes of Autism and Current Vaccine Hesitancy: Comparisons Across FOUR Parent Groups

R. P. Goin-Kochel[1,2], *S. S. Mire*[3], *L. Berry*[1,2], *L. R. Dowell*[1,2], *C. G. Minard*[1], *L. C. Sahni*[4], *R. M. Cunningham*[4] *and J. A. Boom*[4], *(1)Baylor College of Medicine, Houston, TX, (2)Autism Center, Texas Children's Hospital, Houston, TX, (3)Psychological, Health, & Learning Sciences, University of Houston, Houston, TX, (4)Immunization Project, Texas Children's Hospital, Houston, TX*

Background: Â Unfounded fear about a connection between childhood vaccines and autism spectrum disorder (ASD) has been proposed as a leading reason behind a growing number of vaccine delays and refusals. An estimated 20-30% of parents are vaccine hesitant—meaning they have considerable vaccine concerns and may delay or refuse one or more vaccines. Identifying groups of parents more likely to become vaccine hesitant and factors that predict vaccine hesitancy are key to the design and success of tailored, preemptive vaccine-safety educational strategies.
Objectives: To (a) compare parents' beliefs about causes of their children's developmental delays/chronic illness and rates of vaccine hesitancy among parents of children in four groups: those with ASD (ASD), those for whom ASD was *ruled out*(ASD-RO), those with a diagnosed rheumatoid disorder (RD), and those in the general pediatric population (GP); and (b) identify factors that may differentially associate with vaccine hesitancy across groups.
Methods: Data were collected from 165 parents of children seen at the Autism Center at Texas Children's Hospital and enrolled in a research registry (76% ASD; 24% ASD-RO). Families who had agreed to be contacted about new studies were mailed packets that contained a cover letter, a *Parent Attitudes About Childhood Vaccines* questionnaire (PACV; measure of vaccine hesitancy), a *Revised Illness Perception Questionnaire*(IPQ-R; measure of attributions about children's diagnoses and etiological beliefs), and a demographic form. Clinical diagnoses (ASD or ASD-RO) were extracted from the electronic medical record by one co-author and validated by a second. A logistic regression model was used to estimate the odds ratio for vaccine hesitancy with 95% confidence intervals. Variables significant at the 0.20 level in the univariable analysis were included in the multiple logistic regression model, adjusting for diagnostic group (ASD or ASD-RO). Data collection from the RD and GP groups is currently ongoing, with comparable analyses planned.
Results: Overall, 39/165 (23.6%) of parents agreed that toxins in vaccines caused their child's developmental difficulties, while 40/165 (24.2%) were vaccine hesitant (PACV score ≥ 50). Compared to parents in the ASD-RO group, parents in the ASD group were more likely to believe that vaccines contributed to their child's developmental difficulties (27.0% vs. 12.8%) and significantly more likely to be vaccine hesitant (28.6% vs. 10.3%, Fisher's p< 0.02). The odds of being vaccine hesitant were 2.8 times higher among parents endorsing environmental pollution as a cause for their child's difficulties (95%CI: 1.1—7.6) and 12.8 times higher among parents endorsing toxins in vaccines as a cause (95%CI: 4.5—36.2), which were the only factors maintaining statistical significance in the full model (Figure 1). Additional results with the RD and GP groups are forthcoming.
Conclusions: This comparison between the ASD and ASD-RO groups is interesting in that children in *both* groups had been referred for *possible* ASD; final diagnosis—ASD or not ASD—was a distinguishing factor associated with current parental vaccine hesitancy. Comparisons among the RD and GP groups will further elucidate whether a child's ASD diagnosis and/or other factors confer particular risk for becoming vaccine hesitant.

100 **179.100** Broader Autism Phenotype and Perceived Social Support As They Relate to Pro-Social Behavior in Typically Developing Siblings of Children with Autism Spectrum Disorder

L. K. Baker[1]*, T. Tomeny*[2] *and T. D. Barry*[3]*, (1)University of Alabama, Tuscaloosa, AL, (2)The University of Alabama, Tuscaloosa, AL, (3)Washington State University, Pullman, WA*

Background: In light of difficulties associated with core symptoms of autism spectrum disorder (ASD), as well as the behavioral issues that often accompany ASD, having a child with ASD as a family member may be challenging. Research on parents of children with ASD has found negative outcomes, such as stress, depression, and anxiety (e.g., Karst & Van Hecke, 2012). With respect to outcomes for typically-developing (TD) siblings of children with ASD, the results are mixed (e.g., Meaden et al., 2010). Some research has found increased mood and behavior problems in TD siblings (e.g., Bitsika et al., 2015), whereas others have found no evidence for elevated emotional and behavioral difficulties (e.g. Tomeny et al., 2012), and still others have found positive outcomes (e.g., Macks & Reeve, 2007). Given the mixed findings for TD siblings of children with ASD, research should explore factors related to positive outcomes, such pro-social behavior, in these siblings.
Objectives: The present study sought to 1) explore pro-social behavior in TD siblings of children with ASD, and 2) examine broader autism phenotype (BAP) and TD siblings' social support as they relate to TD siblings' pro-social behavior, while controlling for family stressors (parental stress and ASD symptom severity of the child with ASD).
Methods: Â Participants included 113 parents and TD sibling [ages 11 to 17 (M = 13.32, SD = 1.81)] of a child with ASD [ages 3 to 17 (M = 11.98, SD = 3.29). Parents completed the Questionnaire on Resources for Stress – Short Form as a measure of parental stress, the Children's Social Behavior Questionnaire about their child with ASD to assess ASD symptom severity and about their TD child to assess BAP symptoms, and the Strengths and Difficulties Questionnaire (SDQ) to assess TD sibling pro-social behavior. TD siblings completed the SDQ and the Child and Adolescent Social Support Scale to measure their pro-social behavior and perceived social support, respectively.
Results: A series of partial correlations were conducted controlling for ASD symptom severity and parental stress. While holding these covariates constant, pro-social behavior was negatively correlated with BAP symptoms (r = -.27, p = .004 for self- and r = -.57, p < .001 for parent-report), per both reporters. Alternatively, pro-social behavior was positively correlated with TD sibling social support for both reporters (r = .38, p < .001 for self- and r = .21, p = .03 for parent-report). Additionally, parent- and self-reported pro-social behavior were correlated, r = .43, p < .001.
Conclusions: Overall, TD siblings reported pro-social behavior within the Normal range based on normative data (Goodman, 1997), indicating the majority of TD siblings in the present sample are exhibiting some positive behavioral outcomes, despite the potentially challenging factors associated with having a sibling with ASD. Greater pro-social behavior was related to fewer BAP symptoms and greater perceived social support, as reported by both parents and the TD siblings. Although these results are preliminary in nature, they emphasize that future research should examine predictive factors of positive outcomes for TD siblings of children with ASD.

101 **179.101** Caregivers' Voices Regarding Implementation of a Parent-Mediated Early Intervention for Toddlers with ASD

J. Amsbary[1]*, S. L. Odom*[2]*, H. Schertz*[3]*, K. Baggett*[4] *and H. Able*[5]*, (1)UNC Chapel Hill, Chapel Hill, NC, (2)University of North Carolina, Chapel Hill, NC, (3)Indiana University, Bloomington, IN, (4)University of Kansas, Kansas City, KS, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Caregiver-mediated early intervention models for families of toddlers with autism spectrum disorder (ASD) appear to be a viable intervention option. However, these models have been met with mixed findings regarding child outcomes (Oono, Honey, & McConachie, 2013). Due to the nature of these models in which caregivers are implementing the interventions, little is known about what actually happens when the interventions are implemented during these routines and activities. The field of implementation science referring to the study of how evidence based interventions are implemented in the intended manner, specifies the inclusion of stakeholders in the development and improvement of intervention models. However, caregivers, who are stakeholders *and*implementers of caregiver-mediated early intervention models often are not included in the model development. Thus, it is crucial to understand a.) how feasible caregivers find the intervention and b.) what caregivers experience implementing interventions within their daily routines.
Objectives: Â This presentation will share results from a social validity assessment and an interview study with caregivers who participated in a caregiver-mediated intervention. The specific research objectives include: 1.) Describe caregivers' views on feasibility of the intervention and successes and barriers encountered in implementing the intervention 2.) Based on caregivers' views and experiences, recommendations will be made regarding how caregiver-mediated early intervention models may be more feasible.
Methods: Â Following participation in a randomized controlled trial testing the efficacy of Joint Attention Mediated Learning (JAML), data were analyzed. While most caregivers rated the social validity high, there was some variation, which deems further exploration into caregivers' lived experiences in implementation. A purposive sample of caregivers who rated socially validity high and low, will be contacted to participate in a follow-up interview regarding their experiences implementing JAML including its applicability to their daily routines. Interview data will be compared with the data from the social validity forms. Interviews will be audio taped, transcribed, and systematically coded using a constant comparative process to identify themes that emerge from the caregivers' challenges and successes in intervention implementation.
Results: Â Data from social validity forms completed by caregivers in the intervention group indicated that 93% of participants strongly agree that the intervention is important, 63% strongly agree that they enjoyed their caregiver role in the intervention, and 82% strongly agree that they received the optimal amount of support. Caregivers commented positively about components of the intervention such as the systematic instruction and use of videos in the training. Interviews will probe further into what actually happened during implementation and how that relates to social validity. Results will include identified themes in regard to implementation experiences emerging from caregivers interviewed.
Conclusions: In designing interventions, a consumer driven approach is needed in order to truly maximize optimal child and family outcomes. Thus, learning from caregivers what they actually experience implementing interventions would strengthen intervention design and follow through. Key components that were helpful and/or challenging to caregivers will be reported and conclusions will be made based on the themes that emerge from the follow-up interviews and how it relates to social validity.

102 **179.102** Challenges for Females with Autism: A Parental Perspective

M. Mademtzi[1], *K. Koenig*[1], *F. Shic*[2], *C. Foster*[1], *S. Valencia*[1] *and P. Singh*[3], *(1)Yale Child Study Center, New Haven, CT, (2)Seattle Children's Research Institute, Seattle, WA, (3)Yale School of Public Health, Yale University, New Haven, CT*

Background: An ASD diagnosis can be four times more common in males than in females (Fombone, 2011). However, it is suggested that there is a greater prevalence of autism amongst females than statistics report (Attwood, 2007). A wide range of hypotheses regarding the etiology of sex differences has been proposed, including genetics, brain function, and low validity of assessment tools in detecting autism in girls (Rivet&Matson, 2011b). For these reasons, studies investigating the experiences and needs of individuals with ASD have largely focused on males (Hellemans et al. 2007) and those studies that have included females have involved mixed-sex samples, preventing detailed exploration of female-specific issues (Nichols & Blakeley-Smith 2010). More recently it was shown that although some of the issues faced by females with ASD are similar to those of males with ASD, there seem to be some characteristics more unique to females' experience and their families (Cridland et al., 2014). Hence, there is a largely unaddressed need to identify the specific needs of females with ASD.
Objectives: This study investigates parents' perspectives on the challenges that their daughters with ASD face in different aspects of their lives.
Methods: Â In total, 40 parents of 40 females with autism (age range=4-29 years) participated in the study. Five separate, 2-hours long focus groups were conducted, in which 7-10 participants engaged in semi-structured discussions. Field notes were analyzed using thematic analysis (Krueger&Casey, 2000) to identify data that related to predefined categories (challenges). Relevant data from all field notes were then read and re-read to identify patterns and subthemes within each predefined category.Â Through this iterative process, we were able to select the most relevant sub-themes while ensuring that all material could be sub-classified. Once the coding scheme had been established, the notes were subsequently double-coded by two researchers to ensure consistency of approach.
Results: The focus groups generated rich information and revealed several key challenges distinctly experienced by females with ASD. These were classified as themes relating to 'social communication and social interactions', 'restricted, repetitive patterns of behavior, interests or activities and hypo-/hyper-sensitivity to stimuli' and 'life skills'. Some of these points were similar to those experienced by males with ASD, such as sensory sensitivities in relation to loud noises, challenges of learning personal boundaries in interactions with others, difficulties following the demands of hygiene routines and impact of receiving late diagnosis. However, other issues discussed were of particular relevance to girls with ASD, such as difficulties socializing with other girls (both with ASD and typically developing), sex-specific puberty issues, and perceptions of sexual vulnerability.
Conclusions: This study highlights an important research area and is a preliminary step towards understanding the experiences of females with ASD and their families. However, there is a need for further research investigating female autism presentation through direct examination of the females themselves (Lai et al., 2015). Taking this research direction provides a greater potential to contribute to the well-being of females with autism, build meaningful support services and also add to our general understanding of autism.

103 **179.103** Characteristics, Needs and Outcomes of People with ASD Receiving Medicaid-Funded Long-Term Supports and Services (LTSS) While Living in the Home of a Family Member

S. A. Larson *and L. Lahti Anderson, Institute on Community Integration, University of Minnesota, Minneapolis, MN*

Background:
Of the 1.2 million LTSS recipients with intellectual or other developmental disabilities (IDD) served by state IDD agencies in 2014, more than half (56%) lived in the home of a family member, 11% lived in a home of their own, and 33% lived in a group setting or with a host or foster family (Larson, et al., 2016). In the 2014/2015 National Core Indicators (NCI) survey, 16% of the of 25,772 adults served by state IDD agencies in 33 states or regions who were interviewed had ASD (Human Services Research Institute, 2016). In the 2013/2014 NCI Adult Consumer Survey (ACS), 45% of the adults with ASD receiving IDD services lived in the home of a parent or relative. Of the 6,955 2013/2014 NCI family survey respondents from 18 states 11% had an adult or child family member with ASD (80% had a family member with ID and 9% had a family member with another IDD; Anderson, et al., 2016).
Objectives:
Our objective is to describe similarities and differences in characteristics, needs and outcomes for individuals with ASD and those with other IDDs who live with a family member while receiving Medicaid funded LTSS.
Methods:
This presentation describes characteristics, needs and outcomes of people with Autism Spectrum Disorders (ASD) based on secondary data analyses using the 2014/2015 NCI ACS (describing service recipients and experiences) and family surveys (describing family experiences and outcomes).
Results:
Preliminary analyses of 2014 NCI family surveys found many similarities across disability groups (ASD, ID, and other DD). Key differences included: people with ASD were less likely to receive SSI/SSDI or out-of-home respite services or to have a service plan that included all needed services, and families were less likely to report that they had say in who provided direct supports. This presentation summarizes key findings from more detailed analyses of these differences controlling for known covariates.
Previous analyses of NCI ACS results found that adults with ASD were younger, less likely to communicate using speech, and had different co-morbid conditions than other adults with IDD (Hewitt, et al., 2012). Adults with ASD were also less likely to be employed in community settings (Nord, et al., 2016).This presentation summarizes results from analysis of the most recent NCI data on differences in key outcomes for LTSS recipients living with family members who have or do not have ASD controlling for differences in known covariates.
Conclusions:
Only a few national data sources describe the characteristics and needs of people with ASD who receive LTSS. The National Health Interview Survey allows identification of children but not adults with ASD in its sample. The American Community Survey does not identify people with ASD. The NCI survey program identifies respondents with or without ASD. Data from the 2014/2015 NCI surveys were used to examine the characteristics, needs and outcomes of LTSS for people with ASD amongst people with ASD receiving LTSS through state IDD agencies.

104 **179.104** Characterizing the Representation of and Conversation about ASD Treatments on Twitter

***J. Lee**, Y. Stern, J. Felkey, G. Garcia, E. Mason, A. Strunk and M. Roberts, Northwestern University, Evanston, IL*

Background: The process by which parents of young children with autism spectrum disorder (ASD) make treatment decisions is complex and nuanced, often rooted in information retrieved from the internet, and not necessarily with attention to scientific support for treatment options. Current research suggests that information on ASD that is available on websites lacks adequate reference to scientific support. While websites provide health information, social media platforms including Twitter are now additional forums for the exchange of content and opinions related to health. Research has not yet been conducted regarding the spread of information related to ASD treatment recommendations via Twitter.
Objectives: The objective of this study was to characterize the information networks, as well as the content and quality of such information shared on Twitter, specifically with respect to the dissemination of evidence-based recommendations for ASD treatment for young children. We aimed to characterize the content of linked sources from tweets related to ASD treatment recommendations and to identify opinion leaders in networks of users tweeting about ASD treatment recommendations.
Methods: A search of Twitter messages (tweets) was conducted using the social media analysis tool, NodeXL. All tweets shared during a 1-week period in October 2016, were filtered using keywords related to intervention for young children with ASD (AUTISM or ASD and TREATMENT or INTERVENTION or THERAPY or CURE or CARE or HELP). All sources linked to from the extracted tweets were coded with regard to type of source and content. Those Twitter accounts that were most prominent within this network of shared tweets were identified using NodeXL automated analytics of user networks.
Results: 894 tweets met the search criteria and included a URL. Tweets were excluded if their linked URL did not address an intervention, or if the intervention was specified to be inappropriate for children under age 3. Of the remaining 71 unique URLs, a breakdown of source type was as follows: 59% were an 'unbiased' presentation of information about a treatment; 21% provided a personalized testimonial; 9% advertised a therapy product; 4% linked directly to a current event regarding a treatment; 3% linked directly to a peer-reviewed journal article; 2% linked to a crowdsourcing advice page. In terms of the content, 54% of sources described or endorsed a complementary and alternative medicine (see table). Finally, of the top-ten users who were most frequently mentioned by other tweets, 2 user accounts belonged to advocacy organizations (e.g., Autism Speaks), while 4 of these top-ten accounts belonged to self-advocates.
Conclusions: The rationale for this study was to provide evidence of the social media influences that contribute to ASD treatment decisions. Results of this preliminary study indicate that information readily available to parents on Twitter regarding ASD treatments includes a widely varied set of options offered by both stakeholders and providers. However, the significant representation of complementary and alternative medicines that have been identified as lacking scientific evidence suggests that further research is needed to develop methods for using social media to make evidence-based recommendations as accessible as alternative recommendations.

105 **179.105** Childhood Victimization in a National Sample of Youth with Autism Spectrum Disorders

***R. Pfeffer**, Criminal Justice, University of Houston - Downtown, Houston, TX*

Background: There are a number of hidden populations in the United States whose victimization goes undetected and unreported.
Objectives: This studyaims to assess the victimization experiences of one such population: American children diagnosed with autism spectrum disorders (ASDs).
Methods: Utilizing the Juvenile Victimization Questionnaire (JVQ), this study obtained past-year and lifetime prevalence rates of interpersonal violence in a sample of children with ASDs (N5262).
Results: Results showed that almost 89% of these children had experienced an incident of victimization in their lifetime, while almost as many (82.1%) had experienced an incident within the last year. Among those who had been victimized once within the last year, 92% experienced at least a second victimization within that same time period, pointing to significant levels of poly-victimization. Risk ratios confirm that if a child experiences an incident of victimization in the past year, s/he is at risk to experience another type of victimization during that time frame, no matter what type of initial victimization exposure was examined.
Conclusions: Previous research specifically addressing the victimization of children with ASDs in the United States has been limited and often focuses on a specific form of victimization, such as bullying. Implications include considering the impact of exposure to multiple forms of victimization and addressing the possibility of long-term trauma resulting from chronic exposure to victimization.

106 **179.106** Comorbid Anxiety Disorders in Young Children with ASD: Parent and Teacher Report

E. Llanes[1] *and J. Blacher*[2]*, (1)University of California, Riverside, Riverside, CA, (2)University of California - Riverside, Riverside, CA*

Background:
Children with ASD often experience high levels of anxiety. Indeed, a meta-analysis conducted by van Steensel et al. (2011) revealed that 40% of children had at least one comorbid anxiety disorder. Symptoms of anxiety include fear of separation from parents, resistance to change, crying easily, tenseness, shyness, and irritability (Brereton et al., 2006). However, most previous studies have not focused on young children with ASD who are transitioning to early schooling, when a comorbid anxiety disorder compounds the academic and other risk factors these children experience as they transition to school (Perry & Weinstein, 1988).
Objectives:
This study looks at the prevalence and presentation of comorbid anxiety in young children with ASD who are transitioning to school. Specifically: (1) What is the prevalence of anxiety problems in children ages 4 to 7 years? (2) How does anxiety manifest in preschool (ages 4-5) and in the early school grades (ages 6-7) as reported by parents and teachers? (3) Are there differences between parent and teacher reports of anxiety symptoms?
Methods:
Participants in this study included 180 children ages 4 to 7 years old (147 boys, 33 girls) and their parents and teachers, who were participating in the longitudinal, IES-funded Smooth Sailing study. Behavioral information was collected from parents and teachers using the Child Behavior Checklist – Parent Report and the Teacher Report Form, respectively (CBCL and C-TRF; Achenbach & Rescorla, 2001). This study examined narrow band scores in children who scored in the clinically significant range on the CBCL/TRF.
Results:
Parents reported that 31% of preschool children and 50% of school-aged children were experiencing clinically elevated anxiety. Teachers reported much lower rates, identifying clinically elevated anxiety in less than 5% of preschool children and 30% of school-aged children. Parent and teacher reports of anxiety were uncorrelated for both preschool children ($r = -.11$, $p = .40$) and school-aged children ($r = .15$; $p = .20$). Parents of preschool children with clinically elevated anxiety problems reported that their children frequently exhibit dependence, reluctance to sleep alone, and fears. These behaviors were marginally more frequent, per parent-report, than worrying or separation anxiety . Parents of school-aged children with clinically elevated anxiety problems reported that fears and nervousness were frequent behaviors. These behaviors were significantly more frequent, per parent-report, than worrying (. Similarly, teachers of school-aged children also reported nervousness as a frequent behavior. However, they rated fears as occurring much less frequently than parent report of fears.
Conclusions:
Findings were congruent with the literature that reported a discrepancy between parent and teacher report of behavior (Stratis & Lecavalier, 2015), although here we identified specific internalizing behaviors on which reporters differed. Overall, teachers reported less frequent behaviors indicative of anxiety. Lack of recognition by teachers of important internalizing behaviors, such as anxiety, can delay access to intervention. Implications of the specific behaviors reported by parents and teachers during preschool and the early school years will be discussed.

107 **179.107** Comparing Methods to Increase Participation in Spanish Language ASD Parent Training

E. Rotheram-Fuller *and K. S. Turner, Arizona State University, Tempe, AZ*

Background: Â Training in Applied Behavior Analysis for parents of children with ASD can be a critical support for both parents and their children (Bearss, Johnson, Smith, Lecavalier, & Swiezy, 2015). Parent trainings have been shown to be effective in helping improve problem behavior (Bearss et al., 2015), reducing feeding issues and parental stress (Sharp, Burrell, & Jaquess, 2014), and increasing children's skill generalization across settings (Ingersoll & Dvortcsak, 2006). Unfortunately, however, these trainings are not often well attended, and programs in Spanish have been even less frequently examined.
Objectives: Â The current study seeks to compare two methods for engaging participants in a parent training intervention program conducted in Spanish, for Spanish-speaking parents of school-aged children with ASD.
Methods: Â This study was conducted at a clinical site where 75% of families were exclusively Spanish-speaking. Twenty families were recruited who had at least one child with ASD, aged 6-8 years old. Seventeen families ultimately participated in the training program in two separate group models (n=9 in model 1 and n=8 in model 2). In the first model, the interventionist assessed all families, and the intervention included 6 group sessions, followed by 4 individual sessions. In the second model, separate staff assessed families, and the intervention included 4 group sessions, followed by 4 individual sessions. Content was the same in both models, and focused on teaching ABA terms, strategies, and application for issues with their own children. Families completed both parent and child measures before the training began (Vineland-II, Aberrant Behavior Checklist, Parent Stress Inventory, Home-Situations Questionnaire, etc.), including a diagnostic evaluation (ADOS-2 and KBIT-2) with their child. Throughout the intervention, ABC data and parent implementation efforts were recorded, and parents repeated the self-report surveys at the end of the training.
Results: Participating children had a variety of behavioral challenges, and each family who attended sessions consistently (in either model) successfully collected information on their child's behavior, and reported changes in their use of strategies and reduction in their child's behavior as a result. Parent engagement was significantly higher in the first model (6 group and 4 individual sessions) at 84.6% than in the second model (4 group and 4 individual sessions) at 43.8%. Cultural adaptations to the intervention were needed to increase participation in both models, including offering childcare, dinner for participants and children, and extending time for social engagement, but more relationship building opportunities were included in the first model.
Conclusions: Â It is important to include relationship building opportunities before and throughout parent training interventions, especially for Spanish speaking families with children with ASD. The shorter number of group sessions in model 2 hindered the development of parent-to-parent and parent-to-interventionist relationships that appeared to support attendance in model 1. In this particular population, there was a wide variety of parent knowledge and advocacy, which is increasingly difficult with the language barrier. Having peer and interventionist support beyond the curriculum were critical pieces of the intervention delivery.

108 **179.108** Comparing Parent to Student Report Regarding Technology Use By Adolescents with Autism in School and Home Settings

M. Ledoux[1]*, T. Regan*[2] *and S. Hedges*[3]*, (1)San Diego State University, San Diego, CA, (2)UNC-Chapel Hill, Chapel Hill, NC, (3)UNC Chapel Hill, Chapel Hill, NC*

Background: It has been observed that many children with autism have an affinity to screen based technology and research has examined their use of technology for entertainment, in particular to play video games and watch animated movies. It is not well understood how technology is used to support independence and learning and social interactions. Hedges et al., (under review), found in a recent survey of high school students with autism (n=472) that a majority of respondents reported using technology to enhance their learning, increase their social interactions, and to help reduce stress. This current study sought to confirm those findings by asking similar questions to the parents of the student study participants.
Objectives: To compare parent perspectives to their children's on the use of technology, in particular, what they perceive are its benefits and challenges.
Methods: Paper surveys were completed by 321 parents of high school students with autism receiving special education services across 3 states in the US (California, North Carolina, Wisconsin). The questionnaires covered topics related to their children's technology use at home and at school. Technology was described as computers, cell phones, tablets, etc.
Results: Mirroring their children's report, the majority of parents (91%) said their child is "good" at using technology and 66% said they "definitely" consider it an area of strength. Like their children, most respondents see their teen having a career or job using technology in the future. Similarly, 97% report their child uses technology to communicate or socialize including texting, email, and social media. Almost half of respondents felt that online learning would be a good way for their child to learn. Parents (83%) reported a common use of technology by their children included listening to music to help reduce stress or relieve anxiety.
Â In contrast to the benefits of technology use by teens with autism, 71% of parents (compared to 58% of students) reported that technology can distract their teen from learning and 84% said that their teen's technology use can be excessive.
Conclusions: Parent reports of benefits of technology use along with reports of excessive use and distraction from learning were similar to what their children reported. Educators should consider the benefits of providing access to technology tools for their students with autism to help increase independence, communication, and social interactions. They may also need to consider ways to mitigate the distracting aspects of technology.Â Parents may want to consider setting limits on technology use to help their children learn to control excessive use.

109 **179.109** Compassion Meditation for Therapists of Individuals with ASD: Effects on Stress and Cultural Competence

K. Tang[1,2]*, S. Fernandez-Carriba*[1]*, C. A. Saulnier*[3] *and A. Klin*[4]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)University of Notre Dame, South Bend, IN, (3)Children's Healthcare of Atlanta, Emory University, Marcus Autism Center, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA*

Background:
Health care workers are at a higher risk of experiencing severe distress, burnout, and mental and physical illness than employees of any other industry (McVicar, 2003). This risk has been directly linked to adverse consequences for the quality of care that is provided to patients (Irvin et al., 2009). Comparatively, very little is known about the experience of health workers in ASD. Whereas the practice of mindfulness meditation is reportedly associated with stress reduction in several populations, including health care professionals (Goodman Schorling, 2012). We are not aware of any studies describing mindfulness or compassion based interventions for therapists of individuals with ASD.
Objectives:
The goal of this research is to pilot-test Cognitively Based Compassion Training (CBCT), a mindfulness and compassion meditation protocol developed at Emory University and empirically validated in other populations, with therapists of children with ASD in order to reduce stress and burnout and icrease their social competence.
Methods:
Participants were 22 healthy volunteers working with individuals with ASD at the Marcus Autism Center. The experimental group consisted of 12 participants (Age: $M \pm SD$ = 26.33±1.16; 10 females) who received CBCT over the course of 8 weeks and the control group included 10 participants (Age: $M \pm SD$ = 31.60±5.72; 10 females) who were on a wait list and received no intervention. They all completed several measures pre- and post-test: stress and burnout (Perceived Stress Scale or PSS, Maslach Burnout Inventory or MBI, and Brief Symptom Inventory or BSI-18), acceptance (Acceptance and Action Questionnaire or AAQ), empathy and compassion (Interpersonal Reactivity Index or IRI), behavioral flexibility (Mindful Attention Awareness Scale or MAAS, and Behavior Rating Inventory of Executive Function or BRIEF-A), and relational competence (Cultural Competence Checklist or CCC).
Results:
Paired *t*-tests were utilized to evaluate pre- to post-test changes in scores at the .05 significance level. At post-test, the experimental group reported significant improvements on the PSS [T1: $M \pm SD$ = 22.33±8.14; T2: $M \pm SD$ = 13.17±6.37; $t(5) = 5.33$], IRI Personal Distress Scale [T1: $M \pm SD$ = 18.17±3.19; T2: $M \pm SD$ = 15.50±3.15; $t(5) = 3.16$], and CCC [T1: $M \pm SD$ = 60.67±20.62; T2: $M \pm SD$ = 58.00±18.61; $t(5) = 2.61$]. The experimental group also reported a marginally significant improvement at post-test on the AAQ [T1: $M \pm SD$ = 16.33±3.50; T2: $M \pm SD$ = 11.67±3.27; $t(5) = 2.47$, $p = .057$]. There were additional significant improvements on the raw scores corresponding to the BRIEF-A Shift, Initiate, and Working Memory subscales and in the BSI Depression and Anxiety subscales ($p < .05$). The control group reported no significant changes from pre- to post-test on all measures.
Conclusions:
These results highlight the vulnerability of those professionals, with a potential impact on individuals under their care, and the need to address such vulnerability and its effects using a systematic empirically-based approach. CBCT may be a feasible training for therapists of children with ASD, as it has been demonstrated for the parents of these children elsewhere, with potential benefits on their stress and cultural competence. A randomized controlled trial should test its efficacy under controlled conditions.

110 **179.110** Cross-Sectional Comparison of IEP Quality for Transition Age Youth with ASD and Young Children with ASD

J. A. Findley[1]*, W. H. Wong*[1]*, A. D. Rodgers*[1]*, M. W. Jackson*[2] *and L. A. Ruble*[1]*, (1)University of Kentucky, Lexington, KY, (2)University of Kentucky, Winchester, KY*

Background:
The Individuals with Disabilities Education Act (IDEA) mandates all students receiving special education services have an Individualized Education Program (IEP) (IDEA, 2004). Even though there is an increase in students receiving school services for autism spectrum disorder (ASD), there is little known about IEP quality of students with ASD (Wilczynski et al. 2007). For young children, research suggests a need for more "individualized" IEPs that take into account critical areas of the development of social, communication, and independent work skills. For older students who are transition age (16-22), very little is known about IEP quality. Despite a lack of research, data suggest that IEPs for young children and transition age youth are far from best practice, often lacking individualized and measurable objectives.
Objectives:
To (i) conduct a cross-sectional comparison of IEP quality of transition age youth (16-22) with young students (3-9) with ASD and (ii) describe IEP quality of transition age youth in relation to an adapted national measure of postsecondary quality transition planning.
Methods:
Special education teachers of 35 young students with ASD (3-9 years) and 7 transition age students (16-22 years) were recruited as part of larger study. Additional data collection from 18 transition age students will be completed by November 2016, adding to the richness of this study sample. An IEP quality measure for students with ASD was developed based on IDEA requirements for IEPs and National Research Council (NRC, 2001) recommendations for teaching students with ASD. An Indicator 13 checklist developed by the National Secondary Transition Technical Assistance Center (NSTTAC, 2012), was adapted to measure postsecondary planning for transition age youth with ASD. Descriptive statistics were generated for each of the IDEA and NRC indicators and for the overall score on the IEP Evaluation Tool and Indicator 13 in order to assess quality. Higher scores reflected better quality.
Results:
Comparison of IEP Quality: IEP quality based on IDEA recommendations was higher for transition age youth while IEP quality based on NRC recommendations was higher for young children. IEPs for transition youth have less diverse goals with more focus on organizational/work (100%) and basic cognitive skills (42.9%) while IEPs for young students were more diverse and included organization/work (88.5%), academic (71.4%), communication (85.7%), social (80%), and fine and gross motor skills (65.7%).
IEP Quality in Relation to Transition Planning: Assessment of Indicator 13 recommendations for planning for postsecondary outcomes- education and training, employment, and independent living- indicated that all transition age youth had postsecondary goals related to either education/training or employment. However, only 57.1% of students had a post-secondary goal related to independent living. Additionally, only 25% of IEPs for transition age youth described a method of goal measurement.
Conclusions: IEP quality for students with ASD, both for young students and transition age youth show inconsistencies and areas needing improvement. IEPs for transition age youth need to include measurable and well-defined independent living postsecondary goals.

111 **179.111** Defining Stress and Crisis As Experienced By Parents of Children with Autism Navigating Intervention: Sub-Analysis of a Qualitative Study

S. J. Gentles[1], *D. B. Nicholas*[2], *S. M. Jack*[3], *A. McKibbon*[4] *and P. Szatmari*[5], *(1)CanChild Centre for Childhood Disability Research, McMaster University, Hamilton, ON, Canada, (2)University of Calgary, Edmonton, AB, CANADA, (3)School of Nursing, McMaster University, Hamilton, ON, Canada, (4)Clinical Epidemiology & Biostatistics, McMaster University, Hamilton, ON, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, CANADA*

Background: Â Sources of stress associated with parenting a child with autism have been widely documented. Sources of stress attributable to navigating autism intervention, however, have received less attention. Stress has been associated with serious consequences for parents, such as anxiety and depression. These can interfere both with parental functioning, and parents' crucial role as navigators of intervention to address diverse autism-related concerns—endangering wellbeing of the autism unit. To our knowledge, stress and crisis have rarely been directly studied, and remain conceptually undefined, specifically from parents' perspectives with reference to their process of navigating intervention.
Objectives: This work is a sub-analysis of a large qualitative study whose aim was to explain how Ontario parents of children with autism navigate intervention. The purpose of the sub-analysis is to characterize and conceptually define stress and crisis, as experienced by such parents.
Methods: Â A qualitative grounded theory study was conducted to explain, in depth, the social psychological process parents of children with autism use to navigate intervention. Data comprised primarily 45 audio-recorded and transcribed intensive interviews with 9 professionals and 32 parents from urban and rural regions across Ontario with maximally varying perspectives; data also included documents (e.g., parent- and professional-authored books). Data collection and verification of the evolving categories proceeded iteratively according to theoretical sampling informed by ongoing analysis. Analysis consisted of constant comparison employed in coding and concept development, analytic memo writing, and final integrative writing on the topics of stress and crisis, throughout which we ensured findings were grounded in participant data.
Results: We defined stress according to parent accounts as an individual's subjective emotional experience and physiological response to a triggering object or event that the individual experiences or perceives as an imminent threat to personal wellbeing (including that of a child) or continued ability to function. Distinguishing causes from consequences of stress required careful analytic reference to delimited empirical cases. Diverse subtypes of stress were defined according to underlying causes; some common consequences, meanwhile, could be traced back to these subtypes. A typology of stress was thus constructed. We defined crisis to occur when stress (due to parenting, navigating, etc.) reaches a level that disrupts homeostasis of the affected parent-related functioning system (psychological self, physical self, family, or relationship) and results in either a sudden or progressive loss of function, and sometimes a sense that a catastrophic failure is imminent.
Conclusions: The definitions derived from this sub-analysis contribute coherence and family-centeredness to the concepts of stress and crisis because the parent is located as the central actor in defining and responding to stress in her situation. The typology of stress subtypes has strong fit with a substantial qualitative dataset, suggesting potential generalizability. These findings will be useful for increasing the relevance and specificity of future research into and measurement of stress among parents of children with autism. Findings will also be informative to professionals seeking to understand mechanisms and consequences of stress in such parents, as they vary over their long-term navigating process.

112 **179.112** Description and Outcomes of a Parent Education Package in the Context of a Comprehensive Applied Behavior Analysis Early Intervention Program

J. Sigesmund[1] *and M. A. Minjarez*[2], *(1)Autism Center, Seattle Children's Hospital, Seattle, WA, (2)Seattle Children's Autism Center, Seattle, WA*

Background: Â Young children with autism spectrum disorder (ASD) receive recommendations for a range of services, accessed through different service systems (e.g., insurance, schools). For parents, availability of education about how to obtain services is inconsistent. Following diagnosis, Applied Behavior Analysis (ABA) therapy is often recommended. In Washington State, wait times for ABA may exceed 1-2 years, often because families lack knowledge of how to navigate the service system. In effort to provide comprehensive early intervention services, and to potentially reduce wait times for ABA therapy, the ABA Early Intervention (ABA EI) Program at Seattle Children's Autism Center is a short-term (3 months), comprehensive, intensive treatment model that includes a parent education/support package. As part of this package, parents are taught how to access services, including accessing longer-term ABA therapy through insurance.
Objectives: Â The objective of this study is to highlight the parent education/support package included in the ABA EI Program, and to explore its effects on access to care following discharge, parent satisfaction, and parent stress and empowerment from baseline to post-treatment. Access to care findings for ABA EI patients are compared to a population of children with ASD served in an outpatient clinic in order to compare how many children accessed ABA therapy across groups.
Methods: Participants thus far include 43 children diagnosed with ASD, ages 18 months-9 years, and their parents. Children were selected from two groups: ABA EI Program participants (N = 23) or general outpatients (N = 20). To compare access to care across groups, an independent chart review was completed to determine if patients with referrals for ABA therapy were receiving it. Percent of children receiving ABA in each group was then calculated as the primary outcome measure. Additional secondary measures are being completed to evaluate changes in parent stress and empowerment from baseline to post-treatment (Parenting Stress Index; PSI; Abidin, 1995 and Family Empowerment Scale; FES; Koren, DeChillo & Friesen, 1992). The ABA EI Parent Satisfaction Survey is also being collected at post-treatment.
Results: Data collection is ongoing. Results from the primary outcome measure indicate that 61% (N = 23) of children in the ABA EI program successfully accessed ongoing ABA therapy, compared to 15% (N = 20) of outpatients. The mean ABA EI Satisfaction Survey score (N = 8) was 5 (SD = 0) on a scale of 1-5 (1 = unsatisfactory; 5 = very satisfactory). Results from other secondary measures (PSI and FES) have not yet been analyzed, as data collection is ongoing. Projected enrollment prior to presentation of results is 20-30 children.
Conclusions: Families receiving an intensive parent training/support package in the context of a brief early intervention program successfully accessed ongoing ABA therapy services at a much higher rate than children receiving less intensive outpatient services. Parents reported high satisfaction with the ABA EI program. These pilot findings suggest a focus on increased family support may be important for insuring families are able to navigate the complex service systems involved in caring for children with ASD.

113 **179.113** Development of a Standardized Protocol for Food Preference Assessment in Autism through Direct Observation.

***E. Grossi**, S. Melli and M. Norsi, Villa Santa Maria scs, Tavernerio, Italy*

Background:
Food selectivity is a particular feature of the restrictions and stereotypes of Autism. The majority of studies have investigated food preferences and the factors influencing selectivity using caregiver or parent reports such as CEBI (Children's Eating Behavior Inventory), BAMBI (Brief Autism Mealtime Behavior Inventory), FPI (Food Preference Inventory) or YAQ (Youth/Adolescent Food Frequency Questionnaire, FFQ (Food Frequency Questionnaire) or others. All of these assessments document the presence of food selectivity in Autism subjects when comparing them to typically developing children. Thus far, no study in the literature proposes a standardized direct observation of feeding behavior protocol, which in principal should guarantee better accuracy; hence the purpose of our study.
Objectives:
In this pilot study, we assess the feasibility of a standardized protocol application to explore and monitor food selectivity by directly observing eating behavior in children and adolescents with autism residing at our Rehabilitation Institution.
Methods:
The study sample consisted of ten children and adolescents affected by Autism. The assessment of autism symptom severity was performed through the ADOS scale. Only patients with primary autism (with no cerebral damage or genetic diseases) were included in the final sample (subjects with ADOS Calibrated Severity Scale > 6). TenÂ subjects affected by mild-moderate intellectual disability not related to autism but residing at the Institution formed the control group. The caregivers present at each participant meal in the dining halls complied food diaries every day for lunch and dinner, carefully notating which foods the subjects accepted and which ones were refused. The observation period lasted four weeks with 20 days monitored (Monday to Friday of each week). The institution's general menu during this observation period consisted of 39 different serving selections at lunch and 37 at dinner. A comparison between the scores obtained from dietary choice patterns of the two groups and in particular the scores of refused foods was performed using a Mann-Whitney U test; the level of significance was set at $p < 0.05$. In autism group the Spearman non-parametric test was performed in order to explore correlations between the variables studied.
Results:
Subjects with autism resulted significantly more selective than controls (lunch: $p = 0.016$, dinner: $p = 0.042$). Furthermore, children and adolescents with autism were more at risk of becoming underweight or overweight because of unbalanced dietary intake. We found a negative correlation between: food selectivity and duration of stay ($R = - 0.5848$), as well as food selectivity and age ($R = - 0.6437$), but a positive correlation between food refusal and disease severity measured with ADOS II scale ($R = 0.4441$).
Conclusions:
Our data confirm the feasibility of a direct observation monitoring protocol for feeding behavior and the importance of food selectivity in subjects with autism. Younger children are more selective than older ones and the duration of institutional residency seems to positively impact this behavior.

114 **179.114** Do Aggressive Behaviors Accumulate or Exchange over Time?

***P. Hickey**[1], S. M. Attar[1], A. Walsh[1] and E. Hanson[2], (1)Boston Children's Hospital, Boston, MA, (2)Children's Hospital Boston, Boston, MA*

Background: Aggressive behaviors, directed either toward the self or others, can cause severe psychological and physical damage to individuals with autism, their family, or others. Prior research on other common behaviors seen in individuals with ASD, such as restricted and repetitive behaviors, has shown that there are fluctuations in their prevalence over time (Richler et al., 2010). Previous research from this lab has noted that individual aggressive behaviors vary in their age of emergence, with self-injurious behaviors typically starting first, followed by aggression toward individuals in the family, and later by aggression toward others. No study has yet looked at fluctuations in aggressive behavior to see if children acquire a repertoire of several of these behaviors over time or switch from one aggressive behavior to another.
Objectives: We hypothesized that children will acquire several behaviors as they age, starting with self-injurious behaviors, followed by aggression towards family, and ending with aggression towards others.
Methods: A sample of 168 children (79% male) aged 2-22 years (mean=7.6, SD=4.16) were included in the analysis. Diagnosis of ASD was confirmed by both the Autism Diagnostic Interview, Revised (ADI-R) and the Autism Diagnostic Observation Schedule (ADOS). The Behavior and Sensory Interest Questionnaire (BSIQ, Hanson et al, 2015) was administered to parents to understand the time of emergence and cessation of autism related behaviors, including aggression. Children who exhibited at least two different aggressive behaviors were included in the analysis. Descriptive statistics were used to determine the relationship between the age of emergence and age of cessation of different aggressive behaviors. Percentages were calculated to determine how many of the behaviors that emerged later emerged prior to cessation of earlier behaviors.
Results: Descriptive statistics reveal that 23.57% of later behaviors emerge at or after the cessation of the initial aggressive behavior. Additionally in a population of children that acquire two or more aggressive behaviors, the earliest form of aggression is typically aggression towards family members (onset of 3 years, 2 months on average), followed by aggression towards people outside of the family (3 years, 6 months on average) and finally self-injurious behavior (3 years, 10 months on average).
Conclusions: Results regarding accumulation of aggressive behaviors over time are consistent with the initial hypothesis. The low percentage of children that switch from behavior to behavior indicate that children with ASD more frequently tend to build a repertoire of different aggressive behaviors, rather than switching between them. Contrary to the initial hypothesis, aggression towards caregivers and aggression towards people outside of the family tend to emerge earlier than self-injurious behavior in a sample of ASD children that have at least two aggressive behaviors. These results highlight the importance of intervention for children with ASD who develop aggressive behaviors prior to them building a larger repertoire.

115 **179.115** Does Parent Training Have an Effect on Perceived Parenting Competence and Family Life Impairment? the Effects of Parent Training and Ongoing Education on PSOC and Flis Scores

V. Nanclares-Nogues[1] *and Y. Waddell*[2]*, (1)Advocate Illinois Masonic Medical Center, Chicago, IL, (2)Pediatric Developmental Center, Advocate Illinois Masonic Medical Center, Chicago, IL*

Background: The *Parenting Sense of Competence Scale* (PSOC; Gibaud-Wallston and Wandersman,1978), is a scale used to assess parent's perceived efficacy and satisfaction with their parenting roles. Gibaud-Wallston and Wanderman (1978) reported acceptable internal consistency of (Cronbach's alpha = .82). The *Family Life Impairment Scale*(FLIS; Briggs-Gowan, Horwitz, and Carter, 1997), is a parent-report scale used to assess how a child's behavior, personality, or special needs limits their engagement in activities that are common for families with young children. The FLIS has acceptable internal consistency (Cronbach's alpha = 0.81) (Carter et al., 2010). Studies suggest that reducing parental stress and improving their sense of competence provides immediate benefits and prevents behavior that leads to problems within the child and the family (Pisterman et al., 1992; Dawson & Osterling, 1997). Higher stress has been found in families with a child with autism spectrum disorders or with externalizing behaviors, compared to typically developed children (Bitsika & Sharpley, 2004). The goal of parent training and behavior therapy is to help parents gain specific skills that work with their child's behavior, and replace the therapist to generalize their child's skills and change behavior.
Objectives: This study aims to assess if parent trainings and ongoing parent education in therapy will have a significant impact on reported parental competency and reported family impairment.
Methods: The Pediatric Developmental Center treats children with developmental disorders. Families are either English- or Spanish-speaking and must complete a parent training before starting behavior therapy. Parents are also active participants in their child's behavior therapy. In this study, parents filled out the PSOC and FLIS at the first and last session of either an autism or behavior parent training. There were 203 parent-child dyads, children ranged in age from 2-17. A licensed therapist or a therapist in continuing graduate education led parent trainings once a week for 4 weeks and behavior therapy once a week for 12 or 16 weeks.
Results: Paired-samples t-test were run to examine any significant differences present in between pre- and post- tests for the PSOC and FLIS tests. Additional data will be run to compare these results with PSOC and FLIS scores after behavior therapy.
Conclusions: Can parent training improve family functioning? The current study aims to assess the impact of the parent training intervention on perceived parenting competence and family life impairment. Preliminary results show that there is no significant difference between pre- and post- tests for the PSOC and FLIS. This suggests that parent trainings alone may not be sufficient in improving parenting competence and family life impairment and that behavior therapy with parents as co-therapists is an essential component in creating a change (Schopler & Reichler,1971). Data is currently being collected after behavior therapy. It would be beneficial to measure for each parent at 3 time points: first and last day of the parent training program, and last day of the child's behavior therapy. Child's symptom severity would be beneficial information to assess change in maladaptive behaviors and their relationship with parental competency and family impairment.

116 **179.116** Effectiveness of the Military Spouse Online Autism Relocation Readiness Mentor Training Program

J. M. Davis Kremkow[1,2] *and E. H. Finke*[3]*, (1)CSD, Elmhurst College, Chicago, IL, (2)Elmhurst College, Chicago, IL, (3)Pennsylvania State University, University Park, PA*

Background:
Military families with children with autism spectrum disorder (ASD) experience challenges related to being a military family and challenges related to being a family who has a child with ASD; and during relocation, these challenges result in a build-up of stressors (Davis & Finke, 2015a). Qualitative studies of the experiences of military spouses with children with ASD found spouses reported delayed access to therapeutic services, limited providers accepting their insurance, a lack of IEP continuity, emotional and behavioral reactions from their children with ASD, and increased stress as a result of relocating (Davis & Finke, 2015a; Davis et al., 2016; Freuler & Baranek & Baranek, 2016). Some of these difficulties have been echoed in government reports (e.g., Ohio State University Project Team, 2011) and in interviews with military family support personnel (Aronson et al., 2016). Military spouses with children with ASD have stated relocations remove them from the community they have established and leave them feeling isolated (Davis & Finke, 2015a; Freuler & Baranek & Baranek, 2016). One support that may be an effective way to meet support needs of military families with children with ASD is distance peer mentoring. In distance peer mentoring, the mentor has characteristics similar to the mentee and provides emotional, affirmational, and informational support through technology-mediated communication (Dennis, 2003). Other parent groups have reported benefits from participating in distance peer support groups. For example, reviews of online social support groups for parents summarized benefits such as sharing personal experiences, receiving empathy and encouragement, and sharing feelings (Doty & Dworkin, 2014; Niela-Vilen, Axelin, Salantera, & Melender, 2014). Further, other parents of children with ASD have reported benefits of online social support such as encouragement, sharing resources and experiences, and having a connection with others who are similar (Huws, Jones, & Ingledew, 2001).
Objectives:
The main objective of this investigation was to examine the effectiveness of the military spouse online autism relocation readiness mentor training program on military spouse knowledge of training content.
Methods:
A quasi-experimental design, specifically a non-equivalent group pretest-posttest, was used to determine the effect of an online mentor training program on comprehension of program materials. Pretest-posttest quasi-experimental designs are frequently used to evaluate training programs (Bernard, 2013) and are very common designs in the social sciences (Trochim, 2006). However, determining an appropriate research design requires balancing experimental rigor with the purpose of the research and logistical constraints. Since limited research exists for military families regarding peer mentor training, a quasi-experimental design was appropriate to investigate possible outcomes while conserving resources often required for experimental studies.
Results:
Approximately 29 military spouses participated in either the training or control group for the online mentorship training program. Data analysis is currently on-going, but preliminary results suggest the online training was effective at teaching military spouses with children with autism mentoring protocols and strategies.
Conclusions:
Data analysis is currently on-going, but conclusions may impact clinical service providers, military programming and providers, and laws and policies.

117 **179.117** Effects of Parent Training Program for Caregivers of Young Children with Autism Spectrum Disorders (ASD)

T. Takezawa[1], *T. Yoshikawa*[2] *and M. Inoue*[3], *(1)Institute for Developmental Research, Aichi Human Service Center, Kasugai, Aichi, Japan, (2)Child and Adolescent Psychiatry, Central Hospital, Aichi Human Service Center, Kasugai, Aichi, Japan, (3)Tottori University, Yonago, Tottori, JAPAN*

Background: Many parents of children with Autism Spectrum Disorders (ASD) are more likely to experience depression and stress than those of children with/without other types of disabilities. It could become much more pronounced when their children are diagnosed. Therefore, an appropriate program should be provided to reduce the parent's anxiety and parenting stress at a crucial time.
Objectives: The purpose of this study was to examine the effectiveness of a parent training program for caregivers of young children with ASD.
Methods: Fifteen parents participated in a series of lectures and group discussions for 5 months. Beck Depression Inventory-Second Edition (BDI-Ⅱ) and Parenting Stress Index (PSI) were used to measure the parent's anxiety and parenting stress. Knowledge of Behavioral Principle as Applied to Children (KBPAC) was used for a treatment fidelity check. These 3 measures were given at pre- and post-program, and at 3-month follow up. At the end of the program, the participants completed a questionnaire on degree of understanding and satisfaction with the program.
Results: BDI-Ⅱ scores of the participants significantly decreased at the end of the program and were maintained to 3 months. Similarly, PSI scores tended to decline although it was not a statistically significant change. KBPAC scores significantly increased from the beginning of the program, and the improved scores were maintained to 3 months. Most participants developed a better understanding of parenting skills and had a high level of satisfaction with the program.
Conclusions: The results revealed that the program could be effective for reducing the depression of caregivers of young children with ASD. However, the program was not effective enough to reduce parenting stress. A likely explanation is that the caregivers reacknowledged the problems that their children have shown and their responsibility as parents through the program. The program needs to be revised, focusing on reducing parenting stress more effectively. Starting at an early stage of awareness and diagnosis, the parent training program could play an important role as one of the early family intervention programs for ASD.

118 **179.118** Effects of a Psychoeducational Group on Siblings of Children with ASD

N. W. Buerger[1], *L. Tuesday Heathfield*[2] *and J. Kircher*[3], *(1)Department of Psychiatry, Univeristy of Utah Medical School, Salt Lake City, UT, (2)Educational Psychology, Univeristy of Utah/Canyons School District, Salt Lake City, UT, (3)Educational Psychology, University of Utah, Salt Lake City, UT*

Background: Available research on how having a sibling with autism spectrum disorder impacts typically developing children is mixed. Some studies show beneficial effects in the areas of social competence and self-concept and several studies show no additional risk or benefit. There also are many studies that indicate increased risk for adjustment difficulties and diminished quality of sibling relationships. While available research provides no clear answers with regards to impact of autism spectrum disorder on unaffected siblings, it is likely that there are some siblings who may be at risk just as there may be some who are not negatively impacted.
Objectives: Identify whether a psychoeducational group impacts sibling knowledge of ASD, sibling relationship quality, sibling interaction quality, and parent reported internalizing and externalizing symptoms.
Methods: Twenty-six children, their siblings with autism spectrum disorder, and their parents were participants in this study. All target children participated in two hour, weekly sessions over a period of seven weeks. The program (Siblings Helping Siblings) was partially based on a Sibshop model. Session content included recreational games and crafts, as well as discussions about having a sibling with autism spectrum disorder. Lessons were presented during each class that addressed characteristics of autism spectrum disorder, coping skills, and problem solving skills. Outcome variables were measured at preintervention, postintervention, and 8-10 weeks following intervention. Sibling relationship quality was measured through parent and child report and emotional adjustment was measured through parent report only. Sibling interaction quality was assessed through videotaped observations of dyadic interactions between the target sibling and the sibling with autism spectrum disorder.
Results: Analysis of variance was used to analyze obtained data. Sibling knowledge of ASD increased following intervention. Results indicated that parent perceptions of sibling relationship quality improved following intervention and increases in positive sibling interaction during unstructured playtime were also found postintervention. Exploratory analyses also suggested positive effects on target siblings' knowledge of autism spectrum disorder as well as reduction in parent-reported internalizing symptoms in the target children. Results also suggested that response to this intervention program may be impacted to some degree by the sex and diagnostic status of the target child.
Conclusions: These findings imply that there was a significant positive impact on target children after participating in this program. These results paired with high rates of parent and child satisfaction indicate this type of program could be an asset to clinics and schools that serve families affected by autism spectrum disorder. Such programs help service providers meet the needs of not only the child affected with autism spectrum disorder, but also meet the needs of their siblings and potentially other family members. Practitioners who wish to implement such a program should be aware that factors such as sex and disability status of participating children may affect how they respond to the program and adjustments should be considered to ensure the greatest benefit to those participating children. Furthermore, the implications of this study also suggest further research be conducted to further explore variables impacting the effectiveness of such programs.

119 **179.119** Engaging Under-Resourced Parents of Children with ASD in Service Uptake: Using Qualitative Research to Inform Interventions

D. Straiton[1], *S. Iadarola*[2], *J. Smith*[3], *M. Pellecchia*[1], *A. C. Stahmer*[4], *A. Gulsrud*[5] *and C. Kasari*[6], *(1)University of Pennsylvania, Philadelphia, PA, (2)University of Rochester Medical Center, Fairport, NY, (3)University of California Los Angeles, Los Angeles, CA, (4)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (5)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (6)University of California, Los Angeles, Los Angeles, CA*

Background: Ethnically diverse children of low socioeconomic status and from non-English speaking households may receive an ASD diagnosis up to two years later than their white counterparts (Mandell et al., 2009; Valicenti-McDermott et al., 2012). Parent engagement interventions effectively support timely service access. Yet many interventions are developed and tested with White, high-resourced families and may not translate in practice with under-resourced communities. Gathering input from under-resourced communities during intervention development can help address these gaps in ASD diagnosis and treatment.
Objectives: Gather qualitative data from under-resourced families and their service providers for the purposes of identifying barriers, supports, and needs in seeking an ASD diagnosis and services. Utilize these data to inform a new intervention, designed to facilitate parent engagement in autism-specific services in under-resourced populations.
Methods: 19 Focus groups and 17 interviews were conducted in urban and rural neighborhoods of Philadelphia, Rochester, Los Angeles, and Sacramento with 105 parents and 125 providers. Caregivers had a child (2-8 years old) within 3 years of an ASD diagnosis, and received supplemental governmental assistance. Providers worked with families that met the above criteria.
Participants answered questions about barriers and facilitators to accessing evaluations and autism-specific services. We solicited recommendations for an intervention to address these issues in under-resourced families. Data were analyzed using open coding and then thematic analysis. Cross-site coding ensured interrater reliability and consensus across sites.
Results: Major themes that emerged included: (1) the contribution of cultural differences (including language, SES, and rurality); (2) systemic/family barriers (e.g., long waitlists, cultural stigma) to diagnostic and service disparities; and (3) supports, including agencies, practices and people (e.g., family members).
Recommendations included: (1) a parent "coach" immediately following diagnosis to help the family navigate the service system; (2) multiple methods of contacting caregivers (e.g., texting, online resources, outreach at community events); (3) flexible scheduling for parent workshops; (4) caregiver education on ASD; and (5) improving communication between professionals and families.
Conclusions: Â Results demonstrate consistency across sites, despite varying systems at state and district levels. This consistency exhibits the widespread need for a parent engagement intervention that supports under-resourced families in service uptake.
Findings will be used to develop a community-informed intervention that will be tested via RCT (N = 120) with caregivers of newly-diagnosed children from under-resourced backgrounds. Participants will be randomly assigned to either (1) a culturally matched peer parent coaching condition (including online and group trainings), (2) parent coaching condition with added provider consultation plus trainings, (3) a control condition of access to information only. Results from the RCT will be available in 2019 and will fill gaps in current evidence-based treatments that are not traditionally culturally sensitive, easily accessible, or tested with diverse populations. Continuing our community partnership will also increase the recruitment of underserved families in intervention studies.

120 **179.120** Enrollment in Early Intervention Associated with Increased Parental Stress in a Large Cohort of Parents of Young Children at Risk for Autism Spectrum Disorder

S. broder-Fingert[1], ***J. M. Sandler***[2], *A. Bennett*[3], *M. Augustyn*[4], *C. Weitzman*[5], *S. Keys*[6], *M. Credle*[5], *M. Abraham*[6] *and E. Feinberg*[7], *(1)Boston University, Boston, MA, (2)Community Health Sciences, Boston University, Boston, MA, (3)Children's Hospital of Philadelphia, Philadelphia, PA, (4)Boston University School of Medicine, Boston, MA, (5)Yale University School of Medicine, New Haven, CT, (6)Childrens Hospital of Philadelphia, Philadelphia, PA, (7)BU School of Public Health, Boston, MA*

Background: Efforts to identify and treat developmental delay in young children require strengthening caregiver capacity to support their child's needs. While an explicit goal of Birth to Three Early Intervention (EI) services is parent support, there is little data on the impact of such services on parental stress.
Objectives: To determine if low income, urban families involved in EI services experience lower levels of parental stress than those not engaged in EI services.
Methods: We analyzed cross-sectional data from 150 parents/guardians of children ages 15-27 months with confirmed autism risk at the time of enrollment in a large trial. Families were recruited from urban pediatric clinics in Boston, Philadelphia, and New Haven.Â We compared baseline levels of self-reported parenting stress (Parenting Stress Index – Short Form (PSI-SF)), Social Support (MOS-SS), and Negative Feelings toward Parenting (FIQ) among families participating in EI and those not involved in EI. Regression analysis was used to assess relationship between EI enrollment and measures of parental stress, while adjusting for prematurity (gestational age <37 weeks) and severity of child's delays using the Adaptive Behavior Assessment System (ABAS).
Results: In this sample of low-income, minority families, 46.7% were receiving EI services. Family demographics and severity of child delays were similar across groups. Parents of children enrolled in EI reported increased stress across multiple measures. We observed significant differences in Social Support (MOS-SS) and Negative Feelings toward Parenting (FIQ), and a trend toward differences in parenting stress (PSI-SF) (adjusted mean difference, p-value; -0.38, 0.02; 1.66, 0.04; 7.45, 0.08 respectively).
Conclusions: Parents participating in EI services reported lower levels of social support and higher levels of stress and self-blame than parents whose children were not receiving such services, even after adjusting for autism severity. A possible explanation is that new demands related to obtaining developmental services and the acknowledgement that a child has significant delays may place additional burden on caregivers.

121 **179.121** Evaluating the Social Validity of PEERS® for Young Adults, Teens, and Preschoolers in a Clinical Replication

T. Glavin[1]*, R. M. Klinkel*[1]*, T. Rooney*[1]*, K. Ankenman*[1]*, W. Ence*[1] *and G. L. Lyons*[2]*, (1)STAR Center for ASD and NDDs, University of California San Francisco, San Francisco, CA, (2)Psychiatry, STAR Center, UCSF, San Francisco, CA*

Background:
PEERS® is an empirically supported, parent-assisted social skills group for teens. Employing a comprehensive curriculum, the program builds skills through instruction, role-playing, modeling, and practice with feedback. PEERS® research suggests positive and durable effects on the social skills of teens with ASD and related disabilities (Laugeson et al., 2012). Currently, researchers are evaluating PEERS® curricula for young adults and preschoolers.
Few studies are devoted to evaluating the social validity (SV) of research-demonstrated autism interventions such as PEERS®. However, stakeholder approval is paramount when considering intervention diffusion and refinement. Indeed, stakeholders are more likely to select interventions they deem acceptable, while discontinuing those viewed as too demanding or inappropriate (Kazdin, 2000). Capitalizing on the burgeoning PEERS® evidence-base, research must pivot to empirical questions regarding stakeholder experiences.
Objectives:
Informing the development of our PEERS® clinical replication, we are surveying parent and patient participants across four SV domains: *acceptability*, *feasibility*, *perceived effectiveness*, and *satisfaction*.
Methods:
We are collecting clinical replication data of PEERS® at a university-based clinic. We have gathered data from 24 stakeholders involved in one teen, one young adult, and one preschool group (n = 12 parents; n = 12 adolescent/ young adults) and aim to gather data from 56 more participants by May 2017. Our inclusion criteria were identical to those described in PEERS® research. Every group had one female patient and the majority had ASD. Groups were supervised by a certified PEERS clinician and licensed psychologist. Attrition was minimal (three drops after session one). We found adequate reliability of item assignment to SV subdomains. We distributed the social validity questionnaires on the final session (response rate = 92%). The questionnaire used a 5-point scale: *strongly agree* = 5 to *strongly disagree* = 1.
Results:
Overall satisfaction across the groups was 3.9, with relatively high levels of group enjoyment (4.0). Stakeholders were modestly accepting of the intervention (3.6) and found it feasible (3.8)—parents of young adults were more neutral, whereas parents of preschoolers were more positive. For young adults and teens, parents were more neutral than patients. The perceived effectiveness on patients approached neutral (3.4), particularly for young adult perceptions of change (3.16) and parent perceptions of teen change (3.1). Attendance was high (mean = 90%; range: 67-100%). Exploratory correlations suggest, at $p < .05$, that (a) perceived effectiveness on parent behavior was negatively correlated with feasibility (r = -0.62) and positively correlated with overall satisfaction (0.77), (b) perceived effectiveness on patient behavior was positively correlated with program acceptance (r = 0.54), and (c) attendance was correlated with overall satisfaction (r= 0.49). Open-ended responses included: "I enjoyed learning new social skills" (teen), "It got me into the city regularly and reminded me to attend social events" (young adult), and "Now [young adult] is thinking about joining groups where he had not at all before" (parent).
Conclusions:
Preliminary results suggest modestly positive SV of PEERS®. Understanding the SV of PEERS® could help stakeholders improve successful contact with intervention. Our results are promising and warrant more rigorous investigation.

122 **179.122** Examination of Current Needs for ASD Specific Services in Saudi Arabia

R. Alrajhi[1] *and D. Dimitriou*[2]*, (1)Lifespan Learning and Sleep Lab, Institute of Education UCL, London, United Kingdom, (2)UCL, Institute of Education, London, England, United Kingdom*

Background: Saudi Arabia society consists of three main geographies: urban, rural and Badia, which is the desert, inhabited by people called Bedouin, where the healthcare, education and population decreases respectively. This indicates wide diversity with a high population of children and adolescents. This vast difference between the three regions may have a fundamental impact on the individuals with ASD and their families. As a result the services demands may differ as well.
Objectives: The current study aimed to gather data on current services and needs of families with ASD children. The research investigated a number of environmental variables such as family size (nuclear and extended), number of children in the family, number of the children with developmental disorder, number of the children with ASD, gender of the ASD child, the child' order in the family, family income, and the parents' demographic information.
Methods: Mixed methodology was used in this study. Qualitative methods represented as a focus group and quantitative methods as a survey. The methods was conducted in Riyadh/ Saudi Arabia targeting parents of ASD children. The stages of the study were twofold: first phase, parents of children with ASD were invited to take part in the focus group. The purpose of this qualitative method is to identify the parents' most essential needs. One focus groups was conducted. Number of needs and required services was collected. In the second phase, four mother of children with ASD and four mothers of children diagnosed with other developmental disorders, namely: ADHD (2 mothers), language delay 91 mother) and Bardley Bidel (1 mother) were approached and completed the survey.
Results: The current study showed a significant limitation of the current services available in the country. One of the most frequently used programmes was ABA, yet this was also very limited. Mothers indicated that more services and better understanding about the ASD is needed.
Conclusions: ASD is not well recognised in many countries. In Saudi Arabia, ASD is gaining more attention and studies are underway to examine the needs of the families.

123 **179.123** Experiences of Middle School Children with Autism Spectrum Disorders in Adapted Physical Education

***J. Blagrave**, California State University, Chico, Chico, CA*

Background: School-age children with autism spectrum disorders (ASDs) are rarely asked to describe their experiences within the programs that they receive and are largely missing from the narrative of their own lives. Current literature on the experiences of children with autism spectrum disorder (ASD) has focused on special education classrooms, sensory perceptions, and minimally on general physical education class expereinces. However, no prior studies have addressed how school-age children with ASD perceive their APE experience.
Objectives: To understand how children with ASD's perceive their experiences in adapted physical education.
Methods: Data were collected from participants (n=10) through drawings, observations in their APE setting and interviews. Exploratory, linguistic, and conceptual comments were used to deconstruct the data, develop themes in individual cases, and then identify connections across cases.
Results: Themes that emerged from the participants were their positive experiences in APE, understanding of the importance of being physically active, sedentary behavior in their spare time, and desire for time in APE.
Conclusions: Learning the barriers and facilitators to any individual's participation in a positive behavior is important. Barriers and facilitators for these participants included internal (intrapersonal) and external (interpersonal and environmental) factors. It is important in all settings to better identify these factors for populations that, historically, have been thought of as incapable of sharing their experiences.This study focused on a small sample of children with ASD and explored their experiences in APE. Although this study's outcomes cannot be generalized to the ASD population as a whole, this study will helps to lay the groundwork for future studies with larger samples that, in turn, can help facilitate improved learning outcomes for individuals with ASD in the APE setting.

124 **179.124** Experiences of Parents and Providers of ASD Services in Underserved California Communities

*J. Smith[1], A. Osuna[2], **I. Becerra**[2], S. F. Vejnoska[3] and C. Kasari[2], (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)UC Davis MIND Institute, Sacramento, CA*

Background: Â Ethnically diverse children with autism spectrum disorder (ASD) receive services at a later age and receive a different complement of services than White children (Mandell, Listerus, Levy, & Pinto-Martin, 2002; Levy et al., 2003). In California, families of children with ASD with Medi-Cal or other public insurance are less likely to use services considered medically necessary compared to families whose children were covered by private insurance (Thomas et al. 2007). Additionally, minority groups receive fewer services and significantly lower expenditures from California Regional Centers than those from White families (Harrington & Kang, 2008). These data suggest that state policies and socio-economic contexts impact families' access to autism services. The present study utilizes data collected from focus groups in California to investigate barriers minority and low-resource families experience when accessing autism-specific services in the state.
Objectives: Â To identify barriers and challenges facing under-resourced California families as they seek an ASD diagnosis and/or services.
Methods: Eight focus groups (4 provider, 4 parent) and four interviews (3 parent, 1 provider) conducted statewide were analyzed (N=62). Participants were recruited across regions in Northern and Southern California. Parents were eligible to participate if they had a child recently diagnosed with ASD and if they received some form of government assistance. Special efforts were made to recruit parents who identified as a racial or ethnic minority. Providers were eligible if they worked with low-resource or minority families with children with ASD. Transcripts were coded for eight major codes(e.g., barriers, cultural differences, knowledge). Two raters coded each transcript using Dedoose, and 30% of transcripts were coded across focus group collection site to ensure reliability.
Results: Systemic issues and cultural stigma emerged as major barriers to access experienced by under-resourced families. A lack of available quality services and programs was most prominent. Participants reported a need for culturally sensitive, bilingual therapists. Families also expressed frustration over biased practices, such as providers refusing to go into certain homes and neighborhoods, and different services offered to families by education level. Another systemic problem was the funding for autism services and therapies through medical insurance. This introduced additional barriers for families that contributed to long delays in services, and increased financial burdens for families (e.g., insurance co-pays). Navigating the system was a major source of concern for families, including being overwhelmed with scheduling and intrusions to the home environment. Finally, cultural denial was prevalent in both parent and provider conversations about stigma associated with disability. Respondents referenced the absence of vocabulary to describe autism in their native language, as well as the influence of gender roles within the family unit.
Conclusions: These findings highlight several systemic barriers and challenges that low-resource, culturally diverse families face when accessing ASD-specific services in California. Policies and procedures within California that negatively impact these communities warrant further investigation in order to inform efforts to improve access to care.

125 **179.125** Experiences of Sex Education and Sexual Awareness in Young Adults with Autism Spectrum Disorder

***S. Stagg**[1] and L. Hannah[2], (1)Anglia Ruskin University, Cambridge, UNITED KINGDOM, (2)Psychology, Anglia Ruskin University, Cambridge, United Kingdom*

Background: The research investigated feelings towards sex education and sexual awareness in young adults with autism spectrum disorder (ASD)
Objectives: To compare scores on sexual awareness measures between individuals with ASD and typically developing individuals.
Methods: Data were generated from the Sexual Knowledge, Experiences, Feelings and Needs Questionnaire (McCabe, 1999), the Sexual Awareness Questionnaire (Snell, Fisher & Miller, 1991) and semi-structured interviews. Twenty typically developing and twenty ASD individuals took part. Feelings toward sex education did not differ between the groups, but the groups differed significantly on measures of sexual awareness.
Results: The ASD group reported negative experiences of sex education and issues of vulnerability, social anxiety, and confused sexuality were prominent features of the qualitative interviews.
Conclusions: Sex and relationship education is not sufficient to match the needs of people with ASD. More research is needed into how young people with ASD perceive their sexuality, and young people need a voice to express their concerns.

126 **179.126** Exploring How US High School Students with Autism Are Using Social Media

***S. Hedges**[1], S. Kucharczyk[2] and S. L. Odom[3], (1)UNC Chapel Hill, Chapel Hill, NC, (2)Curriculum & Instruction, University of Arkansas, Fayetteville, AR, (3)University of North Carolina, Chapel Hill, NC*

Background: While the primary focus of educators is on increasing academic achievement, high school students with autism are also concerned with the social aspects of their school days such as, entering peer groups, making friends, and developing intimate relationships. These non-academic skills may go unaddressed or overlooked by school staff. Within the social environment of high school, difficulties in the areas of communication and social interaction can put students with autism at risk for social isolation and bullying. For some individuals with autism, adolescence brings a growing self-awareness of social difficulties, and negative experiences with peers which may exacerbate social anxiety. Positive peer relationships have been found to facilitate positive social and academic outcomes. Social media, so commonly used by the majority of teens to navigate the social world, has been rarely examined in the lives of teens with autism.
Objectives: To understand what social media high school students with autism are using and what they perceive are its benefits and challenges.
Methods: Paper surveys were completed by 472 high school students with autism receiving special education services across 3 states in the US (California, North Carolina, Wisconsin) regarding their technology use both in and outside of school hours. Ten survey respondents were interviewed by email to probe more deeply into their perspectives of the benefits and challenges of technology.
Results: The majority of survey respondents (92%) reported using technology to communicate and to socialize. The most common tools they used included the phone (81%), text (69%), email (60%), Facebook (47%), and video calls (41%). Roughly 60% of survey respondents are active on social media using a variety of tools in addition to Facebook such as Instagram, Snapchat, Twitter, Kik, Vine, Tumblr, Steam, Google+, WhatsApp, and a variety of interactive video games. Eighty-six participants indicated they had had a bad experience using social media (e.g. someone was not nice to them). Participant descriptions of these experiences did not always fit the definition of bullying. None of the students said they had stopped using social media because of these experiences and many explained how they handled it using coping techniques such as defriending or blocking an offender, reporting the incident to an adult, or simply ignoring it.
Findings from qualitative email interviews revealed themes related to ways in which technology and social media can facilitate social opportunities. One common theme was bridging distance by providing contact when unable to physically visit someone due to inability to drive, or when the person is located far away. Other themes included providing a variety of options that easily facilitate social interactions from sharing photos using services such as Snapchat or Instagram, messaging friends while playing games online or watching gamers on YouTube channels and sharing comments with other viewers.
Conclusions: Our study showed that many adolescents with autism are using a wide variety of social media to increase their social interactions. This study has implications on how families and educators consider adolescents' access to and use of social media to support social skill development.

127 **179.127** Exploring Perceptions and Experiences of Autism in a UK Somali Community: A Qualitative Study

F. Fox[1]*, N. Aabe*[2]*, S. Redwood*[1] *and D. Rai*[3]*, (1)NIHR CLAHRC West, Bristol, United Kingdom, (2)Autism Independence, Bristol, United Kingdom, (3)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom*

Background: Evidence suggests that autism may be over-represented in some migrant groups in Western countries, including Somalis. Whilst reasons for a higher prevalence of autism in these groups are unclear, it is acknowledged that immigrant populations require appropriate help and support in relation to autism services. The Somali community is the second largest migrant community in Bristol, UK but little is known about the needs of families raising children with autism and the culture specific aspects of seeking help from health, or education and social care services. Such information is essential in order to provide high quality services and reduce inequalities in care for this group.
Objectives: The aim of this qualitative study was to address this gap in knowledge, to gain a better understanding of the perceptions, and experiences of autism within the Somali community, as well as their support needs.
Methods: Using a community-based participatory research approach, the research was conducted in partnership with the local Somali community. Through purposive sampling, Somali parents who had a child with autism were recruited. Fifteen parents participated (12 mothers and 3 fathers), who between them had 17 children with a diagnosis of autism. Two co-researchers conducted in-depth interviews, in both English and Somali, guided by a semi-structured interview schedule. With consent interviews were audio recorded and fully transcribed. Thematic Analysis was used to analyse the data.
Results:
Four major themes were identified through analysis;
1) 'My child is different' covers the parents' experiences of realising that their child was different to other children, their challenging behaviours and the impact on family life. It includes their hopes and fears for their children's future.
2) 'Perceptions of Autism' highlights why many Somali families have difficulty accepting their child's diagnosis, or engaging with services. As there is no Somali word for autism, parents struggle to communicate with, and often face conflicting messages from their community. Consequently children with autism are often hidden and families become isolated. Faith plays a crucial role in the process of acceptance.
3) 'Navigating the System'; Parents often struggle to get help for their child because the health, social and education services are unfamiliar, fragmented and difficult to navigate. Language barriers exacerbate these challenges. At the point of diagnosis many parents wanted better explanations and information about autism. Participants expressed mistrust of social services and confusion about the best form of educational provision.
4) Support; whilst some parents valued the support of specific professionals and organisations, other identified support needs for themselves and their children. In particular peer support was valued and a need to increase understanding about autism within the community was identified.
Conclusions: Â The findings highlight the importance of culture specific issues in autism and the challenges and barriers that Somali parents encounter in understanding and accepting autism and accessing appropriate support. They indicate the need to increase understanding via range of community channels in order to raise awareness, reduce stigma and provide support to encourage families not to delay seeking help for their children.

128 **179.128** Exploring the Components of Stress Responses in Parents of Children with and without ASD

D. Swain*, R. S. Factor and A. Scarpa, Virginia Tech, Blacksburg, VA*

Background: Parenting stress is a complex process that includes external parenting demands, parent-child relationship quality, as well as the emotional and social well-being of parent and child. Parents of children with Autism Spectrum Disorder (ASD) report the highest levels of stress, above and beyond parents of children with typical development and Developmental Disabilities (Carter & Davis, 2008). Previous research focuses primarily on understanding the predictors of parenting stress (e.g. child problem behavior), yet few investigate the various components of stress (e.g. stress related to perceptions of parenting role, physiological markers).
Objectives: Primary aims include the examination of group differences in 5 facets of parent stress. We predict parents of children with ASD will demonstrate higher levels across all measures.
Methods: Participants included 37 mothers (mean age = 39.24 years, 4.94 years SD) of children ages 7 to 12 years (64% male) with and without an ASD diagnosis. While wearing a heart rate monitor, mothers watched a neutral 3-minute baseline video. Self-report measures included 3 subscales (Parental Distress, Parent Child Dysfunctional Interaction, Difficult Child) from the Parenting Stress Index Short Form (PSI-SF; Abidin, 1990) to assess the components of parenting stress, Perceived Stress Responsivity Scale (PSRS; Schlotz, Yim, Zoccola, Jansen, & Schulz, 2011) to assess perceived responses to daily stressful situations, and baseline RMSSD to assess vagally mediated heart rate variability indexing flexible emotional responding to stress.
Results: Due to multiple post-hoc comparisons, ANOVA was utilized with Bonferroni correction. Results revealed significantly higher perceived stress related to parent child interactions reported by parents of children with versus without ASD (p = .007*).* Group differences in the remaining components of stress were not significant at the p = .01 level.
Conclusions: This study adds insight to the literature on increased stress in parents of children with ASD. We sought to identify differences in specific components of stress between parents of children with and without ASD as potential areas of focus for future treatment targets. Results reveal no differences in perceived stress reactivity, HRV, as well as stress related to the parenting role or mother's perception of child difficulty. The only significant difference in stress involved the extent to which the mother perceived interactions with her child to be unsatisfying. This finding demonstrates an important factor to identify and target in parent-mediated treatments. Approaches that address parental stress, such as mindfulness based treatments, may be especially useful for targeting negative perceptions of child expectations during parent-child interactions and help lead to more satisfying mother-child experiences.

129 **179.129** Factors Associated with Participation in Extracurricular Activities in Adolescents with and without Asd from an Australian Representative Cohort.

F. Lami[1,2]*, T. May*[1,2]*, K. Williams*[1,2,3] *and R. Conroy*[2,4,5]*, (1)Paediatrics, The University of Melbourne, Parkville, VIC, Australia, (2)Murdoch Childrens Research Institute, Parkville, VIC, Australia, (3)Developmental Medicine, The Royal Children's Hospital, Parkville, VIC, Australia, (4)Psychology Service, The Royal Children Hospital, Melbourne, Parkville, VIC, Australia, (5)School of Psychological Sciences, The University of Melbourne, Melbourne, VIC, Australia*

Background: According to the International Classification of Functioning Disability and Health (WHO, 2001), participation in social activities is a key determinant of functioning. Participating in social activities during adolescence is considered important for adult functioning. There is some evidence that individuals with autism spectrum disorder (ASD) participate less in social activities compared to their typically developing peers (TD). However, few studies have investigated what factors contribute to reduced participation. Understanding these factors will guide interventions for individuals with ASD and their families to enhance their functioning during adolescence and into adulthood.
Objectives: The objectives of this study were to: (1) compare the number of weekly activities that 14-15 year old adolescents with and without ASD participate in; (2) investigate factors associated with participation such as level of parental education, socio-economic status (SES), parent mental health, language spoken at home and family structure.
Methods: This study used data collected from the Kindergarten cohort of the Longitudinal Study of Australian Children (LSAC), a longitudinal study following up a representative sample of 10,000 Australian children every two years. The data set used for this study comprised 3,360 14-15 year olds without ASD and 94 with parent-reported ASD. These groups were compared based on the number of extracurricular activities they participated in (e.g., going to the cinema, swimming pool, sporting event, religious activity, library, concert, museum or another community event). We also investigated associations between participation and parent-reported characteristics of the family including the level of parental education, SES, parental mental health (depression), being from a family where English is the second language, being from a single parent family.
Results: Adolescents with TD did not differ from those with ASD in the number of extracurricular activities they participated in on a weekly basis (M_{TD}= 1.17, sd $_{TD}$= 1.07; M_{ASD} = 0.89, sd $_{ASD}$= 1.07; p = 0.198). Parents of adolescents with ASD were more likely to have had an episode of depression compared to TD peers (odds ratio= .53; 95% Conf. Interval = .34 - .85). Adjusted regression analyses showed lower participation in adolescents was associated with lower family SES (β= 0.001; p < .001), single parent family (β = 0.16; p = .001), English as a second language (β = 0.29; p<.001), lower parent education level (β = 0.33; p< .001) and the parent having had a major depressive episode during the last year (β= 0.10; p = .01).
Conclusions: Parental mental health, specifically having had depression during the last year, but not the young person's autism status, was associated with adolescents' participation in extracurricular activities. The assessment and treatment of parental depression should therefore be considered as part of a family centred approach when developing a support plan to enhance participation in adolescents with ASD.

130 **179.130** Factors Impacting Parental Belief of an Autism Spectrum Disorder Diagnosis Pre-Evaluation

M. H. Pinkett-Davis[1]*, V. Singh*[2] *and R. Landa*[2]*, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD*

Background:
Â Parental recognition of child symptoms is one of the first levels of the help-seeking process (Goldberg & Huxley, 2003). Studies have shown parents recognize signs of autism much earlier than it is diagnosed (American Psychiatric Association & American Psychiatric Association, 1994). Once symptom recognition leads to seeking services, little is known about parents personal anticipation or belief of their child's autism spectrum disorder (ASD) status before an evaluation is made by the clinician to rule ASD in or out. Identification of the factors associated with parent's pre-evaluation beliefs and their relationship with the final clinical diagnosis can enhance clinicians' ability to contextualize results of diagnostic evaluations and promote parent acceptance of diagnosis and referral guidance.
Objectives:
Assess factors affecting parent belief aboutÂ anticipated child diagnosisÂ prior to ASD evaluation and subsequent factors influencing receiving an ASD diagnosis.
Methods:
Participants included 1035 parents whose children were evaluated at a university-based ASD specialty clinic. Mean child age was 7.12 years (range =0.5-18.5; 18.5% female). Parents completed intake and Background and History Questionnaire prior to their child's evaluation during the period from June 2014 to August 2016. Through this intake process, they answered a question about "whether they believe their child has ASD despite clinician diagnosis" and completed the Child Behavior Checklist (CBCL; Achenbach, 1991). Children were then evaluated by a multidisciplinary team to rule in or out an ASD diagnosis using DSM – IV criteria. 909 children (69.76%) had a confirmed ASD diagnosis (ASD group), while in 394 (30.24%), ASD was ruled out (non-ASD group). Adjusted odds ratios (aOR) were obtained using multivariate logistic regression to predict factors associated with agreement between parents' pre-evaluation belief that their child had ASD and ASD clinical diagnosis.
Results:
Pre-evaluation rate of parents believing their child had ASD was high (81%). Parental belief (aOR=1.68, p=0.007), above all factors, was positively associated with clinician diagnosis. Child age (6-9yrs:aOR=2.07, p= 0.001; 10-13yrs:aOR=2.13, p=0.006; >14yrs:aOR=3.34, p=0.01), behavior (aOR=2.22, p<0.001) and previous ASD diagnosis (aOR=1.95, p=0.001) were significantly positively associated with pre-evaluation parent belief of ASD. However, having an older child (6-9yrs:aOR=0.47, p<0.001; 10-13yrs:aOR=0.40, p<0.001; >14yrs:aOR=0.45, p=0.001) and more behavior problems (per CBCL; aOR=0.65, p<0.001) was associated with lower odds and a previous ASD diagnosis (aOR=5.78, p<0.001) was with higher odds of receiving a clinical diagnosis. Highest parent-clinician agreement was seen in kids >6yrs and those with low behavior problems (%agreement=72%)
Conclusions:
As this sample was seeking clinical services, parent belief status is skewed toward belief that the child has ASD. Half of the sample was below 6 years. Those over the age of 6 are more likely to be attending a structured educational setting providing opportunities for parents to receive more targeted feedback regarding their child from educators. This feedback along with parental observation of same-age peers may influence parents to consider ASD as an explanation for longstanding developmental concerns. Lower diagnosis rate in the older children and those with more behavioral issues might be reflective of other etiologies with behavioral phenotypes similar to ASD and need differential diagnosis.

131 **179.131** Factors That Drive Access to Services for Children with Neurodevelopmental Disorders in Low Income Populations

M. D. Powers[1]*, K. Tiplady*[1]*, B. J. Anthony*[2]*, L. Kenworthy*[1]*, A. D. Verbalis*[1]*, C. K. Kraper*[1]*, D. Limon*[1]*, S. Seese*[1]*, J. Safer-Lichtenstein*[2]*, M. F. Skapek*[1] *and L. G. Anthony*[1]*, (1)Children's National Health System, Washington, DC, (2)Center for Child and Human Development, Georgetown University, Washington, DC*

Background: Â Children with Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) from low-income households are identified later and receive fewer services than children from high-income households. This 'double whammy' in diagnosis and treatment means that, throughout their lives, children from low-income populations receive less intervention than children from middle- and high-income populations (Liptak et al., 2008; Thomas et al., 2007). Disparity in access to medical and non-medical services may result from internal and external factors. To address disparities in low-income, and ethnically and racially diverse ASD and ADHD populations, researchers must understand the factors linked to the presence of services.
Objectives: Â Identify factors related to services that children with neurodevelopmental disorders receive in school and private settings.Â Researchers hypothesized: (1) Elevated scores on BRIEF Global Executive Composite (GEC) and CBCL Problems will positively correlate with the presence of both medication and non-medication services. (2) Families of children without services will report more strain and less competence and self-efficacy.
Methods: Participants included 96 children ages 8-11 (M=9.67, SD=.83) from Title I schools (M=$100,727.23, SD=$83,853.08). Participants were referred to a school-based treatment study with a likely diagnosis of ADHD or ASD. Participants were analyzed by service type: (1) Children receiving non-medication services in school and private settings, N=45, (2) Children receiving both medication services and non-medication services, N=24, and (3) Children not receiving any services, N=27. Children only receiving medication were excluded from analyses. Parents completed self-report measures of caregiver strain, family empowerment, and child service programs.
Results: Findings indicate children's impairments in executive functioning and behavior significantly differ among service type, F(3, 95)=9.429, p<.001. Specifically, children receiving both medication and non-medication services were associated with the highest levels of executive dysfunction and problem behaviors; their families experience significantly greater strain. Children without services show less executive dysfunction and problem behaviors, while their families report less strain. When child behavioral measures were removed from the model, the significance of parental strain in relation to receiving both services persisted (r=.225, p=.040). Families of children without services did not report elevated strain (r=-.216, p=.030). However, absence of services was negatively related to parental self-efficacy (r=-.225, p=.039). When controlling for child behaviors, parental competence was strongly correlated with parental self-efficacy (r=.476, p<.001).
Conclusions: As anticipated, children with greater executive functioning needs and problem behaviors received both medication and non-medication services. Unexpectedly, families of children receiving both services experienced more strain than those who were not receiving services. This finding held true even when child behavioral characteristics were factored out of the relationship. Finally, independent of level of child functioning, parents report low self-efficacy in the absence of services. When parents are not confident in their ability to help their children and do not perceive child difficulties as family strain, children do not receive intervention. This further contributes to disparity in services within the present population. To better understand the relationships that predict services for low-income children with neurodevelopmental disorders, future studies should explore causal relationships that mediate access to services among diverse populations.

132 **179.132** Family Daily Hassles and School Variables in Typically-Developing Siblings of Children with Autism Spectrum Disorder

T. A. Hassenfeldt[1] *and A. Scarpa*[2]*, (1)Marcus Autism Center, Emory School of Medicine, Atlanta, GA, (2)Virginia Tech, Blacksburg, VA*

Background: As Autism Spectrum Disorders (ASD) increase in prevalence, the number of typically-developing (TD) siblings of children with ASD has also increased. Sibling relationships have the potential to be the longest-lasting relationship of one's life. In addition to fulfilling traditional sibling roles, such as friend, protector, or confidante, siblings of children with ASD may take on additional unique roles (e.g., social model, caregiver; Celiberti & Harris, 1993; Bass & Mulick, 2007; Castorina & Negri, 2011). Thus, it is worth investigating the experiences of these TD siblings. While previous literature indicates mixed findings, recent studies with more rigorous methodologies have found that TD siblings of children with ASD fare as well as children without siblings with ASD (Dempsey, Llorens, Brewton, Muchandani, & Goin-Kochel, 2011; Shivers, Deisenroth, & Taylor, 2013; Hastings & Petalas, 2014).
Objectives: Little to no research has explored the academic functioning of TD siblings. We hypothesized that disruptions to families' daily routines (i.e., daily hassles) may have negatively impacted TD siblings' classroom behaviors and grades.
Methods: The *Parenting Daily Hassles Scale* (PDHQ; Crnic & Greenberg, 1990; Crnic & Booth, 1991) was collected as part of a larger battery from 39 parents.Â All parent participants (92% Caucasian, 90% married, 79% college-educated) had a child with an ASD diagnosis (80% male, *M* age = 11.74) and a TD child (62% male, *M* age = 10.31 years). Teachers (*n* = 25) reported on classroom functioning and parents provided report cards.
Results: Seventy-two percent of TD siblings (*n* = 18) had scores above the mean on the Academic Performance Rating Scale (APRS; DuPaul, Rapport, & Perriello, 1991), and 91% (*n* = 32) had grade averages of B or higher. Ninety-six percent (*n* = 24) of TD siblings had scores within the normative range on the Learning Problems and School Problems scales of the Behavior Assessment System for Children, Second Edition (BASC-2; Reynolds & Kamphaus, 2004). The Challenging Behaviors subscale of the PDHQ was not significantly correlated with any school variables for TD siblings. However, correlations with APRS score and report card grades were moderate in effect size; these relationships may have been significant with a larger sample size. The Parenting Tasks subscale was also not significantly correlated with any school measure.
Conclusions: One trend in our data suggests that parents who are distressed by their children's collective problem behaviors might have TD children with better academic performance and grades (perhaps due to coping). Small effect sizes in the relationships between the Parenting Tasks subscale and school variables suggest a minimal relationship between stress about parenting duties and TD childrens' academic functioning. Overall, most TD siblings performed well in the classroom and on their report card. This finding fits well with previous literature that most TD siblings of children with developmental disorders have generally positive outcomes (Sanders & Morgan, 1997; Grant, Ramcharan, & Flynn, 2007).

133 **179.133** Family Needs and Related Factors for Parents of Children with Autism Spectrum Disorder during Transition to Middle School

C. C. Chao[1]*, I. H. D. Wu*[2]*, Y. W. Hsiao*[3] *and H. N. Chen*[1]*, (1)Psychology and Counseling, University of Taipei, Taipei, Taiwan, (2)Special Education, University of Taipei, Taipei, Taiwan, (3)Center for Teacher Education and Career Development, University of Taipei, Taipei, Taiwan*

Background: Parents of children with autism spectrum disorder (ASD) often face many difficulties and challenges in parenting. During transition to middle school, children with ASD are particularly at risk because their deficits in social interaction and communication make adaptation to new environment or new relationships difficult. These children need support from adults, however, their parents, being uncertain about the future of their children and unsure how to help them, also need assistance. In recent years, researchers and practitioners begin to pay more attention to caregiver issues.
Objectives: (1) understand the challenges, needs, and resources of Taiwanese parents of children with ASD during transition to middle school; (2) investigate the relationships among parenting efficacy, mental health, and social support of parents of children with high-functioning ASD (HFASD); and (3) explore the experience of mothers of children with HFASD to understand their views of the parent-teacher interaction and the difficulties in their children's school adjustment.
Methods: Â Both quantitative and qualitative methods were used. First, from the year 2010 database of the Special Needs Education Longitudinal Study (SNELS), 280 parents of six-grade children with autism or Asperger's disorder were selected. Their responses to those items related to family needs during transition to middle school in the SNELS parent questionnaire were analyzed. Secondly, 52 parents of school-aged children with HFASD from northern Taiwan completed a parenting efficacy scale, adult mental health scale, and social support scale. Finally, five mothers participated in a focus group and three of them also received individual interviews. Video and audio recordings from the focus group and individual interviews were verbatim transcribed. The narrative inquiry method was used for data processing.
Results: (1) During transition, the top four family needs were: professional information/service (93.2%), interpersonal support (75.4%), transitional placement (51.4%), and financial aid (27.5%). For children in special classes, their parents reported higher needs for professional information/service and transitional placement. For children with school adjustment difficulties, their parents reported higher needs for interpersonal support. (2) Parents showed an average degree of overall parenting efficacy (PE), mental health (MH), and social support (SS). PE positively correlated with MH and with SS, particularly emotional SS. MH only correlated positively with emotional SS. Both MH and SS demonstrated predictive power for PE, particularly positive mentality, anxiety, and emotional social support. (3) In their school experience, mothers acted as the voice for their children, the bridge between their children and teachers, and the helper to teachers. Mothers felt rejected, unaccepted, and misunderstood when interacting with teachers, particularly self-righteous teachers. Mothers expected teachers to be open, willing to listen and accept, understanding, helpful, and provide learning opportunities to their children; and schools to provide more special education resource and enhance the collaborations among resources and with teachers.
Conclusions: It is suggested that schools provide parent education, support groups, and counseling to help parents develop positive thinking and stress management skills to increase parenting efficacy and to empower parents. Future studies could examine the potential influences of other correlates on parenting efficacy.

134 **179.134** Family Perceptions of Community Autism Spectrum Disorder Stigma: Measure Validation and Ecological Associations

K. Zuckerman[1]*, O. J. Lindly*[2]*, N. M. Reyes*[3]*, A. E. Chavez*[4]*, K. Macias*[5]*, M. Cobian*[6]*, A. M. Reynolds*[7] *and K. Smith*[8]*, (1)Division of General Pediatrics, Oregon Health & Science University, Portland, OR, (2)College of Public Health and Human Sciences, School of Social and Behavioral Health Sciences, Oregon State University, Corvallis, OR, (3)University of Colorado - Denver, Aurora, CO, (4)Oregon Health & Science University, Portland, OR, (5)Department of Pediatrics, Children's Hospital Los Angeles, Los Angeles, CA, (6)Pediatrics, Oregon Health and Science University, Portland, OR, (7)University of Colorado Denver, Aurora, CO, (8)Children's Hospital Los Angeles, Pasadena, CA*

Background: Though studies have documented the experience of stigma among family members of individuals with autism spectrum disorder (ASD), there are no standard scales of perceived community ASD stigma, and no measurement of how ASD stigma varies according to child, family, and health system factors.
Objectives: To develop a parent-reported scale of community ASD stigma. To assess child, family, and health system associations with community ASD stigma.
Methods: A random sample of Latino and non-Latino white parents of children with ASD seen at specialty clinics in California, Colorado, and Oregon in 2014-2015 (n=370; response rate 76.2%) were surveyed about experiences with ASD stigma and barriers to ASD diagnosis. The mixed-mode survey was performed in English or Spanish, and ASD diagnosis was verified via medical record review. Confirmatory factor analysis was used to create a scale of perceived community ASD stigma. Bivariate and multivariable analyses then compared associations of child, family, and health system characteristics with community ASD stigma.
Results: Confirmatory factor analysis results supported a single factor solution with 8 of 11 possible survey items best reflecting community ASD stigma. These eight items demonstrated good internal consistency (α=0.80). Nested regression model results suggested that child characteristics associated with greater community ASD stigma included having public health insurance and experiencing moderate or severe ASD. Family characteristics associated with greater ASD community stigma included having more children with ASD per household, having lived outside the U.S., and having a family structure that was divorced, separated, or widowed. Experiencing a greater number of barriers to ASD care was associated with greater community ASD stigma.
Conclusions: Factors at several ecological layers may influence perception of stigma among parents of children with ASD. These results may be notable to those attempting to reduce stigma about ASD as the identified child, family, and health system factors could be target points for future campaigns.

135 **179.135** Family Quality of Life: Impact of Parent Understanding and Perceptions of Autism Spectrum Disorder.

A. Villagomez[1], *H. M. Crain*[1], *S. Hepburn*[2] *and E. McMahon Griffith*[3], *(1)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO, (2)University of Colorado / JFK Partners, Aurora, CO, (3)University of Colorado School of Medicine, Aurora, CO*

Background:
Unlike many developmental disabilities (e.g., Down syndrome, fragile x syndrome) autism spectrum disorder (ASD) does not have a known universal genetic underpinning. As a result, parents may be less likely to have a firm understanding of the roots of their child's strengths and challenges. In fact, studies show that a genetic diagnosis gives validation and credibility to their child's needs (Makela et al., 2009), and family quality of life (QOL) is directly impacted by feelings of uncertainty (McStay, Trembath, & Dissanayake, 2014). It is well documented that compared to families with typically developing children and children with other neurodevelopmental disorders, families of children with ASD are less satisfied with their QOL (Gardiner & Iarocci, 2015). Bayat (2005) found that families that perceived positive effects of autism (e.g., family cohesion), most strongly predicted QOL. However, there is a paucity of literature exploring how autism severity influences the relationship between parent understanding of their child's disability and family QOL. The present study aims to explore this relationship.
Objectives:
The purpose of the present study is to examine QOL of families waitlisted for a parent-coaching intervention shortly after receiving an initial diagnosis. Specifically, family QOL will be explored as a function of parent perceptions of autism severity (measured by the impact of autism symptoms on everyday life via the *Autism Impact Measure*), and whether this relationship was moderated by parent understanding of their child's disability-related needs and strengths.
Methods:
30 families (n = 15 collected; n = 15 enrolled by March 2017) of children with ASD enrolled in early intervention were asked to complete questionnaires about family QOL and the impact of autism on their family's everyday life, among other measures in a larger research battery. Four items from the *ECO Family Outcomes Survey* (Bailey et al., 2011), were summed together as a measure of parent understanding of their child's strengths, abilities, delays, and/or needs. Two subscales of the *Family Quality of Life Survey* (Hoffman, Marquis, Poston, Summers, & Turnbull, 2006) were included to assess factors related to family interactions and parenting. Families also completed the *Autism Impact Measure* (Kanne, et al., 2014), to measure parent perceptions of the impact of their child's autism symptoms. Measures of child development and social functioning were also collected.
Results:
Based on existing literature, we hypothesize that parent understanding will be a contributing factor to family QOL, in addition to autism severity (i.e., impact on everyday functioning). Exploratory analyses will be used to determine how parent perceptions of autism symptoms predict family QOL and how this relationship is influenced by parent understanding of their child's disability-related needs and strengths.
Conclusions:
Results from the present study will highlight the importance of considering parent understanding of their child's disability on QOL. Findings will also emphasize the importance of educating families about ASD as a part of the intervention in order to potentially facilitate greater family QOL. Future directions include examining this relationship post-intervention as well as further exploring differences among families from varying ethnic and socioeconomic backgrounds.

136 **179.136** How Do We Study Autism As Neurodiversity?: A Review of Theoretical Perspectives, Empirical Findings, and Implications for Future Research

A. McVey, *H. K. Schiltz and A. V. Van Hecke, Marquette University, Milwaukee, WI*

Background: Neurodiversity is quickly becoming a household word, with the publication and dissemination of *NeuroTribes* (Silberman, 2015). Despite some theoretical examination, this concept has received little empirical evaluation.
Objectives: The purpose of the present study was to review the literature on neurodiversity with three primary aims:

1. Explore definitions of neurodiversity and emerging themes
2. Review empirical studies of neurodiversity and consider future research directions
3. Consider implications for viewing autism as neurodiversity (i.e., a culture, minority; Baker, 2006; Jaarsma & Welin, 2012; Lim, 2015)Â

Methods: A review of the term "neurodiversity" was conducted by searching PsycInfo and Web of Science. Only journal articles were included. Ten journal articles were uncovered in PsycInfo (*n* = 10), and forty-eight in Web of Science (*n* = 48), with 6 duplicates (*n* = 6). Articles were included if they discussed the theory of neurodiversity or were a direct empirical study of neurodiversity. Eighteen articles were further excluded for: not English language (*n* = 5), not specifically ASD (*n* = 6), not specifically about neurodiversity (*n* = 3), a response to another writing (*n* = 4). A total of thirty-five articles were then reviewed (*N* = 35). The first and second author independently reviewed half of the articles for themes and empirical findings. Theoretical themes were then discussed and finalized jointly.
Results: Theoretical papers (*n* = 26) broadly highlighted these common themes: application to a topic or field, the idea of autism from a medical vs. social perspective, autism as natural genetic variation, and the rights, advocacy, and justice issues surrounding autism and neurodiversity. Empirical papers (*n*= 9) sought to evaluate neurodiversity in these ways: teaching/pedagogy for neurodiverse individuals, terminology in describing autism, culture and neurodiversity, review of career interests, and visuospatial creativity as neurodiversity.
Conclusions: Themes of neurodiversity included applications, the medical vs. social model, natural variation, and rights, advocacy, and justice. While some empirical work has been conducted surrounding this concept, a great deal more research is needed to further examine the implications of conceptualizing neurodiversity as a minority or culture. Future directions of this work may include the following questions: What are methods for measuring neurodiversity – how is autism a genetic variant of typical functioning? What are the implications of dividing autism by high- and low-functioning – those who are neurodiverse and those who are neurodisabled? If autism is a culture, how then do current practices represent ethnocentrism in attempting to "change" people with autism to "make them fit" into majority culture? Can minority theories be applied to better understand the experience of neurodiverse people?

137 **179.137** Maternal Emotion Socialization and Child Problem Behaviours in an Autism Spectrum Disorder Population: The Role of the Broad Autism Phenotype and Distress

M. I. Duffett[1]*, F. Beiti*[2] *and K. Babb*[2]*, (1)Psychology, University of Windsor, Windsor, ON, CANADA, (2)Psychology, University of Windsor, Windsor, ON, Canada*

Background: Many children with autism spectrum disorder (ASD) exhibit problem behaviours that interfere with everyday activities. As problem behaviours are so prevalent and impactful, it is important to gain a broader understanding of the possible factors that may increase problem behaviours, as well as buffer against the development of problem behaviours. Emotion socialization has been linked to problem behaviours in typically developing children; however, the association between maternal emotion socialization and child problem behaviours in children with ASD has yet to be sufficiently examined. Furthermore, there is strong evidence to support the notion that mothers of children with ASD experience high levels of distress (stress, anxiety, and depression). In typically developing populations, maternal distress has been associated with parenting behaviours, such as emotion socialization, and problem behaviours in children. On average, approximately 16 to 23% of mothers of children with ASD demonstrate characteristics of the broad autism phenotype (BAP; e.g., Bishop et al., 2004; Sasson et al., 2013; Wheelwright et al., 2010), which includes mild deficits in social interaction and pragmatic language. As these deficits affect basic social communication, it is important to understand whether mothers who demonstrate characteristics of the BAP differ from those without these characteristics during efforts to socialize emotion with their children.
Objectives: The purpose of the current study was to explore emotion socialization practices (emotion coaching, supportive reactions, unsupportive reactions, positive expressiveness, and negative expressiveness) and the outcome of child problem behaviours, while taking into account maternal characteristics of the BAP and distress (stress, anxiety, depression, and parenting stress).
Methods: Participants included 57 mothers of children age 6 to 16 years diagnosed with high functioning ASD. Mother's completed a series of questionnaires relating to emotion socialization, distress, characteristics of the BAP, and child problem behaviours.
Results: Mothers were separated into groups: without BAP status group and with BAP status group. Multiple regression and moderation analyses were conducted. The results revealed that emotion socialization practices alone did not predict child problem behaviours. However, with the inclusion of distress as a moderator, the relation between emotion socialization and problem behaviours revealed differences between the BAP groups. That is, in mothers without BAP status, when predicting child problem behaviours, stress moderated emotion coaching, supportive reactions, and positive expressiveness. Anxiety and parenting stress also moderated emotion coaching. In mothers with BAP status, stress and parenting stress moderated the relation between negative expressiveness and child problem behaviours.
Conclusions: The current study highlighted the importance of considering maternal characteristics, such as distress and BAP status, when examining maternal emotion socialization practices and child outcomes within an ASD population. The current study also provides preliminary evidence for the usefulness of the emotion socialization framework within an ASD population, which has implications for both researchers and professionals working with this population.

138 **179.138** Maternal Poor Sleep of Children with ASD in Saudia Arabia and UK

W. A. Bin Eid[1] *and D. Dimitriou*[2]*, (1)Lifespan Learning and Sleep Lab, Institute of Education UCL, London, United Kingdom, (2)UCL, Institute of Education, London, United Kingdom*

Background: Sleep problems in children are common, with around one third of children experiencing some kind of sleep disturbance during their development. Many children with ASD are reported to have severe sleep problems including long night time wakings and sleep onset delay. This is particularly important as sleep plays an active role in children's memory consolidation and impacts daytime functioning.
Objectives: To date, most research has primarily focused on sleep characteristics of children with ASD in western countries. Very little research used objective assessments of sleep parameters and mental health of mothers who have school-age children with ASD. The current study was twofold: 1) examine maternal sleep and mental health (depression and anxiety) and 2) examine if there are *ethnic differences in sleep by comparison two groups: UK and Saudi Arabia.*
Saudi Arabia is a country with very little research carried out on children with ASD and their families. Yet, numbers of diagnosis are on increase as well as awareness. Hence gaining understanding of common sleep issues and maternal mental health status is of great importance.
Methods: Participants included 90 mothers of children with ASD (50% from UK) and 90 mothers in control group (no ASD, 50% from UK). Inclusion criteria were that all children had to be of school age and have current diagnosis of ASD. Maternal sleep was measured using actigraphy for 7 days and further assessed using a large battery of Sleep Questionnaires such as The Pittsburgh Sleep Quality Index and sleep diary. Maternal mental status was measured using Becks Inventory and Parenting Stress Index. Each mother filled in Childhood Sleep and Habits Questionnaire about their child's sleep patterns.
Results: As expected children with ASD had significantly higher sleep onset delay and decreased sleep, large number of night-time wakings in comparison to the control group. Mothers in both groups suffered from sleep onset delay, frequent night wakings and shorter sleep. In sum their sleep quality and quantity significantly differed from the control group. Interestingly, sleep parameters of mothers in Saudi Arabia were significantly worse than both groups. On the depression and stress index mothers from the UK group had higher scores than the Saudi group. Regression models showed that depression and poor sleep were strongly associated with the child's sleep.
Conclusions: The findings confirm previous studies that children with ASD suffer from sleep problems. New findings using objective sleep measures show that maternal sleep is linked to their child' sleep patterns. The association of sleep to depression and anxietyÂ scores ought to be examined further and treatments should be offered to manage sleep issues of mothers and their children as a unit. More proactive work needs to be put towards the ASD awareness in the Middle East countries.

139 **179.139** Maternal Sleep Problems and Depression of Children with ASD

W. A. Bin Eid[1] *and D. Dimitriou*[2]*, (1)Lifespan Learning and Sleep Lab, Institute of Education UCL, London, United Kingdom, (2)UCL, Institute of Education, London, England, United Kingdom*

Background: Sleep problems in children are common, with around one third of children experiencing some kind of sleep disturbance during their development. Many children with ASD are reported to have severe sleep problems including long night time wakings and sleep onset delay. This is particularly important as sleep plays an active role in children's memory consolidation and impacts daytime functioning.
Objectives: To date, most research has primarily focused on sleep characteristics of children with ASD in western countries. Very little research used objective assessments of sleep parameters and mental health of mothers who have school-age children with ASD. The current study was twofold: 1) examine maternal sleep and mental health (depression and anxiety) and 2) examine if there are *ethnic differences in sleep by comparison two groups: UK and Saudi Arabia.*
Saudi Arabia is a country with very little research carried out on children with ASD and their families. Yet, numbers of diagnosis are on increase as well as awareness. Hence gaining understanding of common sleep issues and maternal mental health status is of great importance.
Methods: Participants included 90 mothers of children with ASD (50% from UK) and 90 mothers in control group (no ASD, 50% from UK). Inclusion criteria were that all children had to be of school age and have current diagnosis of ASD. Maternal sleep was measured using actigraphy for 7 days and further assessed using a large battery of Sleep Questionnaires such as The Pittsburgh Sleep Quality Index and sleep diary. Maternal mental status was measured using Becks Inventory and Parenting Stress Index. Each mother filled in Childhood Sleep and Habits Questionnaire about their child's sleep patterns.
Results: As expected children with ASD had significantly higher sleep onset delay and decreased sleep, large number of night-time wakings in comparison to the control group. Mothers in both groups suffered from sleep onset delay, frequent night wakings and shorter sleep. In sum their sleep quality and quantity significantly differed from the control group. Interestingly, sleep parameters of mothers in Saudi Arabia were significantly worse than both groups. On the depression and stress index mothers from the UK group had higher scores than the Saudi group. Regression models showed that depression and poor sleep were strongly associated with the child's sleep.
Conclusions: The findings confirm previous studies that children with ASD suffer from sleep problems. New findings using objective sleep measures show that maternal sleep is linked to their child' sleep patterns. The association of sleep to depression and anxietyÂ scores ought to be examined further and treatments should be offered to manage sleep issues of mothers and their children as a unit. More proactive work needs to be put towards the ASD awareness in the Middle East countries.

140 **179.140** Measures of Treatment Fidelity and Social Validity within a Parent-Mediated Behavior Intervention

A. D. Rodgers[1]*, L. A. Ruble*[1]*, G. M. Kuravackel*[2]*, A. P. Ables*[3] *and R. J. Reese*[4]*, (1)University of Kentucky, Lexington, KY, (2)University of Louisville, Louisville, KY, (3)University of Louisville Autism Center, University of Louisville, Louisville, KY, (4)Educational, School and Counseling Psychology, University of Kentucky, Lexington, KY*

Background: An effective intervention not only results in good outcomes, but has quality features of treatment fidelity (the accuracy and consistency of implementation of an intervention) and social validity (participants' impressions of the importance and acceptability of the intervention, including satisfaction and therapeutic alliance, cf. Ardito & Rabellino, 2011. We examined these constructs within a quasi-experimental study of an 8-week parent training and therapeutic support program for children with ASD and problem behavior called COMPASS for Hope (C-HOPE). Despite the fact that individuals with ASD manifest higher levels of challenging behaviors and that parents are the first-line interventionists (Matson, Wilkins, & Macken, 2009), little parent training group-design research is available targeting these problem behaviors. Moreover, of the extant studies, few measured parent outcomes, none measured multiple parent outcome indicators – parent stress and parent competency – and few measured fidelity and social validity. Given the potential for parent training and support to decrease child problem behavior, increase parent competency, and decrease parent stress, an understanding of factors such as fidelity and social validity is critical for future dissemination.
Objectives: The purpose of this study was to examine (a) therapist treatment fidelity; (b) parent satisfaction; (c) parent outcomes; and (d) therapeutic alliance within C-HOPE. The larger study included both face-to-face (FF) and telehealth (TH) delivery formats, thus, a secondary objective was to determine whether differences exist between delivery methods.
Methods: The larger study employed a pre-post waitlist control design in a sample (N=33) of parents of children with ASD (M_{age}=8.1, SD_{age}=2.5). Participants received C-HOPE delivered via TH (N=20) or FF (N=13). Fidelity was measured using a checklist of essential session components. Satisfaction was measured using a 4-point Likert scale of session characteristics. Parent outcomes were measured using the Outcome Rating Scale (ORS; Miller & Duncan, 2000), which is divided into subscales of Individual, Interpersonal, Social, and Overall outcomes. Therapeutic alliance was measured using the Session Rating Scale (SRS; Johnson, Miller, & Duncan, 2000) and the Group Session Rating Scale (GSRS; Duncan & Miller, 2007), which are divided into subscales of Relationship, Goals/Topics, Approach/Method, and Overall. All ORS, SRS, and GSRS ratings are made using a 10-cm line visual analog scale.
Results: Therapist treatment adherence ranged from 76.2% to 100.0% (*M*=94.2, *SD*=7.1), and parent-reported satisfaction with sessions was high (*M*=3.7, *SD*=0.3). Parent outcome scores improved significantly from the first session (*M*=24.8, *SD*=8.8) to the eighth session (*M*=30.8, *SD*=8.5), t(17)=-3.71, p=0.002. Alliance was high with regard to parent-therapist relationship (*M*=9.3, *SD*=0.7), goals/topics (*M*=9.3, *SD*=0.8), approach/method (*M*=9.4, *SD*=0.6), and overall (*M*=9.2, *SD*=0.8). One-way analysis of variance revealed no differences between FF and TH modalities in the areas measured.
Conclusions: Social validity for C-HOPE is high, and can be implemented with fidelity across cohorts and modalities. Additionally, C-HOPE favorably impacted parents, who were both satisfied and demonstrated improvements individually, relationally, and socially. Future research is needed to assess how these factors impact final outcomes of child problem behavior, parent stress, and parent competency.

141 **179.141** Multi-Informant Assessment of Typically-Developing Sibling Psychological Functioning: Pitfalls of Single-Informant Assessment

J. A. Rankin[1]*, C. A. Paisley*[2]*, L. K. Baker*[2]*, T. Tomeny*[1] *and T. D. Barry*[3]*, (1)The University of Alabama, Tuscaloosa, AL, (2)University of Alabama, Tuscaloosa, AL, (3)Washington State University, Pullman, WA*

Background: Â Self- and parent-reports of typically-developing (TD) sibling psychological maladjustment often vary in their estimates of risk status (Meadan, Stoner, & Angell, 2010). This may be due, in part, to many TD sibling studies examining only one informant (Meadan et al., 2010). However, use of only one informant often leads a measure to demonstrate weaker specificity and sensitivity when determining risk status and an underestimation of actual risk (Goodman et al., 2000).Â Critically, theÂ correspondence of TD sibling "at-risk" status outcomes between parent and youth reports has yet to be examined. Furthermore, whether differences exist in the relation between different informant's reports and known predictors of TD sibling outcomes [e.g., externalizing behaviors associated with ASD, broader autism phenotype (BAP) symptoms; Petalas et al., 2012] has yet to be examined.
Objectives: Â N/A
Methods: Â Participants were 113 dyads, consisting of a parent and a TD sibling of a child with ASD. Parents completed the Strengths and Difficulties Questionnaire (SDQ), assessing emotional and behavioral functioning, and Children's Social Behavior Questionnaire (CSBQ), assessing BAP and ASD symptom severity, about the TD sibling (M_{age} = 13.33, 50% male) and about their child with ASD, respectively; the Symptom Checklist Revised10 (SCLR 10) and Questionnaire on Resources and Stress (QRSF) about themselves, measuring broad mental health and parenting stress, respectively. TD siblings self-reported via the SDQ and the Child and Adolescent Social Support Scale (CASSS), the latter measuring perceived social support.
Results: Â Suggested classification cutoffs on the SDQ (see Goodman, 1997) were used to classify each sibling into no-risk ('normal' classification) or at-risk ('borderline' and 'abnormal' classifications). Overall, 75% of reports yielded no risk on either parent or sibling report. In youth where risk was indicated, only 21% had risk indicated on *both* reports (see Table 1). Hierarchical Linear Modeling (HLM), with informants nested within siblings, examined differences between informants in the effects of predictors of psychological maladjustment (e.g., parental stress) on TD sibling functioning. Overall, the effects of parent mental health concerns (β_{11} = -.17, t = 2.33, p =.02), TD sibling BAP symptoms (β_{11} = -.27, t = 6.46, p < .001), ASD symptoms (β_{11} = -.09, t = 2.47, p =.02), and ASD externalizing symptoms (β_{11} = -.66, t = 2.25, p = .03) all varied in their relations with TD sibling SDQ depending on the informant. No differences based on informantÂ were found for either the effect of parental stress (β_{11} = -.36, t = 1.19, p =.23) or social support on SDQ (β_{11} = -.01, t = 1.06, p = .29).
Conclusions: Â Results suggest that parent and sibling reports may identify different TD youth to be at risk of psychological maladjustment. Thus, single-informant investigations of siblings may be understating actual rates of TD sibling risk status among families with a child with ASD. Furthermore, 4 of 6 factors previously related to TD sibling functioning varied in their effects depending on which informant was used, highlighting the need for investigations to include reports, and perspectives, of parents and the siblings themselves.

142 **179.142** Narratives about the Transition to Adulthood: Parent and Adolescent Differences in Visions of the Future

A. V. Kirby[1]*, S. Wright*[1]*, M. L. Diener*[2]*, C. Wright*[1] *and C. Taylor*[1]*, (1)University of Utah, Salt Lake City, UT, (2)Family & Consumer Studies, University of Utah, Salt Lake City, UT*

Background: Adolescence is a critical time in which families of adolescents with autism spectrum disorder (ASD) plan and prepare for the future. Recent evidence suggests that parental expectations in adolescence act as significant mediators of outcomes in adulthood (Kirby, 2016). However, little is known about alignment between parent and adolescent visions of the future and how their visions influence family decision-making during the transition to adulthood. Narrative approaches allow for in-depth exploration of both parent and adolescent visions of the future, which may help uncover challenges experienced by families and clarify ways for professionals to better meet families' needs.
Objectives: To examine and compare narratives about adulthood from adolescents with ASD and their parents
Methods: To address the study objective, we analyzed qualitative interviews from adolescents with ASD and their parents from two of our research studies. In the total combined sample, we collected qualitative interviews with 23 adolescents with ASD (ages 12-17; *M*=15.6; 2 females) and 21 parents. Adolescent inclusion criteria for the first study was parent-reported ability to participate in an open-ended interview and for the second, anticipated receipt of a high school diploma. In both studies, each adolescent and parent were interviewed separately and asked about their visions for the future related to the adolescent transitioning to adulthood. Interviews were semi-structured in nature, audio-recorded, transcribed verbatim, and are being analyzed using multiple coders. Trustworthiness was further enhanced by using an audit-trail, triangulation with quantitative data sources (i.e., questionnaire data on parental expectations), and use of thick and detailed descriptions in the final report (Brantlinger et al., 2005).
Results: Preliminary qualitative analysis suggests drastic differences in the narratives provided by each adolescent with ASD versus those provided by their parent. In general, adolescents provided more positive and ambitious visions of their adulthood while parents provided more cautious, constrained, and less-independent visions. Quantitative results used during the triangulation process confirm the limited expectations parents held about their children's futures. Specifically, according to parents on a 4- or 5-point scale (scale differed slightly between studies), fewer than half of the adolescents "definitely" would: live independently (17%), participate in social activities outside of work, school, or family functions (30%), get a paid job (48%), or be financially self-sufficient (17%). Complete analysis will be completed by May 2017.
Conclusions: The results of our analysis suggest that parents and adolescents have disparate views of the future which may restrict families' abilities to effectively plan and prepare for the future. These narratives add context to recent findings that suggest parental expectations are longitudinal predictors of adult outcomes. From a justice perspective, it is important to allow adolescents self-determination when it comes to planning for their future (Wehmeyer & Shogren, 2016) while also recognizing the critical role parents play in supporting and protecting their children during this tumultuous time. Clinical implications include the need for families to have open communication during adolescence and for professionals to support both parents and adolescents to set realistic goals in order to work toward shared visions of the future.

Poster Session
180 - International and Cross-Cultural Perspectives
12:00 PM - 1:40 PM - Golden Gate Ballroom

143 **180.143** 'reading the Mind in the Eyes' in Bengali Populations in India and England: Assaying Effects of Language and Culture

M. M. Halder[1] *and M. K. Belmonte*[2]*, (1)Nottingham Trent University, Nottingham, United Kingdom, (2)Com DEALL Trust, Bangalore, INDIA*

Background: Studies of social cognition and its disorders must accommodate local cultural norms if they are to be valid, but must be normed and referred to international standards of diagnosis and assessment if they are to be credible. There thus is a need for translation of standard instruments into local languages, and adaptation for local cultures. The 'Reading the Mind in the Eyes' Test (RMET) is a widely used instrument assessing social perception of complex affective and cognitive states from pictures of eyes, based on linguistic labelling of these states. Despite translations into many European and other languages worldwide, till recently no version of the RMET had been formulated for South Asia. A companion study by Dasgupta et al. has translated the adult RMET into bangla, the language of Bangladesh and the Indian state of West Bengal.
Objectives: To assess cross-cultural validity of the bangla RMET.
Methods: Data from the bangla RMET collected from 135 (70 female) adult native (first language) bangla speakers in Kolkata, India are contrasted to those from a matched sample of 60 native bangla speakers in Nottingham, England. Further samples of native English speakers in Kolkata and native English speakers of South Asian ethnicity in Nottingham, matched to these other samples for age, sex, education and socioeconomic status, are contrasted against these in a 2 x 2 (culture x language) analysis of variance, using both the full 36-item RMET and a version that omits the six items identified by Dasgupta et al. as not reaching criterion validity in the bangla translation.
Results: Preliminary results indicate an effect of language but no effect of culture, and no interaction, on 36-item scores but not on the 30-item shortened version. Data analysis is ongoing.
Conclusions: Despite its faults and confounds, the RMET has demonstrated value as a quick index of one aspect of social cognition. Disentangling effects of language and culture can be difficult, especially for a test such as the RMET that (1) relies so heavily on verbal encodings, and (2) depends on monoracially caucasian images with which most people in the world have little or no perceptual experience. Our preliminary results suggest that in the particular case of the RMET, language is a greater determinant than culture, but that comparability can be achieved by excluding a small set of linguistically problematic items. Future RMET versions should make use of ethnically diverse facial emotion models representative of worldwide populations.

144 **180.144** A Cross-Site Examination of Barriers to Diagnosis and Service Utilization for Autism Spectrum Disorder (ASD) Among Latino Families in California

F. A. Reinosa Segovia[1]*, J. Smith*[1]*, A. Aranbarri*[2] *and C. Kasari*[3]*, (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Davis. MIND Institute, Sacramento, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Â Several barriers have been associated with the challenges involved in obtaining effective early interventions for children with autism spectrum disorder (ASD). Several studies have found that race, ethnicity, and socioeconomic status have been associated with a delay in the diagnosis of ASD and access to services (Liptak et al., 2008; Mandell et al., 2005; Parish et al., 2012). Compared with white children with autism, Latino children are diagnosed at a later age and receive poorer quality of care (Mandell et al., 2009; Magaña et al., 2013; Magaña et al., 2016; Parish et al., 2012). Furthermore, few studies have thoroughly examined the cultural relevance of ASD interventions in order to meet the needs of Latino children with ASD.
Objectives: 1) To examine the experiences and barriers of Latino families seeking an ASD diagnosis and accessing services for their children. 2) Get parents' feedback and opinions to inform and develop a pilot intervention for under-resourced communities.
Methods: Participants were 12 Spanish speaking parents [m_{age} *(SD)*Â = 37.9 (5.2), n = 11 females] who participated in two focus groups and three interviews in two sites in California. Participants were recruited via direct referral from regional centers and non-profit organizations. All interviews and focus groups were led by a Spanish-speaker moderator, audio-recorded, and transcribed in Spanish. A senior member of the research team open-coded transcripts to develop a code book, and Spanish-language coders verified the relevance of these codes to the Spanish language transcripts. Inter-coder reliability reached 60% (Cohen's kappa) and remaining disagreements were resolved via consensus. Demographic data were also collected pertaining to the family's education and income, and the child's age of diagnosis and school placement.
Results: Three main themes emerged through analysis: 1) Logistic Barriers *("Nos traen como pelotita [rebotando]"*): Most parents reported bouncing back and forth between doctors, providers, and regional centers while seeking a diagnosis and services for their children. Parents also reported being redirected or rejected by service agencies due to lack of health insurance. 2) Cultural Differences (*"Buscando las palabras correctas en español"*): All parents commented about language difficulties when working with providers. Challenges included difficulties understanding Spanish translators as well as advocating and securing services for their children effectively. 3) Lack of Knowledge (*"No sé qué es"):* the majority of parents commented about their lack of knowledge related to the causes, signs, and treatments for ASD, wondering if the etiology of ASD could be attributed to a mental disorder andÂ remaining uncertain on how to navigate the process for service initiation.
Conclusions: The findings of this study suggest that Latino families faced different barriers in receiving a diagnostic and treatment services for their children with ASD. Specifically logistic factors, cultural differences, and lack of knowledge acted as prominent barriers that hindered Latino parents' attempts to access services. Future research should examine ways to address the identified obstacles, and tailor interventions to be culturally relevant for under-resourced Latino families who must navigate large, bureaucratic systems of care.

145 **180.145** Age of Initial Caregiver Concern and Diagnosis in Asian Children at a Regional Satellite Autism Clinic

***M. Lambha**, Marcus Autism Center, Atlanta, GA*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication, interaction and restricted, repetitive patterns of behavior/interests (American Psychiatric Association, 2013). Studies have found that caregiver reports regarding initial age of developmental concerns in children occur between 12 and 24 months (Rogers & DiLalla, 1990; DeGiacomo and Fombonne, 1998). ASD diagnoses can be made as early as 24 months (Charman & Baird, 2002), allowing for earlier intervention, leading to improved outcomes (Dawson, Rogers, & Munson, 2010; Eapen, Crncec, & Walkter, 2013; Reichow, 2012). While prevalence rates of autism has increased and the age of diagnosis has decreased among US children, ethnic differences exist (CDC, 2014). Studies have begun to investigate ethnic differences in these areas, with some research finding that the age of initial caregiver concern and first diagnosis is older in Asians compared to other ethnicities (Daley, 2004; Mandell, et al, 2009).
Objectives: This study examined caregiver reports of age of initial concern with regard to their child's development and the age of first diagnosis in an Asian and clinical sample at a regional clinic. It was hypothesized that the age of first concerns and age of first diagnosis for the Asian sample would be significantly older than the clinical sample.
Methods: Data from a sample of 11 Asian children (ages 20 to 44 months) and the clinical sample of 119 children (ages 16 to 44) who were diagnosed with ASD at a regional clinic was used. Data from record review for the Asian sample included age (M=31.09 months), gender (male N = 10, female N = 1), and caregiver report of initial concern (M = 19.09). Similar data was obtained for the clinical sample: age (M = 29.78), gender (male N =99, female N = 20), and caregiver report of initial concern (M = 16.05). Data from the Asian sample were compared to the clinical sample children diagnosed with ASD at a regional clinic using an independent samples t-test.
Results: This sample of Asian children did not differ significantly from the clinical sample with regard to caregiver recognition of developmental concern (19 months and 16 months, respectively) or age of first diagnosis (31 months and 29 months, respectively). Further analyses will be conducted to examine possible relations between type of caregiver concern with age of first concern and age of first diagnosis.
Conclusions: These finding show that parents of Asian children and parents of the clinical sample of children at a regional clinic are reporting similar ages of initial concern. Additionally, these children are being diagnosed at a similar age. Although some studies have suggested that caregiver recognition of initial developmental concerns as well as age at first diagnosis are significantly older for Asian children, the results of this study are not showing these significant differences. These results are encouraging in that they suggest that Asian parents are recognizing concerns and having their children evaluated at an age similar to the clinical sample, allowing for earlier diagnosis and treatment of Asian children.

146 **180.146** Autism in a Korean American Evangelical Community

***P. S. Hong**[1], B. Leventhal[2], A. Sullivan[2], B. Kim[2] and Y. S. Kim[3], (1)Psychiatry, UCSF, San Francisco, CA, (2)UCSF, San Francisco, CA, (3)University of California San Francisco, San Francisco, CA*

Background: There are 1.7 million Korean-Americans in the United States. The majority of Korean-Americans, 71%, identify as Christian. Of Protestant Korean-Americans, 66% identify as evangelical Christian, the largest of any Asian or ethnic group in the United States. Korean-Americans underutilize mental health services, resulting in more severe diagnoses when and if services are eventually utilized. We sought to understand how cultural, spiritual, and religious processes might unfold and influence each other in shaping perceptions of autism spectrum disorder (ASD) in predominantly Korean-American church communities. While previous research has examined ASD in Korean speaking communities, little is known about perceptions toward ASD in predominantly Korean-American church communities where English is the primary spoken language (1.5 to 3rdgeneration).
Objectives: We wanted to generate themes in understanding the following: 1) explanations of ASD in spiritual communities that may encompass processes beyond material disease; 2) the immediate moral context in which the concrete experience of ASD plays out and is acknowledged, appropriated, and analyzed; 3) whether attitudes toward ASD differ from depression and, if so, in what ways and why; and 4) whether greater cultural assimilation may lead to differences in perceptions of ASD.
Methods: A mixed-methods approach was used combining participant observation, textual analysis, semi-structured interviews based on Arthur Kleinman's Explanatory Model, adapted Perceived Devaluation Discrimination Scale (PDDS), and narratives. The lead author conducted ethnographic work from May 2015 to May 2016 in a predominantly Korean-American, English-speaking, evangelical, nondenominational congregation. Twenty-eight attendees, including church leaders, children's ministry leaders, and members of varying commitment levels to the church were interviewed about their perceptions and/or experiences of ASD and/or mental illness. Analysis followed a deductive approach where data were categorized into themes based on existing theories around Kleinman's "What's At Stake" framework, based on how one finds meaning and is able to fully participate in a community. Emergent text from themes was generated using ATLAS.ti (qualitative analysis software), and relational themes were then merged.
Results: This exploratory study yielded numerous themes, indicating that social death is based on the degree to which people are able to achieve what matters most in the local context. A diagnosis of ASD was believed to negatively influence marriage prospects, career prospects, and close friendships. Salient spiritual explanations were held regarding depression, but not ASD, where spirituality was mentioned only in the context of finding support and meaning in a diagnosis. While understandings of symptoms varied, most understood ASD to be a genetic condition and did not feel it would stigmatize the entire family. Structural barriers to obtaining care were not cited. Semantic domains surrounding ASD differed from those found in previous studies in Korean-speaking groups.
Conclusions: Cultural, spiritual, and religious processes influence each other to produce experience of ASD. This study has created a framework by which to conduct research in churches as a step in effectively addressing unmet mental health needs, decreasing stigma, and encouraging the use of professional mental health services in Korean-Americans.

147 **180.147** Caregivers Needs of Persons with Autism Spectrum Disorders in Latin America: Results from Chile

R. A. Garcia[1], *M. Irarrazaval*[2], *S. Riesle*[3], *A. Moyano*[4], *M. Cabezas*[5], *A. Rattazzi*[6], *G. Garrido*[7], *C. S. Paula*[8], *C. Montiel-Nava*[9], *D. Valdez*[10], *A. Rosoli*[11], *S. H. Cukier*[6] *and F. Prieto*[12], *(1)Universidad de Chile, Santiago, CHILE, (2)University of Chile, Santiago, Santiago, Chile, (3)Independent, Santiago, CHILE, (4)Universidad de Chile, Santiago, Chile, (5)Clínica Las Condes, Santiago, Chile, (6)PANAACEA, Programa Argentino para Niños, Adolescentes y Adultos con Condiciones del Espectro Autista, Buenos Aires, Argentina, (7)Universidad de la República, Montevideo, URUGUAY, (8)Developmental Disorder Program, Mackenzie Presbyterian Univesrsity, Sao Paulo, BRAZIL, (9)La Universidad del Zulia, Gainesville, GA, (10)FLACSO, Buenos Aires, Argentina, (11)OEI, Santo Domingo, Dominican Republic, (12)Millenium Institute for Research in Depression and Personality, Santiago de Chile, Chile*

Background:
Research about autism spectrum disorders (ASD) and health and education services are limited. This study is part of a larger study based conducted in six Latin American countries (Argentina, Brazil, Chile, Uruguay, Panama, Dominican Republic) by the Red Espectro Autista Latinoamerica (REAL). Its purpose is to assess the needs of families with a member with ASD, in order to enhance awareness, improve services, and develop long-term policy solutions related to ASD.
Objectives:
Understand and analyze the major needs and challenges regarding access to health and educational services faced by families affected by ASD in REAL countries.
Methods:
Quantitative and qualitative description (n = 2965) study by online survey between Dec-2015 and April-2016, which assessed the needs of families affected by ASD.
Results:
292 Chilean families participated. The diagnosis most prevalent was ASD, being more common in men (8:1). There is a difference of 32 months between the age of early parental concerns ($\bar{x}$ = 28m) and age at diagnosis ($\bar{x}$ = 60m). The professionals more involved in the diagnosis are neurologists (45%) and psychiatrists (18%). There is limited access to health services, and few percent of subjects attend to Cognitive Behavioural Therapy (16%), Sensory Integration Therapy (13%), Ocupational Therapy (36%), Social Skills Therapy (22.3%) and Language Therapy (34.7%). Caregivers considered very important that the child has support for progress in school (83%) or make friends (75%), however 68% experience frustration in relation to their efforts to obtain services. 53% reported side economic problems because of ASD. Their priorities focus on ensuring adequate health services (23%) and education (29%).
Conclusions:
In Chile, there is a late diagnosis, along with low support and satisfaction in health and educational services delivery in children with ASD. These results provide scientific evidence for the development of strategies to improve the clinical and educational services available, and solutions that improve the quality of life of children with ASD and their families.

148 **180.148** Characteristics Associated with Drug Prescription and Compliance Among Children with Autism in South Israel.

G. Meiri[1,2], *H. Azoulay*[1] *and I. Menashe*[1], *(1)Ben-Gurion University of the Negev, Beersheva, Israel, (2)Pre-School Psychiatry Unit, Soroka University Medical Center, Beer-Sheva, Israel*

Background: Currently, there are no effective medical drugs to treat autism. Most medications that are given to people with autism are designed to treat other comorbidities (e.g. ADHD, epilepsy, insomnia, etc.). However, data regarding the prevalence of drug prescription and compliances to these medications in people with autism is limited
Objectives: To study the characteristics associated with medical drugs prescription and compliance among people with autism.
Methods: We studied the characteristics associated with medical drugs prescription and compliance in a population-based sample of children between ages 1-6 years who were diagnosed and followed at the Preschool Psychiatric Unit at the Soroka University Medical Center between the years 2006-2013. Autism diagnosis was determined using DSM-IV and re-confirmed using DSM-V criteria. Data about drug prescription and compliance was acquired from the electronic records of these patients. Drug compliance was calculated as the percentage of purchased drugs out of total prescriptions, and was divided into three categories: 0-49% - no compliance; 50-74% - partial compliance; and 75-100% full compliance.
Results: Of the 211 children in our sample, 50 (23.7%) received one prescription, 19 (9.0%) received two prescriptions, and six children (2.8%) received prescriptions to three or more drugs. The most prevalent prescription in our sample was to atypical antipsychotic drugs (49 children; 23.2%), followed by stimulants (28 children; 13.2%) and old generation antipsychotic drugs (16 children; 7.6%). Drug prescription was positively correlated with autism severity, and was associated with the ethnicity of the child and the type of comorbidities (P<0.001). Compliance to drug prescription was slightly higher among Bedouin than in Jewish children (P – 0.039), and was intriguingly low for stimulants (61%) compared to other drugs (P = 0.05). There was no association between drug compliance and autism severity in our sample.
Conclusions: Â Our preliminary finding suggest that prescription and compliance to medical drugs among children with autism are associated with various clinical and cultural characteristics which should be considered by physicians as part of the general treatment planning.

149 **180.149** Cross-Cultural Validation Study of Emotion-Based Social Skills Training for Children with Autism

M. G. Wong[1], *N. Ma*[2], *C. Tang*[2], *D. Dossetor*[3], *H. Baassiri*[3,4], *B. J. Ratcliffe*[5] *and D. Draybi*[2], *(1)The Children's Hospital at Westmead, Westmead, AUSTRALIA, (2)Transcultural Mental Health Centre, Parramatta, Australia, (3)The Children's Hospital at Westmead, Westmead, Australia, (4)Psychological Medicine, Transcultural Mental Health Centre/ The Children's Hospital at Westmead, Westmead, Australia, (5)Children's Hospital at Westmead, Westmead, AUSTRALIA*

Background:
Emotion-based Social Skills Training (EBSST; Wong et al., 2010) is a manualized therapy program that enhances the emotion competence of children with Autism Spectrum Disorder (ASD), reduces symptoms of mental disorders, and develops emotion coaching skills for parents and educators (Ratcliffe, Wong et al., 2014). EBSST was developed and evaluated in an English-speaking, Australian school context. EBSST program fidelity and effectiveness in other language and cultural groups is yet to be explored. Lau (2006) outlines methods of cultural adaptation of mental health interventions and highlights that cultural sensitivity to the values, concepts and ideas around children, families, disability, and mental health needs to be applied. In the ASD literature, two cross-cultural adaptation studies have been described for manualized social skills interventions: PEERS (Laugeson & Frankel, 2010; Yoo et al., 2014) and KONTAKT (Herbrecht et al., 2007; Olsson et al., 2016). In this study the cultural adaptation of EBSST to Chinese settings was undertaken. This was a joint project between Transcultural Mental Health Centre, who provide mental health interventions to people from culturally and linguistically diverse communities and the Children's Hospital at Westmead, where the EBSST program was developed and researched.
Objectives:
The aims of this study were: (i) develop a protocol for the cultural and language adaptation of EBSST; (ii) evaluate the effectiveness, feasibility and acceptability of Emotion-based Social Skills Training being delivered by bilingual psychologists to children with Autism and their families from the Australian-Chinese community; and (iii) identify adjustments to English-language EBSST that need to be made to maintain fidelity of the EBSST program for children with Autism and their families from the Australian-Chinese community.
Methods:
A convergent mixed-method approach involving quantitative and qualitative evaluation was applied. Six children with ASD aged 8 to 12 years and their parents from the Australian-Chinese community were recruited. Eligibility assessments were conducted using the Autism Diagnostic Observation Schedule (Lord, 2000) and cultural assessments were conducted based on the DSM-5 cultural formulation approach (American Psychiatric Association, 2013). Bilingual psychologists were trained and certified as EBSST facilitators and delivered 16 group EBSST sessions to children. Six group EBSST sessions to parents were delivered in the Chinese language, with culturally appropriate adaptations. Quantitative data on child emotions development and child and parent mental health was collected pre- and post-treatment. Qualitative data on treatment acceptability and feasibility was collected from children, parents and psychologists from questionnaires and semi-structured interviews.
Results:
EBSST for Australian-Chinese families demonstrated improvements on quantitative measures of child emotions competence and child and parent mental health pre- and post-treatment. Children, parents and psychologists all rated the intervention as acceptable and feasible.
Conclusions:
Cultural and language adaptations are important to consider when developing and delivering therapeutic interventions to children with ASD and their families from different cultural groups. The findings of this study will inform an international research collaboration between Australia and China where a control group trial of EBSST in a school for 80 children with Autism in China will be undertaken.

150 **180.150** Cross-Cultural Views of Autism: How Latino and Anglo Parents Report Symptoms of ASD

K. K. Stavropoulos*, J. Blacher, Y. Bolourian and A. N. Racataian, University of California - Riverside, Riverside, CA*

Background: Though ethnic and racial disparities have been reported in both diagnosis and treatment of mental health disorders, few studies have explored potential differences in how parents of varying cultural backgrounds perceive symptoms of autism spectrum disorder (ASD). Most have relied on hypotheses of socioeconomic and access barriers to explain findings, or cultural explanations for the less frequent reporting of symptoms and lower rates of ASD diagnosis among Latino children. Our 2014 published study of 83 families found that although Anglo mothers reported more developmental concerns, Latino children obtained higher severity scores on standardized measures of ASD.
Objectives: The current study was designed to extend our previous findings using a larger sample of Anglo and Latino families collected from a free screening clinic at the University of California, Riverside. We compared how mothers reported current concerns (22 autism-related questions) and ASD symptoms, in relation to their child's performance on standardized measures of ASD.
Methods: Â One-way ANOVAs were conducted (corrected for multiple comparisons where applicable).
Results: Using a sample of 181 families (n = 61 Anglo, n = 120 Latino), Anglo parents reported a significantly higher number of total current concerns compared to Latino parents $F(1,179) = 15.94$, $p < .000$. Using ADOS scores, children were sorted by categories of "non-spectrum", "autism spectrum" or "autism". No significant differences were observed in either ADOS domains for children who scored into the "autism spectrum" category. For children in the "autism" category (n = 25 Anglo, n = 28 Latino), Latino children scored significantly higher on both the social affect ($p < .000$) and restricted and repetitive behavior ($p = .002$) domains. Parent-reported levels of autism symptomology were available from 96 families (n = 49 Anglo, n = 47 Latino). Latino parents reported higher levels of autism symptoms versus Anglo parents for all five subscales (all ps < .029). Note that SRS measures were not scored until after the ADOS took place. Anglo and Latino families did not differ on reported level of income ($p > .1$). However, Anglo parents were significantly more likely to have received a Bachelor's Degree or higher compared to Latino parents ($p < .000$).
Conclusions: These data support the finding that Anglo and Latino parents differ in their perceptions of their children's symptomology.Â Latino parents reported more severe symptoms on the SRS in all domains, yet Anglo parents reported more current concerns during the interview. Finally, results from the ADOS suggest that Latino children who met ASD criteria scored significantly higher than Anglo children on both ADOS domains. Latino parents may not have been aware that the challenging behaviors or the lack of social awarenss thatÂ they observed in their child were related to ASD. Yet when asked directly about the frequency of behaviors (via the SRS), Latino parents reported more severe symptoms of ASD, consistent with examiners' observations on the ADOS.Â These findings provide evidence that regardless of SES, cultural context may affect how parents perceive autism symptoms, andÂ is an important consideration when interpreting parent-report measures.

151 **180.151** Developing a Global Framework for Improving the Lives of Individuals with Autism Spectrum Disorder

T. A. Lavelle[1], *D. T. Helm*[2,3], *M. W. Azeem*[4] *and K. M. Munir*[5,6], *(1)Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Institute for Community Inclusion, Boston, MA, (4)Sidra Medical and Research Center, Doha, Qatar, (5)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA, (6)Harvard Medical School, Boston, MA*

Background: With the growing global prevalence of Autism Spectrum Disorder (ASD), international governments and community members have struggled to meet the increasing needs of individuals with this condition, and their families.
Objectives: Our goal was to identify challenges currently facing communities worldwide in meeting the needs of individuals with ASD, and offer policy recommendations that would support these individuals and their families.
Methods: During the winter and spring of 2016 we conducted 23 semi-structured telephone interviews with a convenience sample of clinicians, researchers, policymakers, and non-profit workers with knowledge regarding ASD services in their country, or internationally. Participants were from 12 countries, ranging from low and middle income to high-income countries worldwide. We asked participants questions related to the current level of services provided in their country, barriers faced in expanding these services, and established practices for overcoming these barriers, if available. Interview data were analyzed using thematic analysis. Research was sponsored by the Qatar Foundation's World Innovation Summit in Health (WISH).
Results: From our interviews, five main themes emerged related to challenges faced in meeting the growing needs of individuals with ASD worldwide: early identification and diagnosis, offering evidence-based therapies, providing family support systems, enabling access to public education, vocational training and assisted employment, and participating in high-quality research and surveillance. Opportunities to overcome these barriers utilized resources available in the health, educational and social sectors of countries. Based on these challenges and opportunities, we developed three overarching recommendations for policymakers worldwide to coordinate the response to ASD, and affect substantive change: (1) Create an interagency coordinating commission to address ASD nationally, (2) Establish interdisciplinary training and research centers for excellence in ASD, and (3) Establish a global partnership framework to address ASD across the lifespan.
Conclusions: The guidance developed from this work will help governments enact policies that improve the lives of individuals with ASD, their families and their communities.

152 **180.152** Differences in Parenting Stress Between Monolingual and Multilingual Parents of Children with Autism Spectrum Disorder (ASD) Participating in an Early Intervention Study

L. M. Chiang[1,2], *W. I. Shih*[3], *A. Gulsrud*[2] *and C. Kasari*[3], *(1)Special Education, California State University, Los Angeles, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background:
As the U.S. immigrant population grows, it becomes pressing for researchers to develop culturally and linguistically responsive interventions to better address the needs of children with ASD and their families from diverse backgrounds. Studies have shown that multilingual parents are often discouraged from speaking their primary language to their children with ASD (Jegatheesan, 2011; Kremer-Sadlik, 2005; Wharton et al., 2000; Yu, 2013). In addition, multilingual parents, with or without high English proficiency, feel less effective in showing affection and expanding their children's language, thus precluding engaging interactions (Kremer-Sadlik, 2005; Wharton et al., 2000; Yu, 2009) and creating parenting stress (Jagatheesan, 2011; Yu, 2009; Yu, 2013). High parenting stress can have a detrimental influence on the effectiveness of intervention, negatively impacting children's outcome (Karst & Van Hecke, 2012). However, extant research on multilingual children with ASD and their families primarily focuses on child's language and social outcomes and rarely focuses on parental outcomes.
Objectives:
This study aims to evaluate stress reduction in monolingual (i.e. English as primary language) and multilingual parents across two treatment conditions, psychoeducational or caregiver-mediated, and to compare the group differences in stress reduction post treatment.
Methods:
Participants (n=86) were part of a larger research study comparing the effects of two parent-mediated interventions on joint attention outcomes of toddlers (22-36 months) with ASD. Parents reported their primary languages in a demographic questionnaire. Parenting Stress Index (PSI; Abdin, 1990) was used to assess parenting stress pre- and post-treatment. Two-way ANOVA was used to compare group differences in stress reduction between monolingual and multilingual parents across treatment groups.
Results:
65% of the participating caregivers were monolingual, with English as their only language, and 77.9% having a college or higher degree. Due to attrition and missing data, only 78 out of the original 86 participants were included (mean age=35.9); 78% of the participants that were not included are monolingual. Two-way ANOVA showed no statistically significant interaction between parents' language status and treatment assignment ($F_{1, 74}$= .995, ns).
Conclusions:
The results find no interaction between parents' language status and group treatment group on stress reduction. However, it is worth noting that majority of the parents participating this study are monolingual and having obtained a college or higher degree. Hence, this particular group of participants might have been at advantage in overcoming potential linguistic barriers, which could contribute to parenting stress, compared to lower-resourced families from culturally and linguistically diverse backgrounds. Future research should explore if accommodating parents' preferred language when developing parent education program and parent-mediated interventions directly reduces parenting stress.

153 **180.153** Effectiveness of Professional Development Training on Autism in Helping Professionals in Ethiopia: A Single Group, Pre-Post Design.

***W. Zeleke**, T. L. Hughes and N. Drozda, Duquesne University, Pittsburgh, PA*

Background:
Data is lacking in terms of how autism spectrum disorders (ASDs) are identified and managed in Africa, which is a pressing concern as autism prevalence has been increasing. Children with ASD in Africa are diagnosed later than children in other less impoverished areas of the world. This disparity may be related to sub-Saharan educators and helping professionals lacking awareness of ASD. The access to mental health services beyond the aforementioned sources is scarce, expensive, or inaccessible in Ethiopia. This lack of access to services results in limited attention for diagnostic processes, therapeutic interventions, and mistreatment of children. For example, a child in Ethiopia with a mental health diagnosis and challenges is likely to be rejected by public regular schools outright; because special education services are available only in few special schools, and few children have access to services (Tirusew, 2006). Additionally, regular public schools are encouraged, but not required by law, to accept children with disabilities (Zeleke, 2016). Further, most of the special schools are equipped only to provide education to children with visual and hearing impairments (Tirusew, 2006). These policies are a result of the lack of mental health training and limited educational backgrounds of the service providers and low levels of community awareness of mental health disorders. This highlights a need for drastic improvement in training of mental health disorders and interventions for health service professionals to provide adequate and appropriate services for the children they care for.
Objectives: Â The purpose of this study was to provide educators and health professionals (i.e. teachers, counselors, psychologists, therapists, therapeutic care workers, social workers, and nurses) with a basic understanding of Autism Spectrum Disorders over the course of ten in-service training days. Specifically we aim to examine the effectiveness of the training on participants' knowledge and understanding of the basic features of ASDs and evidence-based interventions associated with ASDs as well as how to tailor the interventions to fit cultural expectations.
Methods:
Using a single group, pre-post design, the level of awareness, knowledge, and understanding of ASDs treatment and intervention of 35 helping professionals who have been recruited for the professional development training by the host university, was measured. Data collection was the same for all participants. Once permissions were obtained, all participants completed a demographics questionnaire. All participants then received ten days of training about symptoms of and interventions for ASDs.
Results: Â Results identified significant positive changes in participants' awareness, knowledge, and understanding of evidence-based ASDs treatment and intervention..
Â Conclusions:
We believe that this study has important implications for the education of helping professionals about ASDs and culturally-competent, evidence-based interventions in Ethiopia. Because the program appears to be effective, we hope that with continuous professional development training over time, educators and healthcare professionals will be able to work more effectively in addressing the needs of children with ASDs in Ethiopia.

154 **180.154** Factor Analysis of the Parental Concerns Questionnaire in Children with Autism Spectrum Disorder

***F. Alnemary**[1] and F. Alnemary[2], (1)UCLA, Los Angeles, CA, (2)University of California, Los Angeles, CA*

Background:
The Parental Concerns Questionnaire (PCQ) a 13-itme interview-based rating scale designed to assess the presence and severity of developmental and behavioral concerns expr
disorder (ASD). The PCQ yields a single total score (13 to 52) that is reflective of overall symptom severity. Previous research has demonstrated the validity of PCQ in children wit
However, psychometrically-defined factors of the PCQ in children with ASD of non-English speaking parents have not yet been explored.
Objectives:
The purpose of this study was to adopt and examine the factor structure of the PCQ in children with ASD in Saudi Arabia.
Methods:
A total of 205 parents of children with ASD and were younger than 21 (M = 7.9; 3.5 SD) years responded to an online survey. An adapted version of the PCQ was used and factor
was utilized as the data were relatively normally distributed (*Costello & Osborne, 2005*) while the scree plot with the exclusion of the inflexion point's criterion was used to determir
Â
Results:
The 13 items scale appeared to underlie one factor with reliability above the acceptable limit (Cronbach's alpha = 0.80).
Â
Conclusions:

Table 1. Severity of the Autistic Symptoms Factor

Item: My child…	Fact
1- Language use and understanding (Doesn't use words, has difficulty initiating conversations).	
2- Compulsive behavior (Completes routines always in the same manner).	
3- Anxiety (Shows distress from new situations or crowds).	
4- Sensory issues (Reacts to lights, sounds, textures).	
5- Sleep disturbance (Does not fall asleep easily, wakes often).	
6- Aggression (Intentionally hits, bites others).	
7- Hyperactivity (Is constantly moving, jumping, and running).	
8- Attention span (Has difficulty finishing a task).	
9- Mood swings (Has unpredictable changes between emotions).	
10- Eating habits (Eats few foods/certain types of food).	
11- Mood swings (Prefers to be alone has few friends).	
12- Self-stimulatory behavior (Rocks, spins, flaps hands).	
13- Self-injurious behavior (Bangs head, pinches, bites, hits oneself).	

The Arabic version of the PCQ shows promise for assessing the overall symptom severity in children with ASD. Additional exploratory factor analyses may provide further support

155 **180.155** Family Empowerment and Caregiver Strain Among Ethnically Diverse Caregivers of Children with ASD or ADHD

J. Safer-Lichtenstein[1]*, L. G. Anthony*[2]*, L. Kenworthy*[2]*, A. B. Ratto*[3]*, S. Seese*[2]*, A. D. Verbalis*[2]*, B. J. Anthony*[4]*, M. Biel*[1] *and R. Mendez*[4]*, (1)Georgetown University, Washington, DC, (2)Children's National Health System, Washington, DC, (3)Children's National Medical Center, Washington, DC, (4)Center for Child and Human Development, Georgetown University, Washington, DC*

Background:
Caregivers of children with developmental disabilities experience significantly greater stress than parents of typically developing children (Baker et al., 2003). These challenges have been thought to be even greater for ethnic minority parents who face additional difficulties related to socioeconomic status, access to health care and information, and language barriers. However, in previous studies Latino parents have self-reported less family burden than Black and non-Latino White parents (Biel et al., 2015).
Objectives:
This study seeks to compare the extent to which diverse caregivers of children with ASD or ADHD feel strained by their children's difficulties, feel confident in their abilities as caregivers, and feel confident in their ability to use the mental health systems that impact their child.
Methods: Â
Participants in the current study were 103 parents of children diagnosed with ASD (n=33) or ADHD (n=70) who were participating in a larger study comparing two interventions for executive dysfunction. Participants were drawn from Title I eligible schools in the Washington, D.C. area, which resulted in an ethnically and socioeconomically diverse sample (Table 1). White caregivers reported significantly higher levels of income and education than Black and Latino caregivers.
Caregivers completed three self-report measures: the Caregiver Strain Questionnaire-Short Form 7 (CSQ-7) (Brannan et al., 2012), and the Competence and Self-Efficacy subscales of the Family Empowerment Scale (FES) (Singh et al., 1995). Each measure consisted of 5-point Likert scale items. Measures were offered in English and Spanish and presented in paper form or orally by study staff, depending on caregiver preference.
Results:
Overall, the FES Competence total score had a significant negative correlation with CSQ-7 total score, indicating that increased strain was associated with decreased perception of parenting competence (r=-.334, p<.01). FES Competence total score had a significant positive correlation with FES Self-Efficacy total score, (r=.470, p<.01). There was no relationship between FES Self-Efficacy and CSQ-7.
Latino caregivers total scores were higher than White or Black caregivers on both the FES Competence and Self-Efficacy subscales; however, one-way ANOVAs revealed that these differences were only significant for the Competence scale, (F(2,83) = 7.92, p<.001). Post hoc analyses indicated that mean scores were significantly higher for Latino caregivers than White caregivers for 6 of 8 individual items on the Competence scale (Table 2).
No significant differences by race/ethnicity were found for the CSQ-7.
Conclusions:
Studies have shown that although Latino parents report high levels of problem behaviors in their children, they perceive less impact of these problems on family burden. Consistent with these findings, Latino parents of children in this study did not report greater caregiver strain than parents of other racial/ethnic backgrounds. Moreover, Latino caregivers of children rated themselves higher on measures of parenting competence. Of note, many Latino parents chose to complete the measures verbally. Thus, their higher ratings of parenting competence may reflect pressure to provide socially-desirable responses. Future studies need to clarify this increased confidence in parenting abilities among Latinos and how it relates to seeking and accepting services.

156 **180.156** Feasibility of a Smartphone Application to Identify Young Children at Risk for Autism Spectrum Disorder in a Low-Income, Community Setting in South Africa

A. J. Kumm[1], *K. Campbell*[2], *S. Marsan*[3], *J. Hashemi*[4], *S. Espinosa*[4], *R. Bloomfield*[4], *G. Dawson*[3], *G. Sapiro*[4], *H. Egger*[5] *and P. J. de Vries*[6], *(1)Vredehoek, University Of Cape Town, Cape Town, South Africa, (2)Duke Center for Autism and Brain Development, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (4)Duke University, Durham, NC, (5)Child and Adolescent Psychiatry, NYU Langone Medical Center, New York, NY, (6)University of Cape Town, Cape Town, SOUTH AFRICA*

Background:
More than 90% of children with autism spectrum disorder (ASD) live in low- and middle-income countries (LMIC) where there is a great need for culturally appropriate, scalable and effective early identification and intervention tools. Smart phone technology and application ('apps') may potentially play an important role in this regard. Here we investigated the feasibility of a mobile application that elicits and quantifies social referencing and positive emotional behaviours in young children to detect risk for ASD.
Objectives:
Our aim was to determine the technical feasibility and cultural appropriateness of the Autism&Beyond iPhone application to determine risk for ASD in children aged 12-72 months in a naturalistic, low-income South African community setting.
Methods:
Parents of typically-developing African children were recruited from community centres in Khayelitsha Township, Cape Town, South Africa. With appropriate ethicsÂ and consent, parents completed a short technology questionnaire, followed by an iPhone-based demographic and ASD-related questionnaires. Next, children were shown 4 videos of 30s each on a study smartphone while sitting beside or on a parent's lap. The smartphone front facing ("selfie") camera recorded video of the child's facial expressions and head movement. After home-based administration of the app, a subset of families were invited to participate in focus group discussions. For the purpose of this presentation, we examined 1) parental familiarity with and access to smartphones, internet and apps, and 2) parental feedback about the cultural acceptability and accessibility of smartphone technology using apps in the local community.
Results:
A total of 45 families participated in this part of the feasibility study. Parent participants had a mean family income less than $30 per week, representing the lowest socio-economic group in South Africa. The majority of parents (38/45, 84%) owned a cellphone, of which 79% were smartphones. Interestingly, no participant had an iPhone. 13/45 (29%) had email, 24/45 (53%) had a social media account, and 20/45 (44%) used WhatsApp. 10/45 (22%) had internet access at home and 6/45 (13%) and 6/45 (13%) access to WiFi. Interestingly, 27/45 (60%) used mobile data. 25/45 (55%) rated their proficiency using a cellphone as good to very good. Thematic analysis of focus group discussions indicated that families found the app relatively easy to use, and would recommend it to others in their community. Parents did not have any concerns about the fact that videos were 'American', but made a number of recommendations to localise the app. A key theme from families was the importance that the app must be free, and that data transfer should not be at a cost to them.
Conclusions:
The technical feasibility and cultural appropriateness evaluation in this very low-resource community in South Africa suggested that smartphone technology and apps may be a useful tool to reach families for early identification of ASD risk, provided the need for an android platform and free access to app and data to make this feasible. Further evaluation of the children's performance on the app, accuracy of the automated coding, and comparison with US data will extend these early observations.

157 **180.157** In Search of Culturally Appropriate Autism Interventions for Latino Families

M. DuBay*, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Latinos represent the fastest growing minority population in the United States, and the proportion of Latino children with autism spectrum disorder (ASD) in early intervention programs (i.e., for children birth to 5 years of age) shows concomitant increases. Despite these changing demographics, the vast majority of evidence-based ASD interventions have been designed for and tested with mostly White, mid-upper class, monolingual English-speaking populations. Unfortunately, research suggests that interventions that are incongruent with a target population's culture may be less effective. Specifically, participation rates and response to treatment may be reduced. To either adapt current evidence-based interventions or design new interventions for Latino populations, we must have input from members of the Latino community, including knowledge of families' perceptions of intervention models and components of evidence-based practices.
Objectives: The first aim of this mixed methods study was to determine if there were quantitative differences in the ways that Latino Spanish-speaking (LSS) families and non-Latino White English-speaking (NLW) families rate the family-centeredness and helpfulness of their interventions. We hypothesized that because many evidence-based interventions were not designed or tested with LSS families, that these families would perceive lower levels of family-centeredness or helpfulness. The second, qualitative, aim of the study was to identify intervention models, strategies, and targets that are perceived as more culturally appropriate, feasible, and acceptable for LSS families, and to understand the variability that likely exists among these families.
Methods: NLW (n=27) and LSS (n=25) parents of young children with ASD completed the Family Outcomes Survey and Measure of Processes of Care as measures of helpfulness and family-centeredness of intervention, respectively. Additionally, LSS parents and other caregivers of young children with ASD shared perspectives of their child's interventions through focus groups. Topics of discussion included caregivers' level of involvement in therapy, perceptions of caregiver-mediated intervention models, as well as the feasibility, acceptability, and appropriateness of a number of several prominent evidence-based ASD strategies (prompting, video modeling, naturalistic interventions, and discrete trials) in the context of their own family.
Results: Contrary to expectations, preliminary survey results indicate that NLW parents report that intervention is less helpful in teaching parents to help their child develop and learn compared to LSS parents ($t = 2.11$; $p < .05$). However, LSS parents reported having fewer friends or family to rely on for support ($t = 2.48$; $p < .05$). Focus group participants reported a wide range of levels of involvement in therapy and perceptions of the benefits or drawbacks for specific intervention strategies. Preliminary thematic analyses revealed that parents almost unanimously wanted training and education on how to carry out interventions in the home environment even when children receive intervention in the school setting. Other themes will be discussed.
Conclusions: Findings suggest a need to provide specific, ongoing caregiver training and support to families of children with ASD, even for parents of preschool and school-age children. Specific strategies to culturally adapt interventions will be discussed. Future research should examine the benefits of caregiver training and support interventions at the preschool and school-age levels.

158 **180.158** Inclusive Education of Students with ASD in the Province of Misiones, Argentina. Support Devices, NEEDS and Views of People with ASD, Their Families and Teachers.

D. Valdez[1,2], *E. E. Iginio*[3], *J. Mazal*[4] *and V. P. Obermann*[4], *(1)FLACSO, Facultad Latinoamericana de Ciencias Sociales, Buenos Aires, Argentina, (2)Universidad de Buenos Aires, Buenos Aires, Argentina, (3)Creer y Crear. Ayudas para las personas con TEA, Posadas, Argentina, (4)Creer y Crear. Ayudas para las Personas con TEA, Posadas, Argentina*

Background: The central issue of our research focuses on the perception of the students with ASD, their families and the various school actors (teachers, support teachers, principals) on the processes of inclusion in mainstream schools of students with ASD in Misiones. Misiones is a province located in Northeastern, in Argentina. Its population is descended from local Aboriginal communities and European immigration. There are no epidemiological studies of ASD in the region or data known about health and educational services for people with ASD and their families. We believe that this study can initiate a deeper understanding of the topic to promote public policies that address the needs of families in the area.
Objectives: Inquire about the dynamics of educational intervention among actors (teachers, families, support teachers, students with ASD) during the process of educational inclusion in the Province of Misiones, Argentina. Identify the needs of students with ASD and their families related with support devices, access to schools and health services. Explore what human and material resources are involved in the process of inclusion of students with ASD in Misiones.
Methods: Participants: 30 students with ASD through surveys completed by support teachers, families, teachers and students with ASD included in mainstream schools in Misiones. 4 types of surveys were developed: "T" Teachers, "F" Family, "ST" Support teachers and "S" Students. The "T" survey: eighteen (18) statements and questions was given to different teachers of students with ASD. The "F" survey: nineteen (19) statements and questions was given to different family members who are responsible for students with ASD. The "ST" survey: thirty (30) statements and questions was given to support teachers. The "S" survey: thirteen (13) statements and questions was given to different students with ASD included in mainstream schools.
Results: After data collection, we will proceed to process the acquired data for further analysis and interpretation, considering the different variables and interaction of surveys.
Conclusions: In practice, the support teacher has multiple functions such as: intervening with specific support in schoolwork, promoting relationships with class teachers and peers, and advising principals and teachers. This supporting device constitutes a scaffolding which is taken away gradually. The teacher intervention includes three levels: a) the relationship between the main teacher and the student; b) the relationship between the student and his schoolmates; c) the relation with the classroom's tasks, learning process and academic skills. The figure of the support teacher points one of the possible ways of re-including students that were excluded from school. The necessary changes are not possible without inclusive educational policy proposals. The inclusive education become a key area to create educational spaces that assume a commitment to understand the difference instead of deny it or exclude it. The educational research in the area may also be a source of dialogue, growth and search for new ways of teaching. The challenge is to minimize barriers and increase opportunities for people with ASD, to guide schools through a process of inclusive school development in Latin American countries.

159 **180.159** Initial Reaction to an Autism Diagnosis of Their Young Child: Findings from Interviews with 15 Mongolian Mothers

***M. S. Kaff**, Kansas state university, Manhattan, KS*

Background: Â Since its independent status as a democratic nation, Mongolia has worked to improve its educational system. OnlyÂ recently have the educational needs of children with disabilities come to the nation's attention. In particular, little information is available about autism.
Objectives: Â This study explored the impact of having a child with an autism spectrum disorder (ASD) on mothers and families using phenomonological theory, whereby a phenomenon that is otherwise difficult to explain "is brought to expression" (Gadamer, 1975/2006, p. 131). Two micro-level theories guided the study: (a) the relationship between mothers and their child with ASD and (b) the sociocultural context of Mongolia.
Methods: The study used a set of semi-structured interviews and the Parenting Stress Index (PSI-4; Abidin, 2012). The PSI-4, designed to evaluate the magnitude of stress in the parent–child system, focuses on three domains of stress: child characteristics, parent characteristics, and situational/demographic life stress.
The interviews and administration of the PSI-4 took place in fall of 2016 in Ulaanbaatar, Mongolia's capital. Participants were a group of mothers of children, ranging in age from 2.5 to 5.5, who had been diagnosed in July 2016. The children were enrolled in an NGO focusing on autism.
Interview questions addressed:
Initial response to the diagnosis, including that of the immediate family
Hopes and fears for the child
Changes to family life as a result of the diagnosis of ASD
Presentation of autism to the wider community
Results: Results showed that the mothers' total stress was within normal limits. However, the child domain in each instance was significantly higher than the parental domain; that is, the child with ASD was the major source of parental stress. In particular, of the seven subscales making up the child domain, distractibility, reinforces parent, mood, and acceptability, received the highest scores.
Findings showed (a) initial fear, (b) recognition of need for more information, (c) gradual acceptance of the diagnosis, and (d) determination, surrounded by varying degrees of hesitancy, to explain ASD to others in hopes of creating understanding and tolerance for the child. Mothers' hopes centered on their child's ability to live an independent life; their main worry was what would happen to the child when the parents were no longer around to care for them, given the lack of support and services. Finally, with regard to changes in the family as a result of the ASD diagnosis, most mothers noted that they had become more patient, more family-focused, and less judgmental of others.
Conclusions: While most of these findings are similar to those of similar studies in the United States, what clearly stands out is the added stress and challenge of living in a society where knowledge and understanding of autism is just emerging and services, therefore, limited or nonexistent. One of the keys to relieving parental stress came directly from the mothers. They spoke repeatedly of the need for parent training and further education. Implications for working with families with ASD

160 **180.160** Intersectoral Collaboration in Autism Screening and Surveillance - a Four Year Trend from Lagos Nigeria.

***Y. O. Oshodi**[1], E. A. Campbell[2], B. Fadipe[2], A. T. Olagunju[1], M. A. Oyelohunnu[3], C. S. Umeh[4], A. E. Lamikanra[5], A. Lesi[6] and J. D. Adeyemi[1], (1)College of Medicine, University of Lagos, Lagos, Nigeria, (2)Lagos University Teaching Hospital, Lagos, Nigeria, (3)Lagos University Teaching Hospital, Lagos, NIGERIA, (4)Psychiatry, College of Medicine University of Lagos, Lagos, Nigeria, (5)Blazing Trails International, Frisco, TX, (6)University of Lagos, Surulere, Lagos, NIGERIA*

Background: There is a recurring reminder about the need for research to be carried out to determine the burden of Autism in Africa along with the need to address the service gap and related challenges in autism care in many African countries. The perennial non availability of trained personnel which are few and scattered all over the country, making them inaccessible in many regards. Non availability of resources, lack of awareness, and lack of political will to provide solutions continue to worsen these challenges. Collaboration in providing solutions for autism diagnosis for those in need along with the willingness to explore what available options to service provision in this setting, can an be important first step. It is important that health care providers also get trained to identify and appropriately manage cases of ASD and Policymakers are encouraged to focus on providing the necessary infrastructure to manage this condition. One anticipates that when all stakeholders play a roles at varying levels there will be a more sustainable solution evolovlving to address this challenge.
Objectives: This report aims to describe the findings, processes and strengths of a community surveillance program over a period of 4 years (2013,2014, 2015 and 2016).
Methods: The GTB-CMUL autism program is a collaboration run as part of the Orange Ribbon initiative of Guaranty trust bank. The annual exercise involves two broad approaches: firstly the organizing of seminars and secondly, conducting consultative sessions with clients with features suggestive of ASDs often undiagnosed formally. Mode of recruitment is directly from community ; via email invitation, letters to special schools, verbal invitation, print media and radio jingles. Clinical evaluation sessions held over 5 day periods each year. The clinical portion findings are reported here. Clinical evaluation was conducted multidisciplinary team of volunteers. Assessments were made based on the DSM 5 Criteria for Autism.
Results: The collaborative team drawn from the private sector, public sector and academia comprised multidisciplinary professionals involved in autism care. The 4 year experience in program execution reported here showed a total of 626 individuals with neurodevelopmental disorders seen in this time frame. A significant proportion of subjects screened each year met criteria for ASD. For Majority this consultation was their first contact with formal orthodox care. Most of the caregivers suffered significant distress and were enrolled to support groups. The program consistently required to provide appropriate referrals to local services and parental inclusion to much needed support groups.
Conclusions: This program highlights how much can be achieved through team work and commitment. In the face of scarce resources committed collaborative efforts is a useful recourse to ensuring service delivery in Africa where there are little or no ASD relevant services. Monitoring, evaluation and quality assurance processes need to be continually included and reviewed in such programs going forward.

161 **180.161** Khaleeji Parents 'perspective on the Impact of Autism and Stuttering on Their Daily Life.

M. Indargiri *and D. Ward, University of Reading, Reading, United Kingdom*

Background:
Developmental stuttering (DS) arises in childhood, most commonly in the preschool years, for reasons, which are currently not well understood. Current thinking points to multifactorial underpinnings, including the interaction of linguistic, motoric, neurological, environmental and genetic influences.
It is also known that developmental stuttering (DS) can co –occur with a number of communication disorders-including Autism spectrum disorder (*Blood, Blood, Maloney, Meyer,& Qualls ,2007)*. Although there is a lack of research and a very limited evidence on the prevalence of stuttering/disfluency in children with ASD, but there have been several documented cases of stuttering in ASD (Scaler Scott et al., 2006).
Autism spectrum disorder (ASD) is a group of neurodevelopmental disorders, which manifest in the early years of the child's life and characterized by difficulties in social interaction, communication and repetitive behaviors/restricted interests, in varying degrees.Since, stuttering is the result of a number of coexisting factors and that these factors influence the onset, impact, and prognosis of stuttering (Rustin, et al., 1996), each child has his own set of factors combination that makes him/her vulnerable to stuttering (Rustin et al., 1996;Startkweather & Gottwald, 1990;Wall & Myers, 1995). Clinical experience has demonstrated that working with parents and carers to modify some of these behaviors such as slowing the rate of speech and improve turn taking, are often helpful in facilitating fluency (Stephenson-Opsal and Bernstein-Ratner 1988; langlois and long 1988;Guitar et al.,1992) .
Â **Objectives:**
To investigate 1)what are the potential factors that makes children with autism spectrum disorders vulnerable to stuttering in a non- western culture from a parent's perspective,Â 2) parental attitudes and perceptions towards stuttering and autism in Arabic culture since it has been well studied in western cultures. 3) and whether concomitant disorder has an effect on the types ofÂ service delivery to these children.
Methods:
A mixed methodology approach using self –completion, well structured questionnaire that will be distributed to around 100 – 300 Khaleeji parents (Saudi,Oman,Kuwait,Qatar)with children under the age of 18 , from different regions across the Gulf, to access their views, perception and beliefs on: the causes of stuttering and autism; strategies they have used to help their child; impact of stuttering and autism on the child's every day life;impact ofstuttering and autism on parents;level of concern and their views and experiences of the therapy process with the existence of concomitant disorder such as ASD .
Results: Results will be available in few months.
Conclusions: N/A

162 **180.162** Knowledge, Self-Efficacy, and Attitudes Toward Inclusion Among Teachers of Students with ASD in Lebanon

J. Chebli[1], N. Najjar Daou[1], R. Obeid[2], P. J. Brooks[3] and ***K. Gillespie-Lynch****[4], (1)American University of Beirut, Beirut, Lebanon, (2)CUNY Graduate Center, New York, NY, (3)College of Staten Island, Staten Island, NY, (4)Department of Psychology, College of Staten Island and The Graduate Center, CUNY, New York, NY*

Background: More children with ASD are being included in general education classrooms, consistent with the philosophy of inclusion which states that schools should adapt their practices to meet student needs (Kinsella & Senior, 2008). Successful outcomes for children in inclusive classrooms depend largely on teacher self-efficacy, which is potentially enhanced with preservice training and field placement (Atiles et al., 2012); their ASD knowledge; and their attitudes toward inclusion (Rafferty & Griffin, 2005). These are critical in low-resource countries, such as Lebanon (Obeid et al., 2015). Most Lebanese schools lack the needed support and trained staff to run effective programs for children with ASD.
Objectives: (1) To examine the effects of knowledge and stigma about ASD and attitudes toward inclusion on teacher self-efficacy at baseline. (2) To assess the impact of an in-person training lecture on knowledge about ASD, stigma toward ASD, attitudes toward inclusion, and self-efficacy of teachers.
Methods: A within-subject quasi-experimental design assessed whether the training was associated with changes in the aforementioned variables. Participants completed a pre-test, an hour-long lecture-based training about ASD, and a post-test administered four weeks after training. The training included a 63-slide presentation adapted from Gillespie-Lynch et al. (2015), involving information about ASD and inclusion, effective tools/interventions; it was provided in group sessions at two inclusive schools in Lebanon. Seventy-six teachers completed the pretest, 58 also completed the training and post-test. Measures consisted of questionnaires assessing self-efficacy, attitudes toward inclusion, knowledge and stigma toward ASD.
Results: There was a significant positive correlation between knowledge and self-efficacy; $r = .20$, $p = .044$. The model with the predictors (knowledge, stigma, attitudes toward inclusion) was not significantly better than the mean in explaining the variance in baseline self-efficacy, $F (3, 71) = 2.01$, $p = .111$.
Participants scored lower during pretest ($M = 7.57$, $SD = 4.96$) on the knowledge scale than during post-test ($M = 10.83$, $SD = 5.28$), t (46) = -4.28, $p < .001$, $r = 0.5$.
Participants had lower levels of self-efficacy at pre-test ($M = 4.06$, $SD = .49$) compared to posttest ($M = 4.23$, $SD = .44$); $t (57) = -2.55$, $p = .007$, $r = .18$.
Conclusions: Higher ASD knowledge was associated with greater self-efficacy among Lebanese teachers; this is consistent with work demonstrating that higher knowledge about strategies to support students with ASD is associated with more confidence in their ability to act as instructional leaders among administrators in the U.S. (Pazey et al., 2014). Participation in the training was associated with improved ASD knowledge and self-efficacy, which is consistent with previous research wherein online or in-person trainings were associated with increased ASD knowledge among college students and teachers (Gillespie-Lynch et al., 2015; Leblanc et al., 2009). Training teachers to work effectively in inclusive settings is critical, especially in low-resource regions where the limited inclusive schools are under-supported. Effective trainings would enhance conceptions of ASD, attitudes toward inclusion, and self-efficacy, and ultimately the process of inclusion would improve (Cross et al., 2004), leading to more inclusive schools in low-resource countries.

163 **180.163** Maternal Race-Ethnicity, Immigrant Status, Country of Birth, and the Odds of a Child with Autism

J. Fairthorne[1], *N. de Klerk*[2], *H. Leonard*[3], *L. A. Schieve*[4] *and M. Yeargin-Allsopp*[5], *(1)Telethon Kids Institute, Subiaco, Perth, WA, Australia, (2)Biostatistics, Telethon kids Institute, Perth, Australia, (3)Disability, Telethon Kids Institute, West Perth, AUSTRALIA, (4)Centers for Disease Control and Prevention, Atlanta, GA, (5)Centers for Disease Control and Prevention (CDC), Atlanta, GA*

Background:
The risk of autism spectrum disorder (ASD) varies by maternal race-ethnicity, immigration status and birth region.
Objectives:
We aimed to estimate the odds of ASD with intellectual disability (ID) in the children of women by maternal race-ethnicity, immigration status and birth region whilst adjusting for maternal age, parity, socio-economic status, and birth year of the child.
Methods:
In this retrospective cohort study, Western Australian state registries and a study population of 134,204 mothers enabled us to examine the odds of ASD with intellectual disability (ID) in children born from 1994-2005, by maternal race-ethnicity, immigration status and birth region whilst adjusting for the traits described previously.
Results:
Indigenous women were 50% less likely to have a child with ASD with ID than Caucasian, non-immigrant women. Overall, immigrant women were 40% less likely to have a child with ASD with ID than non-immigrant women. However, Black women from East Africa had more than three and a half times the odds of ASD with ID in their children than Caucasian non-immigrant women.
Conclusions:
Research is implicated on risk and protective factors for ASD with ID in the children of immigrant women.

164 **180.164** Mexican Pediatricians´ Role in the Early Identification and Intervention of Autism Spectrum Disorder

A. E. Zúñiga[1], *P. Sanchez Lizardi*[2], *A. Pego*[3] *and L. Romero*[3], *(1)Centro Psicopedagogico Montes Urales, Mexico City, Mexico, (2)School of Psychology, Universidad Panamericana, Mexico, D.F., Mexico, (3)IPSOS, Mexico City, Mexico*

Background: Â Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that usually manifests itself before age two.Â It principally affects a person's social communication and behavior, but impairment in other developmental domains (e.g., cognitive, motor) is frequently observed. The presence of these behaviors at such an early age provides a knowledgeable health care practitioner with an opportunity to refer a young child to a specialist in ASD to conduct a comprehensive evaluation and diagnosis. In this study, we surveyed the knowledge of Mexican pediatricians with respect to early signs of ASD as well as their perception about the challenges of treating patients with autism.
Objectives: Â N/A
Methods: Â In order to address this question, we conducted face-to-face interviews with 400 pediatricians (33% female) in private practice in Mexico City (n=200), Guadalajara (n=100), and Monterrey (n=100). In order to qualify for the interview, the pediatricians had at least 10 years of clinical experience. Our interview included questions used in other studies with adaptation to the Mexican population, including questions about prevalence, behavioral characteristics and diagnostic criteria, early signs, effective interventions and treatment, and continuing education. Each interview lasted, on average, 40 minutes. Pediatricians were paid their hourly fee for participating in the interview.
Results: Only 12% of the participants reported a number close to the actual prevalence of ASD in Mexico (1 in 115), with the remaining pediatricians reporting outdated data (between 1 in 300 and 1 in 1000). With regards to the male/female ratio, 43% of pediatricians reported the accurate 4 to 1 ratio. In relation to the diagnostic characteristics reported in the DSM-5, almost 50% of the participants correctly identified repetitive and restricted patterns of behaviors, 46% reported reactions to loud noises, 38% mentioned unusual responses to physical contact, 35% difficulties in social communication and social interaction, and 28% difficulties in the use of gestures for communication. When talking about early signs, 57% of participants correctly identified abnormal eye contact and playing alone, 47% language delays, and 39% repetitive motor movements. Only 18% of the participants reported reduced social response to name and 30% repetitive patterns of behavior as early signs of ASD. When asked about effective interventions and treatment, 36% mentioned that some form of therapy (language, behavioral and psychological) was the most effective intervention to improve the course of ASD and that follow up with neurologists and psychologists was also effective according to 34% of the interviewed. Finally, 56% reported that they participate in activities related to continued education, 40% in a Pediatrics National Conference (Mexico); however, this conference is not specific to ASD.
Conclusions: Results indicate that Mexican pediatricians have limited knowledge specific to early identification and diagnosis of ASD. Given that early identification allows for the provision of early treatment, which has been demonstrated to improve the quality of life of children and families impacted by autism, it is of utmost importance that pediatricians obtain specialized training to better serve Mexican children at risk of ASD.

165 **180.165** NEEDS, Quality of Life and Stigma of Families of Persons with ASD in Peru. Implementation of the LATIN American Autism Spectrum Network Caregiver NEEDS Survey.

S. Manrique[1], M. D. L. A. del Castillo[2], A. Barreto[2], S. H. Cukier[3], R. A. Garcia[4], G. Garrido[5], C. Montiel-Nava[6], C. S. Paula[7], A. Rattazzi[3], A. Rosoli[8] and ***D. Valdez***[9,10], *(1)CPAL. Centro Peruano de Audicion, Lenguaje y Aprendizaje., Lima, Peru, (2)CPAL, Lima, Peru, (3)PANAACEA, Programa Argentino para Niños, Adolescentes y Adultos con Condiciones del Espectro Autista, Buenos Aires, Argentina, (4)Universidad de Chile, Santiago, CHILE, (5)Universidad de la República, Montevideo, URUGUAY, (6)La Universidad del Zulia, Gainesville, GA, (7)Developmental Disorder Program, Mackenzie Presbyterian Univesrsity, Sao Paulo, BRAZIL, (8)OEI, Santo Domingo, Dominican Republic, (9)FLACSO, Facultad Latinoamericana de Ciencias Sociales, Buenos Aires, Argentina, (10)Universidad de Buenos Aires, Buenos Aires, Argentina*

Background: ASD knowledge, services and research infrastructure in Latin America are limited and unevenly distributed. In Peru there are no epidemiological data on ASD nor accurate data on health and educational services for people with ASD and their families. This research collects data from Peruvian families to meet their needs, their quality of life and if they have suffered stigma from diagnosis of ASD. In 2015, researchers from Argentina, Brazil, Chile, Uruguay, Venezuela and Dominican Republic constituted the Latin American Autism Spectrum Network (Red Espectro Autista Latinoamerica – REAL) in order to conduct international research collaborations related to ASD. The first project undertaken by REAL was the translation, adaptation and implementation of the AS Caregiver Needs Survey. The AS Caregiver Needs Survey was developed by Autism Speaks to assess the needs of families affected by autism in partner countries of its Global Autism Public Health Initiative.
Objectives: To provide a comprehensive picture of the major needs and challenges faced by families affected by ASD in Peru with the purpose of successfully enhancing awareness, improving services, and developing long-term policy solutions related to ASD. Peru data will be compared with data obtained by Latin American countries belonging to the REAL Network (2016). Identify the characteristics of the diagnostic process regarding alerted symptoms, diagnosis time, professionals involved, distance had to travel to get the diagnosis in Peru. Knowing the perceptions of caregivers regarding: Needs; Impact of diagnostic and/or therapeutic processes in the family; Stigma associated with a diagnosis of autism; Quality of life of the family and the person with ASD; Challenges related to parenting/care of a person with autism; Initial diagnosis and/or difficult to obtain
Methods: The Caregiver Needs Survey will be broadly disseminated via social networks in Peru during a period of 4 months (November 2016-February 2017) so that caregivers can complete it online, either assisted by a clinician or not. The survey solicits information about family demographics, affected individual characteristics, service encounters and parent/caregiver perceptions, including stigma. It is estimated that more than 300 surveys will be completed in total. After the collection of completed surveys, REAL researchers will proceed to data cleaning and data analysis, and will draft a country report. Peruvian data will be compared with other Latin American countries.
Results: A summary of the results from the Caregiver Needs Survey in Peru will be presented, and regional similarities and differences will be analyzed.
Conclusions: The assessment of needs and challenges faced by families affected by ASD in Peru is essential for the identification of knowledge gaps, service needs, and stigma. It is also important in the development of culturally relevant strategies for raising autism awareness, guiding the implementation of successful and improved ASD clinical and educational services at the national and regional levels and setting priorities for future national and regional research collaborative efforts. In this era of globalization, REAL is an attempt to generate a collaborative workforce in order to readily identify the best ways to approach issues related to ASD in Latin America.

166 **180.166** Parents' Experiences and Views of Screening and Diagnostic Assessment for Autism Spectrum Disorders (ASD) in Hong Kong: A Mixed-Methods Study

H. Yi[1], *Q. K. Y. Siu[1], F. Y. D. Chan[2], J. Greenberg[3] and S. M. Griffiths[1], (1)JC School of Public Health and Primary Care, The Chinese University of Hong Kong, Shatin, Hong Kong, (2)Department of Pediatrics, The Chinese University of Hong Kong, Shatin, Hong Kong, (3)The Children's Institute of Hong Kong, Kenndy Town, Hong Kong*

Background: A recent increase in recognition and identification of autism spectrum disorders (ASD) calls for system-level responses to addressing unmet needs of individual with ASD through the establishment of a well-integrated infrastructure for healthcare, education, social-welfare and employment. WHO states inappropriate services and a lack of resources for ASD as unjust deprivation towards vulnerable populations representing societal stigma. The first step is to develop a guideline of ASD screening, referral, diagnosis and treatment to facilitate early detection and treatment.
Objectives: The objective of this mixed-methods study was to systemically assess ASD service provisions in Hong Kong by exploring the pathway from screening, diagnosis and post-diagnosis interventions among parents of children with ASD. Narrative analysis of their experience and views aimed to represent direct sources of service-user feedbacks, informing the development of a local guideline.
Methods: A community-based survey was conducted among 249 parents of children with ASD. The instrument was developed based on the guideline for ASD diagnostic pathway of the UK National Institute for Health and Care Excellence (NICE), which includes six key milestones: (1) parental first awareness, (2) referral for assessment, (3) diagnostic assessment, (4) consultation on diagnosis, (5) post-diagnosis follow-up, and (6) entry to special education needs (SEN) program. Correlates of the key milestones were examined. The survey also included open-ended questions about their experiences and views on each key milestone to contextualize the quantitative findings.
Results: About half of parents (51%) were first aware of child's differences by the age of 2 and 70% sought professional help within 3 months. Fifty six percent saw multiple professionals for referral. Significant delays were reported between screening/referral (R), diagnosis (D), post diagnosis follow-up (F), and entry to SEN: 88% were delayed between R and D (>3 month), 60% D and F (>6 weeks), and 70% D and SEN (>3 months). Low income was associated with longer time in access to diagnosis and follow-up. While a shorter time in access to diagnosis was reported after the launch of behavioral surveillance, no effect of the surveillance was found in the time for access to F/SEN. Parental satisfaction was significantly associated with quality of assessment and shorter time for treatment. Parents expressed difficulty and high anxiety with coping with uncertainty while waiting for assessment. Experience of multiple consultations for referral and long delay caused lack of confidence in ASD treatment and care as they felt "missing golden times." They expressed the special need for family needs assessment when they were given ASD diagnosis for child.
Conclusions: The findings indicated considerable delays and lack of coherence and resources in ASD assessment and SEN provisions in Hong Kong. Policy of standard care should provide guidelines of (1) monitoring pre-school children for ASD in pediatric settings, (2) how to inform parents of ASD symptoms and what information to be provided for waiting time, (3) comprehensive needs assessment for child and family, (4) evidence-based treatments, and (5) follow-up protocol for re-assessment on child development and needs.

167 **180.167** Positive Contact Decreases Stigma Associated with Autism Spectrum Disorder – Study through Interviews with Japanese High School Students

M. Torii[1]*, F. A. Someki*[2] *and Y. Nishio*[3]*, (1)Kobe University, Kobe, Japan, (2)Educational Studies, College of Staten Island, Staten Island, NY, (3)Graduate School of Human Development and Environment, Kobe University, Kobe, JAPAN*

Background: Autism spectrum disorder (ASD) is often misunderstood in Japan (Koyama et al., 2008), and the stigma associated with ASD on the part of Japanese college students was higher than that of their American counterparts (Someki et al., 2015). In contrast, accurate knowledge about positive outcomes of people with ASD contributed to less stigma (i.e., less social distance) on the part of Japanese high school students (Torii et al., 2015). Further, accurate knowledge of ASD and opportunities to learn about neurodevelopmental disabilities (ND; e.g., ASD, learning disabilities, attention-deficit/hyperactivity disorder) both correlated with less stigma associated with ASD.
Objectives: The purpose of this study was to examine the relation between previous experiences (i.e., direct interactions) with peers with ND during elementary and middle school years, knowledge about ND, and the level of stigma associated with ASD.
Methods: The data were gathered through both interviews and a survey. Semi-structured interviews were conducted by four high school students of their peers in an urban city in Japan. A total of 69 high school students (23 males, 46 females) participated in the interviews and survey. The interview protocol consisted of six questions about previous interactions with peers with ND, and how they (interviewee) felt during that interaction, their anxiety about interacting with peers with ND, and their friendship with peers with ND. In addition, each participant completed a questionnaire using 5-point Likert-scale. The questionnaire consisted of 26 items: 4 items about knowledge about ASD, 6 items about knowledge about ND, 5 items about life style, 5 items about attitude toward people with ND, and 6 items about social distance (SD) towards individuals with ASD (i.e., stigma measure: Bogardus, 1933).
Results: The ASD Knowledge mean score was 2.36 (SD= 0.56), and Social Distance mean score was 2.03 (SD= 0.76, Fig.1) A lower score indicates more accurate knowledge and less stigma. The mean Social Distance score was correlated with the following items: mean Knowledge about ND score ($r = .486$, $p < .01$), Knowledge about ASD ($r = .445$, $p < .01$), " I have no prejudice towards anyone" ($r = .320$, $p < .01$), "Behaviors by peers with ND need to be tolerated (reverse item)" ($r = .340$, $p < .01$), "I would make friends with peers with ND" ($r = .397$ $p < .01$). Female students were less likely to make friends with peers with ND ($r = .308$ $p < .01$). than males (Table 1). Students also provided some examples of positive interactions with peers with ND. Namely, "My teacher treated us fairly regardless of the presence of ND" and "I had fun playing with peers with ND." Further, students also listed examples of negative interactions, such as "Peers with ND were violent" and "I was harassed by peers with ND."
Conclusions: Positive interactions with peers with ND during elementary and middle school years were significantly correlated with reduced stigma associated with disabilities on the part of high school students.

168 **180.168** Sleep and Behavioral Disturbances in Children with Autism Spectrum Disorders: Evidence from India

P. Malhi[1]*, A. Kaur*[2]*, P. Singhi*[3] *and N. Sankhyan*[4]*, (1)Department of Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarth, UT, India, (2)Department of Pediatrics, Government Medical College and Hospital, Chandigarh, India, (3)Depatment of Pediatrics, PGIMER, Chandigarh, India, (4)Department of Pediatrics, PGIMER, Chandigarh, India*

Background: Sleep problems are considered a common clinical characteristic of children with autism spectrum disorders (ASDs). Little evidence is, however, available on sleep related difficulties in children with autism from developing countries leading to major gaps in the knowledge about children with autism from the majority world and the needs of these children.
Objectives: Â To compare parent reported sleep problems of children with ASD and typically developing children and to study the association of sleep problems with daytime behavioral difficulties in children with ASD.
Methods: Â Sixty children diagnosed with ASD (Mean age= 6.1 years, SD=2.4) were recruited from the Department of Pediatrics of a tertiary care teaching hospital in India. An age and socio-economic status matched group of typically developing children (N=60) were also recruited. The Children's Sleep Habits Questionnaire (CSHQ) was used to measure sleep problems. The 33 items scale assesses resistance to bedtime, delay in onset of sleep, duration of sleep, parasomnias, sleep-disordered breathing, sleep anxiety, awakenings at night, and daytime sleepiness. The Childhood Psychopathology Measurement Schedule, the Indian adaptation of the Child Behavior Checklist, was used to measure day time behavioral difficulties. The study was approved by the ethics committee of the Institute and a written informed consent was taken from all the parents/caregivers.
Results: The prevalence of sleep problems in children with ASD was 88%, nearly twice as more as compared to controls (47%). The ASD group as compared to typically developing children had significantly higher total scores on the CSHQ (t= 5.3, P=.001) and more sleep related problems (t =3.6, P=.001). As compared to controls, significantly higher proportion of children with ASD reported bedtime struggles (25% vs. 7%, P=.001), problems in initiating sleep (28% vs. 0 %, P=.001), sleeping for inadequate duration (30% vs. 1%, P=.001), frequent sleep disruptions (28% vs. 13%, P=.006), not falling sleep in own bed (72% vs. 38%, P=.001), afraid of sleeping in the dark (32% vs. 13%, P=.002), and bed wetting (13% vs. 2%, P=.02). A significant correlation was found between sleep and daytime behavioral problems (r=0.53, P=.01). Sleep difficulties of the ASD children did not differ by socio-economic status, education of the mother, autism severity score as measured by the Childhood Autism Rating Scale (CARS) score.
Conclusions: Children with ASD are at a high risk for sleep problems and this may be associated with daytime behavioral difficulties. Clinicians should routinely screen ASD children for sleep problems and initiate appropriate interventions.

169 **180.169** Supporting Practitioner Responses to Attitudes to Autism and Intellectual Disability in Black and Minority-Ethnic Families in the UK and Beyond

*R. Veeravalli[1] and **S. Fletcher-Watson**[2], (1)University of Edinburgh, Edinburgh, United Kingdom, (2)University of Edinburgh, Edinburgh, Scotland, United Kingdom*

Background: Black and minority-ethnic (BAME) families living in the UK may struggle with the presence of autism and / or intellectual disability in their family members. This is particularly challenging for recent immigrants to the UK and those living in communities where a large majority of people are white British, such as Edinburgh, Scotland.
Objectives: This project combines focus groups, literature review and an online survey to explore the challenges experienced by practitioners supporting BAME families in Edinburgh and to provide evidence-based recommendations for their practice.
Methods: We worked with a charitable organisation providing support to BAME families in Edinburgh. Stage One was a focus group with practitioners from the organisation to discuss the challenges they perceive when providing support to BAME families. Topics were organised into questions about: 1) practitioner challengers; 2) family challenges; and 3) useful resources. Stage Two was a literature review aiming to address two questions derived from the focus group analysis: *How do cultural attitudes to autism and intellectual disability vary worldwide?* and specifically *How can the research literature help practitioners understand attitudes to autism and intellectual disability in BAME families in Scotland?* Stage Three (in progress) will be the design and evaluation, via a practitioner survey, of a website sharing evidence based information about cultural attitudes to autism and intellectual disability. The site will report information about how attitudes vary among different ethnic and religious groups and extract some simple tips for practitioners on working sensitively with BAME families.
Results: The focus group data were analysed thematically and revealed challenges in three domains. 1) Practical Challenges – these included isolation, language barriers and financial barriers (e.g. lack of transport to visit clinical services). 2) Attitude Challenges – these included culturally-specific beliefs about disability (e.g. disability as a punishment) and resulting behaviours. 3) Knowledge Challenges – this encompassed practitioner uncertainty about culturally-sensitive ways to respond to stigma. The BAME community in Edinburgh is highly diverse meaning that it is challenging for one practitioner to be familiar with the range of cultural backgrounds they encounter among clients. Furthermore, specialist practitioners must then refer to diagnostic and support services who have even less experience of BAME families. The Stage Two literature review adopted a systematic search methodology to identify texts which either a) described cultural / religious variation in attitudes to autism and intellectual disability or b) reported on mechanisms to support people experiencing stigma associated with disability. These findings are now being organised into a resource designed to address Knowledge Challenges among practitioners so that they in turn can deal with Attitude Challenges in the community.
Conclusions: We will report on a survey-based evaluation of the finished website (Stage Three, in progress) as well as providing further details of the literature search results. This study reveals the challenges presented to autism diagnostic and support services by increasing multi-culturalism and can help researchers, practitioners and the community sensitively address stigma as well as identifying gaps in our knowledge.

170 **180.170** The Experiences of Special Needs Teachers Working with Children with ASD in Tanzania

***N. Naqvi**[1], J. DeCuffa[1], S. Gordon[1] and A. Martinage[2], (1)Psychology, Iona College, New Rochelle, NY, (2)OMPACO, Boston, MA*

Background: Autism Spectrum Disorder (ASD) is a worldwide phenomenon. There are however large disparities in provision of service for children with ASD around the world (Elsabbagh, 2012). In Africa, many countries lack ASD prevalence data, and limited information on services available (Ruparelia, et al. 2016). One preliminary estimate regarding the number of children with ASD in Tanzania was 437, but is limited to results reported from 15 different intervention centers and considered to be a gross underestimate (Manji & Hogan, 2013). Teachers at the centers reported minimal additional training, and there is a need for substantial increase in facilities and human resources to support children with ASD in Tanzania.
Objectives: Gain more information about the number of children with ASD being serviced in two areas in Tanzania and the qualification and experiences of the teachers working with the children
Methods: This was part of a larger research project that examined special needs teachers' learning outcomes at a training on ASD in two regions of Tanzania, Dar es Salaam (Dar) and Arusha. In this study, 66 special needs teachers from 19 different schools completed the Teacher Feedback Survey (West, Jones, Chambers & Whitehurst, 2012). Survey questions included demographic information, qualifications, professional development experiences, number of children taught, and number of children identified as ASD.
Results: The mean age of the participants 40.5 years old with the majority female (74%). Data was organized based on the following categories; work setting (mainstream setting: 32%, special unit: 67%, and other: 4 %); type of degree (Certificate or Diploma); number of children serviced (1,110 total, Dar= 540, Arusha= 570) and age range of children (4-21 years old). The numbers of children were divided by disability categories (identified by the teachers), which included 218 children with ASD, 527 with intellectual disabilities and 27 with hearing and vision impairments. Fifty- three percent of the teachers reported participating in mentoring activities, and 66% reported that they participated in additional training courses.
Conclusions: Results provide preliminary data on the number of children with special needs who received special education instruction in two urban centers in the country. It is not possible to confirm diagnosis of ASD or ID reported due to a lack of assessment facilities in the country or Africa as a whole (Ruparelia et al., 2016), and numbers are based on teacher report alone. Results add to the literature regarding tentative total numbers of children identified as having ASD in two urban areas in Tanzania, along with information regarding the qualification and training of the teachers who work with them. These numbers are almost certainly significant underestimates and do not capture the numbers of children with developmental disabilities in other parts of the country. It is imperative to know the rates of developmental disabilities including ASD in Tanzania and in the rest of Africa so as to advocate for much needed intervention services for these children and their families and provide additional training and resources to teachers and community members who support children and families.

171 **180.171** Assessing Knowledge of Autism Spectrum Disorders (ASD) in Tanzania; Results from an Intensive Four-Day Training on ASD for Special Educators

N. Naqvi[1]*, A. Martinage*[2]*, M. Collins*[3]*, S. Gordon*[1] *and J. DeCuffa*[1]*, (1)Psychology, Iona College, New Rochelle, NY, (2)OMPACO, Boston, MA, (3)OMPACO/Tufts University, Boston, MA*

Background: Autism Spectrum Disorder (ASD) is a worldwide phenomenon. There are however large disparities in provision of service for children with ASD around the world (Elsabbagh, 2012). In Africa, many countries have small number of professionals dedicated to working with children with ASD. Recommendations to address this include increased engagement with community stakeholders, increase in access to information about ASD, and specific trainings on ASD in community settings (Ruparelia et al., 2016).
Objectives: An examination of results from a pre and post-test measure of ASD knowledge given during two ASD trainings for special education teachers in Tanzania.
Methods: The 20-hour, four-day training occurred in two special needs units in primary schools in Dar es Salaam (Dar) and Arusha, Tanzania in July and August 2016. A total of 79 special education teachers attended the training (Dar, N=39; Arusha, N=40). The training was run by five clinicians from the U.S based non-profit, OMPACO in partnership with special needs units in each location. Topics covered during the training included etiology, characteristics, assessment, instructional and communication strategies, behavior management and sensory processing. Learning outcomes of the training were assessed using a pre-post test methodology with a 19-item measure, the "Autism Knowledge Survey" based on items taken from the "Autism Survey" (Schwartz & Drager, 2008). All items were translated into Swahili and then back translated into English for accuracy.
Results: Â Reliability results were fair (Cronbach alpha= .428). Results from paired-samples t-test indicated a significant difference in scores in Dar, t (31) = 3.22, p< .001 and in Arusha, t (37) = 7.46, p< .001 with effect sizes that were medium in Dar (Cohen's d= .569) and large in Arusha (Cohen's d= 1.209). An analysis of variance between pre and post-test scores was significant for location, F (1, 67) = 15.97, p< .001 with a larger increase in scores on the measure in Arusha.
Conclusions: There was an increase in ASD knowledge on the measure in both locations with a significantly greater increase in scores in Arusha. Reasons why were hypothesized to be multifactorial and included the presence of a translator in Arusha, differences in perception regarding collaboration and partnership between OMPACO and the sponsoring schools, longer travel times for teachers to reach the training site in Dar (teachers came late or missed days of the training), and differences in the facilities provided for the trainings.The low internal consistency result may be because the measure only assesses one construct (characteristics of ASD). It is not possible to compare the alpha value to that of the original measure as no reliability statistics were reported. The reliability finding can be framed within a broader discussion about the need for culturally reliable and valid measures of ASD knowledge. Improved measures that assess different domains of knowledge related to ASD would better reflect learning in different content areas covered in a multi-day training. This could in turn increase specialized knowledge in multiple content areas to key stakeholders working in the field of ASD in Tanzania.

172 **180.172** The Use of M-CHAT (Malay version) As a Screening Tool for Pervasive Developmental Disorders in Malaysia

D. S. C. Lau[1]*, I. Juriza*[2]*, A. L. Zarina*[2] *and* ***R. J. Raja Lope***[3]*, (1)Pediatrics, The National University of Malaysia, Kuala Lumpur, Malaysia, (2)Pediatrics, The National University of Malaysia, Kuala Lumpur, Malaysia, (3)University Kebangsaan Malaysia Medical Centre, Kuala Lumpur, Malaysia*

Background:
The Modified Checklist for Autism in Toddlers (M-CHAT, 1999) was translated in 2008 to Malay, the Malaysian national language (M-CHAT-Malay Version; MCHAT-MV). MCHAT-MV has been used nationwide in maternal and child health clinics in Malaysia from 2012 until the present time. Typically MCHAT-MV would be given to parents by community nurses if there were developmental or behavioural concerns. The results would guide nurses regarding referrals to tertiary diagnostic autism services or to the clinic medical officer. A small initial validation study of MCHAT-MV was performed but there were no subsequent studies. There are no Pervasive Developmental Disorders (PDD) screening tools used for children above 30 months in public health services.
Objectives:
The objective of this study was to determine the sensitivity and specificity of the MCHAT-MV as a screening tool for PDDs in children aged 18 to 60 months with developmental or behavioural problems. Optimal cut-off scores were also evaluated.
Methods:
A prospective study was done in the Child Developmental Centre (CDC) of a tertiary hospital from 1st April 2010 until 31stMay 2012. Parents of children aged 18 – 60 months referred as new cases for developmental or behavioural difficulties, were given the MCHAT-MV to fill in before clinical assessments. The diagnosis of PDD was made after 2 clinic appointments, including a developmental assessment, multi-disciplinary discussion and semi-structured interview and clinical observation byÂ experienced developmental pediatricians using criteria from the Diagnostic and Statistical Manual of Mental Disorders 4th Edition, Text Revision (DSM IV-TR). Diagnosis of other developmental- behavioral disorders were made by developmental pediatricians.
Results:
A total of 130 patients were enrolled and categorized into two main groups, the PDD group and Other Developmental-Behavioural Disorder (ODB) group. The PDD patients were diagnosed with Autistic Disorder (n=50) and Pervasive Developmental Disorder – Not Otherwise Specified (PDD-NOS) (n=13).Â The ODB patients were diagnosed with Global Developmental Delay (n=20), Specific Language Impairment (n=41) and Attention Deficit Hyperactive Disorder (n=6). The MCHAT-MV was found to have the sensitivities and specificities respectively for the corresponding age-groups: overall 18-60 months (n=130), 88.9% and 47.8%; 25-30 months (n=38), 100% and 45.5%; aged 37 – 48 months (n=59), 90.3% and 57.1% and 49 – 60 months (n=27), 80.0% and 50%. Children aged 18-24 months were not analysed in a stratified age group there was only 1 child with autistic disorder. Overall positive predictive value (PPV) was 61.5% while negative predictive value (NPV) was 82.0%. Optimal cut-off values to detect PDD based on the Receiver Operator Characteristic (ROC) curve were failing 1 out of the 6 critical items or 3 of 23 total items from the MCHAT-MV.
Conclusions:
MCHAT-MV is a sensitive screening tool for detecting Malaysian children with PDDs in an expanded age group of 25 – 48 months old in this selected population. The original cut off value of 3 of 23 total items can be used in our population, however further studies are needed to determine the cut-off value for critical items. All children failing MCHAT-MV will require further evaluation due to moderate specificity.

173 **180.173** Training Parents in Saudi Arabia to Implement Discrete-Trial Teaching with Their Children with Autism Spectrum Disorder

A. M. Eid[1], *S. Aljaser*[1], *A. AlSaud*[1], *R. M. Mohtasib*[1], *S. Asfahani*[1], *O. Alhaqbani*[1], *H. M. Al Dhalaan*[1] *and M. Fryling*[2], *(1)Center For Autism Research, Riyadh, Saudi Arabia, (2)California state university, Los Anglos, CA*

Background:
Applied Behavior Analytic (ABA) services for children with autism in Saudi Arabia are presently scarce. Children with autism who could benefit from such services are unable to obtain them. Involving parents in the implementation of certain ABA techniques may help increasing the number of children who may benefit from the training.
Objectives:
The present study evaluates the effects of a behavioral skills training package on parents implementation of discrete-trial teaching with their children with Autism Spectrum Disorder.
Methods:
Three parent-child dyads participated in the study. The effects of the training package on parent implementation and child responding were evaluated using a multiple-probe design. The primary dependent variable was parent implementation of Discrete Trial Teaching . Specifically, parents were scored on the extent to which they: 1) completed a brief mini-preference assessment (choice between two items); 2) required eye contact with the child for at least 1 second prior to the instruction; 3) waited until the child was ready (i.e., no problem behavior) before providing instructions; 4) gave a clear instruction relevant to the task; 5) implemented a least-to-most error correction procedure within 5 s of the instruction after the student failed to respond or responded incorrectly; 6) provided immediate reinforcement for correct responses (using item identified in #1); 7) used behavior-specific praise; and 8) recorded the data for each trial. Child behavior was also measured throughout, and consisted of the child engaging in the correct response (specific to the instructional task) within 5 s of the discriminative stimulus.
Results:
The training package improved implementation for all three of the mothers. Moreover, these improvements generalized to skills that were not taught during training, maintained during follow-up probes, and resulted in improvements in child behavior.
Conclusions:
Overall our results support pervious published studies using this behavioral skills training. The results of the present study show that a brief Behavioral Skills Training program can improve the implementation of discrete-trial teaching with parents of children with ASD in Saudi Arabia.

174 **180.174** Training Parents in Saudi Arabia: Assessing Learning from Doing and Learning from Seeing

A. M. Eid[1], *H. M. Al Dhalaan*[1], *O. Alhaqbani*[1], *R. M. Mohtasib*[1], *A. AlSaud*[1], *M. Alaqil*[1], *M. Fryling*[2] *and S. Asfahani*[1], *(1)Center For Autism Research, Riyadh, Saudi Arabia, (2)California state university, Los Anglos, CA*

Background: A considerable amount of attention has been given to parent training efforts in Applied Behavior Analysis. Still, much remains to be learned, including the extent to which common training protocols are effective with a diverse range of individuals and are viewed as socially valid in different cultural contexts
Objectives: To evaluate the effectiveness of behavioral skills training and observational learning in parents training in Saudi Arabia
Methods: The present study trained six parents of children with Autism Spectrum Disorder to implement the Natural Language Paradigm in Saudi Arabia. Three of the parents received training using a Behavioral Skills Training model involving instructions, modeling, rehearsal, and feedback. The other three parents observed the whole training procedure and then recieved behavioral skills training based on their performance post observation. The effect of training package on parent implementation was evaluated using multiple-probe design.
Results: All three of the participants who were taught using this protocol learned to implement the intervention effectively. As each parent was being trained individually, an additional parent observed the training (i.e., there were three observer-trainee dyads). While all of the parents learned from observing other parents being trained directly, only one observer parent met the predetermined performance criteria, with the other two reaching criteria after being trained directly. All six parents demonstrated maintenance of their skills at follow-up, and indicated that they enjoyed and training and learned a lot from it. Moreover, parents indicated that their child's behavior improved at home, suggesting strong social validity
Conclusions: The behavioral skills training is effective in training parents. The observational learning has considerable effect in parent training , however it is not adequate enough in learning process.

175 **180.175** Transition of Adults with Autism Spectrum Disorders in the U.S. and China: Lessons Across Cultures

D. B. Baker[1]*, M. L. Kelly*[2] *and H. McCabe*[3]*, (1)Hobart and William Smith Colleges, Ithaca, NY, (2)Education, Hobart and William Smith Colleges, Geneva, NY, (3)Hussman Institute for Autism, Geneva, NY*

Background:
Recent developments in both China and the US have led to changes in service opportunities for adults with developmental disabilities (People First Transformation, 2016; Swanson, 2014; Xu, Dempsey, & Foreman, 2014). While many of these changes are positive, and have led to increased choices in services, it is unclear how adults with disabilities and their families are actually experiencing these policy and service changes. While some research has presented examples of intervention programs designed to help students with developmental disabilities transition from high school to adult life (Hagner, Kurtz, Cloutier, Arakelian, Brucker, & May, 2012), other very recent research in the US has found that families experience the transition to adult services to be a stressful process with many unmet needs (Cheak-Zamora, Teti, & First, 2015). In China, there is less research about adults with disabilities; what is available indicates that while adult benefits and services previously were often on a case-by-case basis (McCabe & Wu, 2010), there is increasing attention to vocational programs and adult services (Xu, et al., 2014).Â
Objectives:
At a time of transition in service provision systems in both countries, this study examines the perspectives of beneficiaries of services and service providers, to understand the advantages and challenges that exist in these different services systems (China and the United States). This research investigates the lives of adults with autism and/or intellectual disabilities in China and the United States to gain an in-depth understanding of disability and disability services in adulthood from the perspectives of important stakeholders, including the person with a disability, parents and other family members, current and past service providers, and other important members of each individual's life.
Methods:
This research uses a qualitative multiple case study approach (e.g., Yin, 2009) focusing on the experiences of eleven (5 US, 6 China) transition-age adults with developmental disabilities and their families and service providers. Interviews were guided by semi-structured interview protocols and lasted up to an hour and a half. In addition to interviews, document analysis was conducted with relevant policies, as well as brochures, reports, and websites from any disability-relevant agencies with which the family is involved.
Results:
Qualitative analysis of data led to three main themes. First, there is a tension between promoting the right to make one's own decisions versus supporting emerging adult role & responsibilities. Second, while parent advocacy is essential and makes a difference, there are limits. Adult outcomes are varied, especially in China, due to local services (or lack of), and parent efforts. Finally, results indicate some of the emerging impacts of policy changes in US and China, including advantages and continued challenges.
Conclusions:
Â There are some similar experiences of adults with autism in China and the United States, but due to different policy and educational contexts, the specific nature of the experiences and challenges differ. Together, the experiences of participants in the study indicate that finding best practice solutions for adult services is an ongoing issue, and lessons are to be found in both countries.

176 **180.176** Trends in Autism Research Funding in the Arab World

F. Alnemary[1] *and F. Alnemary*[2]*, (1)UCLA, Los Angeles, CA, (2)University of California, Los Angeles, CA*

Background: Autism Spectrum Disorder (ASD) research in the Arab world is a young but rapidly growing field. Research funding will keep the cycle of this field's growth going and shape the next wave of evidences that will enhance the recognition, understanding, and awareness of ASD in the region. Little information about who is funding ASD research and what type of research being funded.
Objectives: The purpose of this study was to identify: a) the organizations that funded ASD research in the Arab countries, and 2) types of studies are being funded.
Methods: ASD research publications produced in the Arab countries from 1946 to 2014 were screened using four databases: Medline, PubMed, Web of Science and EMBASE. A total of 142 publications were identified, spanning a period from 1992 to January 2014.
Results: Over a third of all ASD articles (40.8%) from the Arab world included 58 funding acknowledgments representing 21 unique funders. The majority of funding sources were governmental agencies (n = 53), whereas little research was funded by private organizations (n = 9). A total of six studies were funded through collaborations between governmental, private, and international funding organizations. Three funders that were acknowledged on ten or more publications included: King Abdulaziz City for Science and Technology, Riyadh, Saudi Arabia; King Saud University, Riyadh, Saudi Arabia; and Sultan Qaboos University, Muscat, Sultanate of Oman. The majority of funding acknowledgments were in publications that addressed basic science research
Conclusions: Funding organizations that were acknowledged the most are in two countries that actively engaged in ASD research: Saudi Arabia and Oman. Indicating that ASD research is a priority in such countries, this finding is consistent with existing literature from the US, showing that states that received most of Federal health-related research funds published most of ASD research (Interagency Autism Coordinating Committee 2012). Funding organizations in the Arab world need to invest in various research areas in order to improve and manage the ASD field effectively. Private organizations in the Arab world should do their fair share to fund ASD research, allowing many potential researchers to reach the required funds for research.

177 **180.177** Validation of the Com Deall Developmental Checklist and the Com Deall Oro-Motor Assessment in Normative and Autistic Populations in India: Linking Motor, Cognitive, and Speech and Language Skills

T. Dash[1], *P. Karanth*[2] *and M. K. Belmonte*[3], *(1)The Com DEALL Trust, Bangalore, India, (2)The Com DEALL Trust, Bangalore, 560043, INDIA, (3)Com DEALL Trust, Bangalore, INDIA*

Background: The many tools globally available for assessment of autism spectrum conditions lack culturally specific adaptations and norms. Whereas social cognitive impairments were once assumed to be primary, early signs of motor speech impairment have gained importance in explaining uneven language profiles in non-verbal autistic children. Motor deficits in children with ASD range from motor delay and motor asymmetries to oro-motor impairments, as well as praxis of limb movements and speech movements. These basic traits of motor dysfunction and dyspraxia correlate with the severity of autism's more immediately apparent, more diagnostic, and more debilitating social communicative deficits, and can impair the later development of social communication and language. Especially because remediation of these basic motor deficits can benefit later communicative development, validated, culturally appropriate, and economically accessible tools are needed to quantify the effects of intervention.
Objectives: To validate against international norms the Com DEALL Developmental Checklist (CDDC) and the Com DEALL Oro-Motor Assessment (CDOMA), low-cost instruments indigenously developed, normed, and tested in India. These culturally adapted and economically accessible test-retest measures assess autistic skills and deficits in motor and particularly oral motor development, receptive and expressive language, and adaptive skills, at baseline and during intervention.
Methods: CDDC and CDOMA were cross-validated against the Mullen Scales of Early Learning (MSEL) and the Verbal Motor Production Assessment for Children (VMPAC), respectively, in 60 children with ASD attending the Com DEALL programme and 155 typically developing children. All subscales of all tests were assayed for correlation against each other, exploratory factor analysis was applied for each diagnostic group separately, and a linear discriminant between groups was constructed with leave-one-out validation for each test separately.
Results: All subscales common to MSEL and CDDC correlated with each other, although correlations with MSEL gross motor and visual reception diminished with age. Nearly all VMPAC subscales correlated with the CDOMA Tongue Movement subscale and most strongly with the CDOMA Speech subscale. The CDDC correctly classified 96.3% of the participants into ASD and age-matched typical groups, with leave-one-out cross-validation; controls were classified more accurately (99.2%) than children with ASD (86.7%). The CDOMA correctly classified 85.8%, controls again more accurately (99.2%) than children with ASD (60%). Cognitive and social skills segregated with language in typical development, but with motor skills in ASD.
Conclusions: Whereas the factor structure of oro-motor assessments in the typical group describes the type of motor or cognitive control assayed (motor control versus sequence maintenance) independently of the complexity of speech production (sounds versus words versus sentences), in the autistic group the variance between factors is a matter of complexity of production, cutting across type of control. These results validate CDDC and CDOMA, suggest a link between autistic motor and cognitive control, and suggest that autistic speech impairment is complexity-specific.

178 **180.178** The Expression, Recognition and Reporting of Autism Symptoms in the Ethiopian Context

R. A. Hoekstra[1], *F. Girma Bayouh*[2], *A. Mihretu*[2], *W. Adamu*[2], *H. Klasen*[3] *and C. Hanlon*[2,4], *(1)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (3)Department of Child Psychiatry, Leiden University Medical Centre, Leiden, Netherlands, (4)Centre for Global Mental Health, Department of Health Services and Population Research, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background: To improve detection of autism worldwide a better understanding is needed of the cultural-specific expression of autism symptoms and the cultural-specific ways of recognising and reporting autism symptoms. A good understanding of these factors is essential for establishing a valid screening tool for use in low-income countries like Ethiopia, where autism is underdiagnosed.
Objectives: To explore the cultural-specific expression, recognition and reporting of autism symptoms in Ethiopia.
Methods: Audiotaped semi-structured interviews were conducted with 16 caregivers of children with autism, recruited through Yekatit 12 hospital's child mental health clinic in Addis Ababa, and with 8 local clinical professionals with autism experience. Informants were asked to describe the child's strengths and difficulties, and the main areas of concern for the caregiver. Probes included autism characteristics listed in international diagnostic criteria. Data were analysed using framework analysis.
Results: Most caregivers identified strengths of their children ('*He is so sweet… It is the kid you most like to live with*') and appreciated the opportunity to describe strengths alongside problems. Clinicians and caregivers both provided examples of all main diagnostic symptoms of autism. Informants described impaired social relationships, ranging from the child preferring to be alone to having difficulty making friends. Problems with social communication were prominent: most caregivers indicated they have difficulty understanding what their child wants or needs. Restricted repetitive behaviours and activities were reported too, including repetitive play (e.g. splitting grass), sensory sensitivity (e.g. disturbed by loud noises or strong odours), insistence on sameness (e.g. wearing the same clothes; dislike of new foods) and motor stereotypies (e.g. hand flapping or head movements). Both caregivers and clinicians most frequently mentioned lack of speech as the cause of first concern. When asked which characteristics were most challenging, the majority of caregivers raised the child's inability to communicate, but several also mentioned severe behavioural problems or lack of self-help skills, especially toilet problems.Â While caregivers could easily describe their primary concerns, there was also evidence of lack of awareness of some core symptoms. One caregiver commented:Â *'I only start thinking about this thing [non-verbal communication problems] now that you raised it. We never see him showing us signs for what he agrees or disagrees with. We never thought of that.'Â* Moreover, several interview comments suggested that symptom reporting may be affected by beliefs, especially the common belief that autism is due to the child being spoilt.
Conclusions: In this exploratory study from Ethiopia, there was no indication that the expression of core autism symptoms differs markedly from what is reported in Western countries. However, due to local belief systems, cultural norms and low levels of awareness it is likely that some core symptoms would be missed when using a standard Western autism screening tool. In a context of low awareness a broad question about e.g. toilet problems may hold high predictive power even when screening for a specific condition like autism. The findings of this study suggest that in order to avoid low sensitivity, existing caregiver-reported screening tools will require careful cultural adaptation.

179 **180.179** Development, Adaptation, and Implementation of a Parent-Mediated Behavioral Intervention for Children with Autism Spectrum Disorder in Rural Bangladesh

E. Rubenstein[1], *J. Blake*[2], *P. C. Tsai*[3], *S. R. Rieth*[4], *H. Ali*[5], *H. Rahman*[6] *and L. C. Lee*[7], *(1)University of North Carolina, Chapel Hill, NC, (2)Johns Hopkins Bloomberg School of Public Health, Joppa, MD, (3)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)San Diego State University, San Diego, CA, (5)Center for Human Nutrition, Department of International Health, JHSPH, Baltimore, Maryland, USA, Gaibandha, BANGLADESH, (6)Jivita, Gaibandha, Bangladesh, (7)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background:
It is often difficult to provide interventions for autism spectrum disorder (ASD) in low and middle-income countries (LMICs) since LMICs often have limited resources, underdeveloped health systems, and scarce ASD knowledge. Community-based strategies where caregivers or family members are interventionists may provide sustainable treatment for children with ASD in LMICs. Gaibandha, a rural district in northwestern Bangladesh, has low literacy and income levels. Families of children with ASD in this district are in great need of means to improve child communication skills and reduce challenging behaviors. Feasible, low cost and sustainable approaches to deliver ASD services are crucial in addressing needs of families of children with ASD in communities like Gaibandha.
Objectives:
To develop and adapt culturally appropriate educational materials for families of children with ASD and to train a local clinician to use these materials to implement a community-based parent-mediated behavioral intervention in Gaibandha.
Methods:
This study was built on of the infrastructure of JiVitA, a long-standing research program that works to improve maternal and child health outcomes in Gaibandha. Our study sampled participants from a prevalence study of ASD in children seven to nine years old that were offspring of a JiVitA cohort. Study investigators were trained in behavioral modification techniques and developed a training program for a local clinician. The program emphasized the fundamental principles of behaviors as well as ASD specific intervention. The study investigators assisted the local clinician in the creation and adaptation of educational materials that focused on understanding developmental milestones across domains and using behavioral modification techniques. All materials were carefully adapted to cultural norms and literacy levels of the Gaibandha population. For example, using culturally appropriate pictures to minimize the use of written words, and adapting concepts that are understandable to local parents who have very little formal education. The local clinician delivered group education sessions to ten families of children with ASD, followed by two one-on-one sessions with each family to discuss individualized strategies and coach parents. A brief qualitative survey was conducted at the end of the sessions to evaluate the program.
Results:
The local clinician successfully delivered the educational program, shared materials and worked one-on-one with families. Preliminary qualitative results indicate the importance of materials that are culturally appropriate and at a proper literacy level. Parents and caregivers were vocal in their need for support and tools to help their children. All families indicated that they wish they were trained with these skills when their child was younger and lamented the difficulties and stigmas of raising a child with ASD in their community.
Conclusions: Families indicated that the intervention was effective and expressed their gratitude for the support. By working to support families earlier, it may be possible to lessen the stigma and parental stress that impacts families of children with ASD in Gaibandha. We believe that this study is the first step in creating a sustainable and low resource intervention to aid families of children with ASD in rural Bangladesh or other communities share similar societal and cultural background.

180 **180.180** Adapting and Testing a Parent Education Program in Colombia

S. Magana[1], *M. Moreno-Angarita*[2], *M. Tejero Hughes*[3] *and K. Salkas*[1], *(1)Disability and Human Development, University of Illinois at Chicago, Chicago, IL, (2)Human Communication, Universidad Nacional de Colombia, Bogota, Colombia, (3)Special Education, University of Illinois at Chicago, Chicago, IL*

Background: ASD affects approximately 1% of the world's population and many children with ASD around the globe, including in Latin America are not receiving the supports needed due to services being limited or not available. In collaboration with a team from the Universidad Nacional de Colombia, Bogota we adapted and pilot tested a parent educational intervention, *Parents Taking Action*(originally developed for Latino immigrant parents of children with ASD in the USA) for parents in Colombia. The intervention uses community health workers or promotoras which is a mode of intervention widely used internationally and is a cost-effective way to deliver education about health conditions and disabilities.
Objectives: In this study we compared two groups: families who received the intervention delivered by parents of children with ASD (parent promotoras), and families who received the intervention delivered by therapists in training (student promotoras). Our research questions are 1) did parents improve on parent outcomes between pre and post-test in the overall sample? and 2) were there differences in parent improvement between those who had parent promotoras and those who had student promotoras?
Methods: Parents of children with ASD were recruited through an inclusive public school in Bogota, and 26 were enrolled in the study and randomized to the 2 groups. Parent outcome measures included the Family Outcome Scale (FOS), the Center for Epidemiological Studies Depression Scale (CES-D) and a scale developed by the authors to measure use of evidence- based strategies. Paired sample t-tests were used to analyze pre and post-test changes and repeated measures of analysis of covariance (ANCOVA) were used to analyze differences between the 2 groups.
Results: Twenty parents completed the study indicating a 77% retention rate. Overall sample results show that parents improved on subscales from the FOS: Understanding child's strengths and needs, helping child develop and learn, and having support systems between pre and post-test. Also parents improved in their use of evidenced-based strategies, and reported fewer depressive symptoms. We found that outcomes differed by group, parents who had student promotoras reported fewer depressive symptoms at post-test, and improved on helping their child develop and learn, and having support systems, while parents who had parent promotoras improved on understanding their child's strength and needs. Both groups improved on the use of evidence-based strategies.
Conclusions: Our findings suggest that using promotoras to deliver parent education shows promise with improving parent outcomes for parents of children with ASD in Latin America. Furthermore, both parent and student promotoras led to positive changes in parent outcomes. However, there were more positive outcome results for parents who had student promotoras. Because students can often participate as part of an internship for their professional training, these findings demonstrate a promising parent education intervention that can be cost-effective.

181 **180.181** Employing Niche Construction to Clarify Ethical Responsibilities in Cases of Autism Spectrum Disorders

J. Anderson*, Ethics Institute, Utrecht University, Utrecht, Netherlands*

Background: Â Appropriate understandings of autism depend crucially on understanding the behavioral context of persons with autism. Diagnosis and treatment involve assessments of "deficits in social communication and social interaction" that hinge on claims about successful functioning in social contexts. Identical neurological conditions can produce significant differences in functioning in different contexts, and this has profound (and contentious) implications for ethics and disability rights, as can be seen from the jurisprudence on the CRPD. What remains fundamentally disputed is the correct way of conceptualizing the interconnections between impaired functioning and the (un)supportive environment. Hence, debates between the "medical model" and the "social model" have reached an unproductive deadlock. Recent work in philosophy of mind and cultural evolution provides a useful tool for reframing these disputes and thereby clarifying the nature of ethical responsibilities in case of ASD. Building on empirical and theoretical work demonstrating human cognition to be "extended, embedded, embodied, enacted, situated, and distributed", a new paradigm has emerged that incorporates elements from evolutionary theory to reveal the role of "niche construction" in enabling individuals to function effectively.
Objectives: Â The objective of this study is to assess the prospects for employing the model of niche construction to clarify the interconnections between impaired functioning and the (un)supportive environment and thereby to clarify the nature of ethical responsibilities in cases of ASD.
Methods: Â This study employs research methods that are both theoretical and data-driven. The theoretical methods involve conceptual analysis of claims regarding "functioning," in light of the inferential implications of competing models. The data come from recent studies showing the effects of "scaffolding" behavioral niches on cognitive performance (in neurotypicals and autistics).
Results: Â From both an explanatory and an ethical perspective, the key result of this study is that the model of "niche construction" is better able to accommodate the agency of individuals in their ongoing and dynamic shaping of their environmental affordances. This helps to clarify the nature of ethical responsibilities in cases of ASD in a way that previous models (such as the "social model of disability" or radical forms of relativism) have not been able to do, in particular by integrating agentic and situational aspects of an individual's ability to meet context specific demands for social communication and social interaction.
Conclusions:Â These results also serve to help orient new empirical and theoretical research in autism into the ways in which individuals with autism and caregivers intentionally or unconsciously construct the niches in which they must function.

182 **180.182** The Meaning of the Diagnosis of Autism for Adults. a Phenomenological Study

***K. Hens**, Department of Philosophy, Universiteit Antwerpen, Antwerp, BELGIUM*

Background: Autism and ASD (autism spectrum disorder) are concepts that cover many realities and that have different meanings for different people. For many people, autism as a term refers *to a specific neurological and biological reality.* Also, the idea of autism as *a genetic* condition has gained popularity over the last years, and a large part of the research is done in this field. Much less is known about what *it means to have a diagnosis of autism* for the person herself. Indeed, although recently more attention has been paid to the values and opinions of people with a diagnosis of ASD with regards to research aims etc, very little research has been done on the meaning of such a label for the individual.
Objectives: With this study, we wanted to investigate what it means to have a diagnosis of autism in adulthood for the individual in question, using a phenomenological approach.
Methods: In the period from June 2016 till August 2016 we have performed in-depth interviews with 22 adults in Belgium and The Netherlands (aged 24-60) with a diagnosis of ASD. We used a phenomenological interview method, which means we have set aside our assumptions about what autism *is*, and we assume that the lived reality of having a diagnosis is an equally important source of information. Respondents had the opportunity to choose an oral interview, or chat sessions, in order to accommodate for those who feel uncomfortable with the former. The interviews were analyzed using a thematic inductive analysis. Interviews and analysis were done by the main researcher and a co-researcher who had received a diagnosis of Asperger syndrome in adulthood. This allowed for different perspectives on the data to be incorporated in the analysis.
Results: Â On the one hand, our respondents welcomed their diagnosis as a scientific and 'brain-based' explanation for difficulties they experienced in their lives. An experience all our respondents shared was that of heightened sensorial awareness. On the other hand, they struggled with the question how to integrate their diagnosis with their personal feeling of "self". Specifically they questioned or even opposed stereotypes about autism, for example by referring to the fact that they do experience empathy. Moreover, many struggled with finding adequate help and assistance after the diagnosis: help was either nonexistent or not tailored to the specific needs of the individual, and/or based on general assumptions about what is autism.
Conclusions: Â An autism diagnosis in adulthood can be conceived as a "walking cane": respondents appreciated the explanatory power of the diagnosis, and considered this a necessary first step in their therapeutic process. How the diagnosis would actually help them therapeutically was far less clear. With this study we hope to demonstrate that input from those diagnosed with autism is an essential part in improving the therapeutic process.

183 **180.183** Predictors of Well-Being Among Mothers of Children with Autism in Lebanon

*S. Eid-Kantar[1], N. Najjar Daou[2], R. Obeid[3], P. J. Brooks[4], E. Goldknopf[5] and **K. Gillespie-Lynch**[6], (1)American University of Beirut, Beirut, Lebanon, (2)American University of Beirut, Beirut, LEBANON, (3)CUNY Graduate Center, New York, NY, (4)College of Staten Island, Staten Island, NY, (5)University of California, Los Angeles, Los Angeles, CA, (6)Department of Psychology, College of Staten Island and The Graduate Center, CUNY, New York, NY*

Background:
This study extends upon our work demonstrating that heightened child behavioral problems were associated with poorer well-being among mothers of children with ASD in Lebanon (Obeid & Daou, 2015). Mothers' coping styles (Benson, 2010) were also associated with well-being; distraction and disengagement were associated with poorer well-being, while cognitive reframing predicted enhanced well-being. Unlike Benson's (2010) finding in the U.S., engagement was *not* associated with maternal well-being in Lebanon. Lebanese mothers reported using more problem-focused than emotion-focused coping, which we believed might be due to the social desirability bias.
We controlled for social desirability; compared benefits of formal and informal social support; and examined the impact of additional factors on well-being: (i) knowledge, given that trainings about ASD enhance knowledge (Gillespie-Lynch et al., 2015) and that Kuhn and Carter (2006) suggested knowledge could facilitate maternal self-efficacy and well-being despite limitations they noted in their knowledge measure; (ii) empowerment, given that parents' understanding of ASD empowers them to improve their children's quality of life (Murray et al., 2011); and (iii) locus of control (LoC), given that prior research (Siman-Tov & Kaniel, 2011) showed that parents with internal LoC cope better with stress than those with external LoC.
Objectives:
(1) To examine if baseline child behavioral problems and maternal coping styles, LoC, autism knowledge, empowerment, and formal and informal social support impacted maternal well-being after controlling for social desirability. (2) To examine if participating in an in-person training about ASD was associated with increased ASD knowledge and maternal well-being.
Methods:
A within-subject quasi-experimental design assessed whether the training was associated with changes in well-being. Participants completed a pre-test, an hour-long lecture-based training about ASD, and a post-test. The training, a 63-slide presentation adapted from Gillespie-Lynch et al. (2015), described ASD and effective tools/interventions, during group sessions. Fifty-four mothers completed the pretest, 33 also completed the training and post-test. Measures assessed behavioral problems, coping styles, ASD knowledge, social support, empowerment, LoC, social-desirability bias, and well-being. The reliability of the ASD knowledge scale (α= .47) was lower than in our work with students and teachers in Lebanon (αs> .61).
Results:
LoC and distraction were significant predictors of maternal well-being, $F(2,49)= 6.72$, $p= .003$. The model explained 21.5% ($R^2= .215$) of the variance in maternal well-being. We found no evidence that the training enhanced ASD knowledge, empowerment, and maternal well-being from pretest to posttest.
Conclusions: Distraction coping and LoC predicted maternal well-being. However, the ASD knowledge measure had lower reliability than in other samples and the intervention was not impactful. Mothers were more knowledgeable about autism than teachers in Lebanon in our concurrent work, likely due to their lived experiences with their children. Deeply rooted experiences may have contributed to low reliability and to difficulty shifting conceptions. It is critical to attune assessments and interventions to the needs of mothers, particularly where resources are scarce (e.g., Harrison et al., 2014). Adopting a bottom-up approach by conducting needs assessments and developing trainings/instruments that address them may be more effective.

184 **180.184** The Status of EARLY Identification of Autism in Brazil

S. H. Ribeiro[1]*, D. Bordini*[2]*, J. J. Mari*[3]*, C. S. Paula*[4] *and S. C. Caetano*[3]*, (1)UNIFESP, Sao Paulo, BRAZIL, (2)Unifesp, Sao Paulo, BRAZIL, (3)psychiatry, Federal Unversity of São Paulo, São Paulo, Brazil, (4)Developmental Disorder Program, Mackenzie Presbyterian Univesrsity, Sao Paulo, BRAZIL*

Background:
Parents seems to perceive that their ASD child´s development is not following the typical pattern as early as in the child first year of life. However, ASD children may not be diagnosed until they are of school age, especially in low and middle-income countries (LMIC).
Parents seems to perceive that their ASD child´s development is not following the typical pattern as early as in the child first year of life. However, ASD children may not be diagnosed until they are of school age, especially in low and middle-income countries (LMIC).
Objectives: To describe the status of ASD early identification in São Paulo, Brazil.
Methods: this cross-sectional study has been conducted in five Psychosocial Community Care Centers for Children and Adolescents (CAPSI), the public services responsible to treat ASD youth in the Brazilian Unified National Health System. In São Paulo city, there are 25 CAPSI, organized into 5 regions. The selection strategy was: firstly, we randomly selected one unit per region, and then all mothers/caretaker of ASD youth were face-to-face individually interviewed. Participants: 196 mothers/caretaker of children diagnosed with ASD in the last 10 years. Instruments: An adapted version of David Mandell's questionnaire about the parental early concerns, that took an average of 45 minutes to be completed (Mandell et al., 2005). This study was approved by the Brazilian ResearchÂ *Ethics Committee.Â*
Results:
mean age of ASD youth was 8.5 years old and age range: 3-21 years old; 80.6% were boys and 79% had language delays. Overall, mothers had their first concerns that their child's development was atypical when children were 25.6 months old (SD± 19; range: 2-144 months old), but these children had a formal diagnosis of ASD only at a mean age of 60 age (SD±2.7) (age range 12-180 months old), resulting in an average delay of 34.4 months in diagnosis. The vast majority of mothers mentioned their concerns firstly to pediatricians (65.3%), while 13.0% of them sought for specialists, mainly neuropediatrician or child psychiatrist. We also asked mothers to recall their first concerns about their child development. Interestingly, these concerns were not related to the core symptoms of autism, such as agitation, hyperactivity and temperament patterns.
Conclusions:
This is the first study presenting data about age of first symptoms noticed by parents and age of formal diagnosis in Brazil. The mean age of parents early concerns in Brazil was slightly higher than those in LMIC, while the age of ASD diagnosis was similar. The delay for diagnosis was almost of 3 years, which is a public health concern. In Brazil, Pediatrician is the first professional that mother seek for help, therefore specialized training in ASD would help them to better identify cases.

185 **180.185** A Proposed Measurement Solution to Psychometric Concerns with Existing ASD Knowledge Assessment Tools

A. J. Harrison[1]*, L. Bradshaw*[1]*, N. Naqvi*[2]*, M. L. Paff*[1] *and J. M. Campbell*[3]*, (1)University of Georgia, Athens, GA, (2)Psychology, Iona College, New Rochelle, NY, (3)University of Kentucky, Lexington, KY*

Background:
ASD knowledge deficits contribute to current disparities in the timing and quality of ASD services throughout the United States and globally (Khan et al., 2012; Magaña, Lopez, Aguinaga, & Morton, 2013). We will present a systematic review of the literature to examine measures used to assess ASD knowledge (Harrison et al., in press). This review examined the psychometric strength of 44 unique ASD knowledge measures across 67 studies conducted in 21 countries. Of the 67 studies reviewed, only 7% were rated as using a measure with strong psychometric support compared to 45% that were rated as using a measure with no reported psychometric support. Additionally, we will describe a tendency to examine a unitary assessment of ASD knowledge rather than thoroughly assessing subdomains of ASD knowledge content overlap and subdomains of ASD knowledge assessed (e.g., etiology, symptoms) and a failure to design measures compatible for cross-cultural research.
Objectives: We will present a subsequent study that arose following this review, in which we developed the Autism Stigma and Knowledge Questionnaire (ASK-Q) with the goal of providing a measure with strong psychometric support, cross-cultural utility, and that comprehensively assesses the multiple subdomains of ASD knowledge.
Methods:
We will describe the measurement development process including the collection of validity data. The ASK-Q has a proposed 4 factor structure including three subscales assessing specific components of ASD knowledge (diagnosis, etiology, and treatment), and a fourth domain assessing the endorsement of stigma. 149 items derived from derived from a pool of pre-existing items drawn from previously published peer-reviewed research were evaluated by a group of 16 international researchers representing 11 countries (US, UK, Iran, India, Saudi Arabia, Malaysia, Tanzania, Senegal, Cape Verde, Zambia, and Burkina Faso). Researchers rated the face, construct, and cross-cultural validity of each item using a Likert scale.
Results:
Of the total 47 items selected from the item pool for inclusion in the ASK-Q, 17 items were categorized into the symptom subscale (item mean range: 3.6 - 4.0), 16 in the etiology subscale (item mean range 3.31 - 3.63), and 14 items in the treatment subscale (item mean range 3.38 - 4.0). Ratings revealed that 7 of these knowledge items would also load on to a factor assessing the endorsement of ASD stigmas (item mean range from 3.62 - 3.89). Three researchers reviewed the remaining items to ensure that each had a clear true or false answer. Additionally, item content was reviewed to minimize repetition and to ensure that each subdomain covered a range of topics. Reponses on the ASK-Q collected from a large sample of college students and the general public (n = 617) allowed for an examination of the proposed four factor structure. Using a newer form of psychometric analysis called Diagnostic Classification Modeling we confirmed the factor structure and evaluated the statistical validity of each item among a lay sample of n = 617.
Conclusions:
The resulting measure will allow for a more valid and reliable measure of multiple domains of ASD knowledge and stigma endorsement across cross-cultural settings.

186 **180.186** Using a Simple Social Communication Chart to Work with Parents

***N. Gaddour**, University Hospital F. Bourguiba, Monastir, TUNISIA*

Background: Tunisian and African context in general are marked by a shortage of human and technical resources to deliver structured and intensive interventions to the fast growing number of children diagnosed with ASD. The race to meet theoretical standards of effective care, such as stated in manualized interventions, seems useless. Hence the importance of simpler interventions using available resources, mainly parents.
Objectives: to design a simple tool for the follow-up of interventions coordinated with parents and educators
Methods: Compilation of literature on social communication development milestones and different interventions (behavioural, developmental) to foster their acquisition, confronted to clinical practice with more than 1000 children with ASD and their families.
Results: the social communication chart is a simple grid in three segments:

1. Basics of communication: eye contact, joint attention, motor imitation, vocal imitation, receptive language, proto-imperative gestures.
2. Symbolic communication: pretend play, sharing experiences, proto-declarative gestures, expressive language
3. Social communication: narrative skills, social rules, theory of mind, pragmatic language.

It was used with more than 200 children and their caregivers and led to more involvement of parents. Each acquisition was explained with appropriate actions proposed to parents as “homework” and checked and rated at follow-up sessions (videos)
Conclusions: Â In our experience, practical and simple actions, proposed by clinicians with a minimal level of structuration, and applied by parents and educators under supervision, can lead to robust improvements for children with ASD.

187 **180.187** Autism in Africa: Community Perception, Implication for Social Development and Learning in Childhood

***M. O. Bakare**, Federal Neuro-Psychiatric Hospital, Upper Chime, New Haven, Enugu, Enugu State, Nigeria, Enugu, NIGERIA*

Background:
The paucity of data on Autism Spectrum Disorder in Africa has lead erroneously to the thought that the disorder is uncommon in Africans and may be a problem of the western population. Hence, only severe cases with marked disruption in behavior are viewed as a disorder in Africa, with milder cases probably considered as normal.
Objectives: Â The emerging interest in the field of Autism in Africa provides an excellent opportunity to review the community perception of the disorder; it’s implication for social development and learning in childhood.
Methods: Â Existing literatures in Africa on community perception of ASD were reviewed.
Results: The age of onset of Autism in Africa tends to coincide with the period of vulnerability to other physical ailments with neurological complications under the age of five years. Hence, high co-morbidity of other neurological complications in cases seen in Africa. There are no known local words to express Autism in most African languages and the disorder is still being considered to be of supernatural causations. This further encourages stigma to the family members which results in late presentation. Review of previous studies in Nigeria shows that among health workers, a small percentage views autism as treatable while few others see it as being preventable. Community perception of autism in Africa has a wide range of implications which include; poor understanding of the disorder, increased stigmatization, social exclusion and lack of appropriate policies by the authorities to improve care and promote community inclusion.
Conclusions: Increased awareness about the disorder would promote early detection, reduced stigma and promote social inclusion.

188 **180.188** Challenges and Innovation in Autism Research Approaches in South Africa

***M. Hoogenhout** and N. M. Ing, Department of Psychology, University of Cape Town, Cape Town, South Africa*

Background: Autism research in South Africa faces daunting obstacles, including lack of prevalence data for autism and other developmental disorders, and lack of funding for chronic, non-communicable diseases that do not directly lead to child mortality. Potential participant cohorts are often not well identified, are dispersed over a large geographical area, and are linguistically and culturally diverse. This challenging context calls for adaptations to the traditional research methods and processes used in the Global North.
Objectives: This presentation will discuss the challenges to expanding autism research within South Africa, as well as the promise that research on this multilingual, multicultural and genetically-diverse, yet understudied, autism population holds.
Methods: The presentation will draw on cognitive, survey, and behavioural data collected by the Autism Research Group at the University of Cape Town, South Africa. The authors will also describe the process of starting autism research within a middle-income African country, and offer insight into the success and pitfalls of this process.
Results: In South Africa, children are diagnosed with autism fairly late in childhood, creating challenges in identifying participants for studies on early identifiers or mechanisms in ASD, as well as studies on early intervention. Encouragingly, research on existing screening and diagnostic tools tentatively show that several of these tools are reliable for use in South African population groups. Use of these tools, as well as increasing awareness of autism generated by ongoing research studies, promises to steadily lower the age of diagnosis. An advantage to research recruitment of children with ASD in South Africa is that many school-age children are in autism-specific schools, which facilitates identification of potential participants. Regarding studies of biopsychosocial pathways in autism, the use of techniques such as magnetic resonance imaging is limited by the cost and availability of equipment and local expertise. However, lower-cost, portable devices to measure peripheral physiological processes are ideal for use in studies with limited funds or where participants are spread over vast areas. Cognitive and diagnostic-observational research are challenged by lack of data on the validity and reliability of the use of standardised tests developed in the Global North in a multilingual and multicultural society such as South Africa. In this area, the field is open for more international collaborations on the development of culturally-unbiased and low-cost or free assessment tools. In the area of intervention research, community-based interventions are more likely to be sustainable in the long term than one-on-one interventions. Inclusion of families and other stakeholders in developing research priorities and developing or adapting interventions are crucial.
Conclusions: Africa has much to offer autism research. The diverse nature of the South African population holds great promise for better describing the complex genetic, molecular, physiological and behavioural presentation(s) of autism. It is hoped that our experiences – successes and pitfalls - in expanding autism research at the University of Cape Town fosters increased autism research in Africa.

189 **180.189** Caregivers' Distress and Care Support Among Caregivers of Patients with Autism in a West Africa Community Surveillance

E. A. Campbell[1]*, B. Fadipe*[1]*, M. Oyelohunnu*[1]*, P. Agboola*[2]*, A. E. Lamikanra*[3]*, A. T. Olagunju*[4]*, Y. O. Oshodi*[4] *and J. D. Adeyemi*[4]*, (1)Lagos University Teaching Hospital, Lagos, Nigeria, (2)Neuropsychiatry Hospital,, Abeokuta, Nigeria, (3)Evergreen Professor, Department of Foreign Studies, Blazing Trail International and Wuhan Polytechnic University, Dallas, TX, (4)College of Medicine, University of Lagos, Lagos, Nigeria*

Background:
Autism is a neurodevelopmental disorder with poor diagnostic coverage in developing world. In Nigeria, most of the subjects have had psychiatric diagnosis other than Autism or an Autistic Spectrum Disorder (ASD) at some point in time, resulting in significantly negative impact on their care and outcome. Parents/caregivers of these subjects may therefore experience frustration while in search for diagnosis, care and support. These experiences affect different facets of their lives.
There is a large gap in the services for these subjects and caregivers. Many fund the care of the subjects by out of pocket expenditure, while others rely on family members and communities for support.
Objectives:
The study aims to determine the distress experienced by caregivers of patients diagnosed and their social support.
Methods:
Subjects were recruited from an autism awareness programme through one-on-one consultation. A sociodemographic questionnairewas administered to all consenting participants following which they were screened using, Modified Check list for Autism in Toddlers (MCHAT) for children aged 3years and younger and Childhood Autism Spectrum Test (CAST) for those older than 3 years of age. Diagnosis of ASD was made based on DSM 5 criteria for autistic spectrum disorder.The perceived social support scale was used to assess the level of social support.
Results:
A hundred and one subjects (101) out of a total of 276 people with neurodevelopmental disorders met the DSM 5 clinical diagnosis of ASD, Fifty eight (57.4%) met a diagnosis of ASD by screening with CAST and MCHAT - 74% by CAST and only 4.2% using MCHAT. Majority of the subjects (82.2%) were males and about a third (32.7%) are less than 5years. More than three quarters (79.2%) are schooling with about two thirds (65.9%) in regular schools.
Only a tenth (10%) of the caregivers belong to a self help group, caring for the subjects had impacted negatively on the relationship of 9% of the caregivers with their spouses, more than 3 quarter (76.8%) of the respondents reported that the care of the subjects had affected their finances, a third of them (32.4%) have people other than the spouses supporting them but area of support or type was not mentioned.
Some (15.5%) had been blaming themselves for the cause of the subjects problem, 9% of the caregivers said they are ashamed to be with the subjects while 4 of them had been contemplating suicide. Less than a fifth (19.4%) had low social support while 37.3% of them reported high level of support.
Conclusions: Caregivers of patients with ASD experience distress in caring for their wards but seem to have a good support system despite for the lack of a structured system of support in our environment. There is a need for to strengthen the support for these caregivers so as to help in alleviating their distress.

190 **180.190** Systems of Service Delivery for Care of Indian Children with Autism Spectrum Disorders

S. M. Kaku*, Clinical Neurosciences and Child and Adolescent Psychiatry, National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore, India*

Background: India has the second largest population in the world. Till date there is no national data which reports the prevalence of ASD in India. However, there are a number of service providers like special educators, speech therapists, occupational therapists, psychologists and psychiatrists catering to the needs of the families. In this complex system of service delivery, parents often see multiple professionals, have to move across the country for consultation and sometimes when living in resource limited areas, have difficulty to access regular help, resulting in the need to deliver home based training programs for their children with ASD.
Objectives: This study aims to describe the current available pathways to care in India.
Methods: Review of literature published in India from centres managing children with ASD was reviewed. Retrospective and prospective data from our centre was reviewed. Various steps in the pathway to care were examined which included the diagnosis, assessment and management components.
Results: While most studies seem to find that symptoms are first detected by 12 to 18 months of age, the first contact is much later as parents would "wait and watch" for children to gain milestones. Very few parents have access to trained child mental health professionals across the country and if they do, they come for a single visit consultation due to financial burden. When they initiate consultation, the first contact person for 60% of families was a Pediatrician. Neurologist (11%) and speech therapist (11%) were the next preferred specialists whom family consulted initially; followed by ENT surgeons, psychiatrists, child and adolescent psychiatrist, psychologists and others. Parents consulted an average of 3.2 doctors (Range: 1-10) before receiving a diagnosis of ASD. Many families would not come to consult in academic institutes due to long waiting hours for consultation and would prefer smaller centers run by trusts, non-governmental organizations and private practitioners. Assessments would be done by professionals systematically; however, families were not adequately satisfied about the intervention methods advised. The need for multidisciplinary inputs and resource limitation brings in enormous pressure on the families who then practice home based intervention methods. Education system is supportive to children with special needs with the government following inclusive education. There are currently very few government funded ASD research programs across the country.
Conclusions: Though awareness about ASD is good, lack of resources makes it a challenge to practice good service delivery. There is need to improvise public programs, promote awareness, advocate the importance of early intervention for children with ASD and provide well integrated and organized pathways to care.

191 **180.191** ASD Service Delivery in South Africa

***N. M. Ing**, M. Hoogenhout, S. Malcolm-Smith and K. Thomas, Department of Psychology, University of Cape Town, Cape Town, South Africa*

Background:
The availability of Autism Spectrum Disorder (ASD) services in low-middle income countries (LAMICs) is poorly documented. Typically, research has focused on high-income countries (HICs) from the global north with a lack of research focusing on LAMICs, like South Africa. This situation is problematic given the likelihood that individuals in LAMICs might, for instance, face comparatively heavy socioeconomic burdens, and that healthcare systems in those countries might bear comparatively heavy burdens of disease. Thus, data from HICs regarding service delivery and quality of life in ASD may not be useful in the LAMIC context. Within South Africa, as in much of Africa, there is no published research concerning service delivery. The lack of service delivery data makes identifying the shortfalls of the services challenging, and hinders calls for improved ASD care in South Africa.
Objectives:
This study addressed the paucity of information on care pathways in LAMICs by examining parents' perspectives of ASD service delivery adequacy and availability.
Methods:
We recruited two hundred parents of ASD children and adults, from various sociodemographic and cultural backgrounds from three different provinces within South Africa. A detailed service delivery questionnaire was administered with each parent. Additionally, six parent focus groups were held to obtain in-depth perspectives on service delivery obstacles and strengths. Various areas of service delivery were examined, including the diagnostic process, current health care, access to and quality of education, and the impact of the ASD diagnosis on the family.
Results:
The majority of children were typically diagnosed later (i.e., after 2 years old) than the age parents first noticed behavioural and developmental difficulties (age = 26 months). Overall, most of the children were diagnosed before 6 years old. Furthermore, some families had to consult multiple professionals before receiving a diagnosis, with most of the families reporting that ASD was not mentioned at their first consultation with the professional. However, most of the parents reported receiving referrals to various services while waiting for the diagnostic assessment. A range of different therapies/interventions were utilised, with speech therapy being the most common. School attendance was predominantly in autism-specific schools, followed by public special needs schools. Furthermore, most parents reported that their child does not receive interventions or any form of therapy at their school. Additionally, most parents reported a lack of, and in turn a need for, community-funded therapies, community organisations, and career and employment assistance for autistic adults. Families reported that their child's ASD diagnosis negatively impacted their financial situation and for some their ability to maintain employment. Additionally, only 28% of parents reported receiving government assistance. Other challenges included services being expensive and far from the parent's home, as well as long waiting lists for services.
Conclusions:
This study provides key information regarding the limitations of the services provided to individuals with ASD and their families within a LAMIC context. It highlights the need for better integration of services, earlier identification and treatment of ASD in South Africa, and greater financial, social and educational support for families.

Poster Session
181 - Interventions - Non-pharmacologic - School-Age, Adolescent, Adult
12:00 PM - 1:40 PM - Golden Gate Ballroom

192 **181.192** A 6-Month Follow-up of a Daily Living Skills Intervention for High Functioning Adolescents with ASD

***A. Duncan**[1], L. A. Ruble[2], C. L. Thomas[1] and L. J. Stark[1], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Kentucky, Lexington, KY*

Background: Â Adolescence is a time of critical milestones, and those with autism spectrum disorder (ASD), even those who are high functioning (IQ >70), have difficulties successfully transitioning to the adult world in areas such as independent living and employment (Hume et al., 2014). In one study, 46% of parents reported that adults with high functioning ASD required “extensive help” completing activities of daily living, which impacted their ability to maintain employment (Farley et al., 2009). Daily living skills are everyday activities such as personal hygiene, cooking, cleaning, and managing money. Daily living skills were the only significant factor that predicted a positive outcome in adulthood for individuals with ASD, and have been linked to a more successful outcome in college, employment, and independent livingÂ (e.g., Klinger et al., 2015). Despite their importance, the daily living skills of adolescents with high functioning ASD fall far below what would be expected based on their IQ and chronological age (Duncan & Bishop, 2015). While daily living skills can be taught using empirically-based strategies, there are no evidence based intervention packages that target the acquisition of daily living skills in adolescents with high functioning ASD. We recently completed a pre-post trial to evaluate the efficacy of an intervention package, Surviving and Thriving in the Real World (STRW), which targeted increasing critical daily living skills in adolescents with high functioning ASD. Results revealed that all 7 adolescent participants with ASD gained an average of 2-2.5 years, as measured by Vineland-II Daily Living Skills domain age equivalent scores, over the course of the 12-week intervention. Adolescent participants also made significant progress, as assessed by goal attainment scaling, in all targeted areas of the STRW intervention.
Objectives: The primary aim of the current study was to evaluate the sustainability of STRW by assessing primary outcome measures (i.e., Vineland-II Daily Living Skills domain and subdomains, goal attainment scaling) at a 6-month follow-up assessment.
Methods: The pre-post trial consisted of 7 adolescents with ASD between 14-18 years and their parents. All participants had IQs>70 and met criteria for ASD on the ADOS-2. Information on daily living skills was collected using (1) the Vineland Adaptive Behavior Scales, 2nd Edition and (2) a goal attainment scale that was created for each adolescent from a parent interview that assessed skills in the goals targeted in the STRW intervention. STRW consists of 12 group sessions with adolescents and their parents that targets skills in the areas of hygiene, cooking, laundry, and money management. Daily living skills were re-evaluated 6 months after completion of STRW.
Results: The 6-month follow-up assessment of STRW is currently being conducted and will be completed by October 2016. Statistical analyses will be conducted to examine primary outcomes.
Conclusions: The current study will assist in determining whether critical daily living skills are sustained and further developed after completion of a daily living skills intervention for high functioning adolescents with ASD. A daily living skills intervention has the potential to directly affect current functioning and future adult outcomes in adolescents with high functioning ASD.

193 **181.193** A Cross-Regional and Multidisciplinary Delphi Consensus Study Describing Usual Care for Anxiety Problems in School to Transition-Age Youth with Autism

C. M. Kerns[1], *L. Moskowitz*[2], *A. Josephson*[2], *M. Jeffay*[2], *C. Day*[3], *A. Guha Ray*[3], *E. Cohn*[4], *A. Drahota*[5], *A. Wainer*[6] *and M. D. Lerner*[7], *(1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)St. John's University, New York, NY, (3)Drexel University, Philadelphia, PA, (4)Adelphi University, Garden City, NY, (5)Michigan State University, East Lansing, MI, (6)Rush University Medical Center, Oak Park, IL, (7)Stony Brook University, Stony Brook, NY*

Background:
Strides have been made in recent years to develop evidence-based practices (EBPs) for core social and highly prevalent comorbid conditions, such as anxiety disorders, in youth with ASD. A critical step to successfully implementing such EBPs is to develop a greater understanding of what comprises usual care for youth with ASD in community settings. Yet, even developing an understanding of the landscape of usual care services is complicated by the lack of a common, inclusive vocabulary and catalog of intervention strategies with which to survey the diverse range of professional disciplines that serve youth with ASD.
Objectives:
This study aimed to develop consensus among experts from multiple disciplines and regions in the U.S. regarding the intervention strategies most familiar to providers serving youth (7-22 years) with ASD, and those considered most useful, commonly-used, and research-supported to address anxiety in this population.
Methods:
Using an online Delphi technique (Hsu, 2007; Bishop et al., 2016),Â snowball sampling was used to recruit a panel of 66 expert ASD providers (i.e., primarily served youth with ASD for >5 years and served >50 ASD individuals) representing multiple disciplines (education, psychology, psychiatry, behavior analysis, social work) from 5 sites (Philadelphia, Chicago, New York City, San Diego, Long Island). Round 1 began with a set of 50 intervention strategies (with descriptive examples) derived from a systematic review of the literature. Participants rated their familiarity with each strategy on a 4-point scale (“not at all” to “very”), added free text comments and suggested additional strategies not represented in the list. Familiar strategies were also rated on the same 4-point scale for: frequency of use, usefulness, and empirical support for reducing anxiety in ASD (ratings for other presenting problems were also collected but our analyses will focus on anxiety). Round 1 responses were synthesized by the research team, who then removed, combined, modified and added items to facilitate consensus. The revised list of strategies was returned to the panel for a second evaluation. Eighty percent of the initial sample completed the revised survey.
Results:
Composite results yielded a list of 56 intervention strategies, 48 of which were familiar/very familiar to >75% of the sample. Of these common strategies, consensus was also established around those most often used (16 strategies >75%), most useful (33 strategies at >75%), and most research supported (8 strategies > 75%) to treat anxiety in ASD. In general, agreement regarding the usefulness of a strategy did not always correspond to beliefs about how often that strategy was used or research supported (Table 1).
Conclusions:
Delphi methodology was used to achieve consensus among expert ASD providers from multiple disciplines and locales regarding the intervention strategies used to support youth with ASD and co-occurring anxiety. Consensus ratings also suggest variability in the perceived usefulness, use and research support for these strategies as treatments for anxiety by expert providers. These findings may support a “two-way” bridge of communication, wherein knowledge from both providers and from clinical research is integrated to identify and disseminate effective interventions.

194 **181.194** A Modified Book Reading Intervention for Students with Complex Communication Needs Who Are English Learners and Have a Severe Intellectual Delay

T. Kemper[1] *and V. Fleury*[2], *(1)400 West First St., California State University Chico, Chico, CA, (2)Educational Psychology, University of Minnesota, Minneapolis, MN*

Background: Reading comprehension is an important skill for individuals with autism to learn. The research in this area has increased but is still lacking in the area of individuals with ASD that have Complex Communication Needs and are English Learners. This study examined using modified books and a bilingual intervention package to increase reading comprehension.
Objectives: The goal of the study was to determine if the intervention package was successful and if an intervention given to an English Learner bilingually would increase reading comprehension. The researcher measured if the participants answered comprehension questions, if they answered them with accuracy and if they had an increase in independent communication, separate from the reading comprehension questions being asked of them.
Methods: An alternating treatment design was used in which participants received the intervention package in English on one day and on a different day received the intervention package Bilingually.
Results: All students demonstrated an increase in independent communication attempts during
the intervention phase. There were no systematic differences between
bilingual or English-only conditions on child outcome measures.
Conclusions: The results did not show any difference in the measures on the English day compared to the Bilingual intervention day. However, there is still very little research in this area. More research needs to be conducted in this area to determine best practices for students with Autism who are English Learners and have Complex Communication Needs.

195 **181.195** A Multiple Single Case and Mixed-Methods Evaluation of a Parent-Mediated CBT Intervention for Children with ASD and Difficulties with Emotional Regulation: Feasibility, Acceptability and an Initial Estimate of Efficacy

*S. A. Shah[1,2], M. Murin[3], D. H. Skuse[4] and **W. Mandy**[1], (1)University College London, London, United Kingdom, (2)Social and Communication Disorders Clinic, Great Ormond Street Hospital, London, United Kingdom, (3)Great Ormond Street Hospital for Children, London, UNITED KINGDOM, (4)UCL GOS Institute of Child Health, London, UNITED KINGDOM*

Background: Â In addition to the core deficits, many young people with Autism Spectrum Disorder (YPASD) have difficulties with emotional regulation which can present as elevated levels of anger and aggression. Such problems left untreated can disrupt the child's psychosocial development and have a longstanding and negative impact on the child and their family. However, in comparison to anxiety management, there is a paucity of research on therapeutic interventions for anger management in this population. Furthermore, there has been no research on individually administered CBT for anger management for YPASD.
Objectives: Â The aim of this study was to obtain an initial estimate of efficacy and investigate the acceptability and feasibility of an individually administered, parent-mediated cognitive behavioural intervention for YPASD (8-14 years old) with emotional regulation difficulties relating to anger.
Methods: Â The study employed a mixed-methods, small-N design which consisted of a series of seven systematic case studies. Participants acted as their own controls. Frequency data was collected fortnightly over a baseline period, during the intervention period and atÂ six week follow-up. The primary outcome measure was a parent report frequency measure of anger outbursts. Secondary outcome measures included the Strengths and Difficulties Questionnaire, the Parenting Stress Index– Short Form, personalised Goal Based Outcomes and post-intervention interviews. Visual analysis of the primary outcome was supplemented by a Tau-U statistical analysis (Parker, Vannest, Davis & Sauber, 2011). The reliable change index (Jacobson and Truax, 1991) was used to calculate reliable differences of pre/post data of the secondary outcome questionnaires. Qualitative interview data were analysed using thematic analysis (Braun and Clarke, 2006).
Results: Â The quantitative and qualitative results indicated preliminary evidence that the intervention was acceptable to most families. Analysis revealed that the intervention led to statistically significant reductions in anger outbursts in two cases. Parents also reported additional improvements to the intensity and duration of outbursts which were not captured by the frequency measure. Qualitative data also revealed other positive child behaviour changes as well as positive changes in parental stress and improved communication between parents and child. The outcome varied across participants which suggests there is a need to better understand how such interventions can be modified to benefit a greater proportion of individuals. Obstacles to progress highlighted through post-intervention interviews with parents and therapist checklists related to the young person's motivation to change, their ability to generalize skills outside sessions and underlying anxiety.
Conclusions: Â Our findings provide preliminary evidence that an individually administered CBT intervention is acceptable and can lead to a number of positive outcomes for families of YPASD. Some obstacles to progress were highlighted by qualitative feedback and this data suggests ways in which CBT interventions could be improved for this population. Overall, the findings support further investigation of a refined version of the intervention through a larger, controlled study.

196 **181.196** A Review of Social Communication Interventions for Students with Autism Spectrum Disorder in School Settings: Contributions from Single-Subject Research

*F. Al-Rasheed[1], **F. Alnemary**[2], J. Lee[1] and W. A. Machalicek[1], (1)College of Education, University of Oregon, Eugene, OR, (2)University of California, Los Angeles, CA*

Background: Poor social communication skills are one of the many barriers that hinder the ability of students with ASD to learn and interact with peers in school settings. Studies evaluating the efficacy of interventions that promote the acquisition and the development of different social communication skills for children with ASD have been reported in the literature and reviews for such a literature have been conducted. However, none of the previously conducted reviews explicitly evaluated single-subject research targeting social communication skills for students with ASD in school settings.
Objectives: The purpose of this study to systematically review peer-reviewed publications that utilized single-subject experimental design to evaluate interventions targeting social communication skills for students with ASD (3 to 21 year old) in school settings.
Methods: Sixty-nine studies, located in ERIC, PschINFO, and MEDLINE and published from 1995 to 2014, met the inclusion criteria. These study were sorted by: 1) the number and the characteristics of participants, 2) settings, 3) targeted outcome(s), 4) intervention practice used, 5) type of single-subject design, 6) documentation of generalization and maintenance, 7) the person delivering the intervention, 8) the rigor of the study (Reichow et al., 2008), and 9) effect size using non-overlap indices Tau-U score (Parker et al., 2011). Inter-rater reliability for coding was 97.91%.
Results: One hundred and ninety two students (150 male, majority of them were between 3-6 years old and elementary school age) with ASD diagnoses were exposed to intervention and intervention packages (mostly based on behavioral principles) targeting social communication skills that were delivered by teachers, researchers, peers in 29, 36 and 8 studies, respectively. The targeted social communication skills were categorized in two ways: 1) based on the function, type, domains of skills, and 2) based on the form and/or the modality of the outcomes. Requesting, joint attention, conversation-related skills, greeting, and commenting were targeted in 39, seven, seven, four , and 12 studies respectively. Ten studies targeted skills were not part of the above-mentioned categories. With respect to the form or modality of skills targeted, verbal responses were targeted in 44 studies and nonverbal responses (e.g., gestures such as pointing, reaching, showing, eye contact, or eye gaze, etc.) were targeted in 20 studies, manual signs were targeted in two studies, picture exchange were targeted in 14 studies, the use of speech-generated devices (SGD) was targeted in 15 studies. In terms of the rigor of the study, only seven studies were rated as strong, 39 were as adequate, and the remaining 23 as weak. The mean Tau-U across all the studies was 0.76 (range from 0.00 to 1.00).
Conclusions: Findings from this review suggest the availability of a wide range of specific interventions (and intervention packages) to improve different social communication skills for students with ASD in school settings.

197 **181.197** A Thematically Structured Educational Program for Children with Autism Spectrum Disorder

***H. M. Chiang**, University of Macau, Taipa, Macao*

Background: **: Limited studies have been conducted to test the effects of an inclusive educational program that aims to adress multiple skills of children with ASD. Most of the ASD intervention studies have focused on a specific ability group (e.g., low-functioning, high-functioning). Yet, there is a limited research efforts on the programs that can accommoate children with ASD across various abilities. A thematically structured eduactional program was created to address the needs of children with ASD. This program was designed to teach multiple skills to children with ASD and their peers with TD.**
Objectives: **This study was conducted to examine the prelimiary effects of this educational program on social and communicatino skills of children with ASD.**
Methods: **A quasi-experimental pre-test/post-test intervention group vs. waitlist control group design was used. Fifth-six children (46 males; 10 females) with an ASD between the ages of 3 and 12 years participated in this study. The inclusion criteria for children with ASD in this study included: (a) the child had a clinical diagnosis of pervasive developmental disorder, autistic disorder, Asperger's disorder, or pervasive developmental disorder-not otherwise specified (PDD-NOS); (b) the child was between the ages of 3 and 12 years; and (c) the child's score on the Childhood Autism Rating Scale, Second Edition (CARS-2) was ≥ 30. This thematically structured educational program consisted of ten 120-minutes sessions and it was delivered once a week over the course of 10-weeks. Each intervention session was led by one theme and composed of four 30-minutes sequential segments: (a) dance party, (b) an interactive story, (c) language arts/math/science, and (d) arts projects. A curriculum detailed teaching activities was developed for each session and teachers in the program were trained to use the curriculum.**
Results: **Mann-Whitney U tests were used to determine the differences between the intervention group and the control group in the improvements in communication and social interaction. The results of Mann-Whitney U tests showed that (a) communication skills improvements as measured by Expressive One-Word Picture Vocabulary Test-Fourth Edition (EOWPVT-4; Martin & Brownell, 2011a), Receptive One-Word Picture Vocabulary Test-Fourth Edition (ROWPVT-4; Martin & Brownell, 2011b), and Vineland Adaptive Behavior Scales, Second Edition-Parent/Caregiver Rating Form (VABS-II-Parent/Caregiver; Sparrow, Cicchetti, & Balla, 2005)communication in the intervention group were significantly greater than those in the control group (EOWPVT: *Z* = 2.84, *p* < .01; ROWPVT: *Z* = 3.92, *p* < .001; Vineland-II communication: Z = 3.22, *p* < .001); (b) social interaction skills improvements as measured by Social Skills Rating System-Parent Form (SSRS-Parent; Gresham & Elliott, 1990) and Vineland-II socialization in the intervention group were significantly greater than those in the control group (SSRS-Parent: *Z* = 3.21, *p* < .001; Vineland-II socialization: *Z* = 3.66, *p* < .001).**
Conclusions: **This study found that the children with ASD who received this program showed significantly greater improvements in communication skills and social interaction skills than did the children who were in the waitlist control group. This educational program appears to hold promise in fostering the development of social interaction and communication skills of children with ASD.**

198 **181.198** ASD Students' Perceptions of the Optimal Practices That Aid Their Transition to Highschool

A. Leroux-Boudreault[1] *and N. Poirier*[2]*, (1)Université du Québec à Montréal, Montreal, PQ, Canada, (2)Université du Québec à Montréal, Montréal, CANADA*

Background: Many structural changes are associated with a transition to highschool, such as novel settings, curricula, peers and teachers. These changes may increase stress during this life period. In addition, students must cope with perbutal changes. Such a life period, which is considered difficult for most teenagers (Lohaus, Elben, Ball, & Klein-Hessing, 2004), can be even more challenging for students with an ASD (Hannah & Topping, 2012).
Objectives: The aim of this study is to identify the optimal practices that aid the transition to highschool according to students. This study also explores whether there is a significant difference between main stream students and ASD students in regards to such perceptions.

Methods: Forteen 6th graders integrated in regular classroom (2 girls and 10 boys) with ASD were selected to be part of group 1. Fourteen other main stream students were then matched to students from group 1 according to age and gender.
The participants were asked whether the intervention services highlighted in the scientific literature was helpful or not. A non-parametric test (McNemar) was designed to determine whether a change of binary state would yield statistical significance between both groups (p<0,05).
Results: There are no significant differences between the two groups. As there are no differences, the results will be specific to ASD students' perception. The most useful practice for students with ASD (n=13) in aiding their transition is to be informed about who their teachers will be. Also, 86 % (n=12) wish to : learn strategies to relax; to have a friend for dinnertime; to know where their locker is and how to open it; to have the opportunity to share their issues with an adult; to visit the school; and to know someone in their classes. Being informed on how much time they should devote to their homework and knowing emergency strategies was also deemed useful for 79 % (n=11) of the respondents. In addition, having a map of the school, a cellphone, a resource teacher, and a place where they can use their strategies with privacy was identified as helpful for 71 % (n=10) of students.
Conclusions: As there is no difference between the two groups, students with ASD in regular classroom should not be treated differently than their peers. However, specific attention should be paid to practices concerning the school setting. Indeed, visiting the school, having access to their future locker and meeting their future teachers should be methods adopted for every student. Also, the curricula and functional information of the school (homework, dinnertime, schedule, textbooks, remedial courses, etc.) should be presented to the future students. As shown by the results, students with ASD attending regular classes and following the regular program seem to cope well with their integration in the regular program.

199 **181.199** Acceptance and Commitment Therapy (ACT)-Based Stress Management for High-Functioning Autism Spectrum Disorder (ASD)

J. Pahnke[1]*, T. Lundgren*[2]*, T. Hirvikoski*[3]*, B. Bohman*[2] *and G. Andersson*[4]*, (1)Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, (2)Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, SWEDEN, (4)Karolinska Institute, Stockholm, Sweden*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder associated with depression, anxiety and stress, as well as decreased quality of life. ACT processes target core difficulties in ASD, such as psychological inflexibility, and has been shown efficient in reducing stress and psychological distress as well as increasing quality of life, although not yet evaluated for this population.
Objectives: To evaluate the efficacy and feasibility of an ACT-based stress management for adolescents and adults with high-functioning ASD.
Methods: Study 1:Â Using a quasi-experimental design we evaluated an adapted ACT-protocol for 28 students with ASD (aged 13–21).Â Study 2: Using an open trialÂ design the ACT treatment was evaluated for adults (n=10; age range 25-65 years) in anÂ outpatient psychiatric context.Â Study 3: Using an RCT designÂ we evaluated the ACT treatment for 40 adults with ASD in an outpatient psychiatric context.
Results: Study 1: Levels of stress, hyperactivity, and emotional distress were significantly reduced and pro-social behavior was increased. Study 2: Levels of stress were significantly reduced and quality of life increased. Study 3: Significantly reduced stress and psychiatric symptoms, and increased psychological flexibility and quality of life. Autistic core symptoms were also reduced.
Conclusions: The ACT-based stress management program may be an efficient and feasible option for adolescents and adults with high-functioning ASD in reducing stress, psychological distress such as depression and anxiety as well as increasing quality of life.

200 **181.200** Accommodating Adolescents with Severe ASD Symptoms in an Extracurricular Technology Club

K. Nester[1], *M. Stotz*[2], *A. S. Huschke*[1], *F. Mancuso*[2], *K. Tang*[2], *H. Miller*[2] *and J. Kaboski*[2], *(1)Saint Mary's College, Notre Dame, IN, (2)University of Notre Dame, South Bend, IN*

Background: Extracurricular clubs have been identified as natural opportunities for adolescents with Autism Spectrum Disorder (ASD) to gain support, practice social skills, explore topics of interest, and form relationships with peers that share those interests (Carter, Harvey, Taylor, & Gotham, 2013). Unfortunately, adolescents with severe ASD symptoms may be turned away from participation in extracurricular activities, as public schools are not required to provide aides for such programming. There is a need to develop a novel approach to include adolescents with ASD who are in effect barred from participating in school-sponsored after school extracurricular programs.
Objectives: The Computer and Technology (CAT) Club provided an engaging and supportive environment for adolescents with ASD to interact with typically developing peers with similar interests. Three of the participants had challenging behaviors that posed serious barriers to full inclusion. In depth case studies are reported to shed light on some potentially effective means of accommodating the unique needs of such adolescents who might still benefit from extracurricular programs when appropriate supports are provided.
Methods: The three participants selected for case studies were part of a larger study that included 11 individuals with ASD and 8 typically developing (TD) peers, ages 12-17, who expressed interest in technology. Participants were not labeled as having ASD, and social/vocational training was given to all participants regardless of diagnosis. Before the start of the club, participants took a test that assessed their knowledge of computer programming and robotics; they took the same test at the conclusion of the club in order to gauge any improvement in their knowledge. While all 19 participants were initially paired with similar aged peers to work as partners, it became evident that three of the participants could not work effectively with peers due to severe communication, social, or sensory problems. These participants were paired with trained volunteer college students who in effect served as one-on-one aides. The volunteers took daily notes; patterns from these notes comprise the data for the case studies. The notes consisted of open-ended narratives as well as answers to structured questions. Case study notes were analyzed both quantitatively and qualitatively in search of patterns of improvements in behavior and social skills that may suggest best ways to support individuals with extra challenges and unique needs.
Results: All three participants experienced significant gains in their knowledge of computer programming and robotics (see Table 1). Qualitative data will be analyzed and presented as case studies (see notes in Table 2).
Conclusions: Preliminary qualitative analysis shows improvement of social behavior and increased peer interaction. Furthermore, despite their challenging behaviors, all three of them made significant gains in their knowledge of technology which could be used to further their vocational options in the future. These results provide support for the benefits of involvement in extracurricular activities for adolescents with severe ASD symptoms and problem behaviors. The use of college student volunteers offers a cost effective solution when schools or parents cannot afford a one-on-one aide for this purpose.

201 **181.201** Adolescent and Parent Factors That Contribute to Non-Completion of the PEERS® Intervention

A. McVey[1], *H. K. Schiltz*[1], *A. D. Haendel*[2], *B. Dolan*[1], *K. A. Willar*[3], *S. Stevens*[4], *A. M. Carson*[5], *F. Mata-Greve*[1], *E. Vogt*[1], *K. M. Rivera*[1], *E. Habisohn*[1], *J. Hilger*[6], *N. Fritz*[1] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Interdisciplinary PhD program (Psychology and Biomed Science), Marquette University, Milwaukee, WI, (3)Children's Hospital Colorado, Aurora, CO, (4)University of Minnesota Medical School, Blaine, MN, (5)Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (6)Illinois State University, Normal, IL*

Background: Although the Program for the Education and Enrichment of Relational Skills (PEERS®) has been shown to be well-accepted and feasible (Laugeson, Frankel, Gantman, Dillon, & Mogil, 2012), some adolescents are still prone to withdrawing from treatment. Little is known regarding factors that may interfere with social skills intervention success among adolescents with ASD (though factors predicting success have been examined; Chang et al., 2014).
Objectives: The primary objective of this study was to examine adolescent and parent factors thought to interfere with intervention completion. It was hypothesized that high levels of anxiety, depression, and arousal, and, conversely, low levels of problematic behaviors common to ASD on behalf of the adolescent, as well as parenting stress on behalf of the parent were likely predictors of withdrawal. Each of these factors was examined from data collected prior to the outset of the intervention.
Methods: One-hundred fifty-four adolescents with ASD (*N*=154) aged 11 to 16 participated in this study. The adolescents completed the Youth Self Report (YSR), Social Anxiety Scale for Adolescents (SAS-A), and Children's Depression Inventory (CDI) to account for anxiety and depression. Parents completed the Social Responsiveness Scale (SRS), Child Behavior Checklist (CBCL), Social Anxiety Scale for Adolescents, Parent (SAS-P) and Stress Index for Parents of Adolescents (SIPA) to gauge autism-related behaviors, anxiety, depression, social anxiety, and parenting stress, respectively. Adolescents completed a resting-state paradigm wherein respiratory sinus arrhythmia (RSA) was collected as a measure of arousal. Adolescents who completed the intervention (completers, *n*=134), both experimental and waitlist participants, were compared to those who withdrew (non-completers, *n*=20).
Results: Significant correlations with the binary completer variable were uncovered for SRS Motivation (*r*=-.157, *p*=.047), CDI Total (*r*=-.316, *p*=.009), and SIPA Delinquency/Antisocial (*r*=.159, *p*=.049). No other subscales, FSIQ, ADOS Total, or RSA, were significantly correlated with completion status. Logistic regression analyses were conducted separately for each measure as a predictor related to completion status (SRS Motivation, CDI Total, and SIPA Delinquency/Antisocial). SRS Motivation reliably distinguished completers and non-completers (chi square=3.995, *p*=.046, *df*=1), Nagelkerke's R^2 of .046 indicated a relationship between prediction and grouping. Prediction success overall was 87.7% (100% completer, 0% non-completer). CDI Total reliably distinguished completers and non-completers (chi square=7.019, *p*=.008, *df*=1), Nagelkerke's R^2 of .157 indicated a relationship between prediction and grouping. Prediction success overall was 82.4% (98.2% completer, 15.4% non-completer). SIPA Delinquency/Antisocial did not reliably distinguish completers and non-completers (chi square=3.538, *p*=.060, *df*=1).
Conclusions: Results suggest that low social motivation, low depressive symptoms, and high delinquency may contribute to withdrawal from PEERS®, however results are limited. General anxiety, autism-related behaviors, most parent stressors, and arousal were not related to, nor predictive of, dropout. It is possible that there is too much variability for what contributes to withdrawal from PEERS® for one family compared with another. The present study was also comprised of a small sample of participants who withdrew; future studies with larger samples may be better able to deduce contributors that interfere with completion of PEERS®.

202 **181.202** An Innovative, Urban, Diverse Teen Mentoring Initiative

S. King[1], *L. Bartolotti*[2] *and S. Rajabiun*[3], *(1)88 East Newton Street, Vose 4, Autism Consortium, Boston, MA, (2)Boston Medical Center, Boston, MA, (3)The Center for Advancing Health Policy and Practice, Boston University School of Public Health, Boston, MA*

Background:
The Autism Program at Boston Medical Center(BMC) has implemented an innovative teen mentoring initiative for youth with Autism Spectrum Disorders (ASD) to address the challenges associated with ASD, adolescence and adult transitioning. Teens Engaged as Mentors (TEAM) aims to empower diverse urban youth through a model that uses mentor dyads (youth with ASD paired with neurotypical youth) to facilitate strong leadership, self-confidence and positive community engagement.Â Taking place across the 2015-2017 school years, key elements of TEAM include training and supervision for mentors, facilitated monthly community service project “hangouts,” and recreational social events.
Objectives:
1) Describe the impact of the TEAM program on participants and key stakeholders with respect to leadership, social awareness, self-esteem, independence/autonomy and community engagement.
2) Identify the key aspects of the mentor relationship that contribute to these outcomes.
Methods:
Researchers conducted three focus groups with stakeholders of the TEAM program. A convenience sample was used to recruit 8 parents of mentees, 5 mentees (all diagnosed with ASD) and 7 mentors (4 neurotypical, 3 diagnosed with ASD). BMC institutional IRB approval was granted and consents were obtained verbally. The focus groups were audiotaped and transcribed and uploaded to a password/protected secure website that is HIPAA compliant. We used a grounded theory framework and standard qualitative analysis techniques of thematic content and comparative analyses Five researchers independently coded the transcripts for key themes and patterns. To ensure inter-rater reliability, coding schemes were compared across stakeholder interviewers and discrepancies were resolved until consensus was reached. Final results compared themes by stakeholders, diagnoses and gender.
Results:
Results revealed numerous perceived benefits of TEAM across all stakeholders, including observations of growth in the areas of self-esteem, confidence, socialization independence and communication skills. Mentors and Mentees described how they gained skills in teamwork and making new friends from the program. Mentors shared how they learned patience, acceptance and being open-minded toward others. Mentees expressed they learned from their mentors the importance being authentic and real, making connections to others, and helping others. Parental feedback highlighted the overarching need for programming such as TEAM due to their child’s struggles with peer isolation, anxiety, and understanding social norms within groups and experiences of restricted community access. Community engagement and the importance of giving back to others was cited by parents, mentees and mentors as a unique aspect of the TEAM interventions.
Conclusions:
This formative research study indicates that teen mentoring is having a positive impact on promoting skills such as socialization, independence and autonomy for both youth with ASD and neurotypical youth. For all youth, mentoring can promote cultural diversity and acceptance of others, build self-confidence and enhance teamwork. Teen mentoring programs that provide structured learning opportunities and community service programs may be an effective strategy for helping youth with ASD foster independent living skills as they transition to adulthood.

203 **181.203** Applying the Theory of Change Approach in a National Autism Charity – Benefits, Challenges and Issues in Selecting Measures.

I. Dale[1]*, C. Povey*[2] *and J. Harris*[3]*, (1)The National Autistic Society, Sheffield, England, United Kingdom, (2)The National Autistic Society, London, UNITED KINGDOM, (3)The National Autistic Society, London, United Kingdom*

Background: Large autism charities typically undertake a wide range of activities including human services, information and signposting, training, campaigns and research. These activities may have emerged over a long period, sometimes in response to need or opportunistically due to funding, without a clear strategy or overarching aim. A theory of change is a planning tool that maps a charity’s path from needs and inputs, to activities, outputs and outcomes. A well constructed theory can bring clarity to a charity’s activities and purpose, and identify assumptions about causality, gaps in activities, and suitable performance measures.
Objectives: (1) To produce an overarching theory of change for a leading nationwide autism charity, to help clarify its strategy and how each service or department contributes to its aims (2) to produce a ‘dashboard’ of performance measures aligned to the theory of change, to report to the charity’s CEO, board of trustees, staff, autism community and other stakeholders.
Methods: Workshops and consultation events were held with staff, trustees, autistic people, families, autism professionals, volunteers, donors, elected representatives, journalists and academics. The initial aim was to identify core beliefs about what the charity should stand for. These were translated into an overall aim. A second round of workshops was held with key staff to develop elements of the theory of change relating to autism professionals, education, human services, public awareness, employers and businesses. Autistic people and families were consulted on the outcomes of most importance to them as part of a national online survey in standard and Easy Read formats. A team of government analysts provided volunteer hours to help identify suitable data sources.
Results: N/A
Conclusions: Producing a theory of change proved worthwhile as it helped to clarify aims and accountabilities, and promoted the distinction between activities (e.g. training), outputs (e.g. autism aware professionals) and outcomes directly experienced by autistic people. It also proved useful in making the case for funding for autism services. A theory of change for a national autism charity is likely to be complex, given the range of challenges faced by autistic people across the life course. There are some limitations to this approach: the evidence base for autism interventions is poor, meaning assumptions about causality are weak; and although being understood, appreciated and supported were seen as important by all stakeholders, there is no consensus within the autism community on outcome measures. Using quantitative measures in an autism setting also exposes a number of issues: many autistic people are undiagnosed and so will not be represented in most data sources; measuring the indirect impact of training and campaigns is difficult; direct support for autistic people usually lacks a counterfactual; a person centred approach works against standard measurement; activities and outcomes for the relatively small number of autistic people with the greatest support needs can get ‘lost’ among bigger numbers. However on balance, the process has been positive as it creates an impetus for improving measurement, and challenges the practice among autism charities of reporting mainly activity measures, rather than outcomes.

204 **181.204** Behavior Analysts & Speech Pathologists: Perspectives Regarding Theories and Treatment of Autism Spectrum Disorder

T. Cardon*, Utah Valley University, Vineyard, UT*

Background: Currently both Behavior Analysts (BA) and Speech Language Pathologists (SLP) provide intervention services for children with ASD. It is not known how much overlap exists between the two disciplines, particularly with regard to theoretical perspectives and intervention practices. SLPs primarily view language through cognitive, developmental frameworks while BAs regard language development from a behavioral perspective. With regard to intervention, SLPs often use a developmental framework for planning intervention and BAs engage in elements of behavior skills training. While there are some approaches such as Naturalistic Developmental Behavioral Interventions where collaboration and interdisciplinary treatment is expected, the majority of SLPs and BAs work independent of one another.
Objectives: Given the challenges that are facing both SLPs and BAs when it comes to supporting children with ASD, it is imperative that we identify ways in which both disciplines can find ways to collaborate effectively. This research is a first step at identifying 1) the theoretical perspectives, and 2) the intervention strategies utilized by members from both disciplines when assessing and treating individuals with ASD.
Methods: A survey was created to identify what types of theories and interventions SLPs and BAs are utilizing in their practice with individuals with ASD. As this is a relatively new area of research, the survey was created based on the author's extensive experience in both disciplines with feedback from expert's in each field. The survey included ten different scenarios followed by a series of answers that were to be selected based on the participants' education and experience. A total of 147 responses were collected. A descriptive analysis to determine similarities and differences in responses from participants was conducted.
Results: Â Responses seem to indicate clear theoretical differences for language acquisition with multiple perspectives dispersed across SLPs while a singular theory is evident among BAs. SLPs responses are spread out across Cognitive/Semantic, Psycholinguistic/Syntactic, Behavioral, and Pragmatic with Cognitive/Semantic garnering 41% of the response. On the other hand, 91% of BAs chose a behavioral construct to language acquisition. Among dually certified individuals, the majority still reside with a behavioral approach (77%) with only 15% indicating a cognitive/semantic approach. These differences may be an indicator as to why there are distinct differences in the intervention approaches subscribed to by each discipline. Behavior analysts overwhelmingly responded to intervention scenarios with behavior analytic strategies (i.e., task analysis, video modeling) and SLPs chose responses that may indicate the use of intervention strategies supported by a developmental, cognitive approach to language acquisition (i.e., visual cueing, social story).
Conclusions: The very definition of ASD indicates that both disciplines are required to address complex needs. While there is a difference in theoretical ideology and approaches to intervention, both SLPs and BAs often have similar outcomes in mind; however, both disciplines would benefit from more familiarity with evidence based practice recommendations as reported by the National Autism Standards. Continuing education across disciplines, as well as inter-professional education to learn about evidence based approaches from the other disciplines is recommended.

205 **181.205** Can We Increase Educational Professionals' Self-Efficacy to Teach the Autism Curriculum?

*J. Salt and **K. Johnsen**, HAVE Dreams, Park Ridge, IL*

Background:
As self-efficacy has been related to many positive benefits in the classroom, and related services, research has begun to look at self-efficacy effects during educator training. General self-efficacy measures appear to make little contribution. *Autism specific* self-efficacy measures are currently being developed and validated. The Autism Self-Efficacy Scale for Teachers (ASSET; Ruble et al., 2013) holds promise and integrates well with our training model.
Our training program is a state-wide, intensive training based on structured teaching principles. The week long, interactive training provides an opportunity to receive in-vivo supervision and feedback from experienced trainers. Through lectures and hands-on construction of visual supports and materials, participants create a classroom, work with children with ASD and teach the autism curriculum. The training is open to teachers and other educational professionals (e.g. Speech, Psychology). To further study the effects of our training model, we added the ASSET measure to our evaluation protocol.
Objectives:
This study investigated the effectiveness of the training model to increase educational professionals competence in delivering the autism curriculum. The study addressed: (i) educator change in self-efficacy pre and post training.
(ii) the relationship of educator self-efficacy to professional experience prior to training.
Methods:
All participating educational personnel (n= 62) who attended the hands on 5 day training workshop, completed the ASSET questionnaire pre and post training. ASSET is a 30-item self-report measure designed to assess ASD specific knowledge and skills. Each question is rated on a 1-100 scale.
To determine if individual variables affect self-efficacy, educators also provided information related to their educational qualifications, number of years in the profession, and experience with students with ASD.
Results:
i) T-test revealed that for the whole group, there was a significant ($p<.001$) increase in ASSET scores pre and post training.
ii) Baseline ASSET scores were divided by the mean score to create high and low self-efficacy groups. To determine the effect of prior experience on educator self-efficacy, data was entered in a logistic regression model with group membership (high and low self-efficacy) as the dependent variable, and lifetime number of ASD students, educational level, and years teaching as covariates. There were no significant effects of professional experience predicting self-efficacy group membership.
Conclusions:
These results indicate the effectiveness of our training program. By attending the training, educators increased their confidence in their ability to teach the autism curriculum, at any level of ability, to individuals with ASD.Â Educators in both the low and high self-efficacy groups increased their scores over the training period. Furthermore, educators' self-efficacy for autism strategies appeared to have little relationship to their prior professional experience, experience with autism or their educational level. This has important implications for training educational professionals. Even professionals who have many years teaching experience, or who have taught many students with ASD, can increase their autism teaching self-efficacy by attending an intensive training. Our follow-up study will determine if self-efficacy predicts *implementation* of specific strategies in the classroom following training.

206 **181.206** Command & Control Cognitive Training: Executive Functioning Intervention for Teens & Young Adults with ASD Pilot Study

***M. Fitch** and M. Baker-Ericzen, Rady Children's Hospital San Diego, San Diego, CA*

Background:
Individuals with ASD are rapidly developing into teens and young adults (Lord & Bishop, 2010) and are in need of functional cognitive skills necessary for positive livelihood (Duncan & Bishop, 2013;) those with these skills demonstrate increased vocational and educational outcomes (Taylor & Mallick, 2014). Executive functioning (EF) skills are the cognitive skills most frequently impacted in autism spectrum disorders (Kenworthy, Yerys, Anthony, & Wallace, 2008). EF skills have been found to be associated with reduced adaptive functioning (Gilotty, Kenworthy, Sirian, Black, & Wagner, 2002) and greater ASD symptoms (Kenworthy, Black, Harrison, Della Rosa, &Wallace, 2009). Many EF abilities improve through childhood and adolescence but mature more slowly and often remain impaired into adulthood in individuals with ASD peers without direct intervention (Rosenthal, 2013).
Objectives:
This study developed a novel treatment, Command & Control Cognitive Training, which is an innovative manualized small group executive functioning curriculum. A pilot study was conducted to obtain estimates of effects of outcomes which include executive functioning skills for teens and young adults with ASD.
Methods:
A total of 14 individuals with ASD (10 teens, 15= yrs, 4 young adults, μ=23 yrs) participated in an open trial pilot study of the Command & Control Cognitive Training program. Command & Control was delivered weekly for 90 minutes via active group participation. In addition, there was a weekly 30 minute parent education component conducted simultaneously with the participant group. The program involves 12 sessions over 3 months with an engaging "tech/gaming focused" curriculum teaching the participants "Commands" which were the following executive functioning skills: sustained attention, cognitive shifting, cognitive flexibility, problem solving, inhibition, goal-oriented thinking, and organization and "Controls" which were specific strategies to use for each construct (i.e. Tune in, Eliminate Distractions for sustained attention). Pre and post assessments included a battery of standardized measures: 1. Behavior Rating Inventory of Executive Function (BRIEF & BRIEF-A), 2. Social Responsiveness Scale-2 (SRS-2) and 3. Satisfaction questionnaire. Participants and parent informants completed each measure. The participants were diverse with about half female (43%) and diverse race/ethnicity (35%). Some were involved with various social services: 57% disability services, 71% special education, and 57% receiving therapy (29% mental health, 50% speech, 43% occupational).
Results:
Analyses consisted of paired-sample t-tests and Cohen's d effect sizes to estimate intervention effects. Preliminary findings reveal small to large positive effects per participant and parent report on the BRIEF/BRIEF-A. This may be a reflection of the effectiveness of the intervention. Small to large positive effects were also found on the SRS-2 subscales per parent report and minimal effects for participants (Refer to Tables). Program satisfaction was very high (8.5 participant and 9.3 parent, out of 10).Â
Conclusions:
This study demonstrates that the engaging "tech/gaming" focused executive functioning intervention, Command & Control Cognitive Training, was well received and demonstrated initial positive outcomes and overall satisfaction. Using small groups to teach EF skills to teens and adults shows promise.

207 **181.207** Comparing Social Skills Outcomes in Adolescents with ASD and Adolescents with ADHD Following the UCLA PEERS® Intervention

L. Forby[1], *A. Ganel*[2], *A. Dahiya*[2], *N. Rosen*[2], *E. Veytsman*[3] *and E. A. Laugeson*[4], *(1)Suite 1268, UCLA, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)UCLA PEERS Clinic, Los Angeles, CA, (4)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background:
Adolescents with ASD or with ADHD often exhibit social deficits (Macintosh & Dissanayake, 2006; Landau & Moore, 1991), which cause them to experience peer rejection or social neglect more than their typically developing peers (Jones & Frederickson, 2010; Hoza et al., 2005). The Program for the Education and Enrichment of Relational Skills (PEERS®) is an evidence-based parent-assisted social skills intervention that improves social skills in adolescents diagnosed with ASD (Laugeson et al., 2009; 2012), and adolescents diagnosed with ADHD (Gardner et al., 2015). While research suggests PEERS® improves social skills for these two groups, the difference in treatment outcomes between youth with ASD and youth with ADHD has yet to be investigated.
Objectives:
This study examines social skills outcomes in adolescents with ASD, compared to adolescents with ADHD, following the PEERS® intervention.
Methods:
Ninety-two adolescents (males= 74; females= 18) aged 11 to 17 years (*M*= 13.74, *SD*= 1.70) and their parents participated in the study. Participants attended PEERS®, a 14-week social skills program that includes 90-minute weekly group sessions that target the development and maintenance of social relationships. Seventy-two of the participants were diagnosed with ASD; 20 were diagnosed with ADHD. Adolescents diagnosed with both ASD and ADHD were excluded from the study. In order to assess treatment outcome, adolescents completed the Quality of Socialization Questionnaire (QSQ; Frankel & Mintz, 2008), which measures social engagement through the number of get-togethers with peers over the previous month. Parents completed the Social Responsiveness Scale-2 (SRS-2; Constantino, 2005), which measures the adolescent's ability to both pick-up on and interpret social cues, the motivation to engage socially, and other impairments such as stereotypical behaviors, highly restricted interests and limited expressive social communication. Both measures where administered pre- and post-intervention.
Results:
Results were analyzed using a Multivariate Analysis of Variance (MANOVA) using SPSS. Findings reveal that both groups significantly improved on the QSQ (T_1 (M = 3.08, SD = 3.54) and T_2 (M = 6.44, SD = 5.62) conditions; t(91) = -5.71, p<0.001) and the SRS-2 (T_1 (M=76.76, SD= 12.35) and T_2 (M= 68.22, SD= 11.04) conditions; t(91)= 8.037, p<0.001) following the intervention. However, there are no statistically significant differences between the ASD and ADHD groups with regard to treatment outcome.Â F(2, 89)=0.18, p>.05, Wilk's $\Lambda = 0.99$, partial $\eta^2 = 0.004$.
Conclusions:
These findings suggest that following the PEERS® intervention, adolescents with ASD and adolescents with ADHD exhibit improvement in social skills in the areas of greater social engagement through get-togethers with peers, and in improved social responsiveness. Results further demonstrate that there were no significant differences in treatment effects across the two groups, suggesting that both adolescents with ASD and adolescents with ADHD equally benefit from the intervention. One limitation in the current study was the relatively small ADHD sample size, something that could be addressed in future studies. Additionally, future research might examine the impact of having comorbid ASD and ADHD on treatment outcomes, as well as other factors including subtypes of ADHD, such as greater inattention and/or hyperactivity/impulsivity.

208 **181.208** Computer and Technology Club As Social Performance Intervention for Adolescents with ASD and Their Peers

J. Kaboski[1], *F. Mancuso*[1], *K. Tang*[1], *J. J. Diehl*[2], *H. Miller*[1], *E. R. Fisher*[1], *J. Georgeson*[3], *K. P. Hendrix*[1], *A. S. Huschke*[3], *D. Klee*[1], *K. Nester*[3], *K. O'Boyle*[1], *G. Ramos*[1], *J. Riemersma*[1], *L. T. Simon*[3] *and M. Stotz*[1], *(1)University of Notre Dame, South Bend, IN, (2)LOGAN Community Resources, Inc. University of Notre Dame, South Bend, IN, (3)Saint Mary's College, Notre Dame, IN*

Background: Although many children with autism spectrum disorder (ASD) are integrated into general education classrooms, they lack opportunities to make friends and generalize acquired social skills outside of the classroom. Such challenges, if continued into adulthood without intervention, are likely to lead to social isolation, depression, and social anxiety (Hammond, 2012; Gillott, Furniss, & Walter, 2001) as well as obstacles to higher education and employment (Schall, 2010; Seltzer et al., 2004). There is emerging evidence that summer camps based on shared interest between children with ASD and typically developing (TD) children can be effective at increasing social skills and decreasing social anxiety in adolescents with ASD (Kaboski et al., 2015). This current study adapted the camp into an after school club, which was offered in a format that allowed adolescents with ASD to learn and practice social skills in a more natural environment over a longer period of time (i.e., once a week for 4 months) than a week-long summer camp.
Objectives: The Computer and Technology (CAT) Club provided a series of technology-related sessions in which adolescents with ASD could practice appropriate social and collaborative skills with neurotypically developing peers in an engaging and supportive environment. The club highlighted strengths and shared interests of participants, rather than ASD or social deficits. The objective of this study was to see if the CAT Club would effectively support the social and vocational development of individuals with ASD through: (1) a decrease in social anxiety, (2) an increase in social performance, and (3) an increase in knowledge of computer game programming and robotics.
Methods: Participants were 8 individuals with ASD and 8 TD peers, ages 12-17, who expressed a special interest in computer and technology. Parent reported ASD diagnoses were independently confirmed using ADOS-2, SCQ-L, and clinical judgment. During the semester-long club, social/vocational training was given to all participants, regardless of diagnosis, and participants were not labeled as having ASD. While programming, participants worked in pairs (1 ASD: 1 TD) on a programming project that culminated in a presentation in front of peers and family. Pre- and post-treatment data were collected on social anxiety, social skills, and participants' knowledge of computer and technology.
Results: A series of paired samples *t*-tests were conducted to compare the baseline data with post-test data. ASD group demonstrated a significant improvement in measures of social skills and social anxiety (see Table 1). TD group did not experience any change in social skills or social anxiety; however, it should be noted that the TD participants came in with above average level of social skills and levels that are significantly below the clinical cut off for social anxiety. For both groups, there was a significant improvement in knowledge of computer game programming and robotics.
Conclusions: These results provide a preliminary support for the effectiveness of an after school club at decreasing social anxiety, increasing social skills, and improving technical knowledge in adolescents with ASD.

209 **181.209** DBT-Informed Group Treatment to Improve Emotion Regulation and Social Interactions in Young Adults with Autism Spectrum Disorder

K. Hartmann[1], *M. Urbano*[1], *T. Kozikowski*[1], *T. V. Williams*[2] *and L. R. Qualls*[2], *(1)Eastern Virginia Medical School, Norfolk, VA, (2)Virginia Consortium Program in Clinical Psychology, Norfolk, VA*

Background: Few treatments are currently available to treat common difficulties experienced by individuals with autism spectrum disorder (ASD) in adulthood, especially for emotion regulation (ER), and social interaction. Dialectical Behavior Therapy (DBT) is a cognitive behavioral treatment approach that continues to be adapted for a variety of diagnoses from its original conception for Borderline Personality Disorder. DBT includes skill training sessions on mindfulness, interpersonal effectiveness, ER, and distress tolerance. To our knowledge, DBT has not yet been used for ASD. Given the ER difficulties young adults with ASD (YA) face, with overwhelming negative affect regulation (e.g. intense anxiety and anger), treatment components of DBT may lend themselves to successful adaptation with this population.
Objectives: The overarching goal of this study was to pilot a DBT-informed intervention to target ER difficulties in YA with ASD, with a particular focus on anxiety and anger. Specific aims included modification of existing interventions to develop a manualized DBT-informed intervention to meet the needs of YA with ASD and examination of feasibility and preliminary effectiveness of the intervention in reducing ER difficulties and improving social interaction skills.
Methods: Â 8 YA participants (3 females, ages 18-25) were recruited from clinical providers and advocacy organizations. All participants' ASD diagnoses and IQ (> 80) were confirmed through administration of the ADOS and WASI by research team members. 2 senior clinicians with ASD expertise led the 14 session groups (12 consecutive weekly sessions with 1 and 6 month follow up sessions) in an outpatient clinic of a medical school. Group sessions were 90 minutes and included a 30-minute didactic portion and a 60-minute imaginary and in-vivo exposure to practice specific anxiety and anger management skills. Through feedback from two previous pilot groups, DBT treatment duration was shortened to 12 weekly sessions and mindfulness practice, modeling in social interaction, video clips, and images were added into each session. Participants also practiced imaginary and real life exposures to manage their anxiety, in clinical and community settings. Effectiveness of treatment was measured by improvements in the Social Responsiveness Scale (SRS), Buss-Perry Aggression Questionnaire, Aberrant Behavior Checklist, Emotion Regulation Questionnaire, and Social Phobia and Anxiety Inventory-2
Results: Preliminary paired samples t-tests assessed changes in ER before and after the initial 12 sessions. Results showed that participant report on the SRS SCI (awareness, cognition, communication and motivation), awareness, and cognition subscales (all $p < 0.04$) subscales significantly improved. Results from the parent report on the SRS total score, and SCI, RRB, and communication subscales had trending results towards improvement (all $p < 0.08$). Post-treatment data collection will be completed in December 2016. RM-ANOVA will be conducted to evaluate changes over time and maintenance of treatment effects.
Conclusions: This treatment study used clinical adaptations from established manualized treatment approaches (DBT and CBT) to improve ER and social interaction skills of YA. DBT intervention was able to be successfully modified and delivered to YA's with ASD. Preliminary evidence suggests that this intervention may serve to improve deficits commonly experienced by YA's, in particular social interaction skills/awareness.

210 **181.210** Design and Efficacy of a Wearable Device for Social Affective Learning in Children with Autism

N. Haber[1], *A. Kline*[2], *C. Voss*[1], *J. Daniels*[1], *P. Washington*[1], *A. Fazel*[1], *T. De*[1], *C. Feinstein*[1], *T. Winograd*[3] *and* ***D. Wall***[4], *(1)Stanford University, Stanford, CA, (2)Pediatrics, Stanford University, Stanford, CA, (3)Computer Science, Stanford University, Stanford, CA, (4)Stanford University, Palo Alto, CA*

Background: Children with autism struggle to recognize facial expressions, make eye contact, and engage in social interactions. The best-known intervention, applied behavioral analysis, relies on teaching these skills in a clinician's office, removed from where they will actually be used and relying on artificial tools like flashcards. Their delivery is increasingly bottlenecked as the number of available therapists lags well behind by the number of children in need of care.
Objectives: We have developed a tool for automatic facial expression recognition that runs on smart glasses and delivers social cues to people with autism. The system employs the glasses' outward-facing camera to read a person's facial expressions by passing video data to an Android app for machine learning-based emotion classification, giving the child wearer real-time social cues. We, through an in-lab pilot and an at-home design trial, sought to refine both the interaction experience and outcome measures that can then be employed to track progress in a more controlled trial.
Methods:
For the in-lab pilot, we tested an interface mockup on 20 autism and 20 control participants. Each of the participants was fitted with the mockup and a custom-built head-mounted pupil tracker while sitting in front of a computer screen. The screen showed faces for 6 seconds alongside two alternating non-social standardized "distractor" images. Subjects attempted to identify the emotion of faces on the screen first without emotion feedback, then with feedback provided via the heads-up display and/or audio system of the unit, and again without feedback.
For the at-home design trial, we worked exclusively with children with ASD. We asked 14 families to take the working prototype home and use it for at least 20 minutes at least 3 times per week. We tracked behavioral progression through the continuously gathered device data and the Social Responsiveness Scale (SRS), a parental report measure.
Results:
In-lab results showed that children adapted quickly to wearing the device; audio feedback promoted a shorter learning curve. Both groups showed improvements in batches 2 and 3. Preliminary qualitative analysis of the eye tracking data collected in this study agreed with the finding that children with autism focus their gaze on the mouth as opposed to the eyes when looking at faces.
For the at-home trial, six participants moved from one range of autism on the scale to a less severe one (4 from "severe" to "moderate", 1 from "moderate" to "mild", and 1 from "mild" to "normal"). The mean total SRS score (a higher score indicates a higher severity of ASD) during the on-boarding sessions was 79.36 (SD=34.92), while the mean total SRS score during the trial conclusions was 72.69 (SD=10.67). This preliminary exploration produced over 9,000 minutes of social video and sensor data, a dataset bigger than any other of its kind.
Conclusions: These trials provided valuable data on the use of such a tool. These results together provide us with a therapeutic tool for which we have strong hypotheses that can now be measured with a more controlled trial.

211 **181.211** Developing an Autism-Specific Workplace Tool for Employers

M. Scott[1,2]*, M. Falkmer*[3]*, T. Falkmer*[1,2] *and S. J. Girdler*[1,3]*, (1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia*

Background: Adults on the autism spectrum are mostly as motivated to engage in employment as adults in the general working population. Despite many adults on the autism spectrum having high levels of skills limited employment opportunities often result in them being unemployed. The need to support adults on the autism spectrum in employment is internationally recognised. Limited research exists from the perspective of employers and the impact of modifying environmental factors on employment outcomes of individuals on the autism spectrum. This study explores the development of an autism-specific workplace tool, the Integrated Employment Success Tool (IEST), designed to support employers in modifying the work environment for employees on the autism spectrum.
Objectives: Developing the IEST to enhance employers' abilities and confidence to modify the work environment for employees on the autism spectrum in open employment.
Methods: Â Development of the IEST was informed by three studies: 1) Q-methodology study obtaining the viewpoints on successful employment from 40 adults on the autism spectrum in open employment and 35 of their employers; 2) a literature review of current employment programs and interventions in the workplace for adults on the autism spectrum; and 3) piloting a prototype tool with 10 employers.
Results: Development of the IEST was informed by the main findings from the Q methodology study, that successful employment of individuals on the autism spectrum requires workplace support, clearly communicated job expectations and knowledge of productivity requirements. Findings from the literature revealed few studies exploring employers' perceptions and the impact of environmental modifications on workplace success. Piloting resulted in a standardised tool, which aims to support the employment process across five phases, from recruitment, interviewing, job commencement, workplace modifications and ongoing support. The IEST is a practical guidebook that contains strategies, checklists and resources for each phase of the employment process. The IEST has been designed to assist with identifying employee strengths, recognising potential difficulties that might occur in the workplace, steps to evaluate the environment and strategies to implement to assist with modifying the workplace throughout the employment process.
Conclusions: The piloting of the IEST confirmed employers' need for a tool to assist with work environment modifications for employees on the autism spectrum. The IEST was perceived as a reliable source of information and to enhance employers' confidence and communication working with employees on the autism spectrum. The IEST was also reported to result in overall improvements within the organisation, particularly during the interview and recruitment process of employees on the autism spectrum.

212 **181.212** Development and Validation of a Virtual Reality Intervention for Adaptive Outdoor Activities in Autism Spectrum Disorder

M. Castelo-Branco[1,2]*, M. Simoes*[3]*, G. Oliveira*[4]*, F. Barros*[5] *and M. Bernardes*[5]*, (1)University of Coimbra, Portugal, Coimbra, Portugal, (2)ICNAS - Produção, Coimbra, Portugal, (3)Institute for Biomedical Imaging and Life Science, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (4)Unidade de Neurodesenvolvimento e Autismo, Pediatric Hospital, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, (5)University of Coimbra, Coimbra, Portugal*

Background:
Teaching a person with autism spectrum disorder (ASD) for outdoor activities such as the use public transports requires parents or therapists to practice with them, until they are ready and comfortable enough to engage in these activities independently and alone. In fact, being able to efficiently use public transports can be particularly challenging for people with ASD due to deficits in adaptive behaviour and anxiety. Virtual reality (VR) simulations represent potentially useful teaching tools for ASD individuals because they create safe and simplified versions of the real environments, providing repetition and control over the elements in the scene. Furthermore, ASD participants have a preference for computerized interventions, which suggests that serious games should be able to produce suitable results as teaching tools for daily activities. Therefore, we developed a serious game designed for teaching the user how to adequately take a bus to reach a desired destination.

Objectives:
To understand if serious games with virtual reality are effective in teaching bus taking routines and procedures to individuals with ASD.

Methods:
Participants with ASD (n=10) underwent up to three therapy sessions, where they received tasks in the game of increased difficulty (i.e., having to commute between buses to reach the destination). Matched articipants with typical development (n=10) performed one session for performance comparison with the ASD group.
The game consisted of a three-dimensional city where participants received tasks which involved taking buses to reach specific destinations. On this city, they had access to a map indicating the bus lines and the stop, and were given a target destination. They then had to find a bus-stop, wait for the right bus, enter, validate the ticket, sit (avoiding reserved places), press the bell stop, leave the bus and reach the destination. Participants were immersed in this virtual world through Oculus® Rift, sat on a rotating stool with 360º of freedom and interacted with the game using a gamepad.
We collected in-game performance metrics and used a debriefing questionnaire to further assess the success of the intervention. The system recorded the correct and incorrect actions the player performed on the process.

Results:
Group differences were found for the number of faults in the process, proving the deficits of the ASD group in this task (Mann-Whitney U = 18.5, p = .012). Regarding the success of the intervention, a Willcoxon Signed Rank test showed statistically improvements between the first and last sessions (Z = -2.220, p = .026).

Conclusions:
According to our observations, by using the game as a intervention training tool, in just three sessions it was possible to improve the general efficiency of participants and expose them to peculiar scenarios in which they could train their planning skills. The developed game stands out for its use of emerging, immersive, virtual reality technologies, whose use in intervention and serious games is still in its infancy.
Serious VR games can be used effectively in teaching people with ASD become more independent, specifically regarding outdoor activities such as the use of buses for transportation, whose know how also applies to most public transportation systems.

213 **181.213** Effect of N-3 Polyunsaturated Fatty Acid on Behavioral Response in Autism: A Systematic Review and Meta-Analysis

***L. Lin**, M. Dai, J. Liang, M. Cao, J. Jing and L. Cai, Department of Maternal and Child Health, Sun Yat-Sen University, Guangzhou, China*

Background: Â The deficits of n-3 polyunsaturated fatty acid (PUFA) is thought to be associated with behavioral abnormalities in autism spectrum disorder (ASD). However, the effectiveness of n-3 PUFA intervention aimed at improving the behavioral symptoms in ASD children has not been well established.
Objectives: Â To examine the effects of n-3 PUFA supplement on behavioral response in ASD children.
Methods: Â We searched PubMed, EMBASE, PsychINFO, Scopus, the Cochrane Library, SinoMed, CNKI, VIP and Wanfang database through February 12, 2016 for relevant full-text articles in English or Chinese. Randomized controlled trials (RCTs) were selected if they implemented n-3 PUFA supplement for at least four weeks in ASD and reported behavioral outcomes. The quality of the studies was examined by the Cochrane Collaboration's tool for assessing risk of bias. Fixed-effects models were used in the meta-analysis.
Results: Among the 1502 identified articles, seven RCTs (n =216 subjects) were included. A few sporadic significant improvements were found in the n-3 PUFA group regarding social functioning, emotional and externalizing problems. Meta-analysis of four included RCTs applying the Aberrant Behavior Checklist (ABC) revealed significant improvements in the n-3 PUFA group compared to the control group with pooled effects of -1.98 (95% CI: -3.57, -0.39; P=0.015) in social withdrawal and -1.11 (95% CI: -2.18, -0.04; P=0.042) in stereotypic behavior of the ABC. Non-significant improvement on inappropriate speech, hyperactivity and irritability in the n-3 PUFA group was found. Variability in other behavioral outcomes across studies precluded meta-analysis.
Conclusions: N-3 PUFA exerted significant improvements in social withdrawal and stereotypic behavior of ASD children. There was still insufficient evidence regarding the effect of n-3 PUFA on other behavioral response. More robust studies are required to establish full efficacy of n-3 PUFA supplement.

214 **181.214** Effectiveness of a Caregiver Mediated Intervention in Publicly -Funded Mental Health Services: Factors Associated with Improvements in Parenting Self-Efficacy

***N. Stadnick**[1,2], S. Roesch[2,3], C. Chlebowski[1,2], W. Ganger[2,3] and L. Brookman-Frazee[2,4], (1)University of California, San Diego, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)San Diego State University, San Diego, CA, (4)University of California, San Diego, La Jolla, CA*

Background: AIM HI ("An Individualized Mental Health Intervention for ASD", Brookman-Frazee and Drahota, 2010) was developed in response to the need for an implementable, evidence-based (EB) intervention for delivery in mental health service (MH) settings. AIM HI is a package of EB strategies designed to reduce challenging behaviors, the most common presenting problem for children with ASD in MH services. Active caregiver involvement in facilitating child skill development is a critical component of AIM HI and consistent with EB practices for ASD. Thus, the impact of treatment on parenting self-efficacy is an important outcome. There is limited research on the effectiveness of parent-mediated interventions when delivered by community providers. The current study examined the impact of training community providers in AIM HI on caregiver parenting self-efficacy. Data were drawn from a large-scale randomized community effectiveness trial of AIM HI conducted in publicly-funded outpatient and school-based MH programs.
Objectives: (1) Examine the impact of AIM HI on changes in parenting self-efficacy from baseline to 6 months. (2) Identify caregiver characteristics and session attendance, and therapist fidelity associated with changes in self-efficacy for caregivers in the AIM HI training condition.
Methods: A waitlist control design was used in which MH programs were randomized to either immediate AIM HI training or Usual Care/Delayed AIM HI training conditions. Therapist and client dyads were enrolled from participant programs. A total of 202 client/therapist dyads were included. Child participants were 84% male, an average of 9.13 years (SD=2.44) and 70% Hispanic. Caregivers were 93% female and 61% Hispanic. The Parenting Sense of Competence Scale (PSOC; Ohan et al., 2000) was the primary outcome measure used and was collected at baseline and after 6 months. Trainer, therapist and caregiver ratings of therapist fidelity were collected after 6 months.
Results: Results from two-level (time nested within client) mixed-effects model indicated a significant group by time interaction for parenting self-efficacy. Specifically, caregivers of children whose therapists completed AIM HI training reported significantly improved parenting self-efficacy compared to caregivers who received Usual Care, $B = 3.22$ ($SE = 1.57$), $p < .05$. To guide post-hoc analyses to probe this treatment effect, bivariate analyses were performed between each proposed predictor and PSOC scores for the AIM HI condition only. The three characteristics (ethnicity, baseline caregiver strain, and caregiver-rated therapist fidelity) that were significantly associated with parenting self-efficacy in the bivariate models were entered into a multilevel multivariable model. Results revealed a significant interaction between time and caregiver rated therapist fidelity, $B = 2.57$ ($SE = 0.88$), $p < .01$, indicating that caregiver perceptions of therapist fidelity (i.e., therapist use of active teaching skills directed towards the caregiver) was associated with improved parenting self-efficacy. Caregiver ethnicity and baseline caregiver strain did not moderate the treatment effect.
Conclusions: These results provide empirical support for the effectiveness of AIM HI on a key targeted outcome when delivered by community providers and highlight the importance of targeting therapist fidelity in bolstering clinical outcomes.

215 **181.215** Effectiveness of a Computer-Assisted Cognitive-Behavioral Therapy Program in Treating Youth with Anxiety and Co-Occurring Autism Spectrum Disorder: Camp Cope-a-Lot

***F. C. Pryor**, A. J. Lincoln and R. Igelman, Alliant International University, San Diego, CA*

Background: It has been reported that nearly 40% of children and adolescents with a diagnosis of ASD meet clinical criteria for at least one co-morbid anxiety disorder (van Steensel, Bögels, & Perrin, 2011) and those with high functioning autism (HFA) experience more anxiety than those with low functioning ASD and accompanying intellectual impairment (White, Oswald, Ollendick, & Scahill, 2009). Cognitive behavioral therapy (CBT) is most often used for treating anxiety ASD youth. Across the limited amount of studies, positive outcomes have been reported, providing preliminary evidence for CBT as an effective treatment modality for anxiety in individuals with HFA or AS (Lang, Regester, Lauderdale, Ashbaugh, & Haring, 2010; McNally Keehn, Lincoln, Brown, & Chavira, 2013; Sofronoff, Attwood, & Hinton, 2005; Wood et al., 2009). In 2008 Kendell and Khanna introduced Camp Cope-A-Lot: The Coping Cat CD Rom (Kendall & Khanna, 2008a), which is a computer-assisted CBT intervention for anxiety in youth based off of the Coping Cat program framework. No studies to date have evaluated the effectiveness of this treatment package for reducing anxious symptoms in children with ASD.
Objectives: The aims of this study was to examine the effectiveness of an empirically supported, computer-assisted CBT intervention for reducing anxiety symptoms in youth with ASD.
Methods: Participants included twenty-seven 8 – 15 year-old children with a diagnosis of ASD and clinically significant anxiety symptoms consistent with Separation Anxiety Disorder, Generalized Anxiety Disorder, Specific Phobia, or Social Phobia. Anxiety disorder classifications were confirmed using the Anxiety Disorders Interview Schedule – Parent Version (ADIS-P). All participants scored ≥ 70 on measures of intellectual and language abilities. Participants were randomly assigned to either 12 sessions of computer-assisted CBT, CCAL (n=15) or a 12-session computer assisted program aimed to improve social skills rather than improve anxious symptoms, The Social Express (TSE) (n=12). Kendell and Khanna's (2008a) twelve-session CCAL CD Rom for anxious children was employed as the primary intervention. Anxiety outcome measures included ADIS-P Parent Severity Ratings (PSR) as well as parent and child ratings on the Multidimensional Anxiety Scale for Children (MASC) and Spence Children's Anxiety Scale (SCAS). Social skills outcome measures were used and the primary outcome measure included the Social Skills Improvement System Parent Form (SSIS-P) total scores as well as total scores on the Social Responsiveness Scale (SRS) and self-report Friendship Quality Scale (FQS) total scores.
Results: Preliminary findings suggest that some children who completed a 12-session CBT computer assisted program evidenced clinically significant reductions in anxiety symptoms as measured by the primary and secondary outcome measures. Comparative outcomes for participants in the CCAL and TSE interventions groups will be presented.
Conclusions: Preliminary evidence suggests that the Camp Cope-A-Lot CD Rom for anxious children may be an effective treatment for reducing anxiety symptoms in children with ASD and co-occurring anxiety. Furthermore, preliminary evidence suggests that the alternate computer assisted intervention; The Social Express may be an effective program in improving social skills acquisition as evidenced by social skills outcome measures.

216 **181.216** Effects of a Classroom-Based Music Therapy Model on Social Skills for Children with Autism Spectrum Disorder

***L. DeMoss**[1], P. Scarbrough[1], Y. White[2], C. Ripple[1], L. Schmid[1], J. Riggsbee[3], J. Witcher Lahiff[2] and G. Dawson[4], (1)Social Science Research Institute, Duke University, Durham, NC, (2)Voices Together, Durham, NC, (3)Program in Education, Duke University, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC*

Background: Students with autism spectrum disorder (ASD) and related developmental disabilities have marked deficits in social and communication skills, which can broadly impact their ability to participate in academic and social activities at school. Music therapy is an increasingly popular intervention for children with ASD, and research evidence supporting its effectiveness is growing. In multiple intervention studies, music therapy produced greater results than standard care with respect to social interaction, verbal and non-verbal communication skills, and social-emotional reciprocity. Additionally, a recent study found that for people with ASD, the areas of the brain that process both speech and song are more effectively engaged during song than during speech. This suggests that musical interaction techniques may provide a promising approach for teaching language and communication. The *Voices Together*® program is a classroom-based music therapy model that utilizes a structured, non-directive approach to teach communication and social-emotional skills. A preliminary study on weekly sessions of *Voices Together*® demonstrated improvements in verbal responsiveness over a period of 15 weeks.
Objectives: To identify the effect of a specialized music therapy program, *Voices Together*®, on communication and social-emotional skills in children with ASD.
Methods: Sixty-four students were recruited to participate from nine elementary school classrooms for children with ASD. All students completed a clinician-administered set of 20 prompts focused on communication and social-emotional adjustment at three baseline time points before treatment began. Trained music therapists then offered the *Voices Together*® intervention for 45 minutes, once a week, for 16 weeks. Students completed the same set of prompts during three treatment time points. In addition, teachers completed the PDD Behavior Inventory (PDDBI) for each student before treatment began and at its conclusion.
Results: Paired t-tests between baseline and treatment indicate statistically significant differences between prompt scores at Baseline 2 (M=29.37) and Treatment 2 (M=32.70), t(49) = 3.48, p<0.05, and between Baseline 3 (M=31.05) and Treatment 3 (M=32.96), t(53) = 2.89, p<0.05, with Treatment scores being higher than Baseline scores. Additionally, paired t-tests of pre- and post- PDDBI assessments indicated a significant decrease in social pragmatic problems (M_{pre} = 14.02, M_{post} = 11.97; t(52) = 2.08, p < 0.05), and a significant increase in expressive language (M_{pre} = 52.08, M_{post}= 55.31; t(52)= 2.45, p < 0.05).
Conclusions: Â While participating in *Voices Together*® music therapy, students' scores on a set of prompts designed to address communication and social-emotional skills increased more than during the non-treatment period. These differences suggest that participation in the music therapy program produced an effect over and above general learning and variability within the measure. Students' improvement in communication and social-emotional skills is further supported by the overall decrease in social pragmatic problems and increase in expressive language suggested by the PDDBI. Understanding the specific outcomes of classroom-based music therapy programs like *Voices Together*® provides further insight into the clinical application of music therapy techniques for the ASD pediatric population.

217 **181.217** Effects of a School-Based Exercise Intervention Program on Stress and Executive Functioning in Adolescents with Autism Spectrum Disorder or Other Special Education Needs

*N. Elliott[1], L. K. Koegel[2], M. Gore[3] and **J. McCleery**[4], (1)University of Birmingham, Birmingham, UNITED KINGDOM, (2)Koegel Autism Center, University of California, Santa Barbara, Santa Barbara, CA, (3)University of Birmingham (UK), Birmingham, United Kingdom, (4)The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Extensive research has shown that physical exercise produces positive impacts on physical and psychological health indicators across numerous populations. With regards to psychological health, evidence suggests reduced stress and improved executive functioning as a result of exercise. As a clinical intervention, exercise has a number of advantages, including feasibility of implementation by staff at various levels of training, or by patients themselves, and completion at low cost to both the individual and society. Thus, exercise intervention has great potential to be a potent and pivotal intervention for improving the health and well-being of individuals with psychiatric disorders. Autism Spectrum Disorder (ASD) is associated with significantly elevated symptoms and rates of anxiety, as well as difficulties with executive functions including inhibitory control and attention switching. However, very little research has been conducted on exercise as an intervention for individuals with ASD to date.
Objectives: To investigate the impacts of a school-based exercise intervention on stress and executive functioning in adolescents with ASD or other Special Education Needs (SEN).
Methods: A Within-Subjects Experimental Design was utilized, with each participant partaking in 1) one week of Exercise Intervention (20-minutes of aerobic exercise per day), and 2) one week of Education As Usual (EAU). Intervention condition order was randomized across classroom (*n*=2), with ASD and SEN participants distributed across classrooms. The exercise intervention was implemented by regular school staff, without specialist equipment or resources. Participants were adolescents with ASD (*n*=24; 1f, 23m) or other SEN (*n*=29; 15f, 14m) with intellectual abilities within the normal to low range, matched on Chronological Age (p=0.24), Verbal Abilities (British Ability Scales Word Definition and Verbal Similarities; p=0.13), and Nonverbal Abilities (British Ability Scales Matrices; p=0.80). The Stress Survey Scale for Individuals with Autism or Other Pervasive Developmental Disorders (SSS; Groden et al., 2001), and computer-based tasks indexing the executive functions of Inhibitory Control and Attention Switching (Burns, Riggs, & Beck, 2012), were each administered during both the Exercise Intervention and EAU conditions. Experimentally blinded research assistants conducted these tasks within 90-minutes of completion of the 4th (Thursday) and 5th (Friday) sessions of each week.
Results: We observed significant reductions in self-reported stress with Exercise relative to EAU (SSS; Exercise M=97.04, SD=23.88; EAU M=107.71, SD=24.38, F(1,52) = 19.920; p < 0.001, np2 = .281). We also observed significant improvements in both of the Executive Function tasks. For the Inhibition Task, Exercise Intervention significantly reduced Congruent/Incongruent trial difference relative to EAU, reflecting improved inhibitory control (Accuracy: F(1,51) = 12.236, p < 0.001, np2 = .193). For the Attention Switching Task, Exercise Intervention reduced Switch/Non-Switch trial difference relative to EAU, reflecting improved attention switching ability (Accuracy: F(1,50)= 15.336, p < 0.001, np2 = .246). These effects did not interact with Group (ASD, SEN), and each effect maintained statistical significance when analyzed separately for the ASD and SEN groups.
Conclusions: The current findings provide evidence for the effectiveness of a school-based aerobic exercise intervention program for reducing stress and enhancing executive functioning in adolescents with ASD.

218 **181.218** Effects of rTMS on Evoked and Induced Gamma Oscillations and Event-Related Potentials in Children with Autism

*E. M. Sokhadze[1], M. F. Casanova[2], A. S. El-Baz[1], G. Sokhadze[1] and **E. V. Lamina**[3], (1)University of Louisville, Louisville, KY, (2)University of South Carolina School of Medicine, Greenville, SC, (3)Biomedical Sciences, University of South Carolina, Greenville, SC*

Background: Neuropathological, neuroimaging and electrophysiological studies indicate that the brains of individuals with autism spectrum disorder (ASD) manifest a dysfunction in neural circuitry that affects many disparate brain regions. The reported findings have led some investigators to conclude that a functional disconnection of brain regions is a core abnormality of ASD. Gamma oscillations and synchrony are important for the integration of information within and across brain regions. Recent studies indicate that gamma oscillations are involved in a variety of perceptual, cognitive and motor process that are affected in ASD.
Objectives: In this study we used gamma oscillations along with more traditional event-related potentials (ERP) in a visual oddball task with illusory figures as a functional marker of response to low frequency repetitive transcranial magnetic stimulation (rTMS) in children with ASD.
Methods: The subject population includes age, gender, and socio-economic matched ASD, and typically developing (TD) children aged 8-19 years. Behavioral evaluations as well as evoked and induced gamma measures and ERPs during visual oddball task with illusory figures tests was collected at pre-, post-TMS course in ASD group (N=23), and at baseline stage in TD group (N=21). After baseline behavioral and EEG/ERP testing the ASD subjects were assigned to 18 weekly sessions of 1 Hz rTMS over the left dorsolateral prefrontal cortex (DLPFC).
Results: Baseline test showed significant differences between ASD and TD groups mostly in terms of responses to non-target illusory figures where children with autism showed excessive evoked and induced gamma oscillation and higher magnitude of ERP as compared to children. Behavioral response differences were manifested mostly in lower accuracy of motor responses and lower error correction function. The rTMS course resulted in improved accuracy of motor response, lower evoked gamma response to non-targets and increased amplitude of induced gamma to target, along with similar improvements in ERP responses. Behavioral evaluation outcomes showed decreased irritability and hyperactivity scores and decreased rating of repetitive and stereotype behaviors.
Conclusions: The study support potential utility of gamma oscillations and ERP as ASD biomarkers for functional diagnostics and predictions of clinical and behavioral responses to rTMS in individuals with autism.

219 **181.219** Elementary School Students' Spontaneous Definitions of Autism

*S. Kerwin, K. A. Scheil and **J. M. Campbell**, University of Kentucky, Lexington, KY*

Background: Â Inclusive education is thought to yield social benefits for students with autism spectrum disorder (ASD), in part, by facilitating social acceptance. Successful inclusion strategies are important as students with ASD experience less social acceptance and peer companionship than their peers.Â In order to facilitate acceptance and enhance peer education, it is important to identify what typical children know, think and believe about autism.Â Magiati et al. (2002) reported that no elementary school children had heard the word "autism;" more recent studies reported that 77% of elementary school students have heard of autism (Silton et al., 2011). Despite being aware of the term autism, most elementary school students report limited knowledge about defining features and associated difficulties for students with autism.Â For example, only 22% of students report that students with autism show social difficulties.
Objectives: Â In the present investigation, we update knowledge about elementary school students' conceptions of autism.Â Overall, we aim to further understand elementary school students' conceptions of autism to identify curricular targets for peer education interventions.
Methods: Participants were 220 students (110 boys, 110 girls), ages 9 to 12 enrolled in 4th or 5th grade in public elementary school. Investigators asked students if they had ever heard of autism and, if so, to provide a written definition of autism.Â Definitions were coded for accuracy and content with a revised version of Campbell et al.'s (2010) *"What is Autism?"* coding manual.
Results: Â A total of 109 (49.5%; *M* age = 10.11; *SD* = 0.76) of the participants reported having heard of the word autism; two students reported not hearing of autism, but provided a definition nonetheless.Â Within our sample, girls (58.7%; *n* = 64) were marginally more likely to have heard of autism when compared to boys (41.3%; *n* = 45), $\chi^2(1, N = 109) = 2.97$, $p = .08$.Â Accuracy coding decisions proved to be reliable with κ = .93 and 1.0 for two pairs of coders. Content coding was also reliable with κ ranging from .73 to 1.0 for one pair of coders and κ = .65 and 1.0 for a second pair. Most (73.6%) responses were judged to be accurate and a majority of respondents (67.3%) reported that autism was a disability; however, few identified social or communication difficulties (10.0%) or restrictive/repetitive behaviors or interests (0.9%) as characteristic of autism (see Table 1).
Conclusions: Â Roughly half of elementary school students in our sample reported having heard of autism and most reported understanding that autism is a disability; however, students reported little understanding about social, communicative, and behavioral difficulties characteristic of students with autism.Â Peers' definitions were remarkably similar to prior work with elementary schoolers. Peer education efforts should target improving students' basic understanding of autism to facilitate greater awareness and acceptance. For example, educational messages targeted to elementary school students should identify behaviors likely encountered within educational settings to understand and interpret autism symptomatology accurately. Improved and accurate interpretation of social, communicative, and behavioral symptoms may reduce misattribution and social distancing.

220 **181.220** Employment Works Canada, a National Program for Young Adults with Autism

***W. Mitchell**[1], D. B. Nicholas[2], M. Clarke[3] and J. Zwicker[4], (1)The Ability Hub, Calgary, AB, CANADA, (2)University of Calgary, Edmonton, AB, CANADA, (3)Sinneave Family Foundation, Calgary, AB, CANADA, (4)University of Calgary, Calgary, AB, CANADA*

Background:
In the Canadian Survey on Disability (2012) 83% of respondents with autism spectrum disorder (ASD) reported no employment income. The literature suggests vocational supports fail to meet the needs of individuals with ASD and there is a lack of research regarding effective employment interventions for individuals with ASD. Employment*Works*Canada (EWC), offers employment preparedness training and experiential community-based job sampling for young adults with ASD to improve employment readiness and enhance employment skills. This national program is embedded within the community and is gathering practice based evidence.
Objectives:
Our objects were to determine: (1) Did participants' perceptions of their employability skills improve as a result of the program? (2) Did participants' social skills improve as a result of the program?
Methods:
The 60 hour program consists of 24 sessions, delivered twice per week for 2.5 hours over 12 weeks. The first weekly module comprises structured, yet tailored content aimed at employment and social skill building, while the second module focuses on review of the learned concepts, follow-up on homework, and the application of learning through experiential activities in a real work environment. A cohort is comprised of 8 participants with ASD supported by a Program Coordinator and two Program Facilitators.
Two self-report measures were used to evaluate employability skills. The Work Readiness Inventory (WRI; JIST Publishing), The WRI is a 36-item self-report that identifies six areas crucial to work readiness: responsibility, flexibility, skills, communication, self-view, and health and safety. Higher scores on the WRI suggest increased worker concerns or areas of weakness. The Ansell-Casey Life Skills Assessment - Modified (ACLSA-M; Nollan, Horn, Downs & Pecora, 2002), is a strengths-based questionnaire that assesses generalized life skill ability by rating (No, Mostly No, Somewhat, Mostly Yes, Yes) how accurately statements describe current functioning in seven domains (Daily Living, Relationship and Communication, Career and Education Planning, Self-Care, Housing and Money Management, Work and Study, and Looking Forward). The Social Skills Improvement System (SSIS; Gresham & Elliot, 2008), a parent-report questionnaire that measures an individual's ability to perform or acquire social skills using standardized scores (*M*=100, *SD*=15) was used to evaluate overall social skill improvement.
Results:
Eighty-one participants (mean age 22 years) from five provinces completed the EWC program.Â Paired-samples t-tests ($p < .05$) were conducted to evaluate the impact of the intervention. Participants concerns on the WRI significantly ($p< .05$) decreased in all domains by the end of the program suggesting that participation in the program positively influenced participants' perceptions about their work readiness skills (Table 1). Significantly ($p< .05$) more positive scores were noted on the ACLSA-M in the domains directly related to the EWC program, Career and Education Planning, Work and Study, and Looking Forward (Table 2). No significant differences were noted on the SSIS.
Conclusions:
These findings are encouraging in demonstrating benefits of EWC. Employment readiness and support are critical components of sustained engagement of persons with ASD in the labour market. To that end, EWC offers important benefits and promising outcomes.

221 **181.221** Evaluating the Effects of Social Intervention on Social Cognition in Young Adults with High Functioning Autism Spectrum Disorder

P. Azarkam[1], *M. C. Coret*[2] *and A. McCrimmon*[2], *(1)University of Calgary, Woodbridge, ON, Canada, (2)University of Calgary, Calgary, AB, CANADA*

Background: Â Adults with Autism Spectrum Disorder (ASD) and without cognitive impairment (i.e., cognitive intelligence >70) face academic, vocational, psychiatric, physical, social and interpersonal concerns and challenges (Eaves & Ho, 2008; Howlin 2012). There is a lack of effective and available empirically-supported social intervention programs for adults with ASD (Hotton & Coles, 2016), though some programs are emerging. The Program for the Education and Enrichment of Relational Skills, Young Adults (PEERS-YA; Laugeson & Frankel, in press) is a 16-week parent/caregiver-supported, evidence-based, and manualized social intervention using a cognitive-behavioural therapy framework. Although previous studies have shown the program to be effective in enhancing social abilities of adults with ASD and without cognitive impairment, additional outcome measures such as Theory of Mind (ToM) and Trait Emotional Intelligence (TEI), which contribute theoretically and conceptually to one's social and emotional capacities and social-communication challenges (Ferguson & Austin, 2010; Montgomery et al., in press), have not been explored.
Objectives: Â Some critiques to previous studies on PEERS-YA include a limited number and range of outcome measures, the use of only American samples, and a lack of confirmation of participants' diagnostic status. Additionally, few studies have examined long-term effects. The present study aimed to replicate and extend previous findings for young adults who completed the program.
Methods: Â Fourteen young adults (M = 11, F = 3) aged 18 to 28 years old (M = 22.91, SD = 2.99) with ASD and without cognitive impairment, and a parent per young adult were recruited from local agencies and community advertisements. The cognitive ability, diagnosis, EI, ToM, and social skills of the young adult participants were evaluated at four time intervals: 1) baseline (three months before the intervention), 2) pre-test (immediately before the intervention), 3) post-test (immediately following the intervention), and 4) follow-up (three months post-intervention).
Results: Â Outcomes of the program were analyzed and interpreted using the Friedman's test. Parent-reported social skills significantly increased from T1 to T3, T1 to T4, and from T2 to T3. Self-reported social skills scores did not significantly change, although there were median increases in self-reported social skills. Participants self-reported statistically significant increases in ToM from T1 to T3, and T2 to T3; however, ToM performance decreased from T3 to T4. Self-reported TEI was statistically improved from T1 to T4, T2 to T3, and T1 to T3.
Conclusions: Â Findings indicate that PEERS-YA improves parent-reported social skills and young-adult reported TEI at post-test and at follow-up, and ToM immediately after completion of the program. These findings suggest the malleability of one's social cognition and its relation to social skill development. This research points to the ongoing need to continue work in this field and to disseminate services for an aging ASD population.

222 **181.222** Evaluation of Multidisciplinary, Multi-Tiered Approach to Anxiety Treatment in Youth with Autism Spectrum Disorder

R. Ma[1], *R. Montague*[2], *R. K. Earl*[3], *C. Ola*[4], *A. Persons-Geer*[2], *F. Orlich*[5], *A. Bohlander*[6], *S. Pickering*[2], *R. Oti*[7] *and S. J. Kim*[2], *(1)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, MA, (2)Seattle Children's Autism Center, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)College of Education, University of Washington, Seattle, WA, (5)Center for Child Health, Behavior and Development, Seattle Children's Hospital, Seattle, WA, (6)Psychiatry, Seattle Children's Hospital, Seattle, WA, (7)Seattle Children's Hospital, Seattle, WA*

Background:
Anxiety is a commonly seen comorbidity in children and adolescents with autism spectrum disorder (ASD). It is estimated that 40% of individuals with ASD meet criteria for an anxiety disorder with some studies reporting up to 80% comorbidity, which is higher than other clinical populations (van Steesel, 2011; Selles & Storch, 2012). Cognitive behavioral therapy has previously been adapted for ASD and mild to moderate anxiety symptoms with promising results (e.g.Â exposure and response-prevention; Ooi et al, 2008; Wood et al, 2008; Sukhodolsky et al, 2013; Shaker-Naeeni et al., 2014), yet little is known about treatment delivery and efficacy with clients who present with *severe* anxiety symptoms in the context of autism. Seattle Children's Hospital Autism Center (SCAC) developed an Anxiety Program consisting of multidisciplinary care and coordination for children and adolescents with ASD and co-occurring anxiety disorders. The Anxiety Program provides a multi-tiered model of service, incorporating time-limited individual CBT, medication management, and group therapy. This multi-tier service model significantly improved access to care for patients seeking treatment. Additionally, a clinical outcome monitoring system has been implemented to evaluate client progress and program efficacy.
Objectives:
Describe and evaluate the efficacy of a multidisciplinary team approach and multi-tiered model of service for youth with acute anxiety symptoms in the context of autism.
Methods:
A total number of 51 clients were seen by the program receiving an average of 18 individual therapy sessions (*SD*=8.77). A total number of 46 patients (M_{age}=12.1, SD_{age}=2.64) were included in this preliminary analysis. Thirty-nine percentof patients (*N*=18) received medication management, and 32% of patients (*N*=15) participated in at least one round of group therapy. Pre-treatment Clinical Global Impression Severity Scale (CGIS; Guy, 1976) and Multidimensional Anxiety Scale for Children – 2nd Edition Parent Report (MASC2-P; March, 2013) were collected to determine the severity of symptoms. The Clinical Global Impression Improvement Scale (CGI-I; Guy, 1976) were measured for post-treatment clinical improvement. Pre- and post-scores of Children's Yale-Brown Obsessive Compulsive Scale (CY-BOCS; Scahill et al., 1997) were analyzed.
Results:
The clinical sample reflects highly acute anxiety symptoms and significant impact on functioning at the start of treatment as indicated by the CGI-S score (*M*=5.19) in the Markedly to Severely Ill range. An average MASC2-P Total Anxiety T score of 72.1 (*N*=16; *SD*=12.06) was in the Very Elevated range. The average post-treatment CGI-I is 2.59, indicating good improvement of symptoms (minimal to moderate improvement), with 36% clients receiving a rating of 1 or 2 (much improved or very much improved). Paired-sample *t* test indicated a significant lower post-treatment CYBOCS score than the pre-treatment score (*t*(4)=4.98, *p*=.008).
Conclusions:
A focused multidisciplinary team approach to treating severe anxiety symptoms among youth with ASD, and a multi-tiered service delivery model appears to reduce symptoms of anxiety as well as improve overall functioning. Additionally, the approach of SCAC's Anxiety Program improves access to care, careful treatment monitoring, and provider satisfaction.

223 **181.223** Evaluation of PEERS® in a Canadian Context: Improvements in Social Skills and Social Competence

L. Purdon[1]*, K. Murphy*[1]*, R. L. Matchullis*[2]*, S. Felicia*[1]*, M. C. Coret*[2] *and A. McCrimmon*[2]*, (1)University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Calgary, AB, CANADA*

Background: Social impairment is a core feature of Autism Spectrum Disorder (ASD) and has a significant impact on an individual's ability to develop and maintain friendships (Bauminger & Kasari, 2000;Â White & Robertson-Nay, 2009). Social impairment also involves challenges in acquiring discrete social skills and social competence (Usher et al., 2015). Throughout adolescence, social environments become increasingly complex and require the use of more sophisticated skills, making this transition for adolescents with ASD especially difficult (Bellini, 2006). The *Program for the Education and Enrichment of Relational Skills* (PEERS®; Laugeson & Frankel, 2010) is an evidence-based, manualized caregiver-assisted intervention specifically designed for adolescents with ASD that teaches ecologically valid social skills needed to make and keep friends.
Objectives: Existing research on PEERS® has indicated numerous positive outcomes including improvements in social skills, increased frequency of get-togethers, and brain-based changes (Laugeson & Park, 2012; Van Hecke et al., 2013). The current study explored the potential for PEERS®to increase social skills as well as other variables related to social competence within a Canadian context, thus extending previous research findings (Laugeson, 2012).
Methods: Â Participants were 35 adolescents (28 males) aged 13-18 (*M* = 15.9, *SD* = 1.5) with a diagnosis of ASD and intact cognitive abilities (i.e., IQ ≥ 70). Adolescents were recruited from the community and completed the standard PEERS® intervention. Improvements in social skills were measured using adolescent and parent reports of the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008). Social competence was measured using adolescent self-reports of the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2005). Data was collected prior to the first session and one week after the last session. Results were analyzed using paired sample *t*-tests and Pearson product-moment correlations.
Results: Analyses revealed moderate, significant correlations between caregiver and student responses on measures of social skills in the SSIS, indicating parent and adolescent agreement in social skills ratings. A paired samples *t*-test on pre- versus post-treatment responses revealed significant improvement in social skills as rated by the parents ($p < 0.019$) and the teens ($p < 0.012$) on the Social Skills total score of the SSIS. Adolescents also showed improvement in social competence, as indicated by the SRS-2. Paired samples *t*-test on pre- versus post-treatment responses revealed significant improvement in SRS-2 subscales of Social Awareness, Social Cognition, Social Motivation, and Social Communication ($p < 0.05$).
Conclusions: These results provide cross-cultural support for PEERS® and corroborate existing research findings which indicate that PEERS® increases adolescents' overall social skills and social competence in the areas of social awareness, social cognition, social motivation, and social communication. Future research assessing long-term maintenance of acquired social skills within a Canadian population is needed.

224 **181.224** Evaluation of Performance-Based Measures of Functional Skills

R. Schaaf[1]*, E. Ridgway*[2]*, A. Carroll*[3]*, M. J. Mulcahey*[4]*, S. Molholm*[5] *and Z. Mailloux*[3]*, (1)Thomas Jefferson University, Phhiladelphia, PA, (2)RFK CERC Einstein/Montefiore, Yonkers, NY, (3)Occupational Therapy, Thomas Jefferson University, Philadelphia, PA, (4)Occupational Therapy, Thomas Jefferson Unviersity, Philadelphia, PA, (5)The Children's Research Unit (CRU), Program in Cognitive Neuroscience,City College of New York, Bronx, NY*

Background: Valid outcome instruments that produce reliable scores and are capable of detecting change are an essential component of research, treatment and program evaluation. Given that interventions for children with Autism Spectrum Disorder (ASD) are often intended to develop functional skills, outcome instruments that are valid indicators of these skills, and that reliably evaluate treatment effects are important. Towards this end, parent-reported outcomes are often obtained, and although they provide important information about function, they may be subject to response bias. Thus, performance-based outcome instruments that objectively evaluate functional skills are needed to supplement parent-reported outcomes, and to support the rigorous and systematic evaluation of interventions for children with ASD.
Objectives: The purpose of this study was to identify performance-based instruments of Activities of Daily Living (ADLs) and socialization, evaluate their psychometric properties, and determine feasibility for use in intervention trials for ethnically diverse children with ASD ages 6-9 years.
Methods: Â This study used mixed methods to achieve its objectives. First, a systematic approach was used to review research and literature to identify performance-based assessments of ADLs and socialization. Assessments were included in the review if they: 1) evaluated ADL's and/or socialization; 2) included normative data for children with ASD ages 6-9 years of age; and 3) were performance-based, with evidence of psychometric support.Â Next, a panel of experts used a 32-point quality indicator scale designed specifically to assess the quality of outcome instruments and to rate psychometric properties, utility, and appropriateness for ASD (Law& MacDermid, 2014; Portney & Watkins, 2009). Using a Modified Delphi Technique, the highest rated instruments were further assessed to identify the two strongest instruments. These two instruments were then administered to 20 ethnically diverse children with ASD to evaluate feasibility, utility and discriminative validity.
Results: Â Seven performance-based outcome measures of ADL's and Socialization were identified and rated. Modified Delphi Technique identified the top-rated instrument for ADL's as The Assessment of Motor and Process Skills (AMPS – Fisher& Jones, 2012) and for socialization, The Evaluation of Social Interaction (ESI - Fisher and Griwold, 2010). Both instruments were successfully administered to 20 children with autism in one hour or less demonstrating feasibility and utility. Discriminant validity testing using the standardized canonical discriminant function coefficient showed that the AMPS Process Score predicted the ADOS Autism Severity score (r = -.63) such that a high AMPS Process score predicted low ADOS severity (as hypothesized). The AMPS Motor score was a moderate predictor (r =.445). The ESI was a strong predictor (r=.84) but in the opposite direction expected.
Conclusions: Â The AMPS shows promise as a performance based outcome measure of ADL's having strong psychometrics and feasibility for administration to children with ASD. Preliminary data suggests that the AMPS shows adequate discriminant validity. While the ESI shows strong psychometrics, utility and feasibility, further assessment of discriminant validity is needed. Implications of these findings for research and practice will be discussed.

225 **181.225** Evaluation of a Peer Education Program about Autism Spectrum Disorder for Elementary School Students

***J. M. Campbell**, E. Caldwell, K. A. Scheil, O. Lochner and S. Kerwin, University of Kentucky, Lexington, KY*

Background: Â The increased identification of students with autism spectrum disorder (ASD) has implications for public education as access to general education and instruction in the least restrictive environment are legal rights. Approximately 30-40% of elementary school students with ASD receive at least some of their instruction in general education settings. As such, students with ASD and typically developing peers will likely encounter each other during school hours. The practice of inclusive education for students with ASD is based upon protecting children's educational rights and, in part, improving social acceptance. Despite the potential social benefits of inclusion, students with ASD often experience limited social interaction, loneliness, social isolation, and bullying. The Kit for Kids (KfK) was developed by the Organization for Autism Research (OAR; see Figure 1) in order to provide evidence-based educational messages to elementary school students to improve peers' knowledge, initial attitudes, and behavior towards students with ASD.
Objectives: Â Investigators evaluated the impact of the KfK program on elementary school students' knowledge of ASD and attitudes towards an unfamiliar student. Our two research questions were: (a) Does the KfK program increase elementary school students' knowledge of ASD? and (b) Does the KfK program increase elementary school students' attitudes towards an unfamiliar student with ASD?
Methods: Â A total of 107 4th and 5thgrade students were randomly assigned to receive the KfK program or not prior to viewing a videotape of a student with ASD. Students completed two measures after viewing the videotape: (a) Knowledge of Autism (KOA; 16 items, □ = .55), a general measure of knowledge of ASD; and (b) a modified version of the Children's Attitudes towards Children with Handicaps (CATCH-A; 36 items; □ = .93), a measure of attitudes about the student with ASD. One week later, controls received the KfK program and completed measures about the videotaped student while treatment participants completed measures about the student a second time.
Results: Two, 2 (Time) by 2 (Condition) mixed-model ANOVAs revealed significant time by condition interactions for knowledge, $F(1, 99) = 19.28$, $p < .001$, = .16, and attitudes, $F(1, 90) = 8.62$, $p < .01$, = .09. The treatment group reported higher knowledge than control group immediately after intervention, $t(103) = 2.65$, $p < .01$. The control group reported more knowledge after receiving the intervention, $t(53) = 5.17$, $p < .001$. Attitudes did not differ between groups immediately after the intervention (i.e., at Time 1); however, the control group reported more favorable attitudes after receiving the intervention, $t(46) = 2.11$, $p < .05$. Treatment group attitudes declined from intervention to follow-up, $t(44) = -2.04$, $p< .05$.
Conclusions: The KfK program resulted in increased knowledge of ASD for elementary school students. The KfK program resulted in improved attitudes over time; however, attitudes declined over a one-week period. The KfK results in improved knowledge and attitudes in an analogue experimental design; future evaluation should consist of testing the materials with actual students with ASD included in elementary school classrooms.

226 **181.226** Examining the Effects of the PEERS® Social Skills Intervention on Racial and Ethnic Minorities with Autism Spectrum Disorder

***K. M. Rivera**[1], A. McVey[1], H. K. Schiltz[1], A. D. Haendel[2], B. Dolan[1], K. A. Willar[3], S. Stevens[4], A. M. Carson[5], F. Mata-Greve[1], E. Vogt[1] and A. V. Van Hecke[1],*

(1)Marquette University, Milwaukee, WI, (2)Interdisciplinary PhD program (Psychology and Biomed Science), Marquette University, Milwaukee, WI, (3)Children's Hospital Colorado, Aurora, CO, (4)University of Minnesota Medical School, Blaine, MN, (5)Baylor College of Medicine/Texas Children's Hospital, Houston, TX

Background: There is limited research examining the effects of a social skills intervention on racial and ethnic minorities with autism spectrum disorder (ASD). Most research studies examining interventions with individuals with ASD are disproportionately non-Latino Caucasian or do not separately examine different racial and ethnic minorities (Lord et al., 2005).
Objectives: The goal of the current study was to examine if the effects of the PEERS® intervention differ among racial and ethnic groups in comparison to non-Latino Caucasian individuals with ASD.
Methods: One hundred and eighty-three (*N* = 183) individuals with ASD aged 11 to 28 participated (M_{age} = 15.2, sd = 3.5); nine identified as Asian, 11 as African American, eight as Latino, 152 as non-Latino Caucasian, and three individuals identified as Hawaiian/Islander, Middle Eastern, and Biracial/Multiracial, and were grouped together as "Other". A randomized controlled trial design was used to examine the effects of PEERS® and PEERS® for Young Adults, parent/caregiver-assisted interventions focused on improving social and friendship skills (Experimental, *n* = 92; Waitlist, *n* = 91). Adolescents and young adults completed the Test of Adolescents Social Skills Knowledge (TASSK; Laugeson et al., 2012) and the Test of Young Adults Social Skills Knowledge (TYASSK; Gantman et al., 2012), respectively at pre- and post-intervention. The TASSK/TYASSK were used to assess social skills taught during PEERS®. Parents or primary caregivers completed the Social Responsiveness Scale (SRS; Constantino et al., 2003) and the Social Skills Improvement Scale-Revised Scales (SSIS-RS; Gresham & Elliott 2007) at both time points, which were used to measure autism-related behaviors and social skills, respectively.
Results: Preliminary analyses were conducted to examine possible group differences by race/ethnicity on demographic variables; no significant differences were found. Repeated measures ANOVAs were conducted for Time (Pre, Post) by Group (EXP, WL) by Race/Ethnicity (Asian, African American, Latino, Caucasian, Other) for each outcome measure. When analyzed by group, no significant difference was uncovered for response to treatment based on race/ethnicity on the TASSK/TYASSK ($F(4,172) = .411$, $p = .801$), SRS ($F(4,160) = 1.600$, $p = .177$), or SSIS-RS ($F(4,169) = 1.229$, $p = .301$). There was a significant difference between EXP and WL improvement on the TASSK/TYASSK ($F(1,182) = 283.542$, $p < .001$), SRS ($F(1,170) = 16.720$, $p < .001$), and SSIS ($F(1,179) = 7.689$, $p = .006$).
Conclusions: The present study provides preliminary evidence that PEERS® is as efficacious for racial and ethnic minority groups as non-Latino Caucasian adolescents and young adults with ASD. Although some research has demonstrated differences among minority compared to majority groups in autism-characteristics (Tek & Landa, 2012; Blacher et al., 2014; Gourdine & Algood, 2014) and shown different cultural interpretations of autism symptoms (Dyches et al., 2004; Bernier et al., 2010; Tincani et al., 2009), racial and ethnic minority groups in the present sample showed the same benefits in response to a social skills intervention as non-Latino Caucasian individuals. These findings are an important addition to the limited research about the effects of social skills interventions on racial and ethnic minorities with ASD.

227 **181.227** Expert Provider Use of Empirically-Evaluated Treatment Elements for Anxiety in Youth with ASD

T. Rosen[1], *R. J. Weber*[1], *B. Marro*[2], *C. M. Kerns*[3], *A. Drahota*[4], *L. Moskowitz*[5], *A. Wainer*[6], *S. Sommer*[1], *A. Josephson*[5] *and M. D. Lerner*[1], *(1)Stony Brook University, Stony Brook, NY, (2)Social Competence & Treatment Lab, Saint James, NY, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)Michigan State University, East Lansing, MI, (5)St. John's University, New York, NY, (6)Rush University Medical Center, Oak Park, IL*

Background: The research-to-practice gap is a well-established phenomenon and extends to treatments for youth with autism spectrum disorders (ASD; e.g., Brookman-Frazee, et al., 2010). ASD, relative to typically-developing youth, are at increased risk for anxiety (van Steensel et al., 2011). There has been a growing interest in the study of efficacious anxiety treatments for individuals with ASD (Danial & Wood, 2013); however, dissemination of these treatments has been limited (Reaven et al., 2014). In order to identify the size and scope of the research-to-practice gap for the treatment of anxiety in ASD, use of empirically-evaluated treatment elements by expert community providers must be examined.
Objectives: The primary purpose of this study was to examine the extent to which expert, community providers are using the most and least empirically-examined treatment elements to treat anxiety in ASD youth.
Methods: We conducted a comprehensive literature search, and reliably coded articles (*N*= 48) for anxiety (excluding OCD) treatment elements (ICC(2,5)=.792). Fifty elements were identified from included articles. For analytical purposes, elements were then sorted into 8 categories ranging from the least (group 8) to most (group 1) frequently used treatment elements (see Figure 1). Groups were divided to provide closest match possible to the frequency distribution in the literature while balancing statistical power. Next, 53 expert providers (primarily treating ASD youth for ≥5 years, and ≥50 ASD youth over the last 5 years) participated in a national, multi-site survey, rating these 50 treatment elements in terms of their frequency of use to target anxiety
Results: Â A one-way ANOVA revealed significant differences in provider ratings of frequency of use of element groups, $F(1,7) = 3.42$, *Â* $p = .006$. Pairwise comparisons between element groups revealed that providers reported using elements in group 1 more often than those in groups 6, 7, and 8 (p's ≤ .005). Next, a repeated-measures ANOVA was conducted to identify differences among strategies within the top and bottom groups. Within group 1, graduated exposure and visual supports were used significantly more by providers than self-management and didactic teaching (p's < .05; see Figure 2A); while within group 8, providers used peer-monitoring significantly less than all other strategies (p's < .05; see Figure 2B).
Conclusions: Â Expert providers in usual care settings are largely using empirically-examined treatment elements to treat anxiety in youth with ASD. Thus, their expertise may be important for identifying clinical variables relevant to treatment elements that have not yet received empirical examination. Toward this end, a "two-way bridge" initiative (Goldfried et al., 2014), which promotes dissemination of clinical experiences to researchers and vice versa, rather than solely relying on the researchers, may be useful for narrowing the research-to-practice gap. In this context, observational studies of treatment elements in usual care settings would augment provider-reported element use. Moreover, whether these frequently used elements are efficacious remains to be seen. Thus, future "two-way" bridge initiatives could focus on evaluating outcomes associated with implementation of these treatment elements in usual care settings, which would pave the way for targeted dissemination efforts.

228 **181.228** Fostering Socio-Emotional Competencies in Children with Autism Spectrum Condition: Results of a Randomized Controlled Trial Using the Interactive Training App „Zirkus Empathico"

I. Dziobek[1], *S. Kirst*[1], *R. Diehm*[2], *S. Wilde-Etzold*[3], *M. A. Noterdaeme*[4] *and L. Poustka*[5], *(1)Berlin School of Mind and Brain, Humboldt University Berlin, Berlin, Germany, (2)Clinic for Child and Adolescent Psychiatry, Medical University of Vienna, Wien, Austria, (3)Clinic for Child and Adolescent Psychiatry and Psychotherapy, Josefinum, Augsburg, Germany, (4)Child and Adolescent Psychiatry, Augsburg, GERMANY, (5)Clinic for Child and Adolescent Psychiatry, Medical University Vienna, Vienna, Austria*

Background:
Given that access to specialist Autism Spectrum Disorder (ASD) service does not meet needs, computer-based interventions offer a cost-effective solution to the problem. Few treatments, especially for socio-emotional competencies, have, however, been rigorously evaluated and could produce improved skills beyond those directly targeted by the intervention.
Objectives:
This study seeks to evaluate the acceptance and effectiveness of „Zirkus Empathico“, a tutor-guided app fostering socio-emotional competencies in pre-school and elementary school children with ASD in a registered, randomized controlled trial (RCT). „Zirkus Empathico“ includes four training modules focusing on i) recognition and verbalization of own emotions, ii) recognition of other's emotions from facial emotions and iii) context films, iv) emotional empathy and prosocial behavior, and v) generalization into daily life via interactive animations, which aid the communication of own and other's emotions.
Methods:
We are conducting a multicenter RCT: Manualized tutor-guided „Zirkus Empathico" (6 weeks with a minimum of 100 min./week) versus an active control group using educational apps not focusing on socio-emotional functions for the same amount of time at three points of assessment (baseline, post training, 3 months follow-up) in children aged 5-10 with high-functioning ASD. N=150 individuals were assessed for eligibility, of which 82 were randomized to participate in the trial. Participants diagnosed with ASD according to ICD-10 criteria, corroborated by ADOS, and have IQ>85. Training takes place at three university centers in Germany and Austria. Parent report Social Responsiveness Scale (SRS) and Griffith Empathy Measure (GEM) ratings serve as outcome measures.
Results:
Preliminary analyses of 36 children that completed the trial show high acceptance, as indicated by low drop-out rates of 2%. Results from repeated measures ANOVA for parent SRS and GEM ratings show significant effects of "Zirkus Empathico" compared to the control intervention on SRS total score, and SRS subscales social motivation, social cognition, and social communication at follow-up. In addition, significant effects were shown on GEM total score and GEM subscore affective empathy (all $p < .05$).
Conclusions:
The findings indicate that "Zirkus Empathico" has high acceptance among children with ASD and leads to improvements in social communication and behavior as well as empathy in affected children. Results of the completed trial as well as moderator analyses for sex, age, ASD symptom severity, and IQ will be reported at the conference.

229 **181.229** Good Practices in Youth Intervention in Autism Spectrum Disorder: A Program to Improve the Social Skills

*M. Robles[1], **C. Francesc**[2], X. Fortuny[1] and J. P. Cruells[3], (1)CERAC, La Garriga, Spain, (2)FUNDACIÓ PRIVADA CONGOST-AUTISME, la Garriga (Barcelona), SPAIN, (3)CERAC, LA GARRIGA, SPAIN*

Background:
People with ASD have persistent deficits in communication and social interaction in different contexts and patterns of behavior, interests and activities restricted and stereotyped (DSM-V, 2013). Studies such as Theory of Mind (Baron - Cohen, 1985) show that people with ASD and other disorders have difficulty inferring mental states of other people affecting their abilities and social skills.
Objectives: People with autism need to learn these skills explicitly make a detailed study and fragmented social relationships because their inability to "read the mind" prevents them from understanding the behavior of others. To respond to these difficulties, implemented an intervention project to work and improve emotional and social skills of adolescents with ASD or low emotional and social skills
Methods:
Sample: Five young people with ASD or other disruptions in the area of social and emotional development between 17-21 years.
Methodology: The project begins with a study of the needs of young people with difficulties in marked areas and socio-emotional. From there, you design a program of social skills with a previous emotional education enough in learning theory and principles of cognitive therapy - behavior.
Duration: months November to April with a two-hour weekly session.
Evaluation: interview, observation, teens-2, WAIS-IV, Vineland, assessment scales of HHSS. Re-test.
Results: the social skills of the sample improved
Conclusions:
The social skills training improve the skills of these people with ASD.

230 **181.230** Group-Delivered Video Model Intervention Package Improves Social Skills in Adults with Autism Spectrum Disorder

***E. S. Brodkin**[1], A. A. Pallathra[1], J. Day-Watkins[2] and J. E. Connell[2], (1)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (2)Drexel University, Philadelphia, PA*

Background: Video modeling (VM) is an evidenced-based intervention proven effective in improving social skills in children and adolescents with autism spectrum disorder (ASD) (Shukla-Mehta et al., 2010; Day-Watkins et al., 2014). Few reports have been published on the development of VM services suitable for adults beyond their early twenties (Cappadocia & Weiss, 2011; Williams et al., 2007). As part of a pilot study of a new cognitive behavioral treatment program, Training to Understand and Navigate Emotions and Interactions (TUNE In), we developed a VM package to train social skills to adults with ASD.
Objectives: To use VM, role-play, and feedback to teach 13 adult participants with ASD four fundamental social skills. The goal of the study was to extend the VM literature to teaching specific social skills to adults with ASD to examine the efficacy and feasibility of delivering the social skills interventions to an adult population and in community behavioral health settings.
Methods: Across eight weekly sessions, participants were taught to engage in four different social skills (e.g. approach a group (skill 1); don't approach a group (skill 2); greet a group (skill 3); and initiate conversation (skill 4)). During sessions facilitated by behavioral coaches, participants role-played with actors (i.e. undergraduate research assistants) on five exemplars of each social skill. The actor engaged in scripted scenes (discriminative stimuli) of each social skill exemplar, setting the occasion for the participant to respond by either demonstrating or not demonstrating the appropriate skill. Baseline data on responses was collected in week 1. In week 2, skills 1 and 2 entered *treatment*, while skills 3 and 4 remained in baseline. During *treatment*, if participants responded incorrectly, they were given a video model depicting an individual correctly engaging in the target skill. After access to the video model, participants repeated role-play trials, and feedback was provided on steps completed correctly and incorrectly. In week 3, training on skill 3 began and training on skill 4 began in weeks 4. Generalization probes were interspersed between training trials. Training on each social skill was staggered across four weeks to assess for the emergence of correct responding to the generalization probes, which had not yet received training with a video model.Â Paired t-tests were used to compare participant scores from final baseline measurements vs. week 8 measurements.
Results: All participants' scores increased from final baseline measurements to week 8 (Figure 1). (*Skills 1-3 $p<0.001$; Skill 4 $p<0.003$*).
Conclusions: Participants demonstrated a significant increase in correct responses for each social skill after receiving this VM intervention package. These data demonstrate the effectiveness of VM of social skills across multiple participants and multiple skills. This group delivery model is critical for the dissemination of behavioral and mental health services to sites where large consumer populations and limited resources don't allow for the delivery of intensive, individualized intervention to individuals with ASD.

231 **181.231** TUNE in, a Novel Cognitive Behavioral Treatment Program to Improve Social Functioning in Adults with ASD: Pilot Study Results

A. A. Pallathra[1], *J. Day-Watkins*[2], *M. E. Calkins*[3], *B. Maddox*[4], *J. Miller*[5], *J. Parish-Morris*[4], *J. D. Herrington*[6], *S. Kangovi*[7], *R. Tomlinson*[8], *T. Creed*[7], *C. M. Kerns*[9], *W. Bilker*[7], *F. Handy*[7], *J. E. Connell*[2], *G. S. Dichter*[10], *D. S. Mandell*[7], *R. T. Schultz*[5] *and E. S. Brodkin*[1], *(1)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Psychiatry, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (7)University of Pennsylvania, Philadelphia, PA, (8)Temple University, Philadelphia, PA, (9)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (10)University of North Carolina - Chapel Hill, Chapel Hill, NC*

Background: Â In the coming decade, approximately 600,000 children with autism spectrum disorder (ASD) will reach adulthood in the United States. They, and the several million adults currently diagnosed with ASD, will need ongoing services and support. However, there are few evidence-based treatment programs for adults with ASD beyond their early twenties to improve social functioning, a key factor in adults' employment, relationships, and overall quality of life (Howlin, Moss, Savage, & Rutter, 2013; Shattuck et al., 2012). We developed an, integrated three-part intervention, TUNE In (Training to Understand & Navigate Emotions and Interactions), which targets the multiple behavioral domains underlying social functioning (social motivation, social anxiety, social cognition, social skills) in adults with ASD, and has components to generalize new social understanding and social skills to community settings.Â By targeting all of these domains, we hypothesized that TUNE In would improve overall social functioning.
Objectives: To preliminarily assess the effects of TUNE In on social functioning in adults with ASD.
Methods: Twenty-nine adults were enrolled and assigned to either immediate treatment (Cohort 1) or delayed treatment (Cohort 2) conditions (Table 1). TUNE In consists of 17 weekly sessions divided into three consecutive components: 1) five one-on-one sessions addressing social motivation and anxiety through cognitive coaching and mindfulness exercises; 2) eight group sessions addressing social cognition through a didactic curriculum, and addressing social skills through video modeling; 3) four sessions addressing generalization of skills to community settings by having participants engage in a philanthropic volunteer work team. To date, participants in both groups underwent assessments of social functioning at two time points: baseline (Time 1) and again after Cohort 1 completed treatment but before Cohort 2 started treatment (Time 2). Cohort 2 has now started treatment, after which data will again be collected from both groups at Time 3. We used the Wilcoxon Rank Sum Test to test the hypothesis that there would be a significant difference between the "immediate treatment" group (Cohort 1) and the "delayed treatment" group (Cohort 2) in percent change in two measures of overall social functioning—the Social Responsiveness Scale-2 (SRS-2) and the Social Network Index - People in Social Network Subscale (SNI; Cohen, 1991)—between Time 1 and Time 2.
Results: Â Seven participants in Cohort 1 completed TUNE In and are compared with the 13 participants in Cohort 2 (delayed treatment group). Evidence of significant social functioning improvements from Time 1 to Time 2 were observed in Cohort 1 but not in Cohort 2, as reflected in percent change in the SRS-2 and SNI.
Conclusions: These pilot data suggest there are benefits to the integrated service strategy of TUNE In that targets multiple behavioral domains underlying social functioning and provides opportunities for skill generalization. Data to be collected at Time 3 will enable us to assess effects in Cohort 2. Further study of TUNE In is warranted in order to address the urgent need for evidence-based treatment options targeting social functioning in adults with ASD.

232 **181.232** Identifying Active Ingredients: Examining the Relationship Between Teacher Fidelity of Implementation of Classroom Pivotal Response Teaching and Student Engagement

V. Li[1], *T. Holt*[2], *S. R. Rieth*[3], *K. S. Dickson*[4], *J. Suhrheinrich*[5] *and A. C. Stahmer*[6], *(1)Child & Adolescent Services Research Center, San Diego, CA, (2)CASRC, San Diego, CA, (3)San Diego State University, San Diego, CA, (4)Child and Adolescent Services Research Center, San Diego, CA, (5)University of California, San Diego, La Jolla, CA, (6)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background:
ASD interventions are complex and generally composed of multiple components targeting skills across several domains. When using packaged interventions, teachers have reported difficulty in utilizing all components effectively (Stahmer, Suhrheinrich, Reed, & Schreibman, 2012). To date, there is little research examining the individual components of multi-component interventions and how they influence student behavior and outcomes. Identification of the active ingredients in interventions may allow for streamlined, more efficient intervention protocols. Classroom Pivotal Response Teaching (CPRT) is a multi-component behavioral intervention developed for use in classroom settings for students with ASD. Close examination of how teachers' use of CPRT relates to student behavior may provide valuable information on how the protocol may be optimally utilized in classroom settings.
Objectives:
The objective of the current project is to examine the relationship between student active participation in learning activities and teachers' fidelity of implementation (FI) of CPRT. Results may inform which components of CPRT are necessary to best promote student engagement.
Methods:
99 special education teachers (94% female) in the greater San Diego area received training in CPRT as part of a randomized trial of the intervention. All teachers supported at least one student with an educational classification of autism. Classroom observations were recorded at multiple time points before, during and after CPRT training during regular classroom activities. Observations were coded using two separate coding systems to evaluate: 1) teachers' FI of CPRT and 2) child engagement in the activity. Fidelity measurement involved rating each teacher on 19 CPRT components using a 5-point Likert scale (1 = does not use, 5 = uses throughout). Student engagement in the activity was continuously coded using observational coding software. Correlations between teacher fidelity on individual components of CPRT and student engagement was examined across all videos.
Results:
Based on nearly 200 video observations thus far, preliminary results indicate that higher student engagement is associated with decreased use of turn taking, motivating materials, direct reinforcement, and reinforcement of good trying strategies by teachers. An additional 300 video observations are being examined to further explore these preliminary relationships, as well as allow for more complex analyses that address questions of prediction. Furthermore, the relationship between fidelity and student characteristics such as ADOS severity scores and communication skills will also be assessed.
Conclusions:
Data suggest that student engagement is related to teachers' fidelity to CPRT strategies. Although current analyses do not allow for interpretation of the direction of influence, a possible explanation is that teachers may be implementing fewer motivational components of CPRT when students are more actively engaged. Teachers may not see a need to take turns or incorporate motivating materials when the students are actively participating. However, if students are consistently engaged without these components present, this is valuable information for determining the active ingredients of multi-component interventions such as CPRT. Further analyses will continue to address the question of active ingredients and student characteristics as a predictor of engagement in order to promote efficient and effective use of the intervention in classroom settings.

233 **181.233** Ifit: A Peer-Supported Physical Activity Program for College Students with ASD

T. Todd[1], *N. Miodrag*[2], *B. Rios*[3], *K. Geary*[3] *and S. Colgate*[3], *(1)California State University, Northridge, CA, (2)Child and Adolescent Development, California State University, Northridge, Northridge, CA, (3)Kinesiology, California State University, Northridge, Northridge, CA*

Background: There is growing evidence that individuals with Autism Spectrum Disorder (ASD) experience deficits in the motor domain, which may prevent them from leading an active lifestyle. Healthy People 2020 recognizes participation in physical activity (PA) as a leading indicator of health, and it is recommended that adults meet the national guidelines of 150 minutes of moderate to vigorous intensity PA each week. Yet meeting this recommendation is rarely achieved in youth and adults with ASD. With such high prevalence rates of ASD, it is critical to develop evidence-based interventions that increase levels of PA and physical fitness before chronic health issues become a major burden for individuals, families, and public health.
Objectives: The aim of this study was to increase time spent in PA and encourage college students with ASD to participate in regular exercise. Specifically, we set out to examine the effects of a PA program on: (1) levels of physical fitness (1-mile walk, sit-ups, push-ups, and sit and reach), and (2) psychosocial wellbeing (anxiety symptoms) of young adults with ASD.
Methods: IFiT (Into Fitness Together) is a 10-week, individualized peer-mentored PA program tailored to address the motor and social barriers to PA among college students with ASD. Eleven male college students with ASD and 11 college Kinesiology majors (peer mentors) participated in the program. Students with ASD were paired with a peer mentor. Dyads met twice a week for 10 weeks for a minimum of 120 minutes of PA of their choice and 30 minutes to plan activities for the coming week, including 30 minutes of individual exercise. Anthropometric, fitness, and anxiety measures were taken pre- and post-intervention. Fitness measures included the timed 1-mile walk to provide an estimate of aerobic capacity, sit-ups and push-ups for muscular strength and endurance, and the sit and reach test for assessing flexibility. Self-reported anxiety was assessed using the Beck Anxiety Inventory.
Results: Cardiovascular endurance, as measured by the timed 1-mile walk, significantly increased from pre- (M = 41.19) to post-intervention (M = 49.13), $t(10)$= 12.26, p < .01. Muscular strength as measured by push-ups increased significantly from pre- to post-intervention (M = 7.33, M = 11.22, respectively), $t(10)$=7.33, p < .05. The sit and reach results were also statistically significant showing gains in flexibility from pre- (M = 12.45) to post-intervention (M = 15.23), $t(10)$= 3.79 p < .05. There were no significant changes from pre- to post-test for muscular endurance or anxiety. Adherence to the program was 96.17%.
Conclusions: College students with ASD increased their fitness levels after participating in a 10-week, peer-mentored PA program. Participants engaged in a variety of activities, attended on a regular basis, and reported enjoying the program. IFiT is a fun, accessible, and low-cost program that holds much promise for increasing PA and fitness amongst young adults with ASD, who generally do not meet the national guidelines for PA. The peer-mentor model may have contributed to the success of the program.

234 **181.234** Improvements in Emotional Intelligence Following Completion of PEERS® in Adolescents with Autism Spectrum Disorder

K. Murphy[1], *L. Purdon*[1], *R. L. Matchullis*[2], *M. C. Coret*[2] *and A. McCrimmon*[2], *(1)University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Calgary, AB, CANADA*

Background: Emotional intelligence (EI) refers to the ability to understand oneself, relate to others, and adapt to variable environmental demands (Bar-On & Parker, 2000). Research has identified EI as a key component of social competence and is related to quality of social interactions (Ferguson & Austin, 2010; Lopes, 2003). Given the significant impairments in social and emotional functioning observed among individuals with Autism Spectrum Disorder (ASD) (Brady et al., 2014; Petrides et al., 2011), further investigation on the relation between EI and social skills is warranted. Individuals with ASD who have intact cognitive ability could benefit from interventions targeted at improving their social and emotional functioning. Therefore, it is important to identify effective interventions that target these problem areas.
Objectives: Limited research has examined the effect of the *Program for the Education and Enrichment of Relational Skills* (PEERS®; Laugeson & Frankel, 2010) on EI in adolescents with ASD. PEERS® is a 14-week evidence-based, caregiver-assisted social skills intervention designed to help adolescents with ASD make and keep friends. The aim of the current study was to investigate the effect of participation in PEERS® on EI in adolescents with ASD.
Methods: Participants were 32 adolescents (27 males) aged 13-18 (M = 15.9, SD = 1.5) with a diagnosis of ASD and intact cognitive functioning (i.e., FSIQ ≥ 70). Adolescents were recruited from the community and completed the standard PEERS® intervention. Improvements in social skills were measured using adolescent self-reports and parent reports of the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008). EI was measured using the BarOn Emotional Quotient Inventory: Youth Version (EQ-i:YV; Bar-On & Parker, 2000). Data was collected both pre and post intervention and was analyzed using paired samples t-tests and Pearson product-moment correlations.Results:
Results: Results indicate that adolescents demonstrated significant improvements in overall EI (p<.05) as well as significant improvements in the intrapersonal, adaptability, and stress management domains of the EQ-i:YV (p<.05). Results also revealed significant improvements in social skills as rated by parents (p<.05) and adolescents (p<0.5) on the SSIS. Overall EI was significantly correlated (p<.05) with both self and parent ratings of social skills on the SSIS (r=.66, r=.51, respectively) prior to starting the intervention. Post-intervention overall EI significantly correlated (p<.001) with self-reported ratings (r=.79), and approached significant correlation for parent ratings (r=.33, p=.067).
Conclusions: These findings suggest that participation in PEERS® may improve EI in adolescents with ASD. Further, significant improvements in EI were related to improvement in social skills. Given the impact of social and emotional deficits in this population, the results represent an important contribution to our current understanding of the relation between EI and social skills in adolescents with ASD. Future research should examine long-term effects of PEERS® on EI to assess maintenance of improvements.

235 **181.235** Improving Amount of Detail and on-Topic Question-Asking in Adults with ASD Using a Visual Framework and Self-Management

E. Engstrom, *R. L. Koegel and L. K. Koegel, Koegel Autism Center, University of California, Santa Barbara, Santa Barbara, CA*

Background: Research shows promise that behavioral interventions can improve social conversation in adults with Autism Spectrum Disorder (ASD). Additionally, research demonstrates that individuals with autism may have strengths in visual processing, and incorporating visual strengths into behavioral interventions may lead to improvement. Self-management techniques that teach multiple communicative behaviors (such as question asking and amount of detail) using a visual component have been shown to lead to improved reciprocal conversation in children with ASD, but it is unclear if this type of intervention can improve these skills in adults.
Objectives: The purpose of the current study is to see whether this type of intervention will lead to empirically measurable improvements in both rates of question-asking and appropriate amount of detail.
Methods: Participants included three adults between the ages of 25 and 42 years diagnosed with ASD according to DSM-5 criteria. Participants demonstrated significant impairments in social communicative functioning level and social competence. A multiple baseline design across participants was used to assess the effects of the self-management intervention program on participants' amount of detail and question asking. During intervention, the visual framework outlined a conversational turn, which is defined in the framework as responding to the question, adding 1-3 details to the response, then asking an on-topic question. There were 10 boxes on the visual framework in which the participant self-managed their conversation points for successfully completing both components. Conversation probes with novel peers were collected every three sessions in conditions similar across baseline and intervention. Dependent measures included (1) *appropriate amount of detail*, defined as 1-3 supplemental pieces of information that is on-topic, focused, and relevant to the conversation; and (2) percentage of *number of on-topic questions*, defined as any question that elicits new information from conversational peers that is on-topic and relevant to the conversation.
Results: Preliminary results indicate that all participants improved their amount of detail and percentage of on-topic questions in the context of a multiple baseline design. Specifically, Participant 1 increased from a mean percentage of appropriate amount of detail from 33% of intervals to 70% of intervals and increased percentage of on topic questions asked from 5% to 36% of the total conversation. Participant 2 increased from a mean percentage of appropriate amount of detail of 57% of intervals to 92% of intervals and increased mean percentage of on topic questions asked from 17% to 31%. Participant 3 increased from a mean percentage of appropriate amount of detail from 61% of intervals to 88% of intervals and increased mean percentage of on topic questions asked from 27% to 39% of trials. These preliminary data show medium to large effect sizes. Generalization data will be collected one month after completion of the intervention.
Conclusions: Preliminary results show promise that this type of intervention may be effective in improving amount of detail and number of on-topic questions among adults with ASD. The results suggest that future research on improving reciprocal conversation in adults with ASD may be highly profitable.

236 **181.236** Improving Engagement on the Playground and in the Classroom for School Age Children with ASD: A Multisite Randomized Trial

W. I. Shih[1], *M. Dean*[2], *J. J. Locke*[3], *J. Caramanico*[4], *K. Zanibbi*[5], *C. Aponte*[6], *D. Senturk*[7], *D. S. Mandell*[8], *T. Smith*[9] *and C. Kasari*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)California State University, Channel Islands, Camarillo, CA, (3)University of Washington Autism Center, Seattle, WA, (4)University of Pennsylvania, Media, PA, (5)University of Rochester, Rochester, NY, (6)University of Rochester Medical Center, Pittsford, NY, (7)University of California Los Angeles, Los Angeles, CA, (8)University of Pennsylvania, Philadelphia, PA, (9)University of Rochester Medical Center, Rochester, NY*

Background: Impairment in social interaction has been recognized as a critical issue for children with autism spectrum disorder (ASD). Several interventions, implemented by research staff, improved child social outcomes in schools. However, little is known about the effectiveness of these interventions when delivered by paraprofessionals, especially the paraprofessionals who spend the most non-instructional time with these children.
Objectives: This study aimed to evaluate the efficacy of a social skills intervention, Remaking Recess (Kretzmann, Locke, & Kasari, 2012), on peer engagement and social network salience for children with ASD using a multi-site, randomized, wait-list-controlled design when implemented by paraprofessionals.
Methods: Eighty children with ASD (age 5-12 years) in grades K-5 recruited from three sites were randomized to Remaking Recess (RR: n=39) or a waitlist (WL: n=41) for 3-months with a 1-month follow-up.
Intervention (Remaking Recess): Paraprofessionals work with research staff over 3 months, held during children's non-instructional time. Sessions consist of information sharing, active coaching, and systematic support. Paraprofessionals were trained with an hour-long group presentation on the social challenges of children with ASD at school and overview of the Remaking Recess intervention and then provided daily active coaching on the playground for twoÂ weeks (8-10 sessions). The researcher provided consultation for 6-8 more sessions over the next 6Â weeks and completely faded consultation and coaching for the last twoÂ weeks.
Measures: The Playground Observation of Peer Engagement is an interval coding system that identifies durations of joint engagement with peers or solitary play. The Friendship Survey is a questionnaire used to assess children's friendships and social networks of peer relationships in the general education classroom. All measures are collected at pre/post intervention and at the 1-month follow-up.
Results: Percentage of time spent in solitary engagement was modeled using the hurdle model (i.e. binary and truncated Gaussian). There was a significant overall treatment difference in the truncated Gaussian model ($F(1,76)=4.01$, $p=0.049$) from pre-treatment to post-treatment, but not in the binary model ($F(1,76)=0.48$, $p=0.492$). This showed that for those children who spent more time in solitary engagement (i.e. those who crossed the hurdle), the children in the RR group showed significantly more reductions in time spent in solitary play from pre-treatment to the post-treatment compared to children in the WL group.
There was no significant treatment difference or overall change in time from pre-treatment to post-treatment ($F(1,67)=0.30$, $p=0.58$ and $F(1,67)=0.45$, $p=0.50$ respectively) in social network salience within the classroom. However, there was a significant treatment difference from pre-intervention to follow-up ($F(1,118)=1.97$, $p=0.05$) where children in the Remaking Recess group, on average, became more salient in their classroom from pre-intervention to follow-up compared to the children in the WL group.
Conclusions: These results suggest that a low dose, brief, and paraprofessionals mediated intervention conducted in schools can be beneficial in increasing peer engagement and classroom salience for children with ASD in inclusive settings. The benefits of Remaking Recess may require more time in order for children with ASD to become more engaged on the playground and salient in their classroom.

237 **181.237** Inclusion-Focused University-Based Community Integration Programs: A Pilot Study of Perceived Benefits By Participating Adults with Autism

C. E. Exner[1], *Z. Zaks*[2] *and A. Frydman*[2], *(1)Towson University, Towson, MD, (2)Hussman Center for Adults with Autism, Towson University, Towson, MD*

Background: Adults with autism often experience challenges with successfully and meaningfully integrating into their communities (Roux et al., 2015). These challenges affect many aspects of quality of life. Adult-focused approaches to supporting various skills that can enhance quality of life are limited. Similarly research on effective approaches to facilitate greater community integration is minimal (Hendricks & Wehman, 2009; Scheeren & Geurts, 2015).
This Center offers programs that are fully inclusive—bringing together adults with autism and students as peer mentors from a wide variety of majors. Programs focus on enhancing opportunities for adults with autism to live as fully engaged members of their communities. Students enrolled in an undergraduate core course with a 20-hour service learning component engage collaboratively with adults with autism ("participants") in group programs under the supervision of faculty/staff instructors. Each program has similar numbers of adults with autism and student peer mentors and meets for 1-2 hours once or twice a week for 10 weeks during a semester. Programs such as fitness, art, comedy/improv, dance, yoga, men's and women's groups emphasize one or more of five key areas: self-advocacy, self-expression, self-regulation, problem solving and decision making, and team work/collaboration.
Objectives: To assess the participants' perceptions of 1) benefit from peer-to-peer interaction with the students; and 2) benefit of the program in addressing key areas for community integration.
Methods: Â Post-program surveys were distributed to all participants enrolled in Fall 2015 and Spring 2016 programs. Total enrollments across the 15 programs that had undergraduate students as peer mentors were 115. Surveys were completed independently or with parent/guardian/other adult support to record feedback, and returned via mail or through a drop-box at the center. A total of 57 surveys were returned (49.5% return rate).
Results: All participants indicated that they benefited by having student peer mentors engaged in their programs. Participants rated students as being helpful in completing tasks or activities (52.6%), improving communication skills (50.9%), improving teamwork skills (43.9%), expanding knowledge of interests or activities (40.4%), and helping with problem solving (36.8%). They reported the students as having positive attitudes (93%), being helpful (82.5%), and interested in talking with them (71.9%). Participants indicated that they benefited by "meeting new people" and "having people [their] age [they] could talk to." Across the programs, around 40% of the participants' comments specified social aspects of the programs as the "best thing" about the program, including "interacting with my mentors," being treated as an "equal," "social interaction," and "students' company." Participants also reported wanting to learn - and subsequently learning the most about - social skills, self-expression, and team work in their programs.
Conclusions: Adults with autism reported that the programs helped them gain skills they deemed were important. Participants also had very positive perceptions of the peer-to-peer interactions they experienced and identified specific benefits from peer-engagement. Further research is needed to determine if the impact of these programs remains over time, especially in these areas: social skills, self-expression, team work and high community engagement.

238 **181.238** Increasing Motivation in Academics for Children with Autism in Inclusive Classrooms

L. B. Glugatch[1] *and K. Oliver*[2]*, (1)Special Education, University California, Santa Barbara, Santa Barbara, CA, (2)University California, Santa Barbara, Santa Barbara, CA*

Background: Many children with ASD show little to no interest in academic assignments that are challenging or uninteresting. This may lead to increases in disruptive behavior in order to avoid or escape the non-preferred tasks. By incorporating motivational components of Pivotal Response Treatment in homework tasks, previous studies found faster completion rates, decreases in disruptive behavior, and improved interest (Koegel, Singh, Koegel, 2010).
Objectives: This study looks to determine if using motivational components during academic tasks will increase child affect, interest, and percentage of correct answers in an inclusive classroom environment.
Methods: An alternating treatment design was employed to assess the effectiveness of two different conditions (i.e., standard worksheet condition and motivation/natural reinforcer condition). The standard worksheet condition consisted of an everyday worksheet that was assigned to the whole class. These worksheets were repetitive and included tasks such as identifying and writing letters and sight words. The motivation/natural reinforcer condition included the core components of PRT techniques of natural reinforcement, child choice, and interspersing maintenance and acquisition tasks. For example, if the target child spelled the word "train", the child would immediately gain access to play with a toy train.
Results: Â During the motivation condition, the participant scored higher in interest ratings (see Figure 1). During the motivation condition, the participant also scored higher in affect ratings (see Figure 2). The participant correctly identified more letters independently in the motivation condition than the standard worksheet condition for 2-letter, 3-letter, and 4-letter words. The child needed on average twice the amount of prompts to finish an academic task during the standard worksheet condition compared to the motivation condition.
Conclusions: Â When motivational components were embedded into academic tasks, the participant showed higher interest, happiness, and identified more letters correctly. Furthermore, these findings support children with ASD have the ability to complete academic tasks, but rather a lack of motivation can contribute to unfinished work and disruptive behaviors during school.

239 **181.239** Increasing Physical Activity for Adults with Autism Spectrum Disorder through Praise and Technology

M. Savage*, Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: There are many benefits to engaging in physical activity. However, individuals with autism spectrum disorder (ASD) often do not engage in recommended levels of physical activity. Low motivation, poor motor skills, and behavioral challenges combine to make engaging in regular physical activity challenging. Due to higher level of sedentary behavior, individuals with ASD were identified as a special risk group for health challenges such as obesity and secondary conditions (e.g., depression, diabetes; Hildebrandt, Chorus, and Stubbe, 2010; Rimmer, Yamaki, Lowry, Wang, & Vogel, 2010). In this study, reinforcement and technology were used to engage individuals with ASD in physical activity.
Objectives: (1) To compare the effectiveness of direct praise statements (i.e., praise delivered in-person) and technology-based praise statements (i.e., praise delivered through an iPod) aimed at increasing engagement in physical activity. (2) To determine if levels of engagement in aerobic activity could be maintained when praise statements were systematically faded. (3) To determine if engagement in aerobic activity could be generalized to a new setting. (4) To explore student and teacher perspectives of physical activity, including aerobic activity, as well as the interventions used in the study.
Methods**:** Three young adults with ASD and intellectual disability participated in this alternating treatment, single-case design study. Three dependent variables were measured including the distance of each session, the duration of each session, and the number of steps participants took in each session. The independent variable was praise statements provided to participants in two conditions: direct praise statements and technology-based praise statements. Study phases included baseline, comparison, best treatment, fading, and generalization phases. Probes were also conducted after baseline to evaluate whether or not the evaluated components had a differential effect on aerobic activity as well as after the best treatment phase that served as an additional component of experimental control. Social validity interviews were conducted before and after intervention for both participants and teachers.
Results**:** Praise statements were effective in increasing engagement in physical activity in both conditions compared to baseline averages. Two participants performed better and preferred the technology-based condition. The two participants who performed better in the technology-based condition were also able to maintain performance levels during the fading conditions and generalize their performance to a new setting while the participant who performed better in the direct condition was unable to maintain performance levels during fading conditions or generalize performance to a new setting. The strategies used in this study were also well-received by teachers and participants. Inter-observer checks were assessed on over 33% of sessions for each phase with mean agreement of 96.9%. Moreover, procedural fidelity was 99.0% (more than 33% of sessions were assessed). Refer to Figure 1 for results across study phases for distance.
Conclusions: The findings indicate that receiving praise through technology may be effective in increasing levels of physical activity for individuals with ASD and ID. With technology commonly used in schools, it is important to determine its advantages or disadvantages to provide needed support over more traditional (non-technology) forms of support.

240 **181.240** Initial Outcomes of a RCT of a Comprehensive School-Based Intervention for Children with HFASD

J. D. Rodgers[1]*, C. Lopata*[1]*, M. L. Thomeer*[1]*, J. P. Donnelly*[1]*, C. A. McDonald*[1]*, H. Wang*[2] *and T. Smith*[3]*, (1)Canisius College, Institute for Autism Research, Buffalo, NY, (2)University of Rochester, Rochester, NY, (3)University of Rochester Medical Center, Rochester, NY*

Background:
There are few evidence-based interventions for the social, social-communication, and behavioral deficits of children with ASD who have relative strengths in cognitive and language domains, i.e., high-functioning ASD (HFASD). School-based interventions for children with HFASD present an opportunity to address these deficits. Previous studies have supported the feasibility and initial efficacy of the current intervention protocol (Lopata et al., 2010; 2012).
Objectives:
This study reports the initial results (years one and two) of an ongoing four-year randomized controlled trial (RCT) of a comprehensive school-based intervention (schoolMAX) for children with HFASD.
Methods:
Participants: The sample included 54 children, aged 6-12 with HFASD (28 children in the treatment condition and 26 children in a "business-as-usual" control condition). Random assignment was at the school level with 8 schools each in the treatment and control condition. Participants had a prior clinical diagnosis of ASD, a WISC-IV short-form full-scale IQ >70 (at least one composite, VCI or PRI >80), and a CASL expressive or receptive language score >75. All diagnoses were confirmed using the ADI-R.
Measures: Adapted Skillstreaming Checklist (ASC, completed by Parent and Teacher), Social Responsiveness Scale - Second edition (SRS-2, completed by Parent and Teacher), Cambridge - Mindreading Face-Voice Battery for Children (CAM-C, Faces and Voices), and the Social Interaction Observation Scale (SIOS).
Procedures: The 10-month schoolMAX intervention included social skills groups, therapeutic activities, computerized instruction in emotion recognition, an individualized behavioral plan, and parent training. The intervention was conducted by school staff with elements integrated into the school day. A manualized training and consultation model was used to monitor and ensure ongoing intervention fidelity in treatment condition schools (Thomeer et al., 2015). Control condition schools were monitored for the presence of elements of treatment fidelity using the same manualized forms. Ratings scales, CAM-C testing, and SIOS observations were completed pre- and post-treatment.
Results:
In treatment schools, intervention fidelity averaged 91% or higher for each intervention element. In control schools, elements of intervention fidelity averaged less than 8% across elements. Hierarchical models (adjusting for full-scale IQ and school socioeconomic status) were used to evaluate the impact of treatment condition on change scores. In this initial evaluation of RCT outcomes, four of the seven measures indicated significant treatment effects ($p < .05$). Specifically, parent-rated ASC indicated increased use of targeted social skills, teacher-rated SRS-2 indicated reduced ASD symptoms, and CAM-C Faces and Voices testing both showed increased emotion recognition skills for the treatment relative to control participants.
Conclusions:
Initial results suggest efficacy for the schoolMAX intervention. Four of the seven outcome measures yielded statistically significant positive results. The training and consultation model utilized appears to have been successful at maintaining intervention fidelity. Finally, as these results present the first two of the four years of the overall study, the current analysis may be underpowered to detect effects in some of the other outcome measures.

241 **181.241** Interventions to Improve Oral Care for Individuals with ASD: A Systematic Review

L. I. Florindez[1]*, S. A. Cermak*[2]*, E. Hong*[1] *and L. I. Duker (Stein)*[1]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: Oral health is important to both physical and psychological health. Certain populations, such as individuals with autism spectrum disorders (ASD), experience greater oral care challenges as compared to their typically developing peers, suggesting that innovative and efficacious interventions to facilitate care are needed. However, little research currently exists examining oral interventions for individuals with ASD.
Objectives: The purpose of this study was to systematically review interventions designed to improve oral health in individuals with ASD.
Methods: Systematic review methodology as outlined in the Cochrane Handbook for Systematic Reviews of Interventions was used for this paper. Six electronic databases were searched, including: PubMed, CINAHL, Web of Science, Clinical Trials, COCHRANE, and PsycINFO using the keywords "oral/dental health/care," "intervention," and "autism." Inclusion criteria for article selection included: (1) implementation and investigation of a home and/or dental office intervention to impact oral care health and/or experiences, (2) participants diagnosed with ASD, (3) published in a peer-reviewed journal, and (4) published in English, Spanish, Korean, and/or Portuguese. No restrictions were placed on year of publication or level of evidence, but pharmacological interventions were excluded. Two reviewers independently screened all articles for inclusion. Of the articles included, three reviewers independently extracted data. Methodological quality of studies was assessed by two reviewers using Reichow, Volkmar, & Cicchetti's Evaluative Method for Determining Evidence Based Practice (EBP) in Autism; disagreements were resolved by a third reviewer.
Results: The search produced 325 articles, with only six studies meeting all inclusion criteria. Using the EBP guidelines, one study was scored as a strong indicator of evidence, one as an adequate indicator, and the remaining four as weak. Three interventions examined in-home caregiver education programs to improve oral care in the home and prepare individuals with ASD for future dental visits (weak quality); the remaining three evaluated strategies to reduce behavioral and sensory difficulties exhibited in the dental office (one adequate, one weak, and one strong). Only one study of the total six included adults with ASD, with the others focused solely on pediatric ASD populations. The intervention scored as 'adequate' examined the use of electronic screen media, such as video peer modeling, and watching movies with video goggles, to reduce fear and uncooperative behavior during dental visits. The only intervention study rated as 'strong' was designed and implemented by an interdisciplinary team led by occupational therapists. This study focused on modifying the sensory environment in order to decrease the behavioral and physiological distress of children with ASD at the dentist.
Conclusions: These findings suggest that preliminary evidence exists supporting the use of behavioral and sensory interventions to improve the experience of individuals with ASD at the dentist. However, there is a need for further large-scale studies investigating the efficacy and effectiveness of these interventions in individuals with ASD across the lifespan, including adolescents and adults with ASD.

242 **181.242** Long Term Outcomes of a Social Skills Intervention for Adolescents with ASD

B. L. Ncube[1]*, J. M. Bebko*[2]*, M. Thompson*[3]*, M. Spoelstra*[3] *and L. Verbeek*[3]*, (1)York University, York, ON, CANADA, (2)York University, Toronto, ON, CANADA, (3)Autism Ontario, Toronto, ON, CANADA*

Background: Friendships are an important source of social support: they provide assistance, facilitate learning, and provide a sense of belonging (Overton & Rausch, 2002). Unfortunately, research by Orsmond, Wyngaarden Krauss, and Mallick Seltzer (2004) suggests that only 8% of adolescents with autism spectrum disorder (ASD) have friendships. The Program for the Education and Enrichment of Relational Skills (PEERS), a social skills intervention for adolescents, has a strong evidence base for use with individuals with ASD (e.g., Mandelberg et al., 2014). Autism Ontario has been running PEERS for adolescents at sites across Ontario for the past three years.
Objectives: Although a number of studies have demonstrated the effectiveness of the PEERS program few have examined long term outcomes. Further, no research was found that explicitly examined parent perceptions of the program after teens had opportunities to practice the skills they learned in the program over a protracted period of time. Similarly, few, if any, studies, have examined barriers to long term application of tools learned in the program. The goal of the present study was to address these knowledge gaps.
Methods: An online questionnaire was circulated to parents and teens who had completed the PEERS program 6 months to 3 years prior. The questionnaire contained standardized measures (e.g., Spence Social Anxiety Scale), and items inquiring about parent perceptions of gains teens made in the program and barriers to implementing skills from the program.
Results: To date seventeen families completed the follow-up questionnaire. Data collection is ongoing (target: 30 participants). Adolescents ranged in age from 12 to 19 years of age (M = 15.50, SD = 2.00) and were 58.82% male. 60% of parents reported that their teen continued to have get-togethers since the completion of the PEERS group sessions. All parents endorsed skills in which they felt their teen had improved since the program ended, even though they did not initially feel their teen had acquired these skills while still in the program. The skill most commonly endorsed was "being a good sport"; endorsed by 46.15% of parents. "Sharing the conversation" and "choosing appropriate friends" were endorsed by 38.46% of parents. 80% of parents reported that the quality of their teen's friendships had improved and 100% of parents reported that the parent training portion of the program had been helpful for themselves and their teens. Despite these overwhelmingly positive results, some challenges were reported. 86.67% of participants reported experiencing barriers to implementing skills learned in the PEERS program. Open-ended responses from parents indicated a range of barriers including difficulty finding and identifying potential friends for their teens and lack of time. Parents were also asked to indicate barriers specific to enrolling their teen in new social activities. Barriers included difficulty finding groups that were of interest to the teen (55.56%) and not enough time (33.33%).
Conclusions: Results are promising and provide evidence for continued improvement in social skills well beyond the end of the PEEERS program. These included skills that had not been seen by parents immediately after the program.

243 **181.243** Mental Health in Adults with ASD: Impact of the Success Program

E. I. Velazquez Villarreal[1]*, M. Baker-Ericzen*[1]*, M. M. Jenkins*[1]*, M. Fitch*[1] *and R. T. Trefas*[2]*, (1)Rady Children's Hospital San Diego, San Diego, CA, (2)Research Resources, Rady Children's Hospital San Diego, La Jolla, CA*

Background:
The burgeoning population of adults with ASD is considered an emerging public health challenge (Bailey, 2012). Clinical reports suggest that mental health disorders are prevalent in adults with autism (Guillot, 2007). Research studies with adults with ASD indicate a rise in emotional disorders such as depression and anxiety in adulthood even when individuals receive autism specific treatments (Mazurek, 2014). The literature to date suggests mental health issues are common among adults with ASD, but what is unknown is how to best address such mental health issues (Trembath, 2012).
Objectives:
This study assessed mental health outcomes in adults with ASD as a result of an innovative intervention, SUpported employment, Comprehensive Cognitive Enhancement and Social Skills (SUCCESS) program. The SUCCESS intervention targets increasing executive functioning and social cognitive skills in adults with ASD. As part of the SUCCESS program, co-occurring mental health issues were measured using the Adult Self-Reports (ASR) and Adult Behavioral Check List (ABCL) to understand the impact the intervention may have on mental health issues, such as anxiety disorders, attention deficit hyperactivity disorder (ADHD), depression and related internalizing and externalizing symptoms.
Methods:
A total of 8 young adults participated in an open trial pilot study of the SUCCESS program (with an additional sample of 12 participants currently receiving the intervention and the data will be available for analyses by April 2017). ASR and ABCL were obtained pre and post the SUCCESS intervention. SUCCESS was delivered weekly for 90minutes via active group participation during a simulated work meeting within a larger vocational training program in a community vocational service. The program involved 24 sessions over 5 months with the first half of the curriculum teaching executive functioning skills as attention, learning, memory, prospective memory, cognitive flexibility, problem solving, goal oriented thinking and contextual awareness. The second half teaching social communication skills including social conversation (giving and receiving compliments, feedback and help), social relationships, initiations and social networking (including do's & don'ts of social media). Participants completed the ASR and parents completed the ABCL.Â The majority of participants were male (77%), white race/ethnicity (88%) with a mean age of 22 years (SD=3.67) and all graduated with a high school diploma. Some were involved with various social services: 33% disability services, 22% department of rehabilitation, 0% social security income.
Results:
Analyses consisted of calculating effect sizes using Cohen's d to measure the magnitude of the effect of the SUCCESS intervention on mental health symptomatology. Preliminary findings reveal positive outcomes per self-reports (ASR). Participants are reporting less anxiety and avoidant issues and less overall internalizing, externalizing and total symptoms. No improvements were reported by parents (ABCL) (Refer to Tables). These differences by informant reflects the differences of an external perception of mental health from parents to the self-perception from individuals.
Conclusions:
This pilot study demonstrates that mental health issues may improve by targeting other core autism related symptoms as executive functioning and social cognition skills. More study is needed before conclusions can be drawn.

244 **181.244** Multi-Informant Assessment of Transition-Related Skills and Skill Importance in Adolescents with Autism Spectrum Disorder

K. Hume[1]*, J. Dykstra Steinbrenner*[2]*, L. E. Smith*[3] *and T. Regan*[4]*, (1)University of North Carolina, Chapel HIll, Carrboro, NC, (2)Frank Porter Graham Child Development Institute, Carrboro, NC, (3)Waisman Center-University of Wisconsin, Madison, WI, (4)UNC-Chapel Hill, Chapel Hill, NC*

Background: Post-high school outcomes are bleak for students with autism spectrum disorder (ASD). One malleable contributor to post-school outcomes is the quality of the transition plans developed as part of the Individualized Education Plan. The Secondary School Success Checklist (SSSC) is a new measure developed to allow students across the spectrum to describe their current skill level in transition-related domains as well as rank their priorities for goal setting, thus actively contributing to the transition planning process. The SSSC is designed to collect data from the perspective of multiple informants including the student, their parents, and the student's teacher.
Objectives: This study examines (a) the transition-related skill level of adolescents with ASD as reported by each respondent group, (b) the perceived importance of each skill across respondent group, and (c) the relationships between the rankings of each respondent group.
Methods: Data were drawn from a larger ongoing RCT of high school students with ASD. The sample includes 547 adolescents (mean age= 16.4; mean nonverbal IQ=85.8; mean Vineland=75.8) and their parents from 3 states. The student version of the SSSC has 20 items, each which is linked to key items on the teacher and parent versions (105 items). Both sets of items were representative of four key domains: independent behavior, transition, social, and academic. For each item, participants indicated on a Likert-type scale if the behavior was: 0="not like me", 1="like me", or 2 = "much like me". Respondents also provided a priority ranking for learning each item. Mean levels of skill performance and importance were reported across domain and informant, and differences between groups and domains were examined. The inter-rater reliability across respondents for skill level and priority scores were conducted, and we ran paired sample t-tests to determine which domains were rated as most important by informant group.
Results: Adolescents rated themselves as higher skilled on SSSC items than did parents or teachers. Teachers rated most skills higher than parents. There were significant differences across the informant groups, with differences on up to 18 of 20 items (adolescent- parent) and very low agreement across raters (weighted Cohen's kappa= adolescents with parents, .10 and teachers .11; parents and teachers=.20). Although the ratings varied, there was some agreement in the ranking of the highest and lowest rated skills across all three groups. Adolescents consistently had lower percentages on items marked as a priority across skills and informant group. Parents were most likely to rate skills as a priority for learning.
Conclusions: This is the first study to examine the perceived skill level and importance of transition-related skills among adolescents with ASD, their parents, and teachers. This is the largest current sample of adolescents with ASD and this data provides an important snapshot into student performance of key transition-related skills, providing a profile of both student strengths and needs as reported by multiple informants. The findings provide guidance for staff and families during the transition planning process, as well as inform researchers on intervention development/ implementation to ensure priorities are addressed.

245 **181.245** Music Improves Social Communication in Autism Spectrum Disorder – a Randomized Control Trial

C. Tuerk[1]*, M. Sharda*[1]*, K. Jamey*[1]*, N. E. Foster*[1]*, R. Chowdhury*[1]*, E. Germain*[1]*, A. Nadig*[2] *and K. L. Hyde*[1,2]*, (1)University of Montreal, Montreal, QC, Canada, (2)Faculty of Medicine, McGill University, Montreal, QC, Canada*

Background: Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder characterized by pronounced difficulties in social and communication abilities. However, many individuals with ASD demonstrate enhanced perceptual skills, especially in the auditory domain (Heaton, 2009). Based on these and other complementary findings, music therapy has been suggested as a promising approach to improve social communication in ASD (Simpson and Keen, 2011). However, there is currently limited empirical evidence supporting its clinical use (Geretsegger et al, 2014).
Objectives: The present study aims to evaluate the effects of a music-based intervention on language and social communication in children with ASD, compared to a non-music control intervention using a randomized control trial design.
Methods: Fifty children aged 6-12 years with a diagnosis of ASD participated in a single-blind, parallel-arm randomized control trial of music therapy that is currently ongoing (ISRCTN26821793). Here, we report data from 18 children who have completed the trial. Participants were randomly assigned to 12 weekly sessions of individual music (MT, n=9) or non-music (NM, n=9) control therapy. Music therapy sessions involved use of songs and rhythmic cues to improve turn-taking and reciprocal social interactions as well as communication. The non-music control therapy targeted similar skills but without the use of music. Both groups were matched on age, sex, IQ and socioeconomic status. Participants underwent extensive behavioral assessment before (T1) and after therapy (T2). Primary outcome measures at both time points included receptive vocabulary using the Peabody Picture Vocabulary Test (PPVT), social skills using the Social Responsiveness Scale (SRS-2), and communication using the Children's Communication Checklist (CCC-2). Data were analysed using repeated measures ANOVA.
Results: Compared to NM, a larger proportion of children in the MT group showed an improvement over 12 weeks in social communication. Specifically, 75% of MT had improved CCC-2 scores at T2 compared to 44% of NM (Figure 1). Overall PPVT and SRS-2 scores showed no significant differences between the groups over time ($p>.05$). However, there was a trend for an interaction between group and time point for CCC-2 in the direction of improvement for MT ($p=.087$). Trends of improvement in MT at T2 compared to NM were observed on the CCC-2 subscales Interests ($p=.061$), Initiation ($p=.077$), and Nonverbal Communication ($p=.094$). Additionally, both groups showed significant improvement on the CCC-2 subscale Social Relations ($p=.023$). A trend towards improvement on the SRS-2 subscales Social Cognition ($p=.062$) and Social Communication ($p=.089$) was also observed for both groups (Figure 2).
Conclusions: These findings suggest that music therapy may lead to specific improvements in social communication in ASD, in particular in terms of interests, initiation, and nonverbal communication compared to non-music interventions. Additionally, music therapy demonstrated equivalent improvement in social relations, social cognition and social communication compared to the non-music therapy. Results from this preliminary analysis provide support for the use of music as a therapeutic tool for children with ASD. This work will provide insight into both behavioural and neural mechanisms mediating response to music-based interventions in children with ASD.

246 **181.246** Parent and Child Factors Related to Homework Completion in Cognitive-Behaviour Therapy for Children with ASD

C. S. Albaum[1] *and J. A. Weiss*[2]*, (1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, CANADA*

Background: Homework is recognized as a crucial component of participation in cognitive behavioural therapy (CBT) for children as it provides opportunities to practice techniques outside of the therapy environment, aiding in skill-mastery (Kazantzis, Deane, Ronan & L'Abate, 2005). Empirical evidence suggests that treatment outcomes are enhanced with CBT that includes homework, in comparison to programs that only involve in-session work (Mausbach, Moore, Roesch, Cardenas & Patterson, 2010). There are a number of parent and child factors related to poor participation (i.e. uncompleted homework), such as parent stress and psychopathology, and child functioning (Kazdin & Wassell, 1999), however research has yet to explore this relation in participants with ASD. With the increasing use of CBT to treat anxiety and behavioural concerns in children with ASD (Danial & Wood, 2013), it is important to understand barriers to participation that could have implications on treatment outcomes.
Objectives: To identify parent and child characteristics that relate to homework completion in CBT for children with ASD
Methods: Data were collected from 56 children with ASD (89.3% male) and their parents (82.1% female) as part of a larger, randomized controlled CBT trial. Children were 8 to 12 years of age ($M = 9.66$, $SD = 1.23$) with average IQ ($M = 102.15$, $SD = 14.78$, Range: 79-140). Parents were 35 to 54 years of age ($M = 43.61$, $SD = 4.33$). Prior to treatment, parents completed measures of child psychopathology, emotion regulation, and autism-symptom severity, as well as a self-report measure of depression, anxiety and stress. Children completed a self-report measure of emotion regulation. Homework completion was reported by session therapists as either incomplete, partially completed, or fully completed. A mean completion score was calculated for nine sessions.
Results: Challenges with emotional regulation were significantly related to less homework completion on both parent-report (r (49) = -.42, p = .003) and child self-report (r (48) = -.47, p = .001) measures. Child internalizing problems were also significantly related to less homework completion (r (48) = -.33, p = .02). Externalizing problems, ASD symptoms severity, and parent self-reported depression, anxiety or stress were not related to homework completion. The overall model of child characteristics accounted for 30% of variance in homework completion, $F(3, 39) = 6.86$, p = .001.
Conclusions: Pre-treatment difficulties with emotion regulation and internalizing problems in children with ASD may have implications for their capacity to complete homework in CBT. To support children in completing homework, clinicians should work with families to modify between-session tasks as needed, in order to promote constructive treatment participation.

247 **181.247** Peer-Play Assessments for RCTs: Feasibility of Measuring Generalization from Clinic-Based Socialization Interventions

L. Soorya[1]*, **M. T. Printen***[2]*, A. Burns*[3] *and A. T. Wang*[4]*, (1)Suite 603, Rush University Medical Center, Chicago, IL, (2)Rush University Medical Center, Chicago, IL, (3)AARTS Center, Rush University Medical Centre, Chicago, IL, (4)Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Previous research has found social skill group interventions to be an effective evidence-based practice for addressing common social deficits in children with ASD (Reichow & Volkmar, 2010). However, generalization is a concern, and the few studies using informant reports have found minimal evidence for generalization across settings and or people (Bellini et al., 2007). Skill maintenance across time has not been supported in studies evaluating retention using caregiver reports (White et al., 2010; Barry et al., 2003). In contrast, research using school-based social skill observational measures have found reliable, feasible strategies for measuring target social skills (Kasari et al., 2012). To our knowledge, these observation strategies have yet to be used to measure target behaviors in clinical settings.
Objectives: The purpose of this study was to evaluate the feasibility of a clinic-based assessment to measure generalization from a randomized controlled trial (RCT) of social cognitive skills training groups (Seaver-NETT, Nonverbal Emotion recognition and Theory of mind Training) and facilitated play groups (Soorya et al., 2014).
Methods: A sample of 38 verbal children with ASD ages 8-11 years old (31 male, 5 female) were enrolled during the last 3 cohorts of the larger RCT. 34 participants were included in baseline analyses and 12 in pre-post evaluations. Analogue peer play sessions conducted at baseline and endpoint included 1-2 participants with ASD and 2-3 unfamiliar typically developing peers. Sessions were approximately 30 minutes long, consisted of limited interaction with adult facilitators, and included a cooperative task (e.g. art collage) and a group game (e.g. Uno). Using ObserverXT 11, blinded raters coded the sessions for frequency of the following behaviors: instrumental bids, relational bids, nonverbal gestures and continuous interactions. Adequate to high interrater reliability was achieved (mean index of accordance = 81.4%, median = 92.21%). Data analyses evaluated the number of discrete behaviors (e.g. instrumental, relational, nonverbal) and the number of continuous interactions within each session.
Results: Baseline data indicated differential numbers of target social behaviors in children with ASD. Chi-square analyses revealed a significant difference between the number of relational and instrumental behaviors within the sample, with significantly fewer instrumental bids observed relative to relational bids ($X2= 23.72$, $p < 0.008$). Analyses of target behaviors at baseline and endpoint indicated an increase in the number of continuous interactions (($X2= 9.00$, $p < 0.003$). Correlational analyses revealed a positive relationship between the number of post-treatment continuous and instrumental behaviors ($r = .82$, $p < .001$). Baseline social cognition scores were also positively associated with the number of post-treatment instrumental behaviors ($r = .57$, $p < .020$).
Conclusions: Data suggest prolonged interactions with unfamiliar peers improved following outpatient social skills groups. These findings support the utility of observational assessment paradigms to measure generalization within clinic-based social skills RCTs. The positive relationship between baseline social cognition scores, endpoint instrumental behaviors, and continuous interactions warrants further study of the role of social cognition in predicting social skills generalization.

248 **181.248** Physiological Wellness Effects of Animal-Assisted Activities in Children with Autism Spectrum Disorder in a Specialized Psychiatric Hospital Program

K. A. Willar[1]*, Z. Pan*[2]*, B. Dechant*[2]*, S. Harmeling*[1]*, M. Germone*[1]*, N. Guerin*[3] *and R. Gabriels*[1]*, (1)Children's Hospital Colorado, Aurora, CO, (2)University of Colorado Denver, Aurora, CO, (3)Purdue University, West Lafayette, IN*

Background: Children with ASD are at higher risk for developing co-existing mental health conditions (Szatmari & McConnell, 2011) and consequently experiencing psychiatric hospitalization, compared to the general pediatric population (Kalb et al., 2012). However, hospital environments can be exceptionally stressful for this population (Siegel & Gabriels, 2014), given their social-communication deficits, ineffective emotional regulation skills and heightened physiological arousal (Mazefsky & White, 2014; Bellini, 2006). While the use of animal-assisted activities (AAA) show potential for various improvements in children with ASD in community settings (Gabriels et al., 2015; O'Haire et al., 2013; O'Haire, In Press), these "stress-reducing" and "social-buffering" (Serpell, 2000) benefits have not yet been studied within a psychiatric hospital setting for youth with ASD.
Objectives: Evaluate whether an AAA with canines can lead to reduced physiological arousal and improvements in social-communication as well as aberrant behaviors in children and adolescents diagnosed with ASD in a specialized psychiatric hospital setting.
Methods: Participants were recruited from the Neuropsychiatric Special Care (NSC) program's inpatient and/or partial day-treatment program. Prior to study participation, baseline demographic measures were acquired from caregivers and participants' ASD diagnosis was confirmed. Participants experienced two, randomly assigned 35-minute sessions (AAA and Control Condition) with a minimum two-day washout period between groups. Each session included a baseline 20-minute social skills group immediately followed by a 10 minute experimental or control condition. The AAA condition introduced a canine and volunteer handler for free interaction time while the control condition introduced a novel toy and a volunteer for free interaction. Participants' physiological arousal was continuously assessed throughout all conditions via the Empatica E-4 wristbands (Empatica Inc. 2014). All sessions were videotaped for behavioral coding using the Observation of Human Animal Interaction for Research – Modified, v.1 (OHAIRE-M1; O'Haire, Gabriels, Germone (unpublished manual).
Results: Baseline demographics: age (*M*=11.1 years, *SD*=3.7), 82.4% male, Aberrant Behavior Checklist (ABC)-Irritability subscale (*N*=28; *M*=26.3, *SD*=9.1), Aberrant Behavior Checklist (ABC)-Hyperactivity (*N*=28; *M*=32.7, *SD*=21.8), Leiter-3 NVIQ (*N*=23; *M*=92.1, *SD*=24.1), ADOS-2 comparison score (*N*=22; *M*=7.1, *SD*=2.7) and 86.4% (*N*=22) have a co-existing psychiatric diagnosis. Due to the timeline of this study, planned analyses will begin in January 2017. Between two conditions analyses will include 1) changes in electrodermal activity and 2) changes in behavioral coding data.
Conclusions: This study is expected to demonstrate that children with ASD show reduced physiological arousal in the presence of canines, compared to a control condition in the context of a specialized psychiatric care hospital unit. Additionally, behavioral data is expected to display improved social communication and reduced aberrant behaviors when in the presence of a canine. While canines are commonly enlisted in hospital settings to promote a positive patient experience, there has been minimal empirical research evaluating potential outcomes of this type of activity in general. This study is the first to provide data regarding the wellness and physiological effects of the human-animal bond for children with ASD in hospital settings.

249 **181.249** Piece It Together: Exercise and Wellness Program for Transitional Age Youth with Autism Spectrum Disorders and Mild Developmental Disorders

E. Spratt*, C. Papa, J. Newton, K. Flynn and L. A. Carpenter, Medical University of South Carolina, Charleston, SC*

Background: Youth with Autism Spectrum Disorder (ASD) and other neurodevelopmental disorders are at increased risk of poor health and obesity due to limited interests, sedentary lifestyles, sensory challenges, restricted diets, and medications used to treat their disorder. The “Piece It Together” Program was developed by multidisciplinary professionals with expertise in fitness, nutrition and mental health to provide a comprehensive wellness program for teens and young adults with ASD and other mild neurodevelopmental disabilities. Five primary components of the program include nutrition, exercise, socialization, stress reduction, and opportunities to get out of your comfort zone. The curriculum includes strength and cardiovascular conditioning, nutrition education, mindfulness, yoga and stress reduction strategies to promote healthy lifestyle choices.
Objectives: To provide an organized environment for transitional age youth with ASD and other mild neurodevelopmental disorders to increase exercise, improve nutrition, socialize with peers with and without disabilities, practice stress reduction strategies, and encourage opportunities to get outside of your comfort zone.
Methods: Participants attended 90 minute sessions at the Medical University of South Carolina Wellness Center twice-a-week, for six-weeks. As each individual had unique strengths and weaknesses, each established nutrition, fitness, socialization, and stress reduction goals. FitBit devices were distributed to participants. Assessments were done at the first and last classes, including InBody 570 Analyzer©2014 assessments, PHQ-9, 5-2-1-0 Healthy Habits Questionnaire, Flourish and Fitness Scale, PHQ-9 questionnaire, and lifestyle questionnaires. Volunteers provided support in class and have included health profession trainees.
Results: The 2015 Summer Program included 12 individuals (7 males) ages 15 to 27. Average PHQ-9 depression scores decreased from 7.67 to 3.42 (from mild to minimal depression; $p<0.000063$). Self-reported 5-2-1-0 Heathy Habits data revealed more fruits and veggies in the diet at time 2 ($p =0.04$) and modest improvement in self-efficacy related questions (e.g., I like the way I look/I am a good worker; $p=0.03$). In 2016, the Summer program included 21 participants (16 males), ages 13-28 that attended regularly and for some it was their fourth summer participating. Challenges were noted with youth with high irritability and cognitive deficits. However, pre and post testing revealed decreases in depression scores, increases in skeletal muscle, decreases in visceral body fat, improvements in nutrition and increases in socialization. The increased support to use Fitbits appeared to increase movement as well as social engagement through Fitbit friends.
Conclusions: This 6-week Summer program successfully brought together a unique group to build friendships and make healthier lifestyle choices and has continued as a weekly program. Individual successes are numerous as each individual has a success story of individualized goals that have been met, and the greatest success has been measured by continued participation focused on 5 main components that are commonly needed for youth with ASD. The use of Fitbits provided a platform for goal setting and increased physical activity outside of class. Almost all participants continue to participate in a weekly class and communicate with each other outside of class. Future efforts are to encourage maintenance of lifestyle changes and minimize barriers to participation.

250 **181.250** Prefrontal Neurofeedback Training in Children with Autism

*E. M. Sokhadze[1], **M. F. Casanova**[2], D. P. Kelly[3], Y. WANG[4] and A. Tasman[1], (1)University of Louisville, Louisville, KY, (2)University of South Carolina School of Medicine, Greenville, SC, (3)Pediatrics, Greenville Health System, Greenville, SC, (4)Allied Health School, Beijing Language and Culture University, Beijing, China*

Background: Electroencephalographic (EEG) biofeedback training (i.e., neurofeedback) is a treatment potentially useful for improvement of self-regulation skills in autism spectrum disorder (ASD). There are several techniques proposed to target symptoms of ASD using neurofeedback, with most differences being in the type of training (e.g., power of EEG bands, theta/beta ratio, coherence), topography (Cz or Pz), guidance by quantitative EEG (qEEG) and number of neurofeedback sessions (e.g., 20 vs. 30, etc.).
Objectives: We proposed that prefrontal neurofeedback training will be accompanied by changes in relative power of EEG bands (e.g., 40 Hz centered gamma band) and ratios of individuals bands (e.g., theta/beta ratio) and will be more effective with higher number of training sessions (e.g., 12 vs 18 sessions). Outcomes measures along with EEG included as well behavioral ratings by parents/caregivers
Methods: In the first pilot study on 8 children and adolescents with ASD (~17.4 yrs) we used 12 session long course of neurofeedback from AFz site, while in the second study on 18 children (~13.2 yrs) we administered 18 sessions of 25 min long prefrontal neurofeedback training. The protocol used a training procedure, which according to specifications, represents wide band EEG amplitude suppression with simultaneous upregulation of 40 Hz centered gamma activity. Custom-made Matlab program developed for the analysis of EEG data using wavelet analysis was useful to detect changes in EEG profiles during neurofeedback sessions. Quantitative EEG analysis at the training site was completed for each session of neurofeedback using a custom-made MATLAB application to determine the relative power of the individual bands (delta, theta, alpha, low beta, high beta, and gamma) and their ratios (theta/low beta, theta/high beta, etc.) within and between sessions. In both studies we analyzed Aberrant Behavior Checklist (ABC) ratings by caregivers (pre- and post-treatment).
Results: The pilot study that used only 12 sessions showed significant qEEG changes sessions but did show only trend of progress across the 12 sessions even though changes of individual EEG bands and their ratios were significant. The 18 session course of neurofeedback showed more significant improvements both in behavioral and qEEG measures. There was found a significant reduction in Lethargy subscale of the ABC. The rating scores showed reduction (from 10.18 ± 6.07 to 7.53 ± 5.82, $t(17)=3.29$, $p=0.005$), while Hyperactivity scores also showed decrease (from 16.65 ± 13.78 to 13.29 ± 11.97, $t(17)=2.56$, $p=0.021$).
Conclusions: Our experiments showed advantages of 18 session long weekly prefrontal neurofeedback course in children with autism. More future research is needed to assess qEEG changes at other topographies using brain mapping and using other outcome measures including behavioral evaluations to judge about clinical utility of prefrontal neurofeedback in children with ASD.

251 **181.251** Prevention of Elopement-Related Injuries in Children with ASD

***A. M. Andersen**[1], J. K. Law[2], A. R. Marvin[3] and P. H. Lipkin[4], (1)Psychiatry, University of Iowa Hospitals and Clinics, Iowa City, IA, (2)Interactive Autism Network, Baltimore, MD, (3)Kennedy Krieger Institute, Baltimore, MD, (4)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD*

Background: Â Elopement behavior (EB), sometimes termed “wandering”, is emerging as a significant contributor to morbidity and mortality among individuals with Autism Spectrum Disorder (ASD). Causes of death among individuals with ASD who elope include drowning and traffic accidents. Prior investigations have established a high rate of elopement among children with ASD, ranging from 26%49%. To prevent elopement-related injury and death, parents implement a wide variety of environmental, behavioral, electronic, and pharmacologic interventions. What is not known, however, are the relative costs, effectiveness, burdens and side effects of these interventions among children with ASD.
Objectives: Â To assess caregiver responses to EB among children and adolescents with ASD and cooccurring disorders such as ID, ADHD, and Language Disorder, as well as their perceived costs, effectiveness, and burden of use.
Methods: Â Parent participants in the Interactive Autism Network (IAN) — a large, validated and verified, internet-mediated, parent-report autism research registry — were invited to complete a survey about their children with ASD ages 4 or older. Inclusion criteria were survey completion, professional diagnosis of ASD, confirmatory Social Communication Questionnaire score of >=12, Social Responsiveness Scale score, and completed birth and diagnosis questionnaire. Survey items included past and current patterns of EB, consequences of the behavior, parental responses and interventions attempted to prevent the behavior (including medications) or harmful outcomes, their perceived effectiveness, burden of use, and estimated costs.
Results: Â Caregivers mobilize community resources including neighbors, school personnel, and police during elopement incidents. Caregivers were nearly twice as likely to receive advice on managing elopement from an ASD advocacy organization (22%) as a physician (12%), and 44% received no advice or guidance from any source. Caregiver strategies to prevent EB and negative consequences included a variety of physical, electronic, and behavioral interventions. Many environmental interventions such as locks, door alarms, security systems, and fencing were rated as highly effective. Security systems were rated as highly effective but more expensive, while GPS trackers were rated as less effective and more burdensome. Aide services were rated as highly effective but generally provided through insurance, school, or local agencies rather than being paid for out of pocket. A variety of medications administered specifically to reduce EB or for other disorders were generally rated as ineffective in reducing EB and parents reported significant rates of side effects.
Conclusions: Caregivers use a variety of intervention strategies to prevent EB and related injuries and death in youth with ASD. Environmental and behavioral interventions are generally rated as much more effective than medications in reducing EB. Clinicians should screen for elopement behavior in children with ASD and advise the use of inexpensive, easy to implement interventions such as locks, door alarms and dead bolts for children who elope. GPS tracking devices may be effective in some patients but more expensive and burdensome. Caution is indicated when prescribing medications off-label to reduce EB given parental reports of their poor effectiveness and side effect burden. Further study of interventions to prevent EB including their associated costs, effectiveness, and burden of use is indicated.

252 **181.252** Profile of Skills and Symptoms in Transition Aged Youth with ASD

E. Edwards[1]*, A. Pearl*[2]*, M. Klemick*[1] *and M. Murray*[1]*, (1)Penn State College of Medicine, Hershey, PA, (2)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hummesltown, PA*

Background: Outcome data for adults with Autism Spectrum Disorder (ASD) are poor, showing under-employment, reduced social engagement, high frequencies of co-morbid mental health issues and lower reported quality of life. Despite progress in assessment and treatment of skills deficits for young children with ASD, few have focused on defining the needs of transition-age youth, specifically to produce more successful outcomes into adulthood. Identifying and addressing the skill gaps relevant to adult life during the high school years, provides the opportunity to better utilize services available to adolescents and better prepare teens for the transition to adulthood.
Objectives: This study provides descriptive profile data of adolescents with Autism Spectrum Disorder, in order to better identify needs specific to transition to adulthood.
Methods: As part of a larger, on-going project, adolescents aged 14-19 with ASD were recruited. Adolescents in the study did not have comorbid ID or active psychosis and were able to self-report. Baseline assessment data were collected. Adolescents completed the ARC Self-Determination Scale (SDS), The Intolerance to Uncertainty Scale (IUS), and a PROMIS profile scale (profile 49 or 43 dependent on age). A parent of the adolescent completed the Waisman Activities of Daily Living (WADL) Scale, the caregiver version of the IUS, and PROMIS proxy scales for Anxiety, Depression, Anger and Peer Relations (for individuals under 18). Currently 17 adolescents have completed the baseline assessments; however it is anticipated to enroll 60 individuals in the project by May, 2017.
Results: Compared to means from a normed sample of adolescents, the individuals with ASD in this study reported lower mean scores on the SDS, particularly on the autonomy subscale (ASD M = 48.38, SD = 17.7, normed population M = 63.35, SD = 15.5, $t = -3.42$, $p < .01$). The autonomy subscale of the SDS was not correlated with the WADL; though the WADL scores showed age-related increases, similar to larger longitudinal studies. Parents rated their child’s IUS (M = 68.35, SD = 22.57) on average 27.7 points higher compared to the participant’s self-report (M = 50.53, SD = 18.9). Adolescent IUS scores correlated with adolescent self-report (PROMIS 49/43) of anxiety ($r = .70$, $p < .01$), and parent proxy IUS scores correlated with parent proxy anxiety scores (PROMIS subscale; $r = .63$, $p < .05$), however parent and adolescent IUS scores did not correlate with each other ($r = .28$, ns). Self-realization scores (related to measures of self-esteem) correlated to self-reported depression symptoms (PROMIS 49/43), $r = -.81$, $p < .001$.
Conclusions: Â Adolescents with ASD scored lowered on self-determination measures compared to reported norms, which may provide insight into important skills areas to target among transition aged students with ASD. Also noticeable was differences between the adolescent’s reporting and parent proxy reporting. This may also be important to consider to gain more complete picture of the adolescent’s needs; current data show very limited involvement in IEP and service planning meeting by the adolescent with ASD, but instead parents and guardians speaking on their behalf.

253 **181.253** Public Perceptions of Autism Treatments: Does Source Credibility Matter?

V. Fleury*, G. Trevors and P. Kendeou, Educational Psychology, University of Minnesota, Minneapolis, MN*

Background: Scientifically validated instructional strategies have been identified to improve behavioral symptoms associated with autism (see Wong, 2014 for a review), however families and practitioners often give credence to “fad” approaches that lack evidentiary support. Not only are fad treatments, such as sensory integration therapy and special diets, unlikely to be effective, but they may delay or even prevent individuals with autism from accessing evidence-based intervention that is more likely to produce favorable outcomes.
Objectives: To explore factors that can influence the public’s acceptance of autism treatments, specifically evidentiary support and source credibility.
Methods: Adults read a series of texts describing different autism treatments (*N*=379). The text presentation was based on a 2 x 2 within-subjects factorial design with treatment status (evidenced-based vs. fad) and credibility of the source in the text (credible vs. non-credible) as the independent variables. Thus, participants read about evidence-based treatments (EBP) presented by credible sources, EBP presented by non-credible sources, fad treatments presented by credible sources, and fad treatments presented by non-credible sources. Participants rated the degree to which they believed the treatment would be effective (believability); the extent to which they would either use or recommend the treatment to someone else (intentionality), and credibility of each treatment using a Likert scale. In a subsequent *instruction manipulation* condition, the text remained the same but participants were instructed to “pay attention to the credibility of the source providing information.”
Results: Â Our analyses reveal an overall main effect of treatment status, $t(377) = 12.56$, $p < .001$ such that EBP were rated as more credible than fad treatments. We also identified a main effect of source credibility, $t(377) = 8.33$, $p < .001$, such that credible sources were rated as more credible than non-credible sources. Participants considered the credibility of the source only when explicitly instructed (instruction manipulation condition). Participants successfully differentiated between the credibility of EBP texts, $t(129) = 5.61$, $p < .001$, with EBP descriptions presented by credible sources ($M = 3.85$, $SE = .07$) receiving higher credibility ratings than those from a non-credible source ($M = 3.33$, $SE = .08$). Â We also find that fad texts from a credible source ($M = 3.68$, $SE = .04$) received higher credibility ratings than those from a non-credible source ($M = 2.81$, $SE = .08$; $t(129) = 6.27$, $p < .001$. In this condition, participants’ ratings of EBP presented by a non-credible source did not differ from fad treatments presented by a credible source.
Conclusions: These results suggest that people do not naturally attend to source credibility when evaluating treatments described in print.Â Manipulation instructions to attend to the credibility of sources had the intended effect: credibility ratings of non-credible sources were reduced and credible sources increased regardless of EBP status. This also meant that credibility ratings increased even for fad approaches presented by credible sources (e.g., physicians presenting pressure/weighted vests), which may indicate a maladaptive over-correction effect.

254 **181.254** Randomised Controlled Trial of the Use of the BLUE Room Virtual Reality Treatment to Reduce Situation Specific Anxiety in Young People with ASD

M. Maskey[1], *V. Grahame*[2], *H. McConachie*[3], *J. Rodgers*[4] *and J. Parr*[4], *(1)Newcastle University, Newcastle upon Tyne, UNITED KINGDOM, (2)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, UNITED KINGDOM, (3)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background:
Young people with ASD are prone to anxiety; around 50% of those with ASD meet criteria for at least one anxiety disorder. Specific fears and phobias are one of the most frequent subtypes.
Graduated exposure and participant modelling are identified as evidence-based treatments for specific fears/phobias, but may require adaptation for individuals with ASD. One adaptation may be the use of a virtual reality environment (VRE) to reproduce the anxiety provoking situation. This removes the need to use imagination, and provides a way to gradually increase exposure to an anxiety provoking stimulus.
Following a successful development study with 9 children (Maskey et al 2014, PLoS One), we investigated further whether the Newcastle Blue Room Treatment may be effective for children attending child mental health services by conducting a randomised trial. The treatment involves sessions in an immersive VRE with a therapist.
Objectives:
To test the effectiveness of virtual reality exposure in overcoming a specific fear/phobia, reporting outcomes at 6 months after treatment.Â
Methods:
32 verbally fluent young people with ASD aged 8-14 years, who have a specific fear/phobia, were recruited from two mental health trusts. Children were randomised to immediate treatment (n=16) or delayed treatment (n=16; receiving treatment after their six month follow-up). Each participant received one preparatory home visit, followed by four 20 minute sessions in the fully immersive VRE with a scene designed specifically around their specific fear/phobia. During each session, they received coaching in relaxation techniques and coping self-statements from a therapist who accompanied them. The Newcastle Blue Room Treatment uses state of the art technology (http://blueroomisv.com/).
Before and after each VRE session, the child and parent (who was observing from another room) rated the child’s anxiety using a six point scale. Anxiety at baseline and six-month end point was measured using the Spence Children’s Anxiety Scale and the FEAR survey. Vignettes describing the anxiety to be addressed during the treatment, and the family impact, were written at baseline. Subsequently, a blinded researcher contacted the families 2 weeks and 6 months post-intervention (or equivalent for the delayed arm) and completed vignettes characterising the child’s anxiety-related behaviour at those timepoints. Change in symptoms across time as depicted in the vignettes was the primary outcome measure. The vignettes were compared by an expert panel (blinded to timepoint and treatment group) to assess degree of improvement/deterioration of symptoms and impact on a 9 point scale. The top three points described a responder.
Results:
At six months follow up the immediate treatment group had improved significantly more than the control group (t= -3.230, p=0.005). Half of the immediate treatment group met criteria for being aÂ ‘responder’; none of the delayed treatment group responded. Results from other outcome measures will be presented at the conference.
Conclusions:
This study has shown that the individually tailored, Newcastle Blue Room Treatment comprising virtual reality exposure in conjunction with CBT is an effective treatment for children with ASD and situation specific anxiety, specific fears and phobias.

255 **181.255** Reduced Levels of Parental Anxiety, Depression and Stress Following Pivotal Response Treatment

S. M. Abdullahi*, M. L. Braconnier, J. Lei, C. Kautz and P. E. Ventola, Yale Child Study Center, New Haven, CT*

Background:
Parents of children with intellectual and developmental disorders are more susceptible to physical health problems, psychological stress, depressive and anxiety disorders (Miodrag & Hodapp, 2010; Taylor & Warren, 2012). Meta-analysis of past studies done by Singer in 2006, estimated that 30-35% mothers of children with developmental disabilities are likely to have elevated levels of depressive symptoms (Singer, 2006).
Objectives:
We characterized the severity of anxiety, depression and stress in parents of children with Autism Spectrum Disorders (ASD) and the change of these symptoms in those who took part in Pivotal Response Treatment (PRT).
Methods:
We measured anxiety, depression and stress in 116 parents of children with ASD using the Beck Anxiety Inventory (BAI), Beck Depression Inventory, Second Edition (BDI-II) and Parental Stress Index, Forth Edition (PSI-4), respectively.
Then, we investigated the reduction of these symptoms in 25 of the parents (15 mothers and 10 fathers) after they participated in a 16-week trial of PRT. PRT is a naturalistic behavioral treatment that aims to improve a child's social communication skill. PRT is a 16-week trial that includes 7 hours/week of individual work with a school-age child with autism and parent training. To measure the change in social functioning of the children who participated in PRT, parents completed Social Responsiveness Scale, Second Edition (SRS-2) before and after the intervention.
Results: Â
Out of 116 parents of children with ASD, 22% reported mild to moderate levels of depression (total BDI score >14), 3% reported moderate to high levels of anxiety (total BAI score >22) and 22% exhibited high levels of stress (total PSI-4 raw score >110).
Of the families who participated in the PRT trial, parents reported a significant decrease in their anxiety (BAI Total Score: pre-PRT M= 5.44, SD= 6.72; post-PRT M= 4.28, SD= 6.07, $p<0.05$) and stress (PSI-4 Total Score: pre-PRT M= 95.67, SD= 18.24; post-PRT M= 82.71, SD= 18.26, $p<0.001$). Individual PSI-4 subdomains, Parental Distress Score ($p< 0.01$), Child Dysfunctional Interaction Score ($p<0.001$) and Difficult Child Score ($p<0.01$) decreased significantly as well. A trend toward decreasing levels of depression was observed (BDI Total Score: pre-PRT M= 8.36, SD= 7.26; post-PRT M= 6.68, SD= 6.62, $p=0.065$).
The improvement in social functioning of children who participated in PRT, as measured by SRS-2, was correlated with the reduction in parental depression ($r=-0.523$, $p<0.001$) and stress ($r=-0.489$, $p<0.01$).
Conclusions:
Our results show that rates of depressive symptoms and stress are high in parents of children with ASD and their symptoms are reduced after participating in PRT. The parent training component of PRT provides parents with the support and training to effectively implement PRT. Being actively engaged in PRT and witnessing the positive improvements in their children due to the intervention relieves the stress and anxiety parents have about their children and their disorder. It also provides them with a sense of hope for the future of their children.

256 **181.256** Regression in Children with ASD: Clinical Profile and Short Term Outcome.

P. K. Panchal[1], *S. Srinath*[2], *S. C. Girimaji*[3], *S. Seshadri*[1] *and J. V. S. Kommu*[2], *(1)National Institute of Mental Health and Neurosciences, Bangalore, India, (2)NIMHANS, Bangalore, INDIA, (3)Child and Adolescent Psychiatry, National Institute of Mental Health and Neurosciences, Bangalore, India*

Background: The phenomenon of developmental regression in children with Autism Spectrum Disorder (ASD) is well studied. Much is known about the prevalence of regression, age of onset and pattern of regression. Few studies have been conducted on the outcome of intervention on children with ASD and developmental regression. The findings from these studies are inconclusive. Present study compared the impact of parent training intervention on young children with ASD and history of regression (ASD-r) to children with ASD and no history of regression (ASD-nr).
Objectives: To assess the short term outcome of children with ASD with/without regression after receiving a two week in-patient, parent training.
Methods: The participants were children (aged 3- 10 years) diagnosed with Autism Spectrum Disorder according to DSM-V. Children and their parents were admitted in the in-patient child psychiatry facility for 2-3 weeks. Detailed baseline assessments were done using Childhood Autism Rating Scale 2ndedition (CARS- 2), Indian Scale for Assessment of Autism (ISAA), Vineland Social Maturity Scale (VSMS), Family Interview for Stress and Coping -ASD (FISC-ASD), Autism Parenting Stress Index (APSI) and Autism Treatment Evaluation Checklist (ATEC). Detailed history of child's development and regression was obtained from the parents. Regression here was defined as loss of a previously acquired skill anytime during the child's development. Parents received daily individualised sessions aimed at home based training. FISC-ASD was re-administered at the time of discharge. APSI and ATEC were re-administered over telephone after three months of discharge from the hospital.
Â Results: Â Out of twenty children (M=16, F=4) recruited in the study, seven children (all males) had history of developmental regression. The mean age at recognition of regression was 24.57 (months) ± 10.72. Out of seven children with regression, four children had regression on the background of delayed development. Four children had regression of language and social milestones, two had regression in all developmental areas and only one child had regression in language. No precipitating factor was reported by parents around the time of regression. Workup for degenerative disease was nil contributory in all these cases. Rate of perinatal complications and co-morbid disorders were lower in children with ASD-r as compared to children with ASD-nr. Baseline scores of CARS – 2, ISAA, VSMS, FISC-ASD, ATEC and APSI were same for children with ASD-r and ASD-nr. Children with ASD-r had statistically significant lower scores on post intervention ATEC as compared to children with ASD-nr.
Conclusions: Â Present study included clinic based sample of twenty children with ASD, out of whom 28% had history of developmental regression. Children with ASD and regression had similar functioning at baseline and had reduced autistic symptoms on three month follow up as compared to children with ASD and no history of regression. Small sample size, lack of an independent blind rater and post intervention assessment over telephone are the main limitations of this study. Strength of the study is the prospective nature of follow up. Long term follow up of these children is planned.

257 **181.257** Results of a RCT on a Transition Support Program for Adults with ASD: Effects on Quality of Life and Self-Determination

A. Nadig[1], *T. Flanagan*[2], *K. White*[2] *and S. Bhatnagar*[3], *(1)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada, (2)Counselling and Educational Psychology, McGill University, Montreal, QC, Canada, (3)Epidemiology, Biostatistics, and Occupational Health, McGill University, Montreal, QC, Canada*

Background:
There is a dearth of evidence-based services for people with autism spectrum disorders (ASD) as they transition into adulthood (Spain & Blainly, 2015). This often leads to poor outcomes with respect to independent living, vocational and community engagement (e.g., Howlin et al., 2004; Roux et al., 2015). Currently, the only RCTs on a comprehensive intervention for young adults with ASD evaluate the UCLA PEERS model (Gantman et al., 2012; Laugeson, et al., 2015; Van Hecke et al., 2016). However, PEERS requires caregiver involvement and assistance, which is not available to all adults with ASD, nor does it foster much needed independence (Hume et al., 2014).
Objectives:
We developed a manualized curriculum for a transition service for young adults with ASD (without Intellectual Disability). Instead of targeting predetermined skills, we empowered participants to identify skills they wanted to develop, a practice supported in the disability literature (Wehman et al., 2014). We surveyed participants' needs in three areas critical for successful adult transition: social communication, self-determination and working with others. Curriculum for each small group session reflected those participants' self-expressed needs. To evaluate the efficacy of this program we conducted an RCT with a delayed intervention control group, focusing on Quality of Life and Self-Determination outcomes (ClinicalTrials.gov:NCT02439671).
Methods: Â
Groups of 4 to 6 participants with ASD and 2 facilitators met for weekly for 2 hours over 10 weeks. Pre- and post- assessments were conducted within 4-6 weeks of the intervention by assessors blind to group status. Community diagnoses of ASD were confirmed with the ADOS-2.Â **RCT analysis:** 34 participants (aged 18 – 29) were randomized to immediate or delayed intervention. Groups did not differ on key demographic variables, nor baseline scores on Quality of Life (QoL-Q; Schalock & Keith, 1993) and Self-Determination (SDS; Wehmeyer & Kelchner, 1995) measures. **Pre-post analysis:**19 participants and 8 caregivers completed ratings of communication, self-determination, and working with others skills before and after intervention.
Results: Â
Two participants did not meet ASD criteria, and 6 did not complete all testing points, leaving 17 participants in the immediate intervention group and 9 in the delayed intervention control group. Intervention effects were investigated with Generalized estimating equations. There was a positive intervention effect on the QoL-Q, with the intervention group scoring on average 2 points higher than the control group, 95% CI [-.2, 3.9]. There was a strong positive intervention effect on a SDS subscale "Interpersonal cognitive problem-solving," with the intervention group scoring 2 points higher than the control group 95% CI [.082, 3.4]. Pre-post analyses revealed strong positive effects on participants' ratings of their own skills as 6 points higher post intervention, 95% CI [3.7, 8.6]. This was echoed by parent ratings of their child's skills as 7 points higher on average post intervention, 95% CI [1, 14].
Conclusions:
This is the first intervention study for adults with ASD targeting QoL and SD outcomes. Results show that in addition to improving skills focused on in the curriculum, important gains were made in QoL and SD during the intervention relative to control.

258 **181.258** Robotics Based Therapy in Chilean Children with Autism Spectrum Disorder (ASD)

*L. Madariaga[1], A. C. Yanez[2], M. Troncoso[2], J. Albo-Canals[3], C. López[2], **P. González**[2], P. Lagos[2], M. Fernández[2] and M. Dorochesi[1], (1)Product Design Engineering, Federico Santa Maria Technical University, Valparaíso, Chile, (2)Child Neuropsychiatry Service, San Borja Arriaran Hospital, Santiago, Chile, (3)Engineering School, La Salle – Ramon Llull University, Barcelona, Spain*

Background: Technology appeals ASD children. The use of this interest to help them improve socialization skills has received increasing research attention in the last decade (Dautenhahn, K. et al, 2002). Furthermore, special interest of ASD children for LEGO toys has been observed because they are highly structured, systematic and predictable. Studies have shown their usefulness when applied in the appropriate therapeutic context; they can decrease disruptive behaviors and improve social skills in ASD children, in a spontaneous and entertaining way, being less exhausting for patients and therapists (Legoff et. al 2006; Owens et. al 2008). However no data or results has been reported in the Chilean context.
Objectives: To determine whether robotics based therapy improves social skills in a group of Chilean ASD children under treatment in a Child Neuropsychiatry Hospital Service, representative of Chile´s context, because of its national referral center condition.
Methods: Cases and controls, prospective longitudinal study. 3 groups of 4 children with ASD diagnosis, confirmed with Autism Diagnostic Observation Schedule (ADOS); age higher than 9 years, normal intellectual coefficient with WISC (Wechsler intelligence scale for children). A group participated in workshops of LEGO Robotics (LEGOr-w), the second in workshops of social skills (SS-w) and the last one was not intervened. Both workshops lasted 10 sessions, and were performed once every two weeks
Results: 4 children of male sex in each group, average age: 11 years. Comparable groups. Vineland: significant differences in categories: socialization (p=0.002) and communication (p=0.039) comparing initial and final average scores of the 3 groups. No differences between groups (p>0.05, confidence level of 95%). Video coding: Children that joined LEGOr-w improved the following behaviors: initiation of meaningful conversation, autonomy for resolution of problems; less disruption to other, less echolalia, fewer episodes of discouragement or abandonment of the activity, however, these changes did not have statistical significance. Surveys: Statistically non-significant difference between scores of satisfaction surveys comparing initial and final assessments of parents and children in both workshops. Workshop attendance: Statistically significant difference in the attendance between the LEGOr-w and the SS-w (p=0.009), being the LEGO robotics group the one with better participation.
Conclusions: Better adherence to LEGOr-w, no differences in Vineland between groups, while the three improved. Novel intervention oriented towards users of Chilean public health system with restricted access to technology and limited offer of therapeutic interventions. Therapy aimed towards an age group where indifference attitudes have negative impact on interventions, contrary to the observations of this study sample. Further research could measure social behavior using the Gilliam Autism Rating Scale-2 in Spanish version and increase the total number of sessions and participants to observe the likelihood of improved socialization, as reported in literature. Maternal interviews in LEGOr-w final session reported improvement in fine motor skills of children; this could be measured in further robotics-based therapy research.

259 **181.259** Self-Esteem As a Mediator of Social Skills Improvement and Social Anxiety for Adolescents with Autism Spectrum Disorder (ASD) Following the UCLA PEERS® Program

***Y. Zhang**[1,2], J. Yang[3], E. Veytsman[1], R. Jalal[1] and E. A. Laugeson[4], (1)UCLA PEERS Clinic, Los Angeles, CA, (2)Pepperdine University, Los Angeles, CA, (3)The Help Group - UCLA Autism Research Alliance, Sherman Oaks, CA, (4)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background:
Studies suggest that teens with Autism Spectrum Disorder (ASD) have greater social impairment and are more likely to experience social anxiety while joining social groups (Brumariu & Kerns, 2008). Previous research has shown a positive relationship between social ability and self-esteem in typically developing youth (Lee & Robbins, 2000). Moreover, changes in self-esteem may trigger changes in social anxiety (de Jong, 2002; Rasmussen, & Pidgeon, 2011). The Program for the Education and Enrichment of Relational Skills (PEERS®) is an evidence-based, parent-assisted social skills treatment, which has been shown to improve social skills and reduce social anxiety in youth with ASD (Laugeson & Frankel 2010). However, self-esteem as a mediator of social anxiety and improvement in social skills following the UCLA PEERS® program has yet to be examined.
Objectives:
The purpose of this study is to examine self-esteem as a mediator of social skills improvement and social anxiety for adolescents with ASD following the UCLA PEERS® Program.
Methods:
Participants included 279 adolescents with ASD (64.2% Male=207; 25.8% Female=72) aging from 11-18 years (*M*=13.62, *SD*=1.95) and their parents. Teens and parents attended weekly 90-minute social skills groups at the UCLA PEERS® Clinic over a 14-week period. Social skills related to making and keeping friends as well as handling conflict and rejection were taught in a small group format. To assess improvement in social skills, parents completed the Social Responsiveness Scale-Second Edition (SRS-2; Constantino, 2012) at pre-and-post intervention, which measures adolescents' ability to interpret and respond to social cues. Adolescent self-esteem and social anxiety were assessed using self-reports on the Piers-Harris Self-Concept Scale-Second Edition (PHS-2; Piers, Harris & Herzberg, 2002) and Social Anxiety Scale (SAS; La Greca, 1998) at post-intervention. A Multiple Linear Regression was used to examine the relationship between changes in SRS-2 scores, and post-treatment PHS-2 and SAS scores, using self-esteem as a mediator variable.
Results:
Results suggest the existence of a mediating effect. Data indicates that changes in SRS-2 Total scores from pre- to post-intervention are positively correlated with SAS Total scores (p<0.01) and PHS-2 Total scores (p<0.01) following treatment. However, Multiple Linear Regression results indicate when self-esteem on the PHS-2 is used as a mediator, the relationship becomes insignificant (r=0.022; p=0.757). These results reveal that self-esteem plays a mediating role in the relationship between social skills improvement and social anxiety, with greater self-esteem mediating reduced social anxiety at post-intervention.
Conclusions:
The current research examined self-esteem as a mediator of social skills improvement and social anxiety for adolescents with ASD following the UCLA PEERS® Program. Findings suggest that self-esteem may act as a mediator between social skills improvement and social anxiety. Specifically, increased social ability appears to increase self-confidence in applying newly acquired social skills, thereby reducing social anxiety when engaging in social activities.

260 **181.260** Sex Differences in Adaptive and Social Behavior and Neural Responses to Biological Motion before and after Pivotal Response Treatment in Autism

C. Kautz[1], *D. Yang*[2,3], *K. A. Pelphrey*[2,3], *J. Lei*[1], *M. L. Braconnier*[1], *S. M. Abdullahi*[1] *and P. E. Ventola*[1], *(1)Yale Child Study Center, New Haven, CT, (2)Autism and Neurodevelopmental Disorders Institute, The George Washington University, Washington, DC, (3)Children's National Health System, Washington, DC*

Background: Research on the clinical presentation of girls with ASD is mixed. Some evidence indicates that girls are more severely affected than boys; however, some girls with ASD may be missed by current diagnostic criteria (Kirkovski, M., Enticott, P.G., Fitzgerald, P.B., 2013; Howe, Y.J., et al, 2015). It is also unclear whether sex differences exist in treatment response.
Objectives: In a sample of young children with ASD, we compared social communication and adaptive skills as well as neural activation in key regions of social perception before and after a 16-week waitlist controlled trial of Pivotal Response Treatment (PRT).
Methods: Twenty-eight children, eleven girls, (mean IQ 96.32; SD 20.39; range 50-128) completed the 16-week trial of PRT. Twenty-one children, six girls, completed the waitlist condition (WLC) (mean IQ 97.00; SD 23.49; range 50-128). Furthermore, a subset of the PRT sample (13 boys, 7 girls) completed an fMRI before and after treatment. They viewed neuroimaging stimuli depicting point light displays of coherent biological or scrambled motion in a 3T scanner. Neuroimaging results were thresholded at Z>2.33 (voxel) and p<.05 (cluster). PRT is a naturalistic behavioral treatment focusing on improving children's social communication skills. PRT condition included 7 hours per week of individual work with the child and parent training. Clinical outcomes were assessed using the SRS-2, a parent report measure of social communication, and the Vineland Adaptive Behavior Scales-II, a semi-structured interview on adaptive functioning.
Results: At baseline, girls had significantly greater impairments in all domains of the Vineland-II (girls Communication mean 80.75, boys 91.588, p<.05; girls Daily Living Skills mean 74.833, boys 88.353, p<.05; girls Socialization mean 75.333, boys 82.47, p<.05; girls Adaptive Behavior Composite mean 76.167, boys 85.188, p<.05). Following treatment, girls' improvement on the ABC was significant (p<.05), whereas boys' improvement was not. After treatment, girls and boys exhibited no significant differences in adaptive functioning. At baseline, girls also had more pronounced social communication deficits than boys as assessed by the SRS-2. Girls' rate of improvement exceeded boys', although the magnitude of the differences was not significant (p>.05). Neither boys nor girls exhibited significant change in adaptive functioning or social communication following the WLC. Neuroimaging results were consistent with behavioral results: at pretreatment baseline, girls exhibited significantly less response to biological vs. scrambled motion than boys in the right inferior frontal gyrus (IFG) and right precentral gyrus (PG), key regions of social information processing. Following treatment, girls exhibited a greater gain in activation in the left fusiform gyrus (FFG), another key region involved in social perception. No regions showed a greater improvement in boys than girls.
Conclusions: Â Compared to boys, girls were more impaired at baseline and made more progress in adaptive functioning. Girls' social communication gains trended toward being significantly greater than boys'. Neuroimaging results were consistent with behavioral results. These findings are promising in that they suggest that girls, even if more impaired at baseline, respond favorably to treatment at the behavioral and neural level, possibly even more so than boys.

261 **181.261** Symptoms of ADHD, Depression, and Social Anxiety As Predictors of Social Skills Outcomes Among Adolescents with ASD Following the UCLA PEERS® Intervention

A. Dahiya[1], *N. Rosen*[1], *R. Ellingsen*[2], *L. Forby*[1], *E. Veytsman*[3] *and E. A. Laugeson*[4], *(1)UCLA, Los Angeles, CA, (2)University of California Los Angeles, Venice, CA, (3)UCLA PEERS Clinic, Los Angeles, CA, (4)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background:
Deficits in social skills, including impaired social-emotional reciprocity and poor nonverbal communicative behaviors, are common hallmarks for those with autism spectrum disorder (ASD) (Otero et al. 2015). These social deficits are often accompanied by deficits associated with other comorbidities that frequently occur in children with ASD (Leyfer et al., 2006). Among these comorbidities, anxiety, depression and Attention-Deficit/Hyperactivity Disorder (ADHD) are most common (Siminoff et al., 2008). Previous research on the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®), an evidence-based social skills intervention for adolescents with ASD, demonstrates increases in social skills outcomes (Laugeson et al. 2012). While research suggests that ADHD, depression, and social anxiety are common symptoms yielding social deficits among adolescents with ASD, the extent to which these symptoms predict social skills outcomes following PEERS®requires examination.
Objectives:
The present study examines symptoms of ADHD, depression, and social anxiety as predictors of social skills outcomes among adolescents with ASD following a 14-week parent-assisted social skills intervention.
Methods:
Ninety-nine adolescents (males=81; females=18) with ASD ranging from 11-17 years of age (*M*=13.74; *SD*=1.65) and their parents participated in the study. Participants attended PEERS®, an empirically-supported parent-assisted social skills intervention. They attended 90-minute group treatment sessions over 14-weeks to learn guidelines related to the development and maintenance of social relationships. To assess baseline adolescent comorbidities, parents completed the Swanson, Nolan, and, Pelham Questionnaire-4thedition (SNAP-IV: Bussing et. al., 2008), which measures ADHD symptoms, and the Social Anxiety Scale (SAS; La Greca, 1999). Adolescents also completed the SAS at baseline, as well as the Children's Depression Inventory (CDI; Kovacs, 1992). Treatment outcome was assessed by examining parent- and adolescent-reported change in frequency of social engagement using the Quality of Socialization Questionnaire (QSQ; Frankel & Mintz 2008), and parent-reported change in social responsiveness on the Social Responsiveness Scale (SRS; Constantino, 2005) pre- and post-intervention.
Results:
Paired samples t-tests reveal significant improvement in number of adolescent-reported hosted (t=-5.22, p<.001) and invited (t=-2.50, p<.05) get-togethers from pre- to post-treatment. Results also reveal significant improvement in parent-reported social responsiveness (t=7.84, p<.001) over the course of treatment. Multiple linear regression was used to assess baseline ADHD, social anxiety, and depression symptoms as potential predictors of treatment outcome. Change in social responsiveness was not related to baseline ADHD-inattentive, ADHD-hyperactive/impulsive, depression, or social anxiety scores (p>.10; R^2=.009). These baseline scores were also not predictive of change in hosted get-togethers (p>.10; R^2=.005). ADHD-inattentive, social anxiety, and depression baseline scores were not predictive of change in invited get-togethers (p>.10), but ADHD-hyperactive/impulsive baseline scores predicted less improvement at a trend-level significance (p<.10; R^2=.075).
Conclusions:
Findings reveal that baseline ADHD, depression, and social anxiety symptoms are not predictive of improvement in social responsiveness or frequency of social engagement following the PEERS® intervention. However, a trend level significance was found for ADHD-hyperactive/impulsive youth, who presented with slightly less social reciprocity through invited get-togethers from peers.

262 **181.262** How Perceived Financial Strain Impacts Autism Support Teachers

M. Seidman[1], *D. R. Adams*[2], *R. Ouellette*[3] *and G. Azad*[4], *(1)Center for Mental Health Policy and Services Research, University of Pennsylvania, Philadelphia, PA, (2)School of Social Service Administration, University of Chicago, Chicago, IL, (3)Florida International University, Miami, FL, (4)University of Pennsylvania, Hamilton, NJ*

Background:
School-age children with autism receive most of their intervention in schools. In under-resourced, urban school districts, teachers tasked with providing students with evidence-based practices often receive low salaries. These low salaries may lead to turnover (Miller et al. 1999) and financial strain (Prawitz et al. 2006)—when one is unable meet his/her financial responsibilities. Previous research suggests that financial strainÂ increases intentions to quit one's job (Adams et al. 2016), reduces commitment to employers and increases absenteeism (Kim & Garman, 2003), worsens physical health (O'Neill et al., 2006), and increases depression (Starkey et al. 2013). To date, no research has examined whether financial strain increases teacher turnover or use of evidence-based practices, a finding that would have important policy implications.
Objectives:
To examine whether teachers' perceived financial strain is associated with turnover, their intentions to implement EBPs for students with autism, and the quality and frequency of EBP implementation.
Methods:
The sample included 52 kindergarten-through-second-grade autism support teachers employed in one urban school district. All participants were enrolled in a multi-year randomized, controlled trial; data for this study was collected as a part of the larger trial. All teachers received training in five EBPs for children with autism: discrete trial training, pivotal response training, data collection, positive reinforcement, and visual schedules. Teachers completed the InCharge Financial Distress/Well-Being Scale, a 10-item questionnaire designed to measure a person's perceived financial strain. Items ranged on a scale of 0 = No financial distressÂ to 10 = overwhelming financial distress. An example itemÂ is "How often do you worry about being able to meet normal monthly living expenses?" The Intent to Implement measure is a 114-item questionnaire measuring teachers' intentions to implement EBPs for students with autism. Several scales, ranging from 1 to 7 were used. An example item is "Think about you …running discrete trial training with most students, at least 3 days a week, for the next 3 months. For me to do this would be…" Teachers' quality and frequency of usage for each EBP was measured through monthly teacher self-report and bimonthly observations. Turnover was defined as teachers leaving their position. The school district provided information about turnover at the start of the following school year.
Results:
Data collection is complete and analyses are underway. Linear regression models will be used to estimate the extent to which teachers' perceived financial strain is associated with their intended and actual use of EBPs. Logistic regression will be used to answer the extent to which teachers' perceived financial strain is related to their turnover.
Conclusions:
The results will lead to a better understanding of how teachers' perceived financial strain impacts their intentions to implement EBPs, fidelity to the EBPs, and sustainment of EBPs in urban public schools. Given the pressing need for EBPs in school settings, this study will provide insight into barriers affecting EBP implementation in resource-limited schools.

263 **181.263** Tailoring Eye Tracking to Specific Targets of Pivotal Response Treatment (PRT): Preliminary Results from Novel Eye-Tracking Tasks in Children with and without ASD

C. Foster[1]*, F. Shic*[2]*, Q. Wang*[3]*, C. A. Wall*[4]*, E. Barney*[5]*, Y. A. Ahn*[2]*, B. Li*[2]*, L. Booth*[1]*, M. C. Lyons*[6]*, C. Paisley*[6]*, S. M. Abdullahi*[1]*, M. L. Braconnier*[1]*, J. Lei*[1]*, M. Kim*[2]*, C. Kautz*[1] *and P. E. Ventola*[1]*, (1)Yale Child Study Center, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's, Seattle, WA, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (4)University of South Carolina, Columbia, SC, (5)Child Study Center, Yale University, New Haven, CT, (6)Yale University, New Haven, CT*

Background: Eye tracking has been used for almost 15 years in autism research but has only recently begun to advance as a viable method for monitoring clinical treatment(Dawson et al, 2010). In an ongoing study, we aim to track change in response to evidence-based behavioral treatment, PRT, through eye tracking. Here we report preliminary results from novel paradigms developed to measure specific PRT intervention targets, including a Dyadic Bid task(DB) examining sensitivity to overtures for engagement, a Conversation Following task(CF) examining conversational engagement, a Social Referencing task(SR) examining monitoring of nonverbal information, and a Theory of Mind task(ToM) examining perspective-taking.
Objectives: To explore baseline between-group differences in children with and without ASD in performance on four novel eye-tracking paradigms tailored specifically to assess change following PRT.
Methods: Participants included thirty-six 4 to 8 year-olds, ASD *n*=14 (11 males, M_{DQ}=88.4 sd=19.8) and non-ASD *n*=22(13 males; M_{DQ}=108.9 sd=12.4). A joint DB and CF task included clips of actors engaging in naturalistic conversation. During each clip, an actor turned to the camera and performed a bid for the participant's attention (question or statement) then paused as though waiting for a response. DB main outcome measure was proportion of time looking at the bid actor's face(*BidActor%*), and for CF, the proportion of time looking at the speaking actor(*Speaker%*). SR included clips of an actor performing an increasingly stressful task(e.g. inflating a balloon until it pops). SR outcome measure was proportion of time looking at the actor's face(*Face%*) and activity(*Activity%*) during the event escalation and resolution. ToM included a hide-and-seek false belief task. ToM outcome measure was proportion of time looking in the hiding place associated with the protagonist's false belief(*FalseBelief%)* and where the target object was actually hidden(*TrueLocation%)*. Univariate ANCOVAs controlling for DAS-II GCA Standard Score were conducted to examine main effects of diagnosis(dx).
Results: *DB:* There was a significant main effect of dx on *BidActor%* during the pause following bids($F(1,36)=6.3$, $p<.05$, $\eta_p^2=.16$), and during bids that were statements($F(1,36)=4.9$, $p<.05$, $\eta_p^2=.129$), with the ASD group looking less. *CF:* There was a significant main effect on *Speaker%*($F(1,36)=4.96$, $p<.05$, $\eta_p^2=.13$) with the ASD group looking less at the speakers. *SR:* There was a significant main effect on *Face%* during the event's resolution($F(1,36)=4.3$, $p<.05$, $\eta_p^2=.115$), and a trend toward a main effect on *Activity%* during the escalation($F(1,36)=3.6$, $p=.066$, $\eta_p^2=.098$) with the ASD group looking less at face and activity. *TOM:* There was a trend toward a main effect on *TrueLocation%*($F(1,36)=3.3$, $p=.078$, $\eta_p^2=.094$) with ASD looking more at the true location. There was no main effect on *FalseBelief%*.
Conclusions: Preliminary between-group differences provide initial validity for these novel eye-tracking paradigms. Children with ASD appear to be less sensitive to overtures for social engagement, particularly during more socially-nuanced bids. They also exhibit decreased monitoring of speakers' faces during conversation, and less referencing of another's face following the culmination of a stressful event. Results from ToM may reflect a deficit in perspective-taking within the ASD group. Further study is needed to assess the ability of these paradigms to measure within-subject change in response to PRT.

264 **181.264** Teaching Adults with Autism Spectrum Disorder Responses to Non-Verbal Pragmatic Behavior

S. J. Cohen[1]*, R. L. Koegel*[2] *and L. K. Koegel*[2]*, (1)University of Hawaii at Manoa, Goleta, CA, (2)Koegel Autism Center, University of California, Santa Barbara, Santa Barbara, CA*

Background: One common challenge discussed in the literature for individuals with autism spectrum disorder (ASD) is in area of recognizing and responding to non-verbal pragmatic cues during social interactions. The use of intervention strategies such as self-management and the incorporation of visual prompts have been empirically supported as effective strategies for improving an array of social skills for adults with ASD.
Objectives: The purpose of the present study was to use self-management and question-asking intervention strategies and to assess the efficacy of the intervention with respect to teaching adults with ASD to recognize and respond appropriately to specific pragmatic behaviors, with the goal of enhancing their social interactions.
Methods: A multiple baseline across participants design was used to assess the efficacy of an intervention for adults who demonstrated a lack of responding to their communicative partners' nonverbal pragmatic behaviors. Participants were taught to ask specific, relevant questions in response to their conversation partner's nonverbal expressions of boredom and confusion. The intervention included clinician modeling of the expression, creation of a question bank for each expression, and practice with self-management for responding to each pragmatic expression. Conversations were video recorded during baseline, intervention, and follow up sessions, and responses to each pragmatic cue was coded as appropriate or inappropriate, yielding a percent of appropriate responses for each pragmatic expression in each session.
Results: Participants showed substantial gains in responding appropriately to targeted pragmatic behaviors during social conversation after beginning the intervention. Moreover, this skill generalized to novel conversation partners and maintained after terminating the intervention. Additionally, the Empathy Quotient (Baron-Cohen & Wheelwright, 2004) scores improved from pre- to post-intervention, lending support to the social validity of this intervention.
Conclusions: An intervention which utilizes modeling, question banks, and self-management can be effective in teaching recognition of, and appropriate responses to, pragmatic social cues for adults with ASD. Improved performance in this skill likely contributes to benefits in their social communication overall.

265 **181.265** Teaching Goal Attainment to Young Adults with Autism Using Self-Regulated Problem-Solving Strategy

G. Yakubova[1]*, A. Zehner*[2] *and M. Aladsani*[2]*, (1)University of Maryland, College Park, MD, (2)Duquesne University, Pittsburgh, PA*

Background: Research examining interventions to teach skills that lead to self-determination to people with autism spectrum disorder (ASD) is rare. Self-determination has been found as one of the predictors of successful adult life. Given poor adult outcomes and scarcity of research on interventions for young adults with ASD (Newman et al., 2011; Shattuck et al., 2012), examining ways of supporting youth with ASD and teaching skills that lead to self-determination is one important step to contributing to improved adult outcomes. One such strategy, self-determined career development model (SDCDM) focuses on teaching students to set goals, make plans for improvement, and evaluate/adjust goals through self-regulated problem-solving process. This session will present the findings of the study examining the effects of SDCDM on goal attainment of a young adult with autism. The presentation will provide attendees with the strategies for teaching youth with ASD self-regulated problem-solving process to set goals, make action plans, and evaluate and adjust goals based on progress.
Objectives: The purpose of this study was to determine the effects of SDCDM on goal attainment of a young adult with autism when working towards career-related goals. Research questions were: (1) To what extent does a young adult with ASD improve performance toward self-selected career-related goals using SDCDM? (2) To what extent does a young adult with ASD maintain performance toward self-selected career-related goals following the use of SDCDM?
Methods: A multiple probe across three goals design of single-case experimental methodology was used to determine the effectiveness of the intervention on goal attainment and skill maintenance of a young adult with ASD. Using phase one of SDCDM, the participant generated three goals he wanted to work on during the project. Once goals were selected, the participant worked through phase two of the model to come up with student-directed strategies for each goal. Young adult participated in a minimum of five baseline sessions per goal, 8-10 intervention sessions, and three follow-up sessions. Data were analyzed using the recommended approaches for single-case experimental data: visual analysis analyzing for trend, level, variability, magnitude of effect and effect size calculation to determine the existence and magnitude of a causal relationship between an intervention and target skills (Kratochwill et al., 2013).
Results: Results supported the effectiveness of SDCDM in teaching a young adult with ASD to problem solve to set career-related goals, make action plans, and evaluate progress towards self-selected goals. The young adult showed immediate improvement in goal attainment from baseline to intervention phase and maintained performance with 100% accuracy. The young adult's supervisor in a community setting and behavior specialist also noted the participant's progress and held positive perceptions toward the use of self-regulated instructional strategies.
Conclusions: The findings add to scarce research in teaching young adults with ASD using self-regulated problem-solving process and student-directed instructional strategies. As an applied research study conducted in the field, findings demonstrate how professionals can design and implement self-regulated instructional strategies to support skill acquisition and learning of young adults with ASD.

266 **181.266** The Benefits of Using a Telehealth Service Delivery Model to Improve Communication Skills in Children with Autism Spectrum Disorder.

M. V. Andrianopoulos *and C. Gargan, Communication Disorders, University of Massachusetts Amherst, Amherst, MA*

Background:
Computerized technologies, video modeling, and robots, are reported to be reinforcing for many children with Autism. The use of computer-assisted instruction and videoconferencing platforms (i.e., telepractice) have become very popular to deliver a variety of services to individuals with autism. A systematic review of the literature during the 1994 - 2016 period regarding the use of telepractice to improve or enhance communication skills in individuals with autism and/or to train families to facilitate language development in young children with autism, revealed that only 3 studies among the total of 53 specifically investigated the effects of delivering Speech Language Pathology (SLP) intervention services to children with autism. Published research over the past 22 years supports positive outcomes of using telepractice to improve early identification of autism, parent/guardian training for early intervention, and applied behavioral therapy services for children and individuals with autism.
Objectives:
1) To empirically investigate student outcomes using a telepractice platform compared to on-site services to deliver speech and language intervention to students with autism between the ages of 9 to 12 years; and 2) To empirically study the effectiveness and satisfaction of using telepractice as a service delivery method among 3 cohorts of participants: a) the 7 children with autism receiving speech language services; b) 9 pre-professional masters SLP graduate clinicians enrolled in a specialty training program in autism, and c) 3 SLP supervisors.
Methods:
An alternating ABA single case time-series research design (Kazdin, 2011) was utilized. Participants included 7 middle school-aged students on the autism spectrum between the ages of 9 to 12 years. Individual and group comparisons were conducted to evaluate student outcomes (Dependent variables) when SLP services were delivered using telepractice vs. on-site vs. telepractice (Independent variables) (TeleTx vs. On-site vs. TeleTx). The 7 students with autism, 9 pre-professional SLP graduate students, and 3 SLP supervisors completed satisfactions surveys at the end of the three service phases.
An equal number of intervention services for the 7 students were delivered in 3 six-week phases: TeleTx-Onsite-TeleTx. The 9 formally trained SLP graduate clinicians delivered the services using stimuli and activities created using the Smart Notebook (Smart Technologies) software applications for each student's intervention program targeting students' treatment goals and objectives. The clinician-student dyads remained constant, as did the computer technologies and software used for intervention
Results:
Comparable outcomes and no significant differences were observed in student performance when SLP services were delivered using telepractice compared to on-site face-to-face. Significant individual and group differences were observed in the number of prompts and reinforcers during intervention when services were delivered via telepractice. Students with autism required a greater number of prompts and reinforcers during speech language therapy when delivered on-site compared to telepractice. A five-point satisfaction survey ranging from 1 (strongly disagree) -5 (strongly agree), yielded a median score of 4 for 7 students with autism; 4 for 9 SLP graduate students; and 4 for SLP supervisors.
Conclusions:
Speech and language intervention outcomes were comparable when services were delivered to students with autism using telepractice vs. on-site.

267 **181.267** The Effects of Mindfulness Practice on Psychological Wellbeing in Mothers of Children with ASD: A PILOT Study

N. Miodrag[1]*, I. Weiner*[2]*, J. Rivas*[3]*, S. Stembridge*[4]*, E. Weible*[5] *and D. Boyns*[6,7]*, (1)California State University, Northridge, Northridge, CA, (2)Special Education, California State University Northridge, Northridge, CA, (3)Child and Adolescent Development, California State University Northridge, Northridge, CA, (4)California State University Northridge, Northridge, CA, (5)Family Focus Resource Center, California State University Northridge, Northridge, CA, (6)Sociology, California State University Northridge, Northridge, CA, (7)Institute for Community Health and Wellbeing, Northridge, CA*

Background: Mothers of children with ASD report high levels of psychological stress, significantly lower sense of self-efficacy about parenting their child with ASD, and higher levels of stress and depressive symptoms compared to mothers of children who are typically developing. Others have found lower levels of life satisfaction, social support, and self-esteem compared to controls. Aspects of the child's diagnosis, lack of service delivery, and daily challenges in care can negatively impact wellbeing. Practicing mindfulness has been shown to reduce stress among vulnerable populations, but such interventions have only recently been examined among mothers of children with ASD. A meta-analysis of mindfulness studies found that of 18,756 studies on mindfulness practice, only a small number fit the standards of scientific rigor because of the absence of either control or comparison groups, or both. This study contributes to the research on mindfulness as a means to increase maternal wellbeing and fill the gap in the literature by incorporating a comparison and control group.
Objectives: This study examines the effectiveness of mindfulness practice on self-esteem, self-efficacy, psychological wellbeing, parenting stress, and life satisfaction among mothers of children with ASD. We also set out to examine group differences across mothers participating in three groups: (1) a mindfulness practice intervention, (2) a discussion-based intervention, and (3) no-intervention controls.
Methods: Twenty-seven mothers were assigned to groups: mindfulness (*n* = 11), discussion-based (*n* = 6), or control (*n* = 10). Mothers in the mindfulness and discussion-based groups attended 8 weekly sessions for 90 minutes. Mindfulness intervention focused on breath counting, seated meditation, body scans, and loving-kindness practice. The discussion-based group served as a comparison for the mindfulness group, focusing on discussions about parenting children with ASD. Controls received no intervention during the 8-week period. All participants completed the following pre- and post-intervention measures: Rosenberg self-esteem scale, Generalized Self-Efficacy scale, Ryff Scales of Psychological Well-being, Parental Stress scale, and Satisfaction with Life scale. In addition, individuals in the mindfulness and support groups participated in focus group interviews after the 8-week intervention.
Results: Z scores were computed for pre-posttest comparisons. The results suggest significant differences from pre- to post-intervention for the mindfulness group on perceived: satisfaction with life, self-esteem, self-efficacy, psychological wellbeing and subscales of autonomy, environmental mastery, personal growth, positive relations, and purpose in life. There were no significant results for the discussion-based and control groups (with the exception of the purpose in life subscale for controls). No significant results were found for parental stress. Results from qualitative focus groups provide support for the pre-post test comparisons. These results suggest that while the subjective experience of parenting stress was not significantly affected by the intervention, participants in the mindfulness group developed considerable acceptance of their life circumstances, as well as practical tools to cope with the uncertainties of stressful parenting.
Conclusions: Findings support the utility of mindfulness practice for increasing aspects of psychological wellbeing. Perceptions of parental stress did not decrease. Mothers of children with ASD can benefit from low cost, non-medical, and readily accessible mindfulness programs.

268 **181.268** The Impact of Self-Regulation Skills on Academic Outcomes in Minimally-Verbal School-Age Children with Autism

H. J. Nuske[1]*, C. Kane*[1]*, K. Rump*[1]*, M. Pellecchia*[1]*, B. Maddox*[2]*, E. Reisinger Blanch*[1] *and D. S. Mandell*[1]*, (1)University of Pennsylvania, Philadelphia, PA, (2)Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Self-regulation skills predict positive long-term academic and social outcomes in typically developing children. Children with autism often have difficulties in the area of self-regulation, particularly children with autism who are minimally verbal.
Objectives: Our primary aim was to examine whether self-regulation skills at baseline moderate academic outcomes in minimally-verbal children with autism compared with children with autism with typical expressive vocabulary.
Methods: Out of 137 children with autism who participated in school-intervention trial, 10 (7%) met minimally-verbal (MV) criteria (DiStefano et al., 2016, *Autism Research*; < 20 words) and 43 (31%) met typical expressive vocabulary criteria (TEV; t score 40-60 on Differential Abilities Scales (DAS) Picture Naming sub-test). The MV and TEV groups were rated on the frequency of their self-regulation difficulties by researchers after a standardised observation and their academic abilities (DAS standard score) were measured at the start and end of the school year (T1 and T2, respectively).
Results: Â As expected, the MV group had more frequent difficulties in self-regulation than the TEV group at the start of the school year (see Figure 1). Contrary to expectations, after controlling for DAS T1 scores, the only significant predictor of DAS T2 scores was self-regulation difficulties at T1, *b*Â = 5.24,Â *t*(48) = 2.44,Â *p*= .02, with more frequent self-regulation difficulties predicting *greater* academic gains. To understand this further, we examined within group correlations between self-regulation difficulties at T1 and DAS changes scores (DAS T2 – DAS T1). Results showed that the above prediction was driven by the TEV group (*r*(41) = .42,Â *p*Â < .01; see Figure 2) rather than the MV group (*r*(8) = .39,Â *p*Â < .27).
Conclusions: Â Results suggest an unusual relationship between self-regulation difficulties and academic outcomes in children with autism with typical expressive vocabulary, which may be indicative of the impact of self regulation difficulties on the accuracy of academic test scores for children at the beginning of the school year. These preliminary results will be followed up in an additional sample of over 400 children with ASD.

269 **181.269** The Job-Train Program: A Community-University Employment Preparation Initiative for Youth with ASD

B. M. Di Rezze[1]*, I. O'Connor*[2]*, R. Brennan*[3]*, S. Honeyman*[4]*, A. Difazio*[5]*, T. Bennett*[6]*, G. Hall*[1] *and S. Georgiades*[1]*, (1)McMaster University, Hamilton, ON, CANADA, (2)McMaster Universtiy-Offord Centre, Dundas, ON, CANADA, (3)Woodview Mental Health and Autism Services, Burlington, ON, CANADA, (4)Hamilton-Wentworth District School Board, Hamilton, ON, CANADA, (5)Hamilton Wentworth District School Board, Hamilton, ON, Canada, (6)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA*

Background: Â Evidence shows that the unemployment rate in adults with ASD is estimated at 75-90%. We also know that earlier job experiences predict better employment outcomes. Secondary school co-op programs aim to provide early job experience; however, challenges exist in providing successful co-op experiences and integrating acquired skills across contexts (home, school, and community). A unique employment program (Job-Train Program; JTP) was developed from a partnership between a Canadian university, a community agency, and a local school board. The JTP is a 14-week program that includes: (1) weekly coach-facilitated group sessions providing an individualized curriculum and support; (2) paid 9-week summer job placement within the university.
Objectives: Â To implement a "Proof-of-Concept" project for the Job Training Program in a sample of secondary school students with ASD.
Methods: This mixed-methods study used a pre-post design to examine the program outcomes in 12 secondary school students with ASD, and gather insights from parents, job coaches and employers within the JTP. Quantitative data for outcome evaluation were analyzed using either parametric or non-parametric analyses, depending on whether data followed a normal distribution. Primary measures included the Canadian Occupational Performance Measure (COPM; youth completed) and the Child Behavior Checklist (CBCL; parent report). Qualitative data were also collected from youth, parents, job coaches and employers regarding their perspectives on the JTP. Qualitative data were analyzed using content analyses of the transcripts from audio-recorded focus groups and individual interviews.
Results:
The sample consisted of 12 youth with ASD (83% males; mean age 17 years). JTP job placements involved the following university departments: housing and conference services, health sciences library, faculty services, and several health science academic departments and research centres.
The total issues identified by youth in the COPM (self-care, work and leisure) ranged from 1-7. Based on the Wilcoxon Signed Ranks test, pre- and post-JTP COPM weighted mean ratings for performance and satisfaction were z= -2.67, p=.008 and z=-2.60, p=0.009, respectively. For the CBCL, there were no significant differences for paired t-tests of pre-post scores for both internalizing and externalizing behaviours, t(8)=.583,p=.576 and t(8)=.629, p=547, respectively.
Qualitative data from parents revealed the following themes:
(1) Perceived benefits of JTP - "fitting in with peers," "improved self-perception," and "motivation for more responsibility at home and in the community."
(2) Â Valuable attributes of JTP – "relevant curriculum," "independence skill opportunities supported outside JTP," and "importance of 'real' and 'paid' work."
(3) Future JTP considerations – "job placements outside of university," and "increase length of work day as placement progressed," "include parent education for support/advocacy."
Conclusions: This study successfully implemented a job training program with the essential elements of individualized supports and programming, weekly coached group sessions and strong community partnerships (agency, school board and university). This study provides useful preliminary results that, despite a small sample size, suggest improvement in issues related to employment skills and independence. Results of this "Proof-of-Concept" study will guide the refinement of the JTP protocol and future work on involving a large-scale study examining its utility and effectiveness in youth with ASD.

270 **181.270** The Labour Market Experience of Women with High Autistic Traits

S. M. Hayward[1]*, M. A. Stokes*[2] *and K. R. McVilly*[1]*, (1)The University of Melbourne, Melbourne, Australia, (2)School of Psychology, Deakin University, Melbourne, Australia*

Background:
Unemployment and underemployment are asserted as issues adversely affecting the economic, health, and social circumstances of women, and in particular individuals with High Autistic Traits (HATs; including those with Asperger's or high functioning Autism). However, little research has been published regarding the labour market experiences of women with HATs.
Objectives:
To compare the labour market experiences of women with HATs to women with low autistic traits (LATs) and men with HATs.
Methods:
An anonymous online survey targeting women with Autism was conducted. Qualitative data was analysed using thematic analysis with an inductive process. Subsequent categories, as well as quantitative data, was analysed using chi square.
Results:
Ninety-nine women aged 18 to 62 years responded to the questionnaire: 69 with HATs aged 18 to 60 years (M=35.51, SD=10.08), and 30 with LATs aged 19 to 62 years (M=38.10, SD=10.09). Also, 53 men aged 20 to 68 years responded: 31 with HATs aged 20 to 68 years (M=44.50, SD=12.76), and 22 with LATs aged 23 to 61 years (M=38.64, SD=8.99).
It was found that women with HATs, compared to women with LATs, reported greater instances of negative employment histories ($\chi^2_{(1)}$=16.40, p<.001, ϕ=.41) and frequent and/or being "stuck" in underemployment situations ($\chi^2_{(1)}$=8.66, p=.003, ϕ=.40). Further, among both women and men, compared to those with LATs, those with HATs were more likely to report difficulties maintaining employment (women, $\chi^2_{(1)}$=4.82, p=.028, ϕ=.22; men, $\chi^2_{(1)}$=7.94, p=.005, ϕ=.39) and were less likely to describe their employment history as stable (women, $\chi^2_{(1)}$=9.40, p=.002, ϕ=.31; men; $\chi^2_{(1)}$=14.35, p<.001, ϕ=.52).
Notably, there was a significant difference between women with HATs compared to men with HATs regarding entry into the labour market. In addition, men with HATs reported barriers that were not significant for their female counterparts.
Conclusions:
Both autistic traits and sex may influence labour market prospects and workplace experiences. Therefore, support for adults with HATs, including the provision of reasonable adjustment in the workplace, need to take into account both an individual's level of autistic traits and their sex.

271 **181.271** The Mediating Role of Teaching Quality and Student Engagement Between Teacher Mental Health and Learning Outcomes of Students with ASD.

W. H. Wong[1]*, L. A. Ruble*[1]*, Y. Yu*[2] *and J. H. McGrew*[3]*, (1)University of Kentucky, Lexington, KY, (2)Indiana University - Purdue University Indianapolis, Indianapolis, IN, (3)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background:
Children with autism spectrum disorder (ASD) are entitled to free and appropriate education in public schools. Teachers play a critical role in delivering educational support for students with ASD on a daily basis. However, teachers of students with ASD report more stress and burnout compared to teachers of students with other disabilities (Kokkinos & Davazoglou, 2009). Despite the attention to burnout and stress, the actual influence of teacher burnout and stress on the learning outcome of students with ASD remains unclear.
Objectives:
(1) To understand the effects of burnout and stress on teaching quality, student engagement, and individual educational program (IEP) outcomes of students with ASD.
(2) To understand the mediating roles of teaching quality and student engagement between teacher burnout and stress and IEP outcomes of students with ASD.
Methods:
Seventy-nine dyads consisting of a special education teacher and one student with ASD selected randomly from each teacher's caseload were recruited. Teachers' levels of stress and burnout, including emotional exhaustion (EE), depersonalization (DP), and personal accomplishment (PA), teaching quality, and student engagement were collected using standardized measures at the beginning of the school year. The students' progress on the IEP goals were tracked throughout the school year using Psychometric Equivalence Tested Goal Attainment Scaling (PET-GAS; Ruble et al., 2013).
Results:
Effects of burnout and stress on teaching quality and student engagement. Multivariate regressions showed that teacher stress was the only significant predictor of both decreased teaching quality (*b* = -.07, *t*(54) = -3.08, *p* = .003; *F*(4, 54) = 3.41, *p* = .015) and of decreased student engagement (*b*Â = -.03,Â *t*(66) = -2.82 ,Â *p*Â = .031, *F*(4,66)= 2.21, *p* = .078).
IEP outcomes. PA was the only significant predictor (*b*Â = .06,Â *t*(60) = 2.90,Â *p*Â =.005) of student IEP outcomes, *F*(1,60) = 6.70, *p* < .001.
The mediating role of teaching quality and student engagement. Despite having no direct influence, entered in parallel, stress, EE, and DP influenced IEP outcomes either through student engagement alone or through student engagement and teaching quality (indirect effect = -.001—-.05, *SE* = -.22 - .001, 95% *CI* = -.21—-.0001). PA had only a direct influence on student IEP outcomes (see Figure 1).
Conclusions:
One of the three burnout subscales (PA) was negatively and directly related to achievement of long-term IEP outcomes for students with ASD. In contrast, stress, EE, and DP, had indirect effects on student IEP outcomes either through student engagement alone or through teaching quality and student engagement together. The results not only document a direct impact of teacher burnout and stress on student learning outcomes, but also provide preliminary documentation of potential mediating mechanisms between burnout and stress and student learning outcomes. The results suggest that stress management and mental health should be addressed in pre-service and in-service training, and in evidence-based programs for students with ASD in school.

272 **181.272** The Quality of High School Programs for Students with ASD from 3 States

L. J. Hall[1]*, B. Kraemer*[2]*, S. L. Odom*[3] *and L. E. Smith*[4]*, (1)Special Education, San Diego State University, San Diego, CA, (2)San Diego State University, Carlsbad, CA, (3)University of North Carolina, Chapel Hill, NC, (4)Waisman Center-University of Wisconsin, Madison, WI*

Background:
According to the National Autism Indicators Report the outcomes for young adults with autism spectrum disorders (ASD) are grim (Roux, Shattuck, Rast, Rava, & Anderson, 2015), and information about the quality of preparation from high school and transition programs serving the increasing number of adolescents and young adults with ASD is scare.
Objectives:
What is the overall quality of high school programs for students with ASD?
What are the areas of strength and weakness in the quality of high school programs in the US for students with ASD?
Do ratings on of the quality of the transition plans on a checklist differ between plans written for students with ASD who will receive a diploma compared with those who participate in an alternative program during high school?
Methods:
Program quality was measured using the Autism Program Environmental Rating Scale (APERS) in 60 high schools participating in a RCT in 3 states (North Carolina, Wisconsin, & California) as part of the Center on Secondary Education for Students with Autism Spectrum Disorders (CSESA). Prior to intervention, the APERS was completed in each school. The APERS-HS is a 66-item, five-point rating scale, with a score of 1 (lowest) to 5 (highest). The APERS ratings are calculated into a total score and 11 sub-domain scores and 1 composite rating for Transition (consisting of items in different domains). The APERS process involves 6 to 8 hours of observation, interviews with administrators, parents, and school personnel, and a record review of the student's IEP and transition plan. The APERS was completed and scored separately for programs where students will receive a diploma and those who follow an alternative or modified curriculum. Inter-rater agreement between two observers/raters using Cronbach's Alpha was .94 for the diploma programs and .95 for the alternative programs. The quality of the transition plans of select students in both diploma and alternative programs will be rated using a modified checklist developed by the state of Maryland.
Results:
The overall ratings for the programs were in the moderate/mediocre range (3.17 for diploma and 3.25 for modified). The results by domain were similar for both diploma and alternative programs with the learning environment, climate, and family involvement scoring above 3.0 and were relative strengths of the programs. Ratings of instructional approaches that focused on areas that tend to be the most needed by students with ASD (social, communication, independence, functional behavior) were uniformly below 3.0. Transition composite scores, also below 3.0, were somewhat higher in the modified classes (2.7) as compared to the diploma (2.35). Future analysis of the ratings from the transition plan checklist will provide information about possible factors that contribute to these overall low Transition scores and differences by program type.
Conclusions:
Overall schools had a medium level of quality. The program strengths were ecological features and family involvement. The lowest ratings of quality were for instructional and intervention practices. Transition practices were quite low overall, with lower ratings occurring in diploma programs.

273 **181.273** The Use of Positive Reframing to Reduce Negative Statements in Adolescents with ASD

J. Hai[1]*, L. K. Koegel*[2] *and R. L. Koegel*[2]*, (1)Education, UC Santa Barbara, Santa Barbara, CA, (2)Koegel Autism Center, University of California, Santa Barbara, Santa Barbara, CA*

Background: Individuals with Autism Spectrum Disorder (ASD) often experience impaired social communication skills. With these difficulties, social isolation can occur which may lead to comorbid disorders such as depression and anxiety (Shtayermman, 2006; Ryden & Bejerot, 2008). New research shows that children with ASD are also susceptible to comorbid disorders such as depression and anxiety (Strang, J., F., Kenworthy, L., Daniolos, P., Case, L., Wills, M., C., Martin, A., & Wallace, G., L., 2012). Not many early interventions are targeting these comorbid disorders at this age (Simonoff, E., Pickles, A., Charman, T., Chandler, S., Loucas, T., Baird, G., 2008). Parents and educators report strained friendships with peers, name calling or bullying. These increased levels of negative affect and commenting may create difficulties in social conversation and establishing meaningful relationships. Positive reframing is the ability to perceive something previously viewed as negative in a positive light (Lambert, Fincham, & Stillman, 2012). It is empirically validated as a beneficial treatment for a range of psychological conditions, including; Depression (Lambert, 2010), Anxiety disorders (Goldin et al., 2012), Depression/anxiety in parents of children with ASD (Benson, 2010). This intervention aims at using positive reframing to increase social communication skill levels for adolescents with ASD.
Objectives: To use positive reframing to effectively decrease the use of negative statements while reframing into neutral or positive statements during social conversations for adolescents with ASD. A second objective included if collateral improvements would be gained in affect/interest during social conversation.
Methods: Participants included three adolescents, ages 9, 11, and 14, diagnosed with ASD. Participant selection criteria included making excessive negative comments to their conversational partner during at least 20% of intervals in 10-minute conversational probes. A multiple baseline design was used along with partial interval recording. Behavioral measures that were coded and analyzed included; negative/positive/neutral statements and affect. For intervention, a combination treatment package was implemented. This included defining reframing, video feedback monitoring and self-management of reframing. Participants were required to reach 80% fidelity before continuing onto each step.
Results: Findings indicated that it is possible to each adolescent with ASD to effectively decrease the use of negative statements while reframing during social conversations with peers. Participant 1 decreased average negative statements from 25% to 2%, participant 2 decreased average negative statements from 24% to 4% and participant 3 decreased average negative statements from 22% to 5%. All three participants saw gains of positive or neutral statements around 15% of conversation, likely to typical range. Results also found that the use of positive reframing raises child affect along with collateral effects where peers have higher affect during social conversation.
Conclusions: Â Implications of this intervention show that the use of positive reframing can improve social interactions and develop meaningful friendship and romantic relationships. Positive reframing may also be useful for adolescent's future in accessing and maintaining employment as well as targeting decreasing symptoms of depression and anxiety. These are applicable techniques that can be used by parents, teachers, and clinicians across a variety of social conversations and settings.

274 **181.274** Therapy Satisfaction As a Predictor of Parent Improvement Following Cognitive Behavioral Therapy for Children with Autism Spectrum Disorder

A. L. Maughan[1]*, V. Chan (Ting)*[2] *and J. A. Weiss*[1]*, (1)York University, Toronto, ON, CANADA, (2)York University, Thornhill, ON, CANADA*

Background: Parents of children with autism spectrum disorder (ASD) can experience significant stress, anxiety and depression (Estes et al., 2009). There is evidence that parent involvement in child-focused therapy may indirectly improve parent functioning (Silverman et al., 2009), but little research to elucidate factors contributing to this change. For family CBT programs, aspects of the therapy experience, such as parent engagement, have been shown to be associated with improved child outcomes (Podell & Kendall, 2010), and for adult participants in therapy, program satisfaction is also related to symptom reduction (Atkisson & Zwick, 1982). As such, it may be useful to examine the therapy experience when investigating predictors of change for parents.
Objectives: Â The current study aimed to test whether post-intervention changes in parent mental health were predicted by program experience ratings, controlling for parents' pre-intervention scores.
Methods: Â Participants included 52 parents (82.7% mothers*; M* age=43.5, *SD*=4.2) of children with ASD participating in a randomized controlled trial of CBT, targeting child emotion regulation. To assess mental health, parents completed the self-report *Depression Anxiety and Stress Scale*(DASS-21, Lovibond & Lovibond, 1995) at baseline and immediately following intervention. To assess therapy experiences, parents completed post-intervention surveys that asked about a) their level of confidence supporting their child, b) perception of child change due to intervention involvement, c) satisfaction with therapist, d) mean satisfaction with pragmatic aspects of the program (location, session length, dates/times program was offered), and e) their child's enjoyment of the program. Responses were provided on a scale from 0 (not at all satisfied) to 5 (very satisfied). To test whether therapy experiences predicted change in parent functioning, a series of multiple regressions were calculated to predict post-intervention DASS scores, each entering the pre-intervention DASS score and one of the therapy experience measures as predictors.
Results: Post-intervention, there were significant improvements in parents' reported depression ($t(49)=2.23$, $p=.03$), and there was a trend toward improvement in total DASS ($t(49)=1.74$, $p=.09$). After controlling for pre-intervention total DASS scores, parent confidence emerged as a significant predictor, explaining 10% of the variance in post-intervention total DASS scores ($t(41)=-2.22$, $p=.03$). There was also a trend toward parent ratings of program pragmatics being a predictor of post-intervention DASS total scores ($\Delta R^2=.10$, $t(41)=-2.00$, $p=.06$). Additional trends emerged when examining post-intervention depression, with program pragmatics ($\Delta R^2=.14$, $t(41)=-1.94$, $p=.06$), and parent perception of child change ($\Delta R^2=.16$, $t(41)=-1.96$, $p=.06$) predicting post-intervention depression scores.
Conclusions: Â Improvements in overall parent mental health and depression following participation in a family-based CBT program were related to their perceptions of therapy. Though correlational, results support the hypothesis that parents' experience of their child's treatment may impact how they benefit from an intervention (Osbourne et al., 2008). The results of the current study provide further support for this model and will be discussed with regard to implications for intervention development and evaluation.

275 **181.275** Training School-Based Consultants to Conduct Data-Based Functional Assessments

V. L. Rodrigues*, J. Staubitz, L. A. Weaver and P. Juárez, Vanderbilt University Medical Center, Nashville, TN*

Background:
For students with autism spectrum disorders (ASD), untreated school-based behavior challenges can reduce a student's access to the least restrictive environment, limiting a student's learning and social opportunities. Functional behavioral assessment (FBA) is an evidence-based practice in which information is systematically gathered to determine the underlying function or purpose of a behavior to inform behavior intervention programming (Wong, et. al., 2014). Even when practitioners understand the importance of function-based interventions for challenging behaviors, their skill and confidence deficits may prevent them from incorporating valid data within the FBAs they are required to develop and implement.
Objectives:
Based on the work of Bassingthwaite, Casey, Wacker and colleagues, the current study was designed as a small-scale replication in which 8 school-based consultants were provided with behavioral skills training on two direct assessment techniques, preference assessments and descriptive behavior assessments, to improve the quality of their FBAs for students. The primary study objective was to measure the impact of behavioral skills training on trainees' knowledge of the FBA process, procedural fidelity and confidence in completing both preference assessments and descriptive behavior assessments, and utilization of data for improving the effectiveness of behavior interventions.
Methods:
Behavioral skills training using a combination of live and telepresence support was conducted across two consecutive years to teach trainees how to plan, conduct, and analyze preference assessments and descriptive behavior assessments and to synthesize assessment results into a valid and complete FBA. Trainees were administrated a questionnaire to assess their knowledge, confidence, and utilization of data to inform student FBAs. Direct observation data were gathered on trainees' procedural fidelity for the assessments conducted.
Results:
Data from the first year of training on preference assessment reflected marked improvements in trainee knowledge and confidence in their skills, along with increased procedural fidelity. Average trainee scores on the preference assessment knowledge exam improved by 53.2 percentage points at follow-up. Average self-rating scores for preference assessments improved by 83.3 percentage points from pre-workshop to follow-up and average procedural fidelity scores increased 9.5 percentage points approximately two months after the initial training day. Initial data from the second year of training on descriptive behavior assessments indicate that average trainees' exam scores on FBA and descriptive assessments improved by 9 percent from pre-workshop to post remote-training. Post training data will be included in the presentation, upon completion of the training on descriptive behavior assessments.
Conclusions:
Given that many educators are tasked with completing FBAs, but often lack the specialized training to effectively do so, this study has many practical implications. Training in this area may result in increased efficiency of the assessment process and the ability to conduct data-based FBAs by district personnel rather than the often expensive and lengthy process of utilizing outside consultants. Ultimately, the goal from this research is to increase the effectiveness of behavior intervention plans utilized for students with ASD that are developed as a result of these assessments.

276 **181.276** Understanding Intolerance of Uncertainty for Autistic Adults: Development of the Adult Coping with Uncertainty in Everyday Situations© Programme

J. Rodgers[1], *R. Herrema*[2], *E. Honey*[3,4] *and M. Freeston*[5], *(1)Newcastle University, Newcastle University, Newcastle, United Kingdom, (2)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, UNITED KINGDOM, (3)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, UNITED KINGDOM, (4)Doctorate in Clinical Psychology, Newcastle University, Newcastle Upon Tyne, United Kingdom, (5)Psychology, Newcastle University, Newcastle, United Kingdom*

Background: Â Anxiety is a common co-occurring condition in adults with ASD. Difficulty tolerating uncertainty is a major contributor to the development and maintenance of anxiety. Our work indicates that Intolerance of Uncertainty (IU) is a key construct in anxiety in ASD that might contribute to the development and maintenance of a range of anxiety subtypes. We recently developed a parent based group intervention (CUES: Coping with Uncertainty in Everyday Situations), aimed at providing parents of young people with ASD with effective strategies to reduce their child's IU. Our development project demonstrated that the intervention was acceptable and feasible to families. No such programme exists to address IU in autistic adults. The aim of this study was initially to understand the experience of uncertainty on a day-to-day basis and identify suitable outcome measures so that we can then adapt and evaluate our intervention programme to make it suitable for use, on an individual basis with autistic adults experiencing IU.
Objectives: To develop and provide evidence of daily measurement of personally salient uncertain situations among autistic adults, in order to understand their experiences of IU and identify and capture suitable targets for treatment.
Methods: A multiple baseline observational single case design was used to identify and track personally salient uncertain situations with 4 autistic adults on a day-to-day basis, over a ten week period. Participants were aged over 18 years, with a diagnosis of ASD, with intellectual ability in the average range. Electronic daily diaries provided individualized self-monitoring of personally relevant symptoms, behaviours and engagement in target uncertain situations. Participants would then receive eight, one hour weekly IU treatment sessions with a qualified CBT therapist. Daily diaries are used throughout to provide individualized self-monitoring of personally relevant symptoms, target behaviours and engagement in target situations.
Results: All four adults identified a personally salient target uncertain situation that impacted on daily functioning. Situations identified included uncertainty related to social situations (x2), uncertainty related to work/professional demands (x2). Participants were able to actively engage in daily self-monitoring of their target uncertain situation and report on a range of symptoms and behaviours (negative affect, avoidance, confidence) associated with the situation. Stable baselines were achieved for all participants within two to three weeks of onset of self-monitoring; the daily diaries were then completed throughout the eight week intervention phase. Changes in self-monitoring of individualised target behaviours during the treatment phase will be reported.
Conclusions:
Our study is the first to explore the impact of intolerance of uncertainty on daily functioning for autistic adults. The single case observational design provides evidence that autistic adults are able to identify uncertain stations that have an impact on daily life. Furthermore, our data indicate that autistic adults find daily self -monitoring of the symptoms and behaviours associated with these situations to be feasible and acceptable. The results provide evidence of the feasibility of self-monitoring diaries as a method of capturing personally salient and meaningful data for use in intervention programmes targeting intolerance of uncertainty for autistic adults.

277 **181.277** Video Self-Modeling (VSM) As an Intervention for Adolescents with Autism Spectrum Disorders (ASD) in School and Clinical Settings

A. Merrill*, Indiana University, Columbus, OH*

Background: Â Video modeling refers to an individual viewing a video demonstrating a target behavior to learn to produce that same modeled behavior. Bandura' social learning theory suggests that new patterns of behavior can be learned through observation. In addition, this learning is strongest when the model is as similar as possible to the true behavior that one is attempting to change (Bandura, 1977). Video self-modeling (VSM) is a form of video modeling that enables the individual to perform the modeled behavior by watching him or herself perform the behavior effectively (Bellini & Peters, 2008). Bellini and Akullian's meta-analysis (2007) showed evidence that VSM is an effective intervention strategy for increasing positive social and communication, behavioral, and functional skills in children and adolescents with ASD. Further research suggests that VSM can generalize across multiple settings and that the learned skills throughout this process may be sustained for months after the intervention (Shukla-Mehta, Miller, & Callahan, 2010).
Objectives: Â Two research studies investigating VSM were completed. The objective of these studies was to determine the effectiveness of VSM in improving academic and conversational skills across school and clinical settings in adolescents with ASD. To the author's knowledge, these were the first studies to target these behaviors in adolescents with ASD.
Methods: Â A multiple baseline single-case design was used in both studies. VSM was implemented by recording videos, editing them, and showing them to the participants on iPads. Videos used were 1 to 3 minutes in length. Data collection was completed by more than one observer to determine inter-observer agreement. In Study 1, positive homework materials management behaviors were targeted in a general education classroom setting.Â In Study 2, conversational and pragmatic language skills were targeted in a clinical outpatient therapy setting.
Results: In Study 1, visual analysis and nonparametric effect size results suggested that the introduction of the VSM intervention was effective in improving compliance with classroom procedures related to homework in students with ASD and other neurodevelopmental and acquired disorders. Social validity data from the students and teachers involved in the project showed that the process was viewed as positive and realistic to implement in the classroom.
In Study 2, visual analysis and nonparametric effect size results suggested that the introduction of the VSM intervention in combination with social skills training was effective in improving conversational skills in 2 out of 3 adolescents with ASD. Social validity data from the parents and adolescents involved showed a positive response to the integration of VSM into the social skills training intervention.
Conclusions: Adolescents with ASD present educators and practitioners with several unique challenges. As social and academic environments becomes more multifaceted, the complexity of teaching individuals with ASD how best to navigate their world does as well. Ubiquitous access to iPad and other tablet technology suggests that video-based interventions are currently under-utilized. Clinicians and educators working with adolescents with a myriad of behavioral and academic challenges may consider ways in which a VSM intervention may be implemented into their practice.

278 **181.278** Who Benefits from Cognitive Training with Neurotracker?: Training Attention in Students with Autism Spectrum Disorder and Other Neurodevelopmental Disorders

D. Tullo[1]*, J. Faubert*[2] *and A. Bertone*[1]*, (1)McGill University, Montreal, QC, Canada, (2)Laboratoire de Psychophysique et de Perception Visuelle, Université de Montréal, Montréal, QC, Canada*

Background: Cognitive remediation involves targeting specific processes to reduce cognitive deficits, such as attention-related difficulties (Sonuga-Barke et al., 2014). For example, training attention is achieved by repeated practice on tasks that can best isolate attention (Willis & Schaie, 2009). A previous school-based study found that training with a multiple object tracking paradigm (*NeuroTracker*) improved performance on a separate, clinically validated measure of attention, for students diagnosed with a neurodevelopmental disorder (Tullo, Guy, Faubert, & Bertone, 2016). With Autism Spectrum Disorder (ASD), Attention Deficit Hyperactivity Disorder (ADHD), and Intellectual Disability exhibiting different profiles of attention (Antshel et al., 2013), an examination of which clinical profile benefits most from visuo-attentive *NeuroTracker* training can provide additional information to tailor cognitive remediation programs from a needs-based perspective.
Objectives: We assessed the efficacy of an attention training program using the *NeuroTracker* task, an adapted three-dimensional multiple object tracking paradigm found to be accessible to children and adolescents diagnosed with ASD or another neurodevelopmental disorder. Furthermore, we explored the effect of training to assess differences regarding improvements after *NeuroTracker* training for students diagnosed with ASD compared to those diagnosed with other neurodevelopmental disorders.
Methods: One hundred and twenty-nine students were included in the study (M_{age} = 13.24). All participants had a primary diagnosis of either ASD (n = 43), or any other neurodevelopmental disorder (n = 86; i.e., ADHD, Intellectual Disorder, genetic-based syndromes). A pre-assessment measure of attention was obtained for all participants via the Conners Continuous Performance Task (CPT-3) and then all participants were equally and randomly into; the experimental *NeuroTracker* training group (n = 43, n_{ASD} = 16), active control group (n = 43, n_{ASD} = 9) playing a strategy-math game: *2048*, or treatment as usual group (n = 43, n_{ASD} = 25). Both experimental and active control groups trained on their respective tasks every other day for a total of 15 training sessions. Post-training performance on the CPT-3 was compared to initial CPT-3 performance to detect an improvement in attention.
Results: Collectively, pre-assessment scores on the CPT-3 revealed that all students had deficits in attention. Results from the training results showed a significant difference in the change in CPT-3 that was specific to the experimental, *NeuroTracker* group. Training by diagnostic group revealed that *NeuroTracker* performance doubled from the first to the last (fifteenth) training session for both the ASD and non-ASD groups. Furthermore, there was no significant difference between change in CPT-3 scores after training with *NeuroTracker* between the ASD and non-ASD groups. This demonstrates that all participants in the experimental group benefitted equally from training with *NeuroTracker*, regardless of their clinical profile.
Conclusions: Our findings demonstrate that attention can be improved for students with ASD using the non-verbal, visuo-attentive *NeuroTracker* task. Furthermore, our findings demonstrate that training with *NeuroTracker* can benefit all students with problematic levels of attention, regardless of primary diagnosis. These results suggest that the *Neurotracker* training program is accessible and effective for children and adolescents with a neurodevelopmental condition that is independent of cognitive status and diagnostic profile.

279 **181.279** Worktopia: Perspectives of a Job Readiness Program for Individuals with Autism Spectrum Disorder

D. B. Nicholas[1]*, W. Mitchell*[2]*, M. Clarke*[3] *and C. Dudley*[4]*, (1)University of Calgary, Edmonton, AB, CANADA, (2)The Ability Hub, Calgary, AB, CANADA, (3)Sinneave Family Foundation, Calgary, AB, CANADA, (4)Sinneave Family Foundation, Calgary, AB, Canada*

Background: Employment opportunity for youth and adults living with Autism Spectrum Disorder (ASD) is unacceptably low. Without the opportunity to enter the work force individuals with ASD may be at greater risk for poverty and isolation. This issue calls for attention to developing capacity and improving opportunity for employment among persons with ASD. Worktopia is a new, nationally funded project in Canada designed to improve the employment futures of youth and young adults with ASD, ages 15 -29 as they transition from high school into independent living. Worktopia is an initiative that offers programs to enhance employment readiness at different ages and for varying levels of ability levels. Worktopia includes Employment Works Canada (EWC) and Community Works Canada (CWC). These programs are delivered by 13 different community agencies across 5 regions of Canada. These agencies are contracted to implement and evaluate these pre-employment training programs.
Objectives: To illuminate aspects of the EWC and CWC programs that promote work readiness; to identify program outcomes including benefits and barriers to participants and families.
Methods: Utilizing a grounded theory approach, qualitative interviews were conducted with a sample of participants with ASD and parents from both EWC and CWC programs across Canada. Findings from the interviews will be presented.
Results: Participants highlight the importance of continuity in relationships between support persons (e.g. program facilitators) and individuals with ASD. Key qualities of support included workers who built relational 'bridges', used humour, demonstrated respect, had previous experience with ASD, and were approachable. Parents also highlighted the importance of ongoing relational 'bridges'. Central teaching approaches embedded in adult learning principles such as structured learning, video modeling, and role play were found to enhance employment readiness. Challenges to program participation were transportation to the varied work sites and scheduling for persons with ASD in combination with their other life commitments (e.g. medical appointments). Successful outcomes included increased self-confidence, improved self-recognition, feeling part of the community and lowered fear of social interactions.
Conclusions: The experiences of participants and parents in the Worktopia employment program give direction for service providers and researches who are creating programs to enhance skills and increase work readiness for persons with ASD.

280 **181.280** "If You Make the Story Good Enough, It Becomes a Reward": Designing a Social Emotional Serious Game from the Perspectives of Youth on the Autism Spectrum and Professionals

J. Tang[1,2]*, M. Falkmer*[1,3,4]*, S. Bolte*[5,6] *and S. J. Girdler*[1,3]*, (1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Queensland, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (4)School of Education and Communication, CHILD programme, Institute of Disability Research, Jönköping University, Jönköping, Jönköping County, Sweden, (5)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (6)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Dept. Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: While computer-based interventions (CBI) have shown promise in improving emotion recognition skills among people on the Autism spectrum, currently there is a need to improve the engagement and generalisation of skills to everyday environments. The Serious Game framework proposes five core design elements which potentially address the limitations of current CBI. It is likely that projects guided by this framework and inclusive of end-users in the development phase will be both more effective and engaging.
Objectives: Employing the Serious Game framework, this study aimed to identify the motivating features of a computer game targeting emotion recognition skills from the perspectives of youth on the Autism spectrum and professionals.
Methods: Four focus groups, three with youth on the Autism spectrum (n=11) and one with professionals experienced in social skills interventions (n=5) were conducted. Data was coded using directed content analysis and framed within the elements of the Serious Game framework of motivating storyline, goal-directed learning, rewards and feedback, progression in level of difficulty and individuation, and provision of choice. The perspectives of the youth on the Autism spectrum were taken as the central focus and were compared and contrasted against those of the professionals.
Results: Â Both groups suggested several features under the five main elements of the serious Game framework. The participants on the Autism spectrum favoured including social dilemmas with a gaming environment that was unpredictable and varied. The youth appreciated that a game provided them with the opportunity to experiment with situations that were potentially complex and overwhelming in real life. The professionals emphasised aspects of the game that supported the transfer of skills to real life contexts.
Conclusions: The youth and professional held differing views, with participants on the Autism spectrum stressing the importance of incorporating 'motivating' features in a story-based game and the professionals focusing mainly on the generalisation of skills to every day contexts. In combination the views of the two groups addressed the two main aims of the Serious Game framework of creating an engaging learning environment and promoting the transfer of skills to real life contexts. The contrasting perspectives of the youth and professionals highlights the importance of involving end-users in developing CBI. To date, CBI have focused on improving skills paying less attention to strategies aimed at motivating and engaging players on the Autism spectrum. Findings from this research suggest that CBI which focus on enhancing these aspects will be likely to experience lower dropout rates than those observed in current effectiveness studies.

281 **181.281** Examining Socialization Improvement Growth Trends of Adolescents Participating in an RCT of the Social Tools and Rules for Teens (START) Program for ASD: A Multi-Level Modeling Study

T. Vernon*, J. Ko, A. Miller, A. Barrett and E. McGarry, University of California Santa Barbara, Santa Barbara, CA*

Background: The interest in effective interventions to target the social vulnerabilities of adolescents with ASD has significantly increased in recent years (Miller et al, 2015). Such intervention efforts are not administered in a single therapeutic dose, but rather are conceptualized as operating through a series of interactions that, over time, aim to build self-sustaining interpersonal capabilities and alter the social trajectory of participating individuals. In recent years, researchers have become increasingly focused on the accumulating effects of an intervention on the unfolding behaviors and skills of a treatment recipient over time (e.g. Lerner et al, 2011). Such knowledge is crucial for further developing promising interventions, as it informs the relationship between dosage, time, accumulating therapy exposure, and eventual outcome. When data is serially collected at multiple time points along the course of an intervention timeline, valuable information about social growth trajectories can be gathered and analyzed.
Objectives: This investigation evaluated the effectiveness of the Social Tools And Rules for Teens (START) intervention program for adolescents with ASD using (a) serial data collection and (b) multilevel modeling to thoroughly understand the intercept and slope of social improvement data.
Methods: The participants of the project were 35 adolescents with ASD. All participants were randomly assigned to (a) the START program group or (b) a waitlist group for 20 weeks. The START program is a motivation-based curriculum that combines experiential and didactic elements into a comprehensive intervention package that includes high school peer models, individualized and group social targets, and self-management of selected skills. Participants assigned to the START condition participated in a weekly two-hour session consisting of: individual check-in sessions, free socialization periods, social activities, videos, social topic discussion and practice, and checkout sessions with parents. Dependent measures included parent and adolescent survey measures (Social Skills Improvement System, Social Responsiveness Scale - 2, Social Competence & Motivation Scale) and regular social conversation probes collected repeatedly at 5-week intervals. Multilevel modeling was used to analyze social competence change both within and between individuals. Unconditional, time-only, and full HLM models were specified.
Results: In the full HLM model, Time alone produced a significant slope effect on the adolescent SSIS scores ($p < .05$) and parent SCMS scores ($p < 0.1$). Treatment Group (i.e. START program participation) created a significant slope effect on adolescent SSIS scores ($p < .05$), SRS scores ($p < .01$), and both parent ($p < .001$) and adolescent ($p < 0.5$) SCMS scores, providing evidence of significant therapeutic gains unique to START program participation.
Conclusions: The full HLM model provides strong evidence that START participants experience markedly improved social growth trends when compared to waitlist controls. Specifically, significant positive trends in social skill (SSIS) and social competence/motivation (SCMS) were noted, along with reductions in ASD-related social impairments (SRS-2). This investigation is one of the first social skills studies to use MLM techniques to model robust changes on multiple measures of social competence. Overall, this study presents promising findings regarding the efficacy of an experiential social intervention for adolescents with ASD.

282 **181.282** The Use of Recommended Practices for Children with ASD in Urban Preschools

A. S. Nahmias[1,2], *S. R. Crabbe*[2] *and D. S. Mandell*[2], *(1)University of California Los Angeles, Los Angeles, CA, (2)University of Pennsylvania, Philadelphia, PA*

Background: University-based treatment studies find substantial gains when intervention is provided to preschoolers with ASD, however children receiving intervention in the community on average make small gains. Evidence-based practices (EBPs) developed in university settings may not be available in community settings, or result in the same types of gains when delivered outside highly-controlled settings. Studying intervention as it is delivered as part of the public education system can provide important insights into which EBPs are in use in different types of preschool settings, and which recommended practices have the potential to be most effective, given the resources available.
Objectives:
To examine the use of recommended practices for children with ASD in different types of urban preschool settings and the association of EBP use with child outcomes.
Methods:
Participants are part of longitudinal observational study of community based interventions for preschoolers with ASD, data collection is ongoing. Implementation of EBPs for children with ASD were evaluated using the Educational Program Review (EPR) in three different school-based educational environments: ASD-only, Mixed disability, and Inclusion. For this measure, skill indicators of Teaming, Classroom Structure, Classroom Environment, Curriculum and Instruction, Social/Peer Relationships, Challenging Behaviors Management, and Building a Positive Instructional Climate are rated from "Minimal/No implementation" to "Full implementation" based on direct classroom observation and a teacher interview. Children's cognitive and language development were assessed 9 months apart (Mullen Scales of Early Learning; MSEL), and parents and teachers completed a questionnaire assessing adaptive behaviors (Adaptive Behavior Assessment System-2ndEd; ABAS). Multiple linear regression analyses controlling for child demographic characteristics were conducted to examine the association between EPR domain scores on developmental (MSEL) and adaptive behavior (ABAS) change scores.
Results:
Based on the preliminary results from 68 preschoolers (Mean age = 45.9 months, *SD* = 7.3, 77.9% Male, 45.6% Black/African American), the use of recommended practices significantly differed across ASD-only (n = 21), Mixed disability (n = 22), and Inclusion (n = 25) settings. ASD-only classrooms scored significantly better on teaming and classroom structure than the other types of classrooms, and on better classroom environment, curriculum, and challenging behaviors management than inclusion ($ps <$ .05). Inclusion classrooms provided better support of social/peer relationships ($ps < .001$). Mixed disability classrooms had better teaming and curriculum than inclusion ($ps <$ .01). The classroom types did not statistically significantly differ in their instructional climate.
In an adjusted analysis, better implementation of recommended practices for social/peer relationships was significantly associated with developmental gains ($b = 3.9$, $t(63) = 2.28$, $p = .03$). EBP use was not significantly associated with changes in adaptive behavior.
Conclusions:
These preliminary results suggest the programming available in ASD-only classroom settings is more closely aligned with recommended practices for preschoolers with ASD, than that available in less restrictive educational placements. However, implementation of EBPs related to supporting social/peer relationships (including opportunities to interact with typically developing peers), which was less available in ASD-only preschools, is an important predictor of developmental gains in urban preschools.

283 **181.283** Implementation Fidelity and Outcomes in School-Based Interventions

M. Pellecchia[1], *M. Seidman*[1], *C. Spaulding*[1], *M. Xie*[2] *and D. S. Mandell*[1], *(1)University of Pennsylvania, Philadelphia, PA, (2)University of Pennsylvania, Philadephia, PA*

Background: Most children with autism in the United States receive the bulk of their treatment through publicly-funded schools. However, most evidence-based practices (EBPs) for children with autism were developed and tested in highly controlled laboratory settings, with very high rates of intervention fidelity. Interventions delivered in the community often are delivered with much lower fidelity. While there is general consensus that intervention fidelity is associated with student outcome, there is little research examining this association in community settings.
Objectives: Using data from a large randomized field trial in an urban public school district of several EBPs for elementary school-age children with autism, we will: 1) evaluate teachers' mean and variation in treatment fidelity; 2) estimate the association between treatment fidelity and child outcomes; and 3) determine factors associated with treatment fidelity.
Methods: Direct observation fidelity measures were used to assess implementation fidelity to three EBPs (discrete trial training (DT), pivotal response training (PRT), and visual schedules (VS)) bi-monthly in 73 classrooms for an academic year (n = 73 teachers and 126 children). Implementation fidelity was measured along three dimensions: intensity (how often the teacher delivered the intervention), accuracy (whether the intervention was delivered as described in the manual), and a composite fidelity score that comprised the product of intensity and accuracy. Child outcome was measured as change in cognitive ability using the Differential Abilities Scales, 2nd edition (DAS-II) and overall performance on the Bracken Basic Concepts Scales. Differences in child outcome were estimated using linear regression models with random effects for classroom. Separate models were used where the independent variables of interest in turn included intervention intensity, accuracy, and the composite fidelity score. Qualitative interviews were conducted with a sample of the teachers to identify barriers and facilitators to treatment fidelity.
Results: Data are collected. Analyses are ongoing. Teachers' fidelity to all three EBPs on a scale ranging from 0-4 was low and varied substantially across teachers (DT accuracy- Mean: 2.3, SD: 1.3; PRT accuracy- Mean: 2.0, SD: 1.3; VS accuracy- Mean: 1.6, SD: 1.2). There was substantial variation in child outcomes for both the DAS (Mean change: 4.0, SD: 7.8) and the Bracken (Receptive Mean Change: 16.4, SD: 22.4; Expressive Mean Change: 11.5, SD: 10.2). The associations of fidelity to each of the intervention components and child outcome, as well as factors associated with treatment fidelity, are being estimated now.
Conclusions: Implementation fidelity to EBPs in public schools is significantly lower than that observed in university-based research settings, and varies substantially across teachers. Many challenges exist to implementing EBPs in public schools including limited resources, training and highly complicated interventions. Strategies to improve the implementation of EBPs in public schools are urgently needed in order to improve access to high quality care and will be discussed. Additionally, students demonstrated higher gains on a measure of overall academic performance than in cognitive ability; academic measures may offer a more sensitive alternative, especially for school-age children, to measures of cognitive ability traditionally used in autism treatment trials.

284 **181.284** Context Matters: A Mixed Methods Study of Organizational Factors That Affect Implementation of Interventions for Children with Autism in Public Schools

J. J. Locke[1], *R. S. Beidas*[2], *S. Marcus*[2], *A. C. Stahmer*[3], *G. A. Aarons*[4], *A. R. Lyon*[5], *C. Cannuscio*[2], *F. Barg*[2], *S. Dorsey*[5] *and D. S. Mandell*[2], *(1)University of Washington Autism Center, Seattle, WA, (2)University of Pennsylvania, Philadelphia, PA, (3)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (4)Psychiatry, University of California, San Diego, La Jolla, CA, (5)University of Washington, Seattle, WA*

Background: The significant lifelong impairments associated with autism spectrum disorder (ASD), combined with the growing number of children diagnosed with ASD, have created urgency in improving school-based quality of care. Although many interventions have shown efficacy in university-based research, few have been effectively implemented and sustained in schools, the primary setting in which children with ASD receive services. Organizational factors such as culture and climate have been shown to predict the implementation of evidence-based interventions (EBIs) for the prevention and treatment of other mental disorders in schools, and may be potential targets to improve implementation of autism EBIs in schools.
Objectives: The purpose of this study was to examine the organizational factors associated with the implementation of EBIs (i.e., discrete trial training, pivotal response training, and visual schedules) for children with ASD in public schools.
Methods: We applied the Domitrovich and colleagues (2008) framework of organizational and other contextual factors (e.g., leadership, implementation climate) that influence intervention implementation in schools. We quantitatively tested whether these factors (organizational culture and climate) were associated with the implementation of autism EBIs. Participants included 37 principals, 50 teachers and 75 classroom staff from 37 under-resourced public schools. We used qualitative methods (semi-structured interviews) to more comprehensively understand the strategies used to achieve successful implementation and sustainment of these interventions (26 principals and 28 teachers from the highest- and lowest-performing classrooms based on their fidelity data). Qualitative data will be analyzed using an integrated approach to conduct a detailed exploration of the intervention-setting fit, and observe similarities and differences in organizational-level factors among high and low performing classrooms. Independent observers rated implementation fidelity (i.e., adherence, dose, and competence) using a fidelity checklist. Participants completed ratings of organizational culture (behavioral expectations that members of an organization are required to meet in their work environment) and climate (individual employees' perceptions of the psychological impact of their work environment on their own function and well-being) using the Organizational Social Context measure.
Results: Data cleaning and coding are underway. Preliminary descriptive analyses indicate that the organizational culture and organizational climate were within average norms. A linear regression with random effects for classroom and school (to account for classrooms nested within schools) will be conducted to estimate individual associations between each organizational-level factor (i.e., organizational culture and climate) and key components of intervention fidelity (adherence, dose, and competence).
Conclusions: The results of this study will provide an in-depth understanding of organizational-level factors that influence the successful implementation of EBIs for children with ASD in under resourced public schools. These data will inform potential implementation targets and tailoring of strategies that will help schools overcome barriers to implementation and ultimately improve the services and outcomes for children with ASD.

285 **181.285** Statewide Interagency Collaboration to Increase Access to Professional Training in Evidence-Based Practice

J. Suhrheinrich[1], *M. Dean*[2], *P. Schetter*[3], *P. Yasuda*[4] *and A. Aspen*[5], *(1)University of California, San Diego, La Jolla, CA, (2)California State University, Channel Islands, Camarillo, CA, (3)UC Davis, Sacramento, CA, (4)Children's Hospital Los Angeles, Los Angeles, CA, (5)Diagnostic Center Central, Fresno, CA*

Background:
Most programs have very limited capacity for scaling up interventions in ways that lead to meaningful improvements in outcomes for individuals with ASD, and collaboration across service systems presents even greater challenges.
The California Autism Professional Training and Information Network (CAPTAIN) is a statewide collaboration of providers from Special Education Local Plan Areas, Regional Centers and Family Resource Centers with the common goal of providing training and technical assistance in evidence-based practices (EBPs) for ASD. CAPTAIN was established in 2012 and currently has over 400 members who were nominated to participate by their employing agency. Members are expected to provide training in EBPs for ASD to providers within their home agency.
A leadership team of cross agency representatives guides the training and support efforts of the organization, including coordinating an annual 2-day training summit for members, maintaining a website and providing a 10hr on-line course on ASD.
Objectives:
The current project will characterize CAPTAIN participation statewide during the 2015/2016 fiscal year and will describe training practices used by CAPTAIN members and identified barriers to training in EBPs for ASD.
Methods:
Administrative data were analyzed to determine agency engagement in CAPTAIN. A 56 item survey was distributed to CAPTAIN cadre members to gather descriptive data on training practices and barriers to implementation of training in EBPs for ASD.
Results:
Three hundred seventy-one CAPTAIN cadre members participated. Member nomination and CAPTAIN endorsement across state agencies was high with 87% of SELPAS, 90% of Regional Centers and 100% of Family Resource Centers participating. Within the group, the majority of cadre members were representing SELPAs (n=303; 82%), then Regional Centers (n=53; 14%) and Family Resource Centers (n=15; 4%).
Preliminary analysis of survey data indicates successful outcomes in terms of the frequency of training offered by cadre members, with 86% of SELPA cadre members conducting some training on EBPs for ASD. Approximately 20% of cadre members reported doing some type of training in EBP (group or 1:1) on a weekly basis, 32% conducted training at least monthly. Of those conducting training, 84% indicated they used live demonstrations, role playing and practice. Seventy percent of cadre members reporting using a fidelity checklist when coaching trainees. Additionally, 75% report collecting data on student outcomes to ensure the EBP is having the desired effect.
Adequate time for training and coaching was identified as a primary barrier to implementation of training in EBP by a majority of cadre members (56%); however other primary barriers were identified by lower percentages of cadre members, including administrative support (6.9%), trainee/staff support (13.8%), knowledge (3.2%), policy (.5%), -organizational issues/turnover (7.4%).
Conclusions:
These data indicate preliminary success for CAPTAIN and the inter-agency collaboration process of disseminating information about EBP for ASD statewide. However, data also indicate variability in the amount of training and types of training provided state-wide. Data collected on barriers and facilitators of implementation of EBP training indicate time as a primary barrier to providing training. Additional analyses are on-going and will be discussed.

Poster Session
182 - Miscellaneous
12:00 PM - 1:40 PM - Golden Gate Ballroom

286 **182.286** Memory in Autism: A Case of Remembering Versus Knowing

S. V. Huemer[1]*, F. Kruggel*[2]*, V. Mann*[2] *and J. Gehricke*[3]*, (1)University of CA - Irvine, Rancho Palos Verdes, CA, (2)University of California Irvine, Irvine, CA, (3)University of California, Irvine, Santa Ana, CA*

Background:
Tulving (1983) divides human memory into two distinct systems that are open to conscious awareness: The semantic system stores timeless facts available mostly upon cued recall recognition, while the episodic system relies on an individual's ability to put stored memories into a spatio-temporal and self-referential context upon free recall (Tulving, 2002). The Remember/Know (R/K) procedure (Tulving, 1985) is used in recognition tasks to study both memory systems. Zelazo and Frye (2001) have shown that children with ASD have problems with episodic remembering. Episodic recognition involving the recollection of contextual information (R) is mediated by hippocampal processes while familiarity based recognition (K), which is intact in ASD, is mediated by perirhinal processes (Brown & Aggleton, 2001).Â Morphological abnormalities of the hippocampus are well documented in ASD (Groen et al., 2010; seeÂ Nicolson et al., 2006).
Objectives:
Our study was interested in finding out how adolescents with ASD process their own first name as opposed to other names. We planned to compare their results to those of neurotypical peers. We predicted that control subjects would activate areas of self-reference and episodic memory, such as the left tempo-parietal cortex, the superior temporal gyrus, and the hippocampus when hearing their own name. Subjects with ASD, on the other hand, were expected to employ compensatory processes including the perirhinal regions when hearing their own name.
Methods:
In this preliminary functional magnetic resonance imaging (fMRI) investigation, we compared brain activity of 9 adolescents with ASD with those of 9 neurotypical adolescents to four categories of auditory language stimuli: their own first name (SFN), familiar people's names (OFN), names of objects of high interest (OBJ), and numbers (NUM). Each participant listened passively to the randomly sequenced names during three sessions. Each session contained the subject's name five times and five different names from each of the other categories. We also administered a test of verbal receptive ability to test whether our results may align with scores on the test.
Results:
When hearing their own names, controls and subjects with ASD who scored high on the verbal ability test activated regions in the insula, superior temporal gyrus as well as the hippocampus, brain regions associated with self-referential processing and long term memory, or, R (remembering). In contrast, subject with ASD who scored low on our test of receptive verbal ability lower-scoring subjects showed activity in the prefrontal cortex and the thalamus, regions associated with new learning and K (knowing).
Conclusions:
Our findings support prior research on episodic memory processing differences in ASD. They also suggest that ASD subjects with lower verbal ability recognize, or, "know" their own name like a newly acquired fact rather than "remember" their name in a self-referential and spatio-temporal context. We also found that the results of controls and ASD subjects with higher verbal ability were more like each other than the results of the higher and the lower scoring ASD groups, which indicates that memory function in ASD aligns with verbal ability. Future studies have to explore these findings with larger samples.

Oral Session - 11A
183 - Mental and Physical Health in Adulthood
1:15 PM - 2:05 PM - Yerba Buena 3-6

Session Moderator: Laura Klinger, *UNC TEACCH Autism Program, Chapel Hill, NC*

1:15 **183.001** Autism and Depression in Young Adulthood: Cohort Studies in Sweden and England

D. Rai[1,2], *I. Culpin*[1], *R. M. Pearson*[1], *C. Dalman*[3], *H. Heuvelman*[1], *M. Lundberg*[3], *P. Carpenter*[2], *J. Golding*[1] *and C. Magnusson*[3], *(1)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (2)BASS Autism Services for Adults, Avon & Wiltshire Partnership NHS Trust, Bristol, United Kingdom, (3)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden*

Background: Depression is considered one of the most common comorbidities in autism, but longitudinal studies following children through early adulthood are scarce. Genetic links between autism and depression have been suggested, but environmental factors such as bullying may be important modifiable intermediaries, but have not been adequately investigated.
Objectives: 1) To use two large population based cohorts with complementary strengths to assess the association between childhood autism spectrum disorders and autistic traits and adult depression. 2) To assess the risk of depression in non autistic siblings. 3) To assess whether bullying in adolescence mediates the relationship between autistic traits and adult depression.
Methods: In the Stockholm Youth Cohort, we assessed the risk of a depression diagnosis in young adulthood (age 18 to 27 years) in children with autism as compared to the general population, and their non autistic siblings. In the Avon Longitudinal Study of Parents and Children (ALSPAC), we studied the trajectory of depressive symptoms (measured by the Moods and Feelings Questionnaire), and relative risks for depression at age 18 years (measured by the Clinical Interview Schedule-Revised) in relation to four dichotomised autistic trait measures known to optimally predict an autism diagnosis in ALSPAC: the Children's Communication Checklist (coherence subscale), the Social and Communication Disorders Checklist, a repetitive behaviour measure, and the Emotionality, Activity and Sociability scale (sociability subscale). We used structural equation models to estimate the mediating effect of bullying in adolescence in the association between autistic traits and depression at age 18 years.
Results: A diagnosis of autism was strongly associated with a diagnosis of depression in young adulthood [adjusted RR 3.7 (95% CI 3.5-3.9)] in the Stockholm Youth Cohort. Individuals with autism were over two fold more likely to have a diagnosis of depression in young adulthood when directly compared to their non autistic siblings [adjusted OR 2.6 (1.9-3.5)], who were themselves at a higher risk of depression than the general population. In ALSPAC, children with all trait measures of autism had higher rates of depressive symptoms at age 10, but the social communication trait had the strongest association with a depression diagnosis at age 18 (adjusted RR 1.56 (1.02 to 2.40), p=0.041]. Bullying in adolescence accounted for 42% of the total estimated association between low social cognition and depression at age18 years in ALSPAC.
Conclusions: Taken together, the findings suggest that children with autism are at a higher risk of depression in young adulthood than the general population, and that social communication impairments may be the key autistic feature in relation to adult depression. Despite the potential role of a genetic predisposition to depression, the substantial role of bullying as a potentially mediating mechanism suggests that this may be a target for intervention and preventative action against depression in young people with autism.

1:27 **183.002** Increased Risk for Self-Harm in Autism: Preliminary Findings from the Stockholm Youth Cohort

I. Bubak[1], *D. Rai*[2], *S. Idring Nordstrom*[3], *M. Lundberg*[4], *I. Culpin*[2], *C. Dalman*[4] *and C. Magnusson*[4], *(1)Department of Public Health, Stockholm County Council and Karolinska Institutet, Stockholm, Sweden, (2)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (3)Department of Public Health Sciences, Stockholm, SWEDEN, (4)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden*

Background:
Recent evidence suggests that mortality from suicide is increased in autism spectrum disorder (ASD), and particularly in ASD without intellectual disability (ID). Self-harm i.e. self-poisoning or self-injury irrespective of suicidal intent, is the strongest known predictor for subsequent suicide. Self-harm is, however, poorly studied in ASD including whether there are patterns in self-harm methods of prognostic relevance for suicide. In addition, little is known about how co-morbid conditions such as ID and Attention Deficit Hyperactivity Disorder (ADHD) affect risk of self-harm.
Objectives:
To determine the relationship between ASD and self-harm in a large total population study. To investigate risk and protective factors for self-harm in ASD, with emphasis on co-morbid ID and ADHD.
Methods:
We conducted a total population study using the Stockholm Youth Cohort (N=696,612). Prospectively recorded data for probands followed-up from 0 to a maximum of 27 years by 2011, and their first and second-degree relatives, was collected through record linkage. A total of 11,663 individuals with ASD were identified. Hospital admissions with discharge diagnoses ICD-10 X60-X84 and Y10-Y34 denoted self-harm. We used multivariable Cox proportional hazards regression models to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) of self-harm, overall and categorized as self-harm by poisoning, self-cutting and severe self-harm (including hanging, strangulation, firearm, drowning, jumping from high place/in front of moving objects).
Results:
A diagnosis of ASD was strongly associated with risk of hospital admission for any self-harm
(adjusted HR 4.5, 95% CI 3.8-5.4), self-poisoning (aHR 4.6, 95% CI 3.7-5.6), self-cutting (aHR 5.6 95% CI 3.8-8.3)
and severe self-harm (aHR 5.7, 95% CI 2.5-13.0). This risk increase was even further marked for ASD with co-morbid ADHD for any self-harm (aHR 8.5, 95% CI 7.0-10.3), self-poisoning (aHR 7.6 95% CI 6.2-9.2), self-cutting (aHR 9.6 95%CI 6.6-13.9) and severe self-harm (aHR 16.1 95% CI 8.6-30.4). In contrast, ASD with ID was not associated with hospital presentations for self-harm.
Conclusions:
These preliminary findings indicate that individuals with ASD have an elevated risk for engaging in self-harm in adolescence and young adulthood, and particularly in severe self-harm. Co-occurring ADHD appears to aggravate this risk, which suggests that identification and treatment of ADHD in ASD may be important for suicide prevention. Co-occurring ID, on the other hand, appears protective. Overall, patients with ASD should be considered a risk group for self-injurious behavior and should be given special attention in clinical settings.

1:39 **183.003** The Relationship Between Mental Health, Employment and Quality of Life: Findings from the Autism Spectrum Cohort-UK

A. Petrou[1], *H. McConachie*[2], *A. Le Couteur*[2], *B. Ingham*[3], *J. Hamilton*[3], *T. Berney*[1], *D. Mason*[2], *D. Garland*[4] *and J. Parr*[1], *(1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, (4)National Autistic Society, Newcastle upon Tyne, United Kingdom*

Background:
Autism is a lifelong neurodevelopmental condition usually diagnosed during child or adulthood, and rarely during older age. Most autism research has been undertaken with children and young people. Much less is known about the course of autism through the many transitions across the lifespan. There is a lack of evidence about effective interventions and little research knowledge regarding the impact of ageing for autistic adults. Very little research has been undertaken to investigate the mental health and personal needs of adults on the autism spectrum.
Objectives:
To examine the prevalence of mental health/neurological conditions of autistic adults, their association with employment status and whether this is mediated by quality of life.
Methods:
Participants are autistic adults, and relatives/carers acting as 'consultees' for adults lacking capacity to consent for themselves to research participation who are part of the Autism Spectrum Cohort–UK (ASC-UK), a longitudinal research project aiming to investigate the life experiences of adults on the autism spectrum. Autistic adults were recruited through health teams, voluntary sector organisations, and the autism community. They completed questions on any current mental/neurological health diagnoses, and employment status. By July 2016, 576 adults had consented to join ASC-UK (males=319, females=245, other gender=12; range=17-86 years; mean age=39.6 years). This included participants across the following age bands: 16-25 years=123, 26-40 years=192, 41-60 years=217, 61+ years=44. 367 autistic adults also completed the World Health Organisation Quality of Life–BREF (QoL).
Results:
Autistic adults reported high current rates of diagnosed depression (46.9%), anxiety (49.7%) and other mental health conditions. 71.9% reported that they had previously tried to access services, of whom 40.6% reported receiving the necessary services. Reasons for not accessing services included a lack of availability or referral routes into services.Â Having a mental health/neurological condition negatively predicted physical, psychological, social, and environmental QoL (β=-.194 to -.274; all p<.001) whereas being employed positively predicted physical QoL only (β=.118, p<.001). Autistic adults aged 41-60 years were more likely to report mental health/neurological diagnoses if they were unemployed compared to employed (Mann-Whitney U=2350.5, z=-4.2, p<.001). In this age group, employment status was related to mental health/neurological conditions (β=1.612, p<.01), and employment status was related to physical QoL (β=.320, p<.001). Physical QoL acted as a mediator between employment status and mental health/neurological conditions (β=-.414, p<.001) such that the relationship between employment status and mental/neurological health conditions was no longer significant (β=.921, p=.151).
Conclusions:
Mental health/neurological conditions are common in autistic adults who, despite trying to access services, have difficulty getting the services that they need. For autistic adults between 41-60 years of age, satisfaction with physical QoL issues such as access to health services, may mediate the relationship between employment status and mental health/neurological conditions. Since autistic adults do not have increased rates of accessing mental health services compared to the general population (Adult Psychiatric Morbidity Survey 2016), increased availability of mental health interventions may be helpful to prevent individuals dropping out of employment in their 40s and 50s.

1:51 **183.004** Health Outcomes of Adults with ASD

W. S. McKinney[1], *M. R. Klinger*[2], *P. S. Powell*[3] *and L. G. Klinger*[2], *(1)Northwestern University, Evanston, IL, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)School of Psychology, Georgia Institute of Technology, Atlanta, GA*

Background: Little research has focused on the health outcomes of adults with ASD. The research that has been done has had either very high or very low rates of comorbid intellectual disabilities, as well as an oversampling of young adults (Croen et al., 2015; Fortuna et al., 2016). Additionally, because of the chart review design of these studies, the age, stability, and method of diagnosis was often unknown.
Objectives: The aim of this study was to characterize the health status of adults diagnosed with an ASD as children by providing descriptive data on prevalence rates for a wide variety of health conditions, as well as to compare these rates to nationwide norms for age-matched participants from the 2015 National Health Interview Survey (National Center for Health Statistics, 2015).
Methods: Caregivers of adults with ASD (N = 268; 213 males, 55 females) completed a survey on the adult's health status. The survey requested diagnostic information on 38 conditions. Adults with ASD (21-50 years; M = 34.99) were diagnosed during childhood between 1970 and 1999 through the UNC TEACCH Autism Program. Health prevalence rates were compared to an age-matched normative sample (N = 16,168; 21-50 years; M = 35.59).
Results: Adults with ASD reported significantly fewer cases of arthritis (ASD: 4%; US: 10%; p =.002), lower back pain (ASD: 4%; US: 27%; p < .001), migraines (ASD: 9%; US: 18%; p < .001), ulcers (ASD: 2%; US: 4%; p <.04), and cancer (ASD: 0.7%; US: 2.5%; p = .05) than the comparison sample. Additionally, adults with ASD reported significantly more cases of high cholesterol (ASD: 22%; US: 14%; p < .001), diabetes (ASD: 6%; US: 4%; p =.02), inflammatory bowel disease (ASD: 3%; US: 1%; p < .001), heart disease (ASD: 2%; US: 0.8%; p = .05), and epilepsy (ASD: 24%; US: 2%; p < .001). Comparable rates of obesity (ASD: 28%; US: 32%; p = .07), hypertension (ASD: 13%; US: 16%; p = .08), heart attacks (ASD: 0.4%; US: 0.5%; p = .50), and asthma (ASD: 10%; US: 13%; p = .11) were observed, although several results trended towards significance.
Conclusions: Similar to research by Croen et al. (2015), this study found significantly higher rates of many diagnoses including high cholesterol, diabetes, heart disease, inflammatory bowel disease, and epilepsy. Additionally, results found that diagnoses principally dependent on client self-report of pain experience (arthritis, lower back pain, migraines, and ulcers) occurred at significantly lower rates than in the normative sample. The unique social communication deficits present in ASD may prevent the proper reporting of pain experience leading to these lower rates of diagnosis. Future work should explore alternative ways of assessing pain for adults with ASD to examine whether adults with ASD genuinely experience fewer pain disorders or are underdiagnosed for these disorders. Additionally, more attention needs to be given to the increased cardiovascular and gastroenterology health risks seen in adults with ASD in order to further document this risk, investigate the source of risk, and develop treatments.

Oral Session - 11B
184 - ASD and Sexuality
2:10 PM - 3:00 PM - Yerba Buena 3-6

Session Moderator: Laura Klinger, *UNC TEACCH Autism Program, Chapel Hill, NC*

2:10 **184.001** Sexuality in ASD: The Female Profile

L. A. Pecora[1,2], *G. Hancock*[3], *G. Mesibov*[4] *and M. A. Stokes*[5], *(1)Deakin University, Parkdale, Australia, (2)School of Psychology, Deakin University, Burwood, Australia, (3)Deakin University, Werribee, Australia, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)School of Psychology, Deakin University, Melbourne, Australia*

Background: Current understandings of sexual development and sexuality of females with High-Functioning Autism (HFA) are limited, and drawn only from few clinical anecdotes and qualitative case reports. Recent systematic reviews and meta-analyses suggest that females with HFA report poorer overall levels of sexual functioning and experience more sex-related problems and harassment than males with HFA and TD counterparts.
Objectives: The objective of this study was to quantitatively investigate sex differences in sexual development and sexuality in males and females with HFA, in order to confirm qualitative accounts that suggest poorer sexual and romantic functioning for females in this group.
Methods:
Participants consisted of 232 individuals with HFA (97 males; 134 Females; 1 unreported [*M* = 25 years]) and 227 non-clinical controls (66 males; 161 females [*M* = 27 years]). Demographic information, self-reported levels of personal wellbeing, and sexual and romantic functioning were assessed using the SBS-III a 236-item online questionnaire that measures a range of social, sexual and romantic domains across 14 subscales.
Results:
While controlling for age, analyses confirmed the hypotheses that females with HFA would report poorer levels of overall sexual and romantic functioning and adverse sexual experiences across a range of sexuality domains than males with HFA.
Males with HFA reported overall greater engagement in a range of sexual behaviours, and thus a greater level of sexual experiences than females with HFA $F(1, 209)=11.41$, $p<.001$, $=.05$. Females however, were found to be more subject to a range of negative and adverse sexual experiences than males with HFA, where they reported greater instances of being victims of unwanted sexual advances $F(1, 209)=25.84$, $p<.001$, $=.01$, and engagement in sexual behaviours with others that they either did not want to $F(1, 209)=15.95$, $p<.001$, $=.07$, or regretted doing so following the event $F(1, 209)=14.53$, $p<.001$, $=.07$.
While there were no significant differences in the level of engagement in sexual behaviours between females with HFA and TD females, females that met diagnosis reported less interest in sex and sexual behaviours $F(1, 283)=7.20$ $p<.01$, $=.03$, fewer reported experiences of any form of sexual attraction to another person $F(1, 283)=6.46$, $p<.05$, $=.02$, and greater instances of bullying or victimisation due to having less sexual knowledge and experiences than other same aged peers than TD females $F(1, 283)=8.82$, $p<.001$, $=.03$.
Analyses revealed that males with HFA reported greater instances of both casual romantic experiences (dating, courting) $F(1, 220)=6.05$, $p<.05$, $=.03$; and being previously or currently involved in a romantic relationship $F(1, 220)=8.26$, $p<.01$, $=.04$.
Conclusions:
The data confirm existing qualitative case reports that suggest females with HFA are subject to a range of adverse experiences in their pursuit of a healthy sexual development and sexual life. While results are preliminary, they warrant the importance of further investigation in order to identify the sex-specific challenges and concerns that are unique to females on the spectrum, and urgency in developing targeted sex education programs and services that meet the needs of this diagnostic group.

2:22 **184.002** Romantic Relationship Experience in Autism Spectrum Disorder

G. Hancock[1], *L. A. Pecora*[2], *G. Mesibov*[3] *and* ***M. A. Stokes***[4], *(1)Deakin University, Werribee, Australia, (2)Deakin University, Parkdale, Australia, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)School of Psychology, Deakin University, Melbourne, Australia*

Background:
Socio-sexual functioning encompasses an individual's interests, behaviours, and understandings with respect to sexual, romantic, and social aspects of life. Previous systematic review and meta-analyses revealed differences in these areas, between typically developing (TD) individuals and individuals with ASD. It was further suggested that an individual's understanding of these domains is developed through both experiences and sex education. However, empirical evidence for the effect of ASD on romantic relationship experience is scant.
Objectives:
A proposed theoretical model predicted that individuals with ASD would report less romantic relationship experience than typically developing (TD) individuals. The aim of this study was to measure and explore this, assessing whether the relationship between ASD status (ASD or non-ASD) and romantic relationship experience, is mediated by peer engagement.
Methods:
An online questionnaire comprising of the Sexual Behaviour Scale – third edition (SBS-III), a measure of sexual functioning validated by item response analysis was completed by 232 individuals with ASD (mean age 25) and 227 individuals without ASD (mean age 22). A mediation analysis was undertaken to assess the indirect relationship between ASD status and romantic relationship experience, as mediated by peer engagement.
Results:
Compared to those without ASD, those with ASD did not differ to the degree that they were interested in being in a relationship (p = ns), however were found to have fewer relationship opportunities, $t_{(457)}=-1.76$, $p<.05$, $d=0.17$, and had relationships that lasted a briefer time, $t_{(321)}=-2.79$, $p<.01$, $d=0.31$. This is consistent with greater worry about not being able to build and maintain good relationships reported by individuals with ASD, compared those without such diagnosis, $t_{(434)}=4.71$, $p<.001$, $d=0.44$. Additionally, those without ASD had greater formal sex-education than those without, $t_{(458)}=2.33$, $p<.05$, $d=0.22$.
While controlling for age and gender, analyses confirmed the presence of an indirect effect between ASD and romantic relationship experience ($b=0.78$, 95%CI [.33, 1.40]). The effect remained evident even when not controlling for age and gender. This indicates that the relationship between ASD status and amount of romantic relationship experience, is mediated by the amount of peer engagement. Additional analyses suggested that gender was also a predictor of relationship total ($b=-3.29$, 95%CI [-1.49, -5.10]), with an increase in gender to female a person with ASD was likely to have had fewer relationships.
Conclusions:
It was found that the impact of an ASD diagnosis on one's ability to establish and maintain romantic relationships is mediated by the amount of engagement that they have with peers. This supports an important part of the proposed model, that is, that having less social peer engagement, along with receiving less sex education, leaves individuals with ASD at a double disadvantage from others, who are receiving this information from both of these avenues. For clinicians, these findings suggest that interventions and supports should be focused on improving the amount of social engagement, as this will also improve the individual's romantic relationship experiences. Such understanding and support is of particular importance given the central role of social and sexual wellbeing on one's quality of life.

2:34 **184.003** Sexuality in the Eyes of Parents and Young Adults with Autism Spectrum Disorder

K. Hartmann[1], *T. Kozikowski*[1], *T. V. Williams*[2], *M. Urbano*[1], *N. L. Kreiser*[3], *L. R. Qualls*[2] *and P. L. Alexander*[1], *(1)Eastern Virginia Medical School, Norfolk, VA, (2)Virginia Consortium Program in Clinical Psychology, Norfolk, VA, (3)Psychiatry and Behavioral Science, Eastern Virginia Medical School, Norfolk, VA*

Background: Â Sexuality is a difficult topic for most people given social rules, whether they are neurotypical or have additional challenges such as ASD. Especially as their child becomes sexually mature, families find themselves facing difficult issues to consider when communicating about sexuality. As many individuals with ASD rely on their family of origin well into their adulthood, this study examined young adults with ASD (YA) and their parents (P) perceptions about the YA's sexuality and sexual behaviors.
Objectives: This study explored YA and P perceptions about sexuality with a focus on sexual privacy, education, behavior, victimization and concerns. Our primary aim was to examine YA's desires for intimate relationships, behaviors towards a person of romantic interest, and sexual experiences. Our second aim was to explore YA and P agreement in their perceptions of YA's sexual experiences and behaviors.
Methods: Â YA and P were recruited largely from a metropolitan East Coast area. Data were collected in an anonymous on-line survey. 118 YA were matched to P responses. All participants completed a series of measures to characterize the YA participants and their sexual experiences including privacy, education and behavior on the Sexual Behavior Scale (SBS), negative experiences including victimization on the Sexual Experience Scale (SES), knowledge on the General Sexual Knowledge Questionnaire (GSKQ), and sexual orientation and contacts on the Klein Sexual Orientation Grid (KSOG)
Results: Â Descriptive statistics were calculated to examine YA's sexual behaviors and experiences. A significant proportion of YAs reported that they have had sexual intercourse (53.4%). However, many YA also indicated that they have never been romantically interested in another person (32.5%). Paired samples t-tests were used to assess discrepancies between P and YA reports on the above measures. Results showed a significant difference between YA and P report on the SBS privacy subscale, SBS sexual behavior subscale, and SES victimization subscale (Table 1). Notably, YAÂ reported more privacy seeking for masturbation than their parents reported (t (92) = -2.12, p = .037). P and YA also significantly aligned on several individual item responses (all Cohen's κ > 0.32, p < 0.001, % agreement > 82.9%; Figure 1).
Conclusions: A large proportion of YA reported having had sexual intercourse while many reported not being romantically interested in another person. YA and their parents agree on many questions about the YAs sexuality. Differences were found in YA's reports of more normal privacy and sexual behaviors than P reported. This may be due to YA perception of their behaviors as typical. It may also be due to parents remembering and reporting the YA's most salient inappropriate behaviors from an earlier developmental stage of the YA. YA reported higher experiences of sexual victimization than their parents reported for them suggesting a communication gap that warrants clinical intervention. Parent and YA overwhelmingly expressed their desire for assistance with sex education and this may be best addressed in the ASD population by improving family communication about sexuality.

2:46 **184.004** Falling in Love and Living Together? Sexual Attraction and Relationship Status in Adolescents and Adults with ASD.

J. Dewinter[1], *H. de Graaf*[2] *and S. Begeer*[3], *(1)Child and adolescent psychiatry, GGzE, Eindhoven, NETHERLANDS, (2)Rutgers, Utrecht, Netherlands, (3)VU University Amsterdam, Amsterdam, NETHERLANDS*

Background:
Sexuality is more and more accepted as a normative part of adolescent development and adult functioning, also in men and women with ASD. The majority of people with ASD without an intellectual impairment reports interest in having a relationship. Notwithstanding that ASD features are assumed to hamper relationship and sexuality development, recent research showed that a major part of people with ASD has experience with a romantic relationship, in contrast to earlier findings. Differences in these relationships compared to the general population remain assumed. Earlier publications suggested that more people with ASD also feel attracted towards people of the same sex or that younger heterosexual men with ASD are more likely to be single.
Objectives:
The aim of this study was to explore sexual attraction and relationship experience in adolescents and adults with ASD.
Methods:
Participants in the Netherlands Autism Register (n=675, 48.3% male, age 15-80) answered online single questions about their experienced gender, sexual attraction, relationship status and how they experienced this, and whether their partner had ASD. These findings are compared to data of a large sexual health study conducted in the Dutch general population.
Results:
About 30% of women with ASD and 10% of men reported some degree of gender non-conformity. Only half of the women with ASD felt only attraction towards men, and 80% of men with ASD towards women. Both experienced gender and sexual attraction were more diverse compared to the general population. About half of the men and women were in a romantic relationship, which is less than peers in the general population. Only a small minority was in a non-heterosexual relationship. Comparable numbers of people lived together with their partner. Of the men, 12% had a partner with (suspected) ASD, compared to a third of the women. Of those in a relationship, the majority evaluated their relationship as satisfactory. In the singles, 30% regretted their lack of a partner.
Conclusions:
In this study, a greater variety in gender experience and sexual attraction appeared in the adults with ASD compared to their peers in the general population, especially in women with ASD. About half of the adults with ASD without an intellectual disability reported to be in a romantic, mostly heterosexual, relationship and the majority of them lived together with their partner. The variety in attraction was not reflected in the number of non-heterosexual relationships. Research on the way people with ASD experience and define their gender and sexual attraction is necessary, for example in order to explore how people with ASD come to a self-definition and which factors influence this. Attention to gender- and attraction diversity in sexuality education and support to adolescents and adults with ASD is important.

Oral Session - 12A
185 - Evaluating Social Attention and Reward in Young Children with ASD
1:15 PM - 2:05 PM - Yerba Buena 7

Session Moderator: Bhismadev Chakrabarti, *School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom*

1:15 **185.001** Initiating Joint Attention: Reduced Gaze Alternation in Infancy Is Related to More ASD Symptomatology in Toddlerhood

E. Thorup[1], *P. Nyström*[2], *G. Gredebäck*[2], *S. Bolte*[3] *and T. Falck-Ytter*[3,4], *(1)Uppsala universitet, Stockholm, SWEDEN, (2)Uppsala University, Uppsala, SWEDEN, (3)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (4)Dept of Psychology, Uppsala University, Uppsala, Sweden*

Background: Â Children with Autism Spectrum Disorder (ASD) are known to initiate Joint Attention (IJA) to a lesser extent than typically developing children. The incidence of higher level IJA behaviors, such as pointing, has been shown to discriminate between children at high vs. low risk (HR vs. LR) for ASD during the second year of life. It is less clear whether lower level IJA behaviors, such as the shifting of gaze between an interaction partner and an event occurring outside that person's field of vision, can discriminate between groups. If valid, the measure would have the advantage of allowing earlier assessment than high level IJA behaviors.
Objectives: The aim of the present study was to assess whether the number of gaze shifts made between a person and an event occurring outside his/her field of vision could discriminate between HR and LR infants at 10 months, and to evaluate possible associations with later autism symptomatology as well as with higher level IJA behaviors.
Â Methods: This face-to-face eye tracking study included a group of ten month old siblings of children with ASD (HR-group; N = 59) and a group of infant siblings of typically developing children (LR-group; N = 21). While the infant interacted with an adult experimenter, blinking lights appeared intermittently outside the experimenter's field of vision. The number of gaze shifts made by the infant between the experimenter and the lights was used as the dependent measure. At 18 months, the infants were assessed with the ADOS-T, and correlations with the primary measure were calculated.
Results: The LR-group made more gaze shifts between the experimenter's face and the lights at 10 months than did the HR-group, $p < .05$. This could not be explained by differences in the ability to disengage (assessed by a modified version of the AOSI disengagement task). Moreover, more alternating gaze behavior was associated with lower ADOS-T scores at 18 months in the HR-group, $r = -.29$, $p < .05$. Finally, making more gaze shifts at 10 months was associated with lower scores on the ADOS-T items showing, $r = -.30$, $p < .05$ and pointing, $r = -.33$, $p < .05$.
Conclusions: This study shows that alternating gaze behavior during face to face communication discriminates between infants at risk for ASD and controls, and that this measure relates to later ASD symptomatology in the HR group. These findings, together with the specific associations observed between alternating gaze and later pointing and showing behaviors, further validate alternating gaze behavior as a measure of IJA in infants. The measure has the advantage of allowing for earlier use than other IJA measures (e.g. pointing), and could potentially detect deviations in social behavior already during the first year of life. The study also highlights the potential of naturalistic paradigms in early ASD research.

1:27 **185.002** Feasibility of a Mobile Phone-Delivered Study of Social and Emotional Behaviors in Young Children at Risk for Autism

H. Egger[1]*, K. Campbell*[2]*, K. Carpenter*[2]*, J. Hashemi*[3]*, S. Espinosa*[3]*, M. Tepper*[3]*, J. Schaich Borg*[3]*, Q. Qiu*[3]*, S. Marsan*[2]*, G. Dawson*[2]*, R. Bloomfield*[3] *and G. Sapiro*[3]*,*

(1)Child and Adolescent Psychiatry, NYU Langone Medical Center, New York, NY, (2)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (3)Duke University, Durham, NC

Background: Effective and accessible screening of young children for autism requires reliable, valid, and efficient tools for evaluation of a child's social-emotional behaviors. Coupling parent-report measures with evidence based observational assessments significantly improve the accuracy of screening and diagnosis. Current validated tools for structured assessment of children's behavior are expensive, training intensive, and time-consuming to administer. Development of tools for low-cost, automatic, objective, and quantifiable measurements of young children's observable behaviors has the potential to increase access to screening and early intervention for children around the globe.
Objectives: To test the feasibility of an iPhone application ("app") to engage parents directly in the collection of survey and video data about their children within their homes and use automatic computer vision algorithms to quantify children's emotions and attention in the uploaded videos.
Methods: Autism & Beyond, a study of young children ages 12 to 72 months, is an iOS app built on Apple's ResearchKit framework. The iPhone app includes self-guided econsent, parent-report surveys, and video activities with the child. The camera on the device recorded the child's behaviors and emotions as s/he watches short film clips while sitting on the parent's lap. Autism risk status of children in the study was based on parent-reported autism diagnosis and/or a positive M-CHAT-R/F (children 16-30 months). Behavioral variables automatically extracted from the videos include positive emotions, attention, and social referencing. Here we present results from first 6 months of the study.
Results: In the first sixth months of the study, 878 families met inclusion criteria. 295 children were in the high risk autism group (parent report of autism diagnosis: 218, high MCHAT: 51, Both: 26). Mean age of high risk children was 43.2 months (SD 14.9); mean age in the low risk group was 40.6 months (SD 16.4). The majority of parents were non-Hispanic/Latino Caucasians (65%), college educated (60%), and employed (63%). 862 participants completed additional surveys about child behaviors. 403 parents agreed to upload full videos of their child and completed at least one video activity with their child. 300 of 878 uploaded only facial landmarks extracted from their child's video. The child's face was identified in 84-92% of the video frames. Children in the high risk autism group showed decreased mean positive affect (-7%, SD 4%, p=0.04 in one stimulus) and lower predicted probability of social referencing (9% vs 24% p=0.02 at oldest ages in one stimulus).
Conclusions: Over 6 months, nearly 900 parents downloaded the study app, consented to participate, and completed study tasks in their homes. The quality of the video data is excellent. Automatic computer vision coding of emotions and head position in the videos enabled us to identify differences between children with and without a high risk for autism. These results are a first step toward the development of globally accessible, affordable, and easy to use app-based tools to improve the science and practice of screening for autism. Collaborations in South Africa and Argentina are enabling us to expand the reach of Autism & Beyond beyond the US.

1:39 **185.003** Imitation of Socially Rewarding and Non-Socially Rewarding Actions in Preschoolers with ASD

G. Vivanti[1]*, D. R. Hocking*[2]*, P. A. Fanning*[3] *and C. Dissanayake*[4]*, (1)AJ Drexel Autism Institute, Philadelphia, PA, (2)Psychology & Counselling, Developmental Neuromotor & Cognition Lab, La Trobe University, Melbourne, AUSTRALIA, (3)La Trobe University, Melbourne, Australia, (4)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: While imitation difficulties and atypical reward processing have been documented in preschoolers with ASD, the link between these phenomena is poorly understood. As imitation is a common treatment target and provision of contingent rewards is a common treatment procedure in ASD early intervention, a fine-grained understanding of how imitative responses in ASD are modulated by reward has the potential to provide critical insight on both mechanisms of impairment and mechanisms of treatment response in this population.
Objectives: We investigated how young children with ASD imitated actions that were either instrumental to achieve a non-social reward or a social reward compared to typically developing children and children with Williams Syndrome (WS). The aim was to identify whether putative imitation differences between the groups were (1) modulated by the social versus non-social nature of the demonstrated actions and (2) linked to learning outcomes in response to early intervention in ASD.
Methods: Â Participants were 35 preschoolers with ASD and 20 peers with WS, matched for age, cognitive, verbal and motor functioning as well as 20 typically developing peers matched for chronological age. We tested participants' spontaneous imitation performance in response to a series of novel eye-tracking-based imitation tasks, in which the to-be-imitated actions achieved either a non-social reward (obtaining a desired toy from a container) or a social reward (shared enjoyment between the demonstrator and the imitator). In the ASD group, we also examined the extent to which individual differences in imitation were correlated to intervention gains occurring in the 12 months following the test.
Results: Â We found that children in the ASD group imitated actions that were instrumental to achieving non-social rewards as frequently as participants in the TD and WS groups. Conversely, imitation performance was lower in ASD compared to the control groups in response to the demonstration of actions accomplishing social rewards ($F(2, 67)= 9.87$; $p< .01$). Similarly, eye-tracking patterns were similar across groups in response the demonstration of actions achieving non-social rewards, while children in the ASD group were less focused on the model's face during the observation of actions achieving a social reward ($p<.05$). Imitative response to socially rewarding actions was associated with response to early intervention outcomes ($r=.7$, $p<.005$).
Conclusions: Atypical reward processing modulates imitation performance in ASD. Imitation of socially rewarding actions is distinctively impaired in young children with ASD and sensitivity to the socially rewarding nature of demonstrated actions is linked to early intervention outcomes.

1:51 **185.004** Positive Affective Response to Dynamic Smiling Faces in Young Children with Autism Spectrum Disorder

P. Heymann[1]*, S. Macari*[1]*, L. DiNicola*[1]*, E. Hilton*[1]*, A. Milgramm*[1]*, F. E. Kane-Grade*[2] *and K. Chawarska*[1]*, (1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale child Study Center, New Haven, CT*

Background: Â Children with Autism Spectrum Disorder (ASD) are able to show a full range of emotions (Braverman, Fein, Lucci & Waterhouse, 1989) but in social situations they reportedly display less positive affect than typically-developing (TD) children (Snow, Hertzif, Shapiro, 1987). For example, children with ASD were less likely to smile back in response to their mothers' smiles (Dawson, Hill, Spencer, Galpert & Watson, 1990). Although this phenomenon has been observed in naturalistic settings, few studies have examined affective response to faces in experimental settings. High-functioning adults with ASD exhibited deficits in automatic mimicry of facial expressions when looking at static facial images (McIntosh, Reichmann-Decker, Winkeilman, Wilbarger, 2006). The current study aims to explore the effects of social and non-social dynamic stimuli on smiling in young children with ASD.
Objectives: To determine whether smiling differs in children with and without ASD while watching social and non-social stimuli. We hypothesized that the children with ASD would express fewer smiles than TD children, especially in response to dynamic faces.
Methods: Â 53 children (ASD, *n=25*, TD, *n=28*) between the ages of 20 and 78 months were shown a gaze-contingent eye-tracking experiment consisting of non-social (fractals) and social (faces) conditions.Â In the non-social condition, two fractal images were presented, one of which became dynamic when the child fixated gaze on it. Similarly, the social condition consisted of two neutral static faces one of which, when fixated upon, became dynamic and smiled. Each condition consisted of 128 trials. The child's positive affect (smiles) was coded offline for both conditions. Proportion of trials with smiles was calculated based on the number of trials in which the child smiled divided by the number of trials the child watched. The ADOS-2 Module 1 was administered to all children with ASD and their parents completed the Vineland-II.
Results: Â The ASD group expressed positive affect on 8.1% (*SD=11*) of face trials versus 5.2% (*SD=11*) of fractal trials, compared to 9.7% (*SD=13*) and 4.0% (*SD=5*), respectively, in the TD group. An ANOVA indicated a significant main effect of condition ($F(1,47) = 4.92$, $p=.032$), whereby both groups expressed more positive affect during the social than during the nonsocial condition, but no main effect of group ($F(1,47)=37.45$, $p = .993$). There was no group by condition interaction ($p=.522$). Furthermore, in the ASD group, smiles were significantly correlated with the Vineland-II Interpersonal V-Score ($r=.519$, $p=.019$) and with shared facial expressions on the ADOS-2 (composite score of the Responsive Social Smile and Facial Expressions Directed to Others items; $r=.423$, $p=.044$).
Conclusions: Young children with ASD expressed positive affect at rates similar to TD children in response to dynamic smiling faces. Smiling seems to be an indicator of adaptive social behavior in ASD, as those who smiled more at the faces stimuli tended to have better interpersonal relationships with peers and were able to share a range of affect in naturalistic situations. This study shows that measuring affective response to dynamic stimuli can provide useful insight into real-world social behaviors.

Oral Session - 12B
186 - Contributors to Social Processing Deficits in ASD

2:10 PM - 3:00 PM - Yerba Buena 7

Session Moderator: Bhismadev Chakrabarti, *School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom*

2:10 **186.001** Exploring Sex Differences in Social Attention in ASD

H. L. Hayward[1]*, L. Mason*[2]*, A. San Jose Caceres*[3]*, R. Holt*[4]*, M. C. Lai*[5]*, S. Baron-Cohen*[6]*, J. K. Buitelaar*[7]*, D. G. Murphy*[8] *and E. Loth*[9]*, (1)Institute of Psychiatry Psychology and Neuroscience, King's College London, London, England, United Kingdom, (2)CBCD, Birkbeck, University of London, Gravesend, UNITED KINGDOM, (3)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Autism Research Centre, University of Cambridge, Cambridge, UNITED KINGDOM, (5)Psychiatry, University of Toronto, Toronto, ON, CANADA, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (7)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (8)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
Autism Spectrum Conditions (ASC) are estimated to affect males about 3 times more often than females. The majority of previous studies only studied males and only recently have systematic investigations of females with ASC begun (Lai, et al, 2015). Sex differences have been found in aspects of social cognition, such as empathy (Baron-Cohen et al, 2004). However, so far, sex differences not been explored in social motivation (often measured as spontaneous social attention), which has been proposed to also underpin social-communicative impairments.
Objectives:
1. To examine sex differences in social attention across different ages; 2. To investigate whether abnormalities in social attention relate to level of social-communicative impairments and/or level of social adaptive function in males/females.
Methods:
Participants with ASC (199 males, 78 females) and age-matched typically developing (TD) participants (151 males, 71 females) were recruited as part of the EU-AIMS Longitudinal European Autism Project (LEAP). An eye-tracking battery included a set of 6 still images of naturalistic social scenes, each presented for 15 seconds. Eye movements were recorded using Tobii eye-trackers. Areas of Interests (AOIs) focused on the whole face, eye region, mouth, relevant objects (defined by their role in a social interaction) and irrelevant objects. IQ was assessed using the WASI, autism social symptom severity using the parent-report Social Responsiveness Scale (SRS), and level of adaptive functioning using the Vineland Adaptive Behaviour Scale (VABS-III). To test our predictions, 2 (group) x 2(sex) x 3 (age group: child, adolescent, adult) between-subject ANOVAs were used.
Results:
We found a significant effect of group on % gaze time on faces ($F(1,487)=8.898$, $p=.05$, $r=.02$) and a significant group x age interaction ($F(2,487)=3.946$, $p<.05$, $r = .01$). Only TD adults looked longer at faces than adults with ASC, while there were no significant group differences in children and adolescents. In both groups, females looked longer at eyes ($F(1,487)=3.729$, $p=.05$, $r=.01$) than males. However, post-hoc analyses suggested that this pattern was only found during childhood. Gaze time on relevant/ irrelevant objects decreased with age, except for TD females: TD females looked longer at relevant objects than any other group during childhood but shorter during adolescence.
In the ASC group, % gaze on the mouth region was related to higher social-communicative impairments ($r =.12$, $p=.05$) and higher levels of adaptive behaviour (VABS composite) ($r=.19$, $p=.01$). Among the TD group, longer looking times on faces was linked to lower social-communicative symptoms ($r=-.20$, $p=.05$) and higher levels of adaptive functioning (all
Conclusions:
In both groups, females looked longer at eyes than males. Contrary to expectations, these sex differences were only seen during childhood. We also found differential relationships between gaze times on face/ mouth and level of social-communicative symptoms in the ASC and control groups.
Background:
Autism Spectrum Conditions (ASC) are estimated to affect males about 3 to 8 times more often than females. The majority of previous studies only studied males and only recently have systematic investigations of females with ASC begun (Lai, et al, 2015). Sex differences have been found in aspects of social cognition, such as empathy (Baron-Cohen et al, 2004). However, so far, sex differences not been explored in social motivation (often measured as spontaneous social attention), which has been proposed to also underpin social-communicative impairments.
Objectives:
1. To examine sex differences in social attention across different ages; specifically the hypothesis that sex differences become more pronounced in adolescence/adulthood in both groups due to biological (Craig et al., 2007) and/or social factors (Gould & Ashton-Smith, 2011). 2. To investigate whether abnormalities in social attention relate to level of social-communicative impairments and/or level of social adaptive function in males/females.
Methods:
Participants with ASC (199 males, 78 females) and age-matched TD participants (151 males, 71 females) were recruited as part of the EU-AIMS Longitudinal European Autism Project (LEAP). An eye-tracking battery included a set of 6 still images of naturalistic social scenes, each presented for 15 seconds. Eye movements were recorded using Tobii eye-trackers. Areas of Interests (AOIs) focused on the whole face, eye region, mouth, relevant objects (defined by their role in a social interaction) and irrelevant objects. IQ was assessed using the WASI, ASD social symptom severity using the parent-report Social Responsiveness Scale (SRS), and level of adaptive functioning using the Vineland Adaptive Behaviour Scale (VABS-III). To test our predictions, 2 (group) x 2(sex) x 3 (age group: child, adolescent, adult) between-subject ANOVAs were used.
Results:
We found a significant effect of group on % gaze time on faces ($F(1,487)=8.898$, $p=.05$, $r=.02$) and a significant group x age interaction ($F(2,487)=3.946$, $p<.05$, $r = .01$). Only TD adults looked longer at faces than adults with ASD, while there were no significant group differences in children and adolescents. A trend indicated that in both groups females looked longer at eyes ($F(1,487)=3.729$, $p=.05$, $r=.01$) than males. However, posthoc analyses suggested that this pattern was only found during childhood. Gaze time on relevant/ irrelevant objects decreased with age, except for TD females: TD females looked longer at relevant objects than any other group during childhood but shorter during adolescence.
In the ASC group, %gaze on the mouth region was related to higher social-communicative impairments ($r =.12$, $p=.05$) and higher levels of adaptive behaviour (VABS composite) ($r=.19$, $p=.01$). Among the TD group, longer looking times on faces was linked to lower social-communicative symptoms ($r=-.20$, $p=.05$) and higher levels of adaptive functioning (all $p=.05$),
Conclusions:
We found a trend suggesting that in both groups, females looked longer at eyes than males. Contrary to expectations, these sex differences were only seen during childhood. We also found differential relationships between gaze times on face/ mouth and level of social-communicative symptoms in the ASC and control groups.

2:22 **186.002** Investigating Gender-Specific Trajectories of Autistic Traits Across Childhood and Adolescence in a Large Birth Cohort

W. Mandy[1], *J. Heron*[2], *E. Pellicano*[3], *B. St. Pourcain*[4] *and D. H. Skuse*[5], *(1)University College London, London, United Kingdom, (2)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (3)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (4)University of Bristol, Bristol, UNITED KINGDOM, (5)UCL GOS Institute of Child Health, London, UNITED KINGDOM*

Background:
Autism spectrum disorder (henceforth 'autism') is a dimensional condition, which sits at the extreme of the continuum of autistic traits (ATs) that extends throughout the general population. There is mounting evidence that autism presents differently in males and females (Lai et al., 2015).Â To date, almost all studies of autism sex/gender differences have been cross-sectional, with a lack of longitudinal research. Therefore, we investigated gender differences in AT trajectories across childhood and adolescence. We tested the opposing predictions of two hypotheses about the development of the female autistic phenotype:

1. The **female compensation hypothesis** - females with autistic difficulties develop strategies to manage their social difficulties, such that their ATs diminish over time (e.g., Mandy et al., 2012).
2. The **adolescent emergence hypothesis** - ATs in females become more overt later in development, such that their ATs escalate during adolescence (e.g., Asperger, 1943).

Current diagnostic criteria, which are largely based on male cases, are relatively insensitive to the female autism phenotype. Therefore, we included participants across the full range of AT severity, not just those with an autism diagnosis, to avoid a systematic bias against participants with female-typical autistic difficulties.
Objectives:
To study gender differences in the trajectories of ATs in a large general population sample across childhood and adolescence.
Methods:
Participants (N=9744) were girls (n=4784) and boys (n=4960) from the Avon Longitudinal Study of Parents and Children (ALSPAC), a UK birth cohort study. ATs were assessed aged 7, 10, 13 and 16 years using the Social Communication Disorders Checklist (SCDC), a widely used and psychometrically sound parent-report AT measure. These longitudinal data were modelled using latent growth curve and growth mixture models.
Results:
We observed different AT trajectories for males and females (Figure 1). A latent growth curve model showed that, controlling for IQ, non-autistic psychopathology and socio-economic status: (a) aged 7, males had higher ATs than females ($p<.001$); (b) males and females both showed a decline in ATs between 7 and 10 years; (c) females, but not males ($p<.001$), showed a substantial escalation in ATs between 10 and 16 years.
This same pattern of findings occurred when we investigated gender ratios of those with very high ATs. For example, aged 7 years, males had much higher odds than females of scoring ≥ 99th AT centile (OR = 6.15, 95% CI [5.44, 6.85]), but by 16 years females and males had similar odds of having ATs ≥ 99th centile (OR=1.18, 95% CI [0.56, 1.80]).
Growth mixture modelling revealed three trajectory groups (Figure 2): Class 1 (26% female) who showed elevated ATs across childhood and adolescence; Class 2 (50% female) who showed persistently low ATs across childhood and adolescence; and Class 3 (52% female) who showed escalation of ATs during adolescence.
Conclusions:
We present the first empirical evidence for the adolescent emergence hypothesis: a sub-group of girls showed substantial escalation of ATs between 10 and 16 years. This may partly explain why females tend to be diagnosed with autism later than males.

2:34 **186.003** What Is Best - Zebra Crossings or Shared Zones? Revealing Pedestrian Viewpoints on Two Uncontrolled Crossing Points.

*R. Earl[1], **S. J. Girdler**[1], M. Falkmer[2], S. L. Morris[3] and T. Falkmer[1], (1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Physiotherapy and Exercise Science, Curtin University, Perth, Australia*

Background: Road crossing is considered a dangerous but necessary life experience for people with and without a disability. Whilst traditional urban landscapes segregate foot and motorized traffic, the pursuit of safer and more pleasant environments has promoted construction of shared traffic environments, or shared zones. Shared zones are characterized by absence of traditional markings segregating the road and footpath. Whilst negotiating a shared zone traffic users are expected to interact with each other. Safety in these environments requires traffic users to rapidly perceive, assess and respond to social stimuli. These abilities may be impacted by impairments in cognitive processing, such as autism spectrum disorders (ASD). Hence, these demands may cause increased anxiety during negotiation of a shared zone compared to traditional pedestrian crossings (zebra crossings), resulting in avoidance of these areas and restrictions in community mobility.
Objectives: To reveal the viewpoints of pedestrians as they pertain to uncontrolled crossing points, specifically shared zones and zebra crossings.
Methods: Â Q method identified and explored the viewpoints of pedestrians specifically relating to shared zones and zebra crossings; 62 participants with ASD (n=20), intellectual impairments (ID) (n=21), and without impairments (TD) (n=22) were asked to complete a series of tasks which required them to cross both a shared zone and zebra crossing. Afterwards, participants were asked to sort 44 predetermined statements about shared zones and zebra crossings onto a grid in a way that reflected their experiences. For this study each statement was supplemented with simple images to enhance understanding, Q methodology has successfully been used in the past to reveal the viewpoints of individuals with ASD in regard to driving and public transport.
Results: Â Analysis revealed two viewpoints for pedestrians with and without cognitive impairment. The first viewpoint of "Confident Users" revealed that those sharing this view (n[TD]=18, n[ASD]=15, n[ID]=6)) would not avoid either environment and were confident in their ability to negotiate both crossings. The second viewpoint consisted of 12 "Confident but wary" participants (n[TD]=2, n[ASD]=4, n[ID]=6) who while confident in their own knowledge of the road rules surrounding the two crossings were less confident negotiating a shared zone, as they did not trust in the knowledge and actions of drivers in this environment. There were 11 participants that did not load on either viewpoint (n[TD]=1, n[ASD]=1, n[ID]=9) .
Conclusions: Â Overall, while participants would not avoid shared zones some preferred to seek out zebra crossings, perceiving them to offer a safer and more secure crossing option. However, the perception of enhanced safety on zebra crossings may be deceiving under certain conditions, especially, if resulting in avoidance of shared zones with lower traffic speed. Pedestrians with ASD loaded in a similar manner to their typically developed peers, suggesting that deficits in social processing and functioning may not impact on perceived safety in traffic environments, such as the shared zone or zebra crossing, nor do these crossing environments negatively impact on this population's community access and mobility.

2:46 **186.004** Social Reinforcement Learning and Its Neural Modulation By Oxytocin in Autism Spectrum Disorder

***J. A. Kruppa**[1,2], A. Gossen[1,2], N. Großheinrich[1], E. Oberwelland[1,2], H. Cholemkery[3], H. Schopf[1], G. Kohls[1], G. R. Fink[2], B. Herpertz-Dahlmann[1], K. Konrad[1,2] and M. Schulte-Rüther[1,2], (1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (2)Cognitive Neuroscience, Institute of Neuroscience and Medicine (INM-3), Jülich Research Center, Jülich, Germany, (3)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt am Main, Germany*

Background: Â Oxytocin (OXT) has recently been shown to enhance motivation and attention to social stimuli. These effects may have the potential to enhance social reinforcement learning (SRL), the core mechanism of behavioral interventions. It is unclear whether OXT can compensate for possible deficits in SRL in ASD and whether such compensatory mechanism is related to an increase in saliency towards social stimuli per se or to a modulation of the brains' reward circuitry (especially nucleus accumbens; NAcc), which is specific for social feedback. These questions are important for future interventions aiming to combine OXT and behavioral treatments in ASD.
Objectives: Â We investigated the potential of OXT to compensate for deficits in socially reinforced learning in ASD and its underlying neural mechanism in a social learning task, which allowed for the differentiation of social feedback stimuli and social stimuli as the target of learning.
Methods: Â Using functional Magnetic Resonance Imaging we assessed brain activation during performance of a probabilistic reinforcement learning task in 24 typically developing controls (TDC) and 15 patients with ASD (18-26 years) in a double-blind placebo-controlled cross-over design. Participants indicated whether social or non-social stimuli belong to category A or B and social or non-social feedback with non-100% contingencies was provided. Data were analyzed using computational modeling according to the Q-Learning model. From the behavioral data, trial-by-trial reward-prediction error (RPE) values were calculated. We assessed the correlation of brain activation with RPE values during feedback and brain activation related to the anticipation of reward during choice. Based on previous studies of RPE learning and anticipation of reward, we focused on brain activation in the nucleus accumbens using an ROI approach ($p<.05$, voxel level corrected for ROI).
Results: In the ASD group, OXT enhanced the correlation of the RPE signal with activation in the NAcc during social *feedback* despite the learning target being non-social, whereas in the TDC group this effect was found in the placebo (PLC) condition. The learning *target* being social did not show a modulation by OXT during feedback in ASD whereas in TDC, an enhanced correlation was found for non-social learning targets during OXT. Behaviorally, subjects from both groups demonstrated significant learning during the task across conditions. Patients with ASD showed better learning when the learning target was social rather than non-social in the OXT but not PLC condition.
Conclusions: Our results demonstrate that in ASD, OXT selectively enhances the correlation of the RPE with brain activation during social feedback, but no selectivity was evident for social stimuli as a learning target. In the TDC group, OXT had a rather attenuating effect. Hence, on the neural level, OXT may disrupt a functioning system in TDC whereas OXT rather compensates for deficits in ASD. Behaviorally, OXT had a facilitating effect in ASD for social learning targets but not social feedback. This pattern suggests that the modulatory role of OXT for social learning is not specifically tied to the learning target or feedback being social, although differential neural effects can be observed.

Oral Session - 13A
187 - Innovative Treatments for School-Aged Children
1:15 PM - 2:05 PM - Yerba Buena 8

Session Moderator: Elizabeth Laugeson, *Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

1:15 **187.001** A Randomized Trial of a Brief Attention Bias Modification Game to Improve Engagement to Social Stimuli for Children with Autism Spectrum Disorder

G. A. Alvares[1,2], *N. T. Chen*[2,3,4], *L. Notebaert*[4], *J. Granich*[1], *C. Mitchell*[4] *and A. J. Whitehouse*[1,2], *(1)Telethon Kids Institute, University of Western Australia, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Psychology and Speech Pathology, Curtin University, Perth, Australia, (4)School of Psychology, University of Western Australia, Perth, Australia*

Background: Reduced social attention in individuals with autism spectrum disorder (ASD) has been demonstrated as early as 12 months of age. This early bias to preferentially allocate attention to non-social objects compared to faces may be an underlying mechanism impacting upon the later development of later social-communicative behaviors. While reduced social attention has been used as both a diagnostic predicator and marker for change in clinical trials, there has been little research aiming to specifically target social attention biases to causally modify social behavior.
Objectives: The aim of this pilot study was to develop and test a novel game-based social attention bias modification paradigm to improve preferences for social stimuli in school-aged children with ASD.
Methods: Participants included 57 children (9 females) diagnosed with ASD aged between 5-12 years randomized to either a bias modification (n=30) or control (n=27) game. Gameplay consisted of 15 one minute trials (levels) on a touchscreen device where children learned to 'swipe' various social and non-social object characters into a score zone. Children playing the bias modification game were rewarded with points for only swiping social characters, whereas children in the control condition were equally rewarded for either character type. Before and after gameplay children completed two eye-tracking tasks to assess change in eye gaze behavior towards social and object stimuli.
Results: Â Eye-tracking data was complete for 50 children; a further four children were excluded from analysis due to failure to complete gameplay (final sample game n=24, control n=22). In-game data confirmed children playing the bias modification game selectively swiped social characters preferentially over objects at game cessation, whereas children in the control condition indiscriminately selected both sets of characters ($t(44)=8.50$, $p<.001$). A significant interaction was observed between groups before and after gameplay on the percentage of engagements (first fixations) to faces, associated with a small effect size; $F(1, 44)=6.15$, $p=.02$, partial $\eta^2=.12$. Follow-up comparisons indicated that children playing the game significantly increased the percentage of engagements to social stimuli relative to objects after gameplay ($p=.04$) compared to children in the control condition ($p=.15$). Although there were no significant differences between groups in overall fixation times to social and object stimuli, exploratory pairwise comparisons indicated that children in the game group tended to decrease total fixation time towards objects after gameplay relative to the control condition ($p=.02$, partial $\eta^2=.12$).
Conclusions: Â This pilot study represents the first attempt to use a brief attention bias modification game to change attention to social stimuli in children with ASD. Preliminary data suggest that brief gameplay increased the tendency to engage with social stimuli and decreased exploration of objects. Further testing is now needed to determine whether extended gameplay can maintain these social attention changes. The implications for modifying attentional biases in a game-based format will be discussed as a potential novel mechanism to alter fundamental social-communicative behaviors such as eye contact, social preference, or emotion recognition.

1:27 **187.002** The Pegasus Psychoeducational Programme for Young People Diagnosed with Autism Spectrum Condition

M. Murin[1], *K. Gordon*[2], *D. H. Skuse*[3] *and W. Mandy*[4], *(1)Great Ormond Street Hospital, Great Ormond Street Hospital for Children, London, United Kingdom, (2)Child and Adolescent Mental Health Service, Berkshire Healthcare Foundation NHS Trust, Reading, UNITED KINGDOM, (3)UCL GOS Institute of Child Health, London, UNITED KINGDOM, (4)University College London, London, United Kingdom*

Background:
To promote empowerment and reduce self-stigma when a young person is diagnosed with autism spectrum condition (ASC) it is essential that they receive psychoeducation, to help them learn about their diagnosis in a positive way. Until recently there were no evidence-based guidelines on how to communicate the diagnosis of ASD to children or their parents. Neither were there any psychoeducational packages available for this purpose. We designed and evaluated PEGASUS, a group psychoeducational programme for young people with ASC. PEGASUS focuses on capacities as well as difficulties: it emphasises that having ASC means being different, but not inferior, to people without ASC. It is aimed at enhancing self-efficacy and development of compensatory strategies through understanding of individual strengths and areas of specific support needs.
Objectives:
The study's main objective was to evaluate the efficacy of PEGASUS. The design of our novel intervention is based upon principles of self-management and cognitive behavioural therapy (CBT). The programme comprises 6 weekly sessions, each lasting 1.5 hours with separate parallel sessions for children and for parents. We aimed to evaluate the acceptability of the intervention to children and their parents. We aimed to evaluate the extent to which participants could acquire a balanced understanding of the child's unique strengths and difficulties and to enhance self-management strategies tailored to that child's individual needs.
Methods:
In total, 48 children (9-14 years) with diagnoses of High Functioning Autism or Asperger's Syndrome and their parents were recruited. Half were randomised to attend the PEGASUS groups and half to the control group, in which they were offered no input over and above "treatment as usual". In total, five PEGASUS groups each including 4-6 children were run. Primary outcomes are of ASD knowledge and ASD-related self-awareness were assessed using a questionnaire specially developed for this study (the Autism Knowledge Quiz). This was completed by both children and their parents. Children also completed the Rosenberg Self-Esteem Scale, a self-concept scale and the Strengths and Difficulties Questionnaire (SDQ). Parents completed the SDQ, the Social Responsiveness Scale, the Parental Stress Index, a measure of parental self-efficacy and a measure of utility of ASD diagnosis. Data were collected at 3 time points: at baseline, after 3 months (i.e. immediately post-treatment) and at 6-month follow-up, by researchers blind to group allocation. The Vineland Adaptive Behaviour Scale was administered at baseline and at 6-month follow-up.
Results:
At the end of PEGASUS, ASC knowledge (β=.29, p<.001, 95% CIs [.13, .44]) and ASC self-awareness (β=.42, p=.001, 95% CIs [.17, .67]) increased significantly for those who attended PEGASUS (n=24) compared to controls (n=24). This effect persisted at follow-up, three months after PEGASUS ended.
Children who attended PEGASUS reported more ASC-related personal strengths than did controls and PEGASUS did not cause any reduction in self-esteem.
Conclusions:
PEGASUS enhanced participants' general knowledge of ASC and awareness of their own unique strengths and difficulties. This RCT provides initial evidence for PEGASUS's efficacy as a psychoeducation programme for people with ASC.

1:39 **187.003** Theatre of Mind: Results from a Large Randomized Control Trial of a Theatre-Based Intervention Showing Improvement in Social Cognition and Behavior in Youth with Autism Spectrum Disorder

B. A. Corbett[1]*, I. Muse*[1]*, R. A. Muscatello*[2]*, A. P. F. Key*[3] *and S. Ioannou*[4]*, (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Lipscomb University, Nashville, TN*

Background: Individuals with Autism Spectrum Disorder (ASD) are impaired across many levels of social competence, to include social cognition and the ability to perceive and respond to others. Theory of Mind (TOM) is the ability to attribute mental states including beliefs, intentions, desires, and knowledge to oneself and others and to understand that these perspectives are different from one's own. Theatre techniques such as role-playing, improvisation, and character development have been shown to enhance TOM skills in typically developing children. SENSE TheatreÒ, a peer-mediated, theatre-based intervention has resulted in significant improvement in social competence in children and adolescents with ASD (Corbett et al., 2016a) as well as reduction in anxiety related to engaging with peers (Corbett et al., 2016b).
Objectives: The purpose of the study was to examine the impact of a peer-mediated, theatre-based intervention, SENSE TheatreÒ, with a large sample of participants with high-functioning ASD using a randomized control trial (RCT) design. It was hypothesized that significant differences between the Experimental (EXP) and the Waitlist Control Group (WLC) would be found for measures of social cognition (TOM), social brain (ERP, Incidental Face Memory (IFM)), social behavior (Cooperative Play), and social functioning (SRS).
Methods: Participants included 80 high-functioning youth with ASD between 8-to-16 years randomly assigned to the EXP (N=43) or the WLC (N=37) group. The 10-session treatment involved theatrical approaches and behavioral strategies, implemented by trained typically developing peers. The primary dependent measures were the NEPSY TOM, including the Verbal (TOM-V) and Contextual (TOM-C) components, IFM, Cooperative Play from the Peer Interaction Paradigm, and the SRS. Analysis of Covariance was used in which the post-intervention score served as the outcome variable, group (EXP/WLC) as a main independent variable, and baseline (pre-intervention) score as a covariate.
Results: The two groups did not differ with regards to age, gender, or symptom profile measured by the Autism Diagnostic Observation Schedule, all p >0.05. However, significant differences between the EXP and the WLC group were observed post-treatment on multiple measures. Specifically, the EXP group showed better performance on the TOM Total $F(2,75)=5.96$, $p=0.02$ and on the TOM-V $F(2,76)=4.54$, $p=0.04$. Regarding social brain IFM, the EXP group showed greater memory for faces $F(1,78)=3.92$, $p=0.05$. In the domain of social behavior, the EXP group engaged in more cooperative play with novel peers $F(2,77)=7.49$, $p=0.008$, and demonstrated more social communication in daily functioning (SRS; $F(2,75)=3.81$, $p=0.05$).
Conclusions: Youth that participated in the treatment were better able to verbalize and attribute mental states and behaviors to others, engage in more cooperative play with peers, and exhibit more daily social communication in community settings. The study replicates and extends previous findings showing that the peer-mediated, theatre-based intervention contributes to improvement in multiple areas of social competence. The results contribute to a modest albeit expanding literature showing the promise of theatre for treating core deficits in youth with ASD.

1:51 **187.004** School-Based RCT Peer Social Intervention for Minimally Verbal Children with ASD

N. Bauminger-Zviely*, Bar-Ilan University, Ramat Gan, ISRAEL*

Background:
Few interventions have been specifically designed for school-age children with ASD who are minimally verbal (MVASD), namely who produce only 20-30 spoken words and/or stereotyped phrases. Within this neglected research area on the spectrum, interventions oriented at peer interaction for MVASD are even more overlooked, despite this population's severe social withdrawal and lack of spontaneous communication. To date, school-age MVASD intervention was adapted from preschool ages, targeted promotion of spoken words, mainly focused on child-adult interaction, and rarely used RCT (Tager-Flusberg & Kasari, 2013).
Objectives:
This study examined the efficacy of a novel manualized RCT, a school-based peer social intervention (S-PSI) designed specifically for MVASD. Its major aim was to increase minimally verbal children's ability to spontaneously interact with peers via preferred communication channels (sign language, computer, tablet, gesture, writing). The study compared two intervention groups targeting core ASD areas of social deficiency – social conversation (*Convers.*) vs. social collaboration (*Collab.*) – vs. a delayed treatment (*Control*) group. Contrasting the two interventions and comparing with controls aimed to identify which children benefited most from each intervention.
Methods:
N=54 participants with MVASD (8-16 years, Peabody receptive language: 37-101; Raven performance IQ: 38-127) were randomly assigned to one of three groups (*Convers., Collab., Control*, *n*=18 per group). Manualized interventions included 60 lessons over 15 weeks (4 per week) in children's special education schools, implemented by children's teachers and supervised by the research team. Both interventions emphasized peer-interaction in fixed peer-dyads matched for preferred communication channel, combining learning and practice with fun activities and games. The *Convers.* group focused on rules, topics, question asking, etc., whereas the *Collab*. group focused on working together, sharing, helping, etc. Children's pretest-posttest improvement in spontaneous peer-interaction was measured by social and communication scales (Vineland Adaptive Behavior Scale, Sparrow et al., 1984) completed by teachers who did not participate in treatment, and research team's direct observation of children's free-play social interactions. Several secondary outcomes were also measured, including children's executive functions and metacognitive abilities (EF-BRIEF, Gioia et al., 2000).
Results: Â Preliminary results demonstrated significant Group X Time effect for the overall Vineland, with *Convers.* showing significant gains, *F*=6.33, *p*<.05, *Collab.* showing near-significant improvement, *F*=3.46, *p*=.069, and *Contol* showing no significant change over time. Gains over time also emerged in Vineland-social subscales: for both intervention groups in interpersonal relationships (*Convers.: p*=.05; *Collab.: p*=.008) and for *Convers.* in play and leisure time (*p*=.011). Results of observations are still undergoing between - and within-group analyses (e.g., by Receptive and performance IQ, CA, EF) to identify who benefited most from which intervention. Interesting trends emerged on the EF-BRIEF, with the *Control* group showing regression over time in planning, organization, and monitoring, whereas the *Convers.* group showed gains in organization and monitoring.
Conclusions:
This S-PSI was the first school-based RCT to increase spontaneous peer-interaction that was directly oriented towards the needs of minimally verbal children along the spectrum. Preliminary results are positive. Strengthening these school-age children's ability to interact more spontaneously with peers holds promise for reducing this high-risk population's social withdrawal.

Oral Session - 13B
188 - Evaluating Outcomes in Social Skills Training
2:10 PM - 3:00 PM - Yerba Buena 8

Session Moderator: Elizabeth Laugeson, *Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

2:10 **188.001** Adolescents with Autism Spectrum Disorder and Social Skills Groups at School: A Randomized Trial Comparing Intervention Approach and Peer Composition

M. Dean[1], *J. Williams*[2], *C. Kasari*[3] *and F. Orlich*[4], *(1)California State University, Channel Islands, Camarillo, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Center for Child Health, Behavior and Development, Seattle Children's Hospital, Seattle, WA*

Background:
Social relationships become increasingly complex during adolescence (Rodkin & Ryan, 2012). Adolescents with autism report having poorer peer relationships, including fewer friends, and less satisfying companionship with their friends compared to typically developing adolescents of the same age (Bauminger & Kasari, 2000). Within general education settings these students report fewer reciprocal friendships (Chamberlain, Kasari & Rotheram-Fuller, 2007), greater loneliness at school (Bauminger & Kasari, 2000), and poorer friendship quality (Bauminger & Kasari, 2000; Chamberlain et al, 2007; Locke et al, 2010) than their classmates. Studies that examine social skills interventions for adolescents with autism generally take place in clinic settings (Laugeson et al., 2014; White, et al., 2013). In the current study, we examined the efficacy of implementing social skills interventions for adolescents with autism at school.
Objectives:
The purpose of this study was to test the effectiveness of two distinct models of social skills group interventions (SKILLS and ENGAGE) with an ethnically and economically diverse group of school age adolescents with autism.
Methods:
We used a randomized controlled multi-site study to compare two different school-based social skills interventions for adolescents with autism. Sixty-one adolescents (ages 13-17) with autism without cognitive impairment participated in the study. Participants were ethnically diverse (Black = 8%, white = 43%, Hispanic = 9%, Asian = 21%, and other or mixed = 14%), and were educated in secondary school general education classrooms. After meeting eligibility criteria, participants were randomized to either a SKILLS or an ENGAGE condition. All group members in the SKILLS condition had a diagnosis of autism. The ENGAGE condition was peer-mediated, and the group consisted of adolescents with autism and typically developing adolescents. Data were collected prior to the start of the intervention, at the end of the intervention, and at fourteen weeks later. Groups met one time a week for eight weeks during lunch or afterschool. Peer engagement states (Joint Engagement, Parallel, and Solitary) were the primary outcome variables.
Results:
We used a linear mixed model with random effects for each participant, and main effects for time, site, treatment, race and a three-way interaction of time-by-treatment-by-race. We found differences approaching significance in Joint Engagement during unstructured times, indicating that the SKILLS intervention increased the Joint Engagement of Caucasian participants, but decreased Joint Engagement in Asian participants (p-value=0.06). There was a significant interaction of treatment by time by race interaction (p-value=0.02, chi-square (4)=12.24). The ENGAGE intervention was effective in raising Parallel for both Caucasian and Asian students, but it seemed to have a negative effect for the other racial groups. Similar effects were identified in Solitary engagement. There was a difference of treatment over time by racial group controlling for site (p-value=0.006). Non-white or Asian decreased their Solitary engagement more than Caucasian or Asian participants.
Conclusions:
Results support the efficacy of social skills interventions for adolescents with autism at school. However, findings highlight the heterogeneity existing within populations of students with autism in ethnically diverse schools. More research is needed to examine cultural factors that influence participant responsiveness to intervention.

2:22 **188.002** Evaluating Changes in Dynamic Social Interaction Skills Following a Randomized Controlled Trial of the START Socialization Intervention for Adolescents with ASD

***J. Ko**, A. Miller, A. Barrett, E. McGarry and T. Vernon, University of California Santa Barbara, Santa Barbara, CA*

Background: Treatment outcomes of interventions for Autism Spectrum Disorder (ASD), as well as social interventions in particular, have been primarily evaluated using parent report measures (Miller et al. 2014). These measures, while serving as valuable indicators of improvement, have notable limitations related to social desirability and other reporting biases (Moskowitz, 2006). Consequently, researchers are calling for more rigorous measurement tools to assess the effects of interventions (e.g. Lord et al., 2005; McMahon et al., 2013). Behavioral observations provide an objective and quantifiable outcome measure that can augment traditionally used survey measures. Systematic coding of observed behaviors during live social exchanges may offer a rigorous method for assessing changes in social competence.
Objectives: This study used direct observation of dynamic social interaction skills during video-recorded conversations to assess the efficacy of a randomized controlled trial (RCT) of the Social Tools and Rules for Teens (START) socialization intervention for adolescents with ASD.
Methods: Thirty-five adolescents with high-functioning ASD, ages 12-17 years, were enrolled in an RCT of the START program. Adolescents were randomized to either a treatment or waitlist group. The 20-week group intervention took place once a week for 90-minutes per session. Five-minute “get to know you” conversations between participants and similar-aged students, whom they have never met, were video-recorded at pre-intervention and post-intervention. Trained and reliable research assistants, but blind to condition and time point, systematically coded the videos for three types of social behaviors targeted during the intervention: question asking, mutual engagement, and positive facial expressions. An ANCOVA, using pre-intervention values of each social behavior as the covariate, compared the outcomes of the treatment and waitlist groups on the target social behaviors to examine if there was a difference. Paired samples t-tests were performed to examine the whole cohort of adolescents who completed the START program, and assess differences between pre-intervention and post-intervention.
Results: Results of the ANCOVA revealed a significant treatment effect for both question asking and positive facial expressions ($p < 0.05$). These skills additionally exhibited significant moderate to strong positive correlations (r values ranging from 0.47 to 0.61) with peer ratings of social ability ($p < 0.01$), which were made by blind observers after watching the video-recorded conversations. Examining the whole cohort collectively revealed significant increases in all three social behaviors from pre-intervention to post-intervention ($p < 0.05$).
Conclusions: To our knowledge, this study presents the first RCT utilizing behavioral coding of dynamic social exchanges to assess the efficacy of a social intervention for adolescents with ASD. Overall, the START program appears to positively impact the use of several verbal and nonverbal conversational strategies that are crucial for both social skill development and positive social impressions. Behavioral coding of specific target behaviors allows an unbiased, directly observable method for measuring social change that cannot be adequately captured by survey measures alone but serves to supplement the results from these measures. These findings provide evidence that these specific social behaviors may be linked to social desirability in every day interactions.

2:34 **188.003** Changes in EEG Asymmetry, ERP to Affective Stimuli, and Social Motivation and Cognition in Young Adults Completing PEERS® Intervention

***B. Dolan**[1], A. Barrington[1], H. K. Schiltz[1], A. McVey[1], S. Stevens[2], K. A. Willar[3], J. S. Karst[4], W. Krueger[1], C. Suhling[1], D. Snyder[1], R. McKindles[1], K. Reiter[1], S. Potts[1], C. Caiozzo[1], A. D. Haendel[5], S. Timmer-Murillo[1], S. Chesney[1], N. Gordon[1] and A. V. Van Hecke[1], (1)Marquette University, Milwaukee, WI, (2)University of Minnesota Medical School, Blaine, MN, (3)Children's Hospital Colorado, Aurora, CO, (4)Medical College of WI, Wauwatosa, WI, (5)Interdisciplinary PhD program (Psychology and Biomed Science), Marquette University, Milwaukee, WI*

Background: Social challenges amongst adults with ASD lead to isolation, lack of friendships, and emotional difficulties (Venter, Lord, & Schopler, 1992). The *Program for the Education and Enrichment of Relational Skills for Young Adults* (PEERS®: Gantman, Kapp, Orenski, & Laugeson, 2012) teaches verbal young adults with ASD the social skills needed in order to make and keep friends. The program was based on PEERS® for adolescents (Laugeson & Frankel, 2010). One study (Van Hecke et al., 2013) found that adolescent PEERS® participants showed changes in EEG (electroencephalogram) asymmetry, indicative of more relative left hemisphere activation, that was also related to social contact gained from the program.
Objectives: No published studies have evaluated the effects of PEERS® for Young Adults on brain function. This study will examine how PEERS® affects measures of EEG asymmetry and ERP (evoked response potential). This study also seeks to understand whether behavioral improvements from the intervention are related to changes in EEG asymmetry and ERP.
Methods: The analysis included 32 young adults with ASD (18 to 26 years old), split evenly between the Experimental Immediate treatment (EXP), and the Waitlist Control (WL) group. All participants had a verbal IQ > 70 and diagnoses were confirmed with the ADOS. The intervention was a randomized controlled trial (RCT) of PEERS® for Young Adults. Measures were taken at pre- and post-intervention and included: (1) the *Social Responsiveness Scale* (caregiver report; SRS: Constantino, 2005); (2) a 3-minute resting state EEG, from which frontal and temporal-parietal alpha asymmetry were calculated, and (3) and an ERP paradigm utilizing positive and negative social/nonsocial IAPS (International Affective Picture System: Lang, Bradley, & Cuthbert, 2008).
Results: A significant time by group interaction for alpha asymmetry in the temporal-parietal region was found ($F(1, 19) = 4.37$, $p < .05$), indicating a relative increase in left-hemisphere activity in the EXP group, versus a decrease in the WL group. Higher relative activity in the left temporal-parietal region at post-treatment was significantly related to better SRS Social Cognition at post-treatment ($r(21) = .49$, $p < .05$) and improvements in SRS Social Motivation ($r(21) = -.45$, $p < .05$).
Preliminary analysis of available ERP data indicated a significant time by group interaction on P300 responses to social, positive IAPS images, which was driven by an increase in P300 amplitude for the EXP group, vs. a decrease for the WL group. Planned analyses will include two additional cohorts of young adults to further assess PEERS®' effects on caregiver-report on the SRS, as well as augment EEG asymmetry and ERP analyses.
Conclusions: Young adults receiving the PEERS® intervention demonstrated significant changes in EEG asymmetry and ERP to social, positive images, and levels of asymmetry after conclusion of the intervention were related to caregiver reports of social motivation and cognition. The results from this study corroborate neural outcomes of PEERS® reported on adolescents with ASD (Van Hecke et al., 2013).

2:46 **188.004** Caregiver Vs. Adolescent Report of Internalizing Symptoms and Relationship to Physiological Arousal Across the PEERS® Intervention

A. Arias[1], *A. McVey*[1], *H. K. Schiltz*[1], *A. D. Haendel*[2], *B. Dolan*[1], *K. A. Willar*[3], *S. Stevens*[4], *J. S. Karst*[5], *A. M. Carson*[6], *F. Mata-Greve*[1], *E. Vogt*[1], *K. M. Rivera*[1], *E. Habisohn*[1], *J. Hilger*[7], *N. Fritz*[1] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Interdisciplinary PhD program (Psychology and Biomed Science), Marquette University, Milwaukee, WI, (3)Children's Hospital Colorado, Aurora, CO, (4)University of Minnesota Medical School, Blaine, MN, (5)Medical College of WI, Wauwatosa, WI, (6)Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (7)Illinois State University, Normal, IL*

Background: Self- and parent/caregiver-report measures are commonly used to assess symptoms of anxiety and depression among adolescents with ASD. However, agreement in these reports has been found to be low (May et al., 2015). Respiratory Sinus Arrhythmia (RSA) and Heart Period (HP) are used to measure physiological arousal associated with anxiety and depression (Licht et al., 2009). In the present study, RSA and HP were used as a more "objective" reference point for the base level of adolescent anxious and depressive symptoms. No known study to date has examined change in discrepancy of self- and parent/caregiver-report measures over the course of a well-validated social skills intervention.
Objectives: Â 1) Determine discrepancies between adolescent self- and parent/caregiver-report of anxious and depressive symptoms at pre- and post-intervention. 2) Explore how two measures of physiological arousal, RSA and HP, compared to self- and parent/caregiver-report at both time points. 3) Examine change in discrepancies in report from pre- to post-intervention.
Methods: 139 adolescents with ASD aged 11-16 and their parents/caregivers participated. Descriptive statistics are in Table 1. A randomized controlled trial (RCT: experimental vs. waitlist control) of the PEERS® intervention (Laugeson & Frankel, 2010) was conducted. Data at pre- and post-PEERS® included self- and parent/caregiver-report of the Social Anxiety Scale-Adolescent (SAD-NEW, fear and anxiety about unfamiliar peers), Spence Children's Anxiety Scale (SCAS), Short Mood and Feelings Questionnaire (SMFQ) and Child Behavior Checklist (CBCL)/Youth Self Report (YSR) Anxious/Depressed, Withdrawn/Depressed, Internalizing Problems subscales, as well as RSA and HP from a sub-sample of participants ($n_{overall}=63$; $n_{waitlist}=29$).
Results: Preliminary results revealed the following effects and correlations. Repeated Measures ANOVAs for Group (EXP vs WL) by Reporter (Parent/caregiver vs. Teen) showed significant main effects for Reporter on the SAS-NEW at Pre, $F(1,117)=23.47$, $p<.001$ and Post, $F(1,122)=48.22$, $p<.001$; Spence at Pre, $F(1,54)=17.51$, $p<.001$; CBCL/YSR Anxious/Depressed at Post, $F(1,44)=7.26$, $p=.01$; CBCL/YSR Withdrawn/Depressed subscale at Post, $F(1,44)=6.17$, $p=.02$. Correlations between behavioral measures and RSA at both time points revealed a significant relationship between RSA and EXP parent/caregiver reports at Post on the CBCL Internalizing Problems subscale, $r(32)=-.585$, $p=.036$, and the Anxious/Depressed subscale, $r(32)=-.645$, $p=.017$. No other correlations were significant.
Conclusions: Results demonstrate reporter discrepancies and correlations between RSA and parent/caregiver-reports. Because no significant correlations in RSA and self-report were uncovered, and lower values of RSA are shown to be associated with higher anxiety, parents/caregivers may be more accurate in reporting adolescents' symptoms post-intervention. This may be a byproduct of the intervention's focus on behavior that results in parents/caregivers recognizing their adolescent's social difficulties more accurately. Discrepancies present prior to intervention may be the result of parent/caregivers' difficulty in recognizing internalizing symptoms (Sourander, Helstelä, & Helenius, 1999). At post-intervention, for the waitlist group, discrepancies on the CBCL/YSR subscales may be due to the parents/caregivers' perceived expectations of themselves in being part of a research study leading them to assess symptoms differently than at the pre- time point.

Oral Session - 14A
189 - Functional Connectivity in ASD: From Infancy to Adulthood
1:15 PM - 2:05 PM - Yerba Buena 9

Session Moderator: Shafali Jeste, *UCLA, Los Angeles, CA*

1:15 **189.001** Altered Patterns of Local Connectivity in Autism Measured By Regional Homogeneity

S. Nair, *R. K. Kana and N. Loomba, University of Alabama at Birmingham, Birmingham, AL*

Background: Disruption in functional connection has been a characteristic feature of brain functioning in autism spectrum disorders (ASD). Studies of regional homogeneity (ReHo), which measure local connectivity, in autism have provided somewhat inconsistent results. Previous reports of local overconnectivity in visual cortices during rest in ASD (Maximo et al., 2013; Keown et al., 2013) were not replicated in some studies using a large shared database ABIDE (Autism Brain Imaging Data Exchange) (DiMartino et al., 2013; Dajani & Uddin, 2015). However, eye status during rest was not accounted for in these studies (samples included both eyes open and eyes closed scans), and studies presented both standardized and unstandardized connectivity maps. Our recent study of subsamples from ABIDE showed variable patterns of posterior ReHo across eye status and processing pipelines (Nair et al., under review).
Objectives: To use a data-driven approach in examining the patterns of local brain connectivity in autism as a function of eye status and processing pipelines during resting state fMRI.
Methods: Resting state fMRI data from ABIDE-II database (Georgetown University sample) were preprocessed using standard processing stream, including motion correction, spatial and temporal filtering, and analysis was performed with global signal regression (GSR). Time points with motion >.5mm were censored, and participants with >80% time points remaining after censoring were included in the analysis. Participants were matched on age (8-14 years; M=11), IQ (93-147; M=116), and RMSD (.03-.14; M=.08), resulting in final samples of 31 ASD, 35 TD participants. Voxel-wise ReHo maps (AFNI's *3dReho*) were derived and standardized, and 2 two-sample t-tests were conducted for standardized and unstandardized ReHo pipelines.
Results: Standardized analysis yielded local overconnectivity in ASD in bilateral paracentral lobule, left precuneus and fusiform gyrus, left superior frontal gyrus, and left inferior parietal lobule (IPL). Local underconnectivity was detected in ASD in bilateral cuneus, right cerebellum and superior temporal gyrus.Â Unstandardized analysis yielded local overconnectivity in ASD in bilateral paracentral lobule and precuneus, left fusiform gyrus, IPL, middle temporal gyrus, inferior frontal gyrus, left cerebellum, and right middle frontal gyrus, and local underconnectivity in right cerebellum. Results were cluster-corrected using Monte Carlo simulations to obtain a corrected significance level of $p<.05$ (uncorrected $p<.01$) and cluster size of 41 voxels (AFNI's *3dClustSim*).
Conclusions: While DiMartino et al. and Dajani & Uddin reported overall patterns of local underconnectivity across posterior areas and overconnectivity across anterior areas (using mixed eyes open and eyes closed sample), both ReHo processing pipelines in the present study do not show such a distinct anterior-posterior pattern of local connectivity. This variable pattern of connectivity in standardized analysis is novel and interesting. Additionally, lateralization effects entailed general diffuse overconnectivity for left and underconnectivity for right hemisphere in ASD. These findings are preliminary and our future analyses will utilize low-motion, high quality eyes open and eyes closed data from ABIDE-II. Assessing differences across local connectivity studies in ASD in relation to our findings is important, as they may underscore effects of multisite data and methodological variability.

1:27 **189.002** Longitudinal Changes in Functional Connectivity in Autism Spectrum Disorder

K. E. Lawrence[1]*, L. M. Hernandez*[2]*, H. Bowman*[3]*, S. Y. Bookheimer*[1] *and M. Dapretto*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)NPI Psychiatry, UCLA, Los Angeles, CA*

Background: Autism spectrum disorder (ASD) has consistently been linked to altered functional connectivity in the brain. However, there are conflicting results as to whether the autistic brain is characterized by increased or decreased connectivity. One recent theory argues that such discrepancies in the functional connectivity literature are due to an atypical developmental trajectory in ASD, as hyperconnectivitiy is more likely to be reported in studies focusing on children, and hypoconnectivity in studies focusing on adolescents or adults (Uddin et al., 2013). Evidence from structural brain connectivity and volumetric studies likewise support the possibility of an atypical developmental course from childhood through adulthood in ASD (Bakhtiari et al., 2012; Hua et al., 2013). However, all studies investigating the developmental trajectory of functional connectivity in ASD thus far have used cross-sectional samples. Yet longitudinal studies are crucial for better understanding how connectivity alterations in ASD may relate to age: longitudinal samples allow for greater sensitivity when mapping trajectories and comparing age groups, as well as greater confidence that age-dependent findings are not due to inherent differences between the subjects included in each age cohort
Objectives: Using a longitudinal sample, characterize how functional connectivity in key intrinsic connectivity networks (e.g. default mode network, DMN; salience network, SN) evolves from early- to late-adolescence in ASD relative to typical development, and investigate the extent to which observed patterns of atypical connectivity in ASD are age-dependent.
Methods: A total of 41 individuals completed a resting-state functional MRI scan in both early-adolescence and late-adolescence; the mean age at time point 1 was 12.74 + 0.92 years old, and the mean age at time point 2 was 15.8 + 0.93 years old. DMN functional connectivity was investigated using a seed located in the posterior cingulate cortex (PCC), and scrubbing was applied to reduce potential motion confounds (Power et al., 2012). Initial group comparisons, focusing on the DMN in a subset of these participants, were completed in FSL and prethresholded with a joint mask of the within group results. Connectivity z-scores were subsequently extracted from regions which displayed an effect of diagnosis and analyzed using a 2 (diagnosis) by 2 (time point) ANOVA.
Results: Both diagnostic groups displayed greater local connectivity with the PCC and angular gyrus in early-adolescence than in late-adolescence. Relative to the TD group, the ASD group displayed hyperconnectivity with the angular gyrus in early-adolescence, and hyperconnectivity of the PCC and medial prefrontal cortex in late adolescence. When extracting connectivity estimates, these regions displayed a significant interaction between diagnosis and time point such that the developmental trajectory of functional connectivity differed between the ASD and TD groups. Furthermore, the connectivity alterations present in ASD in early-adolescence were not present in late adolescence and vice versa when using this region-of-interest approach.
Conclusions: These initial results show distinct patterns of altered DMN connectivity during early vs. late adolescence, which may contribute to the age-dependence of atypical connectivity findings in ASD. Overall, these findings highlight the value of using a longitudinal design when assessing atypical developmental trajectories.

1:39 **189.003** Age-Dependent Alterations in Resting State Connectivity in the Broader Autism Phenotype - a Twin Study

J. Neufeld[1]*, P. Fransson*[2]*, R. Kuja-Halkola*[3]*, E. Cauvet*[1]*, K. Mevel*[4] *and S. Bolte*[1]*, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (2)Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, (3)Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, (4)Laboratory for the Psychology of Child Development and Education (LaPsyDÉ), CNRS UMR 8240, Sorbonne Paris Cité, GIP Cyceron, Université de Caen Normandie, Université Paris Descartes, Paris, France, Paris, France*

Background: Altered functional brain connectivity during the resting state (RS) has commonly been reported in individuals diagnosed with Autism Spectrum Condition (ASC). However, findings are largely inconsistent, showing both increased and decreased connectivity in various regions. Insufficient control for confounding factors, such as genetic and environmental influences, but also head motion during brain scanning (Power et al., 2012), potentially lead to biased results. Further, recent studies suggest that altered connectivity in ASC compared to typically developing (TD) individuals might be age-dependent (Nomi & Uddin, 2015; Dajani & Uddin 2015; Alaerts et al., 2015) while only few studies tested age-effects.
Objectives: The current study aims to specifically test connectivity within two RS networks commonly reported to be altered in ASC: the Default Mode Network (DMN) and the Salience Network (SN). In order to gain more conclusive results 1) a marked reduction of confounding is achieved using a twin design (Mevel et al., 2014) while 2) carefully controlling for head motion. Further, 3) in accordance with the Research Domain Criteria (RDoC) we focus on dimensional rather than categorical outcomes (Insel et al., 2010) and 4) stratification by age is applied in order to detect age-specific differences.
Methods: Monozygotic (MZ) and dizygotic (DZ) twins (N=150, 61.3%MZ; 64%male, age:8-23years, mean=16.2+/-3.3) underwent diagnostic (ADOS/ADI-R), as well as brain imaging assessments including RS fMRI (Bölte et al., 2014). Further behavioral investigations included IQ testing (WISC/WAIS) and autistic traits were assessed using the Social Responsiveness Scale (SRS). Functional images were pre-processed in AFNI, including nuisance signal regression (local white matter lateral ventricle signal) and motion-censoring. RS connectivity (temporal correlations) between major hubs of the DMN (posterior cingulate cortex: [-6,-44,34]; ventromedial prefrontal cortex: [-2,38,-12]) and the SN (right anterior insula:[39,23,-4]; anterior cingulate cortex: [6,24,32]), respectively, were calculated. Conditional linear regressions in R were used to model within-pair associations between RS connectivity and autistic traits while controlling for head motion and IQ. In a second step, analyses were repeated while stratifying by age (children: 8-13, N=44; adolescents: 14-17, N=62; adults: 18-23 years, N=44).
Results: A significant positive within-pair association was found in the whole sample between autistic traits and within-SN connectivity (i.e. between anterior insula and anterior cingulate cortex; β=0.003; Z=2.77; p=0.006; SEM=0.001). In contrast, a negative within-pair association between within-DMN connectivity (posterior cingulate to ventromedial prefrontal cortex) and autistic traits was found only after stratifying by age in adolescents (β=-0.002; Z=-2.24; p=0.025; SEM=0.001) and adults (β=-0.002; Z=-2.06; p=0.040; SEM=0.001) but not in children (β=0.00015; Z=1.426; p=0.154; SEM=0.001).
Conclusions: The results are in line with previous reports of altered RS connectivity in ASC and suggest SN and DMN connectivity as promising candidate biomarkers for ASC. They are further consistent with contemporary developmental models of ASC (Uddin, Supekar, and Menon, 2013), supporting the idea of early over-connectivity and under-connectivity later in life and underline the importance of testing for age effects. However, our results suggest that connectivity differences as well as developmental trajectories of the latter might be network-specific rather than generalizable across the brain.

1:51 **189.004** Decoupling of the GABA / Gamma Relationship during Development in ASD – the Impact of an Atypical Developmental Trajectory

T. P. Roberts[1]*, R. G. Port*[1]*, W. Gaetz*[1]*, L. Bloy*[1]*, L. Blaskey*[1]*, E. S. Kuschner*[1]*, E. S. Brodkin*[2] *and S. E. Levy*[1]*, (1)The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background:
It is believed that neuronal ensemble oscillatory activity, recorded in-vivo using electrophysiological techniques such as electroencephalography (EEG) and magnetoencephalography (MEG), reflects the integrity of underlying local circuitry. Furthermore, the precise operation of such local circuitry is maintained by the delicate balance of excitatory and inhibitory influences, mediated by the neurotransmitters, glutamate and GABA.
Objectives:
The objective of this study is to observe the relationship between estimates of GABA levels, derived from edited magnetic resonance spectroscopy (MEGAPRESS-MRS), and gamma-band oscillatory activity elicited from cortex and recorded using magnetoencephalography (MEG). Specifically, the multi modal study is executed in both children (across a broad age range) and adults in order to determine both the developmental trajectory and ultimate asymptote of each measure, as well as their correlation, or coupling.
Methods:
Spectrally-edited MEGAPRESS MRS from voxels in superior temporal gyrus were obtained in children (age 6-14) and young adults (age 18-40) with ASD as well as typically-developing (TD) controls (N=42 ASD, N=32 TD). In the same subjects, gamma-band oscillatory activity elicited by simple auditory stimulation was recorded using magnetoencephalography and localized to auditory cortex using a beamforming algorithm. Dependent variables were GABA/Cr ratios for MRS and gamma-band phase-locking for MEG. Linear mixed modeling and hierarchical regression were performed across the age range as well as separately for children and adults.
Results:
Across the entire age-range, both GABA/Cr ratios and gamma-band phase locking values were significantly reduced in ASD vs. TD. For GABA/Cr: ASD=0.28+/-0.01, TD=0.31+/-0.01, F=7.93, p<0.01. For gamma-band phase locking: ASD=0.058+/-0.003, TD=0.067+/-0.003, F=4.94, p<0.05. Critically, while in TD children there was a strong coupling between GABA and gamma measures (robust regression, p<0.01), no such correlation was observed in children with ASD (p>0.05). Furthermore, in adults, there was a significant difference in gamma-band oscillatory phase locking between TD and ASD (0.069+/-0.04 vs. 0.57+/-0.004, F=5.25, p<0.01).
Conclusions:
Multimodal studies of neurochemistry and electrophysiology suggest a tight coupling of GABA levels and gamma-band phase synchrony during typical development, interpreted as the formation of intact cortical local circuitry. Consequently, in typical adulthood a high level of gamma-band phase synchrony is observed. Conversely, in ASD, such tight coupling is not observed during development; in adulthood gamma-band phase synchrony also appears to be reduced compared with TD controls. We conclude that there is a critical developmental window in childhood for the formation of local neuronal circuitry, which is associated with a tight association between GABA levels and gamma-band activity. This association is disrupted in ASD during development, with consequent reduction in electrophysiological evidence of local circuitry functioning in adulthood.

Oral Session - 14B
190 - Early Brain Development
2:10 PM - 3:00 PM - Yerba Buena 9

Session Moderator: Shafali Jeste, *UCLA, Los Angeles, CA*

2:10 **190.001** Altered Early Development of Resting-State Network Properties in Infants at High Risk for Autism Spectrum Disorder.

A. Nair[1]*, T. Tsang*[2]*, J. Liu*[2]*, L. P. Jackson*[3]*, C. Ponting*[4]*, H. Bowman*[5]*, S. S. Jeste*[6]*, S. Y. Bookheimer*[2] *and M. Dapretto*[2]*, (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Semel Institute, UCLA, Los Angeles, CA, (4)Clinical Psychology, UCLA, Los Angeles, CA, (5)NPI Psychiatry, UCLA, Los Angeles, CA, (6)UCLA, Los Angeles, CA*

Background: Graph theory is a quantitative technique to measure complex dynamics and small-world topology (i.e., segregation of nearby-networks and integration of more distant networks) between brain networks (Bullmore and Sporns, 2009). Prior studies with healthy neonates have applied graph theoretical analysis to characterize early development of functional networks (Gao et al., 2011; Fransson et al., 2011, De Asis-Cruz, 2015). These studies have shown that functional networks in neonates exhibit similar small-world characteristics as in adults, albeit with denser connections in sensorimotor hubs in infants and in association cortices in adults. However, little is known about early development of small-world topology in infants at elevated risk for autism spectrum disorder (ASD).
Objectives: Given prior studies implicating disrupted cortical connectivity in ASD etiology (Rudie et al., 2013, Kana et al., 2014), it is crucial to understand the evolution of small-world topology of functional networks in infants at high risk for ASD.
Methods: Resting-state fcMRI (rs-fcMRI) data were acquired during natural sleep for 8 minutes on a 3T Siemens scanner for 24 infant siblings (6 weeks post-birth) of children with ASD (i.e., high-risk group; HR) and 28 infants at low risk (LR) for ASD (i.e., no family history of ASD). Data were preprocessed using AFNI and FSL, including motion correction, spatial smoothing, isolation of low frequency fluctuations (.008<*f*<.08), and normalization to the UNC Infant 0-1-2 neonate atlas (Shi, 2011). Time-series were extracted for all voxels within 45 bilateral cortical and subcortical regions of interest (ROIs) using the same atlas. Correlations were computed between all ROI pairs resulting in a 45x45 functional connectivity matrix. Graph theory metrics were used to examine the density of connectivity between ROI pairs (i.e., the percentage of possible voxel in each ROI pair that are correlated above a specified threshold, r>.25, p<.001). Two sample t-tests were performed on z-transformed density values to identify group differences in connection density for each ROI pair.
Results: Consistent with prior studies, results indicated greater overall connection density for rs-fcMRI networks in sensorimotor and subcortical regions in both groups. Between-group comparisons revealed increased connection density for more ROIs pairs in the HR group as compared to the LR group. Specifically, regions involved in visual and sensorimotor processing (i.e., cuneus, middle occipital gyrus, paracentral lobule) demonstrated greater connection density in the HR group compared to the LR group. In contrast, the LR group showed greater connection density in temporal (especially fusiform gyrus) and prefrontal ROIs compared to the HR group.
Conclusions: Our findings suggest that functional network properties may be disrupted as early as the first weeks of life in infants at high risk of developing ASD. Further longitudinal assessment is required to determine if these early differences in connection density could serve as a biomarker in predicting which infants within the HR group will later meet criteria for diagnosis of ASD.

2:22 **190.002** Functional Neuroimaging in High-Risk 6-Month-Old Infants Predicts Later Autism

R. Emerson[1], *C. Adams*[2], *T. Nishino*[2], *H. C. Hazlett*[1], *J. J. Wolff*[3], *L. Zwaigenbaum*[4], *J. N. Constantino*[5], *M. D. Shen*[1], *M. R. Swanson*[6], *J. T. Elison*[3], *S. Kandala*[2], *A. Estes*[7], *K. Botteron*[8], *D. L. Collins*[9], *S. Dager*[10], *A. C. Evans*[11], *G. Gerig*[12], *H. Gu*[13], *R. McKinstry*[14], *S. Paterson*[15], *R. T. Schultz*[16], *M. Background: Effective early interventions that can ameliorate the defining deficits of ASD and improve long-term outcomes rely on early detection. One barrier to early (i.e., prior to 24 months) detection is that the defining behavioral characteristics of ASD generally unfold during the second year of life, sometimes not showing consolidation of the full behavioral syndrome around 24 months or later.
Recent research using functional connectivity magnetic resonance imaging (fcMRI) has linked the functional organization of the human brain to individual cognitive profiles. These measures of brain functional connectivity are reliable and can accommodate participants as young as neonates. Furthermore, in conjunction with machine learning approaches, fcMRI data has provided predictions of brain maturation and diagnostic category at the single-subject level.
Objectives: We aimed to use functional neuroimaging with 6-month-old infants to identify which individual children will receive a research clinical best estimate diagnosis of ASD at 24 months of age.
Methods: Prospective neuroimaging and behavioral data were collected from 59 naturally sleeping infants at high familial risk for developing ASD. First, we defined functional connections in the 6-month-old brain that correlated with 24-month scores on assessments of social interactions, communication, motor development, and repetitive behavior – all features common to the diagnosis of ASD. We then used a fully cross-validated machine learning algorithm to demonstrate that fcMRI can identify 6-month-old infants who progressed to a clinical diagnosis of ASD at 24 months of age. For each infant, we defined brain features and trained a classifier using an independent set of 58 high-risk infants. We then predicted that infant's future diagnosis using only information from their 6-month functional neuroimaging scan. To test the generalizability and validity of our results, we used a similar classification analysis with a greater number of subjects held independent (leave-10-out).
Results: Â The overall classification accuracy for later ASD using functional connectivity data in 6-month old infants was 96.6% (95% CI 87.3–99.4, p<0.001). The positive predictive value of this approach was 100% (95% confidence interval [CI], 62.9–100), correctly predicting 9 of 11 infants who received a diagnosis of ASD at 24 months (sensitivity 81.8% [95% CI 47.8–96.8]).Â All 48 6-month-old infants who were not diagnosed with ASD were correctly classified (specificity 100% [95% CI, 90.8–100]; negative predictive value 96.0% [95% CI 85.1–99.3]). On average, the leave-ten-out analysis performed with 92.7 ± 0.7% accuracy.
Conclusions: These findings demonstrate the potential for early detection of autism in infants at high familial risk and serve as a proof-of-concept that patterns of infant brain measures precede the defining behavioral characteristics of ASD.Â Ultimately, this study represents an initial, but critical, first step toward developing infant diagnostic methods and enabling efficient tests of infant interventions.

2:34 **190.003** Early Developing Functional Connectivity Between Default Mode, Salience, Attention, and Visual Networks Underpins Autism and a Subgroup with Preference for Geometric Images and Lack of Social Orienting

M. V. Lombardo[1,2], *M. Datko*[3], *L. T. Eyler*[3], *C. C. Barnes*[3], *E. Courchesne*[3] *and K. Pierce*[3], *(1)University of Cyprus, Nicosia, Cyprus, (2)University of Cambridge, Cambridge, United Kingdom, (3)University of California, San Diego, San Diego, CA*

Background:
The way in which a toddler with autism (ASD) may atypically sample the social environment during the first years of life may play an important role in shaping experience-dependent neurobiological processes. Most typically-developing (TD) toddlers as well as some toddlers with ASD show early a visual preference for social images when given the choice to look at social versus non-social geometric visual displays. However, we have consistently found that there is a subgroup within early developing ASD toddlers (GeoASD) who atypically lack this preference for social stimuli in their first 4 years of life and instead prefer geometric images (Pierce et al., 2011, 2016). We predicted that this atypical lack of early social orienting may be underpinned by hypoconnectivity between large-scale neural circuits developing early specialization for visual, attention, salience, social cognition/communication functions.
Objectives:
To examine how ASD subgroups defined by early social or non-social geometric visual preferences measured via the GeoPref eye tracking test (Pierce et al., 2011, 2016) are differentiated in intrinsic functional connectivity measured with resting state fMRI (rsfMRI). We predicted hypoconnectivity in an ASD subgroup with preference for non-social geometric displays (GeoASD), particularly between visual, attention, salience, and default mode neural circuits.
Methods:
n=78 ASD (GeoASD n=16, nonGeoASD n = 62) and n=55 scan age and sex-matched TD individuals (age 12-48 months) were evaluated using the GeoPref eye tracking test and also had a 6 min 25 seconds rsfMRI scan during natural sleep. Data were preprocessed using AFNI and denoised by regressing out 6 motion parameters and their derivatives, CSF signal, as well as removal of further noise-related variability identified with wavelet denoising techniques (Patel et al., 2014, Neuroimage). Groups did not differ in mean framewise displacement or DVARS before and after denoising. FSL MELODIC Group Independent Components Analysis (ICA) and dual regression were utilized to identify networks as components. Nine components were identified as default mode, attention, salience, or visual networks and connectivity between these components was estimated with robust regression to be insensitive to outliers. Group differences were examined with ANOVA and multiple comparison correction (FDR q<0.05).
Results:
Confirming our hypotheses, we found significant effects of group for 7 of the total 36 comparisons (all F>8.84, all p<0.0035, all survive FDR q<0.05), involving default mode-visual, default mode-attention, and salience network connections. All effects followed an ordinal rank pattern of GeoPref<nonGeoPref<TD. Default mode-visual connections were significantly reduced in GeoASD compared to nonGeoASD or TD (i.e. GeoASD<nonGeoASD or GeoASD<TD) and for nonGeoASD compared to TD (all p<0.05). Group differences in default mode-attention connectivity as well as connectivity between salience components were driven primarily by more generalized hypoconnectivity in ASD compared to TD.
Conclusions:
ASD within the first 4 years of life is characterized by decreased functional connectivity between default mode subsystems and early developing visual and attention circuits as well as connectivity within the salience network. The main feature differentiating socially oriented nonGeoASD versus non-socially oriented GeoASD toddlers with ASD is further dampening of functional connections between the default mode subsystems and visual cortices.

2:46 **190.004** Fmri Reveals That Toddlers with an ASD Respond Abnormally in the Superior Temporal Sulcus to Social Orienting Stimuli during Natural Sleep

L. T. Eyler[1]*, K. Campbell*[2]*, I. Mutschler*[3]*, C. C. Barnes*[1]*, E. Courchesne*[1] *and K. Pierce*[1]*, (1)University of California, San Diego, San Diego, CA, (2)Duke Center for Autism and Brain Development, Durham, NC, (3)University of San Diego, San Diego, CA*

Background: Â Unusual social responding, such as a failure to respond to name, is a red flag for autism spectrum disorders (ASD) in infants and toddlers, but the neural systems that underlie this deficit are under-studied. The superior temporal sulcus (STS) has been dubbed the “chameleon of the human brain” because of its involvement in many social tasks. It is unknown whether its dysfunction underlies social responding deficits at the time of first clinical signs of autism, and could thus serve as an early biomarker of risk for ASD.
Objectives: Â We aimed to test whether there were early socially-relevant neural differences between infants and toddlers later diagnosed with ASD and those who develop typically by comparing functional magnetic resonance (MR) brain response to social auditory stimuli compared to language and non-social sounds.
Methods: Â A population-based screening method and community referral identified toddlers at risk for an ASD as young as 12 months, and children were followed until their third birthday for final diagnostic judgment. ASD and typically developing (TD) comparison children (12-48 months old) were scanned with MR imaging during natural sleep. Blood oxygen level dependent (BOLD) images were acquired during auditory stimulation with social (calling the child’s own name), language (short, monotone phrases), and non-social (alerting or orienting sounds) stimuli (Figure 1)Â in 61 ASD and 57 TD sleeping participants.Â The number of voxels with significant BOLD response ($p < 0.01$) to each condition was measured within each participant’s left and right STS as determined by hand tracing on the anatomical MR image. The proportion of activated voxels within these two regions between groups and conditions was compared using a general linear model.
Results: Â By design, groups were well-matched on age and gender. In the left STS, response was related to condition across all participants ($F(1,116) = 5.3$, $p = 0.02$), individuals with ASD showed reduced responsiveness across conditions ($F(1,116) = 6.3$, $p = 0.01$), and there was a significantly different pattern of response across conditions in the two groups ($F(1,116)$: 5.9, $p=0.02$). The interaction is illustrated in Figure 2: Whereas the TD group showed a stair-step reduction in response from social to language to non-social stimuli, the ASD response was not differential across conditions. For the right STS, there was no linear effect of condition on brain response ($F(1,116) = 1.96$, $p = 0.17$), but across conditions the ASD group had less response ($F(1,116) = 7.7$, $p= 0.006$). The pattern of response to the conditions was not significantly different between groups ($F(1,116) = 3.0$, $p = 0.08$).
Conclusions: Infants and toddlers who go on to be diagnosed with an ASD show reduced responsiveness in the left and right STS to auditory stimuli during natural sleep. Furthermore, in the left STS, the typical preferential responsiveness to social compared to language and non-social stimuli is not present among ASD infants and toddlers. Failure to demonstrate a graded response of the left STS to socially-meaningful stimuli may be an early neural marker of ASD that portends future behavioral deficits.

Oral Session - 15A
191 - Gene Discovery in ASD
1:15 PM - 2:05 PM - Yerba Buena 10-14

Session Moderator: Alan Packer, *Simons Foundation, New York, NY*

1:15 **191.001** Genome Sequencing of 2,064 Genomes from 516 Simplex Families with Autism

T. Turner[1], *B. P. Coe*[1], *B. J. Nelson*[1], *M. C. Zody*[2], *F. Hormozdiari*[1], *Z. N. Kronenberg*[1], *S. A. McClymont*[3], *P. A. Hook*[3], *K. Hoekzema*[1], *M. H. Duyzend*[1], *A. Raja*[1,4], *C. Baker*[1], *R. Bernier*[5], *A. S. McCallion*[3], *R. B. Darnell*[2,6] *and E. E. Eichler*[1,4], *(1)Department of Genome Sciences, University of Washington, Seattle, WA, (2)New York Genome Center, New York, NY, (3)McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, (4)Howard Hughes Medical Institute, University of Washington, Seattle, WA, (5)University of Washington Autism Center, Seattle, WA, (6)Howard Hughes Medical Institute, Rockefeller University, New York, NY*

Background: The Simons Simplex Collection contains ~2,500 simplex autism families and has been previously studied through microarray and whole exome sequencing approaches. These studies have identified *de novo* and inherited risk factors that contribute to ~20-30% of autism and primarily affect the coding sequence of the genome. The remaining genetic risk factors for autism are currently unknown.
Objectives: To understand the genetic etiology for cases not due to *de novo* gene disruptive events, our hypothesis is that these individuals with autism have variants within the exome and previously missed by other approaches and / or are enriched for variants in noncoding, regulatory DNA.
Methods: We performed deep (30-fold) Illumina whole-genome sequencing (WGS) on 2,064 genomes from 516 simplex autism families negative for *de novo* likely gene-disruptive (LGD) mutation or large (>100 kbp) copy number variants (CNV). Using a hybrid cloud / local compute analysis workflow we processed all genomes in one month. We applied two SNV/indel and four CNV callers to generate a sensitive variant call set of 59 million SNVs/indels and 193 thousand unique CNVs. Extensive, orthogonal experimental validation was undertaken to determine the inheritance status of high-impact variants.
Results: WGS analysis recovered ~25% more *de novo*, exonic SNV/indels and ~85% more gene-disrupting CNVs than previously discovered by whole-exome sequencing (WES) analysis of the same samples. This included *de novo* LGD events in *GLIPR1L2*, *PHIP*, *PCM1*, *MED12L*, and *VARS* and gene-breaking *de novo* CNVs in *CHD2, DDX43, DMD, FANCA, LINC01347, LNPEP*, *MIR3129*, *MUC19*, *PCDHB17*, *PCDHB6*, *TAF1B*, and *ZNF462*. We observed a significant enrichment (p=0.01) of *de novo* missense mutations in children with autism when compared to their unaffected siblings for autism risk genes with known dosage sensitivity. This included proband-specific events in *UBE3C*, *PTEN*, *SUV420H1*, *CREBBP*, *LAMC3*, *GABRB3*, *SYNGAP1*, *NR3C2*, *SRCAP*, *TRIP12*, *UNC45B*, *SCN2A*, *POGZ*, and *TRIO*. We also identified an enrichment of *de novo* SNVs/indels in 5' and 3' UTR events (p=0.02) and in transcription factor binding sites (p=0.03). We report a modest enrichment (p=0.04) of *de novo* and private disruptive mutations for putative regulatory elements for dosage-sensitive autism genes. We define these as fetal central nervous system (CNS) DNase I hypersensitive sites mapping within 50 kbp of the start and end of the candidate gene transcript. Functional testing of the regions affected by these events confirms that the CNVs enrich in enhancers within the central nervous system.
Conclusions: Overall, WGS provides additional insight into the genetic etiology of autism by significantly increasing the yield of gene-disrupting mutations and by providing access to noncoding portions of the genome which when deleted adversely affect dosage of autism-risk genes during development.

1:27 **191.002** Integrative Analyses of Autism and Intellectual Disability Exome Data Reveal Similarities and Divergences and Identify Novel Risk Genes for Both Disorders

S. De Rubeis[1,2], *A. E. Cicek*[3,4], *L. Klei*[5], *B. Devlin*[5], *J. D. Buxbaum*[2] *and K. Roeder*[6,7], *(1)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Department of Computer Engineering, Bilkent University, Ankara, TURKEY, (4)Computational Biology Department, Carnegie Mellon University, Pittsburgh, PA, (5)Department of Psychiatry, University of Pittsburgh, Pittsburgh, PA, (6)Department of Psychiatry, Carnegie Mellon University, Pittsburgh, PA, (7)Department of Statistics, Carnegie Mellon University, Pittsburgh, PA*

Background:
Autism spectrum disorder (ASD) and intellectual disability (ID) are known to have a complex genetic architecture. ASD and ID frequently co-occur and recent analyses suggest that the genetic architecture might differ in individuals with low or high cognitive function. These findings raise questions about shared risk and compel analyses that intersect the genetic studies in ASD and ID since they have so far proceeded along parallel routes.
Objectives:
The objective was to understand the nature of shared genetic risk between ASD and ID.
Methods:
We assimilated rare variants identified via exome sequencing of 4,216 ASD and 1,479 ID trios, as well as 869 ASD cases and 2,829 control samples. We assessed the evidence for association using TADA, a statistical algorithm that combines information across different classes of evidence and produces a set of dominant-effect risk genes with varying levels of significance, measured as q-values. Genes were categorized based on level of evidence as strong ($q < 0.05$), moderate ($0.05 < q < 0.3$), weak ($0.3 < q < 0.6$) and negligible ($q > 0.6$).
Results:
For ASD and ID we find 31 and 64 genes with strong evidence (referred to as tASD and tID), 92 and 99 genes with moderate evidence, and 355 and 320 genes with weak evidence of association, respectively. A cross-classification of genes by FDR level shows substantial overlap in these risk gene lists (Chi-square $p < 10^{-15}$): 12 genes show strong evidence ($p < 10^{-20}$) (referred to as tASD.ID genes) of conferring risk for both disorders. Based on the pattern of de novo LoF, we estimated the total number of autosomal dominant genes in which de novo LoF imparts substantial risk for ASD (K_{ASD}) and ID (K_{ID}), respectively. We estimated a 95% confidence interval for K_{ASD} of 500-950 and K_{ID} of 185-225. Impact on nonverbal IQ (NVIQ) in probands diagnosed with ASD differs across categories: a de novo loss-of-function (LoF) mutation in a tID or tASD.ID gene had an average drop on NVIQ of about 24 points, while a de novo LoF mutation in a tASD gene had a weaker effect (~12 points reduction). The substantial genetic overlap in signal for ID and ASD motivates pooling the data to enhance power and thus gene discovery. Using this strategy, we identified 16 additional risk genes with $q < 0.05$, many of which cross-validated in complementary datasets.
Conclusions:
Despite having a much larger sample of ASD probands, we identify twice as many ID-related genes. This is consistent with a model in which de novo mutations contribute risk in a higher proportion of ID subjects than ASD and/or each mutation contributes a greater degree of risk in ID than ASD. We identified 12 genes that confer risk to both disorders and observed a dearth of genes that show strong evidence for association with ID but no evidence of association with ASD and vice versa. Finally, mutations in ID genes can have a marked impact on IQ of ASD subjects, whereas mutations in ASD-only genes have smaller impact.

1:39 **191.003** Interaction Between Human Sexual Dimorphism and ASD Neurobiology.

S. J. Sanders[1] *and D. M. Werling*[2], *(1)UCSF, San Francisco, CA, (2)Psychiatry, UCSF, San Francisco, CA*

Background: The 4:1 male to female sex bias is one of the most consistent and striking observations in autism spectrum disorder (ASD). One explanation for this sex bias is the existence of a female protective effect (FPE), in which a greater burden of ASD risk factors are required for a diagnosis of ASD in females than in males. Direct observation of de novo ASD risk factors in genomic analysis supports this hypothesis, however indirect assessment of sibling ASD recurrence risk in epidemiological studies finds little supporting evidence for the FPE. Understanding the nature and mechanism of this protection may hold great potential for therapeutic strategies.
Objectives: To assess the role and potential mechanism of female protection in ASD
Methods: To explain the discordant genomic and epidemiological evidence for the FPE we developed a simulation of ASD risk in families to estimate the power to detect a difference in the burden of de novo mutations vs. sibling recurrence risk. Should the FPE exist, it must act through sexually dimorphic processes, including gene expression. We therefore also compared gene expression data from male and female brain samples in the BrainSpan dataset ranging from mid-fetal to adult developmental stages to identify such sex differences in neurobiology.
Results: Under a quantitative model of ASD risk (Gaugler et al.2014), in which 50% of ASD risk in the population comes from unique environmental exposure, 47% comes from common inherited genetic variants and 3% comes from rare de novo mutations, we estimated the power to detect the FPE. Considering de novo mutations we achieve 80% power with a sample of about 500 ASD families, consistent with genomic literature. Furthermore, by combining exome and CNV data for over 5,500 ASD cases we consistently observe an increased burden of ASD risk factors in females, to a similar extent as predicted by the simulation. In contrast, the power to detect a significant difference in sibling recurrence rate in 10,000 ASD families remains below 30%. The FPE hypothesis is therefore also consistent with the epidemiologic literature. To explore the nature of the FPE, we assessed differential gene expression using RNA-Seq from over 1,200 region- and age-specific samples from males and females. We find similar developmental trajectories of gene expression in both sexes, with the exception of genes specific to microglia that are enriched in males during mid-late fetal development. These genes overlap with those observed in co-expression modules previously observed to be upregulated in ASD brains.
Conclusions: The FPE is the leading hypothesis of the underlying mechanism of ASD sex bias, with strong supporting evidence from genomic studies. The existing large-scale epidemiological analyses remain under-powered to corroborate this finding. Analysis of human transcriptome data identifies higher expression of microglial genes during male fetal development and finds that these genes overlap with those over-expressed in the post mortem ASD brain. This cellular and molecular pathway may sensitize males to ASD risk factors, and may account for the apparent female protective effect in ASD.

1:51 **191.004** Role of De Novo Intronic Indels in Autism

***A. Munoz Jimenez**, B. Yamrom, Y. H. Lee, P. Andrews, S. Marks, Z. Wang, M. Wigler and I. Iossifov, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY*

Background: Over the past several years, analysis of whole-exome sequencing and microarray hybridization data from collections of families of children with autism like the Simons Simplex Collection (SSC) has increased our understanding of the genetic architecture of autism.Â Contributions from de novo (DN) mutation, rare and common variants have been established, but most progress has been made in the study of DN variants. DN germ line likely gene-disrupting (LGD), missense and copy number variants have been estimated to jointly contribute to approximately 30 percent of the autism in simplex families (Iossifov et al., 2014). The observed DN mutations in the ~5,000 affected children enabled the identification of lists of few hundred genes that with high confidence are involved in autism's etiology (autism genes). For example, half of the 546 genes targeted by published DN LGD mutations (LGD targets) are expected to be true autism genes.
Objectives: Â Whole-genome sequencing data sets were recently generated from the SSC, and we sought to determine if the additional types of DN variants that can be detected from whole-genome sequencing data, including noncoding variants and complex structural rearrangements, also contribute to autism. In this study, we specifically explored the contribution of DN noncoding mutation by focusing on the introns of the autism genes identified by the exome sequencing.
Methods: We analyzed whole genome data generated from the father, mother, a child with autism and an unaffected child of 510 families from the SSC chosen to have no DN LGDs or CNVs in the exomes of the affected children. The 150bp paired-end dataset was generated at the New York Genome Center with average depth of 30x. About 20,000 de novo intronic substitutions (DIS) and 2,000 de novo intronic indels (DII) were identified, using our multinomial genotyper with stringent cutoffs. We determined that the rate of false positives in this set is <5% and the rates of such de novo events was in agreement with published rates.
Results: There was no significant difference between the numbers of all DIS and all DII between the affected and unaffected children. But in the introns of the 546 LGD target genes, we identified 63 DII in the 510 affected while we found only 37 in the 510 unaffected children. The difference of 26 events is significantly larger than 0, (p-values of 0.01). The significance increases if we restrict to the half of the LGD targets that are more intolerant to damaging variants in human population and are expected to be even more enriched for autism genes (p-value of 0.005) while the delta barely shrinks (from 26 to 23). There was no significant difference in the number of DISs in any of these sets and there was no significant difference of the numbers of DIIs or DISs in gene targets of DN missense or DN synonymous.
Conclusions: From the observed increase in DIIs rates in children with autism, we estimated that DN intronic variants might contribute ~20% of the autistic children in simplex families.

Oral Session - 15B

2:10 **192.001** Transcriptional Gene Silencing of the Autism-Associated Long Noncoding RNA MSNP1AS in Human Neural Progenitor Cells

***J. DeWitt**[1], N. A. Grepo[2], B. Wilkinson[3], O. V. Evgrafov[3], K. V. Morris[4], J. A. Knowles[3] and D. B. Campbell[3], (1)University of Southern California, Alhambra, CA, (2)USC, LOS ANGELES, CA, (3)University of Southern California, Los Angeles, CA, (4)City of Hope, Duarte, CA*

Background: The long noncoding RNA (lncRNA) *MSNP1AS* (moesin pseudogene 1, antisense) is a functional element that was previously associated to autism spectrum disorder (ASD) with genome wide significance. Expression of *MSNP1AS* was increased 12-fold in the cerebral cortex of individuals with ASD and 22-fold in individuals with a genome-wide significantly associated ASD genetic marker on chromosome 5p14.1. Overexpression of *MSNP1AS* in human neuronal cells caused decreased expression of moesin protein, which is involved in neuronal process stability.
Objectives: In this study, we hypothesize that *MSNP1AS* knockdown impacts global transcriptome levels.
Methods: We transfected the human neural progenitor cell line, SK-N-SH, with constructs that caused a 50% suppression of *MSNP1AS* expression. After 24 hours, cells were harvested for total RNA isolation. Strand-specific RNA-Seq analysis revealed changes in gene expression.
Results: RNA-Seq analysis indicated altered expression of 1,352 genes, including altered expression of 318 genes following correction for multiple comparisons. Expression of the *OAS2* gene was increased >150-fold, a result that was validated by quantitative PCR. Gene ontology analysis of the 318 genes with altered expression following correction for multiple comparisons indicated that upregulated genes were significantly enriched for genes involved in immune response and downregulated genes were significantly enriched for genes involved in chromatin remodeling.
Conclusions: These data indicate multiple transcriptional and translational functions of *MSNP1AS* that impact ASD-relevant biological processes. Chromatin remodeling and immune response are biological process implicated by genes with rare mutations associated with ASD. Our data indicate that the functional elements implicated by association of common genetic variants impact the same biological processes, suggesting a shared common molecular pathway of ASD.

2:22 **192.002** RNA-Seq Analyses of RORA-Deficient Neuronal Cells and Brain Tissues from Individuals with ASD Provide Support for RORA As a “Master Regulator” of Genes Impacted By Autism

V. Hu[1] *and T. Sarachana*[1,2]*, (1)Biochemistry and Molecular Medicine, The George Washington University, Washington, DC, (2)Clinical Chemistry, Faculty of Allied Health Sciences, Chulalongkorn University, Bangkok, Thailand*

Background: Â We have previously shown that multiple cohorts of individuals with autism exhibit reduced expression of *RORA*both in the brain as well as in lymphoblastoid cell lines derived from individuals with ASD. We further showed by RORA-dependent chromatin immunoprecipitation followed by microarray (ChIP-on-chip) analyses that RORA, a nuclear hormone receptor, can potentially regulate the transcription of over 2500 genes, including more than 400 genes associated with ASD through genetics and functional analyses. The latter study suggested that RORA may serve as a “master regulator” of genes involved in the pathogenesis of autism.
Objectives: Â This study was conducted to investigate the genome-wide impact of targeted knockdown of *RORA* expression in a neuronal cell model as well as the transcriptomic profile of postmortem brain tissues from individuals with ASD that were previously determined to be *RORA*-deficient by RT-qPCR analyses. Moreover, we were interested in validating altered expression of predicted transcriptional targets of RORA in the RORA-deficient cells and tissues.
Methods: Stable knockdown of *RORA* expression was induced by transfection of SH-SY5Y neuroblastoma cells (an experimental model for neuronal cells) with shRORA RNA, followed by selection of stable transfectants by maintaining the cultures in puromycin. Knockdown of *RORA* expression in the transfected SH-SY5Y cells relative to that in cells transfected with a negative control shRNA was verified by RT-qPCR analyses. The stable *RORA* knockdown and control cells as well as brain tissues from the frontal cortex (BA 9/10 region) of age-matched male cases and controls were submitted for RNA sequencing (RNA-seq) to investigate the transcriptional profiles associated with *RORA*deficiency. Functional analyses of the differentially expressed genes were performed using Ingenuity Pathway Analysis software.
Results: Stable knockdown of *RORA* expression in the SH-SY5Y cells resulted in altered expression of approximately 4500 genes with a fold-change ≥ 1.4. Among the differentially expressed genes, approximately 500 had been previously identified as putative targets of RORA by our ChIP-on-chip analysis. RNA-seq analysis of *RORA*-deficient postmortem brain tissues from autistic individuals in comparison to those from controls revealed 156 differentially expressed genes, with 45 of these genes overlapping those affected by stable *RORA*knockdown in the cell model. Network prediction and pathway analyses of the differentially expressed genes revealed significant over-representation of genes associated with neurological functions (e.g., neuronal migration and neuritogenesis) and canonical pathways (e.g., ephrin receptor and axonal guidance signaling) impacted by ASD.
Conclusions: Â Collectively, the RNA-seq analyses of *RORA*-deficient neuronal cells and brain tissues validate a large number of transcriptional targets of RORA identified by our prior ChIP-on-chip analyses. Moreover, these results support our earlier findings and hypothesis that *RORA* is an autism risk gene whose deficiency in a subgroup of individuals with ASD can lead to much of the molecular pathophysiology currently associated with ASD.

2:34 **192.003** ASD-Associated Genomic Variants in 16p11.2 and CHD8 Exhibit Clinically and Biologically Functional DNA Methylation Signatures

M. T. Siu[1]*, D. T. Butcher*[1]*, S. Choufani*[1]*, A. L. Turinsky*[1,2]*, C. Cytrynbaum*[1,3,4]*, D. J. Stavropoulos*[5,6]*, S. Walker*[7]*, Y. Lou*[1]*, S. W. Scherer*[1,4,7]*, M. Brudno*[1,2,8] *and R. Weksberg*[1,3,4,9,10]*, (1)Program in Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada, (2)Centre for Computational Medicine, The Hospital for Sick Children, Toronto, ON, Canada, (3)Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, ON, Canada, (4)Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada, (5)Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada, (6)Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, (7)The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, ON, Canada, (8)Department of Computer Science, University of Toronto, Toronto, ON, Canada, (9)Institute of Medical Sciences, School of Graduate Studies, University of Toronto, Toronto, ON, Canada, (10)Department of Pediatrics, University of Toronto, Toronto, ON, Canada*

Background: One of the greatest challenges in studying autism spectrum disorder (ASD) is the degree of etiologic heterogeneity. Over 200 ASD-risk genes have been identified, but each gene accounts for <1% of all ASD cases and genetic causes have been identified in only ~25% of cases. A role for epigenetic dysregulation in ASD etiology is supported by the many ASD-risk genes that function as epigenetic regulators. We and others have proposed that aberrant epigenetic mechanisms resulting from genetic and/or environmental influences may alter biological pathways important for normal brain development. Previous studies have identified alterations in DNA methylation (DNAm), the most commonly assessed epigenetic mark, in ASD patients. However, the impact of these findings is limited by small sample sizes and inconsistent results across studies.
Objectives: 1) To investigate the role of epigenetic dysregulation in ASD. 2) Improve the discovery of DNAm differences by examining more homogeneous groups of individuals substratified based on known ASD-associated genomic variants.
Methods: Â Genome-wide DNAm was measured using the Illumina Infinium HumanMethylation450 BeadChip array in DNA extracted from whole blood for all groups. First, we compared DNAm in a heterogeneous ASD group (n=52) with age- and sex-matched neurotypical controls (n=30). Second, DNAm was also assessed from patients with genomic variants conferring an increased risk for ASD: 16p11.2 deletions at the 600kb risk locus (16p11.2del; n=9) or heterozygous loss-of-function mutations in a chromatin modifier, chromodomain helicase DNA binding protein 8 (*CHD8*$^{+/-}$; n=7). These groups were compared with age- and sex-matched controls (n=23 and n=21, respectively). We used a modified version of our laboratory's bioinformatics pipeline employing hierarchical clustering, principal components analysis and non-parametric statistical comparisons to identify significantly differentially methylated CpG sites.
Results: Â Although no significantly differentially methylated sites were identified to fully distinguish heterogeneous ASD cases from controls, unique DNAm patterns were identified for the 16p11.2del and *CHD8*$^{+/-}$ groups when compared with controls. These DNAm patterns consist of specific sets of differentially methylated sites (adjusted p<0.05, absolute difference ≥5%) comprising novel DNAm signatures. These signatures separated 16p11.2del and *CHD8*$^{+/-}$ individuals from both heterogeneous ASD and control groups with high sensitivity and specificity. They also accurately classified 16p11.2 CNV and *CHD8* sequence variants of unknown significance, distinguishing between pathogenic and benign mutations. Examining the genes in each signature revealed biological pathways that could be important to the pathophysiology of ASD, overlapping with known ASD-risk genes. Furthermore, some of the genes identified in our *CHD8*$^{+/-}$ blood DNAm signature overlapped differentially expressed genes in *CHD8*$^{+/-}$ (CRISPR/Cas9) human induced pluripotent stem cell-derived neuronal precursor and neuronal cells, demonstrating the cross-tissue functional significance of our *CHD8*$^{+/-}$ epigenetic signature.
Conclusions: Our approach constitutes a novel and clinically applicable method of molecular classification for ASD, identifying DNAm biomarkers in an easily accessible tissue. These findings elucidate the etiology of subgroups of ASD in the context of the crucial cross-talk between genetics and epigenetics. Combined, these data will enhance our understanding of the underlying biological mechanisms of ASD and facilitate the identification of novel therapeutic targets to facilitate precision medicine-based treatment options.

2:46 **192.004** Whole-Genome Bisulfite Sequencing Reveals Autism-Associated Hypomethylation and Differentially-Methylated Regions in Umbilical Cord Blood Samples from the Prospective Marbles Study

Background: Autism spectrum disorders (ASD) have complex etiologies, likely involving multiple genetic and environmental insults in perinatal life. Genetic susceptibility can interact with environmental risk factors such as pesticides, air pollution, and persistent organic pollutants. The perinatal period is critical for both nutritional protective factors, such as the methyl donor folate, and interactions with genetic regulators of one-carbon metabolism. The epigenetic layer of DNA methylation, at the interface of genetic and environmental risk and protective factors, holds promise for improved understanding of complex ASD etiologies.
Objectives: Currently, ASD is diagnosed behaviorally at two years of age; however, existing interventions are most effective the earlier they are begun. Biomarkers for ASD at birth are largely unknown and would facilitate earlier diagnosis and more effective treatment. We performed this study to identify DNA methylation biomarkers predictive of ASD diagnosis by age three.
Methods: The MARBLES (Markers of Autism Risk in Babies - Learning Early Signs) prospective study is an enriched risk cohort that enrolls couples who have already had a child with ASD and follows their subsequent pregnancy. We investigated human umbilical cord blood samples from the MARBLES study by whole-genome bisulfite sequencing (WGBS) and expression microarray (*n*= 26 TD, 26 ASD).
Results: ASD cord blood samples showed significantly lower global percent CpG methylation compared to typically-developing (TD) controls (ASD 76.6% vs TD 77.4%, p = 0.01). ASD-associated hypomethylation was observed across most chromosomes and gene bodies. 20 kb windowing of the genome demonstrated a global shift of hypomethylation, with 81% of windows hypomethylated in ASD samples. Smaller differentially-methylated regions (DMRs) enriched for CpG islands were also identified in ASD cord blood (5,828 total DMRs). 60% of all DMRs were hypomethylated, but all DMRs that were significant after correction for multiple hypothesis testing were hypermethylated. DMRs in ASD cord blood were nearby genes significantly enriched for functions in organic cyclic compound binding (2797 DMRs, Bonferroni-adjusted $p = 2.4\text{x}10^{-11}$) and abnormal blood cell morphology and development knockout mouse phenotypes (1277 DMRs, Bonferroni-adjusted $p = 1.1\text{x}10^{-11}$), highlighting the potential influence of the environment and immune system in ASD. Hypomethylated DMRs were also significantly enriched near SFARI ASD candidate risk genes (253 genes, Bonferroni-adjusted $p = 7.6\text{x}10^{-4}$). Methylation at four of the DMRs with genome-wide significance showed a significant positive association with Autism Diagnostic Observation Schedule (ADOS) severity scores. Methylation at two significant DMRs showed a significant negative association with mRNA levels of nearby genes.
Conclusions: Global hypomethylation in ASD cord blood suggests a methylation deficiency in ASD during perinatal life, which could be a cumulative effect of genetic variants, environmental exposures, and/or shortage in methyl donors. Identified DMRs are relevant to ASD and have potential as a diagnostic tool. In future studies, methylation will be examined in relation to demographic, genetic, environmental, and nutritional information collected in the MARBLES study. These results are expected to improve understanding of perinatal factors in ASD etiology and aid in future preventative and therapeutic treatments.
