Abstract Book

Oral Session -
- Advocate Award Address
5:00 PM - 5:10 PM - Yerba Buena 8-9

5:00 Advocate Award Address

Oral Session -
100 - Welcome Address and INSAR President Address
8:30 AM - 9:00 AM - Yerba Buena 8-9

8:30 Welcome Address and INSAR President Address

Keynote Address
101 - Biological Origins of Autism Heterogeneity
9:00 AM - 10:00 AM - Yerba Buena 8-9

Speaker: P. Levitt, Institute for the Developing Mind, Children's Hospital Los Angeles, Los Angeles, CA

Typically developing individuals exhibit broad heterogeneity in cognitive, social and emotional behaviors. While neuroscientists are still struggling with understanding the mechanisms that underlie this heterogeneity, the field now has recognized that individual differences, even between two individuals with the same categorical neurodevelopmental diagnosis, can be profound. Thus, the identical causal mutation often leads to clinical symptoms that may differ widely in those who are affected. These differences, in turn, create challenges for implementing the most effective clinical treatments. Studies will be presented that characterize the biological nodes that may contribute to functional heterogeneity. Experiments address the heritable contributions to behavioral heterogeneity broadly, and that different components of complex behavior may be impacted by distinct genetic factors. Moreover, studies will be presented that address circuit, molecular and cellular mechanisms that underlie differences in neurodevelopmental trajectories of vulnerable circuitry. The presentation will emphasize new ideas regarding the biological nodes as being dynamic, and influenced by genetic and environmental factors – all of which can contribute to the thinking about the most effective ways to move away from *'one size fits all'* approaches to treatment.

9:00 Biological Origins of Autism Heterogeneity

***P. Levitt**, Institute for the Developing Mind, Children's Hospital Los Angeles, Los Angeles, CA*

Typically developing individuals exhibit broad heterogeneity in cognitive, social and emotional behaviors. While neuroscientists are still struggling with understanding the mechanisms that underlie this heterogeneity, the field now has recognized that individual differences, even between two individuals with the same categorical neurodevelopmental diagnosis, can be profound. Thus, the identical causal mutation often leads to clinical symptoms that may differ widely in those who are affected. These differences, in turn, create challenges for implementing the most effective clinical treatments. The presentation will emphasize new ideas regarding the biological nodes as being dynamic, and influenced by genetic and environmental factors – all of which can contribute to the thinking about the most effective ways to move away from *'one size fits all'* approaches to treatment.

Panel Session
102 - Autism and Intellectual Disability: Patterns of Familial and Environmental Risk
10:30 AM - 12:00 PM - Yerba Buena 3-6

Panel Chair: Brian Lee, *Drexel University, Philadelphia, PA*

Discussant: Avi Reichenberg, *Mount Sinai School of Medicine, New York, NY*

Although autism spectrum disorders (ASD) are clearly heterogeneous, many risk factor studies often consider ASD as a single entity. However, there is increasing evidence that different genetic and environmental risk factors may predispose to different subtypes of ASD. The purpose of this session is to examine the epidemiological, familial, and genetic evidence regarding how patterns of ASD risk may vary by conditions often noted to co-occur with ASD, especially intellectual disability (ID). The first talk will provide an overview of environmental risk factors that have been observed to have divergent associations for ASD with versus without ID. The second talk will discuss how paternal intelligence and child ASD are associated in a Swedish sample, taking into account co-occurring ADHD and ID. The third talk will discuss how ASD risk is related to cross-disorder risk of other psychiatric diagnostic groups, using a sibling design study from Israel. The fourth talk uses genetic data from two well-characterized samples to examine how common polygenic risk for ASD, educational attainment, schizophrenia, and intelligence are related. Attendees will come away with a greater understanding of the nosologic and etiologic implications in considering ASD with and without co-occurring ID.

10:30 **102.001** Do the Determinants of Autism Vary By Intellectual Disability? a Critical Review of the Concept of the Autism Spectrum and Its Relevance to Epidemiology

***D. Rai**[1], C. Magnusson[2] and C. Dalman[2], (1)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (2)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden*

Background: Â Individual diagnostic categories of autism have now been subsumed into a single overarching category of an autism spectrum disorder in DSM-V. One of the arguments behind this move was that all types of autism, from Asperger syndrome to childhood autism may have a shared etiology. Although recent large epidemiologic studies support this argument for some putative environmental risk factors, for others, different or even divergent associations have been observed for autism with or without intellectual disability.
Objectives: Â The overall objective is to provoke thought and discussion by 1) providing a brief historical overview of the genesis of the concept of the autism spectrum; 2) critically discussing recent findings from a large Swedish cohort differentiating autism by the presence or absence of intellectual disability (ID); 3) reflecting on the utility and the strengths and weaknesses of carrying out epidemiologic studies aimed at studying the 'autism spectrum'.
Methods: The arguments will be discussed using published and unpublished empirical findings of investigations carried out within the Stockholm Youth Cohort, a large total population register based cohort based in Stockholm County, Sweden. Examples include results of studies investigating parental age, migration, socioeconomic status, parental depression, schizophrenia and bipolar disorder, infections, polycystic ovarian syndrome, gestational weight gain, fetal growth and antidepressant, folic acid and multivitamin use during pregnancy.
Results: The associations for advancing parental age, poor fetal growth, parental migration, Vitamin D deficiency, and maternal hospitalisation for infections during pregnancy were greater for autism with intellectual disability than for autism without ID. On the other hand, parental schizophrenia, bipolar disorder or maternal depression and antidepressant use have been reported to have stronger associations with autism without ID. Similar estimates of associations for autism with and without ID have been reported for parental socioeconomic status and gestational weight gain.
Conclusions:
The advantages of studying autism spectrum disorders as a combined group including larger samples and increased statistical power to study relationships with rare exposures will be discussed. On the other hand, it is possible that findings may be diluted where the associations differ markedly by the presence or absence of intellectual disability. The implications for the epidemiology of autism will be discussed.

10:50 **102.002** The Association of Paternal IQ with Autism Spectrum Disorders and Its Comorbidities

R. M. Gardner[1], *C. Dalman*[2], *D. Rai*[3], *B. Lee*[4] *and H. Karlsson*[5], *(1)Karolinska Institutet, Stockholm, SWEDEN, (2)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, (3)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (4)Drexel University, Philadelphia, PA, (5)Neuroscience, Karolinska Institutet, Stockholm, Sweden*

Background: Â Both Leo Kanner and Hans Asperger noted that the parents of the autistic children they originally described tended to be highly educated and intelligent, sewing the seeds of the hypothesis that Autism Spectrum Disorders (ASDs) are a case of "brilliance gone awry". The association between genetic risk for ASD and intelligence in the general population and the notable excess of ASD cases born to parents working in highly technical professions would seem to support this hypothesis.
However, results examining cognitive abilities amongst ASD cases and their family members have been mixed. One potential issue is that co-morbidities common to ASD, such ADHD and intellectual disability (ID) that are themselves heritable impairments of cognitive functions, are often not taken into account.
Objectives: Â Our goal was to examine the association between paternal intelligence and ASD, accounting for co-morbidity with ADHD and ID, in a population-based register study.
Methods: The study included 360,151 children, born 1984-2008, resident in Stockholm, Sweden, with a father that was conscripted to the Swedish military. Paternal IQ was measured on the stanine scale (1-9) during conscription at age 18. Paternal IQ subscale values (Logic, Verbal, Spatial, and Technical Reasoning) were available for 309,803 children. Children's diagnoses were recorded in Swedish health registers.
The association of paternal IQ with offspring risk for ASD, ADHD, ID and overlapping co-morbid groups was evaluated using restricted cubic spline models with paternal IQ=5 (average intelligence) as the referent, to allow flexible fitting of the relationship between paternal IQ and offspring risk for neurodevelopmental disorders.
Results: We observed a U-shaped relationship between paternal IQ and offspring risk of ASD with no co-morbidities ($OR_{IQ=1}$ 1.20, 95% CI 1.00–1.45; $OR_{IQ=9}$ 1.31, 1.14–1.50), after adjustment for socioeconomic status (SES). The association of low paternal IQ and ASD with co-morbid ID was stronger, though the overall relationship was similar ($OR_{IQ=1}$1.81, 1.29–2.54; $OR_{IQ=9}$ 1.30, 0.98–1.72). For ASD with co-morbid ADHD, only the association with low paternal IQ was apparent ($OR_{IQ=1}$ 1.49, 1.24–1.81; $OR_{IQ=9}$ 1.06, 0.88–1.28). The association between high paternal IQ and risk for offspring ASD alone was driven largely by the fathers' technical subdomain score ($OR_{Technical\ IQ=9}$ 1.51, 1.30–1.76). The association between paternal IQ and ID alone was striking ($OR_{IQ=1}$ 4.53, 3.68–5.57; $OR_{IQ=9Â}$ 0.66, 0.47–0.93), and a similar but weaker pattern was observed for ADHD alone ($OR_{IQ=1}$1.65, 1.50–1.82; $OR_{IQ=9Â}$ 0.71, 0.63–0.80). For all outcomes, similar results were observed before and after adjustment for the marked gradient in SES between paternal IQ levels. The associations of low paternal IQ with ASD or ADHD outcomes tended to be attenuated and the associations of high paternal IQ with ASD outcomes were strengthened when SES was considered.
Conclusions: Â High paternal IQ was indeed associated with children's risk of ASD, though this was most apparent in the group without co-morbidities. This risk was driven largely by the fathers' score on the technical sub-scale. Overall, the pattern for risk of ASD was distinct compared to that for ID or ADHD alone.

11:10 **102.003** Shared Genetic Risk Across Psychiatric Disorders

S. Sandin[1] *and A. Reichenberg*[2], *(1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Mount Sinai School of Medicine, New York, NY*

Background: Population based epidemiological studies have shown an association between autism spectrum disorder (ASD) and several other disorders including schizophrenia, psychosis and intellectual disability. Likewise, a variety of genetic studies in children with autism have genetic risk genes and loci shared with other, frequently co-morbid, psychiatric disorders. Genetic and family based studies have extended this also to other family members.
Where previous family-based studies focused either on one disorder as a risk factor for several other disorders or several other disorders as risks for one disorlder, the aim of this study was to assess in one large population a variety of psychiatric disorders both as risk factors and as outcomes. This was examined by the risk for psychiatric disorders in full siblings of probands diagnosed with a range of psychiatric disorders. To verify if the risk is specific to psychiatric disorders, we also assessed the ASD risk and the risk of other psychiatric disorders in siblings of probands with type-1 diabetes and siblings of probands with hernia, two heritable conditions. Not all countries and health systems can provide data to answer these questions. In our study we could use unique data from Israel, including information on family relations as well as clinically ascertained diagnoses of psychiatric disorders and potentially important confounding covariates.
Objectives: To utilize diagnostic data from screening of an entire population to further understand autism risk in relation to risk shared across other psychiatric diagnostic groups
Methods: The study population was recruited from all Israeli adolescents, ages 16-17, with at least one sibling and undergoing mandatory screening for eligibility to serve in the Israeli military, between the years 1998-2014. If the recruit is suspected of any relevant problems a comprehensive psychosocial examination is performed by a clinical social worker or psychologist and board-certified psychiatrist. Among individuals with an ASD diagnosis we calculated the risk of a selected psychiatric disorder in his/her sibling. Next, we repeated these calculations for all selected psychiatric disorders pairwise. We included the disorders: ASD (n=3400), psychotic disorder (n=9028), personality disorders (n=25,211), anxiety disorders (n=16,394), mood disorders (n=12,639), intellectual disability (n=13,667), low cognitive ability (n=23,226), type-1 diabetes (n=3638), and hernia (n=36,806). For each case we included 10 matched controls. We estimated relative risks of each disorder by the odds ratios from logistic regression. The odds ratios were calculated adjusted for sex, socio-economic status and year of birth.
Results: Siblings of probands with any of the psychiatric disorders were at increased risk for all psychiatric disorders examined and for low cognitive ability (most RRs ranging 2-3). For individuals with ASD the sibling RRs (95% confidence intervals) were estimated to be: for psychotic disorder, 3.4 (2.8-4.0); mood disorder, 2.4 (1.9-3.0); anxiety disorder, 2.9 (2.4-3.6); intellectual disability, 6.9 (6.0-7.9); ASD, 11.5 (9.2-14.4); hernia, 0.8 (0.6-0.9); and, diabetes, 1.0 (0.5-2.1).
Conclusions: There appears to be a large cross-sibling risk among individuals with different psychiatric diagnoses. Highest cross-sibling recurrence risk was observed for individuals with ASD, intellectual disability and psychotic disorder.

11:30 **102.004** Polygenic Transmission Disequilibrium Clarifies Common Variant Influences on Cognition in ASDs

D. J. Weiner[1,2]*, E. Wigdor*[1,2]*, M. Daly*[3] *and E. B. Robinson*[1,2]*, (1)Broad Institute, Cambridge, MA, (2)Analytic and Translational Genetics Unit, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (3)Massachusetts General Hospital, Boston, MA*

Background: Autism spectrum disorders (ASDs) are genetically and phenotypically heterogeneous. Recent studies have associated ASDs with classes of genome-wide polygenic risk (PRS) that have diverse influences on cognition (Bulik-Sullivan, 2015 Nature Genetics). For example, ASDs are (i) positively associated with polygenic risk for educational attainment, which itself is positively associated with cognition and (ii) positively associated with PRS for schizophrenia, which is negatively associated with cognition. While genetic correlation analyses are not expected to be transitive, this inconsistent network of associations has raised the potential of confounding and case heterogeneity.
Objectives: The purpose of this analysis was to clarify common variant risk for ASDs, and to better understand the ASD subgroups for whom contributing polygenic risk factors are relevant. We developed a novel analytic technique called the polygenic transmission disequilibrium test (pTDT). Briefly, it is algebraically expected that, in any given set of parent-child trios, the mean of the offspring PRS distribution will equal the mean of the average parent PRS. This expectation is broken in the context of case ascertainment. For example, if a class of PRS (e.g., polygenic risk for educational attainment) is associated with ASD case status, we expect the PRS of ASD cases on average to significantly exceed average parent PRS. The pTDT is immune to confounding by ancestry or case ascertainment, and confers a substantial power advantage over traditional case-control polygenic risk scoring.
Methods: We conducted pTDT using two ASD family cohorts. First, we used the Simons Simplex Collection (SSC), a resource of more than 2,500 families with a child diagnosed with ASD. Second, we used an independent Psychiatric Genomics Consortium ASD (PGC ASD) sample that consisted of 3,870 parent-child trios. The PGC ASD cohort described here does not include individuals from the SSC. Using a standard approach, we calculated common polygenic risk for ASDs, educational attainment (EA) and schizophrenia (SCZ) for all genotyped family members in the SSC and PGC ASD datasets.
Results: We found that ASD cases over inherit polygenic risk for ASD, EA and SCZ ($p < 1.00E-15$ for each pTDT comparison), thereby unambiguously associating these classes of polygenic risk with ASD. In contrast, unaffected siblings on average inherit the expected polygenic burden for these three risk classes ($p > 0.05$ for each pTDT). ASD case over inheritance holds for ASD probands with and without intellectual disability ($p < 0.0005$ for each pTDT), as well as for probands with both intellectual disability and a *de novo* copy number or protein truncating variant ($p < 0.002$ for each pTDT). Finally, we find that EA PRS is positively associated with ASD case IQ, that SCZ PRS is negatively associated with ASD case IQ, and that ASD PRS is not associated with ASD case IQ.
Conclusions: These analyses suggest that ASD-associated common variant risk is etiologically relevant across the IQ distribution in ASDs. Different types of polygenic risk have distinct associations with IQ, which suggests they operate through at least partially distinct biological pathways.

Panel Session
103 - Brain Imaging and Cognition: Findings of the Longitudinal European Autism Project
10:30 AM - 12:00 PM - Yerba Buena 7

Panel Chair: Jan Buitelaar, *Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

Discussant: Declan Murphy, *Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Autism Spectrum Disorder (ASD) is a common neurodevelopmental disorder but effective medical treatments for the core symptoms are still lacking. Although novel genetic and pre-clinical approaches are beginning to identify aetiology-based treatment targets there are still considerable challenges in testing them in clinical trials. This includes the need for objective diagnostic, stratification, and outcome measures that are accepted by international regulatory authorities. The EU-AIMS Longitudinal European Autism Project (LEAP) is a multi-centre, multi-disciplinary study to identify biomarkers that will allow stratification of patients into more biologically homogenous subgroups; and that may serve as surrogate endpoints. The European Medicines Agency (EMA) broadly endorsed the proposed population selection criteria and methodologies (cognitive, eye-tracking, EEG, MRI, FMRI, and biochemical biomarkers) for patient stratification (Loth et al., 2015). This panel will present the first results of the analyses of cognitive tasks, activation tasks using functional MRI, neural network architecture using resting-state MRI data and structural MRI data on volumetry, cortical thickness and surface area. The results will be discussed with the classical case-control paradigm, but also from the perspective of approaches for stratification of ASD.

10:30 **103.001** Identifying Cross-Domain Cognitive Subtypes Among Children, Adolescents and Adults with Autism Spectrum Disorders

E. Loth[1], *J. Ahmad*[2], *L. Mason*[3], *D. V. Crawley*[4], *H. L. Hayward*[5], *A. San Jose Caceres*[6], *B. Oakley*[6], *T. Charman*[2], *J. E. Tillmann*[2], *E. Jones*[7], *R. Holt*[8], *C. C. Bours*[9], *M. C. Lai*[10], *M. V. Lombardo*[11], *S. Baron-Cohen*[11], *M. H. Johnson*[12], *J. K. Buitelaar*[13], *D. G. Murphy*[14] *and G. Dumas*[15], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)CBCD, Birkbeck, University of London, Gravesend, UNITED KINGDOM, (4)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Birkbeck, University of London, London, UNITED KINGDOM, (8)Autism Research Centre, University of Cambridge, Cambridge, UNITED KINGDOM, (9)Department of Cognitive Neuroscience, Radboud University Medical Center, Nijmegen, The Netherlands, Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (10)Psychiatry, University of Toronto, Toronto, ON, CANADA, (11)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (12)School of Psychology, Birkbeck College, London, United Kingdom, (13)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (14)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (15)Institut Pasteur, Paris, France*

Background: Â Autism Spectrum Disorders (ASD) are clinically and etiologically heterogeneous conditions. To make progress in identifying underpinning mechanisms it is essential to parse ASD into more homogeneous (biological) subgroups. However, most analytic approaches have focused on case-control differences - treating ASD as a unitary diagnostic entity. At the cognitive level, no single marker has been found that characterizes all individuals with ASD. Instead, impairments or differences have been reported in several aspects of social cognition, such as theory of mind, social motivation/ social attention, and in "domain-general" cognitive abilities, including aspects of executive function, and weak central coherence (WCC). However, findings are mixed and abnormalities often do not strongly relate to symptom severity. Arguably, an individual's profile of cognitive impairments (and strengths) across domains may be more predictive of symptom severity or adaptive functioning than abnormalities in a single domain.
Objectives: 1) To identify cross-domain cognitive profiles in a large sample of individuals with ASD who were assessed as part of the EU-AIMS Longitudinal European Autism Project (LEAP); and 2) To investigate whether different cognitive subtypes differ in their clinical symptoms.
Methods: Participants completed a battery of cognitive tests tapping explicit and spontaneous theory of mind (a continuous false belief task and the Animated Shapes task), social attention (% gaze time on faces), spatial working memory (SWM), probabilistic reversal learning (PRL), and WCC (Block Design). Across tasks, 349-435 individuals with ASD and 251-297 individuals with typical development (TD) or mild intellectual disabilities aged 6-30 years were included. First, we tested case-control differences on each task. Second, we estimated developmental growth curves by generating normative models for each TD participant's [task score] relative to their age using Gaussian Processes for Machine Learning. For each participant with ASD we then quantified the deviation from the normative model. Finally, to identify cognitive subtypes, we used hierarchical clustering based on each individual's deviations from the means across all tasks.
Results: We found significant mean group differences in social attention (p=.002, d=.26) PRL (p<.0001, d=.35) and SWM (p<.0001, d=.43). However, normative modelling revealed that on the SWM task 66% of participants with ASD performed within +/-1 SD of the age-expected TD means or above; 19.7% fell between 1-2 SDs and 12.8% below 2 SDs. These patterns were very similar for the PRL and social attention measures (Figure 1). Hierarchical clustering (including only participants who completed all tasks) revealed 6 distinct clusters (Figure 2), which partly differed in their symptom presentation. For example, Cluster 6 (impaired ToM+ "intact" EF+ WCC) had on average significantly fewer repetitive behaviors than Cluster 3 (impaired social attention+ impaired SWM) and higher levels of adaptive behaviour than Clusters 3 and 2 (impaired reversal learning + other impairments), perhaps reflecting their ability to recruit 'intact' EF skills as a compensatory mechanism.
Conclusions: Â Using a battery of 'classic' ASD-related cognitive tasks, we show distinct cognitive profiles among people with ASD, with partly differing clinical symptoms. These results point to the value of stratification approaches to reduce heterogeneity, to refine both aetiology and intervention.

10:50 **103.002** The Neuroanatomy of ASD in a Large and Clinically Heterogeneous Sample – Preliminary Results of the EU-AIMS Longitudinal European Autism Project (LEAP)

C. Ecker[1,2], *R. Toro*[3], *D. Goyard*[4], *D. Andrews*[5], *E. Loth*[6], *J. K. Buitelaar*[7,8,9], *D. G. Murphy*[2] *and A. Grigis*[10], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychiatry, Goethe-University Frankfurt am Main, Frankfurt, Germany, (2)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Institut Pasteur, Paris, FRANCE, (4)Neurospin, CEA, Université Paris-Saclay, Gif sur Yvette, France, (5)King's College London, London, UNITED KINGDOM, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (8)Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (9)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (10)UNATI, Neurospin, CEA, Universite Paris-Saclay, Gif-sur-Yvette, France*

Background: Evidence suggests that Autism Spectrum Disorder (ASD) is accompanied by neurodevelopmental differences in brain anatomy and connectivity. Across studies, however, the size of reported effects is often inversely correlated with sample size (i.e. larger effects are typically reported by studies examining a small number of participants). It is thus currently under debate whether findings replicate in large and clinically heterogeneous samples of individuals, and which particular aspects of the cortical architecture underlying ASD are most representative of the broader ASD phenotype in the general population.
Objectives: Here, we therefore examined differences in various aspects of brain anatomy in a large and heterogeneous sample of ASD individuals, acquired across multiple acquisition sites within Europe, in order to (1) determine which neuroanatomical characteristics best represent the ASD phenotype in the general population, (2) to characterize differences in developmental trajectories, and (3) to examine the extent to which demographic variables such as biological sex may affects the neuroanatomy of ASD.
Methods: Across six European sites, we collected structural Magnetic Resonance Imaging (MRI) scans on 350 well-characterized individuals with ASD (*n*=254 males, *n*=96 females, mean age = 17.49+5.59 years, FSIQ = 99.28+19.47), and 255 typically developing (TD) controls (*n*=159 males, *n*=96 females, mean age = 17.34+5.87 years, FSIQ = 105.13+17.41). All individuals with ASD were diagnosed using gold-standard assessment tools for ASD (i.e. ADI-R, and ADOS). The FreeSurfer software suite (v.5.3) was utilized for data pre-processing, and to derive a set of neuroanatomical features that included total grey and white matter volumes, subcortical volumes, and surface-based morphometric features (cortical thickness (CT) and surface area (SA)). Multivariate general linear models were used to examine (1) between-group differences, (2) differences in neurodevelopmental trajectories on the global and local (i.e. vertex-wise) level of brain anatomy, and (3) diagnosis-by- sex interactions.
Results: Overall, we found that individuals with ASD did not differ significantly from TD controls in total grey and white matter volumes, total intracranial volume, or cerebrospinal fluid (p>0.05, two-tailed). There were also no significant between-group differences in the volumes of subcortical structure following correction for multiple statistical comparisons. On the vertex level, we confirmed that individuals with ASD have significant - and mostly non-overlapping - differences in CT and SA (Figure 1), which mediated differences in regional brain volume. As expected, within our observed age range (6.81–30.78 years), both CT and SA displayed complex (i.e. non-linear) neurodevelopmental trajectories, where ASD individuals significantly differed from controls. Last, we report significant sex-by-diagnosis interactions in surface anatomy, thus confirming that the neuroanatomy of ASD is significantly modulated by biological sex.
Conclusions: Taken together, when examining the neurobiological underpinnings of ASD in a large and clinical heterogeneous sample of individuals, our findings suggest that ASD is best characterized by regional differences in CT and SA. This is of importance as CT and SA have different neurodevelopmental origins, and may therefore be used to stratify individuals into genetically and/or phenotypically distinct subgroups. Moreover, these differences vary across the human life span, and also differ between men and women.

11:10 **103.003** A Multi-Site Investigation of Functional MRI Responses in the Longitudinal European Autism Project (LEAP) Cohort

C. Moessnang[1], *S. Baumeister*[2], *D. Goyard*[3], *K. Otto*[1], *S. Baron-Cohen*[4], *S. Durston*[5], *A. M. Persico*[6], *W. Spooren*[7], *D. G. Murphy*[8], *E. Loth*[9], *J. K. Buitelaar*[10], *T. Banaschewski*[11], *D. Brandeis*[2], *H. Tost*[1] *and A. Meyer-Lindenberg*[12], *(1)Department of Psychiatry and Psychotherapy, Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany, (2)Department of Child and Adolescent Psychiatry and Psychotherapy, Central Institute of Mental Health, Mannheim, Germany, (3)Neurospin, CEA, Université Paris-Saclay, Gif sur Yvette, France, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Rudolf Magnus Institute of Neuroscience, University Medical Center Utrecht, Utrecht, NETHERLANDS, (6)University of Messina, Rome, ITALY, (7)Roche Pharmaceutical Research and Early Development, NORD Discovery and Translational Area, Roche Innovation Center, Basel, Switzerland, (8)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (10)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (11)Central Institute of Mental Health, University of Heidelberg, Heidelberg, GERMANY, (12)Central Institute of Mental Health, Mannheim, Mannheim, Germany*

Background: A major goal of neuroimaging research in autism spectrum disorder (ASD) is the characterization of differential task-related neural responses in large-scale cognitive systems, which hitherto has yielded inconsistent findings. A likely reason is the heterogeneity of the disorder which has been insufficiently addressed in smaller-sized samples.
Objectives: As part of the Longitudinal European Autism Project (*LEAP*), we aim at identifying markers of aberrant neural processing in four major cognitive systems (emotion processing, Theory of Mind [ToM], executive control, reward processing) using task-based functional magnetic resonance imaging (fMRI) in a large cohort of ASD and typically developing (TD) subjects.
Methods: A task battery was designed which taps into core ASD deficits, allows for the inclusion of children and less able subjects and meets test-retest reliability criteria for the use in an accelerated longitudinal design including two measurement time points. FMRI was performed at six European centers following standard operations procedures. A total of 672 subjects (6-30 years, 58% ASD, 69% male) participated in the fMRI assessment and tasks were selected according to the individual's ability level. The task battery included a social and monetary reward task, a spontaneous mentalizing task involving animated shapes, an emotional face-matching task, and a flanker/GoNogo task. Baseline assessment was performed between April 2014 and September 2016, and a 12-24 month follow-up is currently under way. A quality control pipeline has been implemented and applied to the data in order to assess effects of site, diagnosis and age on raw data quality. First pass analyses have been performed using standard processing routines implemented in SPM12 (http://www.fil.ion.ucl.ac.uk/spm/).
Results: Â Quality assessment identified prominent effects of site on raw data QC metrics, with no or only modest interaction with diagnosis and age. Motion was elevated in ASD subjects and in younger children across tasks. Preliminary statistical analyses performed within the framework of the General Linear Model revealed robust activation of each of the networks of interest, while simple case-control differences did not pass the significance threshold (p<0.05, family-wise error corrected across the whole brain).
Conclusions: The LEAP cohort represents the largest European task-based fMRI data set on autism. The employed tasks successfully engaged functional activation within four major cognitive systems. In addition, first-pass analyses suggest that a thorough investigation of different sources of variance is warranted. This not only includes the control of various sources of noise (e.g. between-site differences, motion), but also the application of sample stratification procedures in order to address the hypothesized heterogeneity of the sample (e.g. symptom profiles, interaction with sex and age). These analyses will set the stage for an in-depth investigation of the autism phenotype in various functional imaging measures, ranging from regional activation to network-based connectivity metrics.

11:30 **103.004** Analysis of the Resting-State fMRI Data of the EU-AIMS Longitudinal European Autism Project (LEAP)

M. Oldehinkel[1,2], *M. Mennes*[1], *C. F. Beckmann*[1,3] *and J. K. Buitelaar*[1,2,4], *(1)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (2)Department of Cognitive Neuroscience, Radboud University Medical Centre, Nijmegen, Netherlands, (3)Centre for Functional MRI of the Brain, University of Oxford, Oxford, United Kingdom, (4)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands*

Background: Studies applying resting-state functional magnetic resonance imaging (R-fMRI) to investigate functional connectivity in autism spectrum disorders (ASD) have revealed mixed results. Interpretability of findings is further limited by the use of small sample sizes and the focus on a limited number of resting-state networks (RSNs). In this study we used R-fMRI data from 486 participants of the multicentre Longitudinal European Autism Project (LEAP) to investigate ASD-related changes in functional connectivity of 20 large-scale RSNs.
Objectives: To provide a comprehensive characterization of ASD-related alterations in functional connectivity within and between 20 RSNs in a large ASD cohort using 1) classical case-control comparisons and 2) dimensional analyses based on autism severity scores.
Methods: Good quality R-fMRI data was available for 265 ASD participants and 221 controls (age range: 7-30 years). We derived 20 RSNs by applying independent component analysis (FSL Melodic) to R-fMRI data from 75 control participants. Next, we obtained the subject-specific RSNs for each of the remaining participants (FSL dual regression) and compared functional connectivity within these 20 RSNs between the control group and ASD group (categorical analysis). In addition, we correlated functional connectivity within the 20 RSNs to the total score of the social responsiveness scale (SRS) across all participants (to investigate functional connectivity across the ASD continuum; dimensional analysis). In both analyses we applied permutation testing (N=5000; FSL Randomise) and corrected for multiple comparisons (i.e., correcting for testing 20 RSNs using Bonferroni). In addition, we computed Pearson correlations between the timeseries of the 20 RSNs to investigate categorical and dimensional ASD-related changes in between-network connectivity (5000 permutations, FDR-corrected). In all analyses we corrected for effects of scan site, age, gender and head motion.
Results: We obtained 20 RSNs that included common sensory, motor, default-mode, and task-related networks (Figure 1). We did not observe differences in functional connectivity within the 20 RSNs between the ASD and control group. Yet we did observe a significant association in the dimensional analysis: functional connectivity within the medial motor network increased at higher SRS scores (i.e., higher ASD severity scores). Furthermore, the between-network analysis revealed that functional connectivity between the lateral visual network and the auditory, lateral motor, and somatomotor network was decreased in the ASD compared to control group (Table 1).
Conclusions: Our findings suggest that the integration of information from different sensory modalities is disturbed in ASD, which might lead to the abnormalities in sensory processing in ASD. The increased functional connectivity within the motor network might further be related to the repetitive motor behaviors in patients with ASD. Importantly, the relatively limited amount of ASD-related alterations in functional connectivity observed in this large cohort points to a potential large heterogeneity among ASD patients and warrants caution when generalizing results from small sample R-fMRI studies in ASD to the general population. Accordingly, future work will focus on stratification of ASD patients and the investigation of developmental effects in ASD.

Panel Session
104 - Measuring and Predicting Quality of Life in Older Adults with Autism
10:30 AM - 12:00 PM - Yerba Buena 8

Panel Chair: Dermot M. Bowler, *City, University of London, London, United Kingdom*

Although it is widely accepted that the quality of life (QoL) of individuals with ASD is adversely affected in adulthood, particularly towards the later end of the life span, systematic research in this area is scarce. We know little about how to measure the QoL of individuals on the autism spectrum effectively nor about whether the conceptual framework of typical QoL translates easily to the context of ASD. There are also gaps in our knowledge about the wider pattern of factors that are associated with differences in QoL or whether or not there are any autism-specific associations with QoL. The papers in this panel tackle conceptual and practical issues relating to the measurement of QoL in later-life ASD as well as reporting whether factors, such as prospective memory, that are known affect QoL in the typical population operate similarly in ASD. The work reported here represents an important step forward in our understanding of autism in later life

10:30 **104.001** Successfully Engaging with Adults on the Autism Spectrum and Their Relatives about Longitudinal Cohort Research

J. Parr[1], *A. Petrou*[2], *J. E. Mackintosh*[3], *D. Mason*[4], *J. Hamilton*[5], *C. Michael*[6], *T. Goth*[7], *C. Mitchell*[7], *D. Garland*[8], *T. Finch*[7], *A. Le Couteur*[9] *and H. McConachie*[4], *(1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Newcastle University, Newcastle Upon Tyne, UNITED KINGDOM, (3)Newcastle University, Newcastle upon Tyne, UNITED KINGDOM, (4)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (5)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, (6)Autism Age, Notrwich, UNITED KINGDOM, (7)Newcastle University, Newcastle-upon-Tyne, United Kingdom, (8)National Autistic Society, Newcastle upon Tyne, United Kingdom, (9)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, UNITED KINGDOM*

Background: Little is known about how autism is experienced in adulthood or its impact across the life-course. Guidance about undertaking research with autistic adults and relatives is scarce. In setting up the Autism Spectrum Cohort-UK (ASC-UK), we learned many things about how to undertake longitudinal research with adults and relatives – this presentation aims to disseminate that learning, so other groups might benefit and set up successful research partnerships.
Objectives: 1. To disseminate information about a stakeholder-informed research approach for the meaningful engagement of autistic adults, and relatives, in a cohort study; 2. Show how this process has led to excellent recruitment into the cohort, and some early findings.
Methods: Between 2013-4, a series of consultations with around 50 autistic adults and relatives was held over a two year period; 'learning points' were extracted from notes of those meetings. From 2015, adults and relatives were recruited to ASC-UK from a network of over 100 UK National Health Service, Voluntary sector and autism community organisations. As part of mixed methods research, data were collected from all participants using a baseline questionnaire, plus the SRS and the WHOQoL-BREF. Interviews with 30 autistic adults were completed by one researcher, transcribed and coded.
Results: *Preparation for research***:** Recommendations included having autistic adults as paid researchers/advisors, and the development of 'user-friendly' research processes. Ways to include individuals with intellectual impairment were suggested. Questionnaire development focused on font size, spacing, and using plain text.Â A key point was emphasising the utility of the research for adults. The following were amongst the recommendations suggested for direct working: Use alternative ways to exchange information (e.g. text messages, emails, face-to-face discussions); give extra time in discussions and interviews for information processing; use visual materials; consider the sensory impact of interview venues. *Recruitment progress and initial study findings:* After 20 months recruitment, 990 autistic adults and relatives joined the cohorts (including 750 autistic adults, 50 of whom lacked capacity to consent for themselves); 50 adults per month joined in 2016. For the autistic adult cohort, men and women participated in equal numbers; median age was 39 years, range 17-86 years; 25% aged >55 years. Adults on the autism spectrum reported about their current mental health (depression in 47%, anxiety in 50%), and access to services – fewer than half had received the services they needed. Qualitative interviews revealed many themes that people thought important about the quality of their lives including: the importance of routines, the impact of supportive and non-supportive relationships, how a diagnosis led to people making sense of their lives, learning how to act to fit in with others, missed opportunities and achievements, managing responses to others.
Conclusions: Our findings emphasise the importance of utilising the expertise of autistic adults and relatives within the research team. This has led to effectiveness in involving, recruiting and engaging people to participate in the cohort study. In turn that has led to effective research providing detailed data about the quality of the lives of adults on the autism spectrum, and their relatives.

10:50 **104.002** Is the Whoqol-Bref Fit for Purpose in Measuring Quality of Life in Autistic Adults?

H. McConachie[1]*, D. Mason*[1]*, D. Garland*[2]*, C. Wilson*[3]*, A. Petrou*[4]*, J. Rodgers*[4] *and J. Parr*[4]*, (1)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)National Autistic Society, Newcastle upon Tyne, United Kingdom, (3)autism advocate, Sunderland, United Kingdom, (4)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: There is urgent need for health-related research with autistic adults to better understand their needs, lived experience and views. Furthermore, there is a lack of specifically validated outcome measures, in particular for measuring quality of life (QoL). Current research findings about QoL are inconsistent regarding which domains of QoL are most affected in autistic adults, and how QoL may vary with age is unclear.
Objectives: To examine the appropriateness of measuring quality of life of autistic adults with the World Health Organisation brief quality of life scale (WHOQoL-BREF).
To explore particular issues affecting quality of life in older adults on the autism spectrum.
Methods: Participants are members of the Adult Autism Spectrum Cohort (ASC-UK) involved in a longitudinal study of life experiences. Each adult (or proxy where the adult lacks capacity to consent for themselves) completes a baseline questionnaire, the Social Responsiveness Scale, and the WHOQoL-BREF. An exploratory factor analysis was conducted (n = 370) to examine the WHOQoL-BREF's structural validity for autistic adults, i.e. whether the same four subscales (social, psychological, physical, environment) emerge. Experiences and quality of life of older adults (61+ years) and younger adults were compared.
Qualitative information was obtained about determinants of individuals' quality of life, about the importance and interpretation of the items of the questionnaire, and about the suitability of the additional WHO Disabilities module (Power et al 2010) through in-depth interviews, focus groups and cognitive interviewing. Further items relevant to the experience of autistic adults were tested for importance and clarity in a Delphi survey, and all the items tested in a large validation study with the ASC-UK cohort.
Results: A five-factor model emerged showing considerable overlap with the WHO subscales (the physical subscale separating in two). Moderate to good internal consistency was found for the four subscales. In focus groups, some items were found difficult to interpret or suggested as relatively unimportant. Other items were discussed with a different slant, such as '*How satisfied are you with your capacity for work?*' where participants put emphasis on whether employers understood autism or had stereotyped views.
The individual interviews elicited themes from older adults which often reflected health issues, their own or of other members of the family. Some people had gained a positive outlook through obtaining a diagnosis later in life. Older and younger autistic adults on average reported similar QoL, except on the social subscale where older adults reported poorer QoL.
Conclusions: The WHOQoL-BREF appears largely appropriate for measuring quality of life in autistic adults. However, additional Disabilities items give a fuller picture of specific experiences related to autonomy, control and discrimination, as well as newly derived autism-specific items including other people's lack of understanding of autism, financial insecurity and the specific support structures needed by individuals. For older adults, health issues loom large, either for themselves or requiring them to take on a carer role in the family. As autistic adults, they may have great difficulty in asking for and finding appropriate sources of support and health services.

11:10 **104.003** Do ASD Adults Become Happier When Older?

H. M. Geurts*, University of Amsterdam, Amsterdam, NETHERLANDS*

Background: Given the lack of knowledge regarding older ASD adults, researchers, ASD adults, and their relatives agreed that we need to study what the future holds for those with ASD. This is especially important as life-span subjective well-being is reported to be low. Most earlier studies did not include older individuals with ASD (i.e., >50 years) and were cross-sectional in nature. Moreover, several factors (e.g., ASD-severity, IQ, comorbidity) are thought to be relevant to subjective well-being, but the interaction among potentially relevant factors is often ignored. Recently we showed that focusing on the multivariate pattern of these factors is needed to enhance our understanding of subjective well-being in ASD.
Objectives: First, to provide an overview of a series of recent cross-sectional studies in which we focused on subjective well-being in ASD adults. Second, to explore longitudinally the (interaction of) predictors of change in subjective well-being in mid- and old-aged ASD adults.
Methods: A total of 122 (80 males) mid- and old-aged ASD adults (M=53.8, range 31-80 years) were assessed 1 to 4 years (M=3.1 years; T2) after they participated in a large cross-sectional study (T1; Lever & Geurts, 2016). For this abstract, we conducted an exploratory regression analyses with self-reported ASD-symptomatology (AQ), comorbid symptomatology (SCL-90), and educational level at T1 as predictors of change in subjective well-being (WHO-QoL short version, four scales). Please note that network analyses are the planned analyses in which psychotropic medication use (yet to be scored) and occupational status (yet to be scored) will also be included as network factors.
Results: When focusing on the change score (T2-T1) there are large individual differences. Depending on the WHO-QoL subscale 16 to 24% do have a similar score at both time-points. Individuals showing an increase or a decrease were equally prevalent. The exploratory regression models explained hardly any variance, and none of the predictors were statistically significant.
Conclusions: The subjective well-being in mid- and old-aged ASD adults is lower when compared to those without ASD and often changes with age. However, the directionality of these changes differs across individuals. Although, the reported analyses are preliminary, so far the tentative conclusion is that ASD-, comorbid symptomatology, and one's educational level do not seem to be relevant factors to predict the observed change. The results of the aforementioned network analyses will be discussed, as well as alternative predictors.

11:30 **104.004** Prospective Memory and Quality of Life in Older Adults with Autism.

A. Roestorf[1]*, S. B. Gaigg*[1]*, P. Howlin*[2]*, C. Povey*[3] *and D. M. Bowler*[1]*, (1)Psychology, City, University of London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, London, UNITED KINGDOM, (3)The National Autistic Society, London, UNITED KINGDOM*

Background: Prospective memory (PM) is 'remembering-to-remember', or remembering to do something in the future (Brandimonte et al., 1996). In neurotypically ageing (NT) adults, PM is crucial to healthy and independent ageing (d'Ydewalle et al., 2001; Henry et al., 2004) and is a significant factor in preventing age-related memory decline (Maylor, 1996), as well as being one of the most important predictors of quality of life (QoL) (Woods, 2015). PM can involve event-based (EBPM) remembering supported by external referencing cues, and time-based (TBPM) remembering which is reliant on internal self-referencing.
Limited research on PM in ASD has been conducted with children and young adults, using computerised and pseudo-naturalistic paradigms in lab settings. PM studies with ASD adults report variable difficulties in intention formation, rule adherence and everyday memory, compared to non-autistic adults (Altgassen et al., 2012; 2013; Williams et al., 2014). However, the majority of these studies combined EBPM/TBPM assessment in single tasks, involving social demands – remembering something related to someone else (e.g. experimenter), which may have disadvantaged autistic adults to a greater extent than non-autistic individuals.
Objectives: This is the first ASD-related study evaluating the role of social motivation (self-relevant vs other-relevant) in lab-based and truly naturalistic settings and age-related differences in PM, everyday functioning and QoL.
Methods: Forty-nine adults with a diagnosis of ASD and 38 NT adults in a comparison group matched on age (19-80 years) and IQ (>70, mean 115, SD 14) are involved in 4 within-group studies in this extended programme of work. Studies 1 and 2 evaluate (1) EBPM and (2) TBPM ability as separate tasks embedded in a computerised lexical decision paradigm in a lab setting. Studies 3 and 4 explore (3) EBPM and (4) TBPM for (3a, 4a) self-relevant and (3b, 4b) other-relevant tasks in a naturalistic environment, during the course of everyday activities such as participants having to remember to phone in information in a given number of days' time. QoL was measured by WHOQoL-BREF.
Results: Preliminary analyses show the ASD group made fewer accurate but slower PM responses (p<.001) under increased demands of an ongoing lexical decision task (p<.05). Moreover, PM difficulties were highly correlated with poorer physical quality of life in the ASD group (p<.001). The studies are ongoing and our full data will be available by March 2016. Our predictions are based on our recent *Ageing with Autism* work (Roestorf & Bowler, 2016).
We predict: (i) poorer TBPM than EBPM in all ASDs; (ii) impaired EBPM in all ASDs compared to TD comparison groups; (iii) poorer TBPM in younger ASDs compared to TDs but (iv) no differences between the older ASD-TD groups; and (v) no group differences in 'self-relevant' task performance, but (vi) impaired 'other-relevant' task performance in ASDs compared to TDs.
Conclusions: Our findings will enhance our understanding of the role of age-related differences in QoL and different types of PM autistic adults, thus informing the challenges and benefits of growing older with autism.

Panel Session
105 - Towards Elucidating Early Causal Mechanisms of ASD: New Directions for Prospective Longitudinal Studies
10:30 AM - 12:00 PM - Yerba Buena 9

Panel Chair: Emily Jones, *Birkbeck, University of London, London, UNITED KINGDOM*

Discussant: Terje Falck-Ytter, *Dept of Psychology, Uppsala University, Uppsala, Sweden, Dept of Psychology, Uppsala University, Uppsala, Sweden*

Prospective longitudinal studies of high-risk infants have provided a nuanced characterisation of behavioural symptom emergence in infancy and toddlerhood. However, our understanding of the causal neurodevelopmental mechanisms remains limited. We present four theoretically motivated approaches designed to provide insight into mechanisms underlying symptom onset. Our first speaker acquires brain structural, functional and biochemical data from fetuses, neonates and infants with and without risk factors for neurodevelopmental conditions. She will present preliminary evidence of differences in regional brain structure and function and maturation of the glutamate system in these risk groups. Second, we showcase recent work demonstrating that patterns of EEG observed in 3-month-old infants at high risk for developing autism and who are subsequently diagnosed with autism at age 3 differ from infants who do not develop autism. Third, we show that alterations in infants' pupillary light reflex – a basic measure putatively linked to the cholinergic system – may relate to later ASD outcomes. Finally, we will present recent work on altered experience-dependent specialisation of the social brain in early ASD, including new data linking variation to sensory processing atypicalities. Taken together, these talks identify new avenues for generating fundamental insights into the mechanisms that drive symptom onset in ASD.

10:30 **105.001** Applying MRI to Map Typical and Potentially Atypical Brain Development at Fetal, Neonatal and Infant Time-Points

G. M. McAlonan, *Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Until now, we have had few tools to explore early human brain development *in vivo*. This is changing with the advent of sophisticated but safe, Magnetic Resonance (MR) techniques that can be applied at fetal, neonatal and infant stages of development.
Objectives: We aim to acquire brain structural, functional and biochemical data from infants with and without a family history (parent or sibling) of Autism Spectrum Disorder (ASD) from before birth through to 6 months of age. We will first test the hypothesis that a familial risk of ASD causes differences in brain maturational indices. When outcome data becomes available, we will test the hypothesis that these brain maturational differences predict the later appearance of autistic behaviours.
Methods: Advanced MRI protocols at 3Tesla have been optimized for very young children and fetuses. Structural, resting-state functional and magnetic resonance spectroscopy datasets are in progress. At the time of writing data is available for approximately n = 50 fetuses (at approximately 34 weeks gestation); n = 60 neonates; n = 50 6 month old infants; and increasing. A number of these children have been scanned on at least 2 occasions. Approximately half have a family history of ASD. We are currently characterizing brain maturation profiles across the whole group and also testing for potential between group differences. In addition, the infants are invited to return for follow-up developmental assessments (including for traits of ASD), until the age of 3- years, at which time we will examine whether brain indices in very early life predict later childhood outcomes.
Results: I will present preliminary evidence for group differences in brain structure and function and maturation of the glutamate system in very young children at risk of ASD. There appears to be a concentration of differences in the subcortical and interconnected brain regions.
Conclusions: This data will contribute to the longer-term objective to identify early imaging biomarkers which predate and help predict neurodevelopmental outcomes (adverse or not) in childhood.

10:50 **105.002** EEG Variability at 3 Months Correlates with Autism Outcomes

A. R. Levin[1], *H. M. O'Leary*[1], *A. S. Mendez Leal*[2], *A. Acosta*[3], *K. J. Varcin*[4], *J. M. Mayor Torres*[5], *H. Tager-Flusberg*[6] *and C. A. Nelson*[7], *(1)Neurology, Boston Children's Hospital, Boston, MA, (2)Harvard College, Cambridge, MA, (3)Harvard, Cambridge, MA, (4)Telethon Kids Institute, Perth, Australia, (5)Harvard Medical School, Cambridge, MA, (6)Psychological and Brain Sciences, Boston University, Boston, MA, (7)Boston Children's Hospital, Boston, MA*

Background:
There are now a plethora of studies using EEG to elucidate neural connectivity in autism. While within-subject variability in EEG responses to repetitive stimuli are often thought to be a barrier to be overcome in such studies, recent work suggests that variability itself may be an important marker of underlying neurobiological processes, rather than a barrier to be overcome. To this end, elevated intra-participant variability in response to repetitive trials has now been demonstrated in multiple studies of children with autism spectrum disorder (ASD).[1]
Increasing evidence also suggests that alterations in brain development during infancy precede the manifestation of overt, behavioral signs of autism spectrum disorder (ASD). A key finding in infant studies, however, is that findings present in children with ASD may be different from findings in infancy that portend a later ASD diagnosis. For example, prior studies from our group have shown that high frequency frontal power is decreased in 3-month-old infants at high risk for ASD, but increases excessively over the first 3 years of life in infants who later develop ASD.
Here, we therefore assess the extent to which trial-by-trial within-participant variability, previously shown to be elevated in children and adults with ASD, is altered in infants who are later diagnosed with ASD.
Objectives: We analyzed response variability in 3-month-old infants later diagnosed with ASD, compared to infants who were later found not to have ASD.
Methods: ERP data were acquired on 3-month-old infant siblings of children with ASD (high risk; HRA; n = 41) and 3-month-old low risk controls (LRC; n = 16) as part of a prospective, longitudinal investigation. For each infant, we used inter-trial alpha phase coherence (ITPC) to measure variability of the P150 response across trials to a standard native consonant-vowel auditory stimulus (/da/). Diagnosis of ASD(+) or lack thereof(-) was determined at 24-36 months using the Autism Diagnostic Observation Schedule (ADOS) and best clinical estimate (HRA+: n = 11; HRA-: n = 14; LRC-: n = 16).
Results: 3-month-olds later diagnosed with ASD had significantly increased P150 response variability ($p < .05$), compared to 3-month-olds later found not to have ASD.
Conclusions: Increased intra-individual response variability to a repetitive stimulus is present in 3-month-olds who will later develop ASD. This suggests that excessive variability is present prior to the onset of behavioral manifestations of ASD, and thus may be an early marker of altered brain function on the pathway to ASD symptoms.

11:10 **105.003** Enhanced Pupillary Light Reflex in Infancy Predicts Elevated Autistic Symptoms at Two Years of Age

T. Falck-Ytter[1,2], *P. Nyström*[3], *E. Nilsson Jobs*[3], *G. Gredebäck*[3] *and S. Bolte*[1], *(1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (2)Dept of Psychology, Uppsala University, Uppsala, Sweden, (3)Uppsala University, Uppsala, SWEDEN*

Background:
We recently discovered that ten-month-old siblings of children with autism spectrum disorder (ASD) had stronger pupillary light reflexes compared to low risk control infants (Nyström et al., 2015, Molecular Autism), a result which contrasts sharply with the weak pupillary light reflex typically seen in both children and adults with ASD. This finding raises the possibility that the pupillary light reflex captures early neurodevelopmental processes associated with autism risk. According to one hypothesis, atypicalities in the pupillary light reflex reflect a dysregulation in the cholinergic system, which is disrupted in ASD and plays a key role in the regulation of excitatory-inhibitory balance early in life.
Objectives: We followed up the infants in our previous study to an age when ASD outcome could be assessed. Based on the result of our previous study we predicted that infants who later developed high levels of ASD symptoms would have stronger pupillary light reflexes than other infants.
Methods: The pupillary light reflex was assessed using non-invasive eye tracking and the amplitude and latency was calculated in accordance with Nyström et al. (2015; Molecular Autism). 49 infants were included in the final sample. At 24 month of age, the Autism Diagnostic Observation Schedule, second edition (ADOS-2) was administered. ADOS standardized calibrated severity scores (CSS; range 1-10) were calculated, where scores in the 6-10 range indicate moderate-to-severe concern for ASD (Esler et al, 2015, JADD). We classified individuals in the high risk group with scores in this range as ASD positive (n = 6). Remaining infants were either ASD negative (n = 29) or low risk controls (n = 14).
Results: We found that the amplitude of the pupillary light reflex was larger in 10-month-olds who were classified as ASD positive at 24 months compared to unaffected high risk infant siblings – who in turn had larger amplitudes compared to infants with no family history of ASD (both *P*s <.05).
Conclusions: This study indicates that dependent on its magnitude, the pupillary light reflex in infancy signals either sub-threshold ASD risk or full-blown clinical symptoms, and suggests that pupillometry can facilitate risk assessment in human infants.

11:30 **105.004** Sensory Hypersensitivity Predicts Enhanced Attention Capture By Faces in the Early Development of ASD

E. Jones[1], *G. Dawson*[2] *and S. J. Webb*[3], *(1)Birkbeck, University of London, London, UNITED KINGDOM, (2)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (3)University of Washington, Seattle, WA*

Background: Sensory symptoms are highly prevalent in young children with ASD, but their relation to the canonical social communication symptomatology is unclear. Recently, sensory hypersensitivities have been linked to increased allocation of attention to low-level sensory stimuli within the neural salience network (Green et al., 2016). Since people possess many salient low-level features that drive attention capture in early development (e.g. motion, audio-visual synchrony, and relative unpredictability), we reasoned that greater levels of hypersensitivity should predict *greater* early attentional responses to social stimuli. Further, since social attention is thought to promote more optimal social development, we predicted that greater early attentional responses to social stimuli should predict greater social approach within a group of children with ASD.
Objectives: In two longitudinal samples, we tested whether early sensory hypersensitivity predicts later enhanced attention capture by faces, and whether this in turn predicts better social approach within groups of children with ASD.
Methods: We used questionnaire measures to assess sensory hypersensitivity (the perceptual sensitivity subscale of the Infant Behavioral Questionnaire and a composite measure of sensory hypersensitivity from the Sensory Profile) in two cohorts respectively: n=88 infants at low and high familial risk for ASD tested at 6, 12 and 18 months; and n=48 toddlers with ASD tested at 2, 3 and 4 years. Neural attention capture by faces was measured using event-related potential responses to faces and objects. We also examined behavioral attention capture by faces and objects using a habituation paradigm.
Results: In Experiment 1, greater sensory hypersensitivities (lower scores) at 2 years in toddlers with ASD (n=48) predicted larger amplitude ERP responses to faces (P1, P400 and Nc) at 4-years (Fig 1), and this in turn was related to greater social approach (interest and interaction). In Experiment 2, greater perceptual sensitivity at 6 months predicted larger P1 amplitude to faces at 18 months in infants at low (n=45) and high (n=43) familial risk for ASD.
Conclusions: In this study, we provide the first demonstration that early sensory sensitivities predict greater attention capture by faces, and this mediates improved social approach behaviors in the early development of ASD. Our findings are consistent with a theoretical model in which early hypersensitivities are associated with increased attention capture by stimuli with salient sensory features; and that because people tend to have salient sensory features in naturalistic environments (e.g. motion, audiovisual synchrony and unpredictability) attention capture to faces becomes stronger. In the context of a supportive environment, heightened sensory hypersensitivity may support social development for children with ASD. This information may be critical to consider when designing therapeutic strategies or trying to predict individual outcomes for children with ASD.

Poster Session
106 - Animal Models
12:00 PM - 1:40 PM - Golden Gate Ballroom

1 **106.001** A TrkB Partial Agonist Rescues Autistic-like Behaviors in Adult Mice Prenatally Exposed to Valproic Acid

M. Fahnestock[1], *C. Nicolini*[1], *V. Aksenov*[2], *E. Rosa*[1], *B. Michalski*[1], *C. D. Rollo*[2], *J. A. Foster*[1] *and F. M. Longo*[3], *(1)Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada, (2)Biology, McMaster University, Hamilton, ON, Canada, (3)Neurology and Neurological Sciences, Stanford University, Stanford, CA*

Background: The molecular mechanisms underlying autistic behavior remain to be elucidated. We previously demonstrated reduced TrkB and Akt protein expression in postmortem fusiform gyrus tissue from human idiopathic autism. Similarly, total and phosphorylated Akt protein are decreased in cortical tissue from rats prenatally exposed to valproic acid (VPA), a well-established model of environmental/epigenetic origins of autism. These findings implicate defective TrkB signaling through Akt as a molecular substrate of autistic behavior and a potential therapeutic target for autism.
Objectives: We examined whether increasing Akt signaling using the TrkB partial agonist LM22A-4 would restore Akt deficits and ameliorate autistic-like behavior in adult mice prenatally exposed to VPA.
Methods: Pregnant females received a single intraperitoneal (i.p.) injection of 500 mg/kg VPA on gestational day 12.5, while controls were injected with saline. Pups were weaned on postnatal day (PD) 21 and received an i.p. injection of either saline or LM22A-4 dissolved in saline (0.05 mg/g) once daily from PDs 21-35. Sociability and repetitive digging were evaluated on PDs 29-34 using the three-chambered social approach task and marble-burying test, respectively. Litters were killed and brain tissue harvested on PD 35. Akt protein and phosphorylation levels were measured by Western blotting in temporal/parietal neocortex.
Results: Adult mice prenatally exposed to VPA lacked sociability, exhibited increased repetitive digging behavior and had decreased cortical phosphorylated Akt. We demonstrated that treatment of prenatally VPA-exposed, adult mice with LM22A-4 restored sociability and decreased repetitive behavior. Additionally, LM22A-4 treatment together with enrichment from behavioral testing normalized cortical Akt phosphorylation.
Conclusions: Our results show that the TrkB partial agonist LM22A-4 rescues autistic-like behaviors in adult mice prenatally exposed to valproic acid, supporting the hypothesis that reduced Akt signaling contributes to autistic behavior, and that LM22A-4 has potential for treating sociability and repetitive/perseverative behavior in idiopathic autism.

2 **106.002** Alteration in EEG and Auditory Evoked Potential in a Mouse Model of Tuberous Sclerosis Complex

M. Modi[1], *S. Dhamne*[2], *A. Rotenberg*[2] *and M. Sahin*[2], *(1)Pfizer, Inc., Boston, MA, (2)Neurology, Boston Children's Hospital, Boston, MA*

Background:
Tuberous sclerosis complex (TSC) is a rare genetic disorder associated with autism spectrum disorder (ASD) in approximately 50% of cases, making it one of the most common genetic forms of autism. Dysregulation of the mTOR pathway in TSC results in alterations in axon outgrowth and synapse formation similar to many other autism related mutations. TSC, therefore, can be used as a model of autism related synaptopathy. The consequences of synaptopathy can be explored at the systems level through the measurement of neural activity via electroencephalography (EEG). Spectral power and evoked potentials measured from EEG can be used to quantify neural activity in both patients with TSC and in mouse models of *Tsc*mutation. Altered patterns of neural activity could be used as a translational, quantitative biomarker for the development of novel therapeutics.
Objectives:
To characterize auditory evoked potential and resting state EEG in a transgenic mouse model of TSC for use as a translational biomarker of synaptic function.
Methods:
Neural activity was measured using a wireless, telemeterized EEG recording system from mice expressing a hypomorphic *Tsc2*allele under control of a neuronal specific promoter. Electrical activity was recorded from a screw located over the frontal lobe. Spectral power from resting state EEG and auditory evoked potential elicited from a mismatch negativity paradigm were collected.
Results:
Mice with reduced expression of *Tsc2*have a reduction in oscillatory power in low frequency bands (theta) but an increase in power in the high frequency bands (beta and gamma). Mutant animals also have an alteration in the evoked response to auditory tones relative to control animals.
Conclusions:
The resting state and evoked changes in neural activity in the *Tsc2* mutant mouse could be used as a biomarker of alterations in brain connectivity underlying behavioral impairments. Comparison of the effect of pharmacological treatments on behavioral and neurophysiological measures in rodents and patients could enable the use of EEG as a translational biomarker of treatment efficacy.

3 **106.003** An Autism Mouse Model Exhibits Limbic System Alterations That Enhance Susceptibility to Stress

J. W. Lunden[1], *C. C. Peng*[2], *V. R. Mirabella*[3], *S. Prem*[4] *and E. DiCicco-Bloom*[5], *(1)SPH 354, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (2)Rutgers Robert Wood Johnson Medical School, Monmouth Junction, NJ, (3)Neuroscience and Cell Biology, Rutgers-RWJMS/Princeton Training Program, Piscataway, NJ, (4)Robert Wood Johnson Medical School, Piscataway, NJ, (5)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ*

Background:
Autism Spectrum Disorder (ASD) is characterized by abnormalities in social interaction and restricted/repetitive behaviors. *Engrailed-2 (En2)*, a gene associated with ASD, is a neural patterning transcription factor involved in the development of the embryonic mid-hindbrain region, where norepinephrine (NE) producing neurons emerge. Previous studies indicate that *En2* knockout (*En2*-KO) mice display ASD-like deficits in social interactions, and show depressive phenotypes behaviorally (forced swim) and physiologically (decreased cell number in the dentate gyrus and decreased neurons produced in adult neurogenesis), which implicate abnormal stress responses. Environmental stressors elicit physiological responses by increasing Hypothalamic-Pituitary-Adrenal (HPA) axis activity, which initiates in the paraventricular nucleus of the hypothalamus (PVN). HPA axis activation, specifically PVN activity, is modulated by projections from limbic structures, including the amygdala (stimulatory) and the ventral hippocampus (VH) (inhibitory). While dorsal forebrain structures in the *En2-KO* exhibit reduced NE levels and fiber innervation, innervation patterns into the ventral limbic system, including amygdala and PVN, are undefined.
Objectives:
Characterize NE fiber innervation into the basolateral amygdala (BLA) and PVN using biochemical and anatomical approaches, and determine whether neural activity, indicated by c-Fos immunohistochemistry, PVN, and VH following swim-stress correlates with NE innervation.
Methods:
In postnatal day 60-70 wild type (WT) and KO mice (N=4-6/genotype), western blot analysis was performed to determine protein levels of norepinephrine transporter (NET) and tyrosine hydroxylase (TH). NET-containing fibers in BLA and PVN were assessed on tissue sections using immunohistochemistry. To measure stress response, animals were given 10 minutes of swim stress followed by PFA fixation via cardiac perfusion at 120 to 140 minutes. Brain sections were cut at 40 µm, and stained for c-fos using DAB. All forced swim was performed between 12:00 to 2:00 PM EST.
Results:
En2-KO mice exhibited increased NET (1.7-fold, $p<0.02$) and TH (1.5-fold, $p<0.002$) protein levels in the amygdala. NET fiber counts were also increased in BLA (2.3-fold, $p<0.0007$) and PVN (1.7-fold, $p<0.016$). Following swim stress, *En2*-KO mice exhibited a 6-fold increase in c-fos nuclei in the locus coeruleus (the origin of NE fibers) compared to unstressed KO mice, while WT exhibited a 2-fold increase compared to unstressed WT. Further, the KO stress group also had a ~2-fold increase in c-fos signal in the PVN compared to the WT stress. Conversely, the En2-KO ventral hippocampus exhibited a blunted response to stress, where the increase in c-fos levels were approximately a quarter of those exhibited in the WT.
Conclusions:
Our observations indicate that NE fiber innervation in the *En2*-KO mice is markedly increased in the PVN and BLA, whereas it is reduced in the hippocampus. In turn, this pattern of enhanced excitatory signaling accompanied by reduced inhibitory activity will likely lead to excessive activation of the HPA axis, an outcome under current investigation.

4 **106.004** Analysis of Phenotypes in Rodent Models Based on High-Risk ASD Genetic and Environmental Factors

I. Das*, M. A. Estevez, A. A. Sarkar, R. S. Lin, W. Pereanu and S. B. Basu, Mindspec, Inc., McLean, VA*

Background: Â With identification of risk genes associated with autism spectrum disorder (ASD), rodent models provide access to the unique and common phenotypic outcomes for their perturbations. Increasing evidence also presents strong corroboration towards the involvement of environmental factors, such as maternal immune activation (MIA) during fetal development, as a risk factor for development of ASD. Again, rodent models have been successfully used to provide insights into the regulators of perturbation to pivotal pathways in the developing fetus in MIA, e.g., the role of proinflammatory cytokines, like IL-6 and IL-17a. However, given the heterogeneity of ASD features in the human population, as well as the relatively tenuous parallels between face validity in animal models and human behavior in the manifestation of the complex, multifactorial, neurodevelopmental disorders like ASD—i.e., in social behavior, communication and repetitive behavior—we look into the phenotypic characteristics of animal models based on strong genetic or environmental risk factors of ASD.
Objectives: Â Our aim is to assess the face validity of the entire set of models developed for genetic and environmental factors associated with ASD based on multiple lines of evidence. We examine the underlying causes in this set, something that has not been dealt in a detailed manner to the best of our knowledge.
Methods: Â Using the data in the Animal Module of AutDB (also known as SFARI Gene), we look into the detailed phenotypic data on the models based on high-confidence and strong-candidate genesÂ to uncover similarities in complex behaviors as well as in possible underlying neurophysiological or neuroanatomical substrates. Additionally, we also correlate the phenotypic outcomes seen in high-risk genes to those of maternal immune activation in various rodent models using several immune activators: influenza virus infection, viral infection mimicry using polyinosinic–polycytidylic acidÂ (poly(I:C)), bacterial infection, its mimicry using lipopolysaccharide (LPS) and modulation of cytokine levels. Our analysis looks into changes in phenotypes beginning during embryonic development to identify any common anomalies seen in brain development, followed by distinctive patterns in neuroanatomy and neurophysiology, by age: early postnatal, juvenile stages, through adulthood.
Results: Loss of function of high-confidence genes in mice causes increased embryonic lethality, which is not surprising as it is likely that these genes perform important developmental roles that have not been highlighted previously. Data from heterozygous and intricate conditional knockout mice of high-risk genes confirm that mouse models do recapitulate ASD features, reliably preserving face validity. From the data on genetic models combined with MIA models, there is some indication of common underlying changes in brain structure and function that are related to the observed impairments in social and repetitive behavior, even if deficiencies in communication are not that saliently reflected in these models.
Conclusions: Our analysis provides support for looking at large datasets of rodent models showing face validity of some features of ASD in order to elucidate common underlying mechanisms. We believe that, while striking observations are noted by studies conducted on one or two important ASD genes, a combined approach can bring out similarities not otherwise highlighted.

5 **106.005** Autism-Relevant Anatomic Changes in Brain Structure in the Antigen-Driven Animal Model of Maternal Autoantibody Related Autism

K. L. Jones[1]*, J. Ellegood*[2]*, J. P. Lerch*[3] *and J. Van de Water*[1]*, (1)University of California at Davis MIND Institute, Davis, CA, (2)Hospital for Sick Children, Toronto, ON, CANADA, (3)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada*

Background: Numerous researchers have described the presence of maternal autoantibodies reactive to fetal brain proteins in a subset of mothers of children with autism spectrum disorder (ASD). Our lab identified 7 protein antigens for maternal autoantibody related (MAR) risk for ASD, and recently have mapped the antigenic epitope sequences recognized by these ASD-specific maternal autoantibodies. Our lab has now created an antigen-driven mouse model of MAR risk for ASD (MAR-ASD) in which autoantibodies reactive to the salient epitope sequences are generated in female dams prior to breeding, thus allowing for the continual exposure to the salient autoantibodies throughout gestation. Prenatally exposed offspring display robust deficits in social interactions and increased repetitive self-grooming behaviors as juveniles and adults during dyadic social interactions, demonstrating for the first time that these maternal autoantibodies are directly responsible for alterations in behaviors highly relevant to ASD. Furthermore, an association between maternal autoantibodies and alterations in neuronal development, including increased brain volume, has been demonstrated in previous passive transfer models as well as in the clinical population.
Objectives: The present study was designed to characterize the neuroanatomical differences in our clinically relevant antigen-driven mouse model of MAR risk of ASD using high-resolution structural MRI.
Methods: In order to generate epitope-specific autoantibodies that mimic those found in the mothers of children with ASD, C57BL/6J females randomly assigned to MAR-ASD treatment received a series of immunizations prior to breeding containing peptide epitope sequences of the four primary target proteins of MAR ASD (lactate dehydrogenase A and B, collapsin response mediator protein 1, and stress-induced phosphoprotein 1) conjugated via Multiple Antigenetic Peptide system technologies in addition to adjuvant. Control C57BL/6J females were injected with saline only. Following confirmation of autoantibody production in immunized animals by ELISA, females were then paired with male breeders to produce the experimental offspring of interest. Neuroanatomical differences in subsequent male and female offspring were assessed via high-resolution structural MRI at approximately 6 months of age (MAR-ASD = 22; Control = 23).
Results: In comparing MAR-ASD to WT adult brains, 31 of the 159 regions examined were found to be significantly different at an FDR of <5%. MAR-ASD offspring had significant increases in size of several white matter tracts, including the anterior commissure (pars anterior: +2.42%, FDR=4%; pars posterior: +3.89%, FDR=2%), cingulum (+2.52%, FDR=3%), corpus callosum (+3.19%, FDR=1%), and internal capsule (+2.67%, FDR=4%). Outside of the white matter, increases were observed in several cortical regions and in basal nuclei structures (nucleus accumbens: +2.68, FDR=2%; olfactory tubercle: +2.65%, FDR=2%; basal forebrain: +1.90%, FDR = 3%).
Conclusions: Our results suggest that numerous brain regions were significantly increased in offspring prenatally exposed to the salient maternal autoantibodies relative to controls. These findings further support the pathological role of maternal autoantibodies in ASD, with neuroanatomical alterations lasting into adulthood.

6 **106.006** Behavior Phenotyping of a Mouse Model of Phelan Mcdermid Syndrome with a Full Deletion of Shank3 Gene

E. Drapeau[1]*, J. D. Buxbaum*[2] *and M. Riad*[1]*, (1)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Phelan-McDermid Syndrome (PMS) is a rare genetic syndrome in which one copy of the q13 portion of chromosome 22 is missing or mutated leading to a global developmental delay, hypotonia, delayed or absent speech, intellectual disability, and autistic behaviors. SHANK3, a gene coding for a key structural part of the post-synaptic density, is the critical gene for the core neurological and behavioral symptoms in this syndrome, and the loss of one copy of SHANK3, occurring through intragenic deletion or point mutation, is sufficient to cause Phelan-McDermid syndrome. However, the size of the region affected can be highly variable, from point mutation to up to 8 Mb deletions and the deletion size seems to be correlated with the syndrome severity. Due to multiple intragenic promoters and alternatively spliced coding exons within the gene, several Shank3 isoforms have been identified in human and mouse brains.
Objectives: Numerous mouse models have been generated but most target only some of those isoforms while the vast majority of SHANK3 mutations found in PMS patients are deletions of the entire gene. Our aim is based on a novel mouse model, in which all Shank3 isoforms are disrupted and which more closely mirrors the most common genetic mutations found in PMS and our goal was to investigate the behavioral consequences of a disruption of all isoforms of Shank3.
Methods: Our laboratory had previously created a mouse model with a deletion of exons 4 to 9 leading to the disruption of the full length Shank3 protein. We used a Cre-LoxP strategy to add an additional LoxP site flanking exon 22 and disrupt all isoforms. We carried an extensive behavioral phenotyping of neonate, young and adult wild-type, heterozygote and homozygote mice with a battery of test designed to assess the main feature of PMS including neurodevelopmental milestones, sensory and motor functions, sociability, stereotypies and cognitive functioning.
Results: Mice with a full deletion of Shank3 are more severely affected than our previously published mouse model with a partial deletion of Shank3.
Abnormal Mendelian ratios at the time of weaning were observed showing a significant deficit for homozygote mice that can be partially explained by an increase of early postnatal lethality. Both sensory and motor disabilities were detected in neonate and adult mice. While social performances and interest for social stimuli were not impaired, the homozygote mice displayed a strong object avoidance and escape behavior in several tests. Additionally, we observed a deficit in both initial training and reversal of Barnes maze, a spatial memory task involving hippocampal-prefrontal circuits. Electrophysiological recording showed that both hippocampal long-term potentiation and long term depression are impaired in heterozygote and homozygote animals.
Conclusions: Our new mouse model of PMS recapitulates the core symptoms of PMS providing an improvement of both construction and face validity compared to previous model. Ongoing experiments will allow to identify neural mechanisms and brain circuitry involved in PMS and will use this model to screen potential treatments for *Shank3*-haploinsufficiency.

7 **106.007** Behavioral Characterization of SLIT3 Knock-out Mice: SLIT3 Implications in ASD

***S. M. Park**, S. Huang and C. Plachez, Hussman Institute for Autism, Baltimore, MD*

Background: Altered neuronal connectivity is a potential neural signature of Autism Spectrum Disorder (ASD). Slit/Robo signaling plays an important role in axon guidance, cell migration and dendritic spine formation, which is involved in the development of neuronal connectivity and structure. Indeed, Slit/Robo signaling has been implicated in the pathophysiology of ASD, as altered expression level of Slits or Robo receptors is observed in some individuals with autism. Furthermore, a genetic variant of SLIT3, one of genes encoding Slits, was found in individuals with ASD. Nevertheless, a direct relationship between SLIT3 mutation and autism associated behaviors has not been examined.
Objectives: The purpose of the current study is to investigate how SLIT3 mutation affects a variety of behavioral domains associated with autism in mice.
Methods: In order to characterize behavioral changes resulting from SLIT3 mutation, we examined two to four month old male and female SLIT3 knockout (KO) mice for locomotive, emotional, social, and cognitive behaviors using the open field, three chamber social, and novel object recognition tests.
Results: SLIT3 KO mice were observed to travel significantly shorter distances than WT mice in the open field test. In addition, female KO mice tended to spend shorter time in the center area of the open field when compared to the respective controls. Interestingly, KO mice were not different from the controls in social approach behavior and object recognition memory tests.
Conclusions: The reduced activity of SLIT3 KO mice in the open field test indicates that the KO mice are hypo-locomotive. The heightened tendency to avoid center area of the open field shown only in the female KO mice suggests that the deletion of SLIT3 induces a sex-specific anxiety. These findings suggest that SLIT3 may be involved in the formation of neural circuits that regulate locomotion and anxiety rather than social or cognitive behaviors.

8 **106.008** CADM1 Mutation Knock-in Mice As Mice Model of ASD Showing Abnormal Excitatory-Inhibitory Synaptic Balance

***K. Kojima**[1], E. F. Jimbo[2], T. Yamagata[2], M. Momoi[3] and T. Mom[4], (1)Department of Pediatrics, Jichi Medical University, Shimotsuke-shi, Tochigi, Japan, (2)Jichi Medical University, Shimotsuke, Japan, (3)International University of Health and Welfare, Ohtawara, Tochigi, Japan, (4)Department of Neurophysiology, Tokyo Medical University, Tokyo, Japan*

Background: Previously, we detected two missense mutations (Y251S, H246N) on *Cell adhesion molecule1* (*CADM1*) in autism spectrum disorder (ASD) patients. *CADM1* is expressed in the membrane of both presynaptic and postsynaptic neurons, and acts as synaptic adhesion protein. Although *Cadm1*-KO mice showed increased aggression and anxiety behavior, repetitive behavior was not observed. In primary mouse nerve cell culture induced each missense mutations of *CADM1*, inhibition of dendrites extension and aggregation of mutant proteins in the endoplasmic reticulum were observed. Endoplasmic reticulum (ER) stress is considered to be induced by the genetic mutation and caused neural dysfunction.
Objectives: We speculated the two mechanisms as Cadm1 pathogenicity; the loss of function and the gain of function caused by ER stress. To analyze these possibilities and contribution of CADM1 to ASD, we established *CADM1* (Y251S) knock-in (KI) mice and analyzed.
Methods: For behavior analysis, social recognition test, foot print test and stereotyped behavior were performed. Western blotting for α-tubulin, PSD-95, vGlut1 and GABBR2, and fluorescence immunohistochemistry for synaptophysin, vGlut1, vGAT, GABBR2 and calbindin were performed focused in the cerebellum.
Results: A) Behavior analysis: Preference index of heterozygotes and homozygotes of *Cadm1*(Y251S)-KI mice were significantly decreased. Both heterozygotes and homozygotes showed abnormal social behavior.Foot print test did not detected significant difference between three groups.*Cadm1* (Y251S) -KI mice showed repetitive jumping behavior considered to be stereotyped behavior. Frequency were, WT; 0% and 0% in male/female, Heterozygotes; 12.7% and 6.4%, Homozygotes: 4.3% and 0%. On randomly chosen ten mice observation for 2 hours, average numbers of jumping/min for each mouse were 0.08 in WT, 9.26 in heterozygotes and 0.98 in homozygotes.
B) Brain tissue analysis: In immunohistochemical staining of cerebellum, Synaptophysin, a marker for pre-synaptic vesicles, and vGlut1, an excitatory pre-synaptic marker, were not different between WT and homozygotes. vGAT, an inhibitory pre-synaptic marker and GABBR2, inhibitory post-synaptic marker were stained strongly in homozygotes. On Western blotting analysis, GABBR2 was also expressed strongly in homozygotes compared. Expression of vGlut1 and PSD95, a postsynaptic expression marker, were not different between WT and homozygotes.
Conclusions: In behavior analysis, social behavior was impaired in both heterozygotes and homozygotes of *Cadm1*(Y251S)-KI mice. Repetitive jumping in heterozygote male mice may reflect the higher frequency in male in ASD. Abnormal social behavior is common feature of Cadm1-KO and *Cadm1*(Y251S)-KI. However, characteristic stereotypic behavior of ASD patient was seen in *Cadm1*(Y251S) -KI mice but not in Cadm1 KO mice. *CADM1* mutation was suggested to act as a Gain of function in ASD pathogenesis. Synaptic balance was shifted to the inhibitory in *Cadm1* (Y251S)-KI mice. Addition to the report that inhibitory synapses were increased in KI mice that carries *Nlgn3* (R451C) mutation identified in ASD patient. Synaptic balance shifted toward inhibitory is considered to be common mechanism of ASD. From these results, ASD was considered to be caused not only loss of function of mutant protein but also Gain of function induced by mutant protein, and candidate of the mechanisms were ER stress and imbalance of synaptic function.

9 **106.009** CASPR2 Deficiency in Juvenile Rats Recapitulates the Broad Phenotypic Spectrum of CNTNAP2-Related Disorders

*S. Veeraragavan, S. Soriano, C. S. Ward, D. R. Connolly, P. Albelda de la Haza, A. J. Liang, L. A. Yuva, R. Paylor and **R. C. Samaco**, Molecular and Human Genetics, Baylor College of Medicine, Houston, TX*

Background: *CNTNAP2* mutations are associated with neurobehavioral and neuropsychiatric indications present in multiple conditions such as ASD, IDD, ADHD, schizophrenia and bipolar disorder. Mice completely lacking *Cntnap2* have been used to model behavioral impairments, but these findings may not fully delineate the consequences of heterozygous deficiency predominantly reported in humans. Studies of adult *Cntnap2* animals also raise the question of whether features would manifest earlier during a period that is relevant to disease onset in some *CNTNAP2*-related disorders.
Objectives: To evaluate the neurobehavioral and cellular deficits caused by the reduction or absence of CASPR2 in rats.
Methods: We profiled the neurobehavioral and cellular consequences of either haploinsufficiency or the complete loss of *Cntnap2* in juvenile rats, given that we recently reported that the consequences of ASD/IDD-related gene deficiency may differ among divergent rodent species. A battery of behavioral evaluations were conducted from postnatal day 24 to 39 using both male and female *Cntnap2*$^{+/-}$ and *Cntnap2*$^{-/-}$ rats. In addition, molecular studies were conducted to confirm the nature of the targeted allele, as well as to identify whether cellular abnormalities previously reported in *Cntnap2* mice were also present in this novel rat model.
Results: Juvenile *Cntnap2*$^{+/-}$ and *Cntnap2*$^{-/-}$ rats display obsessive-compulsive-like behaviors, increased play behavior, hyperactivity and an increased acoustic startle response. Impairments were dose-dependent in some cases. A limited number of behavioral impairments were altered as a function of both genotype and sex. Juvenile *Cntnap2*$^{-/-}$ rats also showed decreased cortical interneuron number but not abnormal neuronal migration, and behavioral seizures were apparent as early as seven weeks of life.
Conclusions: A reduction or complete absence of CASPR2 results in strikingly different behavioral outcomes in rats compared with mice; however obsessive-compulsive-like behaviors, hyperactivity and some neuropathological alterations are shared between the two species. Taken together, these findings provide insight into the consequences of CASPR2 deficiency in a complementary rodent model, and identify the common features among *Cntnap2* genetic tools that may serve as useful outcome measures for future preclinical studies.

10 **106.010** Cdh11 Deficient Mice Exhibit Autism-like Behavioral Abnormalities

***X. Yuan**, C. Wang and Y. Wang, Hussman Institute for Autism, Baltimore, MD*

Background: Genome-wide association studies and whole exome sequencing have shown that genetic variants of type II cadherins are associated with autism. However whether there is a causal relationship between cadherin deficiency and autism traits at behavioral and pathological levels remains to be clarified. The cerebellum or its input/output structure is among the most consistently-reported areas of vulnerability in autism, as evidenced by cellular and functional pathology. Individuals with ASD exhibit deficits in motor control in addition to core autism symptoms such as difficulties in language and social interaction. Our preliminary results show extensive expression of cadherins in the cerebellum. However the role of cadherins in the development and function of cerebellar circuities is not well understood.
Objectives: The Cadherin-11 gene knockout (KO) mouse was used as a model system to elucidate the behavioral impact of cadherin deficiency and the underlying brain developmental mechanisms, with a focus on pathological changes in the cerebellum.
Methods: In-situ hybridization was used to reveal the expression of Cadherin-11 in developing brain. Immunofluorescence staining of sagittal and coronal brain sections was applied for histological analysis of the Cadherin-11 KO mouse. Standard open field test, elevated plus maze, and 3-chamber social preference test were carried out to evaluate autism-like behaviors. Gripping strength test, horizontal bar test, rotarod test, and footprint analysis were performed to evaluate the motor function of the animal.
Results: In the developing mouse brain, Cadherin-11 is expressed in structures that are known to be closely relevant to autism, including the cerebellum and in the inferior olivary nucleus, which projects to the cerebellum. Compared to wild type (WT) littermates, most Cadherin-11 KO mice showed reduced brain sizes, including the cerebral cortex and the cerebellum. In the cerebellum, the lobes failed to fold to the mature pattern. This developmental deficit appeared to occur postnatally as the brain sizes were largely unaffected when examined at E18.5. Both male and female Cadherin-11 mutant mice are hyperactive, as reflected by a significantly elevated time to explore the central area of the open field arena compared to WT littermates. In an elevated plus maze test, mutant mice spent significantly less time in the open arm, indicating elevated anxiety levels. Consistent with deficits in cerebellum-related motor coordination, mutant mice also exhibited significantly lower scores in the gripping strength test and horizontal bar test and showed abnormal gait pattern in foot print analysis. The 3-chamber social preference test, however, showed that Cadherin-11 mutant mice were not severely impaired in social interactions.
Conclusions: Cadherin-11 is required for the development of some specific brain functions which are altered in autism. Loss-of-function of a single autism risk gene, Cadherin-11, in mice is sufficient to generate several important aspects of the autism-like behavior abnormalities (hyperactivity, high anxiety, and motor deficits) potentially by affecting cerebellar function. Cadherin-11 gene knockout mice may serve as a novel animal model to further dissect the mechanisms of olivocerebellar circuit changes in autism.

11 **106.011** Cerebellar Networks Are Altered in Autism - Examined with Mouse Models

***J. Ellegood**[1], Y. Yee[1], R. M. Henkelman[1], P. Tsai[2] and J. P. Lerch[1], (1)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (2)University of Texas Southwestern Medical Center, Dallas, TX*

Background: Over the past 7 years, we have established a large cohort of mouse models related to autism. This allows for investigation of a large autism population in the mouse, which can be also viewed as representative of idiopathic autism. Therefore, differences in networks or regions across autism can be determined. The cerebellum has been frequently found to be different in autism and autism related disorders (see reviews by Tsai, 2016, Hampson and Blatt 2015, and D'Mello and Stoodley 2015), so the question we asked was: Can we detect cerebellar differences across our model autistic population?
Objectives: To assess differences in the cerebellum and cerebellar networks across multiple autism mouse-lines to determine any commonalties or differences shared across the population.
Methods: The data used in this study was accumulated from 44 different autism mouse-lines and included greater than 60 genotypes and over 1500 mice.
MRI Acquisition – A multi-channel 7.0 Tesla MRI was used to acquire anatomical images of the brain. A T2-weighted, 3-D fast spin-echo sequence was used that yielded an image with 56 µm isotropic voxels (3D pixel) in ~14 h.
Data Analysis – To visualize and compare any differences the images are registered together. The goal of the registration is to model how the deformation fields relate to genotype, wild-type (WT) vs. autism mutant (Lerch et al., 2008). Volume differences are then calculated across the cerebellum in individual voxels or for 39 different cerebellar regions and their corresponding network (Dorr et al. 2008, Ullmann et al. 2013, and Steadman et al. 2014).
Results: Overall the cerebellum as a whole was one of the most affected regions across the brain (Ellegood et al. 2015), and for this work, was further divided into 4 different subgroups, in addition to the cerebellum as whole, we examined the cerebellar cortex, hemispheres, vermis, and deep cerebellar nuclei (DCN). Out of those five regions only the DCN, the outputs of the cerebellum, were significantly smaller in the autism group (t-value of -4.26). Therefore, we further examined the projections from the DCN using anatomical covariance to assess the structural connectivity (Evans, 2013). The connectivity was measured between the DCN and the cerebellar cortex, thalamus, pontine nucleus, and the cortex, and was found to be altered only between the DCN and cortex (Figure 1) in the autism models when compared to the WT
Conclusions: Using anatomical covariance to assess structural connectivity in the mouse models of autism has revealed an alteration in the connectivity between the DCN and the cortex. This alteration preferentially affects the somatosensory, visual and association corticies. Further investigation is warranted to determine the underlying cause of this difference.

12 **106.012** Cerebrospinal Fluid Arginine Vasopressin Is a Predictive Biomarker of Social Impairments in Male Rhesus Monkeys

O. Oztan[1], *J. P. Garner*[2], *V. Sclafani*[1,3], *J. P. Capitanio*[4,5] *and K. J. Parker*[1], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Comparative Medicine, Stanford University, Stanford, CA, (3)Winnicott Research Unit, University of Reading, Reading, United Kingdom, (4)Department of Psychology, University of California, Davis, Davis, CA, (5)California National Primate Research Center, University of California, Davis, Davis, CA*

Background: Autism spectrum disorder (ASD) is characterized by core social impairments, but its basic biology remains poorly understood. Early and accurate diagnoses are difficult and there are no laboratory-based diagnostic tests to detect, nor medications that effectively treat, the social features of ASD. Scientific progress has been impeded by the difficulty of obtaining relevant tissue samples from patients and matched controls. In mouse models, while tissue is available, there is frequently discordance between complex human behavior and laboratory-based mouse behavior, even with shared genetic etiologies. These limitations underscore the tremendous value in developing a monkey model of social impairments with more reliable behavioral and biological homology to the human disease.
Objectives: Like humans, rhesus monkeys (*Macaca mulatta*) are highly social, and both species display stable and pronounced individual differences in social functioning. At the behavioral extremes, low-social compared to high-social male monkeys initiate fewer affiliative interactions and display more inappropriate social behavior, suggesting both lower social motivation and poorer social skills. The aim of this study was to develop a novel primate model using ethological observations to identify low-social male rhesus macaques and test whether they demonstrate abnormalities in key neuropeptide pathways [e.g., arginine-vasopressin (AVP) and oxytocin (OXT)], previously implicated in ASD.
Methods: Study subjects were male rhesus monkeys aged 1-5 years. In cohort 1, N=42 monkeys (selected from a pool of N=222) were identified on the basis of archived behavioral data thought to predict later low (N=21) or high (N=21) social functioning. Quantitative social behavior data and personality assessments were collected by blinded observers using established protocols. After completion of behavioral phenotyping, monkeys with the most extreme scores (N=15 low-social monkeys and N=15 high-social monkeys) were selected for biological sample collection. In a second, independent cohort, N=164 male monkeys were observed and social behavior observations obtained using a higher-throughput scan sampling-based method to identify a subset of N=25 low-social and N=25 high-social monkeys. Cerebrospinal fluid (CSF) and blood samples were concomitantly drawn on two separate occasions and later quantified for AVP and OXT concentrations using established enzyme immunoassays.
Results: Logistic regression showed that CSF AVP concentration (LR ChiSq=16.55; $p<0.0001$) robustly classified monkeys by social group. Using a general linear model, we found that low-social monkeys also had lower CSF AVP concentrations compared to high-social monkeys ($F_{1,18}=9.236$; $P=0.0071$). We then sought to replicate these findings in the second cohort. As before, CSF AVP concentration strongly predicted social classification (LR ChiSq=7.969; $p<0.0048$), with low-social monkeys showing lower CSF AVP concentrations compared to high-social monkeys ($F_{1,24}=8.847$; $P=0.0066$). CSF OXT concentrations did not differ by social group.
Conclusions: Although the majority of research has focused on OXT, rather than AVP, as a biomarker of social deficits in ASD, our findings suggest the provocative notion that the AVP signaling pathway may be a more promising therapeutic target by which to enhance social functioning in male primates.

13 **106.013** Cntnap2 -/- Autism Model Mice Display Deficits in Tonic and Phasic Inhibition in Primary Visual Cortex

M. Bridi*, S. M. Park and S. Huang, Hussman Institute for Autism, Baltimore, MD*

Background: Investigations into the genetics of individuals with autism suggest that mutations in genes involved in synaptic function are a common factor. Both human studies and animal models suggest that such synaptic dysfunction frequently leads to excitatory/inhibitory (E/I) imbalance in the form of reduced inhibition and/or over-excitation, and that neuronal inhibition may be impacted by both pre- and post-synaptic changes. *Cntnap2* -/- mice are a well-established model of ASD. A number of studies have found that these mice exhibit autism-like behaviors including reduced social interaction, hyperactivity, and repetitive/stereotyped behavior. In addition, *Cntnap2*-/- mice exhibit aberrant neuronal migration, reduced interneuron numbers, seizure activity, and alterations in synaptic spines.
Objectives: Due to reported decreases in PV+ interneurons in *Cntnap2* -/- mice, we hypothesized that loss of the neurexin family gene *Cntnap2*would result in reduced inhibition and increased excitation in pyramidal neurons in the visual cortex. We aimed to test multiple forms of inhibition and excitation including intrinsic membrane excitability and tonic inhibition, which is mediated by extrasynaptic GABA receptors and modulates neuronal excitability.
Methods: We used whole-cell patch clamp electrophysiology to examine membrane properties and tonic and phasic inhibition in L2/3 pyramidal cells of primary visual cortex (V1) of *Cntnap2* -/- and +/+ mice at two different time points, 3-4 weeks and 6-8 weeks of age. Tonic inhibitory currents were induced by application of 5 μM GABA or 10 μM THIP, in the presence of blockers of excitatory neurotransmission. $GABA_AR$ subunit protein levels were measured via western blot using tissue lysates prepared from area V1, with antibodies against the γ2 and δ subunits.
Results: We found that L2/3 pyramidal cells from 6-8 week old *Cntnap2* -/- mice exhibited significantly smaller GABA-induced inhibitory tonic conductance. Application of THIP, a specific activator of δ-subunit containing $GABA_ARs$, also induced a smaller tonic current in *Cntnap2* -/- mice compared to controls. In 3-4 week old mice we found no significant effect of genotype on tonic inhibition. We also analyzed sIPSCs in both genotypes and age groups. In 3-4 week old mice we found no differences in sIPSC amplitude, frequency, or kinetics, but did observe an age-dependent effect of genotype in 6-8 week old animals, with lower sIPSC frequency in *Cntnap2* -/- mice. We did not observe an effect of age or genotype on resting potential or intrinsic excitability of L2/3 pyramidal cells in area V1. Western blot analysis of $GABA_AR$ subunit protein levels also found reduced levels of the γ2 subunit, but not the δ subunit, in *Cntnap2*-/- mice.
Conclusions : Our findings indicate that network-level GABAergic function is disturbed in *Cntnap2* -/- mice in a manner dependent on $GABA_ARs$ containing the δ subunit. This result is consistent with previous reports of reduced interneuron numbers, altered network activity, seizure susceptibility, and reduced interneuron numbers in autism. Our data suggest that reduced tonic inhibition could underlie autism-like behaviors, and future studies should investigate cellular/molecular mechanisms of reduced tonic inhibition as well as the effects of diminished inhibition on cortical function *in vivo*.

14 **106.014** Development of Behavioral Assays to Assess ASD-like Behaviors in a Drosophila Model

R. L. Shafer[1]*, A. Shekar*[1]*, J. Aguilar*[1]*, A. Galli*[1] *and J. W. Bodfish*[2]*, (1)Vanderbilt University, Nashville, TN, (2)Vanderbilt University School of Medicine, Nashville, TN*

Background: Autism spectrum disorder (ASD) is a genetically diverse disorder characterized by social deficits and repetitive behaviors. Research has focused on molecular mechanisms and phenotypic consequences of ASD-associated genetic mutations using transgenic animal models. The fruit fly (*Drosophila melanogaster*) is beginning to be used to model genetic mutations associated with neurodevelopmental disorders, including ASD, due to its short gestation period and simple genome. Several assays exist to assess molecular mechanisms in drosophila. However, less work has focused on behavioral assays. The recent use of drosophila in the study of ASD necessitates the development of ASD-relevant behavioral assays in drosophila.
Objectives: We aim to (a) develop a set of behavioral assays and coding schemes to measure ASD-like behavior in drosophila, and (b) estimate reliability, stability, and sensitivity-to-change of the assays. These include assays for stereotyped motor behavior, activity level, and social interaction.
Methods: We used male, transgenic flies expressing either a healthy or mutated copy of the human dopamine transporter (DAT) gene to test our assays. This mutation is a recently discovered rare variant associated with ASD. For the stereotypy and activity assay, flies (9 healthy, 9 mutant) were tested individually in an enclosed arena that permitted locomotion but not flying. The fly's movements were recorded with a high-speed camera (1000 frames/second) during a baseline period and a challenge period. During the challenge period an ecologically relevant predatory wasp sound was presented to elicit stress-induced effects on locomotor and social behaviors. Trained observers coded the flies' behavior by segmenting the videos into 150ms intervals and assigning each interval a behavior code (locomotion, idle, or stereotypy). The social assay used the same arena and stimulus presentation; however, in this assay, 4 flies were present in the arena concurrently (24 healthy and 24 mutants in total). Distance to nearest neighbor preceding and following stimulus onset was used as a measure of social response to the predatory sound. Previous work in drosophila has demonstrated that a distancing response to stress is adaptive and socially relevant.
Results: Our assays indicated that rates of stereotypy were low for both groups and did not change in response to the stimulus. Idle behavior was higher in the mutants than in the healthy flies ($F = 6.43$, $p = .022$) but was not significantly affected by stimulus onset. Locomotion was lower in mutants than in healthy flies ($F = 8.32$, $p = .011$) and demonstrated a trend for a group by time interaction ($F = 3.09$, $p = .059$) suggesting altered locomotor response to stress in the mutants. The social assay indicated that at baseline, the groups did not differ in social distance. After stimulus onset, mutants remained closer together than healthy flies ($F = 6.57$, $p = .0297$) suggesting a failure of mutant flies to display a socially adaptive response.
Conclusions: Our assays were reliable and sensitive for detecting a variety of ASD-relevant behavioral endpoints. Future work is needed to refine these behavioral assays and examine their effectiveness in a larger variety of ASD-related genetic mutations.

15 **106.015** Developmental Control of Cortical Gabaergic Interneuron Number Via Pten Signaling

J. Sejourne*, O. S. Cohen and D. T. Page, The Scripps Research Institute, Jupiter, FL*

Background: GABA is the main inhibitory neurotransmitter in the mammalian nervous system. Proper balance of excitation and inhibition is critical for the normal development of cognition, as evidenced by a range of neuropsychiatric disorders, including autism spectrum disorder (ASD), that feature dysregulation of this process. Cortical GABAergic interneurons (INs) are over-produced during early development, with a substantial fraction undergoing programmed cell death through an unknown mechanism during early postnatal life to arrive at a mature population size. *Pten* encodes a phosphatase that regulates cell death under normal and pathological conditions, and mutations in *PTEN* are a risk factor for ASD.
Objectives: In this study, we test the hypothesis that intrinsically determined cell death of developing cortical GABAergic INs occurs through a Pten-dependent mechanism.
Methods: We have generated mice in which a conditional heterozygous mutation in *Pten* is introduced into developing GABAergic cells. Our analysis of these mice has employed a variety of techniques, including immunohistochemistry, flow cytometry, cell culture and behavioral testing.
Results: We find that mutant animals fail to show the approximately 20% decrease in cortical GABAergic cells during early postnatal development that occurs in control animals. We also observe reduced markers of apoptosis in *Pten* mutant cortical GABAergic cells during development and we present evidence that Pten is both necessary and sufficient to induce the intrinsically determined cell death of this cell type. Mutant animals display increased seizure resistance, decreased social interaction, and altered cortical network activity as indicated by c-Fos, consistent with a net imbalance of excitation and inhibition.
Conclusions: Together, our findings indicate a role for Pten in the intrinsic regulation of cell death and population size in developing cortical GABAergic INs. These results have relevance for understanding abnormal scaling of IN number in the brains of individuals with ASD.

16 **106.016** Developmental and Juvenile Ultrasonic Vocalizations in the Shank3 Mutant Rat Model of Phelan-Mcdermid Syndrome and Autism Spectrum Disorder

E. L. Berg[1], *M. Wöhr*[2], *M. C. Pride*[1], *J. K. Rivera*[1], *M. Careaga*[1], *H. Harony-Nicolas*[3], *J. D. Buxbaum*[3] *and J. L. Silverman*[1], *(1)MIND Institute and Department of Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA, (2)Experimental and Physiological Psychology, Philipps-University of Marburg, Marburg, GERMANY, (3)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Mutations in the *SHANK3* gene lead to autism spectrum disorder (ASD), Phelan-McDermid Syndrome (PMS), as well as intellectual disabilities (Betancur & Buxbaum, 2013; Gauthier et al., 2009; Leblond et al., 2014; Moessner et al., 2007). Reduced expression of *SHANK3*, which codes for a synaptic scaffolding protein, has been hypothesized to lead to impairments in key brain functions underlying social communication and cognition (Durand et al., 2007). Both mutant mouse and, more recently, rat models have been generated in an effort to assess the neurobiological and behavioral effects of mutations in *Shank3* (Yang et al., 2012; Peca et al., 2011; Kouser et al., 2013; Harony-Nicholas et al., 2015; Jaramillo et al., 2016; Zhou et al., 2016).
Objectives: The present experiments aimed to evaluate various aspects of social communication using the sophisticated tool of ultrasonic vocalizations, taking advantage of the only generated rat model of *Shank3* mutations and carrying out studies across early life and during critical juvenile developmental windows in both haploinsufficient and null mutant animals.
Methods: Isolation-induced ultrasonic vocalizations (USVs) were collected from newborn Sprague-Dawley rat pups on postnatal day (PND) 7, the peak day of calling (Wöhr et al., 2008). As juveniles (PND 26-29), a USV playback paradigm was executed by presenting individual rats with a natural 50-kHz USV versus an acoustic control stimulus, and comparing subsequent USV production and approach behavior toward the stimulus source. Juvenile sociability was also assessed via the three-chambered social approach assay in which rats could choose to interact with a novel object or a novel conspecific, a social novelty assay in which rats could choose to interact with a familiar or a novel conspecific, and a play-promoting reciprocal social interaction assay in which rats could freely engage with a novel wildtype (WT), sex-matched conspecific.
Results: Male *Shank3* heterozygous pups exhibited reduced USVs, emitting significantly fewer calls compared to male *Shank3* WT pups. The USV playback assay revealed no genotype differences in locomotor response, as rats of all genotypes and sexes similarly approached the source of the 50-kHz USV and spent more time in close proximity to the source of the affiliative 50-kHz call than the control stimulus. Effects of genotype on USV emission during the playback assay are currently being analyzed. Preliminary data suggest normal sociability during the social approach assay but deficits in the preference for social novelty, as well as subtle genotype effects on some measures of the reciprocal social interaction assay. We are continuing the data analysis and reproducibility experiments at this time.
Conclusions: This study led to the discovery of a novel phenotype, reduced pup call emissions, in the *Shank3* rat model of PMS and ASD. The data presented here lend support for the important role of *Shank3* in social communication and for the use of this rat model as a tool to study the neurobiology underlying the behavioral phenotypes of PMS and ASD. These findings will provide the basis for further investigations into both the behavioral and biological consequences of mutations in *SHANK3*.

17 **106.017** Efficacy of a Multimodal Versus a Selective Serotonin Reuptake Inhibitor to Enhance Sociability and Reduce Marble Burying in BTBR Mice

N. A. Witt[1,2], *B. Lee*[1], *A. Pehrson*[3], *C. Sanchez*[3] *and* ***G. G. Gould***[1], *(1)University of Texas Health Science Center at San Antonio, San Antonio, TX, (2)University of Texas at San Antonio, San Antonio, TX, (3)Lundbeck Research USA, Paramus, NJ*

Background: Impaired social behavior is the most drug treatment-resistant core autism symptom. Selective serotonin reuptake inhibitors (SSRIs, such as fluoxetine or Prozac) block serotonin (5-HT) clearance from brain extracellular fluid by the serotonin transporter (SERT). SSRIs enhance social behavior for some autism patients and in socially deficient BTBRT+Itpr3tf/J (BTBR) mice, but generally they fail to aid the majority of patients with autism. The 5-HT_{1A} receptor partial agonist, buspirone (2 mg/kg) enhanced BTBR sociability just as well as Prozac (10 mg/kg) did. This finding led us to hypothesize that a multimodal SSRI such as vortioxetine might better enhance social and reduce restrictive repetitive behaviors via combined pharmacological targeting of SERT and 5-HT_{1A} receptors.
Objectives: Vortioxetine inhibits SERT, and is a 5-HT_{1A} agonist, among other actions. We sought to compare the efficacy of vortioxetine versus an SSRI to enhance sociability and reduce marble burying in mice. Occupancy of 5-HT_{1A} receptors by vortioxetine in behavior-tested mice was subsequently measured. Since the hormones oxytocin and corticosterone can shape behaviors and 5-HT_{1A} governs their release, their levels in vortioxetine and vehicle treated groups were compared.
Methods: Adult male BTBR mice were used to examine the effects of blocking SERT with the highly specific SSRI citalopram versus vortioxetine, a multimodal antidepressant, at a range of doses on social preferences and on repetitive burying. Vortioxetine (5 or 10 mg/kg) or citalopram (0.5, 5, or 50 mg/kg) were administered by i.p. injection 30, 60 or 120 min before sociability tests, and 75, 105 or 165 min before marble burying tests. [^{3}H] escitalopram was used to assess SERT occupancy, while [^{3}H] WAY-100635 was used for 5-HT_{1A} receptor occupancy by ex vivo autoradiography. Serum hormone levels were measured using enzyme-linked immunoassay kits and a microplate reader.
Results: In social interaction preference tests, vortioxetine (10 mg/kg) administered 30 min before testing enhanced social sniffing ($p<0.05$) relative to vehicle controls, in contrast to citalopram, which lacked efficacy to do so at all doses. However, the sociability enhancing effect of vortioxetine was lost if administered 60 -120 min before testing. Vortioxetine (10 mg/kg) and citalopram (50 mg/kg) significantly reduced marble burying ($p<0.02$) at all post-administration times measured. At 110 min after administration, 10 mg/kg vortioxetine achieved occupancies (%) of 84 ± 1, 31± 12 and 80 ± 5 of SERT, 5-HT_{1A} and also 5-HT_{1B}receptors in various brain regions with relatively high ligand binding densities. Oxytocin levels were slightly elevated ($p <0.05$) in vortioxetine and citalopram treated mice. Corticosterone levels did not significantly differ among treatment groups following the behavior tests.
Conclusions: Overall, these findings indicate that both vortioxetine and citalopram have greater potential to suppress restrictive-repetitive behaviors than to enhance sociability, at least in BTBR mice. Only vortioxetine enhanced social sniffing, albeit transiently.Â Further investigation of vortioxetine as a potential treatment for core autism symptoms in other mouse models would help to establish itsÂ potential as a therapeutic to ameliorate core autism symptoms.Â Vortioxetine's properties at other 5-HT receptor subtype targets might have also contributed to these effects.

18 **106.018** Fronto-Striatal Anatomy, Dependent-Behavior, and Neuronal Activity in a Rat Model of Fragile X Syndrome

C. Golden[1], *S. Sonar*[2], *H. Harony-Nicolas*[3] *and J. D. Buxbaum*[3], *(1)2158370439, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Fragile X Syndrome (FXS) is a neurodevelopmental disorder that is considered to be a leading known monogenic cause of autism spectrum disorder and the most common form of inherited mental retardation. FXS is caused by reduced expression in the Fragile X Mental Retardation Protein (FMRP), which is encoded by the *FMR1* gene. Patients are left with anatomical abnormalities in their fronto-striatal network, deficits in attention and executive function, which are fronto-striatal-dependent behaviors, and dysfunctional recruitment of this network in an attentional task. Currently no pharmacological treatment for FXS is on the market. There are few robust and replicated morphological, physiological, and behavioral findings from the *Fmr1*-KO mouse model of FXS, however, therapeutics that successfully reversed negative symptoms in these mice have so far failed to prove efficacy in clinical studies. Potential therapies are more reliable if their therapeutic effects can be replicated in two species before being progressed to clinical trials. Therefore, the field would benefit from a viable rat model. Rats have a more developed prefrontal cortex (PFC), are faster at acquiring complex cognitive tasks that require the PFC, and have larger brains, which facilitate the study of morphology and behavioral electrophysiology.
Objectives: Studies on the *Fmr1*-KO rat have the potential to extend observations from existing mouse models on the role of Fmrp in the function of a PFC-related network and provide a better platform for development and evaluation of potential therapeutic strategies. Furthermore, since Fmrp is expressed throughout the brain and a loss of Fmrp may differentially affect brain regions, it is important to study circuits such as the fronto-striatal circuit. This study will aim to test whether insufficiency of Fmrp will cause disruption to the fronto-striatal cognitive network and lead to deficits in its morphology, activity, and dependent behaviors.
Methods: To test the effects of Fmrp loss on fronto-striatal circuit anatomy, this study will compare the regional volumes, dependent behaviors, and electrophysiological function of this circuit between *Fmr1*-KO rats and wild type (WT) littermates. Volumetric analyses will be conducted using Magnetic Resonance Imaging (MRI). The five-choice serial reaction time task (5-CSRTT), which tests the ability to correctly identify which of five ports has been briefly illuminated, will be used to test attention. Neuronal activity will be examined by recording local field potentials (LFP) of fronto-striatal regions, the PFC, anterior cingulate cortex, and nucleus accumbens, during the behavioral task.
Results: MRI data has been collected and analysis of these images using a pipeline, which performs automated nonbiased brain segmentation, is underway. *Fmr1*-KO rats display attentional deficits during training on the 5-CSRTT, as evidenced by preliminary data, which show a decrease in accuracy and an increase in omission rate (Figure 1). These deficits suggest that fronto-striatal-associated cognitive behavior is impaired in Fmrp-deficient rats. We are beginning to record LFPs during the 5-CSRTT.
Conclusions: This multi-level approach will allow for a better understanding of neural mechanisms affected in FXS, with the potential of discovering a new type of treatment target and providing an output measure for screening of potential therapies.

19 **106.019** Functionalization of ASD Variants of PTEN in C. Elegans

T. A. McDiarmid[1], *P. Pavlidis*[2], *D. Allan*[1], *T. O'Connor*[1], *S. Bamji*[1], *C. Loewen*[1], *K. Haas*[1] *and C. Rankin*[1], *(1)University of British Columbia, Vancouver, BC, Canada, (2)MSL and Department of Psychiatry, University of British Columbia, Vancouver, BC, Canada*

Background: This study is part of a multi-model platform to functionalize Autism Spectrum Disorder (ASD) gene variants. A primary challenge in studying genes associated with ASD is the lack of an in vivo system in which to rapidly and cost-effectively functionally validate and characterize the large number of candidate risk genes. The sheer number of mutations associated with ASD and the time and money constraints associated with modeling ASD in mammals necessitates an alternative approach.
Objectives: Use the high throughput capacity of Caenorhabditis elegans as an in vivo platform to functionally validate and characterize ASD-associated genes and their variants.
Methods: We have identified a list of high confidence ASD-associated gene variants by combining evidence from >20 exome and whole genome sequence reports. Here, we use our machine vision system, the Multi-Worm Tracker, to characterize morphology, locomotion, and habituation phenotypes of 99 strains of C. elegans covering 87 ASD-associated gene orthologs. In parallel, we have created transgenic C. elegans each expressing a different ASD-associated de novo missense mutation in PTEN in order to validate and assess the functional affects of these putatively pathogenic amino acid substitutions in vivo.
Results: This research has generated a large number of novel genotype to phenotype relationships that range from severe developmental delays and uncoordinated movement to subtle deficits in sensory and learning behaviours, as well as detailed structure-function information indicating which ASD-associated PTEN variants are strong function altering mutations.
Conclusions: This data will be a powerful in vivo tool to identify missense mutations in ASD-associated genes that impact protein function and induce dysfunction in a well characterized neural system assay. Findings will inform future targeted in vivo studies in higher organisms and holds the potential of identifying novel therapeutic targets for ameliorating the effects of ASD.

20 **106.020** Functionalization of ASD Variants of PTEN in Rat and Xenopus

R. Dingwal[1], *M. Edwards*[1], *K. Post*[2], *P. Pavlidis*[3], *T. O'Connor*[1], *C. Rankin*[1], *D. Allan*[1], *C. Loewen*[1], *S. Bamji*[1] *and K. Haas*[1], *(1)University of British Columbia, Vancouver, BC, Canada, (2)University of British Columbia, Vancouver, BC, CANADA, (3)MSL and Department of Psychiatry, University of British Columbia, Vancouver, BC, Canada*

Background: This study is part of a multi-model platform to functionalize Autism Spectrum Disorder (ASD) gene variants. One of the major challenges to understanding the mechanistic causes of ASD is the high, and ever growing, number of associated genes. To date the research community's approach of focusing on one gene at a time using a limited set of very low-throughput assays has yielded potential cellular phenotypes for only a handful of genes. The complexity of this problem is confounded by the identification of multiple mutations of the same ASD-associated genes, culminating in many thousands of gene variants currently without functional phenotyping. A radically different approach is required in order to make significant headway in the near future.
Objectives: We have developed a multiple-platform approach combining high-throughput and high-resolution assays to test large numbers of ASD-associated genes and their multiple variants inÂ *Saccharomyces*,Â *Drosophila*,Â *C. elegans*, *Xenopus*, and mammalian hippocampal culture model systems. We focused on the ASD-associated gene PTEN (phosphatase and tensin homolog), a crucial negative regulator of the PI3K/mTOR pathway. In this presentation we discuss the impact of PTEN variants identified as altering PTEN function in high-throughput assays on the morphological growth and synaptogenesis of rat primary hippocampal neurons and newly differentiated neurons within the intact developing brain of Xenopus tadpoles.
Methods: We have expressed PTEN variants in primary neuron cultures with a PTEN knockdown background and describe effects on neuron morphology, synapse number and balance. Using in vivo time-lapse two-photon imaging in awake, transparent *Xenopus laevis* tadpoles, we report the effects of PTEN variants expressed by single-cell electroportation on the dendritic arbor growth of developing brain neurons.
Results: Rat hippocampal neurons overexpressing human WT PTEN demonstrate a decrease in spines and PSD95 puncta compared to controls, which is not observed in neurons overexpressing the loss-of-function variants. RNAi knockdown of PTEN increased spine number, PSD95 puncta and soma size. These phenotypes were not rescued by expressing loss-of-function human PTEN variants associated with ASD. In Xenopus, expression of ASD-associated variants induced abnormal dendritic arbor growth phenotypes in vivo.
Conclusions: Our high-resolution assays of neuronal morphogenesis and synaptogenesis provide insight into the underlying pathophysiology and neural circuit development abnormalities that may give rise to ASD.

21 **106.021** Functionalization of ASD Variants of PTEN in Yeast and Fly

K. Post[1]*, K. Haas*[2]*, B. Young*[2]*, P. Ganguly*[3]*, P. Pavlidis*[4]*, C. Rankin*[2]*, S. Bamji*[2]*, T. O'Connor*[2]*, D. Allan*[2] *and C. Loewen*[2]*, (1)University of British Columbia, Vancouver, BC, CANADA, (2)University of British Columbia, Vancouver, BC, Canada, (3)Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, BC, Canada, (4)MSL and Department of Psychiatry, University of British Columbia, Vancouver, BC, Canada*

Background: This study is part of a multi-model platform to functionalize Autism Spectrum Disorder (ASD) gene variants. Through whole-exome sequencing efforts, dozens of genes have been identified as strong candidate ASD risk genes. Multiple likely loss-of-function variants have been identified in all of these genes. The research community is now faced with the daunting task of determining how multiple genes may contribute to ASD. Although several bioinformatic tools exist to predict pathogenicity, it is uncertain how accurate these predictions are and impossible to understand the phenotype of each variant through these assays.
Objectives: To address this problem, a two-stage strategy was used to capitalize on high-throughput biological systems to screen for gene mutations most likely to provide strong phenotypes that are then forwarded to secondary, slower throughput but higher resolution assays. The first gene chosen to be studied in this paradigm was PTEN (phosphatase and tensin homolog) which is a crucial negative regulator of the PI3K/mTOR pathway.
Methods: Wildtype, human PTEN and its multiple variants, selected based on bioinformatics assessment of association with ASD or expression in the normal population, were expressed in high-throughput assays in yeast and Drosophila. In yeast, Synthetic Genetic Array (SGA) technology was used to screen ~5,000 yeast strains to identify deletion mutants that were sensitive to overexpression of wild type human PTEN. Strains identified through the yeast SGA with wildtype PTEN were then used to assay the activity of over one hundred PTEN variants. Using GAL4-mediated human gene/variant expression in Drosophila, we identify gain of function phenotypes and variants of altered function. Combined with assays for protein stability in both yeast and Drosophila, these experiments gave quantitative information on variants that likely result in loss of PTEN function in vivo.
Results: From the original SGA screen, a small subset of yeast deletion strains were identified as having genetic interactions with wildtype PTEN. Through the creation of a 'mini array' containing these deletion strains, it was possible to determine an interaction profile for each of the over one hundred PTEN variants selected for study. The results from this screen were then compared to the stability data to identify PTEN variants with varying stability and interaction states as compared to wildtype.
Conclusions: Through these assays we were able to classify PTEN variants based on their protein stability, genetic interactions interactions, and effects on nervous system function in an in vivo model. ASD-associated PTEN variants fell into distinct classes based on these measures. Results guided selection of variants for high-resolution assays.

22 **106.022** Integrity and Functionality of the Hypothalamic Oxytocin System and the Effect of Oxytocin Treatment in Two Rat Models for Autism

H. Harony-Nicolas[1]*, M. Eliava*[2]*, L. Koro*[3]*, M. Riad*[3]*, C. Golden*[4]*, S. Wagner*[5]*, V. Grinevich*[6] *and J. D. Buxbaum*[1]*, (1)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (2)German Cancer Research Center DKFZ, Heidelberg, Germany, (3)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Icahn School of Medicine at Mount Sinai, New York, NY, (5)Neuroscience, University of Haifa, Haifa, Israel, (6)University of Heidelberg, Heidelberg, Germany, Heidelberg, Germany*

Background: Social behavior deficits are a core symptom in autism spectrum disorder (ASD), which up to date have no pharmacological treatment. The hypothalamic oxytocin (OXT) system is a well-known modulator of social behavior, which brought interest in using the OXT peptide to treat social behavioral deficits. Our studies in a rat model for ASD, the *Shank3*-deficient rat, demonstrated that intracerebroventricular (I.C.V) OXT administration ameliorates attentional and social memory deficits. Clinical trials of OXT in ASD produced equivocal results raising questions about (1) whether this equivocally is driven by the heterogeneity in ASD, where some ASD subgroups may benefit better than others and (2) if the efficacy of OT treatment is dependent on the functionality of the OXT system and/or is sensitive to specific developmental window. Addressing these questions is challenging due to the lack of predictive biomarkers to identity relevant subgroups that might be most helped by OXT, and the lack of sufficient and diverse postmortem samples to determine how OXT-system is affected in different ASD subjects. Genetic animal models with mutations in ASD-associated genes are powerful tool to help overcome these limitations, yet to date only few studies have employed these models to tackle these limitations.
Objectives: We aim to determine the effect of ASD-associated mutations, specifically, Shank3 and Fmr1, on the integrity and functionality of the OXT hypothalamic system and to assess the effect of OXT treatment on behavioral deficits, during different developmental stages, using rat models with Shank3 and Fmr1 mutations.
Methods: To assess the integrity of the OXT system, we are applying diaminobenzidine-based method and using anti-OXT antibodies to visualize oxytocin-expressing cells within the hypothalamic periventricular nucleus (PVN) and their axonal projections to their target sites in the brain. To assess the functionality of the OXT system, we are testing the levels of OXT in the peripheral blood, brain and, cerebrospinal fluid, using micor-dialysis, ELISA, and mass spectrometry techniques. To study the effect of OXT administration on behavior, we use the social discrimination task and assess social recognition memory, which we found to be impaired in Shank3-deficits rats. We test performance of the rats on this task, before and after oxytocin intracerebroventricular (I.C.V) or intranasal administration, during different developmental periods.
Results: Our morphological analysis demonstrates that OXT-expressing neurons show increased OT immunoreactivity and dendritic swelling in *Shank3*-knockout (KO) rats, and decreased number of OXT-expressing cells in Fmr1-KO rats. We see no changes in OXT peripheral blood levels in Shank3-deficits rats. Behaviorally, we found that OXT I.C.V treatment during adulthood improves social-recognition memory deficits in Shank3-deficinet rats.
Conclusions: Our findings show that mutations in the Shank3 and Fmr1 genes disturb the integrity of the OXT hypothalamic system. Findings from Shank3-KO rats suggest that OXT release is impaired and that this impairment is specific to oxytocin release within the brain. Altogether, this implies that treatment with OXT may be beneficial in at least in two subset of individuals with ASD, with Shank3 and Fmr1 mutations, where the integrity of the OXT system could be potentially disturbed.

23 **106.023** Learning Recapitulates Development at the Epigenetic Level Highlighting Regulatory Regions Relevant for Autism and Intellectual Disability

*J. Koberstein[1], S. Poplawski[2], T. Abel[2] and **L. Peixoto**[3], (1)Washington State University, Spokane, WA, (2)University of Pennsylvania, Philadelphia, PA, (3)Elson S Floyd College of Medicine, Washington State University, Spokane, WA*

Background:
Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder of high prevalence that clearly involves genetic risk factors. Most current approaches aimed at identifying genetic risk factors in ASD focus on genes. However, most human disease-associated variants are located in regulatory regions that control gene expression. As such, a great number of relevant ASD genetic variants likely lie within regulatory regions. Intellectual Disability (ID), which leads to learning impairments, is the most common ASD comorbidity and the strongest predictor of poor prognosis. The genetic basis and underlying molecular mechanisms shared between learning and ASD therefore hold insights into a key aspect of these disorder.
Epigenetic modifications and regulation of gene expression are necessary for learning. Functionally relevant regulatory regions are determined through epigenetic modifications that define where chromatin is accessible in the genome. The connection between ASD and ID must be determined at least in part by epigenetic modifications that can be measured through chromatin accessibility. Defining regulatory regions relevant to ASD based on learning dependent chromatin remodeling is an unexplored yet potentially fruitful target for investigation.
Objectives:
The goal of this study was to determine which regulatory regions are recruited during memory consolidation and investigate whether they could highlight non-coding regions with genetic links to ASD and ID.
Methods:
We used sonication of cross-linked chromatin followed by sequencing (Sono-seq) to define how learning affects chromatin accessibility genome-wide in mice. We developed a new bioinformatics tool (DEScan) to uncover regulatory regions that show statistically significant differences in chromatin accessibility following learning. We integrated our results with publicly available datasets from ENCODE and SFARI, to better define the relationship between learning regulated regions, mechanisms of epigenetic regulation and known ASD linked genes.
Results:
Our results show that learning increases chromatin accessibility in 2,365 regulatory regions genome-wide (FDR <0.05). These learning regulated regions are bivalent promoters associated with CpG islands and show a strong bias towards being accessible during development relative to adulthood ($p<0.001$). Enrichment for active histone marks (H3K9ac, H3K4me2/3) within learning regulated regions is also higher for embryonic than postnatal datasets ($p<0.05$). Thus, our data shows that learning increases chromatin accessibility of regulatory regions that are active during development. Learning regulated regions are also disproportionally associated with known ASD genes (SFARI, $p< 0.01$). The enrichment was found at any SFARI gene evidence level, and the fold enrichment was higher at lower SFARI scores. Learning regulated regions were associated with 15 forms of syndromic ASD that also present with ID.
Conclusions:
Overall our study suggests that the high comorbidity of ASD and ID could be based at least in part on the fact that learning relies on a subset of regulatory regions that are also required for brain development. We also show that using epigenomic data obtained in mice is a viable strategy to highlight functionally relevant regulatory regions to study the contribution of non-coding genetic variation to ASD. Future studies will focus on testing whether learning regulated regions harbor non-coding genetic variants associated with ASD and ID.

24 **106.024** Longitudinal Behavioural Study of Shank3 KO Mice Combined with Rnaseq Analyses Reveals New Candidate Modifier Genes for Autism

A. Ferhat[1]*, A. Biton*[2]*, T. Bourgeron*[3] *and E. Ey*[4]*, (1)Neuroscience, Institut Pasteur, Paris, France, (2)Institut Pasteur, Paris, France, (3)Université Paris Diderot, Paris, France, (4)Neuroscience, Institut Pasteur, Paris, FRANCE*

Background:
Autism Spectrum disorders (ASD) are neurodevelopmental conditions affecting more than 1% of the population. Diagnosis is based on two main criteria: alteration of social communication and interaction as well as repetitive and stereotyped behaviours (DSM-5). Among the ASD-risk genes, SHANK3 encodes a scaffolding protein at the postsynaptic density (PSD) of glutamatergic synapses. A meta-analysis of SHANK mutations in ASD estimated that 1-2% of patients with ASD and intellectual disability (ID) are carrying a *de novo* deleterious mutation in *SHANK3. SHANK3* is also deleted in the vast majority of the patients with Phelan-McDermid syndrome (PMS). Many patients carrying a mutation in *SHANK3* or diagnosed with PMS show a worsening of the phenotype in adolescence or early adulthood (i.e. a behavioural decline). Several laboratories have generated mouse models lacking *Shank3* to understand the biological role of this protein, but none of these studies analysed the progression of the phenotype during development.
Objectives:
In the present study, we tested whether a mouse model mutated in *Shank3*, namely *Shank3Δex11* displayed a worsening of the phenotype when aging. We therefore studied the stability of the phenotype in this mouse model by following the same individuals in adulthood, over their first year of life.
Methods:
The *Shank3Δex11* mouse model carries a deletion of exon 11, involved in the SH3 domain (Src homology 3 domain). We characterised the same individuals at 3, 8 and 12 months of age. We tested homozygous wild-type, heterozygous and homozygous knock-out littermates of both sexes. We focused on locomotion/exploration, social and stereotyped behaviours at the three times points. We conducted comparisons between genotypes at each times point, but also within genotypes over the three time points. At twelve months of age, the brain from each animal was extracted and dissected. RNA sequencing was performed on four brain regions: cortex, hippocampus, striatum and cerebellum.
Results:
At 3 months of age, the *Shank3*-KO mice displayed a significant decrease in locomotion, a significant increase in self-grooming, but mild impairments in social interactions in comparison with wild-type littermates.
Between 3,8 and 12 months of age, 7 out of 12 males and 4 out of 12 female *Shank3*-KO mice displayed a worsening of the phenotype, with a drastic increase in self-grooming. Interestingly, 4 males and 5 females *Shank3*-KO mice with a lower level of grooming at 3 months remained stable at 1 year. RNA sequencing data already revealed several genes differentially expressed between wild-type littermate and *Shank3*-KO mice. These results point at some biological pathways that could be influenced by the absence of Shank3. Further data on the comparison between the RNA level and the level of grooming will be presented.
Conclusions:
These data showed that some *Shank3Δex11* mutant individual mice displayed a worsening of the phenotype, reminiscent to what is observed in patients carrying a mutation in *Shank3*. These inter-individual variations remain to be better understood in order to identify spontaneous compensations. This should provide new pathways for innovative knowledge-based treatments.

25 **106.025** Loss of KCTD13 Decreases Hippocampal Synaptic Transmission Via the Small Gtpase RhoA

C. Ochoa Escamilla[1], *I. Filonova*[2], *A. Walker*[3], *Z. Xuan*[3], *A. J. Eisch*[4], *J. Ellegood*[5], *J. P. Lerch*[6], *H. E. Speed*[4] *and C. M. Powell*[7], *(1)Neurology and Neurotherapeutics, UT Southwestern, Dallas, TX, (2)UT Southwestern, Bedford, TX, (3)UT Southwestern, Dallas, TX, (4)University of Texas Southwestern Medical Center, Dallas, TX, (5)Hospital for Sick Children, Toronto, ON, CANADA, (6)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (7)Neurology & Neurotherapeutics and Psychiatry, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Autism Spectrum Disorder (ASD) is a complex neurological disorder that affects brain function. Copy number variations (CNVs) are implicated in autism. Deletions/duplications within the 16p11.2 chromosomal region are among the most frequent CNVs associated with neurodevelopmental disorders and are one of the most prevalent CNVs in ASD. Deletions within this region are implicated in autism and intellectual disability (ID), whereas duplications are associated with schizophrenia, bipolar, autism, and ID. Of the many genes within this CNV region, *KCTD13* has been implicated in and hypothesized as a major driver of the neuroanatomical and neurodevelopmental phenotypes. KCTD13 acts as an adaptor protein that forms a complex with the ubiquitin-ligase *CUL3*, an established autism gene. Together KCTD13-CUL3 ubiquitinate RhoA, a small GTPase that regulates many cellular processes. Interestingly, the KCTD13-CUL3-RhoA interaction has been implicated in contributing to brain size and connectivity in humans. However, little is known regarding the function of KCTD13, and its contribution to neurodevelopmental phenotypes in the mammalian brain.
Objectives: In an effort to understand how loss of *Kctd13* might contribute to 16p11.2 deletion pathology, we created a *Kctd13* deletion mouse.
Methods: *Kctd13* effects on synaptic transmission were determined using extracellular and intracellular recordings of neurons in area CA1 of hippocampus from acute slices. CA1 neuronal morphology and spine density/morphology were analyzed using Golgi-Cox staining. Hippocampal lysate was tested biochemically for alterations in total and active RhoA protein levels via western blots and G-LISA RhoA Activation Assay (Cytoskeleton) respectively. Incubation of acute slice in Rho inhibitors occurred for 3.5 hours followed by extracellular and intracellular recordings of neurons in area CA1 of hippocampus.
Results: We have specifically deleted *Kctd13* in mice and demonstrated reduced synaptic transmission correlated with decreased dendritic complexity and spine density in area CA1 the hippocampus. These alterations in synaptic transmission also correlate with increased levels of the KCTD13/CUL3 ubiquitin ligase substrate RhoA. Further, these synaptic phonotypes are reversed by selective RhoA inhibition *in situ,* confirming increased RhoA as the mechanism underlying reduced synaptic transmission.
Conclusions: These findings implicate *Kctd13* in neuronal alterations that may contribute to neuropsychiatric disorders. These data implicate a potential role for RhoA as therapeutic target in disorders associated with deletion of *KCTD13* including 16p11.2 deletion.

26 **106.026** Low Empathy-like Behavior in MICE Associates with Impaired Sociability, Emotional Memory, Physiological Stress Reactivity, and Variations in Neurobiological Regulations

G. Laviola[1], *V. Carito*[2], *F. Zoratto*[3], *M. Fiore*[4] *and S. Macrì*[5], *(1)Istituto Superiore di Sanità, Roma, Italy, (2)Neurobiology, National Research Council, Rome, Italy, (3)BCN, Istituto Superiore Sanità, Rome, Italy, (4)Neurobiology, Rome, Italy, (5)Istituto Superiore Sanità, Rome, Italy*

Background: Deficits in empathy, in the form of limited prosociality have been proposed to constitute a hallmark of highly prevalent child and adolescent psychiatric disturbance. Additional indices of conduct disorder are constituted by a limited sensitivity to punishment, shallow or deficient affect and reduced physiological reactivity to environmental stressors.
Objectives: Empathy has been reliably addressed in preclinical models through the evaluation of the social transmission of emotional states (physiological state matching): specifically, mice exposed to a painful stimulus display a higher response if in the presence of familiar individual experiencing a higher degree of discomfort, than in isolation. In the present study, we investigated whether a reduction of empathy can be considered a predictor of reduced sociality, sensitivity to punishment, and physiological stress reactivity.
Methods: To this aim, we first evaluated empathy-like behavior in a large group of Balb/cJ mice and then discretized their values in four quartiles. The first (high empathy) and the last (low empathy) quartile constituted the experimental population.
Results: indicate that low-empathy mice are characterized by reduced sociability, impaired memory of negative events, and dampened hypothalamic-pituitary-adrenocortical reactivity to external stressors. Furthermore, we show that low empathy mice exhibit elevated concentrations of oxytocin and vasopressin as well as reduced density of BDNF receptors in selected brain areas.
Conclusions: Thus, not only do present results translate to the preclinical investigation of psychiatric disturbances, but also they can contribute to the study of empathy in terms of its adaptive significance.

27 **106.027** Maternal Allergic Asthma during Gestation Leads to Elevated Inflammatory Cytokines in the Fetal Brain

*H. K. Hughes[1], D. Rose[1], H. Yang[2], M. Careaga[3], J. Schwartzer[4] and **P. Ashwood**[5], (1)UC Davis M.I.N.D. Institute, Sacramento, CA, (2)UCD MIND institute, Sacramento, CA, (3)UC Davis/MIND Institute, Sacramento, CA, (4)Mount Holyoke College, South Hadley, MA, (5)UC Davis, Sacramento, CA*

Background: Maternal infection during gestation is a well-established risk factor for neurodevelopmental disorders in offspring, including autism spectrum disorders (ASD). Most preclinical investigations of these risks have focused on specific responses to bacterial or viral pathogens, however data suggests that the increased risk for ASD is generally associated with maternal immune activation (MIA), specifically increases in pro-inflammatory cytokines during gestation. While MIA animal studies have traditionally focused on one arm of the immune response, allergic responses during gestation characterized by increased T-helper 2(T_H2) cytokines have recently been shown to alter offspring behavior. We hypothesized that MIA associated with asthma and allergies may also elicit changes in offspring immune responses in the brain.
Objectives: Previous MIA investigations specific to a maternal immune response to pathogens have found that MIA increases pro-inflammatory cytokines in the fetal brain compartment. We sought to determine whether activation of the allergic/T_H2 arm of the immune system during gestation would elicit differential immune responses in the fetal brain.
Methods: C57 dams were sensitized by exposures to ovalbumin (OVA) prior to pregnancy, then exposed to either aerosolized OVA or PBS-vehicle repeatedly throughout gestation until embryonic day (E)17.5, at which time fetal brains and maternal sera were collected and processed for cytokine analysis via multiplex technology.
Results: Significant elevations of inflammatory cytokines were present in fetal brains from mothers exposed to aerosolized OVA during gestation compared to vehicle control exposed dams. These cytokines included interleukin (IL)-1alpha, IL-1beta, IL-2, IL-7 and IL-9 ($p<0.001$). Elevated levels of chemokines were also present, including chemokine (C-X-C motif) ligand (CXCR)-1, chemokine (C-C motif) ligand (CCL)-3 and CCL5 ($p<0.01$). Fetal brain cytokines positively correlated with gestational maternal sera cytokine levels that are associated with an allergic asthma phenotype.
Conclusions: We demonstrated that the maternal immune responses associated with an allergic T_H2-skewed inflammation during the gestation period in mice lead to significant increases in fetal brain cytokine responses. Our findings provide support that activation of the immune response associated with allergies or asthma during gestation may alter neurobiology and subsequently contribute to the development of neurodevelopmental disorders, including ASD.

28 **106.028** Placental Group B Streptococcus Infection: Sex Specific Inflammatory Response and Autistic-like Traits in Male Offspring

***M. J. Allard**[1], C. Guiraut[1], M. Descoteaux[2], L. Tremblay[2], M. Lepage[2], L. C. Fortier[3] and G. Sébire[1], (1)McGill University, Montreal, QC, Canada, (2)Université de Sherbrooke, Sherbrooke, QC, Canada, (3)Microbiology and infectious diseases, Université de Sherbrooke, Sherbrooke, QC, Canada*

Background: Group B *Streptococcus* (GBS) infection is one of the major causes of chorioamnionitis, which is a risk factor for preterm birth and autism spectrum disorder (ASD). Chorioamnionitis affects the placental synthesis of neurotrophic factors, and triggers the release of neurotoxic inflammatory mediators, such as interleukin-1 (IL-1), which might disrupt myelinated neuroglial fiber tracts. We previously showed, using a new rat model, that GBS-induced maternal infection leads to sex-specific forebrain injuries and ASD-like traits in the offspring. Male offspring from GBS-exposed dams presented developmental impairments characterized by ASD-like behaviors with defective: communication, social interactions, and sensory integration. GBS-exposed dams displayed chorioamnionitis characterized by a higher infiltration of polymorphonuclear cells in male than female (*Allard et al., Autism Research, 2016*). Our hypothesis is that maternal exposure to GBS impacts the placenta through an IL-1 driven inflammatory response leading to brain injuries and ASD-like traits in the offspring.
Objectives: To characterize GBS-induced inflammation on the placenta, and its specific effects on the offspring' developing brain.
Methods: Â Lewis dams were inoculated intraperitoneally on gestational day 19 with live serotype Ia GBS (10^8 CFU). Caesarian-sections were performed at multiple time points following the infection to collect placentas, and maternal and fetal blood samples. The maternofetal inflammatory response was studied by ELISA and immunohistochemistry. Behavioral tests were performed from postnatal day (P)7 to P40 to assess ASD-like behaviors. Brains were collected at P40 for histological studies. Magnetic resonance imaging and diffusion weighted imaging were performed on young adult rats.
Results: GBS placentas were infected, but did not result in pups' infection. Following GBS infection, increased titers of IL-1β were detected in maternal blood, male placentas, and male fetuses' blood, *vs* control tissues. At P40, GBS-exposed males showed a reduced thickness of the external capsule, of the frontal neocortex and of the corpus callosum, with a decreased mean fractional anisotropy in the anterior part of the corpus callosum. Increased hippocampus areas and increased thickness of the cingulum were also measured in GBS-exposed males at P40, compared to male controls. None of these differences were observed in GBS-exposed females. Placental inflammation and forebrain injuries will be further characterized by ongoing studies.
Conclusions: Exposure to live GBS induces maternofetal immune activation resulting in neurodevelopmental abnormalities recapitulating those of human ASD, including sex dichotomy and behavioral phenotype. Our findings pave the way towards the use of IL-1 blockade in therapeutic trials aimed to prevent ASD arising from GBS infection, a common and modifiable gestational environmental factor.

29 **106.029** Polygenic Contribution of the Transcription Factors Gtf2i and Gtf2ird1 of the William's Syndrome Critical Region to Produce Disease Relevant Phenotypes

***N. D. Kopp** and J. Dougherty, Genetics, Washington University School of Medicine, St. Louis, MO*

Background:
Chromosome region 7q11.23 contains dosage-sensitive genes that affect social behavior. The duplication of the region is associated with autism spectrum disorders (ASDs), whereas the reciprocal deletion causes William's syndrome (WS), a neurodevelopmental disorder characterized by increased social motivation but impaired social interactions. There are 28 genes present at the locus making genotype-phenotype correlations difficult to discern, and it is possible that more than one gene in the locus contribute to the social phenotype. Human and mouse studies have highlighted two paralogous transcription factors, *GTF2I* and *GTF2IRD1*, as contributing to the social and anxiety phenotypes. However, prior mouse models that studied these genes individually failed to test the impact of epistatic genetic interactions.
Â Objectives:
Using newly developed mouse models, we aim to test the hypothesis that the two transcription factors, *Gtf2i* and *Gtf2ird1*, interact genetically to affect behaviors related to ASD and WS.
Methods:
We have generated two knockout mouse lines, *Gtf2i*$^{+/-}$ and *Gtf2ird1*$^{+/-}$, using the CRISPR/Cas9 system. Crossing these two lines yields four genotypes in the offspring: wild type, *Gtf2i*$^{+/-}$, *Gtf2ird1*$^{+/-}$, and *Gtf2i*$^{+/-}$/*Gtf2ird1*$^{+/-}$ double mutants. A cohort of these animals (n=83) was run through a battery of behavior tests to assess developmental behaviors, such as maternal separation induced ultrasonic vocalization (USV) and juvenile play, and adult behaviors, such as the sensorimotor battery, open-field, social approach, marble burying, object recognition, T-maze, and tube-test of social dominance. This breeding scheme allows us to determine the main effects of each gene as well as test for genetic interaction between the genes on behavioral performance.
Results:
We show that each gene has a main effect on certain behaviors, but there also exists behaviors that are affected by the interaction of the two genes. During development we see that *Gtf2i* mainly affects the pitch at which pups emit USVs, but that *Gtf2i* and *Gtf2ird1* interact to affect the duration of the USVs. Furthermore, in adulthood we see that *Gtf2i* mutation alone is sufficient to induce hyper-activity, while *Gtf2ird1* mutation alone is sufficient for anxiety-like phenotypes in the open field. Interestingly, we see genetic interactions on multiple behaviors including balance of the mice in the ledge task, and the number of marbles buried during a task of repetitive digging behavior. Finally, we see robust interaction in a social phenotype, the tube test, where only the double mutant mice show a subordinate phenotype.
Conclusions:
Using newly developed mouse lines we have shown that two transcription factors located within a region that is associated with two developmental disorders (ASDs and WS) contribute individually to specific phenotypes such as anxiety and hyperactivity but also interact to affect social and motor behaviors, suggesting the related human disorders may also be polygenic in etiology.

30 **106.030** Preliminary Characterization of Dosage Effects of UBE3A on Cognitive and Motor Phenotypes in Mouse Models

N. Buscher[1], *N. A. Copping*[1], *M. C. Pride*[1], *S. V. Dindot*[2] *and J. L. Silverman*[3], *(1)UC Davis, Sacramento, CA, (2)Texas A&M University, College Station, TX, (3)MIND Institute and Department of Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA*

Background: The ubiquitin protein ligase E3A gene (UBE3A) is located in the 15q11-q13 region of the genome. Mutations within this region have been associated with various types of neurodevelopmental disorders, which suggests UBE3A is dosage-sensitive (Beaudet, 2011; McNamara & Isles, 2013). Maternally derived deletions, mutations, or epimutations that lead to a loss of expression or function of UBE3A cause Angelman syndrome (AS, Jiang et al., 1999), while elevated UBE3A is hypothesized to cause Dup15q syndrome. The discovery of a patient with a severe developmental delay contributed to the idea of gene-dosage effects. In this case study, a maternally inherited 129 Kb duplication in chromosome region 15q11.2 encompassing only the UBE3A gene was described (Noor et al., 2015). Studies of (D)UBE3a in Drosophila (Ferdousy et al., 2011; Hope et al., 2016; Jensen et al., 2013) and rodent models (Daily et al., 2011; Hethorn et al., 2015; Huang et al., 2013) further corroborates the theory.
Objectives: The present experiments were designed to evaluate cognitive and motor phenotypes in mice with mutated *Ube3a* (deletion), similar to AS, or increased *Ube3a* (overexpression), modeling Dup15q syndrome. These domains were chosen due to the phenotypic profile of individuals with AS and Dup15q, which includes deficits in motor abilities, coordination, gait, ataxia and intellectual disabilities. Behaviorally, beam walking, rotarod and open field were utilized to test motoric abnormalities. The touchscreen spatial reversal task was chosen due to its conceptual and technical similarities to the NIH Toolbox battery used for testing cognitive functions in children with minimal demand on motor abilities (Silverman et al., 2013).
Methods: Breeding pairs were acquired from The Jackson Laboratory. Mice were bred in a conventional mouse vivarium at the University of California Davis School of Medicine in Sacramento. Motor assays (beam walking, rotarod and open field) were run according to previously published methods (Silverman et al., 2011; Stanley et al., 2005; Wohr et al., 2013). Spatial reversal was tested in the automated Bussey-Saksida touchscreen system for mice (Campden Instruments Ltd/Lafayette Instruments, Lafayette, IL, USA), using a procedure slightly modified from the methods described previously (Buscher et al., 2016; McTighe et al., 2009).
Results: *Ube3a* mutant mice displayed deficits in open field, rotarod and beam walking when compared to their WT littermates. Our data replicate and extend prior findings (Bruinsma et al., 2015; Huang et al., 2013). Preliminary data indicate impaired touchscreen training for spatial reversal in *Ube3a* mutants by requiring more days to reach criteria in each training phase compared to WT littermates. No genotype differences were detected in *Ube3a*overexpressing mice on motor tasks, while spatial reversal data is currently being analyzed.
Conclusions: The current results suggest a dosage-sensitive effect of *Ube3a* mutations on behavior indicating that an optimal dose of *Ube3a* is required for typical motoric and cognitive flexibility. Importantly, the current findings can and will be utilized as outcome measures for preclinical pharmacological and stem cell-delivered genetic intervention strategies.

31 **106.031** Preliminary Seizure Susceptibility and Threshold Characterization in Mouse Models Relevant to Angelman Syndrome and Chromosome 15q11.2-13 Duplications

N. A. Copping[1], *N. Buscher*[1], *J. A. Foster*[2], *J. P. Lerch*[3], *J. Ellegood*[4], *D. Zolkowska*[5], *S. V. Dindot*[6] *and J. L. Silverman*[7], *(1)UC Davis, Sacramento, CA, (2)Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada, (3)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (4)Hospital for Sick Children, Toronto, ON, CANADA, (5)University of California, Davis, Sacramento, CA, (6)Texas A&M University, College Station, TX, (7)MIND Institute and Department of Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA*

Background: Maternally derived duplications or triplications of 15q11.2-q13 (Dup15q) are one of the most common genetic variations associated with autism spectrum disorder (ASD) detected in ~1-3% of cases (Glessner et al., 2009; Pinto et al., 2010; Moreno-De-Luca et al., 2013) and are characterized by seizures, developmental delay, and minor dysmorphic features (Finucane et al., 1993, Bolton et al., 2001; Urraca et al., 2013). The severity of symptoms correlates with the number of copies of the region with interstitial duplications, causing mild to moderate phenotypes, and isodicentric duplications, associated with severe phenotypes. Angelman Syndrome (AS) is a rare (1 in 15,000 births) neurologic disorder characterized by a wide range of symptoms including intellectual disabilities, lack of speech, ataxia, and seizures (Williams et al., 2006; Jiang et al., 1998). Both AS and Dup15q are believed to be caused by the loss or overexpression, respectively, of the ubiquitin protein ligase E3A (UBE3A) (Beaudet, 2011; McNamara & Isles, 2013). While divergent in gene dosage of UBE3A, both neurodevelopmental disorders exhibit high incidence of seizures.
Objectives: The present experiments were designed to evaluate seizure phenotypes, seizure susceptibility and threshold in mutant mouse models of Dup15q and AS. To identify neuroanatomical phenotypes in these mouse models magnetic resonance imaging (MRI) was used.
Methods: Breeding pairs were purchased from The Jackson Laboratory. Mice were bred in a conventional mouse vivarium at the University of California Davis School of Medicine. We quantified spontaneous seizure occurrence through video recordings and EEG in a home-cage environment. In cases where no spontaneous seizures were observed, we tested the threshold of inducible seizures by latencies to myoclonic jerk, generalized clonic-tonic seizure, and tonic extension or death using chemoconvulsants (pentylenetetrazole [40-80 mg/kg] and/or kainite acid [20-40 mg/kg]) and/or the Ugo Basile electroconvulsive device. Whole brains were harvested from an independent cohort of mice, and ex-vivo structural MRI was performed to identify volume changes in different brain regions associated with seizure susceptibility, as previously described (Ellegood et al., 2015).
Results: No spontaneous seizures were observed in mice with deletions or overexpression of *Ube3a. Ube3a* overexpression mice did, however, exhibit faster onset to generalized clonic seizure and reduced latencies to tonic extension and death. Both deletion and overexpressing *Ube3a* mutant mice showed smaller hippocampal volume ($p<0.05$) when compared to WT controls. Data are currently being collected for seizure susceptibility in mutant mice with deletions in *Ube3a.*
Conclusions: We detected significant outcomes due to the level of expression of *Ube3a* on a variety of seizure parameters as well as neuroanatomical measures, suggesting that these mouse models are useful preclinical tools for studying neurobiological mechanisms behind epilepsy and seizure impairments in Dup15q, AS, and ASD.

32 **106.032** SHANK3 Deletion and Related Phenotypes in Chinese Children with Autism and shank3-KO Zebrafish Display Autistic-like Behaviours

C. Liu[1], *C. Hu*[2], *B. Zhou*[2] *and X. Xu*[2], *(1)Division of Child Health Care, Children's Hospital of Fudan University, Shanghai, China, (2)Children's Hospital of Fudan University, Shanghai, China*

Background: Autism spectrum disorder (ASD) is well known as a heritable, debilitating neurodevelopmental disorder manifesting in early development. A mount of studies showed that *SHANK3* gene had a strong causal relationship with ASD and/or 22q13.3 deletion syndrome. However, the data of Chinese ASD patients with *SHANK3* deletion is insufficient and the mechanism is not clear.
Objectives: N/A
Methods: MLPA and Sanger sequencing were carried out to confirm the *SHANK3* deficiency of Chinese children. Moreover, systematic and comprehensive evaluations were performed to Chinese-specific features. In addition, *shank3* was knock-out (KO) using a CRISPR/Cas9 system in zebrafish to build a transgenic zebrafish model.
Results: As to the patients, six participants lacked the whole gene of *SHANK3* with 22q13.3 deletions ranging in size from 55 kb to 4.8 Mb and three participants with de novo SHANK3 mutation were included. They were characterized by high rates (100%) of ASD, developmental delay, hypotonia, several dysmorphologies and perception abreaction. New and rare features were also viewed in this study: ectropion of nostril sparse hair, ankle deformity, whole-body hairy, hanked-3-lap arms, snaggletoothed or extra teeth and unusual-dehydrated skin, and extreme hyperactivity/self-sitimulation. As to the zebrafish model, the shank3-KO zebrafish displayed varying degrees of developmental retardation compared with the wild-type zebrafish, such as ventral curled body, less melanin, less somites and so on. Moreover, the homozygous zebrafish were more significant than the heterozygotes. What's more, in zebrafish social interaction test, shank3-KO zebrafish showed less interest exploring conspecific zebrafish both in swimming distance ratio and swimming time ratio. Furthermore, in zebrafish social preference test, shank3-KO zebrafish displayed reduced polarization of fish shoals, looser and larger schools, and higher percentage of fish leaving the group and spending time outside the shoal which implied a disorganized social structure. In addition to social deficits, the trace pattern analysis of zebrafish found several obvious behavioral stereotypies, such as repetitive, stereotypic "repeated self-rotation" swimming behavior.
Conclusions: Â In our study, the severity of intellectual, hypotonia, and speech impairments were seen in *SHANK3* deficiency which highlighted the prominence of SHANK3 in ASD. Zebrafish, a typical animal model, will play a critical role in further studying the relationship between phenotype and genotype of ASD and insighting into the molecular mechanisms underlying the clinical heterogeneity of ASD.

33 **106.033** Social and Non-Social Reward in Mouse Models of Autism

C. Weichselbaum[1], *S. E. Maloney*[2], *K. B. McCullough*[2] *and J. Dougherty*[2], *(1)Psychiatry and Genetics, Washington University School of Medicine, St. Louis, MO, (2)Genetics, Washington University School of Medicine, St. Louis, MO*

Background:
The social motivation theory of autism posits that social interaction may be less rewarding for individuals with ASD than typically-developing individuals. However, it has also been suggested that reward processing may be affected more globally in ASD. Mouse models present a promising opportunity to explore how these competing explanations may apply in a variety of ASD etiologies, including ASD-associated genetic mutations. The Fmr1 knockout mouse model of Fragile X Syndrome has been previously shown to exhibit deficits in reward learning, and here we extend these findings to several other genetic models including Celf6 and Nf1 mutants, representing an ASD candidate gene and syndromic form of ASD respectively.
Objectives:
We employed the conditioned place preference assay to measure reward learning in several genetic mouse models of ASD, with the goal of establishing whether any deficits are global or specific to social rewards.
Methods:
In the conditioned place preference assay, mice are conditioned to associate one side of a three-chamber apparatus with a particular reward. Time spent on this side of the apparatus is compared before and after conditioning, and a significant increase indicates that the animal was sufficiently rewarded to learn the association. To assess non-social reward, we injected the mice with cocaine on the conditioned side and saline on the opposite side. Acute locomotor sensitization to cocaine was also measured by total distance traveled in the drug-paired side on each day of conditioning. A social reward version of this task is ongoing, in which mice are exposed to social interaction instead of cocaine.
Results:
Consistent with the global reward impairment hypothesis, cocaine conditioning was not observed in the Celf6 knockout line, indicating a general lack of reward response. Celf6 knockout mice did not show a significant preference for the cocaine-associated chamber after three days of conditioning, in contrast to wildtype littermates. They also did not exhibit typical cocaine sensitization during conditioning, suggesting a lack of acute response to the reward. We also examined reward conditioning and acute responses in the Nf1+/- model of neurofibromatosis, a syndromic form of ASD.
Conclusions:
We have confirmed global reward learning abnormalities among a subset of genetic mouse models, suggesting that reward deficits in ASD may exist beyond impaired social motivation.

34 **106.034** Sulforaphane Improved Social Communication Impairment with Upregulation of Gabaergic Pathway in Cerebral Cortex of Valproic Acid Induced Autism

K. F. Chau[1]*, W. Yang*[2]*, A. Y. T. Choi*[3] *and C. W. Chan*[4]*, (1)The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)The Chinese University of Hong Kong, Hong Kong, Hong Kong, (3)School of Chinese Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (4)School of Chinese Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that is characterized by deficits in social communication, and restricted repetitive pattern of behavior. The etiology of ASD has not yet been defined due to its multiple factors. Valproic acid (VPA), which is for treating epilepsy and depression, has been reported to induce ASD by prenatal exposure in clinical cases and animal model. Current pharmacotherapies are still in clinical trial stages. Sulforaphane (SFN), which is an isothiocyanate derived from vegetables like broccoli, has been showed to ameliorate the social communication impairment in clinical trial. Our previous research demonstrated that that SFN can ameliorate of social impairment in VPA induced mouse model. However, the possible mechanism has not been realized yet.
Objectives: This study aimed to investigate the mechanism of SFN effects on VPA mouse model. Besides, the pathway will be studied in respect to the pathogenesis and treatment of ASD.
Methods: Pregnant BALB/c albino mice were injected intraperitoneally with VPA (600 mg/kg) on embryonic day 12.5, while the PBS group mothers were given with PBS as control group. On postnatal day 28, male pups from VPA-injected mothers were verified the autistic feature by three chambers sociability test. Mice with autistic feature were randomly assigned into SFN treatment group and VPA group. The SFN treatment group (VPA-SFN) mice was given with SFN (3.854 mg/kg/day) by oral gavage; while the VPA and PBS group were fed with saline (VPA-SAL). All groups were fed daily for 22 days. All mice were euthanized on postnatal day 50 and the cerebral cortices were harvested to perform Western Blot and immunohistochemistry analysis of presynaptic glutamic decarboxylase GAD67 and GABAergic receptors including GABRα1, GABRα5 and GABRβ2.
Results: For presynaptic protein, the protein levels of GAD67 were significantly repressed by 77.1% ($p < 0.05$) in VPA mice as compared with PBS group. SFN group showed up-regulation of GAD67 (26.4%, $p < 0.05$) respective to VPA mice. For postsynaptic receptors, expression levels of GABRα1, GABRα5 and GABRβ2 were down-regulated by 29.2% ($p < 0.05$), 15.4% ($p < 0.01$) and 33.0% ($p < 0.05$) significantly in VPA group, while in SFN treatment group, expression levels were rescued by 17.7% ($p< 0.05$), 71.9% ($p<0.05$) (comparable to PBS group), and 44.3% ($p<0.01$) respectively. In the fluorescent histochemistry, SFN treated mice showed intense signals of GAD67, GABRA1 GABRA5 GABRB2 in cerebral cortex, similar to PBS group but less signals in VPA group.
Conclusions: Sulforaphane ameliorates the inhibition of GABAergic proteins in valproic acid induced autistic mice.

35 **106.035** The Association of ASD-like Behavior, Inflammatory Signaling, and Oxidative Stress Cascades in Semaphorin 3F KO Mice

G. Barnes*, E. Gozal and R. Jagadapillai, University of Louisville School of Medicine, Louisville, KY*

Background: The neuropathology of all neural circuits in ASD are dependent on changes in functional connectivity via the excitation/inhibition (E/I) ratio. The changes in E/I ratio impact routine neurotransmission, synaptic plasticity, and network function. We were the first to publish an extensive investigation of an animal model of autism and epilepsy (Barnes et al., 2009). The semaphorin/neuropilin gene family, an ASD associated set of genes, are guidance cues that control processes and cell motility in a wide variety of tissues including the CNS, heart, lung, kidney, and immune system. In the developing brain, these cues control interneuron migration/cell numbers, regulate neurite outgrowth (axon/dendrite), and control both GABA/excitatory synaptogenesis.
Objectives: The objective was to define the associations between inflammation, oxidative stress, and ASD-like behaviors.
Methods: Several groups, including our own, have noted behavioral phenotypes consistent with autism in both the semaphorin 3F and neuropilin 2 (NRP2) knockout mice. Since we observed decreased cell numbers of fast spiking Parv+ interneurons in NRP2 KO mice, we created cell specific knockouts of the ligand Semaphorin 3F (Sema 3F). The interneuron cell numbers, behaviors, inflammatory cascades, and oxidative stress signaling were investigated in these mice.
Results: Similar to NRP2 KO mice, the interneuron specific but not excitatory neuron specific knockout of Sema 3F had decreases in Parv+ and NPY+ interneuron and increased epileptogenesis. As a group, these animals had decreased social behaviors and increased repetitive behaviors compared to wild type littermates. The Sema 3F-NRP2 system signals through the NADPH oxidase MICAL1/2/3 to control the rac/rho mediated growth cone collapse via CRMP2. Interestingly, Judy Atwater and colleagues at the UC Davis MIND institute detected an auto-antibody against CRMP2 among the maternal inflammatory response which correlated with an ASD diagnosis. The staining for oxidative stress markers (4HNE, DHE), iNOS, and 3-nitrotyrosine (markers of inflammation) suggest increased products both within the glia and neurons of the interneuron specific Sema 3F conditional KO mouse. At least one marker of microglial activation Iba1 is increased in these same mice.
Conclusions:
Thus, although this is a single ASD associated gene KO mouse, these data strongly suggest that genetic mouse models of autism with markers of inflammation will be an excellent tool to investigate the role of genomics, environmental factors influencing the immune system (metals, obesity), clinical endophenotypes, and metabolic conditions. Most importantly, these models and others can define molecular mechanisms influencing the interactions among organ systems contributing to ASD brain dysfunction.

36 **106.036** The Effects of Maternal High Fat Diet on Behavioral Measures in C57BL/6J and BTBR T+ Itpr3tf/J Offspring.

K. K. Chadman[1] *and L. A. Leone*[2]*, (1)New York State Institute for Basic Research, Staten Island, NY, (2)Institute of Basic Research in Developmental Disabilities, Staten Island, NY*

Background: The etiology for most cases of autism spectrum disorder (ASD) is unknown at this time. There is strong evidence for the genetic role in ASD but environmental factors also have a modifying role. One potential environmental factor is the maternal diet during pregnancy. Obesity before and during prenatal development increases the vulnerability of affective disorders including schizophrenia and ASD. Prenatal maternal obesity has been shown to be a risk factor for ASD and other developmental disabilities (Krakowiak et al. *Pediatrics* 2012;129;e1121),
Objectives: The objective of these experiments was to determine if a maternal high fat diet increases autistic-like behaviors in the offspring. A commonly used inbred mouse strain, C57BL/6J and a mouse model of ASD, the BTBR T^{+} *Itpr3*^{tf}/J (BTBR) were used.
Methods: Female mice were placed on either a high fat diet (60 kcal% fat D12492, Research Diets Inc, NJ) or a control diet (45 kcal% fat D12451, Research Diets Inc, NJ) for 2 weeks and then mated. The dams remained on the diet through weaning and then were placed on regular mouse chow. Both male and female offspring were behaviorally phenotyped as adults. One female and male per litter were used in up to four tests, each test at least 2 days apart.
Results: Preliminary data suggests that the prenatal high fat diet lowered the sociability in male C57BL/6J mice and to a lesser extent in the female C57BL/6J mice as well. The trend was the opposite in the BTBR mice where the controls were less social than the mice prenatally exposed to the high fat diet. The high fat diet did not have affect anxiety-like behavior the BTBR mice and the C57BL/6J male mice, but increased anxiety-like behavior in the C57BL/6J female mice. The high fat diet did not affect anxiety-like behavior, motor behavior, or exploratory behavior in the offspring.
Conclusions: Maternal obesity is a risk factor for ASD and the preliminary data demonstrated changes in social behavior and anxiety-like behavior that was both strain and sex dependent.

37 **106.037** Toll-like Receptor-Selective Placental Vulnerability, Fetal Brain Impairment, and Post-Natal Behavioral Deficits in Mouse Models of Neurodevelopmental Disorder

A. R. Narayan[1]*, M. L. Kielhold*[1]*, B. A. Babineau*[1]*, H. M. Moon*[1]*, K. M. Correa*[1]*, V. Saravanapandian*[1]*, G. Subramanyam*[1]*, T. Cisneros*[2]*, P. A. Carpentier*[1]*, M. Rivera*[1] *and T. D. Palmer*[1]*, (1)Neurosurgery, Stanford University, Palo Alto, CA, (2)Immunology, Stanford University, Palo Alto, CA*

Background:
Neurodevelopmental disorders (NDD), such as autism and schizophrenia have a diverse and multi-faceted etiology that is poorly understood, though epidemiological studies suggest that environmental risks such as prenatal infections or other gestational immune events correlate with increased NDD risk. Innate immune responses are evoked by toll-like receptor (TLR)-dependent signaling pathways. Both bacterial- (TLR4-selective) and viral- (TLR3-selective) mimetic-mediated maternal immune challenges have been shown to result in brain and behavioral changes (as reviewed by Meyer 2014), however, differences in methodologies prevent the direct comparison of the TLR-selective effects.
Objectives:
Previously, we demonstrated that a TLR4-selective insult at embryonic day 12.5 (E12.5) has adverse effects on fetal and placental health, proliferation of radial glial cells, altered cortical laminar patterning in the adult and behavioral deficits (Carpentier et. al 2013). Here, we aim to directly determine the differential effects of TLR3- and TLR4-selective agonists on a similar set of assays.
Methods:
Pregnant mice were challenged with a TLR3- or TLR4-selective insult on E12.5 and placental pathology and pregnancy outcomes were evaluated by quantifying tissue necrosis and fetal survival, respectively. Neocortical alterations in the developing fetuses were examined via immunohistochemistry for markers of cell proliferation and neural progenitor cell populations. Finally, behavioral outcomes were measured using tasks that evaluate behaviors analogous to the symptoms of NDDs, including pup ultrasonic vocalizations, juvenile play, social approach, and pre-pulse inhibition.
Results:
Our results indicate that bacterial and viral immune insults differentially affect placental health, fetal viability and early embryonic brain development. Post-natal behavioral outcomes also appear divergent with the TLR3-mediated insult leading to a more pronounced behavioral phenotype in the offspring.
Conclusions:
These findings suggest that specific immune events create differential outcomes for the health of the placenta and fetus and lead to distinct changes in cortical patterning which can ultimately manifest as unique behavioral symptoms. Our results have implications for understanding how similar environmental insults may lead to distinct developmental disorders or contribute to the heterogeneity of a specific condition.

Poster Session

38 **107.038** A Longitudinal Study of Gestures Used By Mothers of Infant Siblings of Children with Autism Spectrum Disorder

P. Shah[1], *A. B. Choi*[2], *M. Rowe*[3], *C. A. Nelson*[4] *and H. Tager-Flusberg*[5], *(1)Boston University, Boston, MA, (2)Harvard University, Cambridge, MA, (3)Harvard Graduate School of Education, Cambridge, MA, (4)Boston Children's Hospital, Boston, MA, (5)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Â Typically developing children develop gestures before speech, and differences in types of gestures predict their future language ability (Iverson & Goldin-Meadow, 2005). Environmental factors, particularly parental behavior, influence child language development. Maternal gesture rates closely relate to infant gesture rates, which, in turn, predict language development (Rowe et al., 2008). Diversity of maternal speech was shown to predict concurrent and later child language ability (Rowe, 2012). Children with autism spectrum disorder (ASD) show language and gesture delays as early as 12 months (Özçalışkan et al., 2015). Infants with an older sibling with ASD are at higher risk for ASD and also show delays in language and communication. Talbott et al. (2015) reported that mothers of 12-month high-risk infants who were not later diagnosed with ASD (HRA-) gesture more than mothers of both infants later diagnosed with ASD (HRA+) and low-risk controls (LRC). For HRA- and LRC infants, these gesture rates correlated with 18-month language scores.
Objectives: Â The current study expands on previous research by studying maternal gestures in relation to child gestures and language longitudinally. Our research questions were a) Do mothers of HRA-, HRA+, and LRC infants differ in gestural rates at 12 and 18 months? b) Do maternal gestures correlate with child gestures? c) Do maternal gestures predict child language through 3 years?
Methods: Mothers and 12- and 18-month infant dyads (N=73, n_{HRA-}=25, n_{HRA+}=18, n_{LRC}=30) were observed during a 10 minute free-play as part of a longitudinal study. Speech and frequencies of gesture types (deictic, representational, conventional) were transcribed and coded according to a gestural coding scheme by Özçalışkan & Goldin-Meadow (2009). The Mullen Scales of Early Learning (MSEL) were administered to assess language at 12, 18, 24 and 36 months, and the Autism Diagnostic Observation Scale (ADOS) was administered to determine ASD diagnosis at 36 months (confirmed by clinical evaluation).
Results: Although mothers of HRA- children gestured more than mothers of HRA+ or LRC children, differences in total gestures were not statistically significant at either 12 (X^2=4.17, p=0.17) or 18 (X^2=0.41, p=0.52) months (Figure 1). Maternal gestures were significantly correlated with infant gestures at 12-months only for HRA+ infants (p=0.009, r=0.60, Figure 2A), and at 18-months only for LRC infants (p=0.002, r=0.54, Figure 2B). Maternal gestures at 12-months were positively correlated with child gestures at 18-months only for LRC infants (p=0.016, r=0.44; Figure 2C). Total maternal gestures were not significantly correlated with concurrent or later infant language scores for any of the three groups (p>0.1).
Conclusions: These results demonstrate that mothers of high-risk infants have similar gestural communication qualities as mothers of low-risk infants. Maternal gestures at 12- and 18-months correlated with LRC infant gestures at 18-months, suggesting a more robust relationship between mothers and LRC infants. However, high-risk 18-month infants had no such relationships, suggesting a lack of synchrony during communication. Understanding the nature of communication synchrony between mother-child informs the development of quality early interventions. Future analyses will focus on the interconnection and communicative synchrony between mother and child, and child contributions to conversation.

39 **107.039** A New Approach for Eliciting Expressive Language Samples: Elsa

M. D. Barokova[1], *S. Hassan*[1], *C. Lee*[2], *M. Xu*[3] *and H. Tager-Flusberg*[4], *(1)Boston University, Boston, MA, (2)Psychological and Brian Sciences, Boston University, Boston, MA, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Emergence of expressive language is one of the strongest predictors of positive outcomes in individuals with ASD (Howlin et al., 2004; Venter et al., 1992). Language abilities also play an important role in social communication, which places them at the center of numerous interventions, and consequently requires the use of reliable and valid language measures for their assessment. Natural language samples collected across variety of contexts provide great measures of speakers' expressive language (Tager-Flusberg et al., 2009). Yet, no protocol for language elicitation has been specifically designed for individuals with ASD across a range of ages and language abilities. This is particularly important considering that language ability is one of the most variable characteristics of diagnosed individuals with 30% failing to acquire functional speech (Kjelgaard & Tager-Flusberg, 2001). Many studies rely on the ADOS as a language sampling context. However, presenting participants with different presses and activities depending on the module administered might influence language measures.
Objectives: We aim to evaluate a new Eliciting Language Samples Assessment (ELSA) protocol for individuals with ASD across a range of ages and language ability. The study focuses on its use with minimally verbal children with ASD, arguably the most challenging group from whom to obtain language samples. We evaluated the effectiveness of ELSA in eliciting language and engaging the participants. We compared it to a different language sampling context, the ADOS.
Methods: ELSA includes multiple activities designed to engage individuals across a wide age range including going on a hike, camping, doing crafts (all carried out using a kit with relevant props and materials), watching a short video and retelling its plot, and a short conversation period. We evaluated protocol engagement by examining the duration of engagement of the participants (how long it took to go through all the activities). Utterance frequency per minute was used to assess the effectiveness of ELSA in eliciting language, and compare it to the ADOS.
Results: Participants (N=20) aged 6;7 to 18;10 spent on average 18.96 (SD=4.49) minutes engaging with ELSA. They produced an average of 3.79 (SD=3.91) utterances per minute. The frequency of utterances per minute during ELSA (*M*=3.1817) and ADOS (*M*=2.2760) approached a significant difference (*t*(8)= 2.0491, *p*=0.0746) with more utterances per minute during ELSA.
Conclusions: ELSA was successful at engaging participants across a wide age range and language ability for a prolonged period of time (Table-1). In addition, participants, even minimally verbal ones, produced speech sounds while engaging with the ELSA activities. The video component of the protocol was originally included in order to evaluate the narrative skills of more verbally fluent participants, so it might not be applicable to less verbally fluent individuals as reflected by the small number of vocalizations they produced during this portion of ELSA. Participants tended to make utterances more frequently during ELSA than during the ADOS, which speaks to ELSA's ability to elicit language. These analyses provide support for the use of the newly designed ELSA for the assessment of the highly heterogeneous language ability in ASD.

40 **107.040** A Peer-Mediated Intervention for Preschoolers with Autism Using AAC: Effects on Presymbolic and Symbolic Communication

K. Thiemann-Bourque, *Juniper Gardens Children's Project, Kansas City, KS*

Background:
The Communication Complexity Scale (CCS; Brady et al., 2012) is a measure of prelinguistic and linguistic communication being validated for individuals with autism and other developmental disorders. It was developed to fill a gap in assessment of communication for individuals with complex communication needs who may have severe intellectual impairments. Often it is difficult to determine communication status for this population due to presymbolic means of communicating that may not be revealed on typical standardized assessments.
Objectives:
The purpose of this presentation is to describe how this scale is being used to measure treatment effects of a peer-mediated (PM) communication intervention for preschoolers with autism learning to use augmentative and alternative communication (AAC). The intervention teaches typically developing peers to use a speech generating device (i.e., iPad with voice output app) with a classmate with autism. Procedures of the peer-mediated AAC intervention will be described; as well as CCS outcomes for 17 children with autism in the control group and 18 children in the PM AAC treatment group.
Methods:
Each year for 3 years, 12 children with autism and 1-3 peers per child were recruited. We conducted a series of multiple baseline designs, within an embedded randomized control design with 6 children assigned to an iPad only condition (control) and 6 assigned to iPad + PM condition (treatment) each year. Effects of the intervention were assessed within groups (baseline to treatment) and between groups (control and treatment) for 35 children. We used the CCS to score a Structured Communication Sample: Adult Partner, and the same assessment with a Peer Partner, pre- and post-intervention. We adapted administration with a peer to provide a unique way of measuring effects of the intervention on changes in communication with peers, in addition to the typical adult assessment context. Twelve communicative temptations were presented to elicit behavior regulation and joint attention (JA).
Results:
On the CCS, children in both groups made significant changes with adult and peer partners. However, there were no differential treatment effects in score changes for children in the PM treatment compared to the control group. Calculation of effect sizes suggested a medium effect size (0.4) for changes with peer partners, compared to a small effect size (.2) with adults. Furthermore, 90% of children in the PM treatment and 75% of children in the control group improved from intentional non-symbolic to intentional symbolic communication. Closer analysis of JA behaviors revealed low rates and no significant changes for either group in JA with adults or with peers.
Conclusions:
Following a peer-mediated AAC intervention, we found treatment effects on communication complexity for preschoolers with autism using the CCS - a developmental scale assessing pre-intentional to intentional symbolic communication. Outcomes provide preliminary support that this tool can be used to assess early communication behaviors, and provide a means to measure effects of social communication interventions for this population. Further, early interventions that include peers should consider teaching JA within play, given the relationship of this early core skill to later social communication skills.

41 **107.041** Acquisition of Nouns in Young Children with ASD: Insight into Learning Processes from Item Analyses

S. T. Kover[1], *D. A. Fein*[2] *and L. R. Naigles*[3], *(1)University of Washington, Seattle, WA, (2)University of Connecticut, Storrs, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Â In typical development (TD), vocabulary acquisition has been proposed to result from domain-general associative learning, which, together with statistics in the environment, predicts word learning patterns (McMurray, Horst, & Samuelson, 2012). The size and contents of children's vocabularies support these patterns (Perry & Samuelson, 2011; Samuelson & Smith, 1999). For example, TD children who demonstrate a shape bias also produce many count nouns, especially those that are organized by shape rather than material (that is, most early nouns are solids, organized by shape, and count nouns; Perry & Samuelson, 2011; Samuelson & Smith, 1999). Children with autism spectrum disorder (ASD) fail to show a shape bias (Potrzeba, Fein, & Naigles, 2015; Tek, Jaffery, Fein, & Naigles, 2008), possibly because their lexicons are organized differently (e.g., not dominated by solid+shape+count nouns). We test this by examining the solidity, syntax (i.e., count vs. mass), and category organization (i.e., shape, color, material) of nouns in the receptive and expressive vocabularies of matched samples of toddlers with ASD and TD.
Objectives: Â We asked: (1) do toddlers with ASD, like TD toddlers, understand and produce more nouns on the "shape side" (solid+shape+count; e.g., cup, block) than on the "material side" (nonsolid+material+mass; e.g., rain, milk)? and (2) are "shape side" nouns acquired first such that they represent a higher proportion of nouns in children with small vocabularies?
Methods: Â TD toddlers (*n*=46; *M* age=19 months) and toddlers with ASD (*n*=39; *M* age=32 months) were drawn from a longitudinal study. Expressive and receptive vocabulary were assessed using parent report (MacArthur-Bates Communicative Development Inventories [CDI]: Word and Gestures; Fenson et al., 2007).Â Groups did not differ on number of nouns produced,*p*=.700, *d*=0.08.
Nouns from the CDI (*n*=209) were coded following Samuelson and Smith (1999) for each toddler's lexicon. The proportion of nouns characterized by solid+shape, nonsolid+material, solid+count, and nonsolid+mass was calculated.
Results: Like the TD children, those with ASD understood and produced many more solid+shape than nonsolid+material nouns, *p*s<.001, and many more solid+count than nonsolid+mass nouns, *p*s<.001. See Figures 1 and 2.Â The proportion of noun types was not correlated with vocabulary size in either group after controlling Type I error.
Conclusions: Overall, these findings suggest that the regularities proposed to support learning biases are present in the vocabularies of children with ASD: "shape side" nouns dominate the vocabularies of children in both groups regardless of vocabulary size. Despite this, their performance reveals no consistent shape bias during word learning (Potrzeba et al., 2015). It is possible that children with ASD, rather than lacking the data (vocabulary) are instead lacking the processes by which the data could be analyzed. That is, the process of lexical learning may develop distinctly in children with ASD due to the ways in which or the extent to which these regularities and their organization are utilized over time (Ellawadi, Fein, & Naigles, 2016; Tek et al., 2008). The current study has implications for theories of lexical acquisition in ASD, including shared mechanisms with typically developing children and the role of prior knowledge.

42 **107.042** Adults with ASD More Rigid When Establishing Common Ground during a Referential Communication Task

M. Conca[1], *J. Beriont*[1], *A. de Marchena*[2], *A. Bagdasarov*[3], *B. Maddox*[4], *E. Ferguson*[5], *A. A. Pallathra*[6], *N. Minyanou*[7], *L. Bateman*[5], *Z. M. Dravis*[8], *A. T. Pomykacz*[9], *K. Bartley*[10], *E. S. Brodkin*[6], *J. Pandey*[1], *J. Parish-Morris*[4], *R. T. Schultz*[1] *and E. S. Kim*[1], *(1)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Center for Autism Research/CHOP, Philadelphia, PA, (6)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (7)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (8)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (9)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (10)Center for Autism Research, Malvern, PA*

Background: Â A speaker's ability to manage shared knowledge, or common ground, with a listener is a fundamental aspect of pragmatic language, which in turn is an area of deficit common to autism spectrum disorder (ASD). Common ground management problems observed in individuals with ASD include verbosity (de Marchena & Eigsti 2016), overspecification, and ambiguity caused by pronoun or article-definiteness reversal (Graf & Davies 2014). But little research has examined how interlocutors come to agree on the terms used to describe shared referents. The current study examines whether speakers with ASD choose their own or their interlocutors' word labels for novel figures in a dyadic referential communication task.
Objectives: Â To gauge flexibility in forming common ground.
Methods: Â Adults with ASD (*n*=12) and age-, gender, and IQ-matched controls with typical development (TDC; *n*=8) completed a collaborative referential communication task designed to elicit spontaneous back-and-forth conversation in a controlled setting. (Data from 12 additional participants with ASD, and 16 additional TDCs will be available by IMFAR2017.) Participants were shown a grid of eight abstract figures and tasked with describing them to a confederate—blind to the figures' arrangement—with the shared goal of ordering them correctly. Each participant-confederate dyad completed 5 trials (or grids), each presenting the same set of eight figures in a unique order, so that participants described each figure 5 times. Speech was transcribed, and participant's descriptions for each figure in trials 2-5 were rated with respect to the descriptions used in immediately preceding trials. Descriptions in subsequent trials either reflected each participant's own descriptions from the previous trial, the confederate's, both, or neither.
Results: Â Participants in both groups referred to figures largely using their own (52%) or their interlocutors' (40%) terms from immediately preceding trials, and rarely use both (5.3%) or new terms (2.4%). There were group differences in the proportions with which participants used their own, their interlocutors', both, or neither's terms ($p<.05$), and trending differences particularly in the second trial ($p=.077$). Over trials 2-4, odds ratios indicate that the odds of a participant's using their own terms were 1.148 times higher for the ASD than the TD group. For trial 2, the odds ratio was 1.62.
Conclusions: For both groups of adults with typical development and with ASD, there was variation in usage of participants' own, versus their interlocutors' terms when referring to previously described novel figures. These variations differed between groups. Adults with ASD were more likely to use their own terms than their interlocutor's, potentially reflecting rigidity known to be associated with ASD. Use of one's own description implies a refusal of one's interlocutor's terms, and lead to difficulty achieving or maintaining common ground in conversation.

43 **107.043** Adults with ASD Show Strengths and Weaknesses in Conversation during a Referential Communication Task

Z. M. Dravis[1], *A. Bagdasarov*[2], *E. S. Kim*[3], *Y. Zhang*[4], *M. Cola*[4], *B. Maddox*[5], *E. Ferguson*[6], *L. Adeoye*[2], *F. Fergusson*[2], *A. A. Pallathra*[7], *N. Minyanou*[8], *L. Bateman*[6], *A. T. Pomykacz*[9], *K. Bartley*[10], *E. S. Brodkin*[7], *J. Pandey*[3], *J. Parish-Morris*[5], *R. T. Schultz*[3] *and A. de Marchena*[4,11], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)The Center for Autism Research/CHOP, Philadelphia, PA, (7)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (10)Center for Autism Research, Malvern, PA, (11)University of the Sciences, Philadelphia, PA*

Background:
Although social-communication deficits are central to Autism Spectrum Disorder (ASD), little research has examined how communication changes in real time as social interactions unfold. In typical populations, conversational partners become more efficient communicators as they establish a shared vocabulary, or *common ground*. Other subtle phenomena, such as matching word choice, syntax, and prosody, as well as mimicking one another's hand gestures, are also observed. Some research shows that individuals with ASD employ a range of these skills; for example, interlocutors with ASD *do*establish common ground with interactive partners, pointing to pragmatic strengths in this population. The current study extends prior research by including information about nonverbal communication – specifically, co-speech hand gestures.
Objectives:
To identify how patterns of behavior change as conversation progresses over time.
Methods:
Adults with ASD (n=24) and age-, gender, and IQ-matched typically developing controls (TDC; n=10) completed a five-trial collaborative referential communication task designed to elicit spontaneous back-and-forth conversation in a controlled setting (analyzed data on 14 remaining TDCs will be available by IMFAR2017). Participants were shown a grid of eight abstract figures and tasked with describing the figures to a confederate with the goal of ordering them correctly. Each trial included the same stimuli in a different order, thus participants described each figure 5 times. All hand gestures were tagged and coded for how much *supplementary information* (i.e., information not present in speech) they included, and for their *size* of execution.
Results:
Participants in both groups performed very well on the task (96% accuracy). The pragmatic manipulation employed by this paradigm (i.e., prompting participants to describe the same stimuli across five trials) was effective; all participants took the longest on trial one, describing the items more quickly on each subsequent trial (main effect of trial: p<.001, Cohen's d=3.27; see **Figure 1**). There was no change in how much *supplementary information* was presented in gestures, in either group (main effect of trial: p=0.26, Cohen's d=0.38). In contrast, the *size* of participants' gestures dropped significantly between the first and second trials (main effect of trial: p=.01, Cohen's d=1.06), with a marginally significant group by trial interaction (p=0.11, Cohen's d=0.67; see **Figure 2**), driven by no change in gesture size in the TDC sample (p=.49, Cohen's d=0.16) and a significant drop in gesture size in ASD (p=.003, Cohen's d=0.81).
Conclusions:
Like controls, adults with ASD shorten their discourse as conversation unfolds, consistent with recent findings that adults with ASD are responsive to common ground manipulations (Nadig, Shivani, & Sasson, 2015). Across groups, co-speech gestures presented the same amount of supplementary information throughout the task, suggesting that the *content* of nonverbal communication remains consistent throughout conversation. However, group differences were marginally significant in changes in gesture *size*, which may be a marker of engagement or effort exerted in the interaction. While TDC participants maintained their gesture size, participants with ASD showed a sharp decrease in gesture size between trials, potentially reflecting a decrease in social motivation as the task (and thus, the interaction) becomes less novel and engaging.

44 **107.044** Anxiety, Language, and Heart Rate Variability in Autism Spectrum Disorders

A. E. Muskett[1], *D. Swain*[1], *M. A. Patriquin*[2] *and A. Scarpa*[1], *(1)Virginia Tech, Blacksburg, VA, (2)University of Alabama, Birmingham, Birmingham, AL*

Background:
Anxiety concerns are commonly experienced in children with Autism Spectrum Disorder (ASD) (Kerns et al., 2014). Despite this, those with both ASD and language difficulties are reported to experience less anxiety than those with less language difficulty (Kerns et al., 2014).Â Using objectively measurable biomarkers of anxiety (e.g., reduced heart rate variability; HRV) that do not rely on language ability may provide a way to improve anxiety assessment in Minimally-Verbal ASD (MV-ASD), but first more must be known about the relationship between HRV, anxiety and language. Social Engagement Systems theory, a sub-portion of the Polyvagal Theory, suggests that children with ASD experience deficits in a "social communication circuit" (Porges, 2007). Additionally, it has been shown that, much like anxiety, receptive language can be predictive of lower HRV (Patriquin, Scarpa, Friedman, & Porges, 2013). These studies provide a framework for the relationship of language or anxiety to HRV individually however few studies have looked at the interactions between HRV, language and anxiety.
Objectives:
In a sample of children with ASD it was hypothesized that RSA would be predicted by anxiety and receptive language abilities such that more anxiety and higher receptive ability will result in lower RSA.
Methods:
Participants consisted of 23 children (18 males) age ranged from 51 months to 95 months (mean = 68.70, SD = 14.07). Anxiety was measured by parent report using the Developmental Behavior Checklist, Parent Version- Anxiety Subscale (DBC-P; Einfeld & Tonge, 1992, 1995, 2002). Receptive language was measured using the Peabody Picture Vocabulary Test, Third Edition (PPVT-III; Dunn & Dunn, 1997), which was administered to children during the study visit. Additionally, children watched a 3-minute baseline video, which allowed for the measurement of baseline HRV via LifeShirt! (Vivometrics).
Results:
The model tested the prediction of parent-reported anxiety (DBC-P) and receptive language ability (PPVT-III) and their interaction with HRV (as measured by RSA). Child demographic variables such as age and gender were not correlated to RSA and therefore no covariates were included in the regression analysis. As shown in previous studies, PPVT-III was uniquely and positively related to RSA (βÂ = .545,Â *p*Â = .011). However, neither anxiety nor the interaction term was significant (βÂ = .072,Â *p*Â = .713, βÂ = -.170,Â *p*Â = .075 respectively). The full model with the interaction term was not significant (p = .052); however, the model with level 1 predictors explain 31.6% of the variance in RSA (F(2,19) = 4.390, *p* = .027).
Conclusions:
These findings indicate that, consistent with the Polyvagal Theory of the Social Engagement System (Porges, 2007) and previous studies (Patriquin, Scarpa, Friedman, & Porges, 2013) receptive language seems indicative of lower RSA. However, anxiety does not seem indicative of lowered RSA in this population, and the relationship between anxiety and RSA also does not appear to be moderated by language. This finding is surprising given the existing research on anxiety and HRV. These results may be due to parent-report not being an accurate reflection of child anxiety.

45 **107.045** Cardiac Autonomic Function Predicts Pragmatic Language Features of the Broad Autism Phenotype in Mothers of Children with ASD

J. Klusek[1] *and J. Roberts*[2]*, (1)Communication Sciences and Disorders, University of South Carolina, Columbia, SC, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background: The autonomic nervous system is a stress regulation system that supports social engagement. Despite efforts to characterize autonomic regulation and its role in the social impairments seen in autism spectrum disorder (ASD), evidence is inconsistent, likely due to the significant heterogeneity seen in the disorder (see Klusek et al., 2015, for review). The study of the broad autism phenotype (BAP), or subtle characteristics seen in unaffected family members that mark genetic liability to ASD, offers a framework from which to study core, genetically meaningful features of ASD while foregoing confounds related to the complex clinical presentation of the full disorder. This study adopted a BAP approach to examine cardiac markers of autonomic function among parents of children with ASD, in order to lend insight into the utility of autonomic indices as biomarkers for ASD risk. Autonomic dysregulation was also examined in relation to pragmatic language (i.e., social language) difficulties, which have been documented among parents of children with ASD as part of the BAP and are thought to reflect genetic susceptibility (i.e., Losh et al., 2008).
Objectives: This study had two research questions: (1) Do cardiac autonomic markers (i.e., heart rate, respiratory sinus arrhythmia) differ across mothers of children with ASD and control mothers? (2) Does cardiac autonomic regulation relate to pragmatic language features of the BAP?
Methods: Participants included 28 mothers of children with ASD and 28 control mothers of typically developing children (*M* age=43.5 years, *SD*=9.3). The groups did not differ in age, IQ, race, or education level (*p*'s<.204). Cardiac activity was sampled in a 3-min baseline period and mean estimates for heart rate (an index of general arousal) and respiratory sinus arrhythmia (an index of parasympathetic "rest and digest" function) were derived. Pragmatic language violations were coded from a 20-min conversational interview using a modified version of the Pragmatic Rating Scale (Losh et al., 2012). Samples were coded by two independent raters and consensus scores were used, with reliability prior to consensus at ICC(3,2)=.74. General linear models tested group differences on each of the cardiac variables. General linear models also tested each of the cardiac variables, group, and their interaction as predictors of pragmatic language.
Results: The groups did not differ on heart rate (*p*=.280, η^2_p=.02) or respiratory sinus arrhythmia (*p*=.193, η^2_p=.03). Reduced respiratory sinus arrhythmia was a significant predictor of increased pragmatic language violations across both groups (*F*[1,43]=4.14, *p*=.048, η^2_p=.09).
Conclusions: Mothers of children with ASD did not show evidence of cardiac autonomic dysfunction, suggesting that autonomic dysregulation does not extend to the presentation of the BAP in females. This suggests that autonomic dysfunction in ASD may represent a secondary feature that is not associated with underlying genetic susceptibility. However, respiratory sinus arrhythmia tone did account for variation in pragmatic language variation across both groups, suggesting that parasympathetic function may mediate the presentation of BAP and ASD symptoms. Thus, autonomic regulation may play a role in social-communication competence relevant to both atypical and typical groups, and may represent a mechanistic target for intervention.

46 **107.046** Changes in the Communicative Style of Mothers of Toddlers with ASD Are a Response to the Relatively Low Frequency of Communication in Their Children from 2 to 3 Years of Age

G. Pasco[1]*, T. Charman*[2]*, C. H. Cheung*[3]*, M. H. Johnson*[4] *and T. B. Team*[5]*, (1)16 De Crespigny Park, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Psychology, Institute of Psychiatry, Psychology and Neuroscience, London, UNITED KINGDOM, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (5)Birkbeck College London, London, United Kingdom*

Background:
The British Autism Study of Infant Siblings (BASIS) is a prospective study of children with older siblings with ASD (High-Risk sibs: HR) and controls with older siblings and no history of autism in first degree relatives (Low-Risk sibs: LR). Participants are assessed at various time points from infancy until approximately 36 months of age. At each visit parents are observed playing with their child in an unstructured session.
Objectives:
To investigate the concurrent and longitudinal relationships between parents' communication style and the frequency of their toddler's expressive language in the context of a dyadic play-based interaction within a prospective study of children at risk for ASD.
Methods:
Mothers and their children were observed playing together in an ecologically valid unstructured session when the children were 2 and 3 years of age. The frequency, content and intention of parent and child communicative acts were coded from videos of these sessions. Following the 3-year visit a best estimate research diagnosis was made. Outcome categories are: Low risk controls (LR, n=19), Typically developing (HR-TD, n=40), ASD (HR-ASD, n=10) and Atypical (HR-ATYP, n=19). The latter group consists of children not diagnosed with ASD but meeting ADOS-2 and/or ADI-R ASD criteria and/or being below -1.5 SD on the Mullen Scales of Early Learning.
Results:
Eighty-eight mother-child dyads were observed at both 2- and 3-year visits. The proportion of mothers' communicative acts that were responsive to their children's communication and the overall frequency of children's communicative acts were calculated. Repeated measures ANOVAs were conducted for both variables. For parent communication there was an overall reduction in the proportion of responsive acts over time ($F(1,5.18)$, $p=0.025$, $\eta2=0.058$), but no interaction with group. There was a significant difference between groups ($F(3,4.36)$, $p=0.007$, $\eta2=0.135$): Post-hoc analysis showed that HR-ASD was lower than both the LR and HR-TD groups at the 3-year visit (p=.023 and .022, respectively). For children's communication there was an overall increase in expressive communicative acts ($F(1,40.65)$, $p<0.001$, $\eta2=0.326$) over time but no interaction with group. There was a between-group difference ($F(3,10.44)$, $p<.001$, $\eta2=0.272$), with frequency of child communication in the HR-ASD group being significantly lower than all other groups at both time points (all p<.005).
Conclusions:
Both children and their mothers showed a similar pattern of changes in communication across all groups between 2 and 3 years of age. Mothers typically shifted to a less responsive, style and theirÂ children communicated more frequently. However, the relatively more directive style of communication in the mothers of children with ASD, compared to those of typically developing children, appears to follow the persistent lower frequency of communication used by their children. This may have implications for the type of support and intervention provided for parents of young children with autism.

47 **107.047** Child Reciprocal Vocal Contingency Measure Using Automated Vocal Analysis with Children with Autism Spectrum Disorder

J. McDaniel[1]*, A. L. Harbison*[1]*, P. J. Yoder*[1]*, A. Estes*[2] *and S. J. Rogers*[3]*, (1)Vanderbilt University, Nashville, TN, (2)University of Washington Autism Center, Seattle, WA, (3)University of California, Davis. MIND Institute, Sacramento, CA*

Background: Â Child reciprocal vocal contingency (CRVC) is a new measure of a child's participation in reciprocal vocal interactions in natural settings. Participating in reciprocal vocal interactions could facilitate speech and language development in children with autism spectrum disorder (ASD). Thus, evaluating correlations between CRVC and language development, particularly for preverbal children, might inform use of CRVC as an early indicator of treatment response. Although initial concurrent convergent validity and the stability of CRVC has been documented, CRVC's sensitivity to change, predictive convergent validity, and divergent validity have not been evaluated.
Objectives: (a) What is the sensitivity to change of CRVC across 12 months? (b) Does initial CRVC correlate with expressive vocabulary at 4 time points spanning 18 months? (c) Does CRVC correlate with problem solving concurrently and predictively? A low correlation between CRVC and problem solving would support the divergent validity of CRVC.
Methods: Participants include 68 children aged 13 to 30 months old at study entry. Measures are displayed in Table 1. We quantified CRVC using a three-event sequential analysis to calculate the operant contingency value, which provides an index of contingency that is independent of the frequency of chance sequencing of events. Because this analysis requires long vocal samples, we used daylong Language ENvironment Analysis (LENA) audio recordings and only included participants with at least 1 hour of input near the child on the recordings. Using a computer program to classify vocalizations and compute the index of sequential association minimized human coder measurement error and vastly increased analysis efficiency.
Results: Change in CRVC across 12 months was significant (mean change = 0.037(0.077), $t(25) = 2.41$, $p = .02$). Table 2 displays correlations between CRBC, expressive vocabulary, and problem solving. Initial (Time 1) CRVC correlated significantly with expressive vocabulary at Times 2 and 4, but not Times 1 or 3. CRVC at Time 3 did not correlate with expressive vocabulary concurrently, but did 6 months later (Time 4). As predicted, correlations between CRVC and problem solving were non-significant at Times 1 and 3.
Conclusions: Overall findings suggest continued development of CRVC is warranted, despite mixed results. Positive indicators of potential clinical utility of CRVC include its sensitivity to change for initially preverbal children with ASD, correlation with expressive vocabulary but not problem solving at two time points, and its derivation using computer analysis of acoustic events without human coding, which minimizes clinician and researcher analysis time. The lack of correlation between CRVC and expressive vocabulary concurrently at some time points suggests that CRVC's utility may be restricted to children of a particular language level or across a certain time range. Future research attending to these details is required.

48 **107.048** Children with Autism Spectrum Disorder Can Demonstrate Consistent Word Learning: Expressive Language Measures of Fast- and Slow-Mapping

J. Bang[1] *and A. Nadig*[2]*, (1)McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, CANADA*

Background: Â How children with autism spectrum disorder (ASD) learn new words is often examined using a fast-mapping paradigm. In fast-mapping, children are taught a new word by associating a label they've never heard before (e.g., pagoune) with an object they've never seen before. Oftentimes, assessing learning is limited to receptive language measures, such as asking children to physically indicate the correct object from an array of objects (e.g., where is the pagoune?). More recent studies have begun to include measures of slow-mapping, or children's extended learning of what the word represents beyond an initialÂ association (Norbury et al. 2010). However, prior work has not tracked the consistency of individual children's learning across multiple measures of expressive word learning,Â which would allow us to understand more subtle but important differences that may exist in word learning in ASD.
Objectives: We examined the consistency of word learning across expressive language measures of fast- and slow-mapping in children with ASD and typically-developing (TD) children.
Methods: Children (ASD n = 24, TD n = 24) were matched on age, gender, and nonverbal IQ. Children watched a video that taught the label of a novel object andÂ thenÂ participated in three different measures of expressive knowledge of the word. In word association, children provided the first word they could think of when they heard the newly taught word. In word description, children described the word, and in word production children provided the name of the object when shown an image.
Children's performance on each measure was converted into a binary score: 1 for correct target identifications and 0 for all other responses. Trials with learning across two or three measures were considered as *consistent learning* of the word. Trials with learning on only one measure were considered as *inconsistent learning*. A trial was deemed as *no learningÂ* when children did not identify the word on any measure. Children were assessed immediately after teaching and one week later.
Results: Immediately after teaching, 14 children with ASD and 18 TD children had at least one consistent learning trial across all three measures. Eight children with ASD and 5 TD children did not demonstrate any consistent learning, although they did have a minimum of one inconsistent learning trial. Two children with ASD and 1 TD child demonstrated only trials of no learning. One week later, the number of children with at least one consistent learning trial decreased (9 ASD, 11 TD), whereas more children demonstrated only inconsistent learning (10 ASD, 9 TD), or no learning (5 ASD, 4 TD).
Conclusions: These results reveal that many children with ASD, who have IQ in the normal range, can demonstrate consistent learning across all three expressive language measures, although fewer children in both diagnostic groups are consistent one week later. Future analyses will compare characteristics between children who demonstrated consistent learning versus those who demonstrated inconsistent or no learning. This work provides an important look at how children represent new words and the stability of their word learning.

49 **107.049** Coaching Parents on Effective Communicative Access for Individuals with Autism through the Use of Ipads

F. T. Orsati[1], *J. P. Hussman*[2], *A. Smith*[1] *and C. L. Woodfield*[1], *(1)Hussman Institute for Autism, Catonsville, MD, (2)Hussman Institute for Autism, Inc., Catonsville, MD*

Background:
Recent literature reports that 25% to 30% of individuals with autism do not have a reliable way to verbally communicate. The incorporation of augmentative and alternative communication can be an effective tool for supporting communication and social relationships. Providing parents with adequate coaching for the use of the iPad as a communication tool is promising towards broad-based implementation and long-term outcomes.
Objectives:
The goal of this study was to provide access to alternative means of communication, by investigating the effects of partner coaching using the iPad with a symbol based system for individuals with autism who are minimally verbal, and identifying the effects of these strategies on the individuals' communication skills.
Methods:
This study employed a single-case design to examine coaching parents of individuals with autism to use an iPad for communication with their child. The researcher provided weekly coaching sessions that lasted approximately 40 minutes. Parents were systematically taught elements that comprised a "circle of communication," with each element taught sequentially and introduced as the previous element was mastered. These elements and strategies included: following and expanding on an activity or topic of the individual's choice; taking turns and responding to bids of interactions and shared engagement; providing communicative structure to engage the individual and encourage participant's construction of their own response; modeling language targets; offering structured prompts; and providing contingent reinforcement. This research included 6 parent-child pairs: 6 individuals with autism and 6 parent coaches. All individuals had their clinical autism diagnosis confirmed with the Child Autism Rating Scale.Â The children's ages ranged from 11 to 14 years old, the parents ages ranged from 40 to 48 years of age, and all parents had bachelor's degree. This was a diverse group of participants including two White Americans, two Asian Americans, one African American, one Mixed race (Asian and Latino).
Results:
Preliminary results after 10 to 12 intervention indicate that parents were able to learn to follow their child's lead in their choices of activities. Parents then learned to provoke thought and interaction by asking opinion questions or making comments that require a comment in return, while avoiding "quizzing questions." Parents also learned to model use of target words on the device, particularly during interactions, play time or games. Parents also increased their use of different levels of prompting for responses including verbal and gestural prompts. Parents learned to provide immediate social and natural reinforcement when the child attempted and/or succeeded in producing the word or sentence targets. All participants also demonstrated an increased their use of communication targets on the iPad as well as less dependence on their parents' prompts.
Conclusions:
Full results will be presented in the poster. To-date, parents have benefitted from structured coaching on how to promote language use during interactions and activities that are motivating for their children. The individuals with autism showed prolonged engagement and use of the iPad for communication during these structured interactions. Parents also report increased use of the device for communication at home.

50 **107.050** Communicative Functions of Co-Speech Gestures during Conversation in Adults with ASD

Y. Zhang[1], *A. Bagdasarov*[2], *E. S. Kim*[3], *Z. M. Dravis*[4], *M. Cola*[1], *B. Maddox*[5], *E. Ferguson*[6], *L. Adeoye*[2], *F. Fergusson*[2], *A. A. Pallathra*[7], *N. Minyanou*[8], *L. Bateman*[6], *A. T. Pomykacz*[9], *K. Bartley*[10], *E. S. Brodkin*[7], *J. Pandey*[3], *J. Parish-Morris*[5], *R. T. Schultz*[3] *and* ***A. de Marchena***[1,11], *(1)The Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)The Center for Autism Research/CHOP, Philadelphia, PA, (7)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (10)Center for Autism Research, Malvern, PA, (11)University of the Sciences, Philadelphia, PA*

Background:
Co-speech hand gestures serve many communicative functions, often denoted by gesture "types." For example, gestures can be *interactive* (signaling pragmatic functions, e.g., turn taking), or *representational* (depicting physical properties of referents, e.g., shape/movement). Several studies have reported that people with ASD use the same types of gestures as controls, while others report differential proportions of certain gesture types (e.g., increased iconic/representational gestures). A further function of gesture, across types, is to present information that supplements speech (e.g., saying "the big one", while drawing a circle in the air to indicate roundness, or saying "I don't know" while gesturing toward an interlocutor, indicating their turn to speak). Some studies have shown reduced supplementary gestures in ASD, suggesting less integration across verbal and nonverbal communicative modalities.
Objectives:
Co-speech gestures in ASD have primarily been studied via elicited narratives, which offer limited opportunities for back-and-forth interaction. Gestures serve different functions based on social context, thus, the objective of the current study was to examine the communicative functions of co-speech gestures during back-and-forth interaction.
Methods:
Adults with ASD (n=24) and age-, gender, and IQ-matched typically developing controls (TDC; n=10) completed a five-trial collaborative referential communication task designed to elicit spontaneous back-and-forth conversation in a controlled setting (data on remaining 14 TDCs will be available by May 2017). We examined whether gestures fulfill different communicative functions in ASD in two ways: (1) coding gesture *types*, and (2) examining how often gestures present information that supplements speech. Gestures were coded as interactive, representational, beat (i.e., moving hands in time to speech), and other (less frequent types, including deictic/pointing).
Results:
Participants in both groups used far more representational gestures than interactives and beats (p<.001, Cohen's d=2.21), with no group by type interaction, suggesting that, on this type of task, gestures produced by adults with ASD and TDC fulfill the same communicative functions. Surprisingly, adults with ASD were *more* likely to include supplementary information in their gestures (p=.02, Cohen's d=0.91; Figure 1). Finally, we investigated whether participants in both groups modulated the supplementary information presented in gestures based on their gesture type (interactive vs. representational). All participants included more supplementary information when using interactives relative to representationals (p<.001, Cohen's d= 1.80; Figure 2) with no interaction, suggesting that adults with and without ASD are equally likely to modulate supplementary information based on gesture type.
Conclusions:
Adults with ASD use co-speech gesture to serve similar communicative functions as controls, as evidenced by comparable proportions of gesture types and equivalent patterns of modulation of supplementary information based on gesture type. Surprisingly, adults with ASD were *more* likely to include supplementary information in their gestures, which is inconsistent with previously published work on youth with ASD (e.g., Morett et al., 2016, So et al., 2014), and may reflect differences in task demands or age. Further work with the current dataset will be done to explore *how* people with ASD combine informational content from gestures and speech, and what may be driving them to include different content across communicative modalities.

51 **107.051** Conversational Dynamics in a Longitudinal Corpus of Caregiver-Child Interactions

E. Weed[1]*, R. Fusaroli*[2]*, J. Tranbjerg*[1]*, D. A. Fein*[3] *and L. R. Naigles*[3]*, (1)Aarhus University, Aarhus, Denmark, (2)Aarhus University, Aarhus, DENMARK, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Conversational turn-taking provides a scaffold that helps children learn the elements and rules of language (Dale & Spivey 2006, Yurofsky et al 2016). This relies heavily on social feedback and engagement (Fusaroli et al 2014), and thus conversations involving children with ASD are expected to show different turn-taking dynamics than conversations involving typically-developing (TD) children. These dynamics remain relatively unexplored.
Objectives: Our goal was to explore the turn-taking dynamics between caregivers and children with ASD. More specifically we asked: what significant differences can be observed in the number, duration, and time between conversational contributions by adult caregivers and children in dyads with ASD and TD children?
Methods: We investigated spontaneous speech in caregiver-child dyads from a longitudinal corpus (6 visits over 2 years), consisting of 30 minutes of controlled playful activities between caregivers and 67 children: 35 with ASD (MA = 33 months) and 32 initially-language-matched typically developing (TD; MA = 20 months, cf. Goodwin et al. 2012). Time-coded transcripts were used to calculate utterance duration in seconds, interturn latency (seconds between utterances), and number, and timing of each interlocutor's utterances. Mixed effects models were employed to assess the relation between diagnosis and these measures, separately in children and caregivers, controlling for participant ID, time within conversation, and visit.
Results: Â While there was no main effect of diagnosis, the conversations displayed interactions between diagnosis and time. TD children increased their turn duration over the course of a conversation more than children with ASD (Beta=-0.05, SE=0.02, p=0.003), and this difference increased in later visits (Beta=0.01, SE<0.01, p=0.007). Opposite effects were displayed in interturn latency as the children in the ASD group increased their inter-turn latency more as conversations went on than did their TD peers (Beta>-0.01, SE<0.01, p=0.037). Adults showed no differences in inter-turn latency, but those with TD children increased the length of their turns more as the children aged than adults with children with ASD did (Beta: -0.06, SE=0.02, p=0.006). Moreover, the conversations all showed interpersonal adaptation: the greater the child's latency (Beta=0.1, SE=0.02, p<0.001) and the longer their utterance duration (Beta=1.7, SE=0.01, p<0.001), the more turns per unit of time the adults took.
Conclusions: Â We used turn duration, time between turns, and number of turns per unit of time to probe conversational dynamics between adult caregivers and children with ASD. Although preliminary, our results suggest that the conversational environments in which children learn and practice their linguistic skills are also affected by ASD. Not only did the conversational contributions of children with ASD differ from those of their TD peers, the contributions of adult caregivers also differed between the group, presumably as adults adapt their conversational turns to the child they are speaking with. This highlights the importance of investigating language acquisition in children with ASD within the context of dyadic interaction.

52 **107.052** Correlates of EARLY Reading Skills in Children with ASD

R. Bourourou[1]*, N. Gaddour*[2]*, S. Bouslah*[1] *and L. Gaha*[3]*, (1)Psychiatry, University of Monastir, Monastir, Tunisia, (2)University Hospital F. Bourguiba, Monastir, TUNISIA, (3)University of Monastir, Monastir, TUNISIA*

Background:
Early reading abilities, also referred to as hyperlexia, is a phenomenon that has been reported in many children with ASD (5-10%), but poorly explored.
Objectives:
to describe correlates of hyperlexia in ASD
Methods:
26 children with ASD (age 3 to 11) and early reading skills as documented by a standardized developmental reading assessment (ranging from letter recognition to text reading and comprehension), were assessed regarding global intelligence (Raven Colored Progressive Maps CPM), repetitive behaviours (Repetitive Behaviour Questionnaire RBQ) and Hypersystemiztion (Empathy Questionnaire/Systemization Questionnaire EQ-SQ)
Results:
The average age of onset of t early reading skills was 3 years. Intelligence was normal in most cases.
A fascination with letters, words and especially for logos and written classical Arabic was noted. Difficulties in non-word decoding involved visual rather than phonological reading strategies.
High scores of RBQ (Insistence on Sameness) were also noted.
A compulsive reading was noted in half of cases with high scores on hypersystemization.
Conclusions:
Hyperlexia in ASD could be a stereotyped behavior and a limited interest, related to an anticipated and regular pattern in reading (e.g. alphabet, same rules…). It is hence to be considered as an autistic feature if only limited to superficial reading ability and should be used in interventions aiming at improving social communication skills.

53 **107.053** Developing an Observational Measure of the Flexible Use of Pre-Linguistic Vocalizations in Preverbal Children with Autism

K. D. Slaboch[1], *T. Woynaroski*[2], *P. J. Yoder*[3] *and J. W. Bodfish*[4], *(1)Vanderbilt University, Franklin, TN, (2)Hearing and Speech Sciences, Vanderbilt University Medical Center, Thompsons Stn, TN, (3)Vanderbilt University, Nashville, TN, (4)Vanderbilt University School of Medicine, Nashville, TN*

Background: Why approximately thirty percent of children with Autism Spectrum Disorder (ASD) persist in using minimal spoken language despite intervention is unknown. Previous studies have suggested that differences in pre-linguistic skills are useful in predicting the extent to which children with ASD will develop spoken language. A foundational pre-linguistic skill that has not been investigated in children with ASD who are not using spoken language (i.e., preverbal children with ASD) is the ability to combine vocalizations with different types of affect (i.e. pre-linguistic vocalization functional flexibility).
Objectives: (1) To determine if preverbal children with ASD demonstrate the full range of vocalizations and affect evident in language-matched TD peers, and (2) To develop a measure of pre-linguistic vocalization functional flexibility (PVFF) in preverbal children with ASD to ascertain whether children with ASD are able to use vocalizations with affect flexibly.
Methods: This study used an existing longitudinal data set from The Useful Speech Project (e.g., Yoder, Watson & Lambert., 2015). The children with ASD enrolled in this study were between 20-48 months at baseline and were examined at five total measurement points separated by four month intervals. For the present study, Time 2 multimedia recordings of each child were selected during two different structured assessments with built-in communication presses: Communication and Symbolic Behavior Scales and Early Symbolic Communication Scale. A partial-interval coding scheme was used to code these multimedia recordings for the occurrence of vocalization and affect types. Vocalizations were classified in five categories based on pitch and phonation: squeal, vocant, growl, cry and laughter. Facial affect was categorized as positive, negative or neutral.
Results: The behavioral coding method developed for this study was found to be reliable for both vocalizations (Protophones: mean: 0.88 and range: 0.80-0.98) and affect (mean: 0.92 and range: 0.67-1) and stable (R= 0.97 for protophones, R=0.85 for negative affect, R= 0.85 for neutral affect, and R= 0.93 for positive affect). A significant minority demonstrated limited variety in vocalizations and affect. Six participants (30%) did not demonstrate the full range of protophones, and five participants (25%) did not demonstrate the full range of affect. PVFF was operationalized using operant contingency values (OCV) to quantify the degree of association between vocalization types and affect types. The analysis revealed predominately negative OCVs for neutral affect and protophones in this sample (i.e., vocalizations were more likely to be produced in the absence of neutral affect). OCVs for negative affect and protophones revealed predominately positive values (i.e., vocalizations were more likely to be produced with negative affect than chance).
Conclusions: The results of the analysis indicate that preverbal children with ASD demonstrate limited flexibility in their use of vocalizations with different affect. In a social communication context, this could limit the types of messages that children with ASD are sending to communication partners. If these results are replicated, PVFF could be integrated as an early target in an intervention, due to its early developmental emergence.

54 **107.054** Developmental Social Pragmatic Parent Coaching Intervention Increases Language-Promoting Utterances in Parents of Children with ASD.

A. Binns[1], *M. K. Wang*[2], *D. Casenhiser*[3], *S. Shanker*[4,5] *and J. Oram Cardy*[2], *(1)Western University, London, ON, CANADA, (2)Western University, London, ON, Canada, (3)University of Tennessee, Knoxville, TN, (4)Psychology, York University, Toronto, ON, CANADA, (5)The MEHRIT Centre, Peterborough, Canada*

Background: Developmental Social Pragmatic (DSP) parent-coaching interventions can be effective in promoting communication skills of children with Autism Spectrum Disorder (ASD), however the specific features of such interventions that underlie developmental change are not well understood. DSP models embrace teaching functional skills in a sequence following a typical developmental trajectory, and work within natural contexts. Another component of DSP treatment models is a focus on social communication and the function of language rather than the form. Despite the known impacts of parent language functions on child language development, there is a paucity of knowledge concerning how functions of parental language may change with treatment, and how these changes might interact with language learning in children with ASD.
Objectives: To compare parent language use between a Developmental Social Pragmatic (DSP) Parent Coaching treatment group and a community treatment group, pre- and post-therapy, as a first step toward better understanding how adult language supports functional language use in children with ASD.
Methods: Forty-one parent-child dyads were randomly assigned to either a DSP treatment group (*n*=21) or waitlist, community treatment (CT) group (*n*=20). All children were between 2.0-4.11 years old at study onset and were diagnosed with ASD using the ADOS and ADI. The treatment group received 2 hours per week of DSP therapy from SLPs and OTs, while the CT group sought a variety of other forms of community based therapy (e.g. ABA, SLP, OT, Specialized Education Programs) independently, averaging 3.6 hours per week.
Twenty-five-minute parent-child interactions were videotaped pre-treatment and post-treatment, 12 months apart, and transcribed in CHILDES. The main communicative function of each parent utterance was coded by two blind coders. Six language functions were classified as either language promoting (commenting, open ended questions, responding) or non-language promoting (prompting, directing, and asking questions for which there was only one correct answer; Talbott et al., 2015). The proportion of language promoting and non-language promoting utterances was analyzed using a mixed MANOVA with follow up MANOVAs for individual functions within each category. Paired and independent t-tests examined between and within group effects.
Results: There were significant time by group interactions for both language promoting (*p*<.001) and non-language promoting utterances (*p*=.001). Analyses for individual functions indicated significant group×time interactions for directives (*p*=.008), prompts (*p*=.029), and responses (*p*=.002). The DSP parent group significantly increased their responses and decreased their directives and prompts from pre- to post-therapy, while the CT group showed no change over the year. While the groups did not differ in any function use pre-treatment, the CT group used significantly fewer responses and more directives than the DSP group post-treatment.
Conclusions: Results of this study offer support for parent-implemented interventions, suggesting that parents have the potential to apply strategies obtained from coaching in the facilitation of communication with their children. Future analysis will examine the interaction between parent and child language use.

55 **107.055** Discourse Profiles in Autism Spectrum Disorder: A Family Study of Prosody

S. Patel[1]*, K. Nayar*[1]*, G. E. Martin*[2]*, M. Lee*[1]*, S. Crawford*[1]*, C. LaValle*[1]*, J. J. Diehl*[3] *and M. Losh*[1]*, (1)Northwestern University, Evanston, IL, (2)St. John's University, Staten Island, NY, (3)LOGAN Community Resources, Inc. University of Notre Dame, South Bend, IN*

Background: Impairments in pragmatic (social) domains of language, including narrative and conversation, are a universal feature of autism spectrum disorder (ASD). Subtle differences in pragmatic language have been identified in a subset of parents of individuals with ASD with the broad autism phenotype (BAP; Landa et al., 1992), suggesting that familial characterization of pragmatic language may highlight genetic mechanisms underlying ASD. A crucial aspect of pragmatic language is prosody, or the intonation, stress, rate, and rhythm of speech, which is imperative for signaling communicative intent. Differences in prosody are a hallmark of the social-communicative profile of ASD, and subtler prosodic differences have been noted in first-degree relatives with the BAP (Landa et al., 1992; Losh et al., 2012).
Objectives: To use automated, objective measures of prosody alongside clinical-behavioral measures in two separate contexts to characterize prosodic profiles in ASD and in parents.
Methods: Males with ASD (n=47), their parents (n= 99), and respective control groups (n=22 male proband controls; n=46 parent controls) narrated the wordless picture book, *Frog, Where Are You?* (Mayer, 1969). Prosody was measured from recorded narrations using Praat (Boersma, 2001) to obtain mean fundamental frequency (f_0), standard deviation (SD) of f_0 and f_0 range (both measures of f_0 variability), $f_0$drop, and speaking rate. Pragmatic language was rated from semi-naturalistic conversation using the Pragmatic Rating Scale (PRS; Landa, 1992) and Pragmatic Rating Scale-School Age (PRS-SA; Landa, 2011). Acoustic variables of prosody during narration were examined in relation to pragmatic violations measured by the PRS and PRS-SA (using Principle Component Analysis) to explore how prosodic differences co-segregate with broader discourse profiles across contexts.
Results: Males with ASD demonstrated significantly different utterance-final intonation patterns, consisting of f_0 decline compared to f_0 rise identified in controls (p<.01), marginally slower speaking rate (p=.08), and increased pauses (p=.08) during narration. When prosodic features were examined in the context of broader pragmatic abilities, reserved conversational styles in males with ASD (e.g., reduced reciprocity, poor response elaboration) were associated with greater SD, range of f_0, more pauses, and slower speaking rate (p<.07). The ASD parent group did not differ from controls in features of prosody during narration; however, similar to findings in ASD, a reserved conversational style was related to increased pauses and reduced speaking rate during narration (p<.07).
Conclusions: Consistent with prior work, results indicate key areas of prosodic differences during narration in individuals with ASD and controls. Increased f_0 drop in the ASD group signals potential differences in control of the vocal mechanism to utilize varying intonation patterns, such as high-terminal rise, to highlight socially meaningful information (House, 2006). Though differences in f_0 variability were not identified between the ASD and control groups, prosodic features co-segregated with broader pragmatic styles, such that in the ASD group, those with a reserved discourse style demonstrated greater f_0 variability. Furthermore, reserved discourse styles were associated with increased pauses and reduced speaking rate in the ASD and ASD parent groups. Together, these results demonstrate that specific prosodic differences are closely related to differing broader discourse styles.

56 **107.056** Dyadic Interaction Between Bilingual Parents and Their Young Children with Autism Spectrum Disorders

K. Hudry[1]*, L. Rumney*[1]*, N. Pitt*[1]*, J. Barbaro*[1] *and G. Vivanti*[2]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Given concerns that dual-language exposure might confuse children with Autism Spectrum Disorders (ASD), bilingual parents may choose to restrict a child's exposure to a single language. The empirical evidence to date suggests no particular negative effects of dual-language exposure for children with ASD (e.g., Reetzke et al., 2015; Valicenti-McDermott et al., 2013). However, there is also evidence that some professionals advise against dual-language exposure, and suggest parents should engage the child using the community dominant language (e.g., Ijalba, 2016; Yu, 2015).
Objectives: We investigated a potential side effect of the decision to restrict parent-child interaction to community-dominant English – the possibility that parental non-native language use might alter interaction behaviours usually considered to facilitate child development.
Methods: We recruited 39 dyads – each including a child with ASD (67% boys; M_{age} = 4 years 4 months) and their parent (87% mothers) – into two groups. Around half of parents (*n*=20) were monolingual English speakers, and 19 were bilingual with English as the common non-native language. The ADOS was administered to confirm child diagnosis, and the Mullen Scales of Early Learning were used to ascertain developmental level, with children in each group matched on ADOS Calibrated Severity Score and Non-Verbal Developmental Quotient. Key measures of interest for this study concerned the parent. English language competence was assessed via a standardised measure of expressive vocabulary knowledge. Free-play interaction samples were filmed with each dyad for later coding. One sample was filmed for monolingual adults (i.e., who spoke in English) while two samples were filmed for bilingual adults (i.e., one *each* using their native language and non-native English). Immediately following each interaction sample, parents rated their comfort on 7-point Likert-type scales. Off-line, we then coded parental communicative synchrony (e.g., Hudry et al., 2013) and scaffolding of child language (e.g., Haebig et al., 2013).
Results: The parents in each group were matched on chronological age and most were tertiary-educated. Nevertheless, bilingual parents had significantly poorer non-native English-language vocabularies compared to monolingual parents. Further, during free-play interaction, bilingual parents were less communicatively synchronous with their children, used less verbal imitation of child speech, and modelled grammatically simpler language than did monolinguals. This was apparent irrespective of which language bilingual parents used, with little evidence – in this sample – of *specifically* altered interaction behaviours when using non-native English versus a native language. However, this unanticipated finding may be explained by the apparent presence of subgroups within our bilingual sample – one reporting using English during everyday interactions with their child with ASD (*n*=11), and the other reporting maintained native-language use (*n*=8).
Conclusions: These novel empirical data provide partial support for some accounts provided in previous qualitative studies of the perceived impact of bilingualism and non-native language use for parental interaction with young children with ASD (e.g., Wharton et al., 2000; Yu, 2013, 2015). With rates of both ASD diagnosis and cultural/linguistic diversity growing internationally, understanding the potential impact of language-use choices by parents and language exposure patterns for children clearly warrants further dedicated attention.

57 **107.057** Examining Expressive Language Benchmarks in Young Minimally Verbal Children

J. K. Heidlage[1]*, E. Fuller*[2]*, A. Kaiser*[2] *and L. H. Hampton*[2]*, (1)Vanderbilt, Nashville, TN, (2)Vanderbilt University, Nashville, TN*

Background: Despite accessing early intervention, up to 30% of children diagnosed with ASD are classified as nonverbal or minimally verbal at age five (Anderson, 2007). Within the minimally verbal population of children with ASD, there is high variability in both speech and language abilities, without a single identified pattern of characteristics (Tager-Flusberg & Kasari, 2013). Identifying children in this population according to characteristics of their development has important implications for guiding intervention research.
Objectives: The purpose of this study was to classify young minimally verbal children according to expressive language benchmarks proposed by Tager-Flusberg et al. (2009), and to examine the relationship between expressive language measures and autism symptom severity.
Methods: Data were analyzed from pre-intervention assessments of participants in an ongoing intervention study (HRSA grant #R40MC27707). Fifty-three minimally verbal children with autism between 36 and 54 months of age (mean age=32.6 months) participated in this study. A measure of phonology (consonant inventory) was derived from the Profiles of Early Expressive Phonology (Williams & Stoel-Gammon, 2014). Naturalistic language samples were transcribed and coded to derive measures of vocabulary (number of different words) and pragmatics (number of different communicative functions). The percentage of children in the sample who met benchmarks for each expressive language stage (i.e., pre-verbal, first words, word combinations, sentences) was then calculated for each domain (phonology, vocabulary, pragmatics). Additionally, two separate regression models examined the relationship between phonology and vocabulary with autism symptom severity as measured by the Autism Diagnostic Observation Schedule (ADOS; Lord, Rutter, Dilavore, & Risi, 2008).
Results: For the domain of phonology, 43.3% of the sample met criteria for pre-verbal status (i.e., 6-12 months), 13.6% of the sample met criteria first words (12-18 months), 13.6% of the sample met criteria for word combinations (18-30 months), and 29.6% of the sample met criteria for sentences (i.e., 30-48 months). For the domain of vocabulary, 41.5% of the sample met criteria for pre-verbal status, 58.5% of the sample met criteria first words, and none of the participants met criteria for word combinations or sentences. For the domain of pragmatics, 57% of the sample met criteria for pre-verbal status, 43% of the sample met criteria first words, and none of the participants met criteria for word combinations or sentences. Separate regression analyses indicated that vocabulary and phonology were significantly related to ADOS scores, controlling for IQ (vocabulary: Beta=-.167 p=.049; phonology: Beta=-.169 p=.007).
Conclusions: While the 53 children were dispersed across all developmental phases for phonology, most children remained in early phases of vocabulary and pragmatic development. Although about half of the participants produced speech sounds at the word combination and sentence level, none of the participants met criteria for language use at higher levels. These results are reinforced by findings from the regression analyses, indicating that, on average, children with higher autism symptomology were producing fewer different words and fewer speech sounds. Future research should focus on individualizing interventions to better target specific language weaknesses highlighted in these language profiles for individuals with ASD.

58 **107.058** Examining Spoken Language in Young Children with ASD Following a 12-Week Parent-Implemented Intervention

K. A. Resua[1]*, A. B. Barber*[1]*, H. Noble*[2]*, C. H. Cook*[1] *and B. Ingersoll*[3]*, (1)University of Alabama, Tuscaloosa, AL, (2)Crimson Center, San Diego, CA, (3)Michigan State University, East Lansing, MI*

Background: Language develops in the context of social interaction and joint engagement (Adamson et al., 2009; Dawson, 2008; Kuhl, 2010). Therefore, interventions targeting social engagement and play for young children with autism spectrum disorder (ASD) should facilitate language outcomes (Kasari et al., 2012; Rogers et al., 2012). While some children with ASD use social information to support language learning (Luyster & Lord, 2009), social impairments often limit their opportunities for language development (Landa et al., 2011). Less attention has focused specifically on semantic development, even though language has important influences on academic outcomes and literacy (Hay et al., 2009). Thus, further research is needed to determine the impact of naturalistic developmental behavioral interventions (NDBIs; Schreibman et al., 2015) on more distal intervention targets (Wetherby et al., 2014), such as vocabulary development in young children.
Objectives: The purpose of this study is to examine 1) expressive vocabulary growth measured by the MacArthur-Bates Communicative Development Inventories (MB-CDI; Fenson et al., 2007) following a 12-week parent-implemented intervention, Project ImPACT (Ingersoll & Dvortcsak, 2010), 2) the relationship between vocabulary development on the MB-CDI and social communication measured by the Social Communication Checklist (SCC; Ingersoll & Dvortcsak, 2010), and 3) the development of vocabulary categories on the MB-CDI. A detailed approach to measuring spoken language is critical to demonstrate that results occur secondary to intervention rather than maturation.
Methods: Data are collected through a larger ongoing study of Project ImPACT. Caregiver and child outcomes are measured following 12-week groups delivered in a university clinic setting, with two to four children and their caregivers per group. Interventionists coach caregivers on strategies to support children's social engagement, language, social imitation, and play. Among other measures, caregivers complete the MB-CDI and caregivers and interventionists complete the SCC before and after program participation.
Results: Intervention groups and data collection are ongoing. Preliminary data analysis based on 10 children revealed a mean baseline of words produced of 48.57 (*SD* = 53.60). Post-intervention, mean of total words produced was 71 (*SD* = 70.1), revealing a 46.2% growth in number of words produced. Although each child demonstrated spoken language growth, wide variability across total words produced was observed and pre/post difference was not statistically significant in this small sample ($U = 18.5$; $p = .44$). Qualitative analysis of caregiver feedback indicated that 100% of parents observed growth in their children's spoken language to some degree. A Spearman Rho analysis examined the relationship between measures of vocabulary and social communication. Number of words produced was significantly correlated with the SCC play subscale ($r = .750$; $p = .05$), but not with the social or language domains. Findings on the extended sample will be presented, including visual analysis. Spoken word growth relative to specific vocabulary categories will be discussed.
Conclusions: Preliminary findings demonstrate expressive vocabulary growth following 12-week Project ImPACT with large variability. Spoken language was correlated with play skills, as suggested by previous research (Kasari et al., 2012). This study contributes to understanding of early ASD intervention on more distal intervention targets (vocabulary).

59 **107.059** Expressive Language and Social Functioning in Children with Specific Language Impairment Versus High Functioning Autism

R. Ng[1], *T. T. Brown*[2,3], *U. Bellugi*[4], *E. Halgren*[2,3] *and D. Trauner*[5], *(1)Institute of Child Development, University of Minnesota Twin Cities, Minneapolis, MN, (2)Center for Multimodal Imaging and Genomics, University of California San Diego, San Diego, CA, (3)Department of Radiology, University of California, San Diego School of Medicine, San Diego, CA, (4)THE SALK INSTITUTE, LA JOLLA, CA, (5)Department of Neurosciences, University of California, San Diego School of Medicine, San Diego, CA*

Background: The language phenotype of individuals with autism spectrum disorders (ASD) is heterogeneous, although most findings suggest subgroups of individuals with ASD experience language deficits. Evidence has emerged showing that cognitive and specifically, language profiles, between youth with ASD versus those with specific language impairment (SLI) are distinct. Yet, children with SLI share various social characteristics, including elevated problems with social communication and prosocial gestures.
Objectives: The purpose of this study was to characterize the language and social phenotypes in children with SLI versus high functioning autism (HFA), and to determine whether neural correlates of language processing are differentially associated with interpersonal functioning across the neurodevelopmental disorders.
Methods: Participants were 13 children with SLI, 13 with HFA, and 13 typically developing youth matched on age. The CELF-4, PPVT-3, EOWPVT, and Letter-Word Identification and Spelling subtests from the Woodcock Johnson, 3rdEdition were administered to determine functioning across language domains. The Social Responsiveness Scale (SRS) was completed by caregivers to social functioning. Participants completed MRI and DTI scans to assess for any abnormalities in neural substrates (pars opercularis, pars triangularis, superior temporal gyrus) and circuits involved in language functions (superior longitudinal fasciculus).
Results:
Multivariate analysis of variance (MANOVAs) were performed to assess between-group differences in language domains, and DTI measures (mean diffusivity, MD) and cortical thickness/area, with whole brain fiber, cortical thickness, and area as covariates respectively. Results showed group differences across CELF-4 Receptive and Expressive Language, Letter-Word Identification, and Spelling, Fs> 6.05, ps<0.01, but not receptive and expressive vocabulary knowledge (PPVT-3, EOWPVT). SLI group performed more poorly than the other two groups in CELF-4 Receptive Language and Letter-Word Identification, but comparable to those with HFA in CELF-4 Expressive Language and Spelling. Group differences were observed across SRS subscales, including Awareness, Social Cognition, Social Communication, Motivation, and Autistic Mannerisms, Fs>7.96, ps<0.001. Generally, those with HFA showed more difficulties across each subscale than TD and SLI groups, with the exception of Social Awareness and Motivation, where HFA and SLI children were comparable. No group differences were observed in cortical volume/area, and MD. Pearson correlations were computed per clinical group to assess associations between Total SRS score with language measures, and with MRI/DTI indices. No associations were observed in the TD and SLI groups. However, among children with HFA, greater social impairment was related to poorer performance on the EOWPVT and CELF-4 Receptive and Expressive Language. Additionally, among those with HFA, cortical thinning of the right superior temporal gyrus, $r(13)$=-0.70, p=0.008, and lower MD of the left superior longitudinal fasciculus to the parietal region was related to higher SRS score, $r(11)$=-0.61, p=0.04, reflecting greater social deficits.
Conclusions: In children with HFA, but not SLI or TD, social difficulties were related to their language performance, and structural abnormalities of neural substrates and circuits involved in language comprehension and visual-spatial attention. Results suggest that the etiology of the social phenotype associated with SLI versus ASD youth are likely distinct.

60 **107.060** Features of Co-Speech Hand Gestures Help Predict Diagnostic Group Membership

M. Cola[1], *E. S. Kim*[2], *Y. Zhang*[1], *A. Bagdasarov*[3], *Z. M. Dravis*[4], *B. Maddox*[5], *E. Ferguson*[6], *L. Adeoye*[3], *F. Fergusson*[3], *A. A. Pallathra*[7], *N. Minyanou*[8], *L. Bateman*[6], *A. T. Pomykacz*[9], *K. Bartley*[10], *E. S. Brodkin*[7], *J. Pandey*[2], *J. Parish-Morris*[5], *R. T. Schultz*[2] *and A. de Marchena*[1,11], *(1)The Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)The Center for Autism Research/CHOP, Philadelphia, PA, (7)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (10)Center for Autism Research, Malvern, PA, (11)University of the Sciences, Philadelphia, PA*

Background:
Deficits in nonverbal communication are required for an autism spectrum disorder (ASD) diagnosis. Unfortunately, nonverbal communication is poorly captured by informant-based questionnaires, the standard gatekeeper of ASD screening. Thus, novel measures are needed to assess nonverbal communication, which is central to clinical decision making. During the diagnostic process, clinicians integrate developmental history, including when and how atypical behaviors manifest, with behavioral observation. Behavioral observation includes attention to both *quantitative* (e.g., how often a child makes eye contact) and *qualitative* features of behavior (e.g., how *good* was the eye contact). Questionnaires are most appropriate for measuring quantitative features of behavior, thus we sought to explore how classification of ASD vs. typically developing controls (TDCs) would improve when adding a measure well-suited for quantifying behavioral quality – specifically, features of spontaneously produced co-speech gestures.
The literature on co-speech gesture in ASD is small, but suggests that qualitative differences, e.g., in how gesture is formed, used functionally, or integrated with speech, best discriminate ASD from controls. Here we employ gesture as an example of broader differences in nonverbal communication.
Objectives:
To determine whether continuous gesture variables, including frequency, size, and amount of informational content, could predict diagnostic group membership (ASD versus TDC).
Methods:
Adults with ASD (n=24) and TDCs (n=10) were matched on chronological age, gender, and full scale IQ (see Table 1; analyses of data on 14 additional TDCs will be integrated into this presentation by May 2017). Participants completed a 20-minute referential communication task, employed through two networked laptops, designed to elicit back-and-forth conversational interaction in a controlled setting. All hand gestures produced during the task were tagged and coded by reliable coders for a variety of semantic and motor features. Three continuous variables were included in this analysis: rate, size, and amount of information in gesture. All participants completed the Social Responsiveness Scale: Self-Report (SRS-SR).
Results:
We predicted that the combination of SRS-SR, which measures frequency of social impairment and repetitive behaviors/interests in everyday contexts, and gesture variables, which measure qualitative features of behavior in vivo, would have particularly high predictive power for ASD diagnosis. Logistic regression was used to test this hypothesis. Entered as lone predictors, SRS-SR scores predicted diagnostic group membership with 82.4% accuracy (p<.001), and gesture variables predicted group membership with 85.3% accuracy (p=.005). When combined into a single model, 97.1% classification accuracy was achieved, with between 57% and 81% of the variance explained (p<.001). All participants with ASD were correctly classified, as were 9/10 TDC participants.
Conclusions:
Features of co-speech gestures are able to independently predict ASD diagnosis, and when combined with a self-report questionnaire, predictive power is very high, suggesting that these two types of measurements capture independent variance associated with ASD diagnosis. Questionnaires are an efficient measure of everyday behavior; however, no efficient proxy for behavioral observation exists. Here we demonstrate that features of co-speech gestures capture behavioral differences in ASD that are not easily measured by a questionnaire, and, that when combined with a questionnaire, can have strong predictive power for ASD diagnosis.

61 **107.061** Gesture Comprehension (GeCo) Measure Reveals Deficits in Gesture Processing in Adults with ASD

***A. R. Canfield**, B. Castelluccio, C. Emmett and I. M. Eigsti, Department of Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Diagnostic criteria for autism spectrum disorder (ASD) specify the presence of deficits in the understanding of gesture; however, relatively little research has examined this phenomenon, especially in adults with ASD. One eyetracking study in which gesture information could be utilized to choose which of four available referents was the target reported that the presence of co-speech gesture *facilitated* language comprehension in adolescents with typical development (TD), but *slowed* comprehension in adolescents with ASD (Silverman et al., 2010).
Objectives: The current study was designed to examine performance on a novel, ecologically valid measure of gesture comprehension in adults with ASD and TD. We hypothesized that the ASD group would show decreased comprehension.
Methods: Adults with ASD (*n* = 12) and TD (*n* = 16) completed an experimental measure of gesture comprehension, the **Ge**sture **Co**mprehension (GeCo) Task. Final sample size will be *n*=20 per group. Groups did not differ in age (ASD *M* = 23 years, TD *M* = 22), or verbal, nonverbal, or full-scale IQ (FSIQ ASD *M* = 103, TD *M* = 104; all *p*'s > 0.39). ASD diagnoses were confirmed by ADOS.
Participants watched a 35-second video of a scripted but naturalistic conversation between two young women discussing a friend's recent relocation. Immediately after watching the video, they answered 8 questions. Three questions targeted the verbal content of the video (e.g., "*When did this event happen*?"); five questions targeted information expressed only in gesture (e.g., "*What type of staircase was in Sam's new apartment*?"). A correct response to the "staircase" question required that participants integrated information from a gesture, which depicted the spiraling nature of the staircase, with the spoken conversation ("she had to climb up this huge staircase"). The verbal memory questions were designed as a metric of general motivation and attention; the gesture questions were designed to probe participant comprehension of information conveyed solely in gesture. Participants also completed the Digit Span measure of working memory capacity.
Results: Performance was compared between groups. A repeated-measures ANOVA indicated a main effect of group, $F(1,26)=12.12$, $p=0.002$, a main effect of measure (verbal memory versus gesture memory), $F(1,26)=28.11$, $p<0.001$, and a trend for a group by measure interaction, $F(1,26)=4.16$, $p=0.05$. The ASD group had significantly lower scores on gesture comprehension (ASD *M* = 52%, TD *M* =78%; $F(1,26)=0.08$, $p=0.003$); group differences for the verbal memory items did not differ (ASD *M* = 61%, TD *M* =73%; $p=0.15$). Gesture scores were not correlated with either working memory or ASD symptom severity.
Conclusions: Adults with ASD appeared to have specific difficulty integrating information from gestures, in a novel measure of gesture comprehension, the GeCo. This study extends findings of gesture comprehension deficits in ASD into adulthood. Furthermore, these deficits were apparent when viewing a brief interaction; difficulty understanding gesture is likely even more pronounced during more typical, extended, in-person interactions. This study also highlights the potential utility of the GeCo as a measure of gesture comprehension, a possibility our group will continue to explore.

62 **107.062** Gesture Development and Autism Severity in High-Risk Infants

***L. Rague**[1], K. E. Caravella[1], B. Tonnsen[2] and J. Roberts[2], (1)University of South Carolina, Columbia, SC, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background: Children with autism often demonstrate deficits in gesture use. Studying populations at increased risk for developing autism may illuminate shared or distinct pathways leading to deficits in gestures later in development. Two populations at high risk for autism are infants with fragile X syndrome (FXS; Kover & Abbeduto, 2010) and infants with an older sibling with autism (ASIB; Ozonoff et al, 2011). Given the importance of gesture use on language development, characterizing the emergence of gesture delays contrasted across high-risk populations can have important implications on earlier and more targeted intervention strategies.
Objectives: Identify the effect of autism severity on developmental trajectories of gesture use in infants with FXS and ASIBs, controlling for nonverbal abilities.
Methods: Sample included 35 males (15 FXS, 20 ASIB) recruited through an ongoing longitudinal study conducted at the University of South Carolina. We measured gesture use using the Early Gesture score on the MacArthur-Bates Communicative Development Inventories (CDI), nonverbal ability using a composite of the Visual Reception and Fine Motor domains of the Mullen Scales of Early Learning (MSEL), and autism severity using the ADOS-2 CSS. The MSEL and the CDI were collected at 9, 12 and 24 months, and the ADOS-2 was administered at 24 months.
Results: All models were time-centered at 24 months. The first growth model determined whether number and rate of gestures used differed in FXS and ASIBs. At 24 months, infants with FXS had developed about 4 less gestures than ASIBs (β=4.20, p<0.001), while the rate of gesture development did not differ between groups (β=0.05, p=0.56). When nonverbal abilities were added as a predictor in this model, results were non-significant, suggesting group differences in gesture use at 24 months may be driven by developmental delay in FXS. Next, two growth models were run to determine the relationship of autism severity on gesture use, controlling for nonverbal abilities for each group. In FXS, higher autism severity at outcome was associated with reduced gesture use at 24 months with a trend statistically (β=-0.61, SE=0.31, p=.06), but not the rate of gesture development (β=-0.02, SE=0.02, p=.34). For ASIBs, higher autism severity at outcome was associated with reduced gesture use at 24 months (β=-0.54, SE=0.23, p=.03), but not the rate of gesture development (β=-0.03, SE=0.02, p=.21).
Conclusions: Results indicated that after accounting for nonverbal abilities in FXS, ASIBs and FXS demonstrated profiles of gesture use that were similarly affected by autism severity, where autism severity was related to reduced gesture use at 24 months, but did not affect the rate at which these groups acquire gestures. These results provide evidence that early gesture use may be a shared behavioral profile across these two etiologically distinct populations, such that reduced number of gestures at 24 months in may be a similar marker for autism symptoms as it is in ASIBs. These similar patterns in gesture profiles, and the impact of autism severity on those profiles, also suggest that similar treatments may be effective in both groups.

63 **107.063** Gesturing during Conversation and Free Play in Children with ASD

***S. Tal**, I. Gordon, S. Fridenson-Hayo and O. Golan, Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel*

Background: Non-verbal communication has long been recognized as a core deficit in Autism Spectrum Disorder (ASD), and has recently been acknowledged as a diagnostic criterion. Gesturing, including conventional, informational, descriptive and emotional gestures, forms a main modality for non-verbal communication. Individuals with ASD have been argued to show deficits both in the overall use of gestures and, more specifically, in the use of descriptive and emotional gestures. However, research on gestures is sparse and inconclusive: whereas some point to a lifelong deficit in gesture use among individuals with ASD, others support a developmental delay that may later be diminished. Yet, most studies focus on toddlers with ASD, with little evaluation of older children.
Objectives: To compare gesturing in children with ASD to that of Typically Developing (TD) children, during a mother-child interaction. The effect of activity-type was also explored, by assessing the children with their mothers both during conversation, in which more gesturing was expected, and during free-play which was expected to elicit less gesturing.
Methods: Forty children with ASD (clinically diagnosed, and verified using ADOS-2), aged 5-10 years, and 35 typically developing (TD) controls, matched on gender and cognitive abilities, were video-recorded with their mothers during a free-play, and during a conversation. Videos were micro-coded for use of two types of gestures: conventional and descriptive. Calculated measures included total duration of gesturing, mean duration of each gesture, and onset time for initial gesturing. Levels of autistic symptoms was parent reported, using the SRS-II.
Results: As predicted, children produced longer conventional gestures, on overage, during conversation, compared to free play. This difference was not found for descriptive gestures. Compared to the ASD group, TD children spent more time performing gestures, and, on average, had longer durations for gestures. These differences were found for conversation but not for free play. Onset time for initial gesturing during conversation was shorter for the TD group, compared to the ASD group.
In the TD group, the level of autistic mannerisms was negatively associated with mean duration of conventional and of descriptive gesturing during conversation, but not during free-play. However, during free-play the mean duration of descriptive gesturing was positively associated with autism symptoms.
Conclusions: The study is among the first to investigate gesture use in older children with and without ASD. Results show the effect of activity type on gesture performance in ecological parent-child interactions. Our findings support the notion that children with ASD gesture less, use shorter, less elaborate gestures, and take longer to initiate gestures, compared to matched TD children, specifically during conversation. For TD children, it was found that gesturing less during conversation is associated with elevated autism symptoms, but also that gesturing more during free-play (instead of playing and handling toys) is related to elevated autistic symptoms. Using gestures appropriately in different contexts may be used as a marker for TD children examined for ASD, though more research on the use of gestures during conversation and free play with peers and other figures, in addition to mothers, is needed.

64 **107.064** Growth in Narrative Retelling Abilities of Higher-Functioning Children with ASD: Associations with ASD Symptomatology, Verbal Ability, and Reading Comprehension

***N. S. McIntyre**[1], R. Grimm[1], L. E. Swain-Lerro[2], M. C. Zajic[3], J. McCauley[4], H. K. Schiltz[5], T. Oswald[6] and P. C. Mundy[7], (1)University of California at Davis, Davis, CA, (2)UC Davis, Santa Rosa, CA, (3)University of California at Davis MIND Institute, Davis, CA, (4)UC Davis MIND Institute, Sacramento, CA, (5)Marquette University, Milwaukee, WI, (6)University of California at Davis MIND Institute, Sacramento, CA, (7)University of California at Davis, Sacramento, CA*

Background: Narrative retelling, or story memory (SM), relies on structural and pragmatic language, social cognition, and global/gist processing skills, and has been shown to pose difficulties for children with ASD (Diehl et al.,2006). These language and cognitive skills influence reading development, especially the growth of text comprehension ability (van den Broek et al., 2003). The development of reading comprehension (RC) is a significant challenge for many children with ASD (Nation et al., 2006; Ricketts et al., 2013). These challenges are so pronounced that RC impairment may be an important part of the social communication phenotype of ASD in higher-functioning children (McIntyre et al., 2016; Ricketts et al., 2013). This study was designed to examine the relations between SM, RC, language, and the social communication phenotype of school-aged children with higher-functioning ASD (HFASD).
Objectives: 1) To examine the development of SM over a 30-month period in school-aged children with HFASD using latent growth curve modeling, 2) To test the hypothesis that autism symptom severity and verbal abilities are significantly related to SM development among these children, and 3) To examine the hypothesis that SM development predicts the development of HFASD reading comprehension.
Methods: Â Participants included seventy-eight 8- to 18-year-old children with HFASD (Full-scale IQ ≥ 75). Data were collected at 3 time points across 30 months. ASD symptoms were confirmed with the ADOS-2, which provided symptom severity data. Verbal ability (VIQ) was measured by WASI-2. Narrative retelling was measured with the WRAML2 Story Memory task (SM).Â Reading comprehension (RC) was measured with the Gray Oral Reading Test-5 (GORT-5).
Results: Â The final growth model fit the data well, $\chi^2 = 8.95$ (6 df), p=0.18, CFI=0.98, RMSEA=0.08. 1) Participants varied significantly on SM intercept at T1 (SM1; M=24.99, p=0.009), but individual growth curves did not differ significantly on slope (4.2; p=0.38). 2) ADOS and VIQ both significantly related to the intercept (-1.11, p=.002;0.45, p<.001, respectively) but not slope (-0.07, p=0.77;-0.01, p=0.91, respectively) of SM growth curves. For every 1-unit increase in ADOS scores, a decrease of 1.11 units was seen in SM1; for every 1-unit increase in VIQ, an increase of 0.45 units was seen in SM1. Age was included in the model, but was not significant and was dropped as a result. 3) RC was significantly associated with the intercept (0.90, p<.001) but not the slope (-0.69, p=0.61) of SM growth curves. For every 1-unit increase in SM1, a 0.90 unit increase was seen in RC3 scores.
Conclusions: HFASD improved in their narrative retelling skills with similar 30-month growth rates regardless of initial scores. Lower ASD symptomatology and higher VIQ, but not age, were significantly associated with better SM1 performance, but did not impact growth rates. SM1 was a significant predictor of RC3, but there was no relation between the rate of SM growth and RC. These data provided unique details about the social communication development of school-aged children with HFASD, and raise the possibility that narrative retelling may be an important intervention target to improve reading comprehension in these children.

65 **107.065** High-Resolution Chromosomal Microarray Analysis in Children with Speech & Language Delay: Genetic Findings & Clinical Relevance

A. Peiffer[1,2]*, H. Twede*[2]*, R. Vanzo*[2]*, K. S. Ho*[1,2] *and E. R. Wassman*[2]*, (1)Pediatrics, University of Utah, Salt Lake City, UT, (2)Lineagen, Inc., Salt Lake City, UT*

Background: Chromosomal microarray analysis (CMA) is a whole-genome genetic interrogation that may identify a cause for neurodevelopmental challenges such as autism spectrum disorder (ASD), developmental delay (DD) and intellectual disabilities (ID). For this reason, CMA is recommended in medical guidelines as first-tier testing in the clinical evaluation of children with ASD, DD and ID. Because early diagnosis of ASD is critical for treatment and improved outcomes, screening methods continue to be developed and evaluated. For example, early recognition of speech & language (S&L) delay may identify children who are at risk for ASD sooner than is currently possible. S&L delay is often an early sign of a neurodevelopmental disorder in children who are eventually diagnosed with ASD.
Objectives: We wanted to determine the prevalence of genetic causes, namely copy number variants (CNVs), in children who have S&L delay as an indication for their clinical testing. We could then determine whether CNVs were associated with increased risk for ASD.
Methods: We studied the CMA results of 10,351 patients for whom CMA was ordered as part of a clinical work-up for S&L delay, ASD, DD, ID and other indications using Lineagen's FirstStep^{Dx} PLUS CMA service from 10/29/2010 through 09/30/16. T-test and chi-square analyses were used to determine whether there were significant differences in the average age at testing and detection rate, respectively, between the study groups.
Results: Our results show that children with S&L delay are being referred for genetic testing at an earlier age (~ 2 years younger) than children without S&L delay who have other testing indications. In addition, children with S&L delay have the same rate of pathogenic findings as children with other indications for testing such as ASD. Females with S&L delay have a significantly higher rate of pathogenic findings (12.8%) than males with S&L delay (7.7%). Neurologists order CMA in children with S&L delay more often than other specialists or pediatricians. Comparison of the most common genetic diagnoses shows that the causes of S&L delay vs. other indications are different and that there are important changes in clinical management associated with these genetic disorders.
Conclusions: Children with S&L delay often have an identifiable genetic cause for their clinical challenges. The rate of abnormal genetic findings is the same or greater than in children with other guideline recommended clinical indications (ex: ASD). We do not know whether children with S&L delay who were referred for testing went on to develop ASD. However, this study is important because it suggests that CMA, which can be done at any age upon recognition of S&L delay, may offer objective information that leads to earlier identification of ASD than is currently possible. These findings underscore the importance of CMA as soon as risk factors or developmental delays are identified.

66 **107.066** Higher Maternal Autism Spectrum Quotient Score Predicts Weaker Tendency to See Pragmatic Impairments As a Problem

K. Hanabusa[1]*, M. Oi*[2] *and Y. Yoshimura*[3]*, (1)United Graduate School of Child Development, Kanazawa, Japan, (2)Kanazawa University, United Graduate School of Child Dev., Kanazawa, JAPAN, (3)Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan*

Background: Â Individuals with autism spectrum disorder (ASD) show deficits in reciprocal social interactions and impairment in verbal communication, such as difficulties in understanding humor, irony and sarcasm (Frith, 2003). Sucksmith et al.'s (2011) review of work on the Broader Autism Phenotype states that many studies on the language domain of autistic atypicalities have suggested that the parents and siblings of autistic probands have significantly greater difficulty using language to communicate for social purposes (pragmatics) compared to controls. Komeda et al. (2015) conclude that both individuals with ASD and those with typical development (TD) make selective neural responses toward people who are similar to themselves, although there are differences in the neural mechanisms between ASD and TD. We hypothesized that individuals with higher Autism Spectrum Quotient (AQ) scores are permissive to others with pragmatic language impairments.
Objectives: Â The purpose of this study was to investigate the correlation between maternal AQ score and mothers' evaluation of pragmatic impairments in children.
Methods: Â Participants were selected from 100 mothers who were randomized according to sample allocation from over 800,000 questionnaire respondents by a marketing research corporation in Japan. We applied sample allocation to choose eight or nine mothers of children of each sex in each grade from grades 1 to 6. Mothers' mean age was 40.3 years (standard deviation = 5.3, range = 26-55). AQ and scales D to H (D. coherence, E. inappropriate initiation, F. stereotyped language, G. use of context and H. nonverbal communication) of the Maternal Evaluation of Pragmatic Impairments in Children (MEPC) from the Children's Communication Checklist Second Edition (CCC-2), which measures pragmatic impairments, were administered through an Internet survey. Using MEPC, mothers were asked to estimate how they would feel if their children showed the communication behaviors listed in scales D to H with responses given on a five-point Likert scale from "1. It isn't a problem" to "5.Â It's a problem ."
Results: Â Data were analyzed using Pearson's correlation coefficients and regression analysis. There was a significant negative correlation between maternal AQ scores and MEPC scores ($r=-0.2577$, $p<0.01$). We also found significant negative correlations for each of the communication and imagination subscales of AQ and scores for subscales D to H of MEPC ($p<0.05-0.001$) (see Table 1). There was no correlation between the other AQ subscales including social skills, attention switching and attention to detail and any of the scores for subscales D to H of MPEC.
Conclusions: Â Higher maternal AQ score predicts mothers being more permissive to pragmatic impairments. This study showed correlations between the communication and imagination subscales of AQ and the evaluation scores of pragmatic impairments in CCC-2. However, no correlations were found between the other AQ subscales and the evaluation score of pragmatic impairments in CCC-2.

67 **107.067** Human References: What the Words That Adolescents with ASD Use Reveal about the ASD Phenotype

A. R. Neal-Beevers[1], *B. G. Davidson*[2], *L. Sperle*[3], *D. Ikejimba*[4] *and J. W. Pennebaker*[4], *(1)Stop E9000, University of Texas at Austin, Austin, TX, (2)Pediatrics, University of Miami Miller School of Medicine, Miami, FL, (3)University of Pittsburgh, Pittsburgh, PA, (4)Psychology, University of Texas at Austin, Austin, TX*

Background:
Deficits in verbal communication are evident in varying degrees in individuals with Autism Spectrum Disorder (ASD). Research has documented a host of language symptoms, including idiosyncratic and/or repetitive speech, uneven language development and difficulty with pragmatic aspects of language including aberrant vocal quality, tone, and/or volume. However, we know little about the words used by those with ASD, and how they may differ from those of their neurotypical peers.
Objectives:
This study investigated the ways in which adolescents with ASD (Adol_ASD) use words compared to their neurotypical (Adol_NT) peers.
Methods:
Nineteen Adol_ASD and 14 Adol_NT participants (11-21 years, all male) were enrolled in the study. Participants in the two groups were comparable in chronological ($F(1,31)=1.56$, $p=.22$) and mental age ($F(1,31)=.19$, $p=.67$). The Autism Diagnostic Observation Schedule (ADOS; Lord et. al., 1989) was used to confirm ASD diagnosis. The ADOS was transcribed from video. Transcriptions were analyzed using the Linguistic Inquiry and Word Count program (Pennebaker, Booth, Boyd, & Francis, 2015), yielding information on participant word use across approximately 90 variables. Our analyses focused on variables within three categories: (1) Interpersonal Referents, (2) Internal State Referents and (3) Ambiguous Action Referents.
Results:
Oneway ANOVAs were conducted to compare the LIWC variables between the Adol_ASD and Adol_NT groups (see Table 1). Overall, Adol_ASD participants focused more on themselves (I-words), and used fewer words referring to others (e.g., 3rdperson pronouns) including broad classes of people, events, and actions (interrogatives) compared to Adol_NT participants. Interestingly, the language patterns of the Adol_ASDs suggested they spoke in an interpersonal manner consistent with having lower social status or clout. In terms of Internal State Referents, Adol_ASD use fewer words reflecting feelings, biological or bodily processes, and emotional states, such as anxiety. Finally, Adol_ASD participants more frequently referred to ambiguous action and objects than Adol_NTs.
Conclusions:
The current study provides insight into phenotypic language use in ASD. Our findings suggest that Adol_ASD use words reflecting greater self-focus (e.g., "I"). Further, when Adol_ASD make reference to others, they more often use non-specific impersonal pronouns, and ambiguous referents such as "who", "what", and "where" (interrogatives). Results suggest that adolescents with ASD rely on action words (verbs, auxiliary verbs) and more often employ value-laden references such as "should", "would", and "could" (discrepancy words) when describing events and objects.Â Results reveal that Adol_ASD make less frequent references to human internal states (e.g., anxiety, feelings, biological and body processes). Finally, results suggest that the linguistic profiles of Adol_ASD reflect less clout - or influence – than those of Adol-NT. Interestingly, individuals with high clout more often use "we" and less often use "I."Â They also use more social words and fewer negations. Taken together, this pattern of word use conveys as more confident and influential.Â In sum, our study revealed that adolescents with ASD may engage in patterns of word use reflecting greater self-focus, less awareness of internal states and, also, may be perceived as less influential. These findings may have implications for life skills training programs for individuals with ASD.

68 **107.068** Identifying Endophenotypes in Autism Spectrum Disorder and Fragile X Syndrome: A Multi-Method Approach

K. Nayar[1], *L. Bush*[2], *M. Lee*[3], *G. E. Martin*[4], *S. Crawford*[3] *and M. Losh*[3], *(1)Northwestern University, Chicago, IL, (2)Northwestern Feinberg School of Medicine, Chicago, IL, (3)Northwestern University, Evanston, IL, (4)St. John's University, Staten Island, NY*

Background: Fragile X syndrome (FXS), caused by a mutation of the *FMR1* gene, is the most common single-gene disorder associated with autism spectrum disorder (ASD), with up to 75% of males with FXS meeting diagnostic criteria for ASD (FXS-ASD; Klusek et al., 2014). However, in-depth studies of specific phenotypic domains in idiopathic ASD (ASD-O) and FXS suggest that while substantial overlap may exist in the social-communicative domain (Klusek et al., 2014, Losh et al., 2012), the expression of restricted and repetitive behaviors (RRB) is more distinct (Wolff et al., 2012), suggesting that *FMR1* variation may play a role in selected ASD phenotypes. To address this question, this study directly compared profiles of social communication and RRBs in individuals with FXS-ASD, FXS without ASD (FXS-O), and ASD-O, applying multiple measures of symptoms in both domains.
Objectives: To characterize social communication and restricted and repetitive behaviors in idiopathic ASD and individuals with FXS with and without ASD using a multi-method approach.
Methods: Eighty-four males with ASD-O, 55 males with FXS-ASD, and 16 males with FXS-O were included. The Pragmatic Rating Scale-School Age (PRS-SA; Landa, 2011) and the communication and social items of the Autism Diagnostic Interview-Revised (ADI-R) were used to evaluate social communication. RRBs were assessed using the ADI-R RRB items and the Repetitive Behavior Scale-Revised (RBS-R). Principle Component Analyses were conducted to determine the factor structure of phenotypic profiles across FXS and ASD. Correlations were examined with *FMR1*-molecular variation, including CGG repeat length and levels of FMRP.
Results: On detailed clinical-behavioral ratings of pragmatic language (i.e., PRS-SA), individuals with ASD-O and FXS-ASD did not differ, and demonstrated significantly greater rates of impairment in domains of conversational reciprocity, redundancy, and disinhibition compared to males with FXS-O (ps<.05). For parent-reported difficulties in communication (ADI-R) a stepwise pattern emerged in which males with ASD-O demonstrated the greatest impairment, followed by males with FXS-ASD and then males with FXS-O (ps<.05). In contrast, on both the ADI-R and RBS-R, males with ASD-O demonstrated distinct profiles of RRBs, including significantly greater rates of behaviors associated with insistence on sameness, sensory interests and aversions, compulsions, and self-injury compared to males with FXS-ASD and FXS-O (ps<.05). Additionally, males with FXS-ASD demonstrated greater impairments in sensory seeking and aversive behaviors than those with FXS-O. Variation in *FMR1* expression was related to greater impairments in social communication in all three groups, and greater rates of repetitive sensorimotor behaviors in FXS-O (ps<.05).
Conclusions: Findings confirmed substantial overlap between ASD and FXS-ASD in the social-communicative domain, and revealed significant relationships between social communication and *FMR1*-related variation. In contrast, distinct profiles of RRBs were observed, indicating syndrome-specific areas of difficulty that are impacted by increased ASD symptomatology in FXS. Together, findings suggest that social communication impairments may constitute an important overlapping endophenotype in ASD and FXS, which may be used to clarify the complex etiology of ASD.

69 **107.069** Identifying Factors That Predict, Moderate and Mediate Alternative and Augmentative Communication (AAC) Outcomes for Preschool Children with Autism

S. B. Sievers[1], *D. Trembath*[2] *and M. F. Westerveld*[3], *(1)Allied Health, Griffith University, Gold Coast, Australia, (2)Menzies Health Institute, Griffith University, AUSTRALIA, (3)School of Allied Health Sciences / Griffith Institute for Educational Research, Griffith University, Gold Coast, Australia*

Background: Clinicians must consider numerous factors when prescribing Augmentative and Alternative Communication (AAC) for children with autism, including the children's individual learning profiles, families' preferences, and resource constraints. Furthermore, when considering the research evidence, documented variability in AAC intervention outcomes in research makes it hard for clinicians to select the intervention most likely to be effective for a given individual. The aim of this study was to identify child-related factors associated with AAC intervention outcomes for children with autism through a systematic review of the research literature.
Objectives: N/A
Methods: A systematic search was completed of peer-reviewed research articles presenting studies in which AAC intervention outcomes, and factors associated with these, were reported for children with autism and/or developmental disability. The following data were extracted: (a) participants, (b) AAC intervention/s, (c) communication outcomes, (d) baseline child characteristics, and (f) social environmental factors.
Results: The search yielded 965 titles and abstracts, of which seven articles relating to 7 studies met criteria for inclusion. Child characteristics associated with communication outcomes were pre-intervention cognition, autism severity, communication competence, verbal imitation, vocabulary comprehension, object use, joint attention, and language use.
Conclusions: The findings point to the need for further research to better understand the nature of the association between these factors and outcomes, as well as the potential for these factors to assist in matching children with interventions most likely to meet their individual needs.

70 **107.070** Illuminating the Role of Association and Spatio-Temporal Location for Word Learning in ASD

C. Field[1], *C. Lewis*[2] *and M. L. Allen*[3], *(1)Preston, University of Central Lancashire, Lancashire, United Kingdom, (2)Lancaster University, Lancashire, United Kingdom, (3)Lancaster University, Lancaster, UNITED KINGDOM*

Background:
Research suggests that children with Autism Spectrum Disorder (ASD) learn words from association (e.g. Akechi et al., 2011; Baron-Cohen, Baldwin & Crowson, 1997; Preissler & Carey, 2005). However, these findings may reflect cognitive delay rather than autism per se; and the associational binding between a word may more simply refer to spatio-temporal position or the nature of the symbolic reference by which attention is drawn.Â Little research to date has compared the influence of different symbolic cues to prompt the child to the link between a spoken word and its intended referent.
Objectives:
The three objectives of the research were: to examine the nature of association in word learning within a group of children with ASD with varying verbal mental age (VMA), comparing different symbolic gestures (an arrow, illumination of the object, both, or both but identifying different objects); to investigate the effect of spatio-temporal location on children's word-object mappings; and to tease apart the effects of intellectual disability and autism, by comparing children with ASD to children with intellectual disabilities (ID) and a typically developing (TD) cohort.
Methods:
Children (*N*s: TD = 32; ASD = 31; ID = 22) watched a video of a speaker labelling novel objects. One referent was presented with a cue highlighting attention (i.e. arrow next to the object, light illuminating the object, or arrow and light concurrently presented) as the speaker uttered a novel word. After the video, children were asked to indicate the target referent. On half the trials, the position of the objects was reversed.
Results:
The findings are depicted in Figure 1 and Table 1.
· As would be expected, when the arrow and illumination (light) conflicted children in all three groups were at chance.
· The arrow cue, presented alone or with illumination, enabled children with ASD to perform above chance in learning a new word.
· Word learning occurred when the objects remained in position and when they were reversed.
· (not shown in Table 1 or Figure 1) children with ASD with a higher VMA (mean of six-years-old) tended to perform better than those with a lower VMA (mean of three-years-old), particularly for the arrow trials and reversed position trials
Conclusions:
Word learning in ASD is not simply an association between a word and a place – it refers to the object being labelled.Â We also found that word learning is influenced differentially by the cue which accompanies a label. Children with ASD learn words from arrows but not object illumination and originally only map object labels to particular spatial locations. The three populations showed differences in word learning from the cues relative to each other (see Figure 1). These results emphasise the importance of studying different types of associative cue, a varying VMA range of children and including children with ID as controls in ASD research. Further analysis of these influences might provide insights into how children in various groups grasp word-referent connections.

71 **107.071** Imagining Counterfactual Worlds in Autism Spectrum Disorder

***J. S. Black**, D. M. Williams and H. Ferguson, School of Psychology, University of Kent, Canterbury, United Kingdom*

Background:
Counterfactual reasoning is an important part of social communication and may be a necessary precondition for development of Theory of Mind. Counterfactual reasoning relies on both imaginative and inhibitory processes, both of which may be impaired in people with Autism Spectrum Disorders (ASD). Limited previous research has found counterfactual reasoning ability to be impaired in *children* with ASD, but this has never been explored in *adults*. Past research has also relied on the generation of counterfactual statements or responses to counterfactual reasoning questions, which create ambiguous task demands for people with ASD. Exploring counterfactual reasoning ability with online processing measures eliminates this potential confound.
Objectives:
We present four eye-tracking experiments (experiments 1 and 2 complete; approximately 50% of data collected for 3 and 4) that explore the processing of counterfactual sentences, requiring differing levels of inhibition and imagination, in individuals with ASD and typically developing (TD) participants in an anomaly detection reading task.
Methods:
Experiment 1 depicted everyday events that incur a minimal change from reality (e.g. "If Joanne had remembered her umbrella, her hair would have been dry/wet…"). Experiment 2 described alternative versions of known historical events that require readers to suspend their knowledge of reality and imagine a novel version of the world (e.g. "If Spain were not a member of the European Union, they would pay for things using Pesetas/Euros…"). Experiment 3 presented completely novel scenarios requiring a high degree of imagination (e.g. "If margarine contained soap, mum could use margarine in her washing/baking…"). Experiment 4 explored the processing of counterfactual sentences within well-known fictional worlds (e.g. "If Harry Potter lost his magic powers, he would use his broom to sweep/fly…"). Factual contexts ("Because…") provided a baseline measure of contextual integration.
Results:
Results from Experiments 1 and 2 (*n*=50) revealed similar comprehension strategies for TD and ASD groups (faster counterfactual inconsistency-detection in Experiment 2 than 1). However, relative to controls, participants with ASD were *faster* to detect the factual inconsistency in Experiment 1, and were more likely to regress back to aid comprehension of a counterfactual world in Experiment 2.
Preliminary results suggest similar findings for Experiments 3 and 4 (*n*=20). For example, in Experiment 3, adults with ASD demonstrated typical counterfactual processing with faster detection of anomalies within factual than counterfactual sentences, with some evidence suggesting slower counterfactual processing in Experiment 4.
Conclusions:
Overall, our results across experiments (and two different samples) suggest that adults with ASD are well-able to process counterfactual sentences and do so in a similar time course to TD adults, even when these sentences place demands on imagination and inhibition. This implies that difficulties with Theory of Mind in adults with ASD are not the result of counterfactual processing deficits. However, some subtle between group differences were found when counterfactual processing required inhibitory control. Adults with ASD appeared slower to process counterfactual scenarios requiring inhibition of prior knowledge (whether factual e.g. the Titanic sinking, or fictional e.g. that mermaids have tails). The theoretical and clinical implications of this will be discussed.

72 **107.072** Impaired Resolution of Ambiguous Homographs in High-Functioning Individuals with Autism: An ERP Study

*E. L. Coderre[1], **M. Chernenok**[1,2], T. Brothers[3], B. Gordon[1,4] and K. Ledoux[1], (1)Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, (2)Department of Human Ecology, University of California, Davis, Davis, CA, (3)University of California Davis, Davis, CA, (4)Cognitive Science, Johns Hopkins University, Baltimore, MD*

Background: Â Autism spectrum disorders (ASDs) are partly characterized by deficits in communication and pragmatic language, particularly in determining the meaning of ambiguous words in context. For example, when reading sentences aloud, individuals with ASD are more likely than individuals with typical development (TD) to mispronounce ambiguous homographs like “lead” and “tear”. Traditionally this difficulty has been interpreted within the “weak-central coherence” theory of autism, which suggests that individuals with ASD have impaired contextual integration. However, difficulty with correctly reading homographs could also stem from executive control deficits, such that individuals with ASD have difficulty inhibiting the context-inappropriate meaning of the homograph.
Objectives: Â We used the N400 event-related potential (ERP) to tease apart executive control and context sensitivity processes in individuals with ASD. Using sentence stimuli designed to distinguish between context sensitivity and executive control, we compared N400 responses to lexical ambiguity and semantic incongruity in ASD and TD groups. If impairments in ambiguity resolution in the ASD group result from difficulty attending to contextual clues, then these impairments should correlate with a reduced N400 to incongruous words. Conversely, a dissociation between these two mechanisms would suggest that individuals with ASD have a specific impairment in disambiguating meaning.
Methods: Â Twenty adults with ASD and 20 matched TD adults (ages 18-68) read 120 sentences for comprehension, responding to relatedness probes after each sentence. Materials consisted of sets of four sentences, adapted from Sitnikova et al. (2002). All sentences had a first clause that biased either the dominant or subordinate meaning of a homograph. A second clause contained a target word associated with the homograph’s dominant meaning. Finally, a control word at the end of the sentence was either congruent or incongruent with the preceding sentence context. Sentences were presented in rapid serial visual presentation (RSVP) format during concurrent EEG recording.
Results: Analyses were performed at nine regions across the scalp (representing frontal, central, and parietal sites and left, midline, and right lateralities). Repeated-measure ANOVAs were run with factors of congruity (congruent/incongruent), site (frontal/central/parietal), laterality (left/midline/right), and group (ASD/TD). At the control word, both groups showed a significant N400 effect from 300-500 ms over central and parietal scalp. The magnitude and topography of the N400 effects were comparable between groups. At the target word, the TD group showed a small N400 effect from 350-450 ms over the right hemisphere. In contrast, the ASD group did not show a significant N400 effect in response to the target word.
Conclusions: Both groups showed an N400 effect in response to control words, indicating that the ASD group effectively attended to sentence context. In contrast, the ASD group showed no N400 effect to the target words, indicating inappropriate ambiguity resolution. The dissociation between these two effects suggests that inattention to context is an unlikely explanation for the disambiguation deficits in the ASD group. Instead, atypical ambiguity resolution may result from inappropriate executive control mechanisms, such that individuals with ASD are unable to suppress the context-inappropriate meaning of the homograph.

73 **107.073** Individuals with 16p11.2 Deletions Show Aberrant Feedback Processing during Speaking

C. Demopoulos[1], *H. Kothare*[1], *D. Mizuiri*[1], *J. Henderson-Sabes*[2], *E. Sherr*[3], *B. Fregeau*[4], *J. Tiernagel*[5], *J. F. Houde*[6] *and S. Nagarajan*[1], *(1)Radiology & Biomedical Imaging, UCSF, San Francisco, CA, (2)Otolaryngology-Head and Neck Surgery, UCSF, San Francisco, CA, (3)Neurology, UCSF, San Francisco, CA, (4)Neurology, UCSF, SF, CA, (5)Simons Foundation Autism Research Initiative, New York, NY, (6)University of California, San Francisco, San Francisco, CA*

Background: The specific types of deficits in the sub-processes necessary for speaking are poorly understood in children with Autism Spectrum Disorder (ASD) and 16p11.2 deletions. Given the highly penetrant speech production deficits in children with 16p11.2 deletions, examination of speech sub-processes in this group offers an opportunity to identify discrete points of dysfunction in the speech production system. In particular, a better understanding of the role of auditory feedback in the control of speaking in these participants could potentially lead to insights into novel targets for intervention and directions for therapeutic treatments.
Objectives: To examine the impact of auditory feedback processing on speech production in participants with 16p11.2 deletion compared to sibling controls.
Methods: Two tests of sensitivity to auditory feedback during speech were collected from 12 participants with 16p11.2 deletion and six sibling control participants. The first test, called a pitch perturbation test, examined how subjects quickly changed the pitch of their voice within a trial to correct for a brief perturbation of their auditory feedback, a response known as “pitch feedback compensation”. The second test, called a speech formant adaptation test, examined how, over many trials, subjects learned to adapt to sustained vowel identity changes in their auditory feedback during vowel production.
Results: Results indicated that 16p11.2 deletion carriers showed an exaggerated pitch compensation response to unpredictable mid-vocalization pitch perturbations compared to sibling controls, $t(7.45)=2.54$, $p=.037$). In contrast, they showed reduced adaptation to sustained vowel identity changes in auditory feedback, ($t(12)=3.04$, $p=.010$).
Conclusions: The overcompensation response to unpredictable online auditory feedback alterations demonstrated in our participants with 16p11.2 deletion is similar to what has been observed in a subset of participants with idiopathic ASD. Our data also showed reduced speech sensorimotor adaptation following consecutive trials in which the vowel identity of auditory feedback was altered in a predictable way. A reduced adaptation response has been reported in typically developing younger children and to an even greater extent in toddlers, which may suggest a maturational dysfunction of one or more speech production mechanisms in participants with 16p11.2 deletion. This reduced speech adaptation in the context of the strong compensation response during the pitch perturbation task means that while deletion carriers were able to detect and make some effort at correcting perceived speech errors in real time, they failed to change their speech model in anticipation of highly predictable alterations in auditory feedback.

74 **107.074** Investigating Relationships Between Linguistic and Pictorial Symbolic Domains in Children with Autism Spectrum Disorder and Typical Development

C. Hartley[1], *A. Trainer*[2] *and M. L. L. Allen*[3], *(1)Psychology, Lancaster University, Lancaster, UNITED KINGDOM, (2)Northumbria Healthcare NHS Foundation Trust, North Tyneside, United Kingdom, (3)Lancaster University, Lancaster, UNITED KINGDOM*

Background:
If children are to become effective communicators, it is vital that they learn to comprehend and produce linguistic and pictorial symbols. For typically developing (TD) children, early understanding of pictures is scaffolded by their superior and early-emerging understanding of language. However, autism spectrum disorder (ASD) is often characterised by severe and prolonged language impairments, and recent evidence shows that minimally verbal individuals also have an atypical understanding of pictures. Here, we explore the possibility that deficits in linguistic and pictorial domains are causally related in ASD.
Objectives:
For the first time, this study modelled concurrent predictive relationships between comprehension and production of language and pictures (plus non-verbal intelligence, chronological age, and autism severity) in linguistically-delayed children with ASD and TD controls.
Methods:
Participants were 30 children with ASD (*M* age = 11;4) and 24 TD children (*M* age = 4;5). The Mullen Scales of Early Learning measured language comprehension (ASD: *M* = 3;7; TD: *M* = 4;5) and language production (ASD: *M* = 3;4 ; TD: *M* = 4;8). The Leiter-R measured non-verbal intelligence (ASD: *M* score = 63.5; TD: *M* score = 50.46) and the Childhood Autism Rating Scale measured autism severity (ASD: *M* score = 36.93; TD: *M* score = 15.42). Picture comprehension was assessed by asking children to identify the 3-D referents of line drawings. Picture production was assessed by asking children to draw unfamiliar 3-D objects and having independent raters identify their referents. Predictive relationships between domains were modelled via hierarchical regressions.
Results:
For children with ASD, pictorial understanding was predicted by language abilities (β = .41-.64, p = .03-.001), and autism severity (β = -.45, p = .02). Language comprehension and production predicted each other (β= .65-.85, $p < .001$), and the latter was also predicted by autism severity (β = -.22, $p = .02$). For TD children, picture comprehension was predicted by language abilities (β = .38-.42, $p = .045$-.05), which in turn were predicted by non-verbal intelligence and chronological age (β = .34-.48, $p = .04$-.02). Comparisons between subgroups ($N = 16$ per population) matched on language comprehension and production revealed no differences in pictorial understanding. However, when matched on non-verbal intelligence, children with ASD showed significantly reduced pictorial understanding relative to TD peers ($t = 5.2$-32.3, $p = .03$-<.001).
Conclusions:
As in typical development, pictorial understanding in ASD is scaffolded by language. This between-domain relationship is similar to that observed in young TD children, and aligns with Vygotskian social-cultural theories of development rather than domain-specific theories. The observed predictive relationships indicate that referential language impairments may elicit downstream deficits in picture comprehension and production. Consequently, children with severely impaired language may not understand the representational nature of pictures. From an applied perspective, this has important implications for children's learning and usage of picture-based communication interventions. However, improving language through targeted interventions may elicit advances in understanding across multiple symbol systems.

75 **107.075** Is Autism Left-Handed? Exploring Abnormal Lateralization in Handedness and Language Among Individuals with ASD.

A. Diaz-Stransky[1], *M. J. Rolison*[2], *K. A. McNaughton*[2], *T. C. Day*[3], *B. Lewis*[4], *K. Ellison*[5], *E. Jarzabek*[2], *A. Naples*[6], *J. Wolf*[7] *and J. McPartland*[2], *(1)Psychiatry, Yale Child Study Center, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT, (3)Yale Child Study Center, Yale University, New Haven, CT, (4)Yale School of Medicine, Darien, CT, (5)Yale University, New Haven, CT, (6)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (7)Yale Child Study Center, New Haven, CT*

Background: Language and fine-motor function are typically lateralized to the left hemisphere. Neurologic lateralization during brain development underlies handedness and communication asymmetry. Atypical lateralization of these functions has been observed in individuals with autism spectrum disorder (ASD) and other neurodevelopmental disorders. Recently, a study of handedness in individuals with ASD reported a lower handedness score than typically developing (TD) children. Limited research has suggested a small effect of handedness on language, in that right-handed children had better language scores than non-right-handed subjects.
Objectives: The current study aims to explore the difference in handedness quotient between individuals with ASD vs. TD. In addition, this study investigates the association between handedness and language function among individuals with ASD. Finally, the association between handedness and communication is explored separately for different facets of a handedness assessment. Handedness is measured utilizing the Edinburgh inventory, which measures the degree of dominance of an individual's right or left hand based on eye, hand and foot laterality.
Methods: Â Thirty children diagnosed with ASD and seventeen TD children ages 8-18 years old underwent testing for handedness utilizing the Edinburgh Handedness Laterality quotient. Communicative function was assessed with the Vineland Adaptive Behavior Scales – Second Edition, Communication Domain (VABS-CD). Linear regression analysis was performed to explore the correlation between Edinburgh handedness quotient and communication scores. A t-test comparison of VABS-CD communication scores between right-handed and left handed and ambidextrous/undifferentiated individuals with ASD was completed for each item in the Edinburgh scale as well as global Laterality Quotient.
Results: Â The difference in handedness quotient between individuals with ASD (median 88) and TD (median 100) did not reach significance (p=0.319). There is no significant correlation between handedness quotient and VABS-CD scores (r^2=0.1, p=0.109) Furthermore, there was no significant difference between VABS-CD communication scores among individuals with ASD who are right-handed vs. those that are left handed and ambidextrous/ undifferentiated (p=0.702). No differences emerged even when communication scores were compared based on laterality of each item on Edinburgh handedness quotient scale (lowest p-value was 0.201).
Conclusions: This study failed to replicate the reported association between handedness and communication function among individuals with ASD. Studies controlling for non-verbal intellectual quotient are necessary to explore whether individual differences in cognition may account for discrepant results. Further studies investigating the inter-relation between abnormal lateralization of communication and motor function may inform the neurobiologic basis of autism and other neurodevelopmental disorders.

76 **107.076** Joint Attention at 22 Months As a Predictor of Communication Skills in Preschool

S. W. Nowell[1], *L. R. Watson*[2], *E. Crais*[2], *S. Griffin*[3] *and L. Turner-Brown*[4], *(1)University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Allied Health Sciences, Division of Speech and Hearing Sciences, The University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Early joint attention (JA) skills are known to predict later language skills in children with ASD (Charman, 2003; Poon et al., 2012). However, little is known about the extent to which these skills may be variably related to general language outcomes versus more pragmatic aspects of language use. We aimed to address this gap in the literature via analyses using a sample of children (n=46) who were identified as at-risk for ASD at 12 months of age using a community screener (FYI; Baranek et al., 2003). Specifically, we sought to examine the extent to which general language outcomes versus pragmatic language outcomes at preschool age were predicted by JA skills at 22 months.
Objectives: Our aim was to determine if JA skills at 22 months variably predict general language outcomes versus pragmatic aspects of communicative competence, specifically reciprocity, initiation, and topic maintenance during conversations and narrative retell ability.
Methods: Items on the ADOS Module 1 targeting JA skills (Showing, RJI, and Spontaneous IJA) collected at 20-24 months (m=22, sd=.8) were used in regression models to predict general language skills on the Preschool Language Scales-5th Edition (PLS-5; Zimmerman et al., 2011). Next, JA skills at 22 months were used to predict specific pragmatic skills on the Pragmatic Rating Scales-School Age (PRS-SA; Landa, 2011; Reciprocity, Initiation, and Topic Maintenance), and narrative retell abilities using the Narrative Scoring Scheme (NSS; Heilmann et al., 2010) for a sub-sample of 4-5 year olds (m=59.72 months, sd=6.7), whose language levels were advanced enough to code using the PRS-SA.
Results: In this sample of children identified at 12 months as at-risk for ASD, the three items targeting JA on the ADOS at 22 months accounted for a significant amount of the variance in Expressive Communication (R^2= .21, p=.02) but not Auditory Comprehension on the PLS-5 (R^2=13.98, p=.09) in preschool. RJA was the only significant predictor of Expressive Communication, accounting for most of the variance in preschool expressive language skills. None of the JA items were significant predictors of Reciprocity or Initiation on the PRS-SA, but JA items at 22 months accounted for significant amounts of variance in PRS-SA Topic Maintenance (R^2=.34, p=.03) and total narrative retell skills on the NSS (R^2=.31, p=.02) in preschool. Showing (p=.06) and RJA (p=.06) were the biggest contributors of variance in Topic Maintenance, while Showing (p=.01) was the only significant predictor of narrative retell. The contributions of the JA items in all of these models accounted for significant variance above and beyond the ADOS total algorithm score, which was not a significant predictor in any of the models.
Conclusions: In this at-risk sample, JA skills at 22 months significantly predicted expressive language ability in preschool. However, early JA skills accounted for a larger amount of variance in the children's maintenance of another person's topic and narrative retell ability than they did in general expressive language skills at preschool age. Findings support the importance of interventions targeting JA skills in toddlers at-risk for ASD to improve later pragmatic functioning.

77 **107.077** Language Acquisition and Communicative Development in Mandarin-Learning Preschool Children with ASD: Assessment Via the Pcdi-Infant Form

F. Xie *and Y. E. Su, School of Foreign Languages, Central South University, Changsha, Hunan, CHINA*

Background: English-learning preschool children with autism spectrum disorders (ASD) have often been reported to demonstrate the severe delay of receptive and expressive vocabulary and non-verbal communication, functional object use and play skills (Charman *et al*., 2003; Luyster *et al*., 2007). Recent research has begun to delineate expressive language profiles in Mandarin-learning children with ASD (Su *et al*., 2016). However, little is known about both receptive and expressive, and non-verbal language profiles of Mandarin-learning preschool children with ASD.
Objectives: Using the Putonghua Communicative Development Inventory: Words and Gestures (PCDI-Infant Form; Tardif *et al*., 2008), this study attempts to investigate the early development of understanding of phrases, words comprehension and expression, and production of gestures in Mandarin-learning preschool children with ASD.
Methods: Parents of 75 2-6-year-old children with ASD (66 boys and 9 girls, mean age=54.52±14.40 months) completed the PCDI-Infant Form. Language and communicative abilities were compared with the published norms of typically-developing (TD) infants and the published patterns of English-learning preschool children with ASD respectively.
Results: Â (1) Compared with the published norms of TD infants, the results indicated that Mandarin-learning preschool children with ASD demonstrated the following differences: ①The serious delay in early language development (in domains including First Signs of Understanding, Phrases, Starting to Talk, Vocabulary, Actions and Gestures); ②The considerable variability in language acquisition; ③For the "Vocabulary" part, their impairments of receptive language seemed to be severer than expressive language; ④In the gestural domain, their early gestures (12/27 points) were more impaired than late gestures (17/27 points); ⑤For correlations, results showed an overall significant correlation even with age partialled out (*p*s<.001). There were also strong correlations between vocabulary production and gesture production (r=.537 and r=.542 respectively, both *p*s<.001), and phrases understood (r=.574 and r=.574 respectively, both *ps*<.001), while both showed weak correlations in the published norms of TD infants (r=.41, *p*<.05 and r=.29, *p*>.05 respectively). (2) Compared with English-learning preschool children with ASD, the results indicated the similar developmental patterns: ①The serious delay in early language acquisition and communicative development were demonstrated across languages; ②Gesture production acting as a "bridge" between language comprehension and language production, as these three domains were significantly correlated with each other (*p*s<.001); ③When the participants were divided into 3 age subgroups (2-3-year-olds, 4-year-olds, 5-year-olds and above), results showed insignificant difference of age between the subcategories of the PCDI-Infant Form (*p*s>.05), different from the results of English studies.
Conclusions: Mandarin-learning preschool children with ASD have demonstrated sever impairments in both receptive and expressive, and non-verbal language development. The serious delay compared with the published norms of TD infants highlighted the importance of timely and effective language intervention. While compared with English-learning preschool children with ASD, the patterns of early language acquisition and communicative development demonstrated similarities across languages. Additionally, we conjectured that the reason of no apparent age effect may result from the severer impairments in Mandarin-Learning preschool children with ASD. These findings in general corroborate the early language and communication profiles reported in English-learning preschool children with ASD.

78 **107.078** Language Assessment in Minimally Verbal Children with ASD

A. Holbrook[1]*, C. K. Toolan*[2]*, S. Y. Shire*[1]*, C. DiStefano*[1]*, R. Landa*[3]*, T. Smith*[4]*, A. Kaiser*[5] *and C. Kasari*[2]*, (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Kennedy Krieger Institute, Baltimore, MD, (4)University of Rochester Medical Center, Rochester, NY, (5)Vanderbilt University, Nashville, TN*

Background: Language and communication impairments are common in children with ASD and are particularly salient in minimally verbal (MV) children. There is heterogeneity in language ability even among MV children, and there is still a lack of consensus in the way MV status is defined. As MV status is inherently shaped by the language assessments used with these children, understanding the methods and measures by which language is assessed with this population is one step toward constructing a clear definition of what it means for a child to be "minimally verbal." Additionally, understanding concurrent predictors of language in this population may help inform both research and clinical practice.
Objectives: We present data exploring associations between receptive language (RL) and expressive language (EL) scores from different assessments and examine concurrent predictors of language skills in minimally verbal children.
Methods: Children (n=294) participated in multisite studies targeting social communication in MV preschool and school-aged children. The language measures used in the present study were collected as baseline measures for the original studies. The assessments analyzed were: Mullen Scales of Early Learning, Reynell Developmental Language Scales, Peabody Picture Vocabulary Test, Test of Early Language Development, Vineland Adaptive Behavior Scales and the MacArthur-Bates Communicative Development Inventories: Words and Gestures, and a naturalistic language sample. Concurrent predictors of language ability (using RL and EL composites) analyzed included child's imitation ability, response and initiation of joint attention (JA), symbolic play, non-verbal cognitive ability, and chronological age.
Results: Using Spearman's partial rank correlations controlling for age we found the correlations between EL raw scores to be moderate to strong and all significant at the 0.01, while RL raw scores were strongly correlated at the 0.01 level. We conducted discrepancy analyses using Friedman's test and found that the age equivalents across EL and RL measures were significantly different. Regression models were used to predict concurrent expressive and receptive language. The results indicate that imitation (t=2.26, p=.025) and initiation of JA (t=3.94, p< .001) were significant predictors of concurrent RL (R^2=.20). Additionally, imitation (t=2.51, p=.013), initiation of JA (t=2.38, p=.018), and nonverbal cognitive ability (t=3.35, p<.001) predicted EL (R^2=.25).
Conclusions: Results indicate that there was strong convergent validity in raw scores for EL and RL measures, but the age equivalents produced were different. These findings demonstrate that there are different measures that can be used to effectively capture language abilities in MV children; however, researchers and practitioners should be cautious in using and interpreting the age equivalents given by these measures. Although results show JA, imitation, and nonverbal cognitive abilities are important skills for language, these only account for about 20-25% of variance. This suggests that language development is a complex process for MV children with ASD and needs further investigation.

79 **107.079** Language Development in Dual Language Learners with Autism Spectrum Disorder and Other Developmental Delays

Y. G. Dai[1], *J. D. Burke*[2], *L. R. Naigles*[2], *I. M. Eigsti*[3] *and D. A. Fein*[2], *(1)University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Department of Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Many parents and child-development specialists believe that dual language exposure (DLE) delays language development in children with autism spectrum disorder (ASD). Accordingly, parents report limiting communication directed to children with ASD to one language, which confers additional burdens on parents and further isolates the affected children from their family and culture (e.g., Yu, 2013). Few studies have looked at the impact of DLE on language acquisition in very young children with ASD before they receive intervention.
Objectives: This study aims to assess the early receptive and expressive language abilities of children with ASD and other developmental delays (DD; i.e., Global Developmental Delay or Language Delay) from bilingual and monolingual families.
Methods: Participants were 256 children (199 males; mean age 26 ± 4.66 months) evaluated as part of a larger study on the early detection of ASD. Parents were asked to list all languages that primary caretakers used to communicate with their child. 63 dual-language exposed (DLE) children (37 ASD, 26 DD) were compared to 193 single-language exposed (SLE) children (119 ASD, 74 DD). The Mullen Scales of Early Learning (MSEL) was used to assess nonverbal (visual reception (VR), fine motor (FM)) and verbal (receptive and expressive) abilities. Diagnoses were assigned according to DSM-IV-TR, using clinical best estimate judgment of symptoms based on observation, history, and testing. Multiple regression was used to evaluate the relationship of DLE to language abilities, beyond the influence of nonverbal cognitive abilities, diagnosis, and household income.
Results: Language Group (DLE; SLE) did not predict receptive (β = -.09, p=.14) or expressive (β = -.08, p= 0.22) language ability. When household income, diagnosis (ASD; DD), and nonverbal IQ (VR; FM) were added to the model, all variables explained 42% of variance in receptive language scores. Language group remained nonsignificant in predicting receptive language ability, β = -.08, p=.12. Income (β=.05, p=.30) and FM (β = -.01, p=.86) similarly did not predict receptive language, but diagnosis (β=.22, p<.05) and VR scores (β=.58, p<.05) were associated with receptive language. In the prediction of expressive language scores, income, diagnosis, nonverbal IQ, and language group together predicted 35% of variance. Language group (β = -.04, p=.46), diagnosis (β = .04, p= .41), and income (β = .10, p=.06) did not predict expressive language, but VR (β=.41, p<.05), and FM (β =.20, p<.05) did.
Conclusions: This study explored whether very young children with ASD or other delays growing up in DLE households differed in receptive and expressive language development in comparison with children raised in SLE homes, before diagnosis or intervention. The results suggest that young children with ASD and other developmental delays have comparable receptive and expressive language abilities, regardless of whether they come from a monolingual or bilingual home. Instead, receptive language development is better explained by visual reception abilities and diagnosis, and expressive language is better explained by visual reception and fine motor skills. This study suggests that bilingual parents can communicate with their children in their preferred language, or in both languages, without harm to language development.

80 **107.080** Language Outcomes for Children on the Autism Spectrum with Differing Language Development Profiles: What Is the Role of Nviq?

P. Hickey[1], *S. M. Attar*[1], *A. Walsh*[1] *and E. Hanson*[2], *(1)Boston Children's Hospital, Boston, MA, (2)Children's Hospital Boston, Boston, MA*

Background: Language and Communication deficits are required for a diagnosis of Autism Spectrum Disorders (ASD), and many ASD individuals experience overall language delay or regression. Some children, however, develop basic aspects of language within normal limits (i.e. single words and phrases). IQ has been shown in numerous studies to moderate many areas of development in ASD. No study has looked specifically at Nonverbal IQ and its relationship with different language trajectories.
Objectives: We hypothesized that children with higher NVIQ scores with language delays or regression would have higher receptive and expressive skills. Additionally, we expected that children who developed language predominantly within normal limits would have the strongest receptive and expressive skills.
Methods: A sample of 473 children (77.6% male), aged 5-22 years (mean=9.8, SD=3.6) were included in analysis. All participants had a research confirmed ASD diagnosis using ADOS and ADI-R. Receptive and Expressive skills were assessed with Vineland Adaptive Behavior Scale, Second Edition and IQ was assessed with either the Mullen Scales of Early Learning or Differential Abilities Scales. We divided our sample into three groups: a) normal limits; b) delay; and c) regression. Assignment of groups was based on ADI-R questions regarding language development (Question Items 9, 10, and 11) . Pearson Correlations and One-Way ANOVAs were used to determine the relationship between NVIQ and receptive and expressive language skills. Additionally, Multiple Linear Regression Models were created for receptive and expressive language to assess the contribution of NVIQ and language group. All statistics were run using SPSS.
Results: Both receptive and expressive language skills were positively associated with NVIQ (receptive: r=0.183, p=0.002; expressive r=0.388, p<0.001). There were significant differences in receptive (p=0.05) and expressive skills (p<0.001) across the groups. The significant difference was only between the normal limit group and regression group (Receptive: p=0.03; expressive: p<0.001). Children in the normal limit group had the highest receptive and expressive language skills, followed by the delay group, and the regression group had the poorest language skills. Significant results were found for both regression models (Receptive: F(2,269)=4.911, p=0.009, R2=0.35; Expressive: F(2,270)=26.152, p<0.001, R2=0.162). The language category only significantly contributed the expressive language model (Receptive: Beta=-0.035, p=0.56, n.s; Expressive: Beta=-0.113, p=0.045), while NVIQ significantly contributed to both models (Receptive: Beta=0.178, p=0.004; Expressive: Beta=0.372 , p<0.001).
Conclusions: Results confirm the initial hypothesis. The only significant difference in language skills was seen between children with typical language development and children with language regression. NVIQ was a significant contributor to both regression models, while language category was only significant in the expressive language model. While NVIQ and language category accounted for some variance in language skills, a large percentage of the variance wasn't accounted for.

81 **107.081** Language Subdomains Among Young Children with Autism Spectrum Disorder: Associations with Social Skills

S. Levinson[1], *N. A. Hoch*[2], *J. Blacher*[3], *A. S. Carter*[2] *and A. Eisenhower*[2], *(1)Psychology, University of Massachusetts Boston, Brookline, MA, (2)University of Massachusetts Boston, Boston, MA, (3)University of California - Riverside, Riverside, CA*

Background:
As deficits in both language and social skills often remain impairing symptoms of autism spectrum disorder (ASD), considerable research has been devoted towards better understanding the nature of these co-occurring, yet distinct symptom clusters. Although a meaningful proportion of children with ASD evidence difficulties across language domains, the majority of prior research has focused on pragmatic language skills. However, given the multi-faceted nature of language skills, there is a need for research that examines how specific aspects of language relate to social skills development.
Objectives:
Examine the association between multiple language domains (e.g., phonology, semantics, syntax, pragmatics) and social skills among children with ASD.
Methods:
Participants included children with ASD (N=196) between 4 and 7 years of age, their caregivers, and teachers. Using the Children's Communicative Checklist-2 (CCC-2) and Social Skills Improvement System (SSIS), we examined how multiple aspects of language cumulatively relate to social skills. We also examined whether any one language domain was uniquely related to social skills above and beyond the other language domains.
Results:
The CCC-2 includes multiple pragmatic language subscales, given that pragmatic language is a multi-faceted language domain. Thus, as a first step we examined five aspects of pragmatic language (coherence, scripted language, context, social relations, nonverbal communication) to determine which one was most strongly associated with social skills. Only the non-verbal communication subscale emerged as significantly related to social skills, and thus was included in subsequent analyses. In a combined linear regression with parent-reported social skills as the dependent variable, with phonology, semantics, syntactic, and pragmatic language skills all entered in the same step of the regression, 17.8% of the variance in children's social skills was explained by their language skills, $F(4, 173) = 10.599$, $p = .000$. In this combined model, children's syntactic ($\beta = -.258$, $p = .010$) and pragmatic language skills ($\beta = .320$, $p = .000$) uniquely related to social skills, but semantic and phonological skills did not. In a combined linear regression with teacher-reported social skills as the dependent variable, 6.3% of the variance in social skills was explained by their language skills, $F(4, 129) = 3.234$, $p = .014$. Interestingly, children's syntactic language skills ($\beta = .411$, $p = .002$) uniquely related to social skills, while semantics, phonology, and pragmatics were not significantly associated with teacher-reported social skills. Overall, syntactic language skills emerged as significantly related to social skills in both home and school contexts; whereas pragmatic language skills were significantly associated with home-based, but not school-based social skills.
Conclusions:
The results of the present study indicate that in addition to pragmatic language skills, more structural aspects of language, such syntax, may also influence social skills among children with ASD. Given the well-documented association between pragmatic language skills and social skills in ASD, the majority of intervention programs generally focus on pragmatic language skills development. However, the results of the present study indicate that syntactic language skills are also related to social skills development, and may thus be a critical, yet largely untapped route of intervention.

82 **107.082** Leveraging AAC Usage Patterns for Diagnostic Classification: A Proof of Concept

B. Li[1], *A. Ataybi*[2], *Y. A. Ahn*[3], *L. Boccanfuso*[4], *J. Snider*[5] *and F. Shic*[6], *(1)Seattle Children's Research Institute, Seattle, WA, (2)University of Washington, Seattle, WA, (3)Seattle Children's, Seattle, WA, (4)Yale University, New Haven, CT, (5)Yale Child Study Center, New Haven, CT, (6)Center for Child Health, Behavior and Development, Seattle Children's, Seattle, WA*

Background: Augmentative and Alternative Communication (AAC) apps are widely used to facilitate communication and enhance language learning in individuals with disabilities such as autism spectrum disorder (ASD). However, to date, the utility and potential of the massive streams of usage data generated by these apps has been little explored from a data mining perspective.
Objectives: To use data mining techniques to generate a novel feature representation and analysis approach that targets differences in AAC usage patterns between users with and without ASD.
Methods: The data used in this study represents the key presses of 189 users (81 ASD, 30 TD, and 78 with aphasia, language disorder, learning disability, or other disorders) over several sessions with FreeSpeech, an iPad AAC application that provides audio when users select pictures. The user's keypresses are categorically sorted and each key is given a unique identifier in the range of its associated category. Using a sliding window of 20 keypresses with 75% overlap, usage data is segmented and each segment is considered as a standalone sample. Random Forest (RF) and Linear-Support Vector Machine (Linear-SVM) algorithms are used to distinguish ASD and non-ASD users based on 20 keypress usage patterns. 10 repetitions of K-fold-cross-validation (k=10) with 0.9 and 0.1 ratios for training and testing is considered. Accuracy and Cohen's Kappa were compared for models' performance.
Results: 12882 sessions of 20 keypresses are extracted from the 189 users (ASD=8567 sessions, non-ASD=4315 sessions). Chance-level performance is 50% and naive constant models achieve 66.5% classification accuracy by assigning every session to ASD. Linear-SVM achieved slightly above chance performance (68.27% accuracy and 0.17 Cohen's Kappa). RF achieved 79.33% accuracy (recall=0.85,precision=0.84), 0.53 Cohen's Kappa, and chi-square 3709.3 (p<.001).Â Two additional window sizes of 10 and 15 keypresses were also considered for RF, achieving 74.54% and 74.18% classification accuracy, respectively. Slightly better performances achieved by window-size 20 likely indicate that users' behaviors patterns get distorted when shorter number of keypresses are considered.
Conclusions: We investigated the informativeness of a feature representation mechanism that converts nonstationary keypress recordings to stationary and sliding time-windowed-patterns. The feasibility of our feature representation method is evidenced by the good performance of RF approach. More comprehensive data collection and classification model training will allow for the generation of more robust and accurate models that can be coupled with the application for real time analysis of user usage pattern with ability to provide adaptive content potentially based on usage patterns.

83 **107.083** Linguistic Camouflage in Girls with Autism Spectrum Disorder

L. Bateman[1]*, M. Liberman*[2]*, C. Cieri*[3]*, J. D. Herrington*[4]*, B. E. Yerys*[1]*, E. Ferguson*[1]*, J. Pandey*[5]*, R. T. Schultz*[5] *and J. Parish-Morris*[6]*, (1)The Center for Autism Research/CHOP, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania Linguistic Data Consortium, Philadelphia, PA, (4)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Autism spectrum disorder (ASD) is diagnosed more frequently in boys than girls, even when girls are equally symptomatic (Dworzynski, Ronald, Bolton, & Happé, 2012). Recent research points to "camouflaging" in girls with ASD, in which social behaviors appear superficially typical and contribute to diagnostic challenges (Rynkiewicz et al., 2016). We explore linguistic features that may contribute to the female camouflage effect in ASD. Pauses in natural conversation are filled with words like "um" or "uh", which serve distinct pragmatic functions (Fox Tree, 2001). Typical participants fill more pauses with "um" than participants with ASD (Gorman et al., 2016; Irvine, Eigsti, & Fein, 2016), but it is unknown whether this effect may be moderated by population sex differences, since large-scale studies show that women generally use more "um" and men use more "uh" (Acton, 2011; Wieling et al., 2016). We test whether typical sex differences in "um" vs. "uh" exist in school-aged boys and girls with ASD, and whether filled pauses relate to dimensional measures of socialization.
Objectives: Compare rates of "um" and "uh" use in boys and girls with ASD, and assess relationships between filled pause type and parent reported social functioning.
Methods: Participants were 65 verbal school-aged participants with ASD (49 boys and 16 girls), with IQ estimates in the Average range. Speech samples from the conversation and reporting section of the Autism Diagnostic Observation Schedule – 2nd Edition were orthographically transcribed and time-aligned, and filled pauses marked. Parents completed the Social Communication Questionnaire (SCQ) and the Vineland Adaptive Behavior Scales-2ndEdition.
Results: Multiple regressions using age, IQ, sex, SCQ, and Vineland scores to predict rates of "uh", "um", and "um ratio" revealed significant effects of sex and Vineland Socialization domain scores on "uh" and "relative um" but not "um" alone (see Table 1). Consistent with sex differences in filled pause use in the general population, t-tests revealed that boys with ASD produced more "uh" than girls with ASD. Increased "relative um" use by boys correlated with less severe ASD symptomatology; this effect was driven by increased use of "uh" by boys with greater symptoms. "Uh" was a consistent predictor of poorer parent reported socialization across both sexes, whereas "um" was not (see Figures A, B).
Conclusions: Language may have a significant impact on the way children are perceived, with typical-sounding patterns potentially serving as "linguistic camouflage" for girls with ASD. In this study, the extent to which girls used "um" predicted better parent reported social functioning. This link suggests that "um" is a gender-socialized linguistic marker and not associated with ASD *per se*. On the other hand, increased "uh" use correlated with poorer social functioning in *both* groups, suggesting that it may be associated with ASD across both sexes. This study highlights the importance of continued commitment to understanding the complex web of biological and environmental factors that influence ASD emergence and presentation in children, including sex and gender socialization.

84 **107.084** Measuring Small but Important Changes in Minimally Verbal Children with ASD

N. C. Brady[1]*, K. K. Fleming*[2]*, R. Swinburne Romine*[3]*, A. Holbrook*[4] *and C. Kasari*[5]*, (1)University of Kansas, Lawrence, KS, (2)Life Span Institute, University of Kansas, Lawrence, KS, (3)Lifespan Institute, University of Kansas, Lawrence, KS, (4)University of California Los Angeles, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA*

Background: Few measures are available that reflect changes in the quality of prelinguistic communication. Brady and colleagues have been developing and testing a scale called the Communication Complexity Scale (CCS) designed to reflect qualitative changes in the forms and functions of prelinguistic communication by individuals with severe ID (Brady et al., 2012).
Objectives: The current study focuses on how different scores that can be derived from the CCS compare to scores from other measures, and predict changes over time.
Methods: 125 individuals with ASD between the ages of 3-60 years were concurrently assessed with the CCS and two other measures of early communication- the Communication Matrix (Rowland & Fried-Oken, 2010) and the Communication Subscales from the Vineland II (Sparrow, Cicchetti, & Balla, 2005). 110 additional children with ASD were assessed with the CCS and the Early Social Communication Scales (ESCS) (Mundy, Hogan, & Doehring, 1996) pre and post intervention.
Results: 1. Scores derived from the three best communication attempts during the CCS (Optimal) correlate higher with scores from the Matrix and VABS2 than modal scores. 2. Significant changes pre-post intervention were detected after 6 months of intervention with CCS scores and the rate of joint attention communication. Only changes in rates of behavior regulation were significant for children in shorter interventions. 3. Changes measured with the CCS were similar to those measured with rates of joint attention and behavior regulation measured during the ESCS.
Conclusions: The CCS picked up changes in the quality of prelinguistic communication including advancements in gestures, eye gaze and functions of communication. These changes paralleled changes in quantity of communication.

85 **107.085** Meeting Language Milestones May Not be Associated with Better Functioning at School Age If ASD Is Not Detected Early

***A. Goodwin**, N. L. Matthews and C. J. Smith, Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Previous studies have reported that early language milestones are useful for predicting prognosis of ASD (e.g., Kover et al., 2016; Mayo et al., 2013). However, these studies included only children whose ASD was detected during toddlerhood. There is evidence that ASD tends to be diagnosed earlier in children with language delay (LD) than in children with no language delay (NLD; e.g., Mandell et al., 2005). Therefore, children with LD may be more likely to receive early intervention, which could improve subsequent functioning (Estes et al., 2015). Thus, if ASD remains undetected longer in children with NLD, they may not experience better outcomes than children with LD.
Objectives: This study compared age of diagnosis, adaptive functioning, and ASD symptomatology of a group of children with LD and a well-matched group of children with NLD, whose ASD was not diagnosed during early toddlerhood.
Methods: Using retrospective record review, scores on gold standard diagnostic and developmental assessments were examined in a sample of 110 school-age children (ages 5-18 years) with ASD. All children had a clinical diagnosis of ASD and met criteria on the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R). Fifty-five children had typical phrase speech onset (i.e., < 33 months, as reported on the ADI-R). These children were individually matched on age and sex (45 males, 10 females) to children with delayed phrase speech onset. Measures included ADI-R diagnostic algorithm and current behavior scores, ADOS calibrated severity scores (CSS), Vineland Adaptive Behavior Scales standard scores, and age of diagnosis. Normally distributed variables were compared using 2 (group) x 2 (sex) ANOVAs. Non-normally distributed variables were compared using Mann-Whitney *U* tests.
Results: There was a significant group difference in age of diagnosis (U = 968, p = .001, r = .395), with the NLD group being diagnosed relatively late (M = 8.39 years, median = 6.89) compared to the LD group (M = 5.28 years, median = 4.16). There were significant main effects of group for all ADI-R diagnostic algorithm domains (Fs > 11, ps < .001), as well as ADI-R current behavior scores in the communication and restricted repetitive behavior domains (i.e., fewer/less severe symptoms in the NLD group). However, there were no main effects of group for ADI-R current behavior in the social interaction domain, ADOS CSS or Vineland scores in any domain (all Fs < 3.7, ps > .05).
Conclusions: On average, children with NLD were diagnosed 3 years later than children with LD. Despite having typical language onset and fewer early ASD symptoms (i.e., lower ADI-R diagnostic algorithm scores), the NLD group resembled the LD group in several aspects of functioning at school-age. Specifically, at school age, both groups had moderate-to-severe ASD symptoms (i.e., ADOS CSS) and low adaptive functioning scores (i.e., below age expectations in all Vineland domains). Therefore, typical language onset was not an indicator of better prognosis in late-diagnosed children with ASD. This research highlights the importance of earlier ASD detection and intervention.

86 **107.086** Narrative Generation in Children with ASD: The Effects of a Reading Comprehension Intervention on Mental State Use

***A. R. Henry**[1], N. S. McIntyre[1], M. C. Zajic[2], E. J. Solari[3] and P. C. Mundy[4], (1)University of California at Davis, Davis, CA, (2)University of California at Davis MIND Institute, Davis, CA, (3)University of California, Davis, Davis, CA, (4)University of California at Davis, Sacramento, CA*

Background: Â Higher functioning children with ASD (HFASD) often exhibit well-developed word level reading skills but tend to have deficits in reading comprehension. The cognitive skills involved in narrative retelling of stories is associated with reading comprehension in HFASD students and may be an important target of intervention in schools for these children. Some research has suggested that children with ASD can increase their narrative competence through exposure to storybooks, with prompting to focus attention on characters' cognitive and affective states. Indeed, these types of narrative interventions may contribute to more generalized social outcomes, and have been found to increase perspective-taking and social cognition in school-aged children with ASD.
Objectives: Â The purpose of this preliminary study was to examine if a brief curriculum-based comprehension intervention had effects on the narrative abilities of children with ASD.Â The hypothesis was that children's narratives would include more story elements and evaluative terms following the intervention, indicative of improvements in perspective-taking and social cognitive abilities.
Methods: Â Participants included fifteen 7- to 12-year-old children with ASD. Children participated in an eight-week intervention program, consisting of thrice-weekly, one-hour sessions. Each session emphasized a particular comprehension skill taught explicitly with guided opportunities for practice within a children's book. A spontaneous narrative generation task was administered pre and post intervention, using a wordless picture book to elicit narrative. The book *Frog, Where Are You?* (Mayer, 1969), a story about a boy who searches for his missing pet frog, was used for the pre-intervention narrative assessment, and the post-intervention book, *A Boy, a Dog, and a Frog* (Mayer, 1971) continues the story of the boy and the frog. Narratives were transcribed and coded for terms referring to characters' affective (e.g., "laughed", "upset") and cognitive states (e.g., "know," "wondered").
Results: A paired-samples t-test was conducted to compare pre- and post-mental state usage, and revealed a significant difference in the number of mental state terms used pre- (M = 2.67, SD = 2.89) and post- (M = 4.53, SD = 4.03) intervention; t (14) = 2.56, p< .05. Preliminary analyses also showed a significant bivariate correlation between children's pre-intervention expressive vocabulary score and the frequency of mental state use at post-test, r (13) = .56, p< .05. The results of additional planned analyses will be conducted to include additional codes for story structure and length, and the relations between mental-state use and parent report measures of children's social ability will also be examined.
Conclusions: Â This study provided evidence for the malleability of narrative retelling ability in a sample of HFASD children. This is important because of the ease with which this type of intervention can be integrated into school curriculums and because intervention for narrative retelling may be important to support reading comprehension development in these children. Moreover, such interventions may also provide means to leverage a component of school curriculums to more systematically impact social cognitive development in school aged children with HFASD. Research is planned to more rigorously test these hypotheses with randomized experimental control group intervention study designs.

87 **107.087** Nonshared Environmental Influences on Language Development: A Monozygotic Twin Differences Study

M. Aparicio Betancourt[1] *and L. DeThorne*[2]*, (1)Neuroscience Program, University of Illinois at Urbana-Champaign, Champaign, IL, (2)Speech & Hearing Science, University of Illinois at Urbana-Champaign, Champaign, IL*

Background: Although linguistic impairment is no longer a diagnostic criterion for autism spectrum disorder, it remains a key area of focus and concern for many individuals and families. Given the recent focus on genetic influences on both autism and linguistic impairments more broadly, the study of environmental influences remains underdeveloped. Prior behavioral genetic work on language development has emphasized the role of both genetic and environmental influences, with the specific finding that nonshared (or person-specific) environmental (NSE) influences account for 5-90% of individual variation depending on age and the measures employed. Monozygotic (MZ) twin difference analyses provide a unique opportunity to identify NSE effects by examining the extent to which differences in specific environmental variables, such as diet, are associated with differences in language outcomes within MZ twin pairs who share approximately 100% of their DNA. The present study builds on prior behavioral genetic studies of language (DeThorne et al., 2012; 2016) and offers to the best of our knowledge, the first application of the MZ twin differences method to understanding NSE influence on children's language development.Â Objectives: This work investigates NSE associations between specific environmental measures (i.e., gap between birth, weight at birth, extent of breast feeding, reading exposure, media viewing, and parental warmth) and language development at two time points (mean ages 7 and 12 years). Methods: Participants consist of approximately 215 MZ twin pairs from the Western Reserve Reading and Math Project (WRRMP; Petrill et al., 2006), a longitudinal study of reading development and related skills. The analysis focuses on data collected from home visit 2 (HV2) and HV7, during 1st and 5thgrade respectively. Each annual home visit included standardized measures, language samples, and parent questionnaires; 7-8% of the sample was receiving speech-language pathology services when they entered the study. Language measures were loaded into two latent factors: a Productive language factor and a Formal language factor, measured by language sampling and standardized tests respectively. An MZ differences method will be employed to examine associations between the NSE measures and the two language factors. Results: Based on previous research, we predict that differential birth weight and breastfeeding will be associated with differential language outcomes. Although previous literature has linked reading exposure, media viewing, and parental warmth with language outcomes, few studies have been conducted within the context of a genetically sensitive design. To our knowledge there has been no prior research examining the association between gap between twin birth and language outcomes; research has shown, however, the second-born twin is more likely to have more neonatal complications (e.g., respiratory distress syndrome) than the first-born twin. Subsequently, predictions are less clear. Consistent with prior work, we predict NSE relationships to be moderated by the form of assessment. Finally, we anticipate increased NSE associations at the extremes of discordance compared with the full unselected sample. Conclusions: The present study will elucidate potential NSE factors that may impact language development, measured by both language sampling and standardized tests. Future directions and clinical implications will be discussed.

88 **107.088** Objective Acoustic-Prosodic and Turn-Taking Measures in Interactions with Children with Neurodevelopmental Disorders

D. K. Bone[1]*, S. L. Bishop*[2]*, S. Lee*[1] *and S. Narayanan*[1]*, (1)University of Southern California, Los Angeles, CA, (2)Psychiatry, University of California San Francisco, San Francisco, CA*

Background: Â Speech prosody—referring to the manner in which a phrase is uttered to enhance meaning beyond the spoken words—plays a critical role in social reciprocity and affect. Effective expression (and perception) of prosody is essential to portraying (and understanding) communicative intent, and thus enhancing conversational quality. Atypical prosody is a well-documented behavioral marker of ASD that presents across the lifespan, yet it is not well-defined. Descriptions of atypical prosody are qualitative, subjective, and contrasting, and inter-rater agreement remains low. As such, incidence rates for various types of prosodic abnormalities are unknown.

Objectives: Â Automatic quantitative analysis of large corpora comprising natural communication with ASD subjects has the potential to provide novel information to researchers and clinicians. Further, given the great heterogeneity of symptoms in autism spectrum disorder (ASD), an acoustic-based objective measure would be valuable for clinical assessment and interventions. In this study, we investigate objective speech features in child-psychologist conversational samples. Expanding upon previous studies, we investigate (i) the speech of children with non-ASD developmental disorders (DD) and (ii) the stability of certain prosodic attributes, gaining insights into the effects of ASD severity and diagnosis on the child's prosody and quality of interaction.

Methods: Â Audio-visual data of semi-structured child-psychologist interactions during the Autism Diagnostic Observation Schedule (ADOS) from two collection sites are used for this study. Data consist of age- and IQ-matched ADOS Module 3 administrations for ASD (N=95) and DD (N=81) subjects. Speech acoustic-prosodic features are computed after first aligning lexical transcriptions to the audio signals. Prosody is quantified in terms of segmental intonation (syllable-level), supra-segmental intonation (multi-syllabic contour modeling via Momel/Intsint parameterization), speech rate (syl/s), and coordination of prosodic attributes (pitch/volume/duration); we also investigate measures of turn-taking. Analyses are conducted via correlation and predictive regression between prosodic cues and ADOS severity.

Results: Â The automatically extracted prosodic and turn-taking cues correlate with the child's ASD severity/diagnosis and are demonstrated to have significant predictive performance. For example, in interactions with children having higher ASD severity: segmental and supra-segmental prosodic variability increases for both participants; the child has reduced coordination between their pitch and duration/volume; and the child speaks less, at a slower rate, and with more pausing. Additionally, the psychologist's speech features were as predictive of the child's severity as the child's features. We will also provide a statistical analysis of the stability of these vocal characteristics across the interaction.

Conclusions: Â TheÂ acoustic-prosodic and turn-taking cues are reflective of ASD severity and diagnosis. Likewise, the psychologist, who is also an interlocutor in the interaction, adjusts her behavior in predictably ways. This work is part of a larger effort to create an automatic system for evaluating various dimensions of naturalistic social prosody. Findings support further, large-scale study of objective measures of prosody in interactions involving children with ASD.

Figure 1: Example intonation contour with corresponding Momel/Intsint modeling.

89 **107.089** Optimizing Thin-Slice Observations for Toddlers with Autism

L. H. Hampton[1,2] *and M. Roberts*[2]*, (1)Vanderbilt University, Nashville, TN, (2)Northwestern University, Evanston, IL*

Background: The Thin-Slice is a measure of behavior from using only small observations (less than 5-minutes). When multiple raters observe the same small behavioral sample, the average score is often reliable with other measures of the same construct and valid for predicting future outcomes (Slepian, Bogart & Ambady, 2014). The Thin-Slice has been used to rate a wide variety of personality characteristics and psychological outcomes such as, marital satisfaction, depression, success, and communicative ability. The Thin-Slice has only recently been applied to observations of children with autism (Walton & Ingersoll, 2015). Although a recent application of the Thin-Slice to children with autism demonstrates reliability and validity, it does not provide guidelines for achieving an optimal Thin-Slice score based on observation length and number of raters.
Objectives: The objective of the current study is to extend the current Thin-Slice work in Autism by demonstrating the optimal number of raters and optimal number of observations to determine a stable estimate of communication ability in toddlers with autism by answering the following questions. 1) Are thin-slice observations from a) a 2-minute video and b) a 2-minute audio recording from the home environment a reliable and valid for estimating communicative ability in toddlers with autism? 2) What is the optimal number of raters and 2-minute samples from a) a video and b) audio-only to achieve a stable estimate of communicative ability in toddlers with autism?
Methods: Participants include 40 2-year olds (72% male) with autism. Each child received a diagnostic assessment using the ADOS at the start of the study. Day-long audio recordings, using LENA technology, were also collected at the start of the study. Two-minute slices of assessor-child interactions from the ADOS and 2-minute slices from the LENA recordings will be used to rate the children on 6 features: communication, speech ability, engagement, play, joint attention, and imitation using a 5-point Likert scale by 10 raters. Each two-minute slice will be rated by 20 speech-pathology students, and the scores of each rater will be averaged to obtain a single score for each observation.
Results: Results from this study are ongoing. Final analysis will include generalizability estimates for each additional rater, and a decision study will estimate the optimal number raters and slices necessary to achieve a stable measure of communication ability. Reliability with other baseline communication measures will be established (naturalistic language sample, CSBS, and MCDI) as well as predictive validity to overall ADOS severity score.
Conclusions: Although this tool is highly appealing, it is necessary to provide guidelines for researchers on how to best optimize this tool and provide reliable and valid estimates. Using snap judgements to inform diagnostics in autism may a useful and important tool not only to increase research efficiency, but to potentially provide greater access to diagnosis for more children by simplifying the screening procedure. Discussion will include applications for LENA technology and the Thin-slice methodology for increasing efficiency and accuracy in estimating communication in toddlers with autism.

90 **107.090** Predictors of Speech Improvement in Minimally Verbal Children with Autism Spectrum Disorder

K. V. Chenausky[1], *A. Norton*[1] *and G. Schlaug*[2], *(1)Neurology, Beth Israel Deaconess Medical Center, Boston, MA, (2)Beth Israel Deaconess Medical Center, Boston, MA*

Background:
Of the 1 in 68 children who meet criteria for autism spectrum disorder (ASD), approximately 25% remain minimally verbal (meaning they use fewer than 20 words functionally and have no productive syntax) past the age of 5 years. Previous work has identified both child and therapy characteristics that predict growth in vocabulary and communication rate (Rogers et al. 2006; Paul et al. 2013) and expressive language (Paul et al., 2013; Yoder et al., 2015) in minimally verbal children with ASD, but to date, no research has sought to determine characteristics that predict speech acquisition in minimally verbal children with ASD.
Objectives:
In this study, we aimed to identify child characteristics that predicted response to two therapies designed to facilitate spoken language in minimally verbal children with ASD.
Methods:
Thirty minimally verbal children with ASD (four female) between the ages of 3;5 and 9;8 participated in one of two treatments. Twenty-three children (two female) received 25 sessions of Auditory-Motor Mapping Training (AMMT), an intonation-based treatment involving repetition of sung bisyllabic stimuli and simultaneous tapping on tuned electronic drums. Seven children (two female) receivedÂ 25 sessions of Speech Repetition Therapy (SRT), which involves neither intonation nor drum-tapping but is otherwise matched to AMMT. Children's Baseline responses to two sets of stimuli were transcribed, then scored for percent consonants and vowels correct and percent syllables approximately correct. Chronological age and the number of English phonemes they were able to repeat on request at Baseline were also tallied. All five Baseline measures (age, size of phonetic inventory, percent syllables approximately correct, and percent consonants and vowels correct) were then entered into a hierarchical multiple regression to predict the change score in percent syllables approximately correct.
Results:
The full model, including all five predictors, was significant, $R^2 = .534$, $F(5,24) = 5.508$, $p = .002$. In the hierarchical analysis, only Baseline phonetic inventory, Baseline percent consonants correct, and Baseline percent syllables approximately correct resulted in statistically significant increases in R^2. Examination of regression coefficients showed that size of phonetic inventory was significantly associated with increase in percent syllables approximately correct, while Baseline percent syllables approximately correct and Baseline percent consonants correct were significantly associated with decreases in percent syllables approximately correct.
Conclusions:
The positive moderating effect of phonetic inventory suggests that the ability to correctly imitate phonemes on request is an indicator for degree of improvement in the ability to produce word approximations seen after 25 therapy sessions. The negative moderating effect of baseline percent syllables approximately correct and baseline percent consonants correct suggests that previously learned word approximations may be challenging to improve upon in this amount of time. However, anecdotal observations and parent reports suggest that these children can continue to improve their speech output even after therapy ends.

91 **107.091** Problem Behaviors in Autism Spectrum Disorder: Is Communication a Specialized Adapting/Coping Mechanism?

D. L. Williams[1], *M. Siegel*[2] *and C. A. Mazefsky*[3], *(1)Communication Sciences and Disorders, Pennsylvania State University, University Park, PA, (2)Maine Medical Center - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: The inability of an individual to clearly communicate wants/needs is thought to lead to problem behaviors such as self-injurious behavior (SIB), aggression, temper tantrums, and noncompliance (Ganz et al., 2009; Hartley et al., 2008). Even though a number of studies support the association between problem behaviors and language/communication skills in children with autism spectrum disorder (ASD), this has not been a universal finding (e.g., Chiang, 2008). Problem behaviors have also been characterized as "coping behaviors" (Groden et al., 1994), meaning they are not necessarily externally-directed communication but are responses to perceived increases in undesirable physiological reactions. According to this framework, development of a more appropriate means of communication would be considered as establishing a specialized adapting/coping mechanism (Ladd, 2007).
Objectives: Data from the Autism Inpatient Collection (AIC) was used to examine the proposal that communication is a specialized adapting/coping behavior with the related expectation that measures of socially-acceptable coping skills would be inversely related to the frequency of problem behaviors and would be more predictive of the severity and frequency of problem behaviors than communication ability.
Methods: Participants were 346 psychiatric inpatients with ASD supported by research-reliable ADOS-2, divided into verbal-ability groups based on their required ADOS-2 module [169 minimally-verbal (MV; Modules 1 and 2) and 177 fluently-verbal (FV; Modules 3 and 4)], aged 4 to 21-years [MV Mean = 13.0 (SD 3.7); FV Mean = 12.8 (SD 2.8)]. Dependent measures included the *Repetitive Behavior Scale-Revised*, *Aberrant Behavior Checklist* Stereotypy and Irritability subscales, and *Vineland Adaptive Behavior Scale-II* Externalizing subscale (VABS-II). Independent measures, in addition to verbal ability category and age, included NVIQ (*Leiter International Performance Scale – Third Edition*), and VABS-II Adapting/Coping subdomain (30-item scale including items such as manners, adherence to rules, and flexibility; higher scores indicate greater ability to flexibly adapt to environmental demands.) ANCOVA was used to compare the mean of problem behavior severity for each dependent variable between MV and FV participants with NVIQ and age as covariates. A series of hierarchical linear regressions were conducted to determine the incremental explanatory power of each independent variable, which were entered separately in their own step, in the following order: age, NVIQ, verbal ability, and VABS Adapting/Coping.
Results: The severity of SIB, stereotyped behavior, and irritability (including aggression and tantrums) did not significantly differ between MV and FV, when controlling for age and NVIQ. Adapting/coping was a significant predictor in every regression model, accounting for a significant amount of variance above and beyond age, NVIQ, and verbal ability. Lower adapting/coping scores were associated with greater problem behaviors. Verbal ability accounted for an additional 21.3% of the variance in Externalizing problems above and beyond age and NVIQ IQ, but it did not account for a significant amount of additional variance for any other problem behavior.
Conclusions: Increasing severity of each type of problem behavior was significantly associated with lower adapting/coping scores, even when accounting for verbal ability. Interventions may need to focus on the development of adapting/coping mechanisms to mitigate problem behaviors in individuals with ASD.

92 **107.092** Qualitative Differences of Joint Focus of Attention Between Korean-Speaking Toddlers with Autistic Spectrum Disorder and Toddlers with Developmental Disabilities

*K. S. Lee[1], Y. J. Shin[2], **G. J. Lee**[3], K. A. Lee[4], J. Ryu[5] and S. W. Cho[6], (1)Rehabilitation, Hanshin University, Seoul, Korea, Republic of (South), (2)Psychiatry, Yonsei University Health System, Seoul, Korea, Republic of (South), (3)Rehabilitation, Hanshin University, Osan-si, Korea, Republic of (South), (4)Special Education, Dodakim Child Development Center, Seoul, Korea, Republic of (South), (5)Cognitive Psychology, Yonsei University, Seoul, Korea, Republic of (South), (6)English Literature & Linguistics, Sogang University, Seoul, Korea, Republic of (South)*

Background: It has been reported in the literature that children with autistic spectrum disorder (ASD) share a number of features with other children with developmental disabilities (DD), involving difficulty with joint focus of attention (JFA). As well known, impaired JFA may affect more advanced communication skills.
Objectives: The present study aims at investigating the complexity of child JFA behaviors in toddlers with ASD as compared with those with DD in terms of dyadic and triadic joint interactions. Participants were forty-five in total, composed of twenty-eight Korean-speaking children with ASD (27 males and 1 female, M=30.6 months, CA range=21-37 months, SD=4.5 months) and seventeen Korean-speaking children with DD (14 males and 3 females, M=31.4 months, CA range=13-39 months, SD=6.4 months). For the purpose of this research, dyadic JFA is defined as acts of exchanging facial expressions and of pointing and showing behaviors, triadic JFA being marked by the individual coordinating their attention back and forth between himself and the other individual after looking at the same object in one activity.
Methods: Each of 45 mother-child dyads was observed during a 10-minute videotaped free-play session in a sound-proof lab designed for child study provided with a standardized set of toys such as a doll, cars, trucks, a spinner, books, and stuffed animals. The parent was instructed to respond naturally when the child was seeking an interaction. The video segments of mother-child interactions were transcribed and coded verbatim in CHAT modes by trained students and coders for three main categories of utterances (verbal, non-verbal, and vocative) and two types of interactions (dyadic and triadic), and CLAN was performed for final results to be obtained.
Results: Data analyses showed that there were no statistically significant quantitative differences between the children with ASD and those with DD regarding the JFAs expressed in all three main categories, verbal, nonverbal, and vocative utterances, while the number of JFAs was greater than that of Non-JFAs in both groups. Qualitative differences between them, however, emerged with respect to the JFAs across the three main categories. No statistically significant difference was found between the two groups as far as dyadic interactions were concerned. Importantly, on the other hand, the two groups differed statistically significantly regarding the triadic JFAs across the three main categories (verbal 4.93(SD=10.0) vs. 3.24(SD=6.43), $t(43) = 2.179$, $p = .036$; non-verbal 14.79(SD=15.47) vs. 26.0(SD=20.29), $t(43) = -2.094$, $p = .042$; vocatives 1.36(SD=3.06) vs. 3.47(3.09), $t(43) = -2.241$, $p = .030$).
Conclusions: Overall, our results are noteworthy in that children with ASD were significantly different from and more impaired than those with DD in triadic JFAs, but not in dyadic JFAs. This finding is extremely important in two respects. It supports previous research on prominent impairment of JFAs in children with ASD and with DD. It further provides an insight into the ongoing research on the development of JFA in ASD and DD toddlers, suggesting that they should be differentiated on rather specific terms involving qualitative differences of JFAs, in particular.

93 **107.093** Receptive and Expressive Language Skills and Non-Verbal Cognitive Abilities Among Preschool-Aged Autistic Children with Delayed Expressive Language

***C. Letendre**[1], V. Courchesne[1], D. Girard[2], I. Soulières[3], L. Mottron, M.D.[4] and C. Jacques[5], (1)University of Montreal, Montreal, QC, Canada, (2)Université du Québec à Montréal, Montreal, QC, CANADA, (3)University of Quebec in Montreal, Montréal, QC, Canada, (4)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada, (5)University of Quebec in Outaouais, Gatineau, QC, Canada*

Background: A DSM-5 autism spectrum diagnosis requires specifying the co-occurrence of language impairment. Considering the gap between receptive and expressive language skills, the APA recommends a separate assessment of these subdomains (APA, 2013). Contrary to typically developing (TD) children, receptive language is usually lower than expressive language in autistic children (Maljaars et al., 2012). Nevertheless, it is sometimes anecdotally reported that some school-aged autistic children demonstrate relatively good receptive skills, despite their low expressive skills (Kasari et al., 2013). Little is known however about receptive versus expressive language skills at preschool age in autistic children. Furthermore, as non-verbal cognitive abilities are a well-documented predictor of language outcomes (Luyster et al., 2008; Thurm et al., 2007), documenting both expressive and receptive language in relation to other important developmental domains such as non-verbal cognitive skills could lead to a better understanding of language development in autism.
Objectives: 1-To compare the differences between expressive and receptive language in preschool-aged autistic and TD children. 2-To compare differences between expressive and receptive language between autistic children with and without delayed expressive language. 3-To compare preschool-aged autistic children with and without delayed expressive language on non-verbal cognitive abilities.
Methods: 53 autistic and 38 TD preschoolers aged from 31 to 78 months (autistic children: M=51.70, SD=12.26; TD children: M=48.73, SD=11.5; p=.25) were assessed with the Vineland Adaptive Behavior Scales (VABS). Autistic children were classified in the delayed expressive language group (DL) (n=27) if their VABS expressive language score was below the second percentile and in the non-delayed expressive language group (NDL) (n=26) if their score was in the normal range (≥2nd percentile). DL and NDL autistic groups were matched on age (p<.89). A subgroup of 29 autistic children (DL: n=12; NDL: n=17), matched on age (p=.05), completed the Raven's Color Progressive Matrices (Board form) (RCPM).
Results: Â A significant interaction was found between group and expressive/receptive language (p<.05). Autistic children had a significantly higher level of receptive language compared to their level of expressive language on the VABS (p<.001) while no difference was found between the two subscales in the TD group (p=.23). Furthermore, when comparing DL and NDL autistic children, only a main effect of type of language was found (p<.001), thus indicating that receptive language was higher than expressive language in both DL and NDL groups. Finally, DL and NDL groups did not differ on RCPM scores (p=.58).
Conclusions: Â Whereas TD preschoolers exhibited similar receptive and expressive language skills, autistic preschoolers were characterized by significantly higher receptive than expressive skills. Indeed, language comprehension seems to outdo language production in autistic preschoolers, regardless of their level of expressive language. Furthermore, despite their greater delay in expressive language, DL children performed as well as NDL children on the RCPM, a non-verbal measure of fluid reasoning. These results suggest that each developmental domain has to be documented separately in autistic preschoolers to have a good representation of their skills.

94 **107.094** Relationships Between Auditory Brainstem Responses and Early Language in Typically-Developing Children and Children with Autism Spectrum Disorders

C. N. Meagher[1]*, V. Tecoulesco*[2]*, L. R. Naigles*[3]*, M. Jones*[4]*, M. Figueiredo*[5]*, E. Skoe*[6] *and D. A. Fein*[7]*, (1)Developmental Psychology/Speech, Hearing, and Language Sciences, University of Connecticut, Willington, CT, (2)Psychology, University of Connecticut, North Windham, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Developmental Psychology/Speech, Language, and Hearing Sciences, University of Connecticut, Storrs, CT, (5)Speech, Language, and Hearing Sciences, University of Connecticut, Willington, CT, (6)Speech, Language, and Hearing Sciences, University of Connecticut, Storrs, CT, (7)University of Connecticut, Storrs, CT*

Background: The neurological underpinnings of language in Autism Spectrum Disorders (ASD) have long been sought, both to shed light on possible causes of its complex and multi-faceted behavioral presentation, and to identify targets for intervention.Â Our project explores whether abnormalities in language development can be attributed to disruptions at an early stage of auditory processing, namely the auditory brainstem. Recent research has suggested that instability in the nervous system's response to sound, as revealed by comparisons between initial and later test trials of the auditory brainstem response (ABR), and earlier ABR latencies, might be characteristic of children with lower language skills (Hornickel et al., 2013; Skoe et al., 2013).
Objectives: We collect ABRs in school-age children with ASD and typically developing (TD) children, whose early language development has been documented in rich detail (Tek et al., 2014; Naigles & Chin, 2015).Â We investigate the relationship between the ABRs and earlier language measures.
Methods: Fifteen children (one girl) were tested for ABRs; seven had been diagnosed with ASD (*M*Age=11.25) and eight were TD (*M*Age=11.14).Â At their most recent assessment, group average NVIQs were 74.00(ASD) and 102.75(TD); TACL-Q language scores were 73.71(ASD) and 123.63(TD), and ADOS Calibrated Severity Scores were 6.43(ASD) and 1(TD). The children had participated in four mother-child play sessions when they were between 2 and 4 years; the language measures were drawn from their transcripts.Â ABRs were recorded from scalp electrodes in response to a click stimulus (31.1/sec, 2000 trials) and a 40 millisecondÂ "da" stimulus (10.9/sec, 6000 trials) presented at 80 dB SPL to the right ear.Â The latency of Wave V (the most robust peak within the ABR), plus Click and /da/ response stability (Fisher transformed Pearson's r-values), served as the primary dependent measures of sound encoding.
Results: Although the TD children showed numerically faster Wave V latencies than the children with ASD, t-tests revealed no significant differences between the groups on any ABR measure.Â Bivariate correlations including both groups revealed that children who had produced a higher proportion of utterances with nouns during early language development displayed more consistent ABRs, to both the click and /da/ stimuli (*r*s > .54, *p*s < .05), even when age was covaried (see Figure 1). Moreover, children who had produced a higher proportion of utterances with the progressive –ing in their earliest language sample also displayed more consistent ABRs to the click stimulus (r = .525, p = .045). Finally, children's TACL scores were significantly and independently predicted by their ADOS scores (β=-.681, p =.001) and their /da/ consistency (β= .352, p = .039).
Conclusions: Our procedures for collecting ABR data at home from school-age children with ASD yielded waveforms that resembled those collected in lab settings.Â Although group differences were not observed in this small sample, significant correlations across the entire dataset revealed that children who had displayed more advanced language early in development showed more stable neural responses to sound during school age, supporting links between early lexical and grammatical development and sound processing in the auditory brainstem.

95 **107.095** Scatter: Quantifying a Qualitative Vocabulary Difference in Adults with ASD

M. E. Stothers[1] *and J. Oram Cardy*[2]*, (1)University of Western Ontario, London, ON, Canada, (2)Western University, London, ON, Canada*

Background: Semantic emptiness and odd or imprecise use of vocabulary, in combination with accurate use of unusual words, have been reported in adults with ASD who do not also have language impairment. Such features are not captured by total scores on standardized vocabulary tests, but might be captured by item *scatter*. A scattered or inefficient pattern of responses occurs when early test items are missed and later items are defined correctly, in contrast to a gradual decrease in scores as items become progressively more difficult to define. Scatter is thus consistent with the coexistence of semantic errors and sophisticated word use that has been informally observed in ASD.
Objectives: Whether the uneven quality of vocabulary use in ASD could be quantified using an alternative scoring method of standardized tests was explored here. If adults with ASD demonstrated more scatter in their pattern of responses on a vocabulary test as compared with controls, the result would support observations that have been made both in ASD case studies and in the present sample (Stothers & Oram Cardy, 2016). No significant difference by group in total mean scores for expressive vocabulary was expected. The ASD group was expected to have a significantly higher Scatter score than the control group.
Methods: Adults aged 19–44 years completed the Vocabulary subtest of the Wechsler Abbreviated Scale of Intelligence (WASI), with 21 participants in both the ASD and Control groups (N = 42). Two scoring methods were used. The conventional method followed the WASI scoring protocol. In the Scatter method, original scores of 0 or 1 were coded as failed, and scores of 2 as passed. Item weights were calculated as the percentage of control participants who passed the item. Scatter was equal to the sum of the weights of the items that participants missed, multiplied by the peak item answered correctly.
Results: Â Hypotheses were supported. Group means were not significantly different for the total Vocabulary score, t (40) = .35; p = .78, with a negligible effect size, d = .11. All scaled scores were within or above the average range in both groups. The ASD group had a significantly higher Scatter score than the control group, t (24) = 2.40; p = .02, with a moderate to large effect size, d = .72.
Conclusions: Qualitative differences previously reported for this sample were captured by a quantitative measure. Scatter was shown to be an effective measure of difference, separating the control and ASD groups in the context of equivalent overall scores for Vocabulary. Results supported using this method, in addition to the standard scoring protocol, to more sensitively characterize performance of individuals with ASD without language impairment on standardized tests of word knowledge.

96 **107.096** Second-Order False Belief Reasoning, Recursive Language Competencies and Working Memory in Children with ASD

I. Polyanskaya[1]*, P. Blackburn*[2] *and T. Braüner*[2]*, (1)Roskilde University, Roskilde, DENMARK, (2)University of Roskilde, Roskilde, Denmark*

Background: Second-order (SO) false belief (FB) competency is an important component of Theory of Mind (TOM). In first-order ToM development, links between language and false belief reasoning have been firmly established and proposed as potential factors in explaining the success of children with ASD who succeed on TOM tasks. However, SOFB development is less studied, and the links between language and SOFB reasoning, as well as the potential developmental role of language, remain unclear.
Objectives: We investigate the relationship of SOFB and several language measures, and in particular, whether competency in linguistic recursion (sentential complements) predicts the ability to reason about other's SOFBs. In addition, we investigate the role of working memory in SOFB development.
Methods: The sample consists of Danish speaking children with ASD without ongoing language delays and with working memory within the normal range. Four types of standard SOFB tasks are given. The standardized language measures include the Verbal Comprehension index from WISC-IV and TROG. Linguistic recursion is investigated using a new Danish language tool that measures comprehension of sentential complements. The tool was developed and validated for this study (Cronbach's alphas 0.56). Working memory is measured by the working memory index from WISC-IV. We are using these measures in an ongoing correlation study. To date, 18 children with ASD, with mean age 12.61 (SD = 3.07), have been tested. ASD was diagnosed by psychiatrists, using the ICD-10 criteria.
Results: Â The Pearson correlation analyses of the three language measures and working memory against three types of dependent variable yielded the following findings: Total SOFB correlates with Verbal Comprehension (r=.482, p=.043) and Working Memory (r=.598, p=.009). SOFB without justification correlates with Verbal Comprehension (r=.641, p=.004), Grammar comprehension (r=.558, p=.016) and Working Memory (r=.621, p=.009).Â Justification-only correlates with working memory (r=.571, p=.006) but none of the language measures.
Conclusions: First, the correlational analysis suggests that verbal concept formation skills (which are influenced by semantic knowledge) are related to SOFB reasoning. However this is not the case for syntactic skills, whether general grammar or recursive sentential complements comprehension. This result points to the influence of semantic and conceptual aspects of language, which are sometimes referred to as "tool for thinking". Furthermore, our correlation data suggests that justification responses cannot be accounted for by language skills, and therefore does not support the claim that language plays an expressive role in SOFB reasoning. Second, the correlational analysis suggests that working memory is related to SOFB reasoning, including justification skills, and thus provides further support to "the complexity-only position" (Miller 2009), claiming that information processing skills predict SOFB development. By the time of IMFAR 2017 the size of our sample will enable us to draw conclusions about how much of the variation can be explained by relative contribution of each language measure and working memory based on multiple regression analysis.
Miller, S. A. (2009). Children's understanding of second-order mental states. *Psychological bulletin*, *135*(5), 749.

97 **107.097** Semantics Is Importantly Significant: An Investigation into Lexical Errors in ASD

E. Zane*, J. Mertens, W. J. Lancaster, A. Chugg and R. B. Grossman, FACE Lab, Emerson College, Boston, MA*

Background: Â There is evidence to suggest that language impairment and autism spectrum disorder (ASD) are separable conditions (Tager-Flusberg, 2006; Rapin et al., 2009). Accordingly, the Diagnostic Statistical Manual no longer includes language impairment as a necessary component of an ASD diagnosis (APA, 2013). However, children with ASD who have good language skills still struggle with some aspects of semantics (Dunn et al., 1996; 1997). Semantic impairments have also been noted in "optimal-outcome" children, i.e., children previously diagnosed with ASD whose social communication skills had improved enough to move them out of the ASD range (Kelley et al., 2006). As yet, it is unclear what types of semantic errors children with ASD produce and whether issues with semantics in children with ASD persist through adolescence or are instead evidence of delayed acquisition in younger children.
Objectives: Â To identify and categorize the semantic errors of children (ages 11-17) with ASD in order to determine an impact of ASD diagnosis on later stages of semantic language development.
Methods: Â Preliminary results are based on ten adolescents with ASD (2 females, ages 11-17) and twenty typically-developing controls (8 females, ages 10-16). Groups were not significantly different on language ability as measured by the CELF-5 (ASD *M* = 114, TD *M* = 115; p = 0.9). Participants were audio-recorded as they interviewed a researcher. We transcribed recordings and coded them for semantic errors, defined as moments when an utterance's meaning was unclear and/or redundant.
Results: Â Error frequency: All participants with ASD produced at least one semantic error, and participants with ASD produced more semantic errors on average than their TD peers (ASD *M* = 7, TD *M* = 2; p < 0.05).
Error types: Participants with ASD misused words and produced neologisms (e.g., "mosquito nicked me"; "electroids"). They also made "lexical disinhibition errors," by producing lexical neighbors, i.e. semantically related words, that were inappropriate to sentential semantics (e.g., "...was large and huge"; "[I see] family, friends, resemblance"). Word-choice errors were rare in the TD group; lexical disinhibition errors were not present.
Conclusions: Â Even though both groups' language scores fell within normal bounds on the CELF-5, adolescents with ASD produced more semantic errors than their TD peers during spontaneous speech, indicating that the ASD group has a subtle semantic impairment that is not captured by traditional language tests.
The types of errors produced by participants with ASD (incorrect word choices and strings of unnecessary lexical neighbors) suggest particular impairments in *lexical* semantics. Disinhibition errors have not previously been described as a feature of language in ASD; they indicate dysfunctional lexical access, which could be caused by executive dysfunction. Future research should explore whether and how lexical disinhibition contributes to semantic impairments in ASD and how these errors affect communicative effectiveness during conversation.

98 **107.098** Sensory Abnormalities Impact on Language Ability in Autism Spectrum Disorder

A. Whitten[1] *and J. W. Bodfish*[2]*, (1)Hearing & Speech Sciences, Vanderbilt University, Nashville, TN, (2)Vanderbilt University School of Medicine, Nashville, TN*

Background:
Sensory abnormalities have been found to be highly prevalent in children and adults with autism spectrum disorder (ASD). These manifest as a hypoactive response to sensory input (reduced or absent response), hyperactive response (increased or excessive response), or sensory seeking behaviors (craving or fascination with certain sensory experiences). Research has shown that these sensory disturbances appear early in development, yet it is not clear whether they exert cascading effects on higher cognitive processes like language ability.
Objectives:
We aimed to investigate the relationship between severity of sensory disturbances in children and adolescents with ASD and language ability across both structural and pragmatic language domains. In addition, we were interested in whether language ability is impacted by the type of sensory abnormality (i.e., hyporesponsive, hyperresponsive, or sensory seeking).
Methods:
We used a short sensory questionnaire (Boyd, McBee, Holtzclar, Baranek, & Bodfish, 2009) to create subgroups based on overall sensory severity, and the presence of hyporesponsive, hyperresponsive, and sensory seeking behaviors in a sample of 68 children and adolescents with ASD (mean age: 10.6 years, range 5.9 – 17.9 years; mean IQ: 95.6, range 40-139; 10% female). To examine the relationship between sensory features and language ability, we used Mixed Model ANOVAs to compare the sensory subgroups on their mean subscale scores on the Children's Communication Checklist-2 (*CCC-2*; Bishop, 2003). The *CCC-2Â* is a parent report measure of language functioning with eight subscales including both structural aspects of language (e.g., 'Syntax,' 'Semantics') as well as pragmatic aspects (e.g., 'Use of Context,' 'Nonverbal Communication').
Results:
Children and adolescents with ASD in the high severity sensory subgroup were found to have significantly more impaired language scores compared to the low severity sensory subgroup ($F(1, 46) = 10.2$, $p < .001$) on all *CCC-2* subscales except 'Nonverbal Communication' ($p = .110$). When grouped by the presence of hyporesponsive sensory behaviors, no significant differences were found on language scores between groups ($F(1, 66) = 2.58$, $p = .113$). However, when grouped by the presence of hyperresponsive behaviors, there was a significant main effect of group ($F(1, 66) = 4.6$, $p < .05$), with the hyperresponsive group demonstrating more impaired scores on 'Semantics' and 'Use of Context.' Similarly, the sensory seeking group showed significantly more impaired scores on the 'Syntax' and 'Semantics' subscales compared to individuals without sensory seeking behaviors ($F(1, 66) = 5.88$, $pÂ < .05$).
Conclusions:
Our results suggest that the sensory abnormalities seen in ASD may have downstream effects on both structural and pragmatic language ability, demonstrated by the finding that individuals with more severe sensory scores showed significantly worse language scores. In addition, the type of sensory disturbance may differentially affect aspects of language, with hyperresponsive and sensory seeking behaviors having a greater impact on language ability.

99 **107.099** Sentence Repetition and Nonword Repetition As Markers of Structural Language Impairment in ASD

S. Silleresi[1]*, L. Tuller*[2]*, P. PrÃ©vost*[3]*, S. Ferre*[2]*, R. Zebib*[2] *and F. Bonnet-Brilhault*[4]*, (1)Linguistics, Université François Rabelais de Tours, Tours, FRANCE, (2)Université François Rabelais de Tours, Tours, France, (3)Université François Rabelais, Tours, France, Tours, FRANCE, (4)UMR930, INSERM, Université François –Rabelais de Tours, Tours, France*

Background: The nature of linguistic profiles in ASD remains unclear: many children show structural language abilities similar to typically developing age-peers (TD), others display deficits like those in Specific Language Impairment (SLI) (Leyfer et al., 2008; Lloyd et al., 2006; Loucas et al., 2012; Tuller et al. 2016; Zebib et al., 2013). There is consensus from work on SLI that the most sensitive tools for detecting structural language impairment are Sentence Repetition (SR) and Nonword Repetition (NWR) (Conti-Ramsden et al., 2001). Previous studies using these tools in ASD suggested that low performance is due to low nonverbal level and/or severity of ASD symptoms (Harper-Hill et al., 2013; Williams et al., 2013, a.o.). These studies focused on adolescents and high-functioning individuals, and the specific NWR/SR tasks used contained few structures, and had predominant memory components (Riches et al. 2010, 2011; Whitehouse et al., 2008).
Objectives: With the aim of investigating structural language abilities across the spectrum, we used two experimental tasks, SR and NWR, both linguistically based, targeting structures of increasing complexity that are difficult for children with SLI. We sought to determine whether children with ASD and impaired language (ASD-LI), perform analogously to children with SLI, and whether children with ASD and normal language (ASD-LN), perform like TD children, independently from nonverbal level and ASD severity.
Methods: 15 French-speaking children with ASD (data processing for 10 additional children in progress) aged 7–11;8 (M 9;1, SD *1;9*) were administrated the SR and NWR tasks. Children varied in ASD severity (ADOS range: 4–10) and nonverbal cognitive level (WISC IRP range: 38 - 119). Standardized expressive and receptive language scores revealed children with ASD-LI (7) and children with ASD-LN (8). Comparison groups included 15 children with SLI (data for 10 additional children to be processed) aged 6;1–8;5 (M 7;6; SD *0;4*) and 73 TD children aged 4;0–8;9 (to be completed).
Results: The ASD-LI group performed analogously to the SLI group both, on SR (p=.972) and NWR (p=.084), while the ASD-LN group performed similarly to TD children on SR (when compared to TD 7-8, p=.126) and NWR (when compared to TD 5-6, p=.156). ASD-LI performed significantly worse than ASD-LN on both SR (p=.002) and NWR (p=.019).Â In the whole ASD group, a significant correlation was found between performance on SR and NWR (r_s=.575; p=.025) and between each repetition task and a composite standardized language score: SR (r_s=.890; p= .000) NWR (r_s=.643; p=.010). No significant correlations were found between SR and ADOS (r_s=-.186; p=.543) or SR and IRP scores (r_s=.513; p=.061) and between NWR and ADOS (r_s=-.450; p=.122)Â or NWR and IRP scores (r_s=.189; p=.517). No significant correlation was found between either task and age (SR, r_s=.176; p=.531; NWR, r_s=.477; p=.072).
Conclusions: Our study shows the validity of linguistically based SR and NWR tasks as markers of structural language deficits in children with ASD. Furthermore, it found that the LI/LN distinction in ASD cuts across both nonverbal abilities and ASD severity, suggesting that language can be independent in verbal ASD.

100 **107.100** Social Communication Outcomes for Young Children with Autism: A Meta-Analysis

E. Fuller *and A. Kaiser, Vanderbilt University, Nashville, TN*

Background:
Deficits in social communication are a core feature of autism spectrum disorder (ASD) and are correlated with long-term language and communication outcomes (Mundy, Sigman, & Kasari, 1990; Sigman & Ruskin, 1999). As a result, improving social communication is the focus of many early interventions for children with ASD. Understanding the effectiveness of these early intervention is critical to implementing, evaluating, and improving widespread treatment plans for children with ASD.
Objectives:
The objectives of this meta-analysis were to answer the following questions: (1) Are early interventions effective at increasing social communication for young children with ASD? And, (2) do the effects of intervention differ depending on the dose of intervention, the person administering the intervention, or the age of the participants?
Methods:
A systematic review of the literature returned a total of 1,624 articles that were reviewed for inclusion. Studies were included if the study: (a) enrolled participants with ASD younger than 9, (b) used a group design that included a business-as-usual comparison group, (c) implemented a behavioral intervention that did not include a pharmacological component, (d) reported a pre-post outcome measure of social communication, and (e) was published in English.
Results:
A total of 21 studies met inclusion criteria. A standardized mean difference effect size estimate was used to account for the heterogeneous measures used across studies. A total of 996 participants were included in the analysis: 552 intervention participants and 444 control participants. The mean age of the participants was 3.34 years. The random effects model aggregated the effect sizes for an overall effect size of .521 (p-value < 0.001). These findings suggest that children in early interventions showed significantly higher initiations of social communication than children in control groups. Moderator analyses indicated that the length of intervention was not a significant moderator of outcomes (=0.02, p=0.570). Age of the participants significantly moderated outcomes, such that an increase of one year of age predicted an increase in the effect size of 0.289 (p=0.041); suggesting that older children benefitted more from the treatment. Lastly, a subgroup analysis examined the effect of the person who delivered the intervention. The largest effects were shown when the intervention was delivered by researchers (ES=1.206, Q=1.84, I^2=0%), followed by teachers (ES=0.391, Q=2.14, I^2=6.5%), a combination of researchers and parents (ES=0.373, Q=13.6, I^2=70.6%), parents alone (ES=0.321, Q=17.56 I^2=60.1%), and finally a combination of parents and teachers (ES=0.048, Q and I^2cannot be determined from one study). The only effect size that was not statistically significant at the 0.05 level in this subgroup analysis was in the case of parents and teachers as interventionists together; however, this finding is from only one study.
Conclusions: This meta-analysis indicated positive effects of early intervention on social communication for young children with ASD. An effect size of 0.521 immediately after intervention for this population characterized by deficits in this area is a notable increase. It is particularly important given the long-term benefits of social communication behaviors. Limitations of the study and implications for research and practice will be discussed.

101 **107.101** Social Communication in High School Students on the Autism Spectrum: Examining Profiles, Correlations, and Subgroups

J. Dykstra Steinbrenner[1]*, J. Sideris*[2] *and S. W. Nowell*[3]*, (1)Frank Porter Graham Child Development Institute, Carrboro, NC, (2)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (3)University of North Carolina - Chapel Hill, Chapel Hill, NC*

Background: Although all individuals with ASD have social-communication impairments, their social-communication profiles can be quite varied. A deeper understanding of social-communication characteristics and how those relate to other skills and behaviors may be helpful in tailoring intervention approaches for individuals with ASD. This knowledge could also support identifying successful pathways for community involvement and employment in the transition to adulthood. This study will examine relationships between cognitive, academic, social, adaptive, and communication skills in a large sample of high school students on the autism spectrum (n= 545) and explore potential subgroups related to social-communication skills using latent-profile analysis.
Objectives: The objectives of this study are (1) to examine the social-communication profiles of high school students with ASD, (2) to explore subgroups of high school students with ASD in relation to receptive and expressive communication, interpersonal skills, and social abilities, and (3) to examine relationships of social-communication skills with other skills and behaviors (e.g., IQ, adaptive functioning, social participation).
Methods: The participants included a sample of 545 adolescents with autism from 60 high schools in three states from the larger Center on Secondary Education for Students with Autism Spectrum Disorders (CSESA) study. Social-communication profiles were examined using three Vineland subdomains (receptive communication, expressive communication, and interpersonal relations) and the Social Responsiveness Scale (SRS-2). Other characteristics that were examined included: non-verbal IQ (Leiter-3), adaptive functioning (Vineland), and academic performance (Woodcock-Johnson-III). Additionally, the research team collected parent and teacher report of social behaviors and skills.
Descriptive statistics were used to examine the social-communication profiles. The subgroups were explored using latent-profile analysis (LPA), a person-centered analytic method that seeks to subset the members of a sample into smaller more homogeneous profiles. Correlations were used to examine relationships of social-communication characteristics with other characteristics and behaviors.
Results:
The adolescents exhibited a wide range of social-communication characteristics on the Vineland subdomains and SRS-2 (see Table 1). The LPA results indicated three subgroups. Subgroup 1 was low on all Vineland scores and high on the SRS-2; subgroup 2 was in the middle on the Vineland subdomains and the SRS-2; and subgroup 3 was high on the Vineland subdomains and low on the SRS-2. Correlations (see Table 2) revealed that communication characteristics (receptive and expressive) tended to have stronger relationships than the social characteristics (interpersonal relations and SRS-2) with cognitive and academic measures. Further, the social characteristics tended to have stronger correlations with parent and teacher reported social behaviors compared to communication characteristics.
Conclusions:
Adolescents in this sample demonstrated a very wide range of social-communication skills. However, the three groups identified by the LPA appear to represent different ranges of ability on the spectrum of social-communication rather than distinct subgroups. Results indicate that social characteristics of adolescents with ASD are more strongly associated with peer interaction and social participation than communication characteristics; therefore, interventions may need to focus more on social skills. Our results also show a relationship between technology and social-communication skills, which may support technology use during treatment. Clinical implications and alternate conclusions will be discussed.

102 **107.102** Social Impairment in Conversation: Disfluency and Compensatory Mechanisms

R. Fusaroli[1], *A. Lambrechts*[2], *E. Weed*[3], *K. L. Maras*[4], *K. Yarrow*[5], *D. M. Bowler*[6] *and S. B. Gaigg*[6], *(1)Aarhus University, Aarhus, DENMARK, (2)City University London, Ruislip, UNITED KINGDOM, (3)Aarhus University, Beder, DENMARK, (4)University of Bath, Bath, UNITED KINGDOM, (5)City University London, London, United Kingdom, (6)Psychology, City, University of London, London, United Kingdom*

Background: Social impairment is a defining clinical feature of ASD. However, little is known about how it concretely unfolds during social exchanges: how interlocutors pick up and react to disfluency, and how patterns of interaction are affected. A better understanding of the dynamics of interactions with adults with ASD will help us understand how social impairment affects the life of people with ASD and which compensatory mechanisms can be used to minimize its effects.
Objectives: We want to develop automated quantitative methods to assess dysfluency and compensatory dynamics in conversation. Using simple measures of conversational turn-taking, we ask the following questions: i) How does autistic social impairment manifest itself in conversations? ii) How does the interlocutor react? iii) Are these dynamics related to specific clinical features?
Methods: 17 ASD and 17 matched Typically Developing (TD) adults were interviewed about the details they could recall of a standardised event they had participated in. Time-coded transcripts were used to calculate turn duration, inter-turn latency, number of turns for each interlocutor and percentage of spoken time in the conversation produced by the interviewee. Mixed effects models were employed to assess the relationship between these measures and diagnosis in interviewer and participants. Finally, we assessed whether participant behavior would predict the interviewer's behavior.
Results: Participant's Behavior: There was no main effect of ASD in turn duration or inter-turn latency ($p>0.7$), but significant interaction with time: TD participants increased their turn duration over time, while participants with ASD did not (Beta= -0.13, SE=0.04, p=0.003), an effect modulated by the ADOS Communication scores as well (Beta=-0.03, SE=0.015, p=0.036). Inter-turn latency increased less over time for ASD than for TD participants (Beta=-0.01, SE=0.005, p=0.03). Severity of clinical features did not affect inter-turn latency. Interviewer's Behavior: The interviewer did not show any effect of diagnosis in contributions' length and interturn latency, but provided more turns per unit of time in conversations with participants with ASD (Beta:0.26, SE=0.05, $p<0.001$), with a median time between turns of 5.4 seconds, against 9.75 seconds with TD participants. This effect was predicted by the participant's inter-turn latency (Beta=1.4, SE=0.4, p=0.0007) and turn duration (Beta=-2.4, SE=0.64, p=0.0002), but did not interact with diagnosis ($p>.3$). This might also explain why the amount of information provided by the participants was not affected by diagnosis (Beta=-0.06, SE=0.03, p=0.07) or severity of clinical features ($p>0.5$).
Conclusions: Using simple turn-taking measures, we observe clear compensatory dynamics at work in the interviews. The more disfluency is displayed in the participant, the more the interviewer provides scaffolding. Future work will investigate whether these effects are modulated by practice and context, and how they affect the success of the interactions and the experience of the participants.

103 **107.103** Social and Communication Subtypes in Autism Spectrum Disorders (ASD) without Intellectual Disability (ID)

S. Rau[1], *G. Wallace*[2], ***D. Limon***[3], *L. G. Anthony*[3], *A. C. Armour*[4], *B. Orionzi*[5] *and L. Kenworthy*[3], *(1)Children's National Health System, Rockville, MD, (2)The George Washington University, Washington, DC, (3)Children's National Health System, Washington, DC, (4)Children's National Medical Center, Washington, DC, (5)University of Minnesota Medical School, Minneapolis, MN*

Background: Individuals with ASD without ID have been understudied relative to their lower functioning counterparts even though they comprise a large proportion of those with ASD. Social and communication symptoms are particularly valuable areas of study within this population as previous research has established impairments in these areas predict functioning across multiple domains. While individuals with higher functioning ASD manifest social/communication symptoms heterogeneously, prior research using person-centered approaches (e.g., latent class analysis [LCA], cluster analysis) has demonstrated homogenous subgroups exist within this context of variability, and can be been used to predict diagnostic presentation and language development. Previous work utilizing these approaches indicates derived classes differ on age, intellectual functioning, adaptive functioning, and ASD symptomatology, though these studies were primarily done in samples with ID and/or language impairment. The present study uniquely contributes to the literature by examining social/communication impairments in a sample with ASD without ID.
Objectives: Employ an exploratory approach by using LCA to examine subtypes of social/communication symptoms in a sample with ASD without ID. Determine the variables on which derived classes differ from one another.
Methods: Participants included 367 individuals (307 males, 60 females) with ASD without ID who were verbally fluent and ranged in age from 4-28 years. Scores from 20 overlapping items in Modules 3 and 4 of the Communication and Reciprocal Social Interaction sections of the Autism Diagnostic Observation Schedule (ADOS) were used in an LCA; derived subgroups were compared on ASD symptomatology, demographic variables, intellectual functioning, and adaptive functioning.
Results: A three-class solution fit the data well and was conceptually meaningful. Classes 1, 2, and 3 comprised 43%, 29%, and 28% of the study sample, respectively. Classes significantly differed on ASD symptomatology, age $F(2,361)=12.40$,$p<.001$, full scale IQ $F(2,359)=10.37$,$p<.001$, verbal IQ $F(2,317)=14.41$,$p<.001$, and aspects of adaptive functioning (e.g., Daily Living Skills) $F(2,266)=7.41$,$p=.001$.
Conclusions: These findings indicate social/communication impairments are meaningful variables to differentiate subtypes amongst a sample with ASD without ID. They support previous research documenting considerable social/communication impairment in the context of intact intellectual functioning. Between class comparisons on variables of interest indicate overall and verbal IQ have a protective effect for some aspects of the ASD phenotype (e.g.,structural language skills) but do not protect against symptoms that are multiply determined and involve core social problem solving. Comparison of age and ASD symptomatology across classes suggests abatement of social symptoms may occur up until a certain point (i.e.,adolescence) but the rate of symptom decline decreases thereafter. Adaptive functioning (daily living skills), was strongest in the class that demonstrated the fewest language–related symptoms, a finding that supports previous work relating language skills to adaptive skill development. These findings underscore the need for more intensive social skills' intervention to promote better social outcomes and more externally valid measures of ASD symptomatology. Limitations of the current study include use of a cross-sectional design and future directions should attempt to examine longitudinal changes in social and communication symptoms across classes.

104 **107.104** Strategic Reading Comprehension Intervention for Children with ASD: Developing an Observational Tool to Identify Patterns of Active Engagement and Instructional Support

N. J. Sparapani[1]*, E. J. Solari*[2]*, N. S. McIntyre*[3]*, M. C. Zajic*[4]*, A. R. Henry*[3] *and P. C. Mundy*[5]*, (1)School of Education, University of California, Davis, Davis, CA, (2)University of California, Davis, Davis, CA, (3)University of California at Davis, Davis, CA, (4)University of California at Davis MIND Institute, Davis, CA, (5)University of California at Davis, Sacramento, CA*

Background:
Children with high functioning Autism Spectrum Disorder (HFASD) frequently access general education curricula but often experience reading comprehension difficulties (e.g., Nation et al., 2006; Whalon et al., 2009). It has been hypothesized that reading difficulties might be part of the expression of the social communication phenotype of HFASD (Randi et al., 2010). Thus, reading comprehension instruction may provide an important strategy to target social communication and academic skills in school-age children with ASD. Investigations identifying instructional strategies that impact student active engagement in reading instruction have important implications for children with ASD.
Objectives:
To develop an observational tool for identifying patterns of student active engagement and instructional support strategies that facilitate reading comprehension in children with ASD.
Methods:
Twenty-one children with ASD between 7–11 years (M = 8.88, SD = 1.40; 80% male) participated in an 8-week (3x per week) reading intervention targeting listening comprehension and vocabulary. Each session was video-recorded and lessons averaged 36:03 minutes (SD= 5:05). All lessons included the following activities: 1) reviewing reading rules; 2) hand signals to prompt use of cognitive reading strategies; 3) listening to a story to practice narrative comprehension; 4) answering content questions to monitor understanding; and 5) reviewing vocabulary to build background knowledge. Children completed a battery of cognitive, language, and reading measures at the beginning and end of the intervention and parents completed questionnaires about their child's social-emotional and academic development. Using the video-recorded observations and Noldus Observer® Video-Pro Software, student active engagement across three dimensions (Attention and Self-regulation, Initiating Communication, and Language Comprehension) and instructional strategies across four dimensions (Planning and Organizing, Scaffolding Questions, Supporting Comprehension, and Encouraging Participation) were coded at three time points; beginning, middle, and end of the intervention.
Results:
Preliminary results (n = 10) indicated that on average, children initiated communication 31.8 (SD = 18.21) times during the lesson; however, only 52% of these initiations (SD = 26.91) were on-topic (M = 16.1, SD = 11.55). On average, children responded to questions about instructional content 21.00 (SD = 11.45) times, with 62% (SD = 27.40) of their contributions demonstrating understanding (M = 14.2, SD = 10.34). Initiating off-topic comments (r = 0.81, p < 0.05) was positively related to Communication subscale scores on the Social Responsiveness Scale (SRS; Constantino, 2012), and challenges answering questions that require thinking or inferential reasoning (r = 0.67, p < 0.03) was positively related to SRS Total scores. After controlling for pretest scores on the Expressive Vocabulary Test (EVT-2; Williams, 2007; M = 70.20, SD = 18.49), initiating on-topic questions demonstrated a trend-level relation to expressive vocabulary measured by the EVT-2 at posttest (r = 0.95, p= 0.06).
Conclusions:
These data suggest that differences in active engagement in reading comprehension instruction may interact with individual differences in ASD related symptom intensity. These findings provide preliminary data suggesting that the tendency to initiate communication at a high rate, struggle with inferencing, and ask content-related questions about the text may moderate response to intervention in children with ASD.

105 **107.105** Talker Expectations: Top-Down Information Integration during Speech Perception in ASD

A. Hogstrom*, J. J. Green, B. Castelluccio, A. R. Canfield, C. Irvine and I. M. Eigsti, Department of Psychological Sciences, University of Connecticut, Storrs, CT*

Background: The acoustic realization of phonemes differs substantially between talkers[1]; *talker normalization* refers to the process of determining the appropriate talker-specific mapping from acoustics to phonological categories. A 2007 study[2] tested whether talker normalization involves top-down constraints or is purely signal-driven. Subjects heard words produced by synthetic talkers with identical voices save except for a 10Hz F0 difference. If subjects believed that they would hear *two talkers*, they were reliably slower in a word-monitoring task when the talker varied randomly from trial-to-trial, compared to when trials were blocked by talker. In contrast, listeners who expected *one talker* showed no slowing, indicating that expectations sufficed to trigger talker normalization. Here, we asked whether individuals with ASD would exhibit this expectation effect, in light of evidence that such individuals have reduced susceptibility to top-down expectations [3].Â
Objectives: Assess the relative influences of talker variability and top-down expectations on speech processing in ASD.
Methods: We compared adolescents with typical development (TD) (*n* = 15) and ASD (*n* = 15), matched for age (*M*=15, range=12-17 years) and IQ (FSIQ>85). Using materials from Magnuson and Nusbaum, 2007[2], participants monitored a stream of auditory words for a variable target (e.g., ball, cave). Stimuli were monosyllabic words produced by synthetic "talkers:" male voices (otherwise identical) with F0=150 or F0=160. Within single-talker condition blocks, all targets and distractors were produced by one *talker*; in mixed-talker blocks, the talker changed randomly from word to word. There was a between-subjects manipulation of expectation; given identical stimuli, some subjects were told to expect one talker with variable pitch; others expected two talkers differing in pitch. Assignment to the two expectation conditions was counterbalanced by group.
Results: Analyses included age and NVIQ as covariates. Overall accuracy was high across groups (range in the ASD group, .80-.98; TD group, .84-.97), with a trend for lower accuracy in the ASD group, *p*=.05; thus, accuracy was a covariate in subsequent analyses. Reaction time (RT), a more sensitive index of cognitive processing or load, did not differ by group, *p*=.58. There was a near-significant Group by Expectation by Block interaction, *F*(1, 23)=3.76, *p*=.06. The TD group was slower for mixed-talker blocks when they expected two talkers; when they only expected a single talker, the difference in voices did not lead to slower RT (Fig 1). The ASD group did not show this effect. While expecting to hear two talkers rather than one was associated with slower RT in the ASD group (Fig1), this effect may reflect individual RT differences in this small-n between-subjects study.
Conclusions: In TD individuals, expectations about the number of talkers influenced RT for mixed versus single-talker blocks; this effect was less apparent in the ASD group. These results suggest that speech comprehension is more signal-driven and less influenced by top-down expectations in individuals with ASD. If this finding is replicated, it could illuminate some of the conversational deficits that characterize autism.

106 **107.106** The Acquisition of Flexible Word Order and Case-Markings in Korean Children with Autism Spectrum Disorder

*J. Park[1], M. Nam[2], S. W. Cho[3], S. J. Lee[2] and **L. R. Naigles**[1], (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Seoul Metropolitan Eunpyeong Hospital, Seoul, Korea, Republic of (South), (3)Sogang University, Seoul, Korea, Republic of (South)*

Background: Researchers generally agree that the language impairments of children with ASD include pragmatic deficits (Naigles & Chin, 2015); however, less consensus exists concerning whether they also have morphosyntactic deficits. Children's productions have revealed omitted morphemes and sparse use of questions (Eigsti, Bennetto, & Dadlani, 2007; Roberts, Rice, & Tager-Flusberg, 2004); however, their *comprehension* data generally indicate intact, if somewhat delayed, grammatical understanding. However, most of the previous studies were conducted with English-speaking children with ASD, and morphosyntactic features existing in other languages such as flexible word order or case-markings have been barely studied. In Korean, case markers provide the cues to the relations between agents and patient and multiple word orders are permissible (Kim, 1997). Learning how to use both word order and case markings to interpret syntactic relations may be challenging not only for TD Korean learners, but also for Korean children with ASD.
Objectives: We used Intermodal Preferential Looking (IPL: Naigles & Tovar, 2012) to investigate Korean children's comprehension of SOV and OSV word order presented with nominative and accusative case-markers; we compare TD preschoolers with those with ASD.
Methods: Monolingual Korean-speaking TD children (n=16, *MA*=51.19months, Leiter-R Brief IQ=45.75, expressive language AE of 54~59months) and children with ASD (n=13, *MA*=70.47months, Leiter-R Brief IQ=48.00, expressive language AE of 54~66months) participated. Children viewed IPL videos, whose test sentences followed SOV ((a) A-***Nom*** B-***Acc*** Verb**)** or OSV ((b) B-***Acc*** A-***Nom*** Verb) order. The videos showed familiar actions (e.g. pushing) with agent A-patient B on one side paired with agent B-patient A on the other side; baseline trials had no directing audio. Children's eye movements were coded and two dependent variables were calculated: 'Percent looking to match' and 'Percent looking to the 1st NP as agent' during the test vs. baseline trials. Children who understand the audios will look longer to the matching scene during both SOV and OSV test trials; however, children who simply treat the 1st NP as the agent regardless of case marker will look longer to the nonmatch during OSV trials(Naigles, Kelty, Jaffery, & Fein, 2011).
Results: The TD children looked longer to the match during the test trials compared to baseline trials for SOV order (*t*(15)=2.02, *p*=.03), but not OSV order (*t*(15)=-.41, *p*=.34). With the percent looking to 1st NP as agent measure, though, the SOV/OSV comparison yielded a significant Frame effect (*F*(1, 15) = 8.78, *p* = .01). In contrast, children with ASD looked significantly *away from* the matching video during SOV trials compared to the baseline trial (*t*(12)= -2.27, *p*=.02). For OSV sentences, no significant effect was found (*t*(12)= .08, *p*=.47).
Conclusions: In sum, TD children demonstrated successful comprehension of SOV orders; moreover, they seem to pay attention to case-markers because they differentiated the OSV trials from the SOV trials. In contrast, language-matched children with ASD did not appear to make use of the case markers at all, and seemed not to understand either the canonical SOV nor OSV word order. This study suggests that Korean morphosyntax places unique challenges for children with ASD.

107 **107.107** The Development of Early Gesture-Speech Combinations in Infants at High Risk for Autism Spectrum Disorder

A. B. Choi[1], *P. Shah[2], M. Rowe[3], C. A. Nelson[4] and H. Tager-Flusberg[5], (1)Harvard University, Cambridge, MA, (2)Boston University, Boston, MA, (3)Harvard Graduate School of Education, Cambridge, MA, (4)Boston Children's Hospital, Boston, MA, (5)Psychological and Brain Sciences, Boston University, Boston, MA*

Background:
Children use gestures to communicate before producing speech in the first year of life (Bates, 1976). Beginning around 14-22 months of age, children start to produce gestures with speech, conveying a sentence-like meaning (Butcher & Goldin-Meadow, 2000). For instance, a child may point to a bottle and say, "want," communicating that s/he wants a bottle. Importantly, early gesture-speech combinations are related to language skills in typical and atypical populations (Rowe, Ozcaliskan, & Goldin-Meadow; 2008). One specific population, who show deficits in gestures, is children with autism spectrum disorder (ASD). For example, Winder et al. (2013) found that infant siblings of children with ASD, who are at high risk for ASD (hereafter, "high-risk"), produce fewer gesture-speech combinations than low risk peers with no family history of ASD at 13 and 18 months. While much work has focused on exploring early gesture use in ASD, little research exists on gesture-speech combinations in high-risk infants.
Objectives:
The purpose of the present study is to expand on previous studies to examine the development of gesture-speech combinations in high-risk infants who were later diagnosed with ASD (HRA+), unaffected high-risk infants (HRA-), and unaffected low risk controls (LRC) at 12 and 18 months. Specifically, we addressed the following research questions (RQ): (1) Do HRA+, HRA-, and LRC infants show differences in gesture-speech combinations at 12 and 18 months? (2) Do early gesture-speech combinations predict infants' later language skills and/or ASD outcomes?
Methods:
73 mother-child dyads engaged in a free play for 10 minutes in the lab at 12 and 18 months (n_{HRA+} = 18, n_{HRA-} = 25, n_{LRC} = 30). Following the coding scheme developed by Özçalışkan and Goldin-Meadow (2009), we transcribed gesture and speech from videotaped sessions. We converted frequency variables to rates per 10 minutes. At 12 and 18 months, we administered receptive and expressive language subscales from Mullen and combined raw scores to calculate language scores. Also, we administered ADOS to assess infants' ASD diagnoses at 36 months. Based on ADOS and final clinical judgment, infants were categorized as HRA+, HRA-, and LRC.
Results:
RQ1: At 12 months, HRA+ infants produced significantly lower rate of gesture-speech combinations than HRA- infants (χ^2 = 6.36, p = 0.012) and LRC infants (χ^2 = 4.14, p = 0.042). At 18 months, HRA+ children produced significantly lower rate of gesture-speech combinations than LRC children (χ^2 = 6.863, p = 0.009). *RQ2:* Gesture-speech combinations rate predicted infants' language scores at both 12 and 18 months in combined HRA group ($p_{12\text{-}months}$ = 0.001, R^2 = 0.23; $p_{18\text{-}months}$ = 0.02, R^2 = 0.13), but not LRC group. Finally, total gestures rate (with or without speech) at 12 months predicted high-risk infants' ASD outcomes at 36 months, when controlling for 12-month language scores (z = -2.31, p = 0.021, R^2= 0.18).
Conclusions:
HRA+ infants produced significantly fewer gesture-speech combinations, compared to HRA- and LRC infants at 12 and 18 months. These results provide further evidence for differences in early gesture-speech combinations that predict language skills in young children.

108 **107.108** The Hands Have It: Variation in the Latency of Neural Activity during Beat Gesture-Speech Integration in ASD

L. Morett[1]*, N. Landi*[2,3]*, J. Irwin*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)Psychology, University of Connecticut, Storrs, CT, (3)Haskins Laboratories, Yale University, New Haven, CT*

Background: Ineffective communication via speech and gesture is a primary diagnostic characteristic of Autism Spectrum Disorder (ASD). Beat gestures, which convey emphasis in conjunction with speech, are particularly likely to be interpreted abnormally in ASD. Abnormal processing of beat gestures in ASD is associated with greater activity in high-level visual cortex and less activity in planum temporale, which is active during beat gesture and speech integration in typically developing (TD) individuals (Hubbard et al., 2012). At present, however, the time course of the neural activity underlying beat gesture and speech integration in ASD is unclear.
Objectives: The objectives of this research were (1) to determine the time course of gesture-speech processing in ASD and (2) to examine how neural activity is affected by the temporal asynchrony of beat gesture. It was predicted that individuals with ASD would be less sensitive to temporal asynchrony of beat gesture and speech than their TD peers. Furthermore, it was predicted that the time course of neural activity in TD would reflect gesture-speech synchrony, whereas that the time course of neural activity in ASD would not reflect it.
Methods: Participants in Study 1 included 18 high-functioning ASD and 23 TD individuals matched in age, gender, and verbal IQ (all *p*s < .05). In this study, participants viewed a brief cartoon video and retold its events to an experimenter while being tacitly video recorded. Gestures and speech were transcribed and coded by two raters unaware of the experimental design and predictions (ICC=.79 for speech onset; .89 for gesture onset). Participants in Study 2 included 15 TD individuals. In this study, participants viewed clips excerpted from a longer video of a speech, such that a beat gesture always occurred at 1.5 s. Accompanying audio clips were presented either simultaneously with or 500 ms preceding video clips. Data was collected continuously using magnetoencepholagraphy (MEG), a neurophysiological method with high spatiotemporal accuracy, and was temporally synched to gesture onset for analysis.
Results: In Study 1, individuals with ASD produced more temporally asynchronous beat gestures than TD individuals (see Fig. 1). In Study 2, activity was observed in inferior frontal gyrus (IFG) and proximal regions between 150-300 ms after first stimulus onset (see Fig. 2). Additionally, activity was observed in posterior temporal cortex (pSTC) between 500-650 ms after first stimulus onset. Notably, this activity varied on the basis of both latency and laterality, such that greater activation in response to temporally asynchronous beat gesture and speech was associated with shorter latencies and left hemisphere. By contrast, greater activation in response to temporally synchronous beat gesture and speech was associated with longer latencies and right hemisphere.
Conclusions: Together, the results show that the latency of neural activity reflects sensitivity to temporal beat gesture-speech asynchrony and that that integration of temporally asynchronous beat gesture and speech is atypical in ASD. These results form the basis of future research examining the latency of neural activity during beat gesture-speech integration in ASD, providing insight into the neural bases of abnormal gesture-speech integration in ASD.

109 **107.109** The Impact of Bilingualism on Conversational Understanding in Adolescents with Autism Spectrum Disorders.

M. Marukhnyak*, Department of French, University of Toronto, Toronto, ON, Canada*

Background: Bilingual families who have children with autism are often advised to use only English and not the primary language with their children in order to avoid further confusion. However, to date there is no research to support this belief. In fact, several recent studies show that bilingualism does not have a detrimental impact on language development in young children with autism. Moreover, it has been shown that bilingualism contributes to the ability to detect conversational faux-pas in typically-developing children. While conversational understanding has been studied extensively in monolingual English-speaking children with autism, to date there has been no studies examining conversational understanding in bilingual adolescents with autism.
Objectives: The purpose of the present research is to fill this gap by examining conversational understanding in three monolingual English-speaking and three bilingual English-French-speaking adolescents with autism.
Methods: To examine conversational understanding, we asked a speech and language pathologist to administer a standardized pragmatic test where our participants were first asked to identify utterances that violated conversational rules and then to provide explanations for their answers. The obtained data was analyzed both quantitatively and qualitatively. First, we analyzed the answers provided by our participants quantitatively. We then asked three independent raters to analyze the explanations provided by our participants.
Results: The results of our study show that bilingualism does not have a negative impact on the ability of adolescents with autism to detect conversational faux-pas. More specifically, we found that bilingual participants with autism examined in our study were able to detect violations of conversational rules at the same success rate as their monolingual peers with autism. Moreover, our study showed that our bilingual participants with autism were able to provide better explanations for their answers than their monolingual peers.
Conclusions: We hypothesize that a daily exposure of our bilingual participants to a richer linguistic environment could contribute to the development of more advanced linguistic, cognitive and social skills. The information provided in this study can be used to better support the needs of bilingual families who have children with autism.

110 **107.110** The Influence of Social Communication on Written Expression in School-Age, Higher-Functioning Children with Autism Spectrum Disorders

M. C. Zajic[1], *N. S. McIntyre*[2], *L. E. Swain-Lerro*[3], *J. McCauley*[4], *H. K. Schiltz*[5], *T. Oswald*[6] *and P. C. Mundy*[7], *(1)University of California at Davis MIND Institute, Davis, CA, (2)University of California at Davis, Davis, CA, (3)UC Davis, Santa Rosa, CA, (4)UC Davis MIND Institute, Sacramento, CA, (5)Marquette University, Milwaukee, WI, (6)University of California at Davis MIND Institute, Sacramento, CA, (7)University of California at Davis, Sacramento, CA*

Background: Higher-functioning children with ASD (HFASD) remain affected by social-communication impairments. However, we know little about how these difficulties affect school performance or how to leverage curriculums to improve their social-communication development. It may be that the reading comprehension and written expression problems exhibited by children with HFASD are components of the social communication phenotype of school-age HFASD and, therefore, may be important targets for school-based intervention (e.g., McIntyre et al., 2016; Randi et al., 2010; Zajic et al., in press). This study examined the hypothesis that impairments in written expression reflect an important part of the social-communication phenotype of school-aged children with HFASD.
Objectives: The study tested the hypotheses that a) 8–16-year-old children with HFASD would display specific writing impairments compared to either a clinical or a typical control sample, and b) HFASD group differences in writing performance would be significantly associated with differences in symptom severity.
Methods: The participants were 65 children with HFASD, 34 children with ADHD, and 34 children with typical development (TD). ASD symptoms were confirmed with the ADOS-2; ADHD symptoms were confirmed with the Conners-3. IQ was assessed with the WASI-II. Writing was assessed with the Word Count and Theme Development and Text Organization subscales of the Wechsler Individual Achievement Test, 3rd Edition (WIAT-III) and the Contextual Conventions (CC) and Story Composition (SC) subscales of the Test of Written Language, 4thÂ Edition (TOWL-4). Factors that may influence writing performance were assessed with the Story Memory Recall task of the Wide Range Assessment of Memory and Learning-2 and the Reading Comprehension measure of the Gray Oral Reading Test-5.
Results: A MANCOVA controlling for IQ revealed a Diagnostic Group effect on the writing measures, $F(8,242)=3.15$, $p<.002$, Wilks' $\Lambda=.898$, partial $\eta^2=.09$. Univariate effects were observed for the CC, $F(2,124)=6.44$, $p<.002$, partial $\eta^2=.09$, and for SC, $F(2,124)=10.1$, $p<.001$, partial $\eta^2=.14$. Pair-wise comparisons with Bonferroni correction indicated that the HFASD and ADHD groups performed worse than the TD group on the CC scale ($p<.002$, $p<.02$), but the two clinical groups did not differ. The HFASD group performed worse than either the ADHD ($p<.02$) or the TD group ($p<.001$) on SS, but the latter two groups did not differ. No reliable differences were observed on the two WIAT-III writing scales. ADOS-2 Total scores and TOWL-4 SC scores were correlated in the HFASD group, $r=-.39$, $p<.002$, and this association held when controlling for IQ. SC was also associated with Reading Comprehension, $r=.38$, and Story Memory, $r=.53$, $p<.001$, in the HFASD group.
Conclusions: This study revealed evidence of a syndrome-specific deficit in writing development in children with HFASD compared to clinical and typically developing controls. Differences in writing were also significantly correlated with symptom presentation consistent with the hypothesis that impairment in writing development is associated with the development of the social-communication phenotype of school-aged children with HFASD. Possible intervention implications will be discussed.

111 **107.111** The Linguistic and Cognitive Effects of Bilingualism on Children with Autism Spectrum Disorders

A. M. Gonzalez Barrero *and A. Nadig, McGill University, Montreal, QC, CANADA*

Background: Parents of bilingual children with Autism Spectrum Disorders (ASD) are often advised to talk to their child using only one language to simplify the input they hear (Bird et al., 2012). This stems from the belief that bilingualism may be harmful for language acquisition in children with ASD (Kremer-Sadlik, 2005). Research concerning the language development of bilingual children with ASD is scarce, but the available evidence does not support this claim. That is, bilingual children with ASD do not exhibit additional language delays relative to their monolingual peers with ASD (Hambly & Fombonne, 2012). However, most studies have focused on initial stages of language development using parent report measures. We do not know how bilingualism impacts linguistic abilities at school age, when more complex language should be mastered. Furthermore, no previous study has investigated the effects of bilingualism on executive functions in children with ASD, and whether they may experience a bilingual advantage (Bialystok, 2007).
Objectives: In study 1, we investigated the lexical and morphological abilities of school-age bilingual children with ASD using standardized tests. In study 2, we examined the impact of bilingualism on executive functions (including set-shifting) using direct-testing and parent report of everyday executive functioning abilities.
Methods: Twenty 5- to 9-year-old children with ASD participated in the studies (10 monolinguals and 10 bilinguals) along with 20 typically-developing children. Bilingual status was confirmed by a combination of direct testing and parent report. Participants' languages included English, French, and Spanish. Children were matched on chronological age and NVIQ. Language skills were assessed using the Peabody Picture Vocabulary Test (Dunn & Dunn, 2007) and the Clinical Evaluation of Language Fundamentals (Semel et al., 2003), or their French/Spanish equivalent. Set-shifting was measured using a computerized version of the Dimensional Change Card Sort Task (DCCS; Zelazo, 2006) along with a measure of executive functioning in daily life (Behavior Rating Inventory of Executive Functioning - BRIEF; Gioia et al., 2000).
Results: *LANGUAGE:* Although both groups scored in the normal range, there was a significant difference in vocabulary ($p = .04$), where monolingual children with ASD exhibited higher scores relative to bilingual children with ASD. No significant differences were found on morphological skills ($p = .33$). *DCCS:* Bilingual participants with ASD showed better performance relative to their monolingual ASD counterparts ($p = .026$). *BRIEF:* The ASD group exhibited poorer set-shifting skills relative to the TYP group ($p < .01$). However, there where no significant differences related to bilingualism.
Conclusions: Although not presenting delays, bilinguals exhibited lower scores relative to their monolingual peers with ASD on standardized measures of vocabulary, which is likely explained by the relationship between language exposure and language proficiency (Thordardottir, 2011). We provide novel evidence that bilingualism may hold advantages for executive functioning in children with ASD, this was found for the DCCS task but not for parent report of set-shifting in daily life. These findings build on previous research suggesting that bilingualism is not detrimental for the language skills of children with ASD and in fact may provide some advantages.

112 **107.112** The Role of Sleep in Language Acquisition in Children with Autism Spectrum Disorder

F. E. Fletcher[1]*, V. Knowland*[1]*, S. Walker*[1]*, C. Norbury*[2]*, G. Gaskell*[1] *and L. M. Henderson*[1]*, (1)University of York, York, United Kingdom, (2)UCL, London, United Kingdom*

Background:
Sleep plays a crucial role in the consolidation of newly learnt language, strengthening memory traces and integrating them into existing semantic and lexical networks. Numerous studies have examined the immediate consequences of new word learning in ASD, but the nature and time course of vocabulary consolidation is currently unclear. This is particularly salient given that sleep problems are highly prevalent in children with ASD, present in up to 80% of children. These sleep problems are largely characterised by difficulties in the initiation and maintenance of sleep but emerging evidence suggests differences may also exist in the microstructure of sleep, including the extent of slow wave activity. However, the extent to which the sleep profiles of children with ASD contribute to the complex and heterogeneous language development in this population of children remains untested.
Objectives:
To characterise the time course of the consolidation of new lexical and semantic information in children with and without ASD. Additionally, to explore the role that sleep plays in the heterogeneity of these processes across children ASD.
Methods:
In an initial study 19 boys with ASD aged 7-13 years and 19 typically developing (TD) boys matched on age and receptive vocabulary were exposed to the phonological forms of 16 novel words (e.g., dolpheg). Children were tested immediately after training and 24 hours later. Explicit recall was measured via cued recall and 2AFC old-new recognition. Lexical integration was measured via a pause detection task, in which children made speeded responses about the presence/absence of a 200ms pause in the basewords (e.g., dolphin) and a set of control words for which no new competitors had been taught. Our more recent studies have addressed how children with ASD and typical peers learn and integrate new semantic information. In these latter studies children learned rare animals and then completed a size congruency task in which they made speeded judgements about the size of existing and new animal pairs. Children also underwent overnight polysomnography to capture the relationship between sleep architecture and overnight changes in memory for the new language.
Results:
Explicit word knowledge improved significantly from day 1 to day 2. There was no interaction between group and day, whereby the increase in explicit word knowledge was comparable between children with ASD and TD children. Whilst typical children showed evidence of integration after sleep (with larger increases in lexical integration correlating with greater slow oscillation activity), children with ASD did not show evidence of integration after sleep.
Conclusions:
The consolidation of explicit word knowledge appears in tact in ASD. However, there may be an aberrant time course for the integration of new vocabulary knowledge in children with ASD, which may be attributed to differences in sleep-associated memory consolidation. These results suggest that sleep difficulties may contribute to the language learning difficulties which often characterise ASD, and emphasise the importance of identifying and treating sleep difficulties in this disorder.
*This research was funded by an ESRC grant awarded to L.M Henderson and G. Gaskell

113 **107.113** The Serial Relation of Theory of Mind and Functional Communication in the Externalizing Problems of Children with ASD

T. Estrada*, R. Bowler, T. Rutter, E. A. Lovell and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: Previous research indicates children with autism spectrum disorder (ASD) exhibit greater externalizing problems than typically developing (TD) peers (Mahan & Matson, 2011). One factor that has been found to contribute to these greater externalizing problems is lower functional communication (FC) skills (Boonen et al., 2014). While lower FC skills may play a role in the increased externalizing problems observed in children with ASD, it alone accounts for only part of variance in this relation. Other factors related to FC, such as theory of mind (ToM), may also play a role in this well-established association. Understanding the relation among these factors is essential in determining appropriate treatment for children with ASD who have comorbid externalizing problems.
Objectives: Our objective was to develop a greater understanding of factors that may contribute to externalizing problems in children with ASD. We hypothesized that ToM abilities and FC skills would serially mediate the relation between children's status and externalizing problems.
Methods: Our sample included 111 children (ages 3:0 to 6:11) and their parents.Â Sixty-five TD children (40% female) and 46 children with ASD (21% female) were examined. Children completed a ToM battery in a laboratory setting. Parents' ratings from the *BASC-2* (Reynolds & Kamphaus, 2004) were used to evaluate children's externalizing problems and FC. The *DAS-II*(Elliott, 2007) was used to assess children's language abilities.
Results: A serial mediation model was conducted using the SPSS 24 macro PROCESS (Hayes, 2008), which provided bootstrapped estimates of the indirect effects based on 5000 resamples. Age, language abilities, and gender were controlled for in the analysis.
Results indicated status was negatively associated with ToM abilities (B = -.91, p < .05) and parent-reported FC skills (B = -7.21, p < .001). The direct effect of status on externalizing problems was also significant (B = 9.55, p < .001). Results supported the mediating role of the child's FC skills (B = 2.29, CI_{95} = .70 to 5.02) in the relation between status and externalizing problems. However, the mediating role of the child's ToM abilities was not significant (B = -.22, CI_{95} = -1.67 to .67) in the association between status and externalizing problems. The results supported a serial mediation, such that when compared to TD children, children with ASD had lower ToM abilities, which predicted lower FC skills, which was associated with greater externalizing problems (B = .25, CI_{95}= .02 to .98). This model accounted for 32% of the variance in predicting externalizing problems in our sample.
Conclusions: These results supported our hypothesis that the association between status and externalizing problems was serially mediated by ToM and FC skills. These results indicate that, compared to TD children, children with ASD may have difficulty understanding others' perspectives, as evidenced by lower ToM abilities, and this may impact their ability to communicate effectively. Lower FC skills may increase frustration and subsequently lead to greater externalizing problems. These findings suggest interventions that incorporate ToM training may not only increase FC skills, but also lead to decreased externalizing problems in children with ASD.

114 **107.114** Trajectories of Receptive Vocabulary Development from 4 to 8 Years in Children with and without Autism Spectrum Disorder: A Population-Based Study

A. Brignell[1]*, T. May*[1]*, A. T. Morgan*[1,2] *and K. Williams*[1,2,3]*, (1)Paediatrics, The University of Melbourne, Parkville, VIC, Australia, (2)Murdoch Childrens Research Institute, Parkville, VIC, Australia, (3)Developmental Medicine, The Royal Children's Hospital, Parkville, VIC, Australia*

Background: Language difficulties are common in children with autism spectrum disorder (ASD), occurring in around 60% of children. Language difficulties can severely impact functioning and participation and result in a number of adverse sequelae such as poor academic achievement and behavioural and emotional difficulties. To date the literature has reported most children with ASD make some progress in their language ability over time. The majority of studies have used clinical samples however, and no studies have compared language development in children with ASD to children without ASD in a large population-based sample using direct standardised measures of language.
Objectives: The aim of this study was to describe trajectories of receptive vocabulary development in children with ASD compared to a large population-based sample of children without ASD.
Methods: Participants were drawn from the Longitudinal Study of Australian Children (LSAC), which is a nationally representative, population-based study. There are two cohorts of children followed in LSAC using bi-yearly direct assessments and/or questionnaires. One cohort was recruited at birth (n=4983) and the other in kindergarten (n=5107). Both cohorts were combined for the current study. Of the combined cohort, 237 children were reported by parents to have received a diagnosis of ASD by 10 years. Receptive vocabulary (Adapted Peabody Picture Vocabulary Test-III) for children with ASD was compared to children without ASD at 4 years (n=188, n=7136, respectively), 6 years (n=215, n=7297) and 8 years (n=216, n=7408). Mean trajectories of receptive vocabulary development were plotted using generalised estimating equations and compared across the two groups. The proportion of children in each group who had declining, stable and improving trajectories was also compared based on one standard deviation change as the cut point for defining the 3 different trajectory types.
Results: There was variability in individual scores for both the ASD and non-ASD groups. Mean scores at 4, 6 and 8 years were lower for children with ASD compared to those without ASD at all 3 time points (4 years ASD: 63.3 (SD 6.5), non-ASD: 64.7 (6.3); 6 years ASD: 73.2 (6.3), non-ASD: 74.1 (5.1); 8 years ASD: 77.7 (6.0), non-ASD: 78.7 (4.9)). Estimated mean receptive vocabulary scores were 0.68 units lower for the ASD than the non-ASD group across the three waves of data collection ($p=0.050$; 95% confidence interval 0.001-1.364). The estimated mean difference approached significance. There was no significant difference (chi^2; $p>0.05$ for all comparisons) between the proportions of children with ASD who had stable (ASD=54%, non-ASD=54%), improving (ASD=38%, non-ASD=35%) and declining (ASD = 8%, non-ASD=11%) trajectories. Trajectory plots of receptive vocabulary showed children with ASD progressed at a similar pace as children without ASD.
Conclusions: Receptive vocabulary trajectories were heterogeneous for children regardless of ASD diagnosis. The trajectory of receptive language development growth over time was similar across children with and without ASD, but mean scores for children with ASD were lower at each time point.

115 **107.115** Using Computational Measures of Social Communication Dynamics for Children with Autism Spectrum Disorder

V. Romero[1], *P. Fitzpatrick*[2], *A. Duncan*[3], *R. Schmidt*[4], *P. L. Silva*[5] *and M. J. Richardson*[6], *(1)University of Cincinnati, Cincinnati, OH, (2)Assumption College, Worcester, MA, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)College of the Holy Cross, Worcester, MA, (5)Psychology, University of Cincinnati, Cincinnati, OH, (6)University of Cincinnati -Center for Cognition Action & Perception, Cincinnati, OH*

Background: Children with Autism Spectrum Disorder (ASD) exhibit impairments in social interactions and at the core of these impairments are social communication deficits. Recent advances in the quantitative and computational measurement of conversational content has resulted in a novel set of methods that might provide a more objective and reliable way of identifying the conversational biomarkers of ASD, as well as a better understanding of the time-evolving dynamics of social communication in these individuals.
Objectives: The current study has two objectives: (1) to validate the use of newly developed computational measures of conversational interaction for assessing deficits in social communication in adolescents with ASD; and (2) to further identify whether deficits in social communication are interrelated to deficits in the social motor coordination that supports effective social interaction.
Methods: Thirty children previously diagnosed with ASD completed the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2). The conversations that each participant had with the clinician during the ADOS-2 administration were evaluated using Discursis, a computational time-series method that analyzes the conceptual and semantic content of an exchange between two or more individuals. Various measures were extracted to quantify different aspects of the conversation (e.g. self-similarity, other-similarity). Additionally, measures of the child's and administrator's social motor coordination were obtained during these conversations (e.g. coherence). Of particular interest is the relationship between ASD symptom severity and the dynamical measures of communication and social motor coordination and the degree to which some of these dynamical measures better predict ASD communication deficits.
Results: Some Discursis measures were correlated with some ADOS-2 sub-category scores (e.g. social affect), as well as the composite score obtained from the test. Stepwise regressions confirmed that Discursis measures can be used to predict composite scores and traditional multiple regression showed that by including a measure of social coordination we are able to account for more of the variability present in ADOS-2 composite scores as well as some sub-category scores.
Conclusions: This data indicates that Discursis could be a sensible and important addition to our diagnostic procedures that would help us better understand the communicational deficits exhibited by some children with ASD. Furthermore, it seems that the social motor coordination that takes place during conversations is interrelated to the verbal communication and necessary to quantify for further understanding of this deficit.

116 **107.116** When "Easy" Conversations Seem Harder: Filler Words and Social Context in Adults with ASD

A. Okocha[1], *J. Boorse*[1], *L. Bateman*[2], *A. A. Pallathra*[3], *B. Maddox*[4], *E. S. Brodkin*[3], *E. Ferguson*[2], *Z. M. Dravis*[1], *N. Minyanou*[5], *A. T. Pomykacz*[6], *K. Bartley*[7], *E. S. Kim*[8], *A. B. de Marchena*[9], *J. Pandey*[8], *R. T. Schultz*[8] *and* ***J. Parish-Morris***[1], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (7)Center for Autism Research, Malvern, PA, (8)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Center for Autism Research, Philadelphia, PA*

Background: Social communication is a core challenge in autism spectrum disorder (ASD), but has proven difficult to reliably measure, especially in natural contexts. In this study, we use techniques from Natural Language Processing and theories of conversational dynamics to assess speech during different types of informal conversations. Speech disfluencies occur when speakers pause, revise, or add filler words to otherwise fluent speech, and may indicate problems with planning or may serve as a pragmatic tool to communicate information with interlocutors (Arnold, Fagnano, & Tanenhaus, 2003; Bell et al., 2003). Prior research shows that individuals with ASD generally exhibit higher disfluency rates than matched controls, but it is not yet known how different kinds of conversational settings affect fluency in this population.
Objectives: Compare disfluency rates, measured by filler words, in adults with ASD and typical adult interlocutors during conversations that are socially "easy" (i.e., with an interested interlocutor) and socially "hard" (i.e., with a bored interlocutor).
Methods: Â Twenty-nine adults with ASD (mean age=27y; mean IQ=104) engaged in 3-minute conversations with two different typical adult confederates as part of the Contextual Assessment of Social Skills (Ratto et al., 2011). The first confederate acted interested in the participant (Interested condition), while the second acted bored (Bored condition). Audio recordings of both conversations were orthographically transcribed. Percentage of filler words (e.g., uh, um, er, eh) relative to total words produced was calculated using Linguistic Inquiry and Word Count software (Tausczik & Pennebaker, 2010).
Results: A repeated measures ANOVA with condition (Interested, Bored) and speaker (Participant, Confederate) as within-subjects factors revealed a significant interactive effect on filler rates, $F(1,28)=8.60$, $p=.007$; Figure 1). Whereas adults with ASD produced a significantly higher percentage of filler words in the Interested condition (M=7.34%) than the Bored condition (M=6.34%, $t(1,28)=-2.42$, $p=.02$), typical confederates showed the reverse pattern, producing significantly *fewer* filler words in the Interested condition (M=5.25%) than the Bored condition (M=6.90%, $t(1,28)=2.26$, $p=.03$). Comparing filler word rates across diagnostic groups revealed no difference in the Bored condition, $t(1,28)=-.59$, $p=.56$). Significant group differences emerged in the Interested condition $t(1,28)=2.61$, $p=.01$; Figure 1).
Conclusions: Subtle language differences can influence whether social communication is successful, and examining conversational dynamics could shed light on meaningful heterogeneity in this domain. In this study, we found that rates of filler words were affected by social context in adults with ASD, with higher rates occurring during interactions that may otherwise be seen as socially "easy" (i.e., with an interested interlocutor) and lower rates when interactions are socially "hard" (i.e., with a bored interlocutor). Using more filler words during conversations with an interested partner could indicate increased responsiveness to social expectations (positive or negative), and will be clarified as we conduct the next iteration of this study on typical adults conversing with typical confederates (anticipated by May, 2017). Our findings have implications for understanding the effect of context on social communication in ASD, and may be valuable for clinicians interested in improving conversational competence in adults.

117 **107.117** Conversational Compensation Predicts Autism Symptom Severity: An Ecologically Valid Marker of Social Motivation

*J. Boorse[1], A. Okocha[1], L. Bateman[2], A. A. Pallathra[3], B. Maddox[4], E. S. Brodkin[3], E. Ferguson[2], Z. M. Dravis[1], N. Minyanou[5], A. T. Pomykacz[6], K. Bartley[7], E. S. Kim[8], A. B. de Marchena[9], J. Pandey[8], R. T. Schultz[8] and **J. Parish-Morris**[4], (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (7)Center for Autism Research, Malvern, PA, (8)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Center for Autism Research, Philadelphia, PA*

Background:
Everyday conversation is often challenging for people with autism spectrum disorder (ASD), but the impact on a given individual can vary from mild to profound. In this study, we explore a behavior that facilitates social communication and could index social motivation: conversational compensation via increased word production. During natural conversation, partners engage in verbal give-and-take. When one partner reaches a lull or becomes quiet, the other partner picks up the conversational slack and "fills in the blanks". The effort expended to scaffold a conversation could serve as a naturalistic measure of social motivation that is ecologically valid and minimally affected by repeated administration.
Objectives:
Assess whether verbal compensation during natural conversation predicts symptom severity in adults with ASD.
Methods:
Twenty-nine adults with ASD (mean age=27 years; mean IQ=104) engaged in 3-minute conversations with two different confederates as part of the Contextual Assessment of Social Skills (Ratto, Turner-Brown, Rupp, Mesibov, & Penn, 2011). The first confederate acted interested in the participant (Interested condition), while the second acted bored (Bored condition). Audio recordings of both conversations were orthographically transcribed. Word counts were calculated using Linguistic Inquiry and Word Count software (Tausczik & Pennebaker, 2010) and percent change in word count from the Interested to the Bored condition was analyzed using SPSS 23.
Results:
Preliminary analyses revealed that confederates produced significantly fewer words in the Bored condition than the Interested condition ($p<.001$). Participants who produced more words to compensate for the "bored" demeanor of the confederate also had less severe behavioral symptoms as rated by an expert clinician (Pearson $r=-.46$, $p=.01$; Figure 1a). Differences in confederate word count by condition were unrelated to participant autism symptoms ($r=.007$, $p=.97$; Figure 1b). Multiple regression analysis revealed that conversational compensation by participants predicted significant additional variance in ADOS severity score after accounting for age, sex, and IQ ($\Delta F=16.05$, $p=.001$). The addition of a self-report measure of social responsiveness (SRS-SR) did not improve model fit, indicating that objective measures of conversational compensation could potentially replace self-report.
Conclusions:
Our results suggest that individuals with ASD that have less severe autism symptoms engage in "conversational compensation" to support flagging social interactions with bored interlocutors. This metric could index social motivation, and given that natural language measures avoid problems associated with subjective judgment or self-report, this measure could hold the advantage of being easily collected outside of the lab (e.g. via telephone or Skype). Quantifying such compensatory behaviors during natural conversation could shed light on the clinical heterogeneity currently complicating the search for the biological basis of ASD, and an ecologically valid metric of social motivation could serve as a treatment response indicator that taps the "essence" of ASD.

118 **107.118** Facetime Vs. Screentime: Decreased Modulation of Gaze Patterns to Live and Recorded Social Stimuli in ASD

***R. B. Grossman**, J. Mertens and E. Zane, FACE Lab, Emerson College, Boston, MA*

Background:
One of the primary characteristics of individuals with ASD is atypical eye gaze during social interactions (Kanner, 1943), but most quantitative data on how individuals with ASD explore social stimuli is based on eyetracking studies of participants watching videos. This study represents an innovative investigation into quantifiable gaze patterns of adolescents with ASD during live social interaction vs. passive viewing of recorded social information.
Objectives:
To determine whether adolescents with and without ASD modulate their gaze patterns with social context.
Methods:
Adolescents (mean age 13:6, 17 ASD, 22 TD) watched four 60-second videos of TD adolescents talking about family, hobbies, vacation, and school. ASD diagnosis was confirmed via ADOS-2 and groups did not differ on age, IQ (KBIT, IQ>80), language ability (CELF), or sex. After several distractor tasks, participants sat across a table from a research assistant (RA), answered questions on the same four topics and also formulated their own questions to the RA (Winner et al. 2002).Â We used an SMI remote eyetracker to record the percent dwell time to the face during passive viewing (video) and the live interview.
Results:
Both groups gazed longer at the video face than the live face of the RA (p = .002), indicating that individuals in both groups similarly and appropriately reduced gaze duration (i.e., less staring) when facing a conversation partner compared to watching a video.Â Gaze patterns of TD adolescents for both tasks were significantly correlated (p = .01), suggesting internally consistent gaze strategies for social stimuli. Participants with ASD did not show this correlation (p = .23). We calculated between-task difference scores for gaze duration to ascertain each person's modulation in gaze behavior as a function of task. Compared to the TD group, the ASD group showed less difference in looking time to the recorded video vs. the live interview (p = .06), maintaining similar gaze patterns for both conditions, while TD participants increased their gaze significantly more in the video task. Greater social communication impairment (SCQ) among ASD participants was correlated with decreased task-based modulation in gaze (p= .02; see Figure). The gaze patterns of TD participants were not correlated with SCQ scores.
Conclusions:
Both groups gazed longer at the video than the live person, but individuals with ASD modulated their gaze behavior less between the two tasks than TD peers. Greater social communication deficits in adolescents with ASD were correlated with increased dampening of this task-based gaze change, suggesting that reduced social insight may prevent individuals with ASD from fully modulating their gaze behavior for social stimuli. It is important to point out that the two groups differed most in gaze behavior to the *video* stimulus, not the live interaction, indicating that prior reports of significant eyetracking differences in ASD using video stimuli may not be describing the true social gaze behavior of children who have preserved language and cognitive abilities. More sophisticated and ecologically valid methods are required to quantify the foundations of aberrant social gaze during live interaction in this population.

119 **107.119** Linguistic and Prosodic Correlates of Perceived Social Skills in Conversation

A. Shield[1], *D. K. Bone*[2], *S. Narayanan*[2] *and R. B. Grossman*[3], *(1)Miami University, Oxford, OH, (2)University of Southern California, Los Angeles, CA, (3)FACE Lab, Emerson College, Boston, MA*

Background:
Autism spectrum disorder (ASD) is characterized by deficits in social communication, and even fluent children with ASD are often perceived by conversational partners as more socially awkward than typically-developing (TD) peers, even after very brief exposure (Grossman, 2015). However, little research has investigated how such rapid social judgments are made, nor if there are specific conversational (linguistic or prosodic) cues that are associated with such judgments.
Objectives:
To determine if specific linguistic and prosodic patterns are associated with positive or negative social perceptions of speakers during conversation.
Methods:
Thirty-four children and adolescents (mean age = 11.7 years, SD = 2.27 years) with ASD (N=12), autism (N=11), and typical development (N=11) participated in a short (2-5 minute) semi-structured conversation with an adult speaker. The first 30 seconds of each conversation were rated by a large number (M = 72.9, SD = 1.2, range=70-76) of native American English-speaking Mechanical Turk workers from 0 to 100 on five social dimensions: likability, outgoingness, social skillfulness, responsiveness, and fluency. The same 30 seconds of each conversation were transcribed and analyzed for linguistic characteristics (pauses during and between conversational turns, length and number of speech turns, errors, stutters, echoes, self-repairs, overlaps, "filler" words such as *ah, eh, em, er, oh, um*, and *like*) and robust prosodic features (median fundamental frequency (f_0), $f_0$range, and median syllable rate).
Results:
A one-way ANOVA found no differences between the ASD, autism, and TD groups on any of the five social dimensions. In fact, the ASD group was rated non-significantly higher than both the TD and autism groups on all dimensions (Figure 1). However, several linguistic and prosodic variables were associated with perceived social skills. The total amount of time that the child was silent throughout the interaction (*total pauses*) as well as the amount of time that the child was silent immediately after his partner's conversational turn (*no responses*) were strongly negatively correlated with perceptions of social skills (Table 1). Conversely, the quantity of child speech (*total speech*) was strongly positively correlated with social perceptions on all five dimensions (Table 1). Of the prosodic characteristics, median f_0 was moderately positively correlated with likability only; this relation is maintained after controlling for gender, age, and ASD diagnosis; r = 0.52 (p< 0.01).
Conclusions:
Contrary to our hypothesis, we did not find that children with ASD/autism were perceived more negatively than TD children on five social dimensions. Rather, our research suggests that conversational partners are sensitive to the *quantity* of speech and silence produced during a conversation, as well as the *timing*of such responses. These factors, which may be indicative of individual style, personality, and temperament, could drive rapid judgments of social skills more than diagnostic classification.
Table 1. Pearson's r values between language sample characteristics and perceived social skills (p < .001 for all correlations).

Â	Likable	Outgoing	Socially skilled	Responsive	Fluent
Total pauses	-0.66	-0.70	-0.74	-0.75	-0.84
No responses	-0.73	-0.70	-0.72	-0.78	-0.75
Total speech	0.56	0.68	0.67	0.74	0.66

Figure 1. Mean ratings of the three groups on five social dimensions.

120 **107.120** Reduced Phonetic Convergence in Autism Spectrum Disorder

A. R. Canfield[1], *B. Castelluccio*[1], *A. Hogstrom*[1], *J. J. Green*[1], *C. Irvine*[1], *R. M. Theodore*[2] *and* ***I. M. Eigsti***[1], *(1)Department of Psychological Sciences, University of Connecticut, Storrs, CT, (2)Speech, Language, and Hearing Sciences, University of Connecticut, Storrs, CT*

Background: ASD is characterized by enhanced low-level acoustic processing[1]. Little is known about how heightened low-level acoustic processing in ASD interacts with speech production and with auditory hypersensitivities. This study investigates the production of acoustic detail in speech by probing phonetic convergence, a phenomenon in which, after engaging in a cooperative sociocommunicative task, talkers tend to produce speech sounds that are more similar to their interlocutor than the same sounds produced prior to the task[2]. Previous research indicates that children with ASD are less likely to adopt speech characteristics including dialect[3], but no research to date has looked at more specific phonetic characteristics. We predicted that individuals with ASD would show reduced phonetic convergence, and that differences would be associated with social abilities and sensory sensitivities.
Objectives: Assess whether symptom severity and sensory hypersensitivity predict phonetic convergence during natural conversation in teens with ASD.
Methods: Twenty-three teens with ASD (*n*=10) and typical development (TD; *n*=13) (of a final sample of 30) engaged in 30- to 45-minute interactions with a research assistant. Participants were ages 12-18 years (*M*=15) with IQ scores (>85) and hearing abilities (pure-tone hearing screen) in the normal range. In the dyadic interaction, the "guide" directs the "tourist" to find a route on a series of six maps via verbal instructions (an opaque barrier blocked nonverbal communication). Partners alternated between guide and tourist roles. Before and after the interaction, participants and RAs produced a set of utterances designed to elicit exemplars of multiple phonemes. Exemplar recordings were subjected to acoustic measurements of voice-onset-time for /*p*/, /*t*/, and /*k*/; phoneme duration for /*s*/; centroid frequency for /*s*/; articulation rate; and fundamental frequency. Accordingly, the acoustic measurements afford examination of convergence for both temporal and spectral properties of individual speech sounds in addition to global prosodic properties. Measurements were made by a team of trained coders using the waveform and spectrogram displays in Praat to identify regions of vocal energy associated with each measurement.
Results: Analyses (ongoing) focus on phoneme duration for /*s*/. For each dyad, we calculated the absolute value of duration differences (subject minus RA) before and after their interaction. These values were analyzed via repeated-measures ANOVA, which revealed a significant group (ASD vs. TD) by time (before vs. after) interaction, $p<.05$. A correlational analysis of the difference in duration after the interaction and ASD severity (SCQ score) approached significance, $p=.08$; greater severity was associated with less convergence. Hypersensitivity on the Sensory Profile was associated with less convergence, $p=.03$.
Conclusions: Given strengths in auditory processing, one might expect heightened sensitivity to phonetic qualities in ASD. Instead, dyads including teens with ASD were less likely to modulate phonetic qualities to conform to interlocutors compared to TD teens. Lesser convergence was associated with symptom severity (weakly) and with sensory hypersensitivities. Prior research[2] suggests that socially influential participants show more convergence than less influential ones; these preliminary results suggest that phonetic convergence is socially complex, and reflect not just auditory processes but also social influence.

121 **107.121** Animating Characters and Experiencing Others: A Look at Peer Groups' Storyboard Narratives

***K. Bottema-Beutel**, Lynch School of Education, Boston College, Boston, MA*

Background: Individuals with autism spectrum disorder (ASD) are thought to be impaired in narrative abilities, especially those related to perspective taking (Colle, Baron-Cohen, Wheelwright, & van der Lely, 2008). The most prominent account for these difficulties is that individuals with ASD lack a Theory of Mind (e.g., Baron-Cohen, 1995). However, more recent 'enactive' approaches situate an understanding of others as an embodied interactional practice, rather than as an abstract process of mind-reading (De Jaegher, 2013; Gallagher & Hutto, 2008).
Objectives: This study combined enactive theoretical accounts of perspective taking with Discourse Analysis in order to examine the construction of fictional narratives ('storyboards') within small adolescent social groups, where at least one member of the group was diagnosed with ASD.
Methods: . The data corpus was comprised of 7 hours of video recordings, which featured 9 adolescents with ASD and 19 neurotypical peers, divided into groups of 4-6 adolescents. The data was collected during a team building workshop at a summer camp. Social groups were given a set of photographs of previous workshop or camp activities, which depicted group members, campers, camp administrators, and others at camp. They were instructed to create a storyboard using at least 10 photos. Videos were transcribed using conversation analysis conventions (Atkinson & Heritage, 1984). Transcripts were coded for instances where the perspective of the developing characters, author, narrator, or audience was made relevant. Fine-grained analyses of extended stretches of talk were then conducted in order to determine the ways in which story characters and the larger narrative were constructed through discourse.
Results: Two major findings emerged that reflected participants' perspective taking abilities. First, participants indirectly referenced story character's mental lives by offering contextualized descriptions of characters' actions. There was variation in the extent to which action descriptions linked to mental states; action descriptions could *entail, imply, or index* character mental states (see Table 1 for transcript extracts and descriptions). Second, participants relied on the enactment of *genre conventionsÂ* when constructing their narratives as a means to meet the expectations of the presumed audience.Â This strategy allowed participants to circumvent anticipating or 'mentalizing' about the expectations of a particular audience, and instead apply generic fidelity criteria that would presumably be recognized by a broad, hypothetical audience. Participants'' drew upon genre conventions related to plot structure, character identities (e.g., villains and heroes), and the physical layout of the storyboard. In keeping with previous discourse analytic work in ASD, this reflected 'socio-cultural' perspective taking (Ochs et al., 2002).
Conclusions: This study illustrates two ways that adolescents with ASD engaged in perspective taking when constructing fictional narratives with peers: describing character actions and enacting genre conventions. These findings suggest that narrower approaches to identifying perspective taking abilities in individuals with ASD, especially those that restrict analysis to the word level (e.g., tallying the number of mental state terms used in a narrative retelling) may not capture the full range of narrative or perspective taking abilities in which individuals with ASD can engage.

Poster Session
108 - Genetics
12:00 PM - 1:40 PM - Golden Gate Ballroom

122 **108.122** Age at First Birth Has Genetic Determinants and Is Related to Social Responsiveness

***M. Vysotskiy**[1], I. Mitra[1], M. Traglia[1], L. A. Croen[2] and L. Weiss[1], (1)Department of Psychiatry and Institute for Human Genetics, University of California San Francisco, San Francisco, CA, (2)Kaiser Permanente Division of Research, Oakland, CA*

Background: The age at which parents of both sexes have children has been associated with increased risk of autism spectrum disorders (ASDs). Though the reasons for this are unknown, they are often hypothesized to be due to chromosomal changes in eggs and *de novo* mutations in sperm. An alternative mechanism has been speculated that subclinical ASD-like behaviors lead to delayed childbearing. Social aptitude (measured as Social Responsiveness Scale score, SRS) is heritable and closely related to ASDs. It has been observed that, on average, parents of children with ASDs have lower social responsiveness. This leads to a hypothesis that the age a parent has a first child (age at first birth, ageFB) is not a causal risk factor for ASDs, but instead, parental social responsiveness may influence ageFB and ASD risk separately. As SRS is highly heritable, these effects are likely mediated by genetics.
Objectives: The study aimed to clarify the nature of the relationship between ageFB and ASD risk. We used genome-wide genetic data from several ASD datasets to measure the heritability of ageFB and assess the relationship between ageFB and SRS. These data were additionally used to identify common variants associated with both traits.
Methods: In order to estimate the genetic component of ageFB, the heritability of the trait was measured in the Early Markers for Autism (EMA, N=333 primiparous mothers of cases and controls) dataset and Simons Simplex Collection (SSC, N=1,580 trio parents) dataset. Correlation between ageFB and SRS, as well as a GWAS of SRS, were performed in the SSC for both parents. A GWAS of ageFB was performed as a meta-analysis across the EMA, SSC, and part of the Autism Genetic Resource Exchange (AGRE) datasets (N=3,855).
Results: In SSC parents, adjusting for genetic ancestry, sex, and educational attainment, ageFB was found to be significantly heritable ($P<5.8x10^{-4}$). Correlation between ageFB and parental SRS in SSC was significant in a similarly adjusted model ($P<2.2x10^{-16}$). The top ageFB locus ($P=9.1x10^{-11}$) fell near the *ASTN2* gene, close to an ASD candidate gene identified by the Psychiatric Genomics Consortium (PGC) and implicated previously in ASDs based on analysis of rare variants. The ageFB loci identified in ASD parents show several overlapping loci with published population-based ageFB studies. Further, one of the top loci associated with SRS in ASD parents was a population ageFB locus, suggesting the relationship between social aptitude and ageFB is likely to generalize beyond ASD families.
Conclusions: This study of parents of children with ASDs finds that ageFB appears heritable and correlated with SRS. Furthermore, both traits have associated genetic variants, with overlap between loci associated with ageFB, SRS, and ASDs. The relationship between ageFB and SRS supports a hypothesis that the link between parental age and ASD risk in offspring is mediated through the genetics of social responsiveness. Because the parental behaviors leading to delayed childbearing are heritable, these traits may present themselves as ASDs in offspring. The information gained from our study can help parents make informed decisions.

123 **108.123** Assortative Mating in Autism Spectrum Disorder

S. Connolly[1], *R. J. Anney*[2], *L. Gallagher*[3] *and E. Heron*[4], *(1)St James, Trinity College Dublin, Dublin, Ireland, (2)Cardiff University, Cardiff, United Kingdom, (3)Trinity Centre for Health Sciences, Institute of Molecular Medicine, Dublin, IRELAND, (4)Trinity College Dublin, Dublin, IRELAND*

Background:
Assortative mating is a non-random mating system in which individuals with similar genotypes and/or phenotypes mate with one another more frequently than would be expected in a random mating system. Autism Spectrum Disorder (ASD) is considered to be a heritable neurodevelopmental disorder and when investigating the genetic components of ASD, random mating is assumed, although this may not necessarily be the case. The prevalence of ASD has increased from 4 in 1000 in the early nineties to a more recent estimate of 1 in 68 children aged 8 in the US. This increase in prevalence is due to many factors such as increased awareness and diagnoses but it has been hypothesised that some of this increase in prevalence is due to assortative mating.
Objectives:
Assortative mating can be explored through both phenotypic and genotypic data, although it has never been investigated through genotypic measures in ASD. The objectives here are to investigate evidence of genetic assortative mating between ASD parents.
Methods:
We investigated whether or not there is evidence of excess of genotypically similar mating pairs using genome-wide Single Nucleotide Polymorphisms (SNP) data on trio families (Autism Genome Project (AGP) data (1,650 family trios) and Simons Simplex Collection (SSC) data (1,962 family trios)). Determining whether an excess in genetic similarity was present or not was explored through kinship coefficients and spousal correlation between the principle components in both the AGP and SSC datasets.
Results:
We found evidence of assortative mating in the AGP data using both methods. There was no significant evidence of assortative mating using the kinship coefficients in the SSC data. Although, there was significant evidence when investigating assortative mating using correlation between the principle components in the SSC dataset.
Conclusions:
Although both the AGP and the SSC show evidence of assortative mating when exploring the correlation of the principle components, the AGP shows further evidence of assortative mating when investigating genetic similarity of parents of ASD offspring using kinship coefficients. Therefore, this stronger evidence of assortative mating in the AGP (contains mulitplex and simplex families) compared to the SSC (strictly contains simplex families) reflects the differences that have previously been observed between multiplex ASD families and simplex ASD families (Klei et al. 2012, Chaste et al. 2012).

124 **108.124** Atypical Neural Sensory Processing of Auditory Stimulus Change Among Children with De Novo Disruptive Mutations to SCN2A

T. DesChamps[1], *B. E. Cairney*[2], *C. M. Hudac*[3], *R. Ma*[4], *A. S. Wallace*[2], *V. Troiani*[5], *A. S. DiCriscio*[6], *C. M. Taylor*[7] *and R. Bernier*[2], *(1)University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA, (3)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (4)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, MA, (5)Geisinger-Bucknell Autism & Developmental Medicine Institute, Lewisburg, PA, (6)Autism & Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA, (7)Geisinger Health System, Lewisburg, PA*

Background: Recurrent gene disrupting mutations are implicated in 10% of autism spectrum disorder diagnoses (Iossofov et al., 2014). Based on such findings, promising “genetics-first” approaches characterize ASD phenotypes based on known genetic etiologies to parse heterogeneity (Stessman, Bernier, & Eichler, 2014). Unique phenotypic patterns of genetically-defined subtypes have emerged (e.g., *CHD8,* Bernier et al., 2014). Disruptive mutations to the voltage-gated sodium channel alpha subunit *SCN2A* are implicated in ASD (Weiss et al., 2003; Sanders et al., 2012) and may represent a unique ASD-related phenotype (Tavassoli et al., 2014). Common ASD behaviors such as atypical behavioral responsivity to sensory stimuli (Liss et al., 2006) are observed in human carriers of *SCN2A* (Tavassoli et al., 2014) and *Scn2a* mouse models (Kearney et al., 2001) suggesting that impaired low-level sensory processing may be associated with the *SCN2A*phenotype.
Objectives: Characterization of the phenotype associated with disruptive *SCN2A* mutations is critical to understanding genotype-phenotype relations and illuminating the pathophysiology of ASD in genetically defined subgroups. This study aims to contribute to a fuller description of the *SCN2A* phenotype by examining neural correlates of sensory processing.
Methods: Children with *de novo* mutations to *SCN2A* and their biological siblings participated in an auditory oddball event-related potential task measuring low-level sensory processing of auditory stimulus change. To date, participants included children with *de novo SCN2A* mutations (*n* = 8, 5 male, 5 ASD, mean age = 10.77, range = 5.75 - 15.58) and their biological parents (*n* = 17,Â mean age = 43.35, range = 35.0 – 51.25*),* siblings (*n* = 5, 3 male, mean age = 9.18, range = 4.58 - 17.58). *ERP Paradigm:*Standard pure tones (82%), and deviant tones varying in duration (6%), frequency (6%), and combined duration and frequency (6%) were presented during passive viewing of a silent movie. Responses to deviant tone types were averaged together. Peak latency of the P3a component were extracted from frontocentral medial electrodes.
Results: Preliminary analyses were conducted in SAS 9.4 using multilevel models tested condition and group differences. A random-intercept single-trial analysis was utilized to account for ongoing variance across the session. All groups exhibited a faster P3a latency to deviant compared to standard conditions, $F(2, 32000) = 149.65$, $p < .0001$. A group by condition interaction on P3a peak latency, $F(2, 32000) = 21.39$, $p < .0001$, indicated that SCN2A carriers had less condition discrimination (diff = 3.56 ms, $p = .0033$) than parents (diff = 11.12 ms, $p < .0001$) or siblings (diff = 6.01 ms, $p < .0001$).
Conclusions:
Compared to non-carrier relatives, *SCN2A* carriers exhibited reduced neural discrimination between standard and deviant tones as measured by P3a latency. This finding suggests diminished sensory sensitivity to auditory stimulus change among *SCN2A* carriers and a potential reduction in bottom-up regulatory systems that are critical for attending to and integrating information in the environment. Future efforts to characterize the *SCN2A* phenotype will examine relationships between atypical sensory processing and behavioral features.

125 **108.125** Autism and Obesity: Assessing Antipsychotic-Induced Weight Gain and BMI Associated SNPs

Z. Talebizadeh[1]*, A. Shah*[1]*, J. Noel-MacDonnell*[1]*, H. Dai*[1]*, J. N. Constantino*[2] *and D. J. Mueller*[3]*, (1)Children's Mercy Hospital, Kansas City, MO, (2)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada*

Background: A *general assumption* is that the observed elevated rate of obesity in autism (i.e., 40%) is caused by antipsychotic-induced weight gain (AIWG). It is not clear if obesity is co-occurring with autism or is related to AIWG.
Objectives: Our hypothesis is that the prevalence of known AIWG associated SNPs in obese and non-obese autistic subjects is comparable; thus, AIWG cannot be the only reason for the observed higher rate of obesity. To test this hypothesis, we evaluated the prevalence of AIWG associated SNPs in obese and non-obese autistic subjects.
Methods: We curated a list of about n=150 SNPs with at least one report of association with AIWG. We assessed phenotypic and genotyping data (three Illumina platforms) from Simons Simplex Collection (SSC). We analyzed genotyping data for n=115 AIWG SNPs from > 2000 probands from SSC. BMI data on probands was used to identify obese and non-obese subjects (> 1000 probands met the applied BMI cut off for each weight category). Similarly, we evaluated unaffected SSC siblings (> 2000) stratified to obese and non-obese groups.
Results: Â **AIWG SNPs analysis.** (1) Only one out of 115 AIWG SNPs (rs7702361) achieved an FDR corrected significant p-value, comparing obese versus non-obese autistic subjects. (2) No difference was found for rs7702361, comparing obese versus non-obese unaffected siblings. (3) Current medication history data (i.e., Attention Deficit-ADD medication and Mood Stabilizers) were used to assess the potential medication effects on obesity in probands. Analyses were run separately for probands stratified by medication use (e.g., Mood Stabilizers “Yes” or “No”). The rs7702361 SNP showed an association with both Mood Stabilizers “Yes” or “No” subsets and none with the subjects on ADD medication; suggesting that the detected association of this SNP with obesity category in probands is more likely independent of drug exposure and may be related to the underlying condition (i.e., co-occurring autism and obesity). Comparing obese probands stratified by Mood Stabilizers use (i.e., “Yes” versus “No”) did not detect any differences for rs7702361, which further validates the above conclusion about the potential association of this SNP with the underlying co-occurring conditions not drug exposure. **BMI SNPs analysis.** Similarly, we evaluated genotyping data for n=74 BMI SNPs for SSC subjects. This analysis showed both shared (i.e., familial BMI/obesity risk factors) and distinct BMI associated SNPs in probands and siblings, which may indicate potential differences in the underlying mechanism of obesity in autistic and non-autistic family members. This observation further complements/strengthens our finding for the AIWG SNPs.
Conclusions: Â Our results suggest that factors beyond drug side effect may contribute to the observed higher rate of obesity in autism. Furthermore, an association with rs7702361 (located in the RXFP3 gene, ch5p13.2) in autistic subject with obesity was found, which appears to be independent to anti-psychotic medication use. It is intriguing that recent reports highlight the importance of this gene and related networks in neuropsychiatric disease and eating disorders. Further investigations are warranted on the potential role of the RXFP3 gene in association with co-occurring autism and obesity.

126 **108.126** Chemical-Gene-Disease Interaction Analysis Reveals Overlaps Between Autism and Cancer

Y. Wen[1,2] *and M. R. Herbert*[1,2]*, (1)Neurology, Massachusetts General Hospital, Charlestown, MA, (2)Harvard Medical School, Boston, MA*

Background:
Published research increasingly supports the contribution of environmental factors such as toxicants and nutrients to Autism Spectrum Disorders (ASDs). Finding associations between chemicals and ASDs can provide a starting point for investigation of possible mechanisms by which these substances may contribute to ASDs and their features.
Objectives:
We set out to generate informatics-based data linking autism-associated genes and autism-associated chemicals and substances in order to provide insight into the underlying molecular means by which environmental factors influence ASDs.
Methods:
We used a well-established chemical-gene-disease database, Comparative Toxicogenomics Database (CTD), as our data source to investigate gene-chemical interactions in relation to ASD-associated chemicals.Â 1) We used the MeSH term “Autism Spectrum Disorder” as a search term under the “Disease” category in CTD.Â Under the “Chemical” sub-category for ASD, we chose the chemicals that have a curated association to the disorder, which means that the chemicals have been reported to be related to ASDs by what CTD categorizes as “direct evidence.” 2) Then, for each ASD associated chemical, CTD’s “top 10 interacting genes” were used in further analysis. Some chemicals had less than 10 interacting genes, in which case all genes noted in this CTD category were used. 3) We pooled all the top genes for every selected chemical and used the Gene Set Analyzer tool provided within CTD to perform a gene set enrichment analysis to identify enriched pathways and gene ontologies. 4) Some of the genes interacted with more than one ASD substance; we tabulated the number of substances with which each gene interacted and ranked the genes by this number.
Results:
16 substances were found to be associated with ASDs by presently available direct evidence: Valproic Acid, Arsenic, 5-Methylcytosine, 5-hydroxymethylcytosine, Testosterone, Serotonin, Air Pollutants, Lead, Zinc, 8-oxo-7-hydrodeoxyguanosine, Triiodothyronine, Cadmium, Magnesium, Mercury, Aluminum, and Androstenedione. A total 109 genes that interact with these chemicals were investigated. The enrichment analysis found that these genes were enriched for pathways “Pathways in Cancer” (p-value 5.03e-16) from pathway database KEGG; and “Metabolism” (p-value 1.01e-18), and “Signal Transduction” (p-value 6.57e-15) from pathway database REACTOME. The Gene Ontology enrichment analysis found that these 109 genes were enriched for “Response to Chemical” (Biological Process, 4.92e-62) and “Binding” (Molecular Function 4.04e-33). The most impacted genes with most number of interactions with ASD chemicals/substances were: a*) CASP3, CYP1A1, HMOX1, MT1, PTGS2*, and *TNF*, each with 4 interactions; and b) *CAT*, and *MAPK3*, each with 3 interactions.
Conclusions:
The gene enrichment findings for KEGG “Pathways in Cancer” and for REACTOME “Metabolism” suggest overlaps between ASDs and both cancer and metabolism. All of the most impacted genes listed above are also associated with cancers. The ASD-cancer overlap, while previously reported, is derived here from chemical-gene interactions—a new source. The enriched GO categories “Response to Chemical” and “Binding” – together with the enriched REACTOME pathway “Signal Transduction” – are cellular reactions that process “environmental information.” Our results suggest that information processing procedures may play a mechanistically crucial role in environmental contributions to ASDs.

127 **108.127** Clinical Characterisation of Neurexin1 Deletions and Their Role in Neurodevelopmental Disorders

J. E. Fitzgerald[1], *M. Al-Shehhi*[2], *S. A. Lynch*[2], *H. Peeters*[3], *N. Cosemans*[4], *A. C. Tabet*[5], *R. Delorme*[6], *T. Bourgeron*[7], *M. van den Bree*[8], *J. Hall*[9], *S. Shen*[10] *and L. Gallagher*[11], *(1)Trinity College, Trinity College Dublin, Dublin 2, Ireland, (2)National Centre for Medical Genetics, Our Lady's Children's Hospital Crumlin, Dublin, Ireland, (3)Centre for Human Genetics, KU Leuven and Leuven Autism Reasearch, Leuven, BELGIUM, (4)KU Leuven, Leuven, Belgium, (5)AP HP, Robert Debre Hospital, PARIS, FRANCE, (6)Institut Pasteur, Paris, France, (7)Neuroscience, Institut Pasteur, Paris, France, (8)Council Centre for Neuropsychiatric Genetics and Genomics, Institute of Psychological Medicine and Clinical Neurosciences, Cardiff University, Wales, United Kingdom, (9)Neuroscience Mental Health Research Institute, Cardiff University, Wales, United Kingdom, (10)REMEDI, National University Ireland Galway, Galway, Ireland, (11)Trinity Centre for Health Sciences, Institute of Molecular Medicine, Dublin, IRELAND*

Background:
The Neurexin1 (NRXN1; 2p16.3) gene has been identified as a rare but significant genetic risk factor for a number of neurodevelopmental disorders including autism spectrum disorder (ASD), schizophrenia, intellectual disability and bipolar disorder. NRXN1 encodes neurexins, presynaptic neuronal adhesion molecules that bind to postsynaptic neuroligins to stabilise synapse formation and facilitate neuronal transmission. Common clinical features are associated with NRXN1 deletions but these have not been deconstructed using in-depth neuropsychological, neurocognitive and neuroimaging techniques.
Objectives:
This collaboration aims to use a multi-modal approach to deep phenotype individuals and characterise the clinicopathological features of NRXN1 deletions in order to establish diagnostic biomarkers and targeted therapeutic interventions.
Methods:
To date, 19 families (n = 31) identified with NRXN1 deletions have been recruited. Participants completed a battery of semi-structured neuropsychological assessments (CAPA, PAS-ADD) and questionnaires to probe for existing and/or sub-threshold psychiatric disorders or symptoms. The WASI-II and a comprehensive cognition battery (CANTAB) which, included tests of reaction time (RTI), attention (MTS, RVP), executive functioning (SOC), working memory (SWM), cognitive flexibility (IED) and social cognition (ERT), was administered to assess neurocognitive functioning. Abnormal brain structure and function was investigated using MRI. High-resolution T1, diffusion, spectroscopy and resting state data was collected. Structural T1 and diffusion data have been analysed using FSL (TBSS/VBM) and ExploreDTI software. Age and gender matched controls were used to explore preliminary findings.
Results:
Clinical assessments indicated that of the 31 individuals with NRXN1 deletions, 14 met criteria for ASD, 8 for ID (3 mild ID and 5 severe ID), 3 for ADHD, 3 for an anxiety disorder, 1 for a psychotic disorder and 1 for conduct disorder. The NRXN group (n=15) had significantly lower IQ scores than the control group (n=9), ($t(22) = -3.272$, $p = 0.004$). Neurocognitive assessments indicated that the NRXN group performed significantly poorer on tasks of attention (MTS; $t(22) = -2.263$, $p = 0.011$), executive functioning (SOC; $t(22) = -2.940$, $p = 0.005$), cognitive flexibility (IED; $t(22) = 1.863$, $p = 0.047$) and social cognition (ERT; $t(22) = 2.168$, $p = 0.032$). TBSS results indicated that that there was lower FA in the NRXN group relative to the control group in the body of the corpus callosum, the inferior longitudinal fasciculus and the posterior radiate trending towards significance. VBM results revealed no difference in grey matter volume between the groups. The remaining individuals were either too low functioning or too young to complete assessments.
Conclusions:
Although the study data are preliminary, interesting clinical characteristics of NRXN1 deletions are emerging. Psychological assessments indicate a clear link between the presentation of clinical symptoms and a NRXN1 deletion. Neurocognitive testing illustrated that poor attention, executive dysfunction and reduced social cognition are most characteristic of individuals with NRXN1 deletions. Furthermore, disrupted white matter organisation may potentially be established as a neuroanatomical phenotype underpinning the clinical and cognitive deficits observed. Additional clinical and neurobiological phenotyping in large numbers of individuals with NRXN1 deletions in addition to mapping of the NRXN1 genotype may elucidate the underlying neurobiological processes contributing to neurodevelopmental disorders.

128 **108.128** Comparison of Phenotypic Severity Associated with Autism Risk CNVs in Clinically Identified Samples of High Functioning Males and Females

D. H. Skuse[1], *I. Lee*[2], *M. Murin*[3] *and W. Mandy*[4], *(1)Institute of Child Health, London, United Kingdom, (2)Behavioual an Brain Sciences Unit, UCL Institute of Child Health, London, UNITED KINGDOM, (3)Great Ormond Street Hospital for Children, London, UNITED KINGDOM, (4)University College London, London, United Kingdom*

Background: Clinically identified samples of ASD typically exhibit a male:female sex ratio > 4:1. Many genetic studies report females possess a greater genetic 'burden' and substantially lower IQ than males with an equivalent phenotype (SFARI Foundation Autism Research Initiative). Current estimates point to 10-20% of ASD being caused by Copy Number Variants (SFARI database). It is not known whether apparently large sex differences in ASD prevalence (especially in normal/high IQ samples) reflect a failure of ascertainment of 'high functioning' females, rather than any substantial differences in genetic risk, as measured by the burden of CNVs.
Objectives: To investigate in a 'high-functioning' sample of clinically identified autistic children, with IQs in the normal/high range, the impact of ASD-risk CNVs (as compiled by SFARI) on ASD symptoms and cognitive abilities. To compare and contrast male and female phenotypes in those with and without 'pathogenic CNVs'. To test the hypothesis that females with pathogenic CNVs have more severe phenotypes than males with equivalent genetic risk.
Methods: Subjects were consecutive referrals to the National Centre for High Functioning Autism in London, UK. The autistic traits of 253 participants with autism were measured using a standardized interview (ADI algorithm) and the Autism Diagnostic Observation Schedule (ADOS). IQ was tested with the Wechsler Intelligence Scale for Children-IV (UK). Salivary or buccal cells were collected from the participants for DNA extraction. The microarray analysis carried out in the North East Thames Regional Genetics Laboratory was applied on Affymetrix 750K oligo SNP array. Ratio plots generated by infoQuant Fusion v6 software to show the copy number losses or gains were analysed with an electronic reference file, supplied by Affymetrix, which was based on averaging the results from 1000 sex-matched individuals from 4 major ethnicities.
Results: We compared male:female phenotypes in terms of ADI algorithm scores, ADOS algorithm scores, and IQ subscales. The mean verbal IQ of females with no pathogenic CNV was 91.7 (SD 20.6); that of females with a pathogenic CNV was 104.2 (SD 19.9). Comparing males and females without CNVs (233), no significant gender differences were found in terms of severity of phenotypes, in any domain of the ADI, ADOS, or IQ subscale. In those with pathogenic CNV (20) the effect sizes of gender differences in ADI algorithm scores were in the range 0.03-0.6, with females tending to show more severe phenotypes in social interaction and repetitive/stereotyped behaviours. On all ADOS subscales, the rated phenotype was more severe in males (effect sizes in range 0.4 – 1.4). In the sample with a pathogenic CNV, verbal and performance IQ were higher in females than males (effect sizes in range 0.5-0.6). CNV burden was no greater in females than in males.
Conclusions: There has been a probable ascertainment bias in recruitment studies, leading to erroneous conclusions about the impact of pathogenic ASD-related CNV in females. Females with ASD who are at genetic risk, but who have normal/high range IQ, are being missed by clinical research methodologies. They have milder phenotypes than males when assessed by standardized observation.

129 **108.129** Creatine Transporter Deficiency: A Rare Neurodevelopmental Disorder with ASD Symptomatology

J. Miller[1], *R. P. Thomas*[2], *A. Bruchey*[3], *R. J. Davis*[3] *and A. Thurm*[4], *(1)The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Philadelphia, PA, (3)Lumos Pharma, Inc., Austin, TX, (4)National Institute of Mental Health, Bethesda, MD*

Background: Creatine transporter deficiency (CTD) is a rare X-linked inherited neurometabolic condition associated with intellectual disability, minimal verbal development and, in some cases, ASD. Seizures are also common. CTD is caused by mutations in the SLC6A8 gene, and was discovered in 2001. It is estimated that 0.2% to 3.5% of males with Intellectual Disability or Autism Spectrum Disorder (ASD) may have CTD (Thurm et al., 2016). Unfortunately, CTD cannot be identified through microarrays, which are commonly ordered for children with ASD. Like other genetic conditions associated with ASD characteristics, it is important to increase identification and to understand the behavioral phenotype, as these children may have a distinct developmental trajectory.
Objectives: The objective of the study was to understand the potential relationship between CTD and ASD with regard to identification, characteristics, and developmental course.
Methods: We studied 20 children and adults with CTD, ages 1-21 years, through parent interviews, questionnaires, medical records and direct testing. Parent interviews were relatively unstructured but were informed by our familiarity with the ADI-R. We asked about first concerns, concerns in hindsight, the path to diagnosis, and parents' top current concerns. We administered the Vineland Adaptive Behavior Scales, Social Communication Questionnaire (SCQ) and Aberrant Behavior Checklist (ABC) to all 20; the Mullen Scales of Early Learning to seven (some of whom were older than 60 months).
Results: Â Six participants had a documented diagnosis of ASD in addition to CTD. One participant had a biological sibling with ASD, but not ASD himself.Â The quality of early concerns was not different between children with CTD+ASD or CTD alone. Across the entire group, parents' first concerns were most often about delayed speech or motor milestones (most often walking, but sometimes crawling). In hindsight, parents reported high rates of vomiting in the first year of life (66%). Across the entire group, the average SCQ was 20.8 (range 10-34), with 16/20 (81.25%) individuals scoring 15 or higher. ABC average Irritability domain score was 17.6 (range: 4-38). Vineland and Mullen scores were generally in the very low ranges such that it would be difficult to calculate mental ages accurately. Even with high SCQ scores, parent top concerns were: language, negative behaviors, independence skills, attention, and emotion regulation. Most individuals with CTD continue to struggle with basic self-help skills such as dressing and bathing, but parents did not describe the social aloofness or withdrawal often seen in severely impaired children with ASD.
Conclusions: As new genetic disorders are discovered, it will be important for ASD researchers and clinicians to consider whether they have undiagnosed individuals in their caseloads or samples. Individuals with CTD are likely to have a different developmental trajectory and diminished response to behavioral treatment than most children with ASD. While not universal, possible signs of CTD include minimal verbal development, a history of delayed crawling or walking, vomiting during the first year of life, and possible seizures. Challenging, attention-seeking behaviors are also common. Referral to a metabolic geneticist is important for both diagnosis and treatment.

130 **108.130** Developmental Markers of Genetic Liability to Autism in Parents: A Longitudinal, Multigenerational Study

M. Losh[1], *G. E. Martin*[2], *M. Lee*[1], *J. Klusek*[3], *J. Sideris*[4], *T. Wassink*[5] *and S. Barron*[5], *(1)Northwestern University, Evanston, IL, (2)St. John's University, Staten Island, NY, (3)Communication Sciences and Disorders, University of South Carolina, Columbia, SC, (4)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (5)University of Iowa, Iowa City, IA*

Background: Genetic liability to autism spectrum disorder (ASD) can be expressed in unaffected relatives through subclinical, genetically meaningful traits, or endophenotypes. To date, investigations of ASD endophenotypes in parents have necessarily been restricted to assessments administered in adulthood, when status as a parent of a child with ASD is determined. This leaves unexamined a large swath of time during which ASD endophenotypes are likely to first arise, and might be most profitably studied for clues into underlying biology. This study aimed to identify developmental endophenotypes in parents of individuals with ASD by examining parents' childhood academic development over the school-age period, using archival standardized testing records from kindergarten-high school. Parents' childhood developmental profiles were examined in relationship to endophenotypes in adulthood, and ASD symptom expression in the next generation.
Â
Objectives: To identify developmental endophenotypes in parents of individuals with ASD using archival testing data from childhood.

Methods: A cohort of 139 parents and their children with ASD, and 28 adult controls participated. Archival records of standardized test performance in the domains of language, reading, and math were examined from grades K-12. Additionally, a battery of cognitive, language and personality measures were administered to parents. ASD symptoms in children were measured using the gold-standard diagnostic measures for children with ASD. Parents' performance over time was examined relative to controls as well as in relationship to clinical-behavioral endophenotypes in adulthood, and their children's ASD symptoms.
Â
Results: Subtle differences were observed in the language domain, with the ASD parent group showing lower language skills than controls overall. Additionally, relatively slower development of language and math skills, and a fractionated, or uneven rate of development across domains in the ASD parent group predicted ASD endophenotypes in adulthood for parents, and increased symptom severity in their children diagnosed with ASD.
Â
Conclusions: Results identified developmental profiles in parents of individuals with ASD that are related to endophenotypes measureable in adulthood among parents, and ASD symptom severity in parents' offspring. Evidence of such early expression of genetic liability, in patterns of academic performance across major curricular domains of language, reading, and math (and perhaps language in particular), a generation removed from affected individuals, may help to advance neural and genetic research by stratifying individuals and families to examine biological factors differentially associated with genetically meaningful developmental phenotypes in parents.

131 **108.131** Differential Alternative Splicing in Superior Temporal Gyrus of Autism Spectrum Disorders Brains

B. Stamova[1], *B. P. Ander*[1], *A. Omanska*[2], *F. R. Sharp*[1] *and C. M. Schumann*[2,3], *(1)Neurology, University of California, Davis School of Medicine, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California, Davis, Sacramento, CA, (3)Psychiatry & Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA*

Background: Gene expression studies in postmortem brain in Autism Spectrum Disorders (ASD) have revealed dysregulated immune and neuronal networks. Differential alternative splicing (DAS) in genes targeted by the neural-specific splicing regulator FOX1 (A2BP1) has been reported in ASD brain. Thus, we investigated genome-wide DAS in superior temporal gyrus (STG) of brains of ASD subjects compared to typically developing (TD) controls. STG is an association cortex involved in social perception, joint attention, face perception and speech perception and is implicated in ASD.
Objectives: To assess DAS in the STG transcriptome in postmortem human brains of ASD subjects compared to TD controls.
Methods: RNA libraries from 45 subjects (16 ASD, 14/2 M/F and 29 TD, 23/6 M/F) were sequenced to 40M 2×150 bp reads using Illumina sequencing-by-synthesis technology. Alignments to the human genome (hg19) (STAR 2.4.1d aligner) and quantification using the Ensembl 75 transcript database were performed. DAS was assessed using Log-normal with shrinkage models as implemented in Partek Flow, considering Diagnosis (ASD, TD), Sex (F, M) and Age (continuous variable). Gene-Specific Algorithm (GSA) was applied to each transcript separately to identify factors and interactions that affected DAS. After filtering low expressing transcripts, DAS between the groups was considered significant with |Fold-Change| >1.2, and FDR-corrected p<0.3 (nominal p<0.01). Gene Ontology and Ingenuity Pathway Analysis were used to identify relevant biological functions.
Results: There was no significant age difference between ASD (Average age: 30 years, range 9-56)) and TD (Average age: 25.2, range 5-68) groups. Most transcripts (41.4%) were best described by the model: Dx + Sex + Dx *Sex, followed by the Dx + Sex + Age + Dx*Age +Dx*Sex model (24.9% of the transcripts). 330 genes displayed DAS in ASD vs. TD considering both sexes, there were 795 in ASD-Male vs. TD-Male, and 41 in ASD-Female vs. TD-Female. Genes with DAS were over-represented in immune and neurotransmitter pathways. Some of these have previously been implicated in ASD, such as mTOR Signaling, CREB Signaling in neurons, and Glutamate and GABA Receptor Signaling pathways (Males analysis). There was significant overlap with ASD-implicated genes from the SFARI database with our all ASD vs. TD (33 genes, hypergeometric probability = 1.3E-06) and ASD-Male vs TD-Male (81 genes, p=7.9E-15) differentially alternatively spliced gene lists. Among the genes with DAS in ASD-Male, the RBFOX2-12 transcript was down-regulated. RBFOX2 (RNA Binding Protein, FOX1 Homologue 2) regulates alternative exon splicing in the nervous system and is homologous to the neural-specific splicing regulator FOX1 (A2BP1) which has been reported to be down-regulated in ASD brain (Voineagu et al, 2011). We compared our genes with DAS to the 196 genes with FOX1-dependent DAS identified by Voineagu et al. (2011). There was a significant overlap with our all ASD vs. TD (9 genes, p=0.004) and ASD-Male vs. TD-Male (32 genes, p=4.1E-12) gene lists.
Conclusions: There is differential transcript isoform expression in STG in ASD which is modulated by age and sex, and which likely contributes to ASD pathophysiology. Future studies will need to confirm these findings.

132 **108.132** Dysregulation of Cortical Neuron DNA Methylation in Autism: Implication of Gabaergic and Immune System-Related Genes

S. Nardone[1], *D. S. Sams*[1], *A. Zito*[2], *E. Reuveni*[1] *and* ***E. Elliott***[3], *(1)Bar Ilan University, Safed, Israel, (2)King's College, London, United Kingdom, (3)Bar-Ilan University, Safed, ISRAEL*

Background: Epigenetics has been implicated as a primary molecular mechanism that may mediate the interaction between environmental factors and the development of ASD. Previous epigenetic studies in post-mortem brains have been severely limited by the cellular heterogeneity of the brain tissue, which impairs our ability to determine specific and robust epigenetic changes in the brain.
Objectives: Our main objective is to determine changes in the epigenetic signature in cortical neurons of individuals diagnosed with autism, compared to matched controls. Further objectives include to understand the biological function of the dysregulated epigenetic signature and to determine if genomic regions that display epigenetic plasticity during brain development are particularly sensitive to dysregulation in ASD.
Methods: To investigate methylation changes specifically in neurons from the frontal cortex of autistic and control subjects, we employed Fluorescent Activated Cell Sorting (FACS) of neuronal nuclei from post-mortem brains, followed by hybridization of DNA on 450K BeadArray. Bumphunting analysis (using CHAMP tool) was performed to find differentially methylated regions and WGCNA analysis was performed to determine co-methylated modules of CpGs that correlate with autism status, followed by gene ontology and protein-protein interaction analysis. Targeted Bisulfite Sequencing was used to validate differentially methylated regions. Differentially methylated regions and correlated modules were compared to published datasets of CpGs that are differentially methylated during neurodevelopment.
Results: We identified 58 Differentially Methylated Regions (DMRs) at *FDR* <0.05 that included genomic loci associated to GABAergic system genes, in particular *ABAT* and *GABBR1*, and brain-specific MicroRNAs, *Mir124-1* and *Mir124-2*. We verified a subset of these DMRs by targeted bisulfite sequencing. At system level, Weighted Co-Methylation Network Analysis (WGCNA) detected three major modules significantly correlated to ASD. Two modules (p=2e-04; p=0.008) were inversely correlated with ASD and were enriched for regions underlying neuronal genes (synaptic genes, as well as GABAergic genes), whereas one module (p=0.001) showed direct correlation and was enriched for regions underlying immune genes. Protein-protein interaction networks determined a subset of neurotransmitter-related genes that were enriched in several of these modules. In a comparison between our data and published data on neurodevelopment-associated DMRS, A remarkable overlap of the 58 autism-related DMRs with age-specific (from embryonic to late-fetal neurodevelopment) and cell-type specific (neuron; glia) DMRs was observed. Finally, we established the specificity of these three modules to ASD by assessing their enrichment for GWAS databases related to other psychiatric and non-psychiatric disorders.
Conclusions: We have identified multiple genomic regions that display dysregulated DNA methylation in cortical neurons from individuals with ASD. These regions are highly relevant to biological mechanisms that have been implicated in autism. Our study suggests that robust analysis of specific cells in the brain is an important goal in understanding the epigenetics and molecular biology of the development of ASD. Our study identifies alterations of DNA methylation in cortical neurons as a plausible environment-mediated component to ASD aetiology.

133 **108.133** Epigenomic Mechanisms Underlying Pathology in Chd8 Haploinsufficiency

***A. A. Wade**, L. Su-Feher, A. Gompers, R. Catta-Preta, I. Zdilar, T. W. Stradleigh and A. S. Nord, Center for Neuroscience, Department of Neurobiology, Physiology, & Behavior, University of California, Davis, Davis, CA*

Background: Exome sequencing studies of patients with autism spectrum disorder (ASD) have identified *de novo* mutations in *CHD8*. *CHD8* haploinsufficiency is proposed to drive neurodevelopmental pathology via genome-wide changes in chromatin state and gene expression. However, the biological processes and underlying regulatory mechanisms negatively impacted during neurodevelopment by reduced CHD8 dosage remain unknown. Mapping these changes may give insight into ASD pathophysiology.
Objectives: We used a mouse model harboring a germline loss-of-function mutation in *Chd8* to study the role of Chd8 and chromatin remodeling in neurodevelopment through genomic characterization.
Methods: Bulk forebrain was dissected from $Chd8^{+/-}$ and wildtype littermates at post-conception days 12.5, 14.5, 17.5, 21, and ~77. We used RNA-seq and ChIP-seq to map the transcriptional and genomic impact of *Chd8* haploinsufficiency during development.
Results: Transcriptional profiling of $Chd8^{+/-}$ mice revealed widespread transcriptional changes throughout development involving genes important for RNA processing and chromatin remodeling as well as genes previously implicated in studies of genetic contributions to ASD. Epigenomic profiling of Chd8 binding provides evidence that it directly regulates expression of differentially expressed genes, including RNA processing, chromatin remodeling, and ASD-relevant genes. Further analysis shows strong Chd8 binding to genes with decreasing expression over neurodevelopment, suggesting typical Chd8 expression is required for transcriptional activation during brain development.
Conclusions: These results reveal pathophysiology associated with single copy loss-of-function mutations of chromatin remodeling genes, providing insight into one of the most intriguing findings from large-scale ASD genetic studies.

134 **108.134** Examining Minor Physical Anomalies in Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD): A Twin Study

***L. H. Myers**[1,2], K. Tammimies[3], B. M. Anderlid[4], A. Nordgren[4] and S. Bolte[5,6], (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, (2)Stockholm County Council, Center for Psychiatry Research, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, SWEDEN, (4)Department of Clinical Genetics, Karolinska University Hospital, Stockholm, Sweden, (5)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (6)Stockholm County Council, Stockholm, Sweden, Division of Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm, Sweden*

Background: Â Minor physical anomalies (MPAs) represent subtle anatomical deviations in one's appearance such as low-set ears, widely spaced eyes, and a short neck. MPAs may suggest some type of abnormal development that occurred in the early embryogenic or fetal periods. MPAs have been shown to be more common in individuals with ASD and ADHD. Further studies are needed, especially with a well-controlled genetic background, to examine this relationship in children and young adults with ASD and ADHD.
Objectives: To describe the findings from clinical morphology exams on monozygotic (MZ) and dizygotic (DZ) twins to identify MPAs in children and young adults with ASD and ADHD, with a special focus on differences in the number of MPAs based on the presence of a diagnosis, the most common MPAs in participants with ASD or ADHD, differences in MPAs in highly discordant pairs, and the relationship between MPAs in twin pairs based on zygosity.
Methods: Clinical morphology exams to identify the presence of MPAs were conducted on 120 individuals representing 51 MZ pairs, 7 DZ pairs, 1 trio of triplets (MZ sisters and DZ brother), and 1 DZ twin. Two clinical geneticists utilized a checklist covering all major body systems to uniformly identify MPAs. All participants also received detailed clinical assessments, including determination of ASD and ADHD through gold standard assessments (e.g., ADOS, ADI-R, SRS, Connors-3, K-SADS, etc.). Roughly 24% of participants had a diagnosis of ASD, 28.3% had a diagnosis of ADHD, and 42.5% were typically developing (42.5%). Descriptive and correlational statistics were performed to summarize the findings from the clinical exams.
Results: The clinical exams revealed the presence of more physical anomalies in participants with ASD (median=9) and ADHD (median=7) compared to those with typical development (median=5). The most common physical anomalies in participants with ASD (n=29) and ADHD (n=34) included hypermobility (37.9% with ASD and 32.4% with ADHD) and being overweight (37.9% with ASD and 26.5% with ADHD). Comparing highly discordant pairs for ASD (i.e., MZ pairs where only one twin has ASD; n=7 pairs), scoliosis was present in the twin with ASD in two pairs. Using a correlation plot, twins who were MZ, regardless of the presence of a diagnosis, demonstrated a positive linear relationship (r_s=.883, p<.001) between the number of MPAs within each twin pair, compared to DZ twins who demonstrated a non-linear relationship (r_s=.209, p=.653), thereby, suggesting a strong genetic basis to MPAs.
Conclusions: Minor physical anomalies were present in children and young adults with ASD and ADHD in greater amounts compared to those without either disorder and appear to have a strong genetic basis when looking at the relationship in the number of MPAs within MZ and DZ twin pairs. Examination of minor physical anomalies in children and young adults with ASD and ADHD may serve as a biomarker to identify individuals with a genetic cause to ASD or ADHD and thereby, help identify potential subtypes of each disorder and/or individuals who would benefit from further testing (i.e., genetic testing).

135 **108.135** Exploring Heterogeneity in the ASD Blood Transcriptome: Machine-Learning Classification Accuracy Is Improved By Modeling Subgroups.

D. S. Tylee[1]*, J. L. Hess*[1]*, T. P. Quinn*[1]*, B. Stamova*[2]*, F. R. Sharp*[3]*, I. Hertz-Picciotto*[4]*, S. V. V. Faraone*[5]*, S. W. Kong*[6] *and S. J. Glatt*[1]*, (1)SUNY Upstate Medical University, Syracuse, NY, (2)UC Davis MIND Institute, Sacramento, CA, (3)Neurology, University of California, Davis School of Medicine, Sacramento, CA, (4)University of California at Davis, Davis, CA, (5)Psychiatry, SUNY Upstate Medical University, Syracuse, NY, (6)Computational Health Informatics Program, Boston Children's Hospital, Boston, MA*

Background: Blood-based microarray studies comparing individuals affected by autism spectrum disorder (ASD) and typically developing individuals have helped characterize differences in circulating immune cell functions and offer potential biomarker signal. Genetic heterogeneity is widely recognized within the ASD phenotype and at the level of etiology, yet relatively few studies have explicitly examined heterogeneity in the transcriptome.
Objectives: We sought to examine heterogeneity in the ASD blood transcriptome.
Methods: Recently, we combined the subject-level data from previously published blood microarray studies in order to perform combined-samples mega-analysis. The present study utilized a subset of these data (male samples self-identified as European ancestry; n_{asd} =417, $n_{control}$= 243). We identified genes and functional gene-sets that were differentially expressed within this sample. We then clustered ASD-affected samples into putative subgroups based on genes and gene-sets, as well as expression principal components.
Results: Machine-learning classification accuracy in withheld samples was significantly improved for subgroup-informed classification problems (*e.g.,* ASD subgroup *k vs.* all comparison; overall accuracies ranging from 67 to 76%), as compared with the baseline classification problem (*i.e.,* all ASD samples *vs.*all comparison; overall accuracies ranging from 61 to 63%); this effect was most pronounced for gene-set- and PCA-based subgroups. All subgroup solutions showed pronounced differences in leukocyte-specific marker genes, indicating that heterogeneity in cellular composition contributes critically to transcriptomic heterogeneity. Additionally, many of the subgroup solutions showed significant differences in domains of the Mullen Early Learning Scale and comorbid developmental conditions.
Conclusions: These findings begin to shed light on heterogeneity within the ASD blood transcriptome.

136 **108.136** Gene Expression Correlates of Language Regression in Autism Spectrum Disorder

S. Trinh[1] *and R. Bernier*[2]*, (1)University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA*

Background: Language regression occurs in approximately one-third of children with autism spectrum disorder (ASD) in the first three years of life (Goin-Kochel et al., 2014). Individuals with ASD who experience regression were found to have poorer outcomes of adaptive, cognitive, and social-communicative functioning, compared to those with ASD with no regression (Parr et al., 2011). However, the mechanisms underlying this behavioral phenotype remain unknown (Jones & Campbell, 2010). Recently, gene coexpression network analysis has identified specific spatial and temporal expression patterns in genes associated with ASD (Willsey et al., 2013). Further analysis of gene expression trajectories in the canonical language region of the superior temporal cortex during prenatal and early postnatal development may help to reveal molecular mechanisms of language regression in children with ASD.
Objectives: To investigate superior temporal cortical gene expression correlates of language development and regression in individuals with ASD with likely gene disrupting mutations.
Methods: Participants were 353 children from the Simons Simplex Collection with likely gene disrupting mutations (as defined by Iossifov et al., 2014) who meet strict criteria for ASD. Superior temporal cortical gene expression data from eight weeks post-conception to three years post-birth was extracted from the BrainSpan transcriptome RNA-seq data (http://www.brainspan.org). Coexpression modules were constructed using signed weighted gene coexpression network analysis (WGCNA; Parikshak et al., 2013). 56 children with parentally reported history of developmental regression in language skills were compared to 294 children without language regression. First, a nonparametric analysis was performed to examine the relationship between the presence of language regression and gene expression trajectories as identified in coexpression modules. Next, coexpression groups were compared using one-way analysis of variance on parentally reported age of first spoken single words and age of first spoken phrases.
Results: Five coexpression modules were identified with two modules representing clear increases in expression levels and one module representing decreasing levels of expression over prenatal and early postnatal development. No relationship was found between coexpression module and rate of language regression ($\chi 2 = 4.44$, $p = 0.35$). In addition, no significant differences in age of first spoken words ($F(4,289) = .542$, $p = .71$) or first spoken phrases ($F(4,270) = 1.001$, $p = .41$) were found among coexpression module groups.
Conclusions: Gene coexpression network analysis was used to identify differential gene expression patterns among children with ASD with and without language regression. Our evidence suggests that differential gene expression trajectories in the superior temporal cortex are unlikely to contribute independently to the language regression seen in some children with ASD. Future studies should investigate gene coexpression networks focused on other brain regions implicated in language development. Better understanding of the developmental timing of gene expression in genes disrupted in individuals with ASD may aid in explaining the phenotypic variability in language outcomes among children with ASD.

137 **108.137** Genetic Influence on Treatment Response in Children with ASD

*M. Arranz[1], **A. Hervas**[2], I. Rueda Barcena[3], S. Guijarro[4], N. Balmaña[5], A. Ruiz[4] and A. Gonzalez[4], (1)Terrassa, Fundacio Mutua Terressa - HUMT (UB), Barcelona, Spain, (2)Hospital Mutua de Terrassa, Barcelona, SPAIN, (3)HOSPITAL SANT JOAN DE DEU - BARCELONA, BARCELONA, SPAIN, (4)Hospital Universitari Mutua Terrassa - University of Barcelona, Terrassa (Barcelona), Spain, (5)Hospital Universitari Mutua de Terrassa, Terrassa, SPAIN*

Background: Antipsychotic, antidepressant or stimulant medications are used for the treatment of ASD comorbidity, including symptoms such as aggressiveness, euphoria, anxiety, and depression. However, 30-40% of treated children do not respond to pharmacological treatment and an important proportion present clear deterioration. In addition, 60-70% of them present severe and long-lasting side effects. The reasons behind treatment failure are unclear, and few studies have investigated response determinants in ASD children.
Objectives: We hypothesised that genetic factors in genes coding for metabolic enzymes and in genes coding for drug targets may contribute to treatment failure. The identification of the genetic factors that influence response and side effects may help to improve treatment in ASD children
Methods: To test this hypothesis we investigated 32 single nucleotide polymorphisms (SNPs) in 16 genes relevant to pharmacological treatment (CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP3A5, MDR1, D2, D3, 5-HT1A, 5-HT2A, 5-HT2C, BDNF, COMT, MC4R, LEP and CNR1) in 72 ASD children (88% males, mean age: 8 ± 2.6) treated with a antipsychotics and stimulant medications (risperidone, aripripazole and methylphenidate).
Results: a genetic variant (rs4244285) in the enzyme CYP2C19, was found associated with treatment-induced weight gain ($p<0.04$). A trend towards association between a polymorphism in the CNR1 gene (rs489693) and weight gain was also observed ($p=0.06$). No significant associations were detected with level of treatment efficacy.
Conclusions: if confirmed, this pharmacogenetic information may help to identify children susceptible of gaining weight during pharmacological treatment, who may benefit from alternative medications and/or palliative interventions.

138 **108.138** Genetic Investigation of Restricted and Repetitive Behaviors in Autism

***M. L. Cuccaro**[1], S. Luzi[1], E. R. Martin[1], H. N. Cukier[2], A. J. Griswold[1] and M. A. Pericak-Vance[1], (1)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (2)John P. Hussman Institute for Human Genomics, Department of Neurology, University of Miami Miller School of Medicine, Miami, FL*

Background: Restricted and repetitive behaviors (RRBs) are a defining feature of Autism Spectrum Disorder (ASD). Two RRB subdomains, repetitive sensory motor behaviors (RSMB) and insistence on sameness (IS), have yielded suggestive association in prior genetic studies of ASD. We hypothesize that genetic variants modify the expression of RRBs in individuals with ASD, and that this genetic variation will be associated with RSMB and IS scores.
Objectives: The primary objective of this study is to search for genetic association to RSMB and IS scores using targeted sequence data.
Methods: Using the ADI-R, a semi-structured interview for ASD, RSMB and IS scores were calculated in 1118 ASD participants from the Hussman Institute for Human Genomics and the Simons Simplex Collection. All individuals had DNA sequence data available from a 17Mb custom capture covering 681 genes within regions identified by GWAS of ASD. Gene-based and single-variant tests for association with IS and RSMB as quantitative traits were conducted using SKAT-O. Combinations of synonymous, non-synonymous, missense, stop, loss-of-function and splice variants were investigated in different hypothesis tests. A Bonferroni correction for the number of genes tested was used as a significance threshold for each hypothesis with an experiment-wise significance level of 0.05.
Results: Gene-based tests revealed different genes in association for the respective traits although none passed Bonferroni correction. For the IS trait, two zinc finger genes were most significant when all exonic variants were included (ZNF397 p=2.24E-03, ZSCAN30 p=2.63E-03) and when only missense variants were examined (ZNF397 p=2.73E-03, ZSCAN30 p=3.16E-03). For the RSMB trait, we observed a convergence on the gene PTPRT for analyses of both damaging (p=1.49E-04) and missense (p=1.63E-04) variants. PTPRT (protein tyrosine phosphatase, receptor type, T) is a gene which is highly expressed in the developing and adult CNS and is involved in both CNS signal transduction and cellular adhesion.
Conclusions: These results are in line with prior clinical studies showing IS and RSMB as distinct types of RRBs, potentially supporting this distinction at a biological level. This work is preliminary but suggests that there is value in dissecting the ASD phenotype into measurable traits that can be tested for association to genetic variants.

139 **108.139** Genetic Stratification Based on Biological Networks in Autism Spectrum Disorders

***Y. M. KIM**[1], T. Rolland[1], R. Delorme[1], G. Dumas[1] and T. Bourgeron[2], (1)Institut Pasteur, Paris, France, (2)Neuroscience, Institut Pasteur, Paris, France*

Background:
The genetic architecture of Autism Spectrum Disorders (ASD) has proved to be complex and heterogeneous. For better prognosis and treatment, genetic stratification is suggested which aims to classify patients into more homogeneous subgroups. Cancer research has recently proposed Network Based Stratification (NBS) to stratify tumors into meaningful subtypes of similar molecular profiles by integrating protein interactions (Hofree *et al* 2013).
Objectives:
We aim to classify heterogeneous patients with genomic data into more homogeneous subgroups to associate them with clinical outcomes. NBS combines genomic information of each patient and Protein-Protein Interaction (PPI) networks. We developed an open source NBS toolkit in Python and propose to probe the impact of mathematical parameters on ASD stratification at both biological and phenotypical levels.
Methods:
At first, we validate the NBS method with the original cancer data contributed by The Cancer Genome Atlas: 235 patients with uterine cancer. Once validated, we applied the NBS to an ASD cohort that involves 115 autistic patients, 354Â related and 230 controls. We have the whole exome sequence of all participants, and clinical data.
After mutated gene's score were diffused over neighbors, just like a thermal conduction, we reduced matrix dimension using Non-negative Matrix Factorization (NMF). This procedure aims to decompose a matrix into two lower rank matrices whose product can approximate the original matrix (Lee *et al* 1999). In addition, for the second application of graph topology, we introduce a Graph regularized NMF (GNMF) algorithm which respects the structure of the underlying gene interaction network and avoids the limitation of Euclidean space by incorporating a geometrically based regularization (Cai *et al* 2010). Finally, a consensus is calculated across 1,000 resampling iterations with hierarchical clustering. We then compare and analyze each subgroup characteristics at genomic, phenotypic and network topological level.
Results:
Our systematic and exhaustive investigation of all the parameters delivers the first guidelines to run NBS in ASD cohorts. The pilot study on cancer data already indicated that: 1) the diffusion step was essential but not the GNMF; 2) median quantile normalization could lead to even better results with just diffusion and NMF. Our ASD study focused on rare deleterious germline mutations, whether inherited or *de novo*. Our preliminary results on ASD data reveal that: 1) in contrast to cancer, homogeneity of mutation profile across patients is preventing a drive of the clustering by mutation numbers; 2) modifying the diffusion factor allows to change the size of the mutated sub-network areas and potentially open up the ability to investigate local and global effects; and 3) NBS with a systematic PPI network (Rolland *et al* 2014) outperforms previous attempt with literature based networks. Moreover, several subnetworks stratifying patients with ASD were identified and will be presented.
Conclusions:
Moving beyond the traditional dichotomy between monogenic and polygenic approaches, the NBS provides a versatile method to tackle heterogeneity of ASD and combined with proper clinical data has the possibility to uncover new relevant genotype-phenotype relationships, such as comorbidities and drugs response, for better prognosis and care of patients with ASD.

140 **108.140** Genetic Test Results in Children Under 3 Years of Age Who Are at-Risk for Neurodevelopmental Disorders: An Update

C. Hensel[1], *R. Vanzo*[1], *M. Serrano*[1], *E. R. Wassman*[1] *and C. Samango-Sprouse*[2], *(1)Lineagen, Inc., Salt Lake City, UT, (2)The Focus Foundation, Davidsonville, MD*

Background: A significant incidence of genetic aberrations has been documented in individuals with autism spectrum disorder and other neurodevelopmental disabilities (NDD) [Roberts et al., 2014]. The earlier these genetic alterations are identified, the sooner the individual can receive targeted interventions to reduce the impact of these disorders and improve outcomes. Several neurodevelopmental assessments have been designed to identify at-risk infants, including the Comprehensive Autism Spectrum Screening for Infants (CASS-i), which is meant to identify infants younger than 12 months who are at-risk for ASD/NDD [Samango-Sprouse et al., 2015].
Objectives: To report the genetic aberrations in infants who fail the CASS-i . Specifically, we provide an update of copy number variants (CNVs) identified by chromosomal microarray analysis (CMA; which was reported at the IMFAR in 2016) and report on newly identified findings from whole exome sequencing (WES) in the same patient cohort.
Methods: Fourteen infants under the age of 3 years who failed the CASS-i were offered clinical CMA testing and research-based WES. CMA was done on a custom Affymetrix platform designed to optimize detection for genetic variants that underlie ASD as other NDD (FirstStep^{Dx} PLUS ®; Salt Lake City, UT). WES was performed using the AmpliSeq Exome target capture kit and Ion Torrent sequencers (ThermoFisher Scientific, Inc.) to an average read depth of 100X. Analysis of the sequence data was performed using the WuXi/NextCode Clinical Sequence Analysis pipeline (https://www.wuxinextcode.com/). Additional analysis of copy number variants and sequence variants using the method of Uddin et al. (2014) was used to identify novel genes possibly relevant to neurodevelopmental disorders.
Results: Fourteen patients underwent clinical CMA testing and 4/14 had a reportable CMA finding (~28%) Thirteen patients underwent research WES; following variant filtration based on allele frequency and phenotypic relevance, roughly 40-50 variants requiring further evaluation were identified in each individual. A summary of these findings from both methodologies will be presented, along with specific examples to demonstrate the improved medical management that comes with a specific genetic diagnosis.
Conclusions: Genetic testing is an important component in the clinical work-up of individuals with ASD/NDD. Of patients who fail early developmental screens, over 10% are expected to have a reportable finding on CMA and over 80% of are expected to have a reportable finding on WES. Clinicians should implement screening and genetic testing protocols to improve early detection and implement personalized medical management for patients with ASD/NDD. This often affords families both individualized and targeted treatment.

141 **108.141** Genetic and Neurobehavioral Profile of the SHANK3 Gene Deficiency Children in China

C. Liu[1], *B. Zhou*[2], *C. Hu*[2] *and X. Xu*[2], *(1)15111240007@Fudan.Edu.Cn, Children's Hospital of Fudan University, Shanghai, China, (2)Children's Hospital of Fudan University, Shanghai, China*

Background: SHANK3 is a scaffolding protein of excitatory glutamatergic synapses. Genetic studies suggested that molecular variations in the *SHANK3* gene had a strong causal relationship with ASD and/or 22q13.3 deletion syndrome, and different defects in this gene potentially resulting in clinical heterogeneity.
Objectives: To determine the data of Chinese ASD patients with *SHANK3* deletion.
Methods: MLPA and Sanger sequencing were carried out to confirm the *SHANK3* deficiency of nine Chinese children. Moreover, systematic and comprehensive evaluations were performed to Chinese-specific features. ADOS scale was applied to examine the severity of autism and Griffith scale was used to assess the development level.
Results: Six participants lacked the whole gene of *SHANK3* with 22q13.3 deletions ranging in size from 55 kb to 4.8 Mb and three participants with de novo *SHANK3* mutation were included. The samples were characterized by high rates (100%) of ASD, developmental delay, hypotonia, several dysmorphologies and perception abreaction. New and rare features were also viewed in this study: ectropion of nostril sparse hair, ankle deformity, whole-body hairy, hanked-3-lap arms, snaggletoothed or extra teeth and unusual-dehydrated skin, and extreme hyperactivity/self-sitimulation. There was no significant statistical difference between SHANK3 defect group and ASD group. However, SHANK3 defect children displayed severer developmental delay in language, social, gross motor, fine motor, adaptability and other items comparing with ASD group. In addition, separating numerous phenotypes into inherent phenotypes and ameliorable phenotypes may contribute to better analyze genotype-phenotype correlations. Ameliorable phenotypes may be independent of gene deficiency and improvable. Epilepsy and degeneration could aggravate symptoms and deteriorate prognosis of diseases.
Conclusions: This study supports findings from previous research on the severity of intellectual, hypotonia, and speech impairments seen in *SHANK3* deficiency, and highlights the prominence of SHANK3 in the syndrome. Early diagnosis and early intervention, as well as consciousness and training of caregivers were very critical in the improvement of these children.

142 **108.142** Genome-Wide Association Study Suggests Genetic Homogeneity within Complex Autism Subgroup

M. Spencer[1], *T. N. Takahashi*[2], *J. H. Miles*[3] *and C. R. Shyu*[1], *(1)Informatics Institute, University of Missouri, Columbia, MO, (2)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (3)Thompson Center at the University of Missouri, Columbia, MO*

Background:
Autism is phenotypically and genetically heterogeneous, prompting our focus on identifying, defining, and studying genotypic differences between clinical autism subgroups. Few studies have examined genetic differences between subgroups on a genome-wide scale. Furthermore, though the development of autism can seldom be explained by a single factor, little is known about how genetic factors interrelate to cause autism.
Objectives:
Since a large proportion of autism heritability is thought to be caused by common genetic variants (Gaugler et al., 2014), we expect that many cases of autism arise from specific combinations of common variants. We aim to discover associations between common variants and clinical autism subgroups. In particular, we focus on testing combinations of multiple variants to identify potential interactions that contribute to the development of autism. Examining all combinations of millions of variants is impossible, so we generate candidate combinations using a data-driven method that measures the prevalence of minor alleles in autism subgroups.
Methods:
Using the SFARI SSC dataset containing ~3 million variants, ASD probands were sorted as “essential” (n=436) or “complex” (n=76). Using a well-studied autism subtype classification, individuals are designated “complex” based on physical evidence of an insult to early morphogenesis (Miles, et al., 2008, Tammimies et al., 2015). Frequent pattern mining, a data mining algorithm, was used to calculate prevalence of variant combinations within each subgroup. We identified the variant combinations that had the highest difference in subgroup prevalence; these were tested for association with the subgroups.
Results:
After excluding combinations exhibiting linkage disequilibrium due to physical proximity, frequent pattern mining identified 14 individual variants and 27 combinations of variants that were at least twice as prevalent in the complex subgroup, versus 13 individual variants in the essential subgroup. 8 of the individual variants and 23 variant pairs were significantly associated with the complex subgroup (family-based association test; $p<.01$). In contrast, the essential subgroup had no associated variants, individually or in combination. We speculate that the complex subgroup is a more genotypically homogeneous group, leading to these stronger associations. We found multiple variants within the LPPR3 gene to be associated with the complex subgroup; to our knowledge this gene was not previously associated with autism. 16 of the 23 significant variant pairs involved the ISM1 gene, linking it to genes and non-genic regions on various chromosomes. Stewart, et al. (2013) previously associated ISM1 with obsessive-compulsive disorder and noted several ISM1 gene-gene correlations related to that disorder as well, but the gene has not been specifically associated with autism.
Conclusions:
Our preliminary study identified several combinations of common variants associated with the complex dysmorphology autism subgroup. This suggests that the complex subtype is more genetically homogeneous than the essential subtype, contrary to prior belief. Further analysis is required to study the relationships between the implicated genes and how they might contribute to autism development. We expect that applying this method to more autism subtypes will lead to the discovery of more genetic distinctions between groups.

143 **108.143** Genomewide Association and Meta-Analysis of Autism Spectrum Disorder in the Multi-Ethnic Charge Cohort

C. L. Simpson[1], *R. J. Schmidt*[2], *K. Kim*[3], *R. Hansen*[4] *and I. Hertz-Picciotto*[2], *(1)University of Tennessee Health Science Center, Memphis, TN, (2)University of California at Davis, Davis, CA, (3)Department of Public Health Sciences, University of California, Davis, Davis, CA, (4)UCD MIND Institute, Sacramento, CA*

Background:
The Childhood Autism Risks from Genetics and the Environment (CHARGE) study is population-based cohort of children with autism or developmental delay and typically developing children, recruited from a statewide database of persons receiving services from regional centers in northern California, from clinical and self-referrals and referrals from other studies at the MIND Institute. Genomewide association studies (GWAS) are a standard genetic epidemiological tool for the assessment of genetic contributions to risk of disease and have produced evidence for genetic variants in a range of psychiatric and neurodevelopmental disorders. A number of GWAS have been performed in ASD and identified many associations, however there have been few successful replications, perhaps in part because of high polygenicity and variable effect sizes.
Objectives:
We performed GWAS in the CHARGE cohort using the Affymetrix European-specific array, which was developed in conjunction with UCSF and Kaiser Permanente.
Methods:
Genotypes were called in Genotyping Console and standard quality control measures were applied. Principal components analysis (PCA) was used to compare self-reported ancestry with HapMap anchors and extreme outliers removed. Each ethnic ancestry population was then subject to separate PCA to generate eigenvalues and used to control population stratification in the association analysis. Data were imputed to the Haplotype Reference Consortium reference panel. All quality control and analyses for each population were performed in R and PLINK, and meta-analysis across populations performed using METAL.
Results:
Subjects were separated into six ethnically distinct; non-Hispanic whites, Hispanic whites, Hispanic other, African American, Asian and Multi-ethnic. The African American and Asian groups were not analyzed due to very low subject numbers.
Five genomewide significant signals were detected on chromosome 2, with a minimum p value of $1.6x10^{-8}$. All signals were located in introns of the ceramide kinase-like gene CERKL. This gene contains multiple transcripts and non-coding RNA's and encodes a protein with ceramide kinase-like domains but does not phosphorylate ceramide and is currently of unknown function. It is widely expressed, but different transcripts are expressed in different tissues and at different time points of development.
Conclusions:
Meta-analysis of multi-ethnic cohorts is a useful tool for dissection of complex traits such as autism and here identifies genome-wide significant signals on chromosome 2 in the CERKL gene. This gene is of unknown function and so its relevance to ASD cannot be assessed. Other genes in the region include integrin alpha 4 (ITGA4), a cell surface adhesion and signaling protein associated with the autoimmune disorders inflammatory bowel disease and multiple sclerosis and the neuronal differentiation gene NEUROD1, known to be associated with Type 1 diabetes. Additional analyses and deeper investigation into these results will be presented.

144 **108.144** Hierarchical Cortical Transcriptome Disorganization in Autism

*M. V. Lombardo[1,2], E. Courchesne[3], N. E. Lewis[4] and **T. Pramparo**[5], (1)University of Cambridge, Cambridge, United Kingdom, (2)University of Cyprus, Nicosia, Cyprus, (3)University of California, San Diego, San Diego, CA, (4)university of california san diego, san diego, CA, (5)Autism Center of Excellence, UCSD, La Jolla, CA*

Background: The pathophysiology behind atypical brain development in autism spectrum disorder (ASD) is highly complex. Several elegant genetic studies have unveiled a diverse array of biological mechanisms associated with ASD and functional genomics work has begun to identify specific dysregulated transcriptomic pathways. In particular, examination of the ASD cortical transcriptome at the systems-level has highlighted dysregulation in two important gene modules (i.e. collections of genes whose expression levels are highly correlated). The first module is downregulated and enriched for synaptic processes and neuronal markers, while the second module is upregulated and enriched for immune/inflammation processes and astrocyte and M2 microglia activation state markers.
Objectives: A key question that remains unclear is whether these pathways are independently dysregulated or some convergence/interaction exists between such systems.
Methods: To address this question we analyzed the cortical transcriptome of two independent ASD datasets (Gupta et al., 2014; Voineagu et al., 2011) using different statistical and network-based gene expression and protein-protein interaction approaches. We tested the hypothesis that diverse molecular mechanisms are hierarchically disrupted in the cortical transcriptome of ASD and point towards interacting systems-level pathology rather than multiple independent types of pathology in synaptic and immune processes. Specifically, we hypothesize that dysregulated gene co-expression modules may work in synergy to form emergent pathology not visible by looking at single modules in isolation.
Results: We identify replicable evidence for 10 gene co-expression modules that are differentially expressed (DE) in ASD cortical tissue. Rather than underlying distinct non-interacting pathology, these modules DE modules are highly correlated and such correlations increased in ASD. Moreover, this synergy and interaction was present at the protein level. This systems-level pathology is characterized by downregulated synaptic and neural developmental processes and upregulated catabolism, viral processes, translation, protein targeting and localization, interferon signaling, glia-relevant, and apoptosis processes. Our hierarchical examination of the ASD cortical transcriptome also shows important disorganization at the level of meta-modules (clusters of highly correlated modules). We identify subtle and specific changes in summary measures of networks organization or global patterns of network reorganization providing important insights on how the ASD cortical transcriptome is affected at the systems-level.
Conclusions: This work highlights a hierarchical view of cortical transcriptome dysregulation in ASD. In doing so, we provide novel insight into new dysregulated processes coordinated with other previously described dysregulated signals. Our approach allows for a better bird's eye view of how multiple pathophysiological processes may operate in ASD and may hint at new systems level phenomena as a potentially more accurate description of the pathophysiology affecting the brain in ASD. This perspective may have important translational and clinical implications as well as potential to help enable cross-level work connecting systems biology with systems neuroscience.

145 **108.145** High Diagnostic YIELD and Low Therapeutic IMPACT of Array-CGH in the Clinical Management of Autistic Patients.

***A. M. Persico**[1], C. Lintas[2], C. Brogna[2], S. Gabriele[2], C. Picinelli[3], P. Tomaiuolo[4], I. S. Piras[5], M. Lamberti[6] and R. Sacco[7], (1)University of Messina, Messina, Italy, (2)University Campus Bio-Medico, Rome, ITALY, (3)Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy, (4)Mafalda Luce Center for Pervasive Developmental Disorders, Milan, ITALY, (5)TGEN, Phoenix, AZ, (6)University of Messina, Messina, ITALY, (7)Univ. Campus Bio-Medico, Rome, ITALY*

Background: Â Array-CGH has become a first-tier clinical diagnostic test in the medical management of children with autism spectrum disorder (ASD). However, the full medical implications of this approach beyond diagnosis have not been explored.
Objectives: Â (1) To propose specific criteria for the definition of a "positive" or "negative" array-CGH outcome; (2) Based on these criteria, to define the diagnostic yield of array-CGH in a sample of Italian ASD patients; (3) To define the follow-up diagnostic and therapeutic yield, whereby further positive diagnostic assessments and therapeutic interventions were driven by array-CGH results.
Methods: Â Array-CGH was performed using the Human Genome CGH SurePrint G3 Microarray 4x180K Kit (Agilent Technologies). CNVs were classified into "rare" or "common" using the last release of Database of Genomic Variants (DGV) setting the threshold for "rare" at ≤4 gains or losses in DGV. All genes spanned in rare CNVs were sought in the autism candidate gene lists present on the Simons Foundation web site (https://id.sfari.org/) and the AutismKB database (http://autismkb.cbi.pku.edu.cn/).
Results: Â Array-CGH outcomes were blindly classified by four authors (AMP, CL, SG, CP) into five categories, based on a stringent set of criteria: 1-"Positive - certainly causal", 2-"Positive - probably causal or with relevant functional consequences", 3-"Uncertain causality", 4-"Negative - common variant with modulatory effects", 5-"Negative - No functional role". Array-CGH results were obtained for 182 families (159 simplex and 23 multiplex), including 581 individuals. A positive yield was obtained from 21 (10.0%) and 39 (18.8%) of 209 ASD patients for outcome cat. n. 1 and 2, respectively. Based on array-CGH results, further medical testing was undertaken in 43/209 (20.1%) ASD patients and 10/372 (2.7%) first-degree relatives. These exams include: brain MRI (with/without 31P spectroscopy); urinary and blood levels of Mg++ or proline; EKG; cardiac or abdominal sonogram; consultations with cardiology, immunology, pneumology, ophtalmology; auditory evoked potentials; capillary fragility testing; blood liver parameters and lipids; blood amino acids; glucose tolerance test; IQ and memory (in family members). These tests turned out positive in 8/209 (3.8%) ASD patients and in 3/372 (0.8%) first-degree relatives. Pharmacological or supplement therapies driven by array-CGH results were prescribed in 2/209 (1.0%) of ASD patients and clinical improvement was recorded in 1/209 (0.5%) case.
Conclusions: The high diagnostic yield obtained by array-CGH in our sample confirms the usefulness of this test in the autism clinic. Array-CGH are also able to successfully guide further medical testing in a small percentage of ASD cases, who would not have been further assessed otherwise. To this date, the therapeutic impact of positive array-CGH results remains elusive, due to the lack of ASD-specific drugs. Nonetheless, array-CGH appears a strong candidate to contribute, in conjunction with whole-exome sequencing and with other exams and specific biomarkers, to the molecular characterization of ASD patients in view of future targeted personalized pharmacological therapies.

146 **108.146** High Frequency of CNVs Targeting Genes That Regulate Exposure to Toxicants in Autism Spectrum Disorder (ASD) – a Role for Gene-Environment Interactions

J. X. Santos[1,2], *C. Rasga*[1,2], *M. Asif*[1,2], *A. R. Marques*[1,2] *and A. M. Vicente*[1,2,3], *(1)Instituto Nacional de Saúde Doutor Ricardo Jorge (INSA), Lisbon, Portugal, (2)Biosystems and Integrative Sciences Institute (BioISI), Lisbon, Portugal, (3)Instituto Gulbenkian de Ciência, Oeiras, Portugal*

Background:
ASD is a neurodevelopmental disorder characterized by complex clinical presentation and multifactorial etiology. While genetic variants, including Copy Number Variants (CNV), are responsible for a substantial fraction of ASD etiology, pre-, peri- and post-natal exposure to environmental factors has also been implicated. Permeability barriers, such as placenta and blood-brain barrier (BBB), are crucial in limiting the exposure to toxicants, particularly during neurodevelopment, while detoxification is fundamental for removal of toxic substances from the organism. Genes encoding molecules involved in these processes are therefore obvious candidates to mediate an increased genetic susceptibility to environmental toxicants in ASD.
Objectives:
In this study we seek to identify genetic variants that may interact with environmental factors in ASD.
Methods:
Genes relevant for detoxification and permeability of the BBB or the placenta to environmental toxicants were selected through literature review and databases (Human Protein Atlas and The Toxin and Toxin-Target Database). We examined the frequency of CNVs deleting or duplicating selected detoxification and permeability genes in ASD subjects genotyped by the Autism Genome Project (N=2157), and compared with CNV frequencies in a control dataset (N=10355), available from the Database of Genomic Variants (DGV). ASD and control subjects were genotyped using Illumina platforms. Statistical analysis was performed using SPSS, and Bonferroni correction for multiple testing was applied. Pathway enrichment analysis was performed using STRING.
Results:
We identified 491 genes involved in detoxification or permeability for toxic substances. In 1107 ASD individuals (51%) we found that 240 (49%) of the selected genes were targeted by CNVs. Comparing with a control subject dataset, we identified 51 genes (21%) exclusively found in CNVs from 88 ASD patients (4%). *CYP2D6* was the most frequently targeted gene (in 16 ASD subjects, 0.74%), followed by *GAL3ST2*, *ARSF* and *TRIM64B*, targeted by CNVs found in 6, 5 and 4 ASD patients, respectively. From the 189 genes identified in CNVs from both patient and control subjects, 40 genes were significantly more frequent in CNVs from individuals with ASD compared with controls, after correction for multiple testing ($P<2.6x10^{-4}$). Many of the ASD-exclusive or associated genes clustered in xenobiotics-related processes (*eg. CYP450* and *UGT* genes), in transport mechanisms (*ABCB1, SLC2A3* and *SLC2A14*) or in tight-junctions function (*CLDN5*, *OCLN*, *PARD6G* and *PRKCZ*); others, like *COMT* and *SHANK2*, were previously implicated in ASD etiology.
Conclusions:
This work reinforces the hypothesis that interactions between environmental exposure and genetic variation may contribute to ASD. Some of the genes more frequently deleted/duplicated in ASD subjects are part of ubiquitous metabolic or transport pathways, suggesting overarching sensitivities to a wide variety of toxicants. Others, with specific targets, may identify the most damaging toxicants for genetically susceptible individuals, suggesting preventive and therapeutic measures. Clinical correlations are currently being explored.

147 **108.147** Mapping Developmental Trajectories in 22q11.2 Deletion Syndrome

T. Lan[1], *M. Meyer*[2], *A. Merz*[3] *and* ***C. M. Taylor***[3], *(1)Bucknell University, Lewisburg, PA, (2)Georgetown University, Washington, DC, (3)Geisinger Health System, Lewisburg, PA*

Background: 22q11.2 deletion syndrome is a common, recurrent CNV that is associated with autism spectrum disorder, with 20% of children with this genetic syndrome also having an autism diagnosis. However, the variability in developmental outcomes of children with 22q11.2 deletion syndrome is very broad, with varying amounts of ASD symptomology and varying degrees of intellectual disability. This variability makes it difficult to accurately predict outcomes (e.g., ASD v. non-ASD; level of cognitive impairment) that can be helpful for future planning. We have a pressing need for a comprehensive approach accounting for behavioral presentation while recognizing key factors that affect long-term phenotypic variability (e.g., genetic etiology, familial background and medical comorbidities).
Objectives: Our study aims to better understand longitudinal outcomes of children with 22q11.2 deletion syndrome (22qDS) by combining developmental assessments, medical comorbidities, genetic etiology, and family background in an ordinal logistic regression model.
Methods: We have identified 15 probands with 22qDS who have been consented for research and have been entered into our research database. All of these probands have at least one developmental assessment; in addition, 7 have at least two assessments ranging through as many as five developmental assessments already completed (at least annually). We used mathematical approaches, including generalized linear mixed models (GLMMs) and generalized estimating equations (GEEs), to identify clinical factors that are the most predictive of developmental outcomes. In particular, clinical factors we investigated include genetic diagnosis, and medical comorbidities. Longitudinal developmental profiles were developed for children with 22qDS were informed by the child's and parents' performance on various assessments of cognition.
Results: Â Two separate models of language and visual motor age equivalents were created. We identified that both age and sex had a significant effect on the developmental trajectory of the child. In terms of sex, we found that gender was significantly associated with path of developmental trajectory in the language domains.
Conclusions: Overall, this project indicates initial evidence that mapping of developmental trajectories can lead to improved prediction of future outcomes including severity of cognitive impairment and presence of clinical ASD. Future results of our study has the potential to lead to an improved understanding of the quantitative effects of genetics, as well as behavioral and medical factors, on phenotypic outcome.

148 **108.148** Neurobehavioral Traits in Family Members Inform GENE Discovery in ASD

S. Luzi[1], *M. L. Cuccaro*[2], *E. R. Martin*[2], *L. Gomez*[3], *A. J. Griswold*[2], *H. N. Cukier*[4], *P. whitehead-Gay*[5], *J. Haines*[6], *J. P. Hussman*[7] *and M. A. Pericak-Vance*[2], *(1)University of Miami Miller School of Medicine, Miami, FL, (2)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (3)hussman institute for human genomics, university of miami, miami, FL, (4)John P. Hussman Institute for Human Genomics, Department of Neurology, University of Miami Miller School of Medicine, Miami, FL, (5)university of miami, miami, FL, (6)Institute for Computational Biology Case Western Reserve University School of Medicine, cleveland, OH, (7)Hussman Institute for Autism, Inc., Catonsville, MD*

Background: Autism spectrum disorder (ASD) is highly prevalent and has a complex genetic architecture. The ASD phenotype is multi-dimensional and variable.Changes in diagnostic criteria have contributed to an increased phenotypic heterogeneity. We aim to identify a narrower ASD phenotype based on core ASD features. Furthermore, it has been demonstrated that neuropsychiatric (NPD) and neurodevelopmental (NDD) disorders are part of a connected molecular system. There may be up to 4000 genes contributing to their etiology. Individuals with ASD harbor several different risk alleles and symptoms overlap across NPD and NDD.They are not single biological identities, rather a spectrum of conditions.
Objectives: We hypothetize that inherited molecular complexity featuring the presence of several NPD and NDD within the same family, together with sub clinical ASD features among family members, concentrates autistic liability across generations with common genetic drivers.
Methods: We developed a Quantitative Autism Score (QAS) using items from the ADI-R which consistently discriminate ASD from non-ASD, occur early in development and remain stable throughout changing diagnostic criteria. We then divided our sample (520 ASD individuals) in 2 groups, according to their family history of NPD, NDD and sub clinical autistic features in first degree relatives. Our first group consisted of 185 individuals with ASD from families with a high burden of NPD, NDD and sub clinical autistic features in first degree relatives. Our comparison group consisted of 335 individuals with ASD from families with a very low or no burden of NPD, NDD or subclinical autistic features in first degree relatives. The outcome measure was the QAS score to try to capture a more homogeneous phenotypic manifestation. We conducted a SKAT-O gene-based test on WES data available; we analyzed the 2 groups separately.
Results: in the first group analyzed, LMAN1L, GREB1L and EIF4A2 were significant (p-value=9.7E-06; p-value=6.4E-05 and p-value=6.8E-05 respectively).LMAN1L was also the most significant gene when only predicted damaging variants were analyzed (P-value=2.4E-05). LMAN1L exerts its function in glycoprotein transportation and organelle targeting, an important mechanism that if defective, increases unfolded proteins within cells. EIF42A was reported to be overexpressed in fronto-temporal dementia and down-regulated in schizophrenia. In the comparison group PMFBP1, MIS18A and RPL14 were significant (p-value=3.2E-06; p-value=7.2E-05 and p-value=9.9E-05 respectively). When only predicted damaging variants were analyzed, SLC35F1 was the most significant gene (p-value=5.7E-05). PMFBP1 is involved in the general organization of the cellular cytoskeleton and localized in the 16q22,1-q22.3 CNV-enriched region in ASD cases. RPL14 is reported to interact with other genes in mice models of ASD.
Conclusions: our two groups consisted of individuals with a very homogenous phenotypic manifestation of ASD as measured by our newly developed QAS. They differed in their autistic liability derived from family history. Two different sets of genes were found significant, pointing towards the presence of different mechanisms/different genes leading to ASD. Refining the ASD phenotype using the QAS and considering family liability allowed for identification of several potential risk genes. This novel approach is the first step towards dissecting a polygenic and multi-dimensional condition to clarify its underlying biology.

149 **108.149** Phenotypic Description of Individuals with PTEN Mutations, ASD and Macrocephaly

F. Duque[1,2], *J. Almeida*[1], *S. Mouga*[1,3], *C. Café*[1], *F. Ramos*[4] *and G. Oliveira*[1,2,3], *(1)Unidade de Neurodesenvolvimento e Autismo, Pediatric Hospital, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, (2)University Clinic of Pediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (3)Institute for Biomedical Imaging and Life Science, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (4)Serviço de Genética Médica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

Background: Autism spectrum disorder (ASD) is a challenging neurodevelopmental disorder, with a multifactorial origin and a complex inheritance. Studying proven susceptibility genes and working on clinical endophenotypes is needed to define more valid genotype-phenotype relationships. *PTEN* is a tumor suppressor gene whose inactivation results in upregulation of the PI3K/AKT signaling pathway, affecting multiple cellular processes, namely cell growth and proliferation. *PTEN* germline mutations are associated with tumor susceptibility and neurodevelopmental disorders such as autism. They have been reported in up to 20% of children diagnosed with ASD and major macrocephaly. Studies have emphasized macrocephaly as a consistently encountered clinical finding amongst ASD, estimated in about 15%. Hence, a *PTEN* mutation testing is a major consideration in cases of ASD and macrocephaly.
Objectives: To report a subset of individuals with a *PTEN* germline mutation and both ASD and macrocephaly.
Methods: We describe three Caucasian-portuguese patients, two male, with current ages 5, 7 and 13 years old, with a diagnosis of ASD (positive score for both ADI-R and ADOS, and fulfilment of DSM-5 criteria) and macrocephaly (ranging from +3SD to +4SD). Moreover, these ASD children underwent intellectual and functional adaptive evaluations with *Griffiths Mental Development Scale* and *Vineland Adaptive Behaviour Scale* (VABS), respectively. Besides PTEN molecular analysis, genetic testing was performed to rule out other medical conditions.
Results: Our findings revealed significant phenotypical heterogeneity. Three *PTEN* mutations were found: a missense variant c.737C>T (p.Pro246Leu) heterozygous in exon 7 (Patient 1), a *de novo* duplication in exon 6 [c.493-?_634+?(2)] (Patient 2), and a missense mutation c.359C>A (p.Ala120Glu) heterozygous in exon 5 (Patient 3). Brain Magnetic Resonance Imaging showed enlarged perivascular spaces and white matter abnormalities of both cerebral hemispheres (Patient 1) and had no brain alterations in the other two subjects. All the three ASD subjects had moderate to severe intellectual disability and VABS functional adaptive profiles were lower than the expected for their age (ranging from -2SD (Patient 2) to -3SD (Patients 1 and 3). Noteworthy, all patients have already initiated cancer risk surveillance.
Conclusions: We report concordant data with contemporaneous investigation on the field and add a novel mutation, not yet described, with clinical evidence strongly pointing to the pathogenicity of this variant. We also intend to present functional studies that are being done. A multidisciplinary cancer surveillance regimen extended to adulthood is mandatory in all cases of *PTEN* mutation. Additional research in ASD patients with known *PTEN* mutation etiology is necessary to enhance knowledge and disclose the full potential of target therapeutics in this neurobehavioral syndrome.

150 **108.150** Placental DNA Methylation in Relation to Maternal Periconceptional Prenatal Vitamin Use and Child Outcomes in the Marbles Prospective Autism Study

Y. Zhu[1], *J. M. LaSalle*[2], *D. I. Schroeder*[3], *P. Krakowiak*[4], *C. E. Mordaunt*[5], *K. W. Dunaway*[5], *F. K. Crary*[3], *C. K. Walker*[6], *S. Ozonoff*[7], *I. Hertz-Picciotto*[2] *and R. J. Schmidt*[2], *(1)University of California, Davis, Davis, CA, (2)University of California at Davis, Davis, CA, (3)University of California Davis, Davis, CA, (4)UC Davis, Sacramento, CA, (5)Center for Children's Environmental Health, University of California, Davis, Davis, CA, (6)University of California, Sacramento, CA, (7)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA*

Background: Placental tissue, usually discarded at birth, is a potential rich source of for epigenetic biomarkers that the interface of genetic risk and in utero exposures in autism spectrum disorders (ASD). In addition, maternal use of prenatal vitamins containing the methyl donor folic acid could alter placental methylation in persistent ways that influence neurodevelopment, especially during a period of dynamic methylation and reprogramming around conception. Compared with other human tissues, placenta contains partially methylated domains (PMDs) that are more similar to oocytes and pre-implantation stages of development.
Objectives: This study was designed to identify regions of differential DNA methylation in placenta from a prospective ASD study in high-risk families. We also studied the relationship between maternal prenatal vitamin use and DNA methylation.
Methods: MARBLES (Markers of Autism Risk in Babies-Learning Early Signs) study involves families with at least one child with ASD so subsequent children were at significantly higher risk (nearly 18%) of having another autistic child and were planning another pregnancy. Mothers were interviewed about prenatal vitamin use during a new pregnancy. Placentas were collected for the younger siblings who were followed until they were 3 years old and clinically diagnosed with ASD or typical development (TD). MethylC-seq was performed on DNA isolated from 20 ASD and 21 TD male placentas using Illumina next-generation sequencing on HiSeq 2000 machine with one sample per lane using single-end 100 bp sequencing. We identified differentially methylated regions (DMR) using the DMR finder approach based on bsseq R package.
Results: Two DMRs showed significant differences after FDR correction between ASD and TD selected by DMR finder based on MethyC-seq data and validated by pyrosequencing (Fig. 1). One DMR that was hypomethylated in ASD compared with TD showed a positive association between prenatal vitamins taken during the first pregnancy month and percent methylation. The other DMR was hypermethylated and its methylation tended to be negatively associated with prenatal vitamin intake. Both DMRs were also associated with Mullen Scales of Early Learning on four subscales categories (Visual Reception, Fine Motor, Receptive Language and Expressive Language) and the Early Learning Composite (Fig. 2).
Conclusions: This relatively small study of DNA methylation differences in placental samples from the MARBLES prospective study identified two high confidence DMRs that could be useful in assessing risk for ASD at birth and determining the impact of maternal prenatal vitamin usage on ASD occurrence in offspring.

151 **108.151** Possible Maternally Acting Gene Alleles (MAGAs) in Autism

W. G. Johnson[1], *S. Buyske*[2] *and E. S. Stenroos*[3], *(1)661 Hoes Lane, Rutgers University, Piscataway, NJ, (2)Statistics Dept, Rutgers University, Piscataway, NJ, (3)Neurology, Rutgers-RWJMS, Piscataway, NJ*

Background: Â Maternally Acting Gene Alleles (MAGAs) may act in maternal tissues prenatally to alter fetal environment or in the developing embryo prior to the maternal – zygote transition altering development and affecting offspring phenotype, independently of whether or not they are inherited by the fetus. At least 169 MAGAs have been reported, mostly in neurodevelopmental disorders.
Objectives: Â Here, we carried out an analysis of possible MAGAs in SSC trios.
Methods: Â We used families of the Simons Simplex Collection (SSC) Version 14 that were largely genotyped on the Illumina Human 1M duo array for imputation of un-genotyped SNPs and subsequent analysis using the Weinberg log-linear method through a convenient implementation in EMIM.
Results: One SNP, while not reaching genome wide significance, was of particular interest. SNP rs6482968, Chr10:129525038, 5' of *FOXI2* gave a corrected p-value of 1.02E−6 with a large number of SNPs in strong LD (r2 > 0.80) and below p-value 1.00E-4, a threshold used for suggestive results.
Conclusions: *FOXI2,* which belongs to the forkhead-box (FOX) superfamily of transcription factors makes an interesting candidate for a maternally acting allele. It has been reported in a model system that *Foxi2* derived from maternal mRNA is an activator of zygotic *Foxi1e*, an important factor in the early expression of ectoderm specific genes and so may be important in the maternal-zygotic transition. *FOXI2* and the gene region have been previously implicated in autism. It has been implicated in Expression quantitative trait loci mapping (eQTLs) in autism. Additionally, CNV's that span this region have been described in individuals with developmental disorders including autism spectrum disorder. This large group of SNPs may represent a haplotype but since the Weinberg method looks at asymmetries in paternal vs. maternal transmissions, it can not be excluded that our results may be due to maternally derived CNV's. A different SNP 5' to *FOXI2* and our index SNP gave a p-value of 7.66E-05 in a case GWAS analysis. Others have reported increased *FOXI2* mRNA levels in post mortem autism brains. This may suggest that it acts both maternally and in her child. Other forkhead genes have also been implicated in autism such as *FOXP2.* Last, it has been reported that *FOXI2* is a target for 3 miRNA's previously implicated in autism. Follow up studies are needed to confirm these results.

152 **108.152** Prenatal Air Pollution Exposure and Cord Blood DNA Methylation in the Early Autism Risk Longitudinal Investigation (EARLI)

J. I. Feinberg[1], *K. M. Bakulski*[2], *C. Ladd-Acosta*[1], *S. C. Brown*[1], *L. A. Croen*[3], *I. Hertz-Picciotto*[4], *C. J. Newschaffer*[5], *A. P. Feinberg*[6], *M. D. Fallin*[7] *and H. E. Volk*[1], *(1)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)University of Michigan School of Public Health, Ann Arbor, MI, (3)Kaiser Permanente Division of Research, Oakland, CA, (4)University of California at Davis, Davis, CA, (5)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (6)Johns Hopkins University, Baltimore, MD, (7)Department of Mental Health, Johns Hopkins School of Public Health, Baltimore, MD*

Background: Several epidemiological studies have shown associations between prenatal exposure to environmental contaminants such as air pollution and an increased risk for autism spectrum disorder (ASD) and adverse neurodevelopment in children. While the underlying biological mechanisms of these exposures in relation to disease risk are not well characterized, it is possible that epigenetic mechanisms such as DNA methylation can mediate the effects of prenatal exposures on neurodevelopmental outcomes.
Objectives: Our work seeks to investigate associations between prenatal exposure to criteria air pollutants (particulate matter less than 2.5 ($PM_{2.5}$) and 10 microns in diameter (PM_{10}), nitrogen dioxide (NO_2) and ozone (O_3)) and DNA methylation at birth in order to identify and characterize potential biological mechanisms that might explain the observed relationships between air pollution exposure and increased ASD risk.
Methods: DNA was extracted from 175 umbilical cord blood samples from babies born in the ASD enriched-risk pregnancy cohort, the Early Autism Risk Longitudinal Investigation (EARLI), at 4 different study sites (Drexel University, University of California Davis & MIND Institute, Johns Hopkins University, and Kaiser Permanente in Northern California). Genome-wide DNA methylation was then assessed using the Illumina Infinium HumanMethylation450 bead chip array (450k). We assigned prenatal exposure to ambient levels of criteria pollutants for each pregnancy address location reported by EARLI mothers based on data collected from the Environmental Protection Agency's AirNOW monitoring network using inverse distance weighting. We performed single-site and region-based statistical analyses to identify genomic locations showing differential methylation associated with exposures. We further examined if such differences are associated with ASD phenotype.
Results: Air pollution exposure and methylation data were available for 158 cord blood samples. We report the top-ranked differentially methylated regions and individual CpG loci and explore the potential functional implications of these genomic sites in relation to ASD risk and neurodevelopment.
Conclusions: Our work helps to describe environmental exposure biology generally and also how in utero exposure to air pollution might contribute to the etiology of ASD and neurocognitive development.

153 **108.153** Prioritization of ASD-Associated Genes By Variant Annotation Identifies Trends in Genetic Variant Discovery

E. Larsen[1], *W. Pereanu*[2] *and S. B. Basu*[2], *(1)MindSpec Inc., McLean, VA, (2)Mindspec, Inc., McLean, VA*

Background:
The search for genetic causes of autism spectrum disorders (ASD) has led to the identification of hundreds of genes containing thousands of variants that differ in their mode of inheritance, effect size, and frequency in cases and controls, and exhibit a broad range of putative functional effects. These data are richly annotated in AutDB (also known as SFARI Gene), an open-access database for ASD-associated genetic variation.
Objectives:
We previously described a scoring algorithm for the prioritization of candidate genes based on the cumulative strength of evidence from each ASD-associated variant curated in AutDB. Here, we present the results using an expanded and up-to-date dataset of ASD-associated variants.
Methods:
A total of 1176 annotated research articles were analyzed to generate a dataset of 3557 ASD-associated rare variants and 861 ASD-associated common variants distributed across 787 candidate genes (September 2016 data freeze). Under our algorithm, each individual variant is manually annotated with multiple attributes extracted from the original report, followed by score assignment using a set of standardized scoring parameters that were summed up to yield a single score for each gene in the database. We also performed a time-course analysis of ASD-associated gene scores to identify trends in rare and common variant discovery and assess how newly discovered variants affected the scores of the genes in which they were identified.
Results:
We observed remarkable variation in gene scores resulting in a distribution with a mean gene score of 23.53 ± 38.73. We were able to identify a set of 14 high confidence candidate genes with scores deviating more than two standard deviations (SDs) from the mean score of all genes. The gene scores generated by our approach once again significantly correlated with other ASD candidate gene ranking systems, including the expert-mediated SFARI Gene scoring initiative and gene prioritization based on Transmission and De Novo Association (TADA) analysis of ASD cohorts. Finally, time course analysis of ASD-associated gene scores identified a subset of candidate genes that showed a marked increase in gene score based on the identification of novel genetic variants in those genes.
Conclusions:
Altogether, our scoring algorithm continues to provide a framework for assessment of diverse types of ASD-associated genetic variants that are likely to be important for defining the genetic risk architecture of ASD.

154 **108.154** Quantification of FMRP in Human and Mouse Tissues By Capture Immunoassay

W. T. Brown[1], *G. LaFauci*[2], *T. Adayev*[2], *R. Kascsak*[3], *R. Kascsak*[4], *C. Dobkin*[5] *and S. Nolin*[6], *(1)Human Genetics, NYS Institute for Basic Research in DD, Staten Island, NY, (2)Developmental Biochemistry, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (3)Developmental Biochemistry, NYS Institute for Basic Research in Develpmental Disabilities, Staten Island, NY, (4)Develpmental Biochemistry, NYS Institute for Basic Research in Develpmental Disabilities, Staten Island, NY, (5)Human Genetics, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (6)Human Genetics, NYS Institute for Basic Research in Develpmental Disabilities, Staten Island, NY*

Background: The Fragile X syndrome is a leading inherited cause of ASD. The Fragile X syndrome is due to mutations of the FMR1 gene that result in the lack of gene expression and the loss of its gene product the fragile X mental retardation protein (FMRP).
Objectives: To develop a screening test for FMRP.
Methods: We have developed a rapid, highly sensitive method for quantifying FMRP from dried blood spots and lymphocytes. This assay uses new FMRP antibodies, a human specific mAb 6B8 (Biolegend) and rabbit polyclonal R477, a bacterially expressed abbreviated FMRP standard, and a Luminex platform to quantify FMRP.
Results:
The assay readily distinguishes between samples from males with fragile X full mutations and samples from normal males. It also differentiates mosaic from non-mosaic full-mutation male samples. We have employed the assay to screen 2000 newborn dried blood spots (DBS) and present their distribution. We also applied the assay in a retrospective study of 76 newborn DBS that had been stored for an extended period and included full mutation males as well as normal individuals. We were able to correctly identify all 5 known male fragile X positive cases among samples stored up to 47 months. Variable amount of FMRP are detected in typical individuals. In DBS samples, normalization of FMRP levels to the number of leukocytes reduced this variability and could allow to distinguish premutation carriers from typical individuals.
Using human and mouse detecting mAb 5C2 (Biolegend) and R477, we have also developed a similar immunoassay for the quantification of Fmrp in mouse tissues. This assay was used to quantify Fmrp in the brainstem, cerebellum, hippocampus, and cortex two strains of mice (C57BL and FVB) in seven and ten week-old animals, showing developmental variations exist.
Conclusions: A rapid qualitative assay has been developed for the diagnosis of Fragile-X Syndrome. This sensitive assay allows for the screening of newborn infants using routinely collected dried blood spots. The assay will also allow further studies on variations of mouse Fmrp expression in different models and organs.

155 **108.155** Role of ANK2 in Autism Spectrum Disorder

R. Bina[1]*, J. Li*[1]*, B. Fregeau*[1]*, K. A. Dies*[2]*, M. Martyn*[3] *and E. Sherr*[4]*, (1)Neurology, UCSF, SF, CA, (2)Neurology, Boston children's hospital, Boston, MA, (3)Hospital Infantil Sabará, São Paulo, Brazil, (4)UCSF, San Francisco, CA*

Background:
ANK2 encodes a member of the ankyrin family of proteins (Ankyrin B) that link integral membrane proteins (e.g. L1CAM) to the underlying spectrin-actin cytoskeleton. Ankyrins play key roles in activities such as cell motility, activation, proliferation, cell-cell contact and the maintenance of specialized plasma membrane domains. Loss-of-function variants in *ANK2*cause a dominantly-inherited cardiac arrhythmia with increased risk for sudden cardiac death, initially termed type 4 long QT Syndrome, and more recently renamed the “Ankyrin-B” Syndrome. Recent next generation DNA sequencing projects in autism spectrum disorder (ASD) cohorts (the Simons Simplex Collection) have revealed several heterozygous de novo ANK2 missense and nonsense mutations marking ANK2 as a ‘high-confidence’ autism candidate gene. Additionally, our lab has identified individuals with ANK2 sequence changes who not only have cognitive and behavioral deficits, but also have abnormalities of the corpus callosum. These genetic findings highlight the importance of ANK2 in neurodevelopment, but how mutations in ANK2 lead to these brain disorders is still unknown.
Objectives:
To determine the interaction between ANK2 and L1CAM and its role in ASD development and abnormalities of the corpus callosum.
Methods:
whole genome sequencing and breaking point analysis were performed in a patient with a balanced chromosomal translocation t (4; 8) (q25; q23), quantitative PCR and Western blot were used to compare ANK2 and L1CAM expression among ASD patients from the SSC cohort. Immunohistochemistry (IHC) was used to show overlapping expression pattern of ANK2 and L1CAM during corpus callosum development in mouse.
Results:
We reported an expected and significant decrease in expression of ANK2 mRNA and protein in patient compared to control PBMC’s. We also investigated the abundance of the neuronal adhesion protein, L1CAM. We found that L1CAM protein abundance is decreased in patients with ANK2 mutations (one with a balanced chromosomal translocation through ANK2 t (4; 8) (q25; q23), and in two other ASD patients with nonsense mutations in ANK2) and that L1CAM expression is rescued after transient transfection of ANK2 into a cell line from one patient carrying a nonsense mutation in ANK2.
Conclusions:
Our results suggest that disruption of the normal interaction and balance between ANK2 and L1CAM may play an important role in ASD and other neurodevelopmental disorders such as agenesis of the corpus callosum (ACC). Moreover, this linkage between ACC and ASD has implications for the mechanistic overlap for these two groups of disorders.

156 **108.156** Sexually Dimorphic Regulation of Norepinephrine Projection Neurons:Â Transcriptional Profiling of Mouse Locus Coeruleus

B. Mulvey[1] *and J. Dougherty*[2]*, (1)Washington University in St. Louis, St. Louis, MO, (2)Genetics, Washington University School of Medicine, St. Louis, MO*

Background: A number of neuropsychiatric diseases demonstrate sex-biased incidence, including ADHD and autism. The locus coeruleus (LC), which sends noradrenergic projections throughout the brain, is known to demonstrate sex-specific responses to stress-related molecules like corticotropin-releasing factor at both cellular and behavioral levels (Curtis et al 06, Bangasser et al 16). Moreover, the engrailed-2 (En2) knockout mouse—an animal model for autism spectrum disorders—has been demonstrated to have sex specific deficiencies in norepinephrine signaling (Genestine et al 2015). However, the full extent and clinical significance of sex differences in the LC have not been defined. We employed Translating Ribosome Affinity Purification (TRAP) to selectively profile the transcriptome of mouse LC, providing a new look into the breadth of—and cellular functions implicated by—sex-specific gene expression in the LC.
Objectives:

1. Identify genes whose expression is unique to the LC (among hindbrain cells).
2. Identify genes expressed in a sex-specific manner within the mouse LC.
3. Verify expression patterns using existing resources, as well as immunohistochemistry (IHC) and *in-situ* hybridization (ISH).
4. Identify functional consequences of sex-specific gene expression.

Methods: TRAP utilizes transgenic mice expressing a GFP-tagged ribosomal subunit under the control of a cell-type specific promoter (in this case, the Slc6a2, aka NET, the norepeniphrine transporter). Affinity purification of GFP-conjugated ribosomes from brain homogenate allows for collection of mRNAs being translated at the time of collection in the LC, and subsequent quantification—for analysis of cell-type specific gene expression and comparison of cell-type specific expression between the sexes. Using the Allen Brain Atlas, IHC, and ISH, and electrophysiology, we validate our findings of LC-specific gene expression.
Results: We identified 188 transcripts enriched in the LC compared to the rest of the hindbrain, and validated these with independent methods. Moreover, we identified 84 transcripts significantly enriched in female LC, and 75 enriched in male LC, suggesting broad mechanisms of sex-specific gene expression and cellular function. In contrast, we find almost no (≤10 total) genes with sex-specific expression in TRAP of serotonergic neurons, indicating the LC is strikingly dimorphic by comparison. Among the genes we found to be both LC-specific and differentially expressed (>2-fold enriched in females) was a prostaglandin receptor, Ptger3. Electrophysiology of LC neurons in the presence of a Ptger3 agonist, sulprostone, revealed a robust response of female LC neurons compared to male LC neurons.
Conclusions: A comprehensive analysis of gene utilization has not been performed on the LC. Here, we identify transcripts uniquely expressed in LC and demonstrate that the LC has robust of sex differences, which may underlie sexually dimorphic behaviors in LC related functions such as response to stress, novelty, and attention. Moreover, this work raises the question of whether dimorphic regulation of the norepinephrine signaling in the brain might affect dosing and efficacy of noradrenergic drugs in the treatment of neurodevelopmental and psychiatric diseases. Finally, we have discovered a receptor that may be used to alter noradrenergic signaling in a sex specific manner.

157 **108.157** The Challenge of Whole Exome Sequencing As a Molecular Diagnosis for ASD

M. R. P. Bueno[1], *T. Almeida*[2], *D. P. Moreira*[3], *S. A. Ezquina*[4], *G. L. Yamamoto*[5] *and E. C. Zachi*[6], *(1)Universidade de sao Paulo-USP, Sao Paulo, Brazil, (2)Centro de Pesquisas sobre o Genoma Humano e Células-tronco (CEGH-CEL), Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil, (3)Universidade de São Paulo, Sao Paulo, Brazil, (4)Centro de Pesquisas sobre o Genoma Humano e Células-tronco (CEGH-CEL), Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, (5)Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil, (6)Instituto de Psicologia, Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil*

Background: The search for an objective diagnosis for autism spectrum disorder (ASD) is a major concern of the scientific community. The availability of new molecular tests increased the expectations for an etiologic diagnosis of ASD. Nowadays, it would be expected that these tests would allow a conclusive result in about 20-30% of the cases. Whole exome sequencing (WES) are being offered as an approach for ASD diagnosis, but because of the amount of data and difficulties in interpreting the clinical significance of the variants in most situations it is a challenge to prioritize variants and return a final conclusive report for the family. In this context to determine the actual power of the WES as a diagnostic test is imperative.
Objectives: To investigate the specificity and sensitivity of WES as a molecular test for ASD.
Methods: 40 individuals with ASD, 115 individuals with other clinical diagnosis than ASD and 609 higid individuals with more than 60 years old. The sequencing was made with Illumina's platform and alignment were performed with bwa and variant calling for ASD and 115 control samples (OSC) together with Unified Genotyper from GATK, and the 609 control(HSC) were called separately with the same software. Annotation was performed with ANNOVAR and internal pipelines. The variants were filtered for 243 genes present in SFARI database from the three first categories and syndromic. Variants of Low Quality, outside exonic regions, genotype calling under 99, and minor alelle frequency inferior to 0,3 were removed from the analysis. Variants were separated by frequency in 3 groups, above 0.05, between 0.05 and 0.01 and below 0.01. Each individual had their variants accounted and prioritized, loss-of-function (LoF) variants (frameshift, stopgain/loss and splicing site) were divided into two groups, one considering all the variants in the SFARI genes, and other taking into account the ExAC LoF intolerance genes, creating a subset of 151 genes from SFARI. Missense variants were prioritized using SPRING software, and only those variants with p-value below 1.10^{-12}, were included. False positive and false negative rates were calculated for each type of variants and ROC curves were plotted.
Results: There were no difference in the mean number of LoF (ASD: mean 6.01, sd 6.31; OSC: mean 6.90, sd7.10; HSC: mean 5.92, sd5.06), ExAC LoF (ASD: mean 3.69, sd 4.01; OSC: mean 4.17, sd 5.01; HSC: mean 3.60,sd 3.93), and missense variants between the groups (ASD:mean 6.07, sd 3.34; OSC: mean 6.44, sd 3.66; HSC: mean 6.59, sd 3.49). The false positive rates and false negative rates for all the groups were above 50%. The area under de ROC curve were very close to 0,5 in all occasions.
Conclusions: The prioritized methods chosen above were not sufficient to discriminate between individuals with ASD and controls. Further studies must be completed in order to create an effective analysis for WES in patients with ASD. Research supported by FAPESP-CEPID, CNPq, INCT.

158 **108.158** The Feature Landscape of Autism Risk Genes Indicates Their Enrichment in Developmental Regulation

E. L. Casanova[1], *A. E. Switala*[2] *and M. F. Casanova*[3], *(1)University of South Carolina, School of Medicine, Greenville, SC, (2)University of Louisville, Louisville, KY, (3)University of South Carolina School of Medicine, Greenville, SC*

Background: While there have been many studies investigating the functional enrichment of classes of autism risk genes, few have studied their structural commonalities as an additional indicator of function.
Objectives: The purpose of this study is to investigate characteristic features of autism risk genes in order to better understand the function and evolutionary history of conserved elements and features of these genes.
Methods: Utilizing various bioinformatics approaches, we have studied commonalities across different genomic features, such as gene length, protein complexity, and intronic regulatory content.
Results: We find that autism risk genes tend to be highly conserved and have low allelic variability (i.e., low mutation tolerance). In addition, compared to whole genome control (WGC), these mutation-intolerant genes display long gene length, long peptides indicative of enriched protein complexity, increased numbers of transcript variants, and enrichment of both intronic conserved noncoding elements (CNE) and transposable elements. These latter two features in particular are likely indicative of complex internal regulatory content in these autism risk genes. Most of the structural and functional features investigated here typify gene classes involved in the regulation of development and transcription, as has been reported in previous studies such as Sironi et al (2005).
Conclusions: As we have shown here, gene function is reflected, not only in the structure of the protein, but the structure of the gene as well. From this vantage point, we add further support to the growing body of evidence that suggests that autism risk genes of major effect are enriched in developmental regulation and transcription, both of which help to control the timing of neurogenesis, migration, neuritogenesis, synaptogenesis, and ongoing plasticity (Casanova et al., 2016).

159 **108.159** The Genetic Architecture of Autism Spectrum Disorders in the Faroe Islands

C. Carton[1,2]*, G. Huguet*[1]*, A. Mathieu*[1]*, J. Buratti*[3]*, A. Boland*[4]*, D. Bacq*[4]*, J. Halling*[5]*, G. Andorsdóttir*[6]*, C. S. Leblond*[1,2]*, M. T. Bihoreau*[4]*, V. Meyer*[4]*, J. F. Deleuze*[4]*, E. Billstedt*[7]*, T. Bourgeron*[2,8] *and C. Gillberg*[7]*, (1)Institut Pasteur, Paris, France, (2)Université Paris Diderot, Paris, France, (3)Hôpital Pitié-Salpêtrière, Paris, France, (4)Centre National de Génotypage, Evry, France, (5)Clinical Pharmacology, Faculty of Health Sciences, Institute of Public Health, University of Southern Denmark, Odense, Denmark, (6)Genetic Biobank of the Faroe Islands, Tórshavn, Faroe Islands, (7)Gillberg Neuropsychiatry Centre, Gothenburg, SWEDEN, (8)Neuroscience, Institut Pasteur, Paris, France*

Background:
Autism spectrum disorders (ASD) are a group of neuropsychiatric disorders characterized by deficits in social communication, as well as presence of restricted interests, stereotyped and repetitive behaviors. The biological causes of ASD remain largely unknown mostly because of the clinical and genetic heterogeneity of this complex condition.
Objectives:
This project aims to characterize the genetic architecture of ASD in the Faroe islands located between the Norwegian Sea and the North Atlantic Ocean, approximately half distance from Norway and Iceland.
Methods:
We obtained the genetic profiles of 380 individuals from the Faroe Islands (36 patients with ASD, 129 relatives and 215 controls) using genome-wide genotyping of >5 millions SNPs and whole-exome sequencing.
Results:
We first analysed the contribution of *de novo* mutations (CNVs, SNVs and indels) in 28 patients with ASD. For 3 patients, we identified *de novo* mutations in known ASD-risk genes/loci : 1 22q11.1 deletion, 1 deletion of *NRXN1*, and 1 damaging *MECP2* missense mutation. We also identified inherited rare exonic CNVs and SNVs altering genes previously associated with ASD (*ADNP*, *BCL9*, *IMMP2L*, *TBL1X*, *TBL1XR1, ACACA, ROBO1, RARS2 and ALDH3A2*). As expected, we observed a relatively higher homozygosity compared to other world-wide populations (P<0.0001). Interestingly, patients with ASD had a slightly higher inbreeding coefficient compared with controls (F_{ASD}=0.007; $F_{Controls}$= -0.004; P=0.0002), suggesting that, in a subset of patients, recessive mutations could contribute to the increase risk of having ASD. In a consanguineous family, we found a rare homozygous missense variant affecting *KIRREL3,* a member of the nephrin-like protein family. Finally, our analysis also revealed new compelling candidate genes for ASD such as *IQSEC3*, a guanine nucleotide exchange factor highly expressed in the brain, *RIMS4,* a key regulator for neuronal arborisation and *SMG7*, a gene involved in mRNA non-sense mediated decay.
Conclusions:
In summary, we identified deleterious mutations in known ASD-risk genes in 36% of the patients indicating that the genetic architecture of ASD in the Faroe Islands might not be very different from other populations. Remarkably, recessive mutations might not increase dramatically the risk of ASD in the genetic isolate. Further analyses are currently in progress to better understand the interplay between the common and the rare variants in the susceptibility and the severity of ASD in these patients.

160 **108.160** The Genetics of Educational Attainment, Autism, and Schizophrenia Show Points of Convergence

V. Warrier[1]*, R. A. Bethlehem*[2] *and S. Baron-Cohen*[3]*, (1)University of Cambridge, Cambridge, England, United Kingdom, (2)Department of Psychiatry, University of Cambridge, Cambridge, UNITED KINGDOM, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Different studies have identified a link between educational attainment and psychiatric conditions like schizophrenia and autism. Biologically, this relationship can be construed in terms of two different but not necessarily mutually exclusive hypothesis: Genes for educational attainment (edu genes) are more frequently mutated in conditions like schizophrenia and autism, or genes for educational attainment interact with downstream risk pathways for autism and schizophrenia.
Objectives: Here, we investigate both the hypothesis using summary data available from large genome-wide association studies and transcriptome studies.
Methods: We examine the relationship between genes robustly associated with edu genes and genes and pathways implicated in autism and schizophrenia. We use genes previously identified for educational attainment using DEPICT, thereby restricting our analysis to Single Nucleotide Polymorphisms (SNPs) with $P < 1x10^{-5}$. We investigate if these genes are signficantly enriched in transcriptional modules for schizophrenia, autism, and general cognition.
Results: We show that edu genes are highly intolerant to loss of function and are enriched in a gene-coexpression module for cognition. We identify that genes for educational attainment are more frequently mutated in autism and developmental disorders than expected by chance. We also find evidence for enrichment of edu genes in a module dysregulated in schizophrenia.
Conclusions: In conclusion, our results highlight a role for edu genes in both upstream and downstream hypotheses.

161 **108.161** Towards a Pathway Driven Clinical-Molecular Framework for Classifying Neurodevelopmental Disorders

C. A. Ziats[1] *and M. N. Ziats*[2]*, (1)Neurological Surgery, University of Michigan, Ann Arbor, MI, (2)Internal Medicine, University of Michigan, Ann Arbor, MI*

Background:
The current clinical classification system of neurodevelopmental disorders is outdated, offering little insight into the molecular pathophysiology of disease that would guide targeted treatment. Neurodevelopmental disorders share common molecular and cellular pathways of dysregulation and recently, there has been a move toward gene-specific classification of neurodevelopmental disease, however, classification at this level of detail is not immediately clinically useful.
Objectives:
Â ToÂ propose an intermediate classification scheme based on molecular and cellular pathways and their clinical features.
Methods:
We compiled a list of all OMIM genes and syndromes with the keywords 'autism' and 'epilepsy or seizure' and used gene set enrichment analysis to determine shared pathways significantly over-represented among this set of genes (with Benjamini-corrected p-value < 0.05). We manually curated all one-hundred twelve OMIM entries into molecular pathways, and then compared the clinical features of syndromes within these pathways.
Results:
Ninety-eight of one-hundred twelve OMIM entries curated enriched for one of three pathways: transcriptional regulation, molecular transport, or cellular synaptic function. Transcriptional regulation was the most commonly enriched pathway (n=50), and included 23 recognized syndromes. Syndromes enriching for the transcriptional regulation pathway had the highest incidence of systemic symptoms (n=20/23), the molecular transport group had the highest incidence of psychiatric symptoms (n=5/6), and the cellular transport pathway the highest incidence of motor symptoms (n=11/13).
Conclusions:
A classification system such as this would allow clinicians to leverage the expanding genetic information in a clinically-actionable manner, providing information about disease pathophysiology and be used to guide treatment and influence the development of new therapies.

162 **108.162** Transcriptome Analysis in Neuronal Cells of an Autistic Patient with 17p13.3 Duplication: Identification of Upregulation of Ywhae and Crk and Possible Contributor Factors for Penetrance.

K. Griesi-Oliveira[1,2], *M. S. Fogo*[1,2], *A. M. Suzuki*[2], *A. G. Morales*[2], *O. J. Sosa*[3], *S. A. Ezquina*[2], *D. P. Moreira*[2], *S. S. Costa*[2], *C. Rosenberg*[2], *E. M. Reis*[3] *and M. R. P. Bueno*[2], *(1)Albert Einstein Hospital, Sao Paulo, Brazil, (2)Centro de Pesquisas sobre o Genoma Humano e Células-tronco (CEGH-CEL), Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, (3)Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, Brazil*

Background: Duplications in chromosomic region 17p13.3 have been identified in individuals with autism spectrum disorders (ASD) and intellectual disability (ID). However, 17p13.3 duplication carriers present incomplete penetrance and significant variability of the phenotype, suggesting that other genetic and/or environmental factors might be necessary for clinical manifestation. Association of genes in this region to ASD and ID, particularly *YWHAE* and *CRK*, is based on analysis of overlapping duplications and some sporadic functional studies showing the relevance of such genes to neurodevelopment, but no study has been conducted using the cells of the patients so far.
Objectives: In this study, we aimed to investigate the consequences of 17p13.3 duplication for gene expression using neuronal cells derived from an autistic individual, as well as to explore other possible factors that might be contributing for the penetrance of the phenotype in this individual.
Methods: Array-CGH was used to identify and delineate the boundaries of the duplication. Induced pluripotent stem cells (iPSC) were derived from stem cells from exfoliated teeth from the patient and 6 controls, and next differentiated in neuronal progenitor cells (NPCs) and neurons. We generated transcriptome data of these cells as well as exome data from DNA obtained from patient's peripheral blood cells.
Results: Â We have identified an autistic individual that harbors a *de novo* 345kb duplication in 17p13.3, spanning the genes *ABR*, *BHLHA9, TUSC5, YWHAE, CRK* and *MYO1C*. In accordance to phenotypic descriptions of other patients with duplications of similar size and location, the current case present only mild learning disabilities and mild autistic features. Our transcriptome analysis revealed 65 differentially expressed genes in patient's NPCs compared to control NPCs, among which *YWHAE* and *CRK* was found as upregulated. We then searched for rare potential pathogenic variants in the remaining 63 differentially expressed genes, aiming to find other genetic alterations that could contribute for the penetrance of the phenotype. Interestingly, we identified a rare stop codon mutation in a downregulated gene, *NGDN*, which codifies an EIF4E-binding protein that regulates translation during nervous system development. Indeed, comparing genotypes found in exome and RNAseq data, we could identify a bias in the expression towards the normal allele, indicating the existence of RNA decay. Investigation of *YWHAE, CRK* and *NGDN* expression levels in the iPSC-derived neurons from the patient confirmed the same changes observed in NPCs.
Conclusions:
Our results add further support for the role of *YWHAE* and *CRK* for the manifestation of neurodevelopmental disorders presented by 17p13.3 duplication carriers. Also, we suggest that a loss of function mutation in *NGDN* may acts as the second hit necessary for the penetrance of ASD in the presence of 17p13.3 duplication.

163 **108.163** Umbilical Cord Blood Androgen Related Gene Expression and Risk of Autism Spectrum Disorder in an Enriched Pregnancy Cohort

K. M. Bakulski[1], *B. Y. Park*[2], *J. I. Feinberg*[3], *L. A. Croen*[4], *I. Hertz-Picciotto*[5], *C. Ladd-Acosta*[6], *C. J. Newschaffer*[7], *H. E. Volk*[6] *and M. D. Fallin*[8], *(1)University of Michigan School of Public Health, Ann Arbor, MI, (2)Johns Hopkins Bloomberg School of Public Health, Baltimore,, MD, (3)Johns Hopkins University, Baltimore, MD, (4)Kaiser Permanente Division of Research, Oakland, CA, (5)University of California at Davis, Davis, CA, (6)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (8)Department of Mental Health, Johns Hopkins School of Public Health, Baltimore, MD*

Background: Autism spectrum disorder (ASD) affects more than 1% of children in the United States. The male-to-female ASD prevalence ratio is roughly 4:1, but the biological mechanisms are poorly understood. An explicit focus on etiologic pathways underlying this sex difference, such as the hormonal *in utero*environment, may help elucidate causes of ASD.
Objectives: To examine the relationship between androgen levels and RNA expression in cord blood and the relationship to ASD diagnosis at 36-months.
Methods: Genome-wide RNA expression was measured in 155 cord blood samples from the Early Autism Risk Longitudinal Investigation (EARLI), an enriched-risk pregnancy cohort of families with a child previously diagnosed with ASD. Families were recruited from 4 study sites (Drexel University, University of California Davis & MIND Institute, Johns Hopkins University, and Kaiser Permanente in Northern California). RNA expression was assessed using the Affymetrix Human Gene 2.0 array. Cord blood androgen levels (testosterone, androstenedione, dehydroepiandrosterone) were also measured. Standard RNA data quality control and RMA normalization pipelines were implemented. Surrogate variable analysis was used to adjust for potential cell-type and batch effects. We tested for gene expression differences by androgen levels stratified by sex. We further examined whether expression of androgen related genes, including steroidogenic pathway genes related to androgen synthesis and degradation, were associated with ASD risk. ASD diagnosis at 36-months and cord blood RNA and androgen data were available in 116 samples (20 ASD, 46 non-typical development, and 50 typical development).
Results: Cord blood gene expression differences between typically developing children and children with ASD did not reach genome wide significance (FDR q-value<0.05) adjusting for multiple comparisons in either sex. We will report top-ranked differentially expressed genes by androgen and will explore implicated regions for their potential functional relevance to ASD risk.
Conclusions: This study describes differences in RNA expression by androgen levels, and further examines the role of androgen-related genes in ASD risk, which may play a role in the ASD sex disparity.

164 **108.164** Variable Expressivity of Neurodevelopmental Disturbances Due to Loss-of-Function of AP1S2

D. P. Moreira[1], *T. Almeida*[2], *E. C. Zachi*[3], *S. A. Ezquina*[1], *G. L. Yamamoto*[4] *and M. R. P. Bueno*[1], *(1)Centro de Pesquisas sobre o Genoma Humano e Células-tronco (CEGH-CEL), Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, (2)Centro de Pesquisas sobre o Genoma Humano e Células-tronco (CEGH-CEL), Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil, (3)Instituto de Psicologia, Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil, (4)Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil*

Background: Autism spectrum disorder (ASD) is a common neurodevelopmental disorder phenotypically and genetically heterogeneous. One of the most concurrent conditions in ASD individuals is intellectual disability (ID), which affects approximately 50% of the cases. Among the ASD familial cases, which represent less than 20% of the families, it has been recognized all Mendelian patterns of inheritance. The genetic factors associated with ASD familial cases are still unclear in most of them. Thus, it is essential to analyze family history and pedigree to figure out the inheritance model that best fit to each family, and, consecutively, conduct genetic analysis in order to identify the major pathogenic event leading to the phenotype.
Objectives: To investigate genetic variants that would explain the ASD and ID segregating in 4 generations in a family with an X-linked inheritance pattern.
Methods: We selected two distant related cousins (individuals IV-2 and IV-4 in Figure 1), which belong to a family (Family F8293) with a total of 3 autistic individuals (individuals III-7, IV-2 and IV-4 in Figure 1) and 4 ID affected individuals (individuals II-4, II-5, III-6 and III-8 in Figure 1), to perform whole-exome sequencing (WES) using the Nextera Rapid Capture Exome kit (Illumina) for library preparation and sequencing on a HighSeq 2500 (Illumina). The alignment, processing, variant calling and annotation were carried out on BWA, GATK and ANNOVAR. To filter possible pathogenic variants we used a MAF<0.01, adopting as references 1000g, 6500 exomes and Brazilian control 60+ databases. Sanger sequencing was used to investigate if the selected candidate variants were shared among the other members of the family.
Results: We first search for shared variants between both cousins, but we did not detect any X-linked or autosomal variant that could explain the phenotype. Next, we searched for loss of function variants (LoFs) in brain expressed genes located in the chromosome X that were exclusive of each affected individual. In individual IV-4 we identified a stop codon variant in *AP1S2*. We verified that the same variant was shared among all other affected individuals, except for individual IV-2. *AP1S2* is already associated with syndromic mental retardation, but it had not been linked to ASD yet. No relevant LoF variant in the X-chromosome or in autosomes of IV-2 was identified.
Conclusions: Our findings show the complexity of the analysis of each ASD family and highlight the relevance of another ID-associated gene to ASD.

165 **108.165** Visualising Multiple Hits in Autism Spectrum Disorders Using Whole Genome Sequencing and Protein-Protein Interaction Networks

F. Cliquet[1], *C. Carton*[1,2], *T. Kergrohen*[1], *A. Mathieu*[1], *A. Ziegler*[3], *J. Van-Gils*[4], *J. Buratti*[5], *F. Amsellem*[1,6], *T. Rolland*[1], *C. S. Leblond*[1,2], *D. Bonneau*[3], *B. Schwikowski*[1], *R. Delorme*[1,6] *and T. Bourgeron*[2,7], *(1)Institut Pasteur, Paris, France, (2)Université Paris Diderot, Paris, France, (3)CHU Angers, Angers, France, (4)CHU Bordeaux, Bordeaux, France, (5)Hôpital Pitié-Salpêtrière, Paris, France, (6)Hôpital Robert-Debré, Paris, France, (7)Neuroscience, Institut Pasteur, Paris, France*

Background: The biological causes of autism spectrum disorders (ASD) remain largely unknown mostly because of the high clinical and genetic heterogeneity. Furthermore, many studies indicated that, in a single patient, multiple hits affecting different genes/pathways might underlie the increased risk to have ASD. Several tools, such as Cytoscape, exist to visualize protein-protein interactions networks, but no application was designed to visualise variants affecting these networks.
Objectives: We aimed at developing a tool to help geneticists to visualise both protein-protein interactions and whole genome/exome data. This tool should help identifying multiple hits in individuals with ASD and providing a very precise characterization of each variants.
Methods: We sequenced the whole genome of 152 individuals from simplex and multiplex families with autism (57 patients, 68 parents and 51 relatives). We then designed GRAVITY a new Cytoscape App to rapidly visualise variants affecting ASD-risk genes (for example the SFARI gene list) or pathways (for example the glutamatergic, the GABAergic or the FMRP pathways). The tool can help filter the data on various user-defined criteria, such as the quality of the base calling, the type of mutation (synonymous, missense, stopgain…), the inheritance (*de novo*, recessive, dominant), the allele frequency as well as various scores to predict the deleteriousness impact of the variants (CADD, polyphen, SIFT).
Results: We first identified patients carrying a "first hit" affecting a known ASD-risk gene (*SHANK2, SHANK3, NLGN4X, CNTNAP2, CNTNAP4, TBC1D5, KCNB1, HYDIN, MEF2C*) or new compelling candidate genes (*EPHA4, SMG1)*. Using GRAVITY, we could also visualize additional hits in known ASD-risk gene and providing an estimation of the burden of multiple hits for each affected and unaffected individuals.
Conclusions: GRAVITY is a new tool simplifying the discovery of multiple hit in patients, saving a lot of time in the process. Thanks to GRAVITY, we were able to analyse the genetic architecture of 152 individuals revealing new candidate genes and confirming that multiple hits are frequently observed in patients with ASD. Further studies are warranted to ascertain if the burden of multiple hits contribute to the severity of the symptoms in the patients.

166 **108.166** Whole Exome Sequencing of Autism Spectrum Disorder Reveals Novel De Novo Variants in Korean Population

H. J. Yoo[1,2], *S. A. Kim*[3], *M. Park*[4], *J. Kim*[5], *W. J. Lim*[5,6], *G. Bong*[1], *D. H. Noh*[1], *D. W. Han*[7], *C. Shin*[8] *and N. Kim*[5,6], *(1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Psychiatry, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), (3)Pharmacology, Eulji University, Daejon, Korea, Republic of (South), (4)Epidemiology, Eulji University, Daejon, Korea, Republic of (South), (5)Personalized Genomic Medicine Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejon, Korea, Republic of (South), (6)Functional Genomics, Korea University of Science and Technology, Daejon, Korea, Republic of (South), (7)Stem Cell Biology, Konkuk University, Seoul, Korea, Republic of (South), (8)Pharmacology, Konkuk University, Seoul, Korea, Republic of (South)*

Background: Â *De novo*genetic variations have been revealed as a risk factor in ASD (Jiang et al., 2013). Whole exome sequencing (WES) techniques provide the opportunity for elucidation of the de novo genetic causes of ASDs.
Objectives: The objective of this family-based whole exome sequencing (WES) is to examine genetic variants of autism spectrum disorder (ASD) in Korean population.
Methods: Â The probands with ASD and their biological parents were recruited in this study. We ascertained diagnosis based on DSM-5^{TM}criteria, using Autism Diagnostic Observation Schedule and Autism Diagnostic Interview – Revised. We selected probands with typical phenotypes of ASD both in social interaction/communication and repetitive behaviour/limited interest domains, with intellectual disability (IQ<70), for attaining homogeneity of the phenotypes. First, we performed WES minimum 50x for 13 probands and high-coverage pooled sequencing for their parents. We performed additional WES for 38 trio families, at least 100x depth. *De novo* mutations were confirmed by Sanger sequencing. All the sequence reads were mapped onto the human reference genome (hg19 without Y chromosome). Bioinformatics analyses were performed by BWA-MEM, Picard, GATK, and snpEff for variant annotation. We selected mutation candidates from probands, which are neither detected in two pooled samples nor both parents.
Results: Fifty one subjects with ASD (5 females, 40~175 months, mean IQ 42) and their families were included in this study. We discovered 109 *de novo* variants from 46 families. Twenty nine variants are expected to be amino acid changing, potentially causing deleterious effects. We assume *CELSR3, MYH1, ATXN1, IDUA, NFKB1, ADCY7* and *DLEC1* may have adverse effect on central nerve system. Additionally *KCNE3*, previously observed in deleterious mutation in periodic paralysis, may be related with ASD.
Conclusions: We observed novel variants which are assumed to contribute to development of ASD with typical phenotypes and low intelligence in WES study.

167 **108.167** Whole Genome Sequencing and Rare Variant Discovery in the Aspire Autism Spectrum Disorder Cohort

S. Rogic[1], *B. Callaghan*[1], *P. Tan*[1], *K. Calli*[2], *Y. Qiao*[3], *M. Jacobson*[1], *M. Belmadani*[1], *N. Holmes*[1], *C. Yu*[4], *Y. Li*[4], *Y. Li*[4], *F. E. Kurtzke*[2], *A. Yu*[2], *M. Pavlidis*[1], *(1)MSL and Department of Psychiatry, University of British Columbia, Vancouver, BC, Canada, (2)Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada, (3)Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, (4)BGI Tech Solutions, Hong Kong, China, (5)Department of Psychiatry, Queen's University, Kingston, ON, Canada, (6)Queen's Genomics Lab at Ongwanada, Ongwanada Resource Center, Kingston, ON, Canada, (7)Department of Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (8)Montreal Neurological Institute, Montreal, QC, Canada, (9)Department of Human Genetics, McGill University, Montreal, QC, Canada, (10)Brock University, St. Catharines, ON, Canada, (11)Department of Psychiatry, Queen's University, Kingston, ON, Canada*

Background:
ASPIRE (Autism SPectrum Interdisciplinary REsearch) cohort is comprised of Individuals that have been diagnosed with ASD (DSM-IV; ADOS-G/ADI-R) and underwent a detailed standardized phenotyping protocol, including morphometrics, through Provincial Medical Genetics Program in BC.
Objectives:
Our goal was to characterize rare genetic variation using whole genome sequencing in a subset of the ASPIRE cohort and to examine genetic findings in the context of patients' deep phenotype data. To achieve this, we assembled a robust bioinformatics pipeline for identification and prioritization of potentially ASD associated variants that incorporates publically available resources and tools as well as in-house developed ones.
Methods:
We obtained whole genome sequences (Illumina paired-end 100 base pair reads, average depth 30x) for each subject. Variants were called using the Genome Analysis Toolkit (GATK) against the human reference genome, and filtered for quality and rarity in population data. To prioritize variants further, we relied on a combination of existing and in-house bioinformatics tools incorporating both gene-level metrics (genic intolerance to mutation, functional effect prediction) and variant level metrics (population frequency, predicted damage). Our efforts included recurating and harmonizing variants reported in the ASD literature, totalling close to 5000 variants from over 2500 ASD individuals. We have made the resulting database available as MARVdb (www.chibi.ubc.ca/marvdb). To collaboratively analyze variants in the context of phenotypes, we used ASPIREdb (aspiredb.chibi.ubc.ca), an interactive web application developed by our lab, which allows researchers to search, organize, analyze and visualize variants and phenotypes associated with a set of human subjects.
Results:
In total 97 high-priority candidate variants were identified, affecting 66 subjects. All of these variants were heterozygous and all but one were autosomal. Of these, 31 were predicted loss-of-function mutations, 3 affecting genes previously associated with ASD and 3 affecting genes associated with other neurodevelopmental disorders. A total of 66 candidate MS mutations were prioritized as potentially pathogenic, including 12 affecting literature-associated ASD genes, and 8 affecting genes associated with other neurodevelopmental disorders. High priority variants were subjected to trio resequencing to assess inheritance.
Conclusions:
Using this approach we have identified, among others, a novel de novo splice site variant in *SCN2A*, predicted to result in a loss of function, in an individual with severe autism and intellectual disability. This finding adds to the evidence that mutations in this gene can be associated with autism without comorbid seizure disorders.

168 **108.168** Whole Genome Sequencing of Extended Families Reveals Novel ASD Risk Variants

H. N. Cukier[1,2], *A. J. Griswold*[1,3], *D. Van Booven*[1], *N. K. Hofmann*[1], *P. L. Whitehead*[1], *E. R. Martin*[1], *M. L. Cuccaro*[1], *J. R. Gilbert*[1], *J. P. Hussman*[4] *and M. A. Pericak-Vance*[1,2], *(1)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (2)Department of Neurology, University of Miami Miller School of Medicine, Miami, FL, (3)Department of Pathology, University of Miami Miller School of Medicine, Miami, FL, (4)Hussman Institute for Autism, Inc., Catonsville, MD*

Background: Massively parallel sequencing in autism spectrum disorder (ASD) has focused on whole exome sequencing (WES) and whole genome sequencing (WGS) in trio cohorts for identifying *de novo*protein coding variants. These studies have largely utilized simplex families or siblings with ASD, and a majority of WGS analyses have reported only on protein coding variants.
Objectives: Our study applies WGS to extended, multiplex families with at least two cousins with ASD likely to carry rare, inherited and partially penetrant alterations. We hypothesize that identical by descent (IBD) filtering in these pedigrees would define genomic regions of shared ASD risk and allow for the identification of variants in noncoding regions, coding variants missed by exome sequencing, and structural variants, which could potentially isolate new ASD loci.
Methods: We performed WGS on at least two cousins with ASD across six extended families (15 individuals). Sequencing was performed on the Illumina HiSeq2500 and analyzed through pipelines including BWA-MEM alignment, quality recalibration by GATK, and variant calling with the GATK HaplotypeCaller and FreeBayes. Structural variants (SVs) were called with the SWAN and GenomeSTRiP algorithms. Annotations were applied with ANNOVAR including functional predictions for noncoding variants (CADD, FATHMM-MKL, and Eigen). We determined IBD regions using whole genome genotyping data and the MERLIN package. Variants were prioritized which were shared in all individuals with ASD within each family, rare in the population (<1%), and predicted to have functional significance through *in silico*programs (CADD >10, FATHMM-noncoding >0.5, and Eigen >1).
Results: We sequenced each genome to ~40x coverage and identified >4 million single nucleotide variants (SNVs) and small indels and >100 SVs per individual. Variant calls between HaplotypeCaller and FreeBayes were >95% concordant. IBD filtering in each family limited the total number of SNVs and short indels for analysis to between 732 and 1,020,713, depending on the family's structure. Among coding SNVs, ~94% concordance was found with existing whole exome data (Cukier, et al, 2014); however, WGS identified ~10% more coding variant calls. These include a family with a rare missense mutation in the neurogenesis growth factor *GDF11* and another with a frameshift in the axonal development gene *SLAIN1*. *In silico* prioritization of noncoding regions revealed several variants of interest. For example, two variants were identified in the putative promoter of the chromatin remodeling gene *ARID1B* in one family, and two other variants upstream of ankyrin repeat gene *KANK1* were present in another family. Finally, rare copy number variants were found; one CNV disrupted the promoter of the neurodevelopmental *WWOX* gene and another deleted an exon of the lincRNA *FIRRE*, which is involved in chromosomal organization.
Conclusions: By studying these unique pedigrees, applying cutting edge sequencing and analysis methods, and employing IBD filtering, we establish that WGS of extended families can identify inherited ASD risk alterations. These methods extend the scope of WGS beyond *de novo* protein coding variants to functional noncoding SNVs, SNVs not captured by exome sequencing, and SVs that may contribute to ASD. Taken together, WGS identifies new ASD candidate genes and pathways.

169 **108.169** Sex-Modulated Structural Covariance Networks in Autism

R. A. Bethlehem[1], *M. V. Lombardo*[2,3], *A. N. Ruigrok*[2], *B. Auyeung*[4], *J. Suckling*[5], *E. Bullmore*[5], *M. Consortium*[6], *S. Baron-Cohen*[2], *B. Chakrabarti*[7] *and M. C. Lai*[8],

(1)University of Cambridge, Cambridge, England, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)University of Cyprus, Nicosia, Cyprus, (4)University of Edinburgh, Edinburgh, United Kingdom, (5)Brain Mapping Unit, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (7)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (8)Psychiatry, University of Toronto, Toronto, ON, CANADA

Background:
Atypical neural connectivity has been proposed as a biomarker for autism, entailing decreased fronto-posterior and enhanced parietal-occipital connectivity, reduced long-range and increased short-range connectivity, and temporal binding deficits. Empirical findings vary substantially depending on the aspects of connectivity examined, the developmental stage of the individual, the spatial and temporal scales, task versus no-task conditions, how motion artefacts are handled, and the specific neural systems of concern. Heterogeneity in connectivity findings is likely further due to key aspects of sample variation, such as sex/gender.
Objectives:
(1) To explore if biological sex moderates the characteristics of structural covariance in autism; (2) To explore the atypical connectivity hypothesis of autism using structural covariance network analysis.
Methods:
Structural covariance of T1 weighted MRI data from 117 individuals in 4 groups (males with autism N=25, neurotypical males N=33, females with autism N=30, neurotypical females N=29), matched for age and IQ. IQ was in the average range or above. Data was analyzed using Freesurfer segmentation for cortical thickness and custom Matlab code to assess graph theoretical and network properties. We specifically investigated metrics describing the relation between cortical thickness and network topology in reference to long versus short-range connectivity. For example, we looked at the relation between anatomical distance and covariance correlation strength and properties of the degree distribution. Statistical significance was assessed using pair-wise Monte-Carlo permutation tests.
Results:
Inter-regional correlation strength as a function of Euclidean distance differed across all 4 groups. Specifically, the female autism group showed a much steeper decline in correlation strength with increased anatomical distance, indicating a balance that more strongly favours local over global connections. In addition, the overall cumulative distribution of the degree of network parcels showed a strong sex difference, with the male control group having a reduced incidence of high degree nodes. This difference was absent in the autism group.
Conclusions:
We report evidence for atypical connectivity in adults with autism compared to neurotypical adults, but the pattern is heterogeneous, both moderated by sex and dependent on the metrics examined. More fine-grained descriptions on patterns of atypical connectivity are needed. These results challenge an over-simplified view that general hypo- or hyper-connectivity marks the atypical neurobiology of autism.

170 **108.170** Cognitive and Head Circumference Differences in 16p11.2 CNV Carriers with and without Autism.

Background: The phenotypic and etiologic heterogeneity of Autism Spectrum Disorder (ASD) represents a significant hurdle for research. “Genetic-first” studies have allowed focusing on groups of individuals who share the same genetic risk factor for ASD. This condition is multifactorial, and even genetic variants that carry large risk for ASD are not always associated with ASD (eg. 20% of 16p11.2 – 29.6-30.2 Mb-Hg19 – deletion and duplication carriers meet criteria for ASD). The nature of the additional factors present in these individuals with ASD is unknown.
Objectives: The aim of this study is to characterize cognitive dimensions and head circumference (HC) –a proxy for brain size – in carriers of a 16p11.2 copy number variant (CNV) with ASD and those without ASD.
Methods: A total of 265 probands carrying 16p11.2 rearrangements (174 deletion; 91 duplication) and 421 intrafamilial controls recruited from the 16p11.2 European Consortium, the Cardiff University Experiences of Children with Copy Number Variants Study and the Simons Variation in Individuals Project were included in the study. Measures included HC, ADI-R and IQ. We used linear mixed models to compare differences in phenotype between deletion and duplication carriers with and without ASD.
Results: Both the deletion and the duplication are associated with an IQ that is about 25 points lower than familial controls. ASD diagnosis in deletion carriers is associated with a 6.6-point increase in IQ mainly driven by nonverbal skills (p=0.018) and larger HC (+0.78 z-score, p=0.001) compared to deletion carriers without ASD. In contrast, duplication carriers with ASD show an additional decrease of 15 points in IQ (p= 0.002) compared to duplication carriers without ASD. Additional genetic factors underlying the ASD diagnosis in deletion carriers may be inherited since mothers have a significantly higher IQ (8 points; p=0.006) compared to mothers of carriers without ASD. The clinical profile of duplication carriers with ASD also differs significantly from that of deletion carriers with ASD. The former display more repetitive and stereotyped behaviors on the ADI-R (p=0.01).
Conclusions: The clinical differences between CNV carriers with and without ASD may inform on the nature of the additional factors present in the subgroup diagnosed with ASD. In addition, these results highlight the fact that deletion and duplication at the 16p11.2 locus are associated with two distinct underlying mechanisms predisposing to ASD.

171 **108.171** The Effects of 16p11.2 Gene Dosage on Brain Structure

Reymond*[11], *R. L. Buckner*[12,13,14], *B. Draganski*[7] *and S. Jacquemont*[15], *(1)Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, (2)CHU Sainte-Justine Research Center, Université de Montréal, Montreal, QC, Canada, (3)Harvard University, Cambridge, MA, (4)CHU Sainte Justine, University of Montreal, Montreal, QC, Canada, (5)Service de Génétique Médicale, Lausanne University Hospital, Pully, SWITZERLAND, (6)Genetics, University of Lausanne, Lausanne, Switzerland, (7)Department for Clinical Neurosciences, University of Lausanne, Lausanne, Switzerland, (8)Service of Medical Genetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, (9)Swiss Federal Institute of Technology (EPFL), Lausanne, SWITZERLAND, (10)Martinos Center for Biomedical Imaging, Charlestown, MA, (11)University of Lausanne, Lausanne, SWITZERLAND, (12)Department of Radiology, Harvard Medical School, Boston, MA, (13)Psychology Department, Harvard University, Boston, MA, (14)Center for Brain Sciences, Harvard University, Cambridge, MA, (15)University of Montreal, Montreal, QC, CANADA*

Background: Copy Number Variants - CNVs are major contributors to neurodevelopmental disorders. Carriers of the deletion or duplication at the 16p11.2 locus (29.6-30.2 Mb-Hg 19) have a 10-fold increased risk of developing autism spectrum disorder (ASD) and present an inverse gene dosage on Body Mass Index and head circumference. Some recent neuroimaging studies have revealed an association between the number of 16p11.2 genomic copies and global brain metrics, as well as regional structural changes in the reward system, language circuitry and social cognition.
Objectives:
Our goals for this study were to 1) Replicate and extend previously published findings on a larger dataset of families with 16p11.2 CNV by pooling new and previously published data; 2) Demonstrate that individuals, who share the same autism risk factor, show robust brain alterations through different cohorts and scanning sites.
Methods: Participants, above 6 years old, were evaluated in the European 16p11.2 consortium and the American Simons VIP study. 361 participants were examined on a 3T whole body MRI scanner on 7 different sites. T1-weighted anatomical images were acquired using a multi-echo magnetization prepared rapid gradient echo sequences (ME-MPRAGE) on 264 participants and a single-echo MPRAGE sequences on 97 participants. Data analyses were performed using the SPM12 and FreeSurfer software packages.
Results: We analyzed MRI data in 78 16p11.2 deletion carriers, 71 duplication carriers, 72 familial controls, as well as 140 extra-familial controls. 11 deletion and 8 duplication carriers met criteria for ASD (13%). Intracranial Volume correlated negatively with the number of genomic copies at the 16p11.2 locus in the European and American cohorts. Both gray and white matter total volumes contributed to this effect. Using Voxel-Based Morphometry in both cohorts, we found a negative relationship between the number of 16p11.2 genomic copies and the volume of bilateral insula, putamen, superior temporal gyri, orbital part of inferior frontal gyri, lingual gyri, and some cerebellar lobules. Both cohorts also presented a positive relationship between the number of genomic copies and the volume of bilateral middle temporal gyri.â€¨We did not find any interaction between the genetic status and the two cohorts, the 7 sites or the gender. Results were also stable across the 7 iterative analyses successively leaving out one of the scanning sites. Subdividing the genetic group in 2 categorical age groups showed the same profile of structural brain abnormalities.
Conclusions: Â These results demonstrate that different ascertainment methods in Europe and the USA led to the same brain differences. The robustness and power of this combined dataset and the relevance of the global and regional findings show that multisite MRI studies are extremely powerful, especially when neurobiological heterogeneity can be reduced by focusing on individuals who share a common ASD risk factor.

12:00 PM - 1:40 PM - Golden Gate Ballroom

172 **109.172** A Longitudinal Analysis of Parent Responsiveness Following Intervention

M. DuBay[1], *A. Alzamel*[2], *T. Uzonyi*[3], *S. W. Nowell*[4], *L. Turner-Brown*[5], *L. R. Watson*[6] *and E. Crais*[6], *(1)University of North Carolina at Chapel Hill, Durham, NC, (2)Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of North Carolina - Chapel Hill, Chapel Hill, NC, (5)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Carrboro, NC, (6)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Replicated findings demonstrate that parent responsiveness (PR) is associated with later child outcomes, and that PR in parents of children at-risk for ASD can be increased by intervention. Further, child behaviors, including sensory hypo-reactivity and social communication, predict later PR, emphasizing the transactional nature of PR. The current study follows up on infants at-risk for ASD participating in an RCT that demonstrated a positive treatment effect on PR at posttest.
Objectives: (1) Determine if there was a continuing treatment effect on PR at preschool follow-up. (2) Examine the longitudinal trajectory of PR by group. (3) Determine if post-test hypo-responsiveness and/or social communication skills predicted PR at follow-up.
Methods: Parents and community-identified infants at-risk for ASD aged 13-15 months (n=87) participated in a RCT of a parent-mediated intervention, Adapted Responsive Teaching (ART). All families received information about community services and monthly monitoring phone calls, while those randomized to ART were coached using a manualized intervention designed to promote using responsive strategies while targeting social communication and sensory regulation. Measures of social communication (Communication & Symbolic Behavior Scales, Social Composite), sensory regulation (hypo-reactivity, measured by the Sensory Experiences Questionnaire and Sensory Processing Assessment), and PR (proportion of 5-second intervals with parent responses, using partial interval coding of 10-minute parent-child videos) were completed at pre- and post-test. When children were 3-5 years old, a subset (n=47) were re-recruited for follow-up assessments, including a third measurement of PR.
Results: Preliminary analyses used coded data from 28 children at follow-up. Although ART parents in the preliminary analyses were not significantly different in PR than comparison group parents at post-test, they reflected the trend of higher PR found in the full sample. At follow-up, however, they were significantly lower in PR than the comparison group, t = -3.02, p < .01 (Figure 1). Posttest social communication, t = -2.24, p = .04, and hypo-reactivity, t = -2.07, p = .05, predicted follow-up PR. Also, an interaction between posttest social communication and group, t = 2.93, p < .01, reflected that higher post-test social communication was associated with lower follow-up parent responsiveness in the comparison group (Figure 2). Overall, findings were significant only in a model incorporating parent report measures of child predictors, but not in a model using observational measures. Models will be examined further with the larger sample when coding is completed.
Conclusions: These preliminary results may be unstable due to the small subsample. We anticipate that full sample results will show that ART group PR was higher than the comparison group at post-test but that this difference was not maintained at follow-up. Reductions in PR in the ART group at follow-up could be concerning, given the theoretical importance of PR for child outcomes. Such a finding may suggest the need to provide ongoing support/coaching to families of children at risk for ASD beyond a 6-month intervention. Possibly strategies parents learned to apply with infants are harder to apply or less developmentally appropriate as children mature and gain new abilities or manifest new symptoms.

173 **109.173** A Meta-Analysis of Pivotal Response Treatment As an Early Naturalistic Developmental Behavior Intervention for Autism

R. M. Klinkel[1] *and G. L. Lyons*[2], *(1)STAR Center for ASD and NDDs, University of California San Francisco, San Francisco, CA, (2)STAR Center, UCSF, San Francisco, CA*

Background: In contrast to Early Intensive Behavioral Intervention (EIBI), there are far fewer systematic reviews and meta-analyses evaluating Naturalistic Developmental Behavioral Interventions (NDBIs), a group of behavioral interventions that (a) share critical treatment components and (b) are often deemed evidence-based (Schreibman et al., 2015). For instance, as an NDBI, stakeholders routinely consider Pivotal Response Treatment (PRT) empirically supported in treating core social-communication deficits; however, the literature lacks sophisticated meta-analytical studies aimed at ascertaining cumulative PRT evidence and effect sizes (ES) across early intervention outcomes. Indeed, stakeholders need clarity regarding PRT's effect on outcomes beyond social-communication. Furthermore, meta-analyses should dually investigate single-case (SCD) and group designs (GD), but researchers typically do not employ the necessary methodology (i.e., hierarchical linear modeling, HLM; Shadish *d*-statistic). Critical to understanding PRT and individualization, such methods also allow for analyses of key moderators (e.g., child characteristics, outcomes, study quality).
Objectives: We answer the following research questions: (a) For both GD and SCD, what are PRT ESs across outcome areas and ES types?; (b) What key variables moderate PRT effects?; (c) What components best constitute PRT?; and (d) What descriptive variables contextualize the findings?
Methods: We systematically selected articles that compared PRT to no-treatment conditions for children with autism under 6 years old; 36 studies (30 SCD, 6 GD) were included. We gathered adequate inter-coder agreement at every stage of search, selection, and variable coding. We coded numerous variables from each study, and extracted SCD data point coordinates and GD statistics. For SCD, we employed HLM, Tau-*U*, and the Shadish *d*-statistic analog of GD standardized mean differences. For GD, we aggregated Cohen's *d*random effects by inverse variances.
Results: Accounting for study quality, we found medium-to-high SCD ESs across social-communication and language, play, and affect outcomes (omnibus HLM ES: γ_{100} Â = 0.87 standardized units, p< .001), with larger estimates for social-communication and language. The GD meta-analysis indicated a moderate-sized effect across outcomes, with larger estimates for measures of communication and language. Observed utterances showed slightly larger comparable effect sizes for SCD versus GD studies. For SCD, higher study quality significantly penalized PRT effects. The HLM analysis of SCD also revealed PRT effects significantly varied between participants. We gleaned inconsistent PRT procedures across studies, but key components (i.e., choice and natural reinforcement) were ubiquitous.
Conclusions: We found early PRT was generally effective across studies and outcomes, evinced by moderate to large ESs. The social-communication and language area, however, generated the largest effect sizes (functional speech, in particular) and greatest confidence (representing 73.6% of the weighted data). PRT produced favorable play and affect outcomes; however, with slightly smaller and/or far fewer effect sizes, claims of positive PRT effects beyond social-communication and language are tenuous. Evidence for PRT's effect on receptive language and cognitive functioning is also weak, while its effects on adaptive behavior is emerging – making it difficult to draw comparisons with EIBI meta-analyses, or understand PRT as a comprehensive early intervention. Based on our findings, we outline a model for advancing PRT and NDBI research.

174 **109.174** AAC: Attention, Exploration and Response in Children with Autism

V. Rose[1]*, D. Trembath*[2]*, J. M. Paynter*[3] *and D. Keen*[4]*, (1)Menzies Health Institute, Griffith University, Southport, Australia, (2)Menzies Health Institute, Griffith University, AUSTRALIA, (3)School of Applied Psychology, Griffith University, Southport, Australia, (4)Griffith University, Mt Gravatt, AUSTRALIA*

Background: Augmentative and Alternative Communication (AAC) is a commonly prescribed intervention for pre- and minimally- verbal children with Autism Spectrum Disorder (ASD). Despite widespread use and emerging evidence for its effectiveness, little research exists examining the mechanisms underpinning individual differences in response to AAC intervention. Variability in outcomes may be related to the complex social-communication needs of the children, given that AAC is generally prescribed to those with the most significant needs. However, differences in response to this intervention may also partly be related to visual attention to, and propensity to spontaneously engage with the AAC system.
Objectives: The aims of this study were to look at the relationship between (a) visual attention to, and (b) physical exploration of, a picture-based AAC system upon first exposure, and subsequent response to instructions provided by a teacher using a picture-based AAC system in a simulated activity.
Methods: Participants were children with a diagnosis of ASD between the ages of two and five years at intake to a community-based early intervention program. The extent to which children visually attended to and physically explored AAC was gathered from a free play activity, during which children were given the opportunity to interact with a picture-based AAC system for 1 minute. Five second interval coding was used to code for the presence/absence of these behaviours. Children's responses to the picture-based AAC system were determined by their ability to carry out a set of 8 instructions delivered to them using AAC in a simulated teaching activity (e.g., "I want you to pick up the [object] and put it in the [container]"). Children received 1 point for collecting the correct item and attempting to insert it in the correct container, for a maximum of 8 points.
Results: The participants in this study visually attended to, and physically explored, the AAC system during an average of 79.39% (SD 27.33%, range 8% to 100%) and 79.38% (SD 23.78%, range 25% to 100%) of intervals, respectively. Average performance score (i.e., ability to follow instructions delivered using AAC) was 2 (25%; SD 3.01, range 0 to 8), with only two children (14.3%) achieving the highest possible score of 8. Using Spearman's correlation coefficient, we found no relationship (r = -.030, p = .918) between visual attention to AAC during free play and subsequent performance, and no relationship (r = .066, p = .822) between physical exploration of AAC and subsequent performance.
Conclusions: Preliminary findings suggest no link between visual attention to, and exploration of, AAC, and subsequent task performance on first exposure to the system. It remains to be tested whether initial response to AAC is associated with response to interventions in which AAC is either a primary or central component in the longer term.

175 **109.175** An Analysis of Changes in Child Behavior during Esdm Parent Coaching

M. L. Rocha[1]*, A. C. Stahmer*[1]*, D. K. Cain*[2]*, L. A. Vismara*[3]*, G. Dawson*[4] *and S. J. Rogers*[1]*, (1)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Human Ecology, UC Davis MIND Institute, Davis, CA, (3)York University, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC*

Background: Children with ASD or ASD risk under the age of 3 are eligible for public early intervention services and for those who live in low resource communities, these are often their only services. Providers from those settings typically use parent coaching to serve a wide range of young children with developmental problems and may have little knowledge of the specific intervention needs of toddlers with ASD. The Early Start Denver Model (ESDM) is an evidence-based practice developed specifically for toddlers with or at risk for ASD. ESDM is appropriate for public early intervention services because of its combination of developmental and behavioral strategies, its defined and manualized developmental curriculum and teaching practices, its interdisciplinary orientation, and its family-centered focus. However, the impact that each ESDM Parent Coaching strategy has on child behavior is unknown. Helping providers and families in low resource areas to adapt Community ESDM requires us to determine the most important strategies of ESDM Parent Coaching as the first step toward adapting ESDM for very young children and families living in rural or low income, and highly diverse settings.
Objectives: This study assessed the effect of four different ESDM Parent Coaching topics on target child behaviors. In addition, we assessed the impact of the order in which the strategies are taught.
Methods: Four children with ASD, ages 17-27 months old, and their parents participated in a single subject multiple baseline component analysis design across subjects. Each child and family received parent coaching sessions in the clinic 3 times per week for 4 weeks. Ten-minute video recordings of parent-child dyad interactions during baseline and treatment sessions were coded for child behaviors.
Results: Preliminary data from the first two participants suggest differential changes in child behavior based on strategies parents learned during sessions. Increases in sensory social play were seen for the first time when parents learned 4 step joint activity routines and these increases persisted through the rest of the treatment. Parent learning to (1) balance social communication exchanges (nonverbal communication; developmentally appropriate language; narrating and pointing) and (2) gain child attention were associated with greater instances of children imitating object related actions. Object toy play increased throughout all conditions regardless of component order. Additional patterns and order effects will be examined once the remainder of the data is coded.
Conclusions: Results will be discussed in terms of the active ingredients of ESDM and the implications of this data for adapting ESDM for diverse early intervention service systems.

176 **109.176** An Examination of the Social Validity of Jumpstart, an Education and Training Program for Parents of Children with Autism Spectrum Disorder

J. A. Muhlenkamp[1], *K. Hale*[1], *R. Tewksbury*[1], *S. Zwicker*[1], *A. Gonzales*[1], *B. C. Orr*[2], *B. Harris*[1], *N. L. Matthews*[3] *and C. J. Smith*[3], *(1)Southwest Autism Research and Resource Center, Phoenix, AZ, (2)Southwest Autism Research & Resource Center (SARRC), Phoenix, AZ, (3)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Â JumpStart is a short-term education program for parents of children with autism spectrum disorder (ASD). Previous research has documented objective parent and child outcomes, including increased parent knowledge, parent fidelity of implementation of pivotal response treatment (PRT), child responsivity, and reduced child aberrant behavior (Matthews et al., under review). Social validity of the program remains unexamined.
Objectives: Â To examine social validity of JumpStart by comparing changes in parent perceptions of their own knowledge between treatment and delayed treatment control (DTC) groups.
Methods: Â Participants were 25 parents of children recruited from the JumpStart waitlist who were enrolled in the treatment (n = 12; 0 fathers; child M_{age} = 37.92 months, SD = 9.34) or DTC (n = 13; 1 father; child M_{age} = 40.00 months, SD = 12.54) group. Children had an ASD diagnosis (n = 21) or an 'at-risk for autism' (n = 4) classification.
JumpStart meets twice weekly over a 4-week period (weeks 2-5). At a study visit 6 weeks prior to the program (DTC group only), orientation (week 1), and a 1-week follow-up (week 6), parents completed a 17-item questionnaire (Table 1) that asked parents to rate their perceived knowledge of topics covered during JumpStart using a Likert scale ranging from "strongly disagree" (1) to "strongly agree" (7).
Results:
Descriptive statistics are reported in Table 1. Separate 2 (group) x 2 (time point) ANOVAs were conducted (adjusted alpha of .002 used to account for multiple comparisons). There were significant group by time interactions on items assessing parents perceived knowledge of ASD (p < .001), applied behavior analysis (p < .001), PRT (p < .001), and perceived ability to implement PRT (p < .001) and respond appropriately to their child's disruptive behaviors (p = .002). On all items, the treatment group demonstrated larger gains than the DTC group. Following a similar pattern, but only approaching statistical significance, were parents' perceived ability to prevent disruptive behaviors (p = .04), knowledge of autism-related services funded by the state (p = .01), understanding of services covered by health insurance (p = .09), understanding of parents' roles in creating and revising IEPs (p = .02), ability to arrange an appropriate educational placement (p = .004) and special education services (p = .004), and ability to toilet train their child (p = .03).
Conclusions: Â Arguably as important as objective outcomes are parent perceptions of the knowledge and skills gained during JumpStart. Parents in the treatment group reported gains compared to the DTC group on a number of topics. Perhaps most important to consider are the items on which groups did not demonstrate differences, suggesting that parents who complete JumpStart are not perceiving increased knowledge in these areas compared to controls. The treatment group did not differ from the DTC group in changes in perceived understanding of the causes of their child's behavior, understanding of the Arizona Long Term Care System, ability to obtain appropriate state-funded services, and understanding of/satisfaction with their child's IEP. Implications of these findings and future directions will be discussed.

177 **109.177** Autism Spectrum Disorder and Early Intervention Services in New Jersey from 2006-2012

J. Shenouda[1], *K. Sidwell*[2], *J. Solis*[3], *J. Howell*[4] *and W. W. Zahorodny*[5], *(1)Pediatrics, Rutgers University - NJ Medical School, Newark, NJ, (2)Rutgers University, Great Meadows, NJ, (3)Rutgers University - New Jersey Autism Study, Elizabeth, NJ, (4)Pediatrics, Rutgers - NJ Medical School, Newark, NJ, (5)New Jersey Medical School, Westfield, NJ*

Background:
Over the past decade Autism Spectrum Disorder (ASD) has increased significantly. One general consensus among all stakeholders is that ASD should be identified early which can allow for benefits of early intervention. Through early intervention, children make gains in cognitive ability, social functioning and even changes in core symptom severity.
Objectives:
The purpose of this study was to describe EI utilization by ASD children in NJ over time and to identify sex, race, ethnicity and SES-based disparities in EI utilization.
Methods:
Data were collected as part of the New Jersey Autism Study (NJAS), an ASD surveillance investigation carried out in Essex, Union, Hudson and Ocean counties. Using an active case-finding method established by the Centers for Disease Control and Prevention (CDC), case-specific data were developed for children who were born in 1998, 2002, and 2004 and resided in the surveillance region during Study Years (SY) 2006, 2010, and 2012 respectively. NJAS data were based on review, analysis and independent ASD case- determination derived from information contained in health and education records. Demographic and case-specific information reflecting and case-specific interventions, including receipt of EI Services, were analyzed. The socioeconomic status (SES) of children with ASD was represented by the District Factor Group (DFG) ranking, a community-level index.Â Statistical analysis was performed using chi-square tests.
Results:
Information from 2,029 8-year-old ASD-confirmed children identified from three cycles of ASD surveillance in New Jersey between 2006-2012 (SY2006: 533; SY2010: 696; SY2012: 800) was analyzed to determine differences by group, over time. Increasing proportions of ASD children received EI services during the period (EIP – SY2006: 39%; SY2010: 43%; SY2012: 50%) (p<.001). Boys and girls with ASD were equally likely to receive EI services and both males and females enjoyed increased levels of EI participation in the period (Girls - SY2006: 36% and SY2012: 52% (p<.01); Boys – SY2006: 40% and SY2012: 50% (p<.01)). We observed declining race and ethnicity-based disparities, most notably among Hispanic children, 17% increase from 2006 to 2012, from 28% in 2006 to 45% in 2012 (p<.05). SES was associated with greater EI participation in each cycle and increased significantly, across all levels. However, In 2006, 34% of children with ASD from Low SES areas and 36% of children from Mid SES areas were receiving EI services compared to 49% from High SES areas (p<.01). By 2012, there was still a SES disparity where 44% of Low SES children were receiving EI services compared to 50% of children from Mid SES, and 63% of children from High SES areas (p<.001).
Conclusions:
As of 2012, the most recently-completed cycle of ASD monitoring in NJ, half of ASD children received EI services. EI participation increased significantly (11%) between 2006 and 2012.Â Some disparities may be declining, while SES-based differences are prominent. Improved strategies are necessary to decrease disparities in receipt of Early Intervention services.

178 **109.178** Characterizing Children with Autism Spectrum Disorder (ASD) Who Respond to a Gluten-Free Casein-Free (GFCF) Diet

S. N. Brasher[1]*, N. Worthington*[2] *and J. Elder*[3]*, (1)Emory University, Atlanta, GA, (2)Worthington Pediatrics, Gainesville, FL, (3)College of Nursing University of Florida, Gainesville, FL*

Background: The Gluten-Free Casein-Free (GFCF) diet continues to be one of the most commonly used complementary and alternative treatments in children with Autism Spectrum Disorders (ASD). However, the current state of science on the GFCF diet is mixed with some studies showing the diet may improve ASD symptoms in some children, while other studies have found no effects from the diet. Similarly, several healthcare providers and parents of children with ASD adamantly report some children to have noticeable positive effects from the GFCF diet. Given these mixed findings, evidence is mounting to indicate that a subgroup of children with ASD may exist, which could potentially explain the mixed effects of the GFCF diet. Yet, to date, there has been no attempt to identify this subgroup of children with ASD and the characteristics they possess.
Objectives: To identify children with ASD documented as responding to the GFCF diet and characterize them based on clinical presentations, laboratory findings, and medical histories.
Methods: A retrospective chart review was conducted at a pediatric primary care clinic to examine medical records of children with ASD on a GFCF diet (2005-2015). IRB approval was obtained. Data collected from the medical records were inputted into the statistical software program SPSS. Statistical analysis evaluated the differences between GFCF diet responders and non-responders using a chi-square and Wilcoxon rank sum test.
Results: A total of 33 participants (n=33) were included in this study. The sample included 26 males and seven females. The age of participants ranged from 1.5-16 years (mean=5.07 years, SD=4.04). A total of 1,195 variables were collected from 33 participants. Twenty-two participants (n=22) were identified as responders to the GFCF diet and 11 participants (n=11) were identified as non-responders. Three types of ASD were identified: regressive after 12-months-old (n=13), non-regressive (n=18), and failed to progress after 12-months-old (n=2). A chi-square determined a significant difference existed in GFCF diet response and type of ASD (p=.026), plasma amino acid 3-methylhistidine (p=.013), and plasma amino acid alanine (p=.034). A Wilcoxon rank sum found significant differences between GFCF non-responders and responders in urine octenedioic (p=.006), fecal SIgA (p=.006), urine 3-hydroxyglutaric (p=.007), plasma amino acid glycine (p=.019), plasma amino acid alanine (p=.037), and serum alkaline phosphatase (p=.044).
Conclusions: Findings from this study indicate statistically significant differences in stool, plasma, and urine variables between children with ASD who responded to a GFCF diet and those who did not. These findings lend preliminary support for the clinical accounts of some children with ASD responding more favorably to a GFCF diet than others. It is expected that characterizing known responders to the GFCF diet will provide critical information to assist in clinical decision making, as well as help develop inclusion/exclusion criteria necessary for future clinical trials. Additionally, findings from this study revealed unexpected similarities among laboratory markers of all participants. Findings are expected to not only contribute to what is currently known, but also generate future research on biomarkers, microbiome, and characterization of all children with ASD.

179 **109.179** Evaluation of the Autism Distance Education Parent Training (ADEPT) Program in Boise, Idaho

E. Harlan Drewel*, St. Luke's Children's Hospital, Boise, ID*

Background:
Autism Spectrum Disorder (ASD) symptoms are optimally mitigated when treatment is started as early as possible (Zweigenbaum, et al., 2015). An effective intervention for young children with ASD is Applied Behavioral Analysis (ABA) (Rogers and Vismara, 2008).
In Idaho, access to ABA treatment is lacking. A semblance of ABA is provided by developmental disability agencies to children who qualify. Generally, those providing the treatment obtain less training and supervision in ABA compared to behavior therapists in other states. Also, the quality and type of behavioral intervention offered by school districts is variable.
Professionals at the MIND Institute at UC Davis have addressed ABA access issues by designing the Autism Distance Education Parent Training (ADEPT) program for parents who have a child with an ASD. Parents review on-line modules that demonstrate how to use ABA principles to improve functional skills and reduce problematic behaviors in children with ASD. Parents then attend two, twelve hour, group parent training workshops led by treatment professionals to enhance their ABA knowledge. Parents then have a home visit with two of the treatment professionals after each workshop. Findings from an unpublished pilot study at MIND found a significant increase from pre to post training in parent-reported confidence in the ability to implement ABA principles and parent knowledge of ABA principles.
Objectives:
Providers at a children's hospital in Boise, Idaho wanted to determine the benefit of the ADEPT program for local parents of children with ASD.Â Specifically, would parent-reported confidence in the ability to implement ABA principles and parent knowledge of ABA principles increase from pre to post training? Also, would parenting sense of competence increase and autism-related parenting stress decrease from pre to post training? Positive outcomes would support funding for broader investigation and implementation of the ADEPT program throughout the state.
Methods:
Five providers from the children's hospital (mental health providers and an occupational therapist) were trained by a trainer from UC Davis MIND Institute on how to conduct the ADEPT training. Simultaneously, eight parents who had a child with an ASD (ages 2 to 5) underwent the ADEPT training, which was led mainly by the providers. Parents of children with a recent diagnosis of ASD were recruited to participate from a referral pool created by the providers.
Before and after training, parents completed the Autism Parenting Stress Index (Silva and Schalock, 2012), Parenting Sense of Competence Scale (Johnson and Mash, 1989), and surveys that assessed parent-reported confidence in the ability to implement ABA principles and parent knowledge of ABA principles (unpublished).
Results:
Parent-reported confidence in the ability to implement ABA principles increased from pre to post training. Parent knowledge of ABA principles either remained the same or impoved from pre to post training. Parenting sense of competence and autism-related parenting stress did not change from pre to post training.
Conclusions:
Initial results are promising and are generally consistent with the MIND Institute pilot study. Future studies will examine the benefit of the ADEPT training across Idaho.

180 **109.180** Examining Fidelity of Implementation in a Naturalistic Developmental Behavioral Intervention in Community Settings: The Influence of Provider Characteristics

S. Arbiv[1]*, K. S. Dickson*[2]*, S. R. Rieth*[3] *and A. C. Stahmer*[4]*, (1)University of California, San Diego, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)San Diego State University, San Diego, CA, (4)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background: Research supports the critical need for early intervention to improve outcomes for young children at risk for autism spectrum disorder (ASD). Parent-mediated naturalistic developmental behavioral early interventions (NDBI) have demonstrated positive family outcomes and offer the potential for increased intervention intensity (Burrell & Borrego, 2012). However, there has been little dissemination of parent-mediated NDBI into community settings. Community providers with expertise in both implementation of NDBI strategies and parent coaching are needed to effectively deliver NDBIs. However, based on the multiple avenues through which children with ASD may receive services, community providers have a range of educational backgrounds and ASD specific experience. As communities struggle to effectively serve the growing number of toddlers at risk for ASD, more information is needed on provider characteristics that may influence the appropriate use of NDBIs in community settings.
Objectives: This study provides a preliminary examination of provider characteristics as potential moderators of providers' fidelity of implementation of an evidenced-based parent mediated NDBI for toddlers at risk for ASD (Project ImPACT for Toddlers or PI for T; Ingersoll & Dvortscak, 2010).
Methods: Â Participants include 33 early intervention providers with varied training backgrounds, specializations and education levels working in a range of community-based settings. Participants received 12 weeks of training in PI for T from a leader within their agency who was trained by the research team. Video observations of providers utilizing intervention strategies with families were collected before, during, and after training. Observations were behaviorally scored for intervention fidelity of implementation (FI). Coders rated each intervention component on a 5-point scale (1=did not use; 5 = used throughout). FI scores were compared at baseline, post-training, and after three months of use. Provider characteristics (e.g. education, discipline, experience) and setting variables were examined as potential moderators of FI.
Results: Â Preliminary results suggest that while many providers do not meet FI overall after training, they demonstrate improvement over time in some domains, including allowing the child to choose the activity, modeling developmentally appropriate communication and play, and expanding/adding complexity to the child's responses. Preliminary analyses show no difference in FI based on education level. Providers' years experience in early intervention demonstrate a relationship with appropriate use of prompting strategies, such that providers with moderate experience demonstrate highest fidelity. Additionally, providers with 20+ years of experience in either early intervention broadly or ASD specifically haveÂ lower FI scores in some domains. Further moderators, including intervention setting, will be analyzed to identify any additional impacts on fidelity.
Conclusions:
Identifying relationships between provider characteristics and FI of parent-mediated NDBIs can support improved dissemination of these evidence-based strategies in community settings. Providers who have been in the field longer may need individualized training on how to shift their current practice to best align with an evidence-based approach. Future research should continue to address the fit between community providers and the use of evidence based practices.

181 **109.181** Exportable Communication Intervention for Classroom Staff Serving Children with Autism Spectrum Disorder: Towards Improving the Feasibility of Evidence-Based Practices in Community Settings

G. M. Tiede[1] *and K. M. Walton*[2]*, (1)The Ohio State University, Columbus, OH, (2)Psychology & Psychiatry, The Ohio State University, Columbus, OH*

Background:
Naturalistic Developmental Behavioral Intervention (NDBI) is an intervention model for young children with autism based on behavioral and developmental principles, naturally occurring contexts and contingencies, and shared control between the interventionist and student. Recent studies have found empirical support for NDBI in controlled research trials. Further, a number of studies have replicated findings in community preschool settings with some degree of success. However, reported roadblocks to community implementation include teacher's lack of time to add new components to their preschool day, insufficient staffing numbers to work in one-on-one settings with children, and difficulty understanding and applying the less structured techniques that characterize NDBI, (as opposed to more manualized behavioral practices). A further complication for community-based intervention studies is that implementation data for intervention in preschool classes is often under-reported and challenging to collect.
Objectives:
1. Develop an NDBI program that maximizes feasibility, acceptability and implementation fidelity for stakeholders.
To meet this objective, NDBI principles were mapped onto four existing classroom routines (e.g. snack, outdoor/gross motor time, story time and free play) resulting in the development of four curricula. This was done to improve the fit of NDBI principles to preschool contexts and promote implementation fidelity.Â Additionally, intervention activities and coaching sessions took place within an integrated classroom environment, and did not rely on "pull out time" for students in order to maximize feasibility and sustainability.
2. Promote positive changes in target children's social communication as measured by both quantity and quality of communication bids.
Â To meet this objective, consent for video-taped data was obtained from the majority of students in classrooms, allowing for outcome data to be analyzed in natural preschool contexts from video-recorded samples of whole class activities.
Methods:
This multiple-baseline design study piloted a social communication intervention using NDBI principles with four teacher/target child dyads in the Early Childhood Education Center at the Nisonger Center. After two to six weeks of baseline data collection, participating classroom staff members received eight weeks of intervention. Active intervention consisted of four didactic training sessions and seven live-coaching sessions. Implementation fidelity data and communication outcomes were video-recorded and coded by blinded research assistants.
Results:
Regarding outcomes, the present study examined 1) teacher fidelity to intervention practices in pre-identified classroom contexts 2) child outcomes in terms of communication targets and classroom engagement 3) stakeholder ratings of feasibility/acceptability and effectiveness.
Preliminary findings indicate that classroom staff are able to implement NDBI techniques at high levels of fidelity within classroom contexts (no "pull out" time required), report that the intervention is feasible, and that target children have increased communication bids as a result of intervention.
Conclusions:
Integration within whole class activities, as well as presenting strategies in a clearly delineated, exportable fashion while keeping intervention intensity minimal may have been key to high teacher fidelity, high ratings of feasibility, and in turn, increased communication on the part of target children. Future research and clinical intervention efforts should focus on considering the match between intervention strategies, their presentation, and integration into natural contexts.

182 **109.182** Home-Based Play Routines in Low-Resourced Families of Young Children with ASD: Parent Strategy Implementation

Y. C. Chang[1]*, W. I. Shih*[2] *and C. Kasari*[2]*, (1)California State University, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

Background:
In recent years, there has been much discussion about bridging the research-to-practice gap in autism research. Dingfelder and Mandell (2011) propose that one of the best ways to examine whether interventions are effective is to examine how the intervention is implemented in real-life context. This is particularly critical for families who have limited access to resources. Many autism interventions with parent training components have demonstrated effectiveness in increasing child outcomes but rarely are data reported on parent implementation in contexts outside the training sessions (Green et al., 2010; Landa, Holman, O'Neill, & Stuart, 2012).
Objectives:
The current study will examine 1) group differences in caregivers' generalized implementation of intervention strategies, and 2) change scores in strategy implementation within the caregiver mediated intervention group.
Methods:
Participants were 28 dyads of caregivers and young children with autism spectrum disorder (ASD), ages 2-5. The sample is a subset of a larger RCT that examined children's social communication skills in a naturalistic developmental behavioral intervention (NDBI) targeting joint engagement, play, and joint attention (Kasari et al., 2014). Caregivers were randomized to receive either 3 months of group caregiver education (CEM) or individualized caregiver-mediated intervention (CMM).
The *Mullen Scales of Early Learning* (MSEL; Mullen, 1989) was used to determine children's cognitive ability. The Mullen yields age-equivalent scores for visual reception, fine motor, receptive and expressive language skills.
Home Observation. The home observation is a 30-minute videotaped session that records everyday home routines, including play, that the child and his/ her caregiver spent time doing together without the presence of the interventionist. These home observations are videotaped by research assistant blind to treatment condition. Parent strategy implementation was coded during the 30-minute taping, specifically during play interactions. Strategies coded include: Basic strategies, Setting up the Environment, Following the Child's Lead, Play Routines, Expanding Routines, Joint Attention, and Language.
Results:
Linear mixed models were used to model the change in strategies from baseline to exit. Caregivers in the CMM group improved significantly more in all strategies except for play routines compared the CEM group from baseline to exit (Basic Strategies: $F(1,24)=11.23$, $p=0.003$, Setting up the Environment: $F(1,24)=21.50$, $p<0.001$, Following the Child's Lead: $F(1,24)=29.07$, $p<0.001$, Play Routines: $F(1,24)=3.42$, $p=0.077$, Expanding Routines: $F(1,24)=6.25$, $p=0.02$, Joint Attention: $F(1,24)=14.33$, $p<0.001$, LanguageÂ $F(1,24)=21.44$, $p<0.001$ and overall strategies: $F(1,24)=45.66$, $p<0.001$). On average, the CMM group increased 40.2% in their overall strategy implementation at exit (fidelity score: 70.2%) compared to the CEM group who stayed relatively the same from entry to exit (fidelity score at exit: 33.4%).
Conclusions:
This study demonstrates generalization from training sessions with parents to naturalistic demonstration of skills when videotaped by a blinded videographer in their home. The two strategies that caregivers improved the most suggests that by end of treatment, they were allowing their children to initiate more and were also becoming more aware and responsive to their children's communication. Future parent-mediated interventions should continue to focus on child outcomes, but also include parent fidelity implementation measures to assess the adoption, feasibility, and maintenance of these intervention strategies.

183 **109.183** Imitation in Improvisational Music Therapy Supports Engagement in Children Autism Spectrum Disorder

D. Casenhiser[1] *and J. A. Carpente*[2]*, (1)Audiology & Speech Pathology, University of Tennessee Health Science Center, Knoxville, TN, (2)Rebecca Center for Music Therapy at Molloy College, Rockville Centre, NY*

Background:
Imitation plays a crucial role in learning to communicate, and allows individuals to engage in reciprocal communication. Previous research by has suggested that exact imitation is more effective than contingent responding at improving social interaction in children with autism. In addition, many naturalistic treatments for autism include an imitation phase at the beginning of the treatment to foster engagement and joint attention. For some treatments, the imitation is exact while others have suggested that elaborative imitation can serve both to build rapport with the child as well as provide a means of social-interaction. This study is the first study to test the specific technique of imitation in improvised music therapy (IMT) and is the first to test the relative effectiveness of exact imitation versus elaborative imitation, and contingent responding.
Objectives:
This study tests the relative effectiveness of three treatment strategies used during IMT for children on the autism spectrum.
Â Methods:
7 preschoolers with autism participated in the study. A single-subject multiple treatment design tested the relative effectiveness of three IMT treatment techniques: 1) exact imitation (ExI) in which the therapist imitated the rhythm or melody of each child's turn, 2) imitation with elaboration (IE) in which the therapist first imitated the child directly and then added to or elaborated on the child's turn, and 3) contingent response/accompaniment (CRA) in which the therapist played music to match the tempo, intensity, or mood of the child's turn. Children participated in three 30-minute therapy sessions of each condition. The order of conditions was randomized for each participant. Sessions were videotaped and later coded for treatment fidelity of each of the therapist's turns. Relative effectiveness of the treatments was assessed by measuring child engagement behaviors using the 5 non-symbol infused engagement states from Adamson et al.'s (2000) engagement scale.
Â Results:
The results suggest that ExI (.22) and IE (.23) resulted in the highest median rates of positive engagement behaviors, and the lowest median rates (.06 and .09 respectively) of unengaged behaviors. CRA resulted in the lowest median rate of engaged behaviors (.14) and highest median rate of unengaged behaviors (.11).Â Scrutiny of individual participant's scores, however, suggests that certain treatment conditions are better at encouraging certain types of engagement. EI almost uniformly (6/7 participants) resulted in the worst coordinated joint attention while CRA resulted in the best coordinated joint attention in 5 out of 7 participants. Supported joint attention, on the other hand, was best in the EI.
Â Conclusions:
This the first study to compare the effectiveness of individual treatment strategies used in IMT. The results suggest that techniques that involve imitation (either exact or elaborated) may be best at encouraging positive engagement states in children on the autism spectrum during improvised music therapy. We note that as a single-subject study, this is only a first foray into the topic and further work needs to be done with a more rigorous experimental design.

184 **109.184** Impact of Early Childhood Intervention Programme (Developmental Journal VI) on Behaviour Difficulties in 3 Year Old Children with Severe Visual Impairment 'at High Risk' for ASD

N. Dale[1]*, E. Sakkalou*[2]*, M. O'Reilly*[3] *and A. Salt*[4]*, (1)Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom, (2)Clinical Neurosciences, UCL Great Ormond Street Institute of Child Health, London, United Kingdom, (3)UCL Institute of Child Health, London, UNITED KINGDOM, (4)Great Ormond Street Hospital for Children, London, UNITED KINGDOM*

Background:
Congenital visual impairment (VI) is associated with social communication difficulties and a high risk of later diagnosis of autism (11-40%)(Brown et al, 1997; Mukkades *et al.,* 2007). A first national UK prospective longitudinal cohort study of infants with congenital disorders of the peripheral visual system (CDPVS) and profound-severe VI has been investigating the antecedents, pathogenesis of and impact of early intervention on developmental and social communication outcomes at 3 years in this vulnerable clinical population (Dale et al) The Developmental Journal for Young children with VI (DJ) (Dale and Salt 2008),designed specifically for children with VI, is a parent-delivered early intervention supported by practitioners, with specific guidance to facilitate parent child interactions and strategies in the context of individualised developmental goals including social. The materials are derived from extended clinical and research work of the Developmental Vision team (Great Ormond Street Hospital).
Objectives:
This part of the study investigates the impact of early community based intervention (DJ) vs other community support (CS) on early behaviour difficulties and 'pervasive developmental difficulties' (CBCL) which have been shown to be early risk signs for ASD in children with VI (Absoud et al 2011).
Methods:
This analysis included the subgroup of children with 'potentially simple' CDPVS and severe VI (N=22). Children with 'complex' disorders and profound VI were not included (N=14). Practitioners particularly specialist teachers for VI reported through visitation logs on the type of intervention they used with the child over a 12 month period (DJ:N = 9; CS:N = 13). At 3 years of age (M=38.73 months; SD=2.88), children's nonverbal cognition (Sensorimotor Understanding-SMU) was assessed using the Reynell-Zinkin Scales for Children with VI and parents completed the Child Behavior Checklist (CBCL).
Results:
Non-parametric Mann-Whitney U analyses with intervention type (DJ vs CS) as a grouping variable and the T-scores from 3 subscales of the CBCL as outcome variables (Withdrawn, Pervasive Developmental Problems (PDP), Internalizing composite) revealed differences between the two groups. Children receiving the DJ intervention were reported to have lower Withdrawn problems (M=51.89 SD=3.21) compared to children receiving the CS intervention (M=58.31 SD=7.66; p<.05), with an effect size of 0.52. Similarly, there were trends in the same direction for PDP, (DJ: M=53.56 SD=5.22; CS: M=58.54 SD=8.32;p=.07) and Internalizing composite, (DJ: M=43.56 SD=10.06; CS: M=51.85 SD=9.55; p=.08). The children's cognitive level (SMU) was not significantly different across the two types of intervention (DJ: M=119.45 SD=7.73; CS: M=112.74 SD=34.15; p=.79).
Conclusions:
For the first time early childhood intervention with a VI-specific parent mediated developmental programme between 1 to 2 years has shown positive impact in reducing behaviour difficulties in 3 year olds with congenital severe VI. Community delivery of the Developmental Journal appears to provide supports to parents which help mitigate the tendency of children with VI to withdraw and become more socially disengaged in the early years. The evidence will be considered further in the context of other parent-practitioner factors such as quality of relationship and frequency of home visiting and other child associations.

185 **109.185** Intervention in the Community for Toddlers with ASD: Paraprofessionals' Ratings of Implementation Complexity and the Association with Observed Intervention Implementation

M. Pizzano[1]*, S. Y. Shire*[2]*, M. Kodjoe*[3]*, S. Bracaglia*[3] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)New York Center for Child Development, New York, NY*

Background: Treatment fidelity is a concern across intervention studies for children with autism both in clinic and when transferring practices into the community (Dingfelder and Mandell, 2011). To enhance researchers' ability to support community implementation, it is necessary to better understand factors that may influence intervention fidelity. The present examination looks at paraprofessionals teaching assistants (TAs) observed implementation scores and their self-report of perceived complexity to deliver the intervention including effort, experience, as well as comfort and confidence in implementing the intervention.
Objectives: To determine whether there is an association between TAs' intervention implementation fidelity and their self-reports of the perceived complexity of the intervention.
Methods: The analysis includes 43 children who were randomized to receive the JASPER intervention (Kasari et al, 2006; 2008) as part of a larger intervention trial. Eighteen TAs delivered the JASPER intervention. On average TAs were 30.25 years old and worked at the center for 2.27 years. All but one of the TAs were ethnic minorities. Ten-minute TA-child play interactions were videotaped at treatment exit and coded for strategy use (implementation). Implementation codes include subscale scores (i.e., basic strategies, setting up the environment, following the child's lead, play routines, joint attention/requesting skills, and language). TA Diaries (adapted from Kasari et al., 2003) were completed at study entry. TAs rated 6 questions using a 1-5 scale (1=strongly disagree, 5=strongly agree) to represent their experience in implementation (e.g., strategies feel new/complicated, goes beyond their comfort zone, requires extra work/time). These items were summed to report total perceived complexity, the degree to which TAs felt the intervention was challenging to implement.
Results: Average total diary scores were 17.07 (SD=4.31) out of a total possible score of 30. A Pearson bivariate correlation coefficient was computed to determine the association between implementation and complexity rating scores. There was a positive correlation between the fidelity subscale of following the child's lead and total perceived complexity rating (r= 0.333, n= 43, p=0.029). There were also a positive correlation between the fidelity subscale of setting up the environment and total difficulty score (r=0.354, n=43, p=0.020). TAs' average implementation of setting up the environment in the sample was 90.02% (SD=10.78%), and average implementation of following the child's lead was 85.72% (SD=11.31%).
Conclusions: TAs' initial perception of implementation complexity may be linked to higher quality intervention implementation in the particular areas of setting up the environment and following the child's lead. In this intervention, these strategies are foundational, providing a framework to layer on more strategies and learning opportunities. Awareness of the time and work required to implement unfamiliar environment and following strategies is correlated with implementing these strategies more effectively. It is possible that focusing more on the complexities and newness of an intervention translates to better foundational practices because these strategies are the first thing that the TAs do in implementation before incorporating higher level strategies.

186 **109.186** Meta-Analysis on Technology-Based Versus Non-Technology Based Social Communication Interventions for Children with ASD

***E. Kwok**, J. Holt-Ulacia and J. Oram Cardy, Western University, London, ON, Canada*

Background:
Educators and clinicians now have access to a growing number of technologies that they can incorporate into their interventions with children with ASD. Captivating sound and visual effects, as well as consistency in target demonstrations are amongst the reasons that support the use of technology in intervention (Moore & Calvert, 2000; Bernard-Opitz, Sriram, Nakhoda-Sapuan, 2001). Meta-analysis studies that explored the benefits of technology-based social-communication interventions yielded mixed findings. One meta-analysis (Grynszpan, Weiss, Perez-Diaz, & Gal, 2014) demonstrated a positive effect with the use of technology in therapy, whereas another meta-analysis (Wang & Parrila, 2011) found no evidence to support the use of technology. Existing meta-analyses either concentrated on studies that compared children receiving technology-based therapy to a waitlist/typically developing group, or on single-subject intervention studies where a comparison group was lacking. A meta-analysis conducted on studies that included children with ASD in both a technology-based intervention group and a non-technology intervention control group would improve clinical decision-making regarding therapy delivery method.
Objectives:
To compare the effectiveness of technology-based versus non-technology based social communication interventions for children with ASD using a meta-analysis approach.
Methods:
A systematic literature search was performed using keywords including "autism," "ASD," "technology," "computer," "robot," "video," and "virtual." A total of 5386 studies were identified. 24 studies met the inclusion criteria: a) included at least one participant with diagnosis of ASD; b) employed randomized control trial or alternating treatment designs; c) contain at least one dependent measure of social communication (verbalizations, affect, imitation, joint attention, turn-taking, requesting, pointing, or social interaction). 12 studies did not report Ms or SDs and thus were excluded from further analysis. A total of 12 studies containing 89 participants with ASD were included in the analysis. Across all studies, we extracted 37 dependent measures that were related to social communication. For each dependent measure, we calculated the standardised mean difference (SMD) between the technology-based intervention and non-technology based intervention groups. Then, a Z-test determined whether the SMDs across studies were reliably different from zero.
Results:
Overall, interventions conducted through technology did not result in better social communication outcomes compared to those conducted without technology (Cohen's d = 0.14; standard error =0.68, p=0.17).
Conclusions:
Based on studies with the most stringent methodological designs, our meta-analysis found that children with ASD did not benefit more from technology-based intervention compared to non-technology based intervention. Studies (e.g. Bernard-Opitz et al., 2001) have suggested that technology-based interventions can result in more long-term improvements of skills in children with ASD. Future studies on this topic should consider both immediate intervention outcomes and the generalizability and sustainability of newly learnt skills.

187 **109.187** Occupational Performance Coaching Via Telehealth: A 12-Week Intervention for Families of Children with Autism Spectrum Disorders

***A. Wallisch**, L. Little, E. Pope and W. Dunn, University of Kansas Medical Center, Kansas City, KS*

Background: Underserved families of children with ASD often have difficulty accessing services, which may negatively impact family and child health. Telehealth has been shown as a promising way to deliver services to an increased number of underserved families (Vismara, Young & Rogers, 2012). When professionals partner with parents to identify solutions together (called occupational performance coaching [OPC]), parents are increasingly efficacious in supporting their child (Graham et al., 2013).
Objectives: The aims of this study included: (1) Determine the feasibility (i.e., acceptability, satisfaction, cost-effectiveness of OPC for families of children with ASD delivered via telehealth; (2) Examine the extent to which OPC via telehealth impacted parent competence and child participation.
Methods: This study used a within group, pre-post quasi-experimental design. We enrolled n=17 families of children with (mean age=43.46 mos; SD=13.91 mos; range=26-63 mos). Parents completed the Telehealth Acceptability Questionnaire, a 14 item six-point scale (1=highly agree to 6=highly disagree) evaluating satisfaction with the use of telehealth as well as the intervention content/process. Parent report measures gathered pre- and post-12 weeks (i.e., parent competence, child participation). To address the cost-effectiveness of the intervention, we calculated the number of driving miles, travel time, lost family wages, and transportation costs at $0.54/mile. We used descriptives to examine telehealth acceptability and satisfaction. We used paired sample t-tests to analyze effects on parent efficacy and child participation
Results: To date, cost-effectiveness analyses show that the use of telehealth equated to $97,297.50 in savings when compared to traditional service delivery models. In addition, parents may lose approximately 11.3% of their income to receive services. The use of a telehealth method of intervention delivery was highly acceptable to parents (mean=1.18; SD=.39; range1-2.29). Parent also highly rated the intervention content/process (mean=1.18; SD=.21; range=1-2.14). Findings suggest that parent efficacy scores significantly increased (p<.05). In addition, children's frequency of activation participation significantly increased (p<0.01), and the diversity of children's activities significantly increased (p<0.01)
Conclusions: Telehealth is a promising method of delivery of OPC for families of young children with ASD, particularly for rural families and underserved families with limited access to services. A 12-week OPC intervention for families of children with ASD delivered via telehealth significantly increased parent efficacy and child participation. Results suggest that parents are highly satisfied with the content and process of this family-focused intervention, as well as the use of telehealth. When parents have the support of an occupational therapist to identify strategies that increase child participation in everyday activities, they likely feel increasingly efficacious in their parenting role.

188 **109.188** Outcomes for ASD Children with Feeding Problems in a Community Mental Health Setting

D. N. Top[1], *N. C. Russell*[1], *H. Rimmasch*[2] *and M. South*[3], *(1)Brigham Young University, Provo, UT, (2)Wasatch Mental Health, Provo, UT, (3)Psychology and Neuroscience, Brigham Young University, Provo, UT*

Background: Although not a core feature of Autism Spectrum Disorder (ASD), children with ASD often have restricted food intake problems and disruptive mealtime behaviors. Escape extinction, a common evidence-based practice for restrictive food intake disorder for children with ASD, is controversial and considered unethical for many clinicians because of the aversive nature of the technique. Because of this, researchers and clinicians are striving to create and evaluate new feeding treatments for this population. An alternative feeding intervention with limited support in the ASD population is known as the Sequential Oral Sensory (SOS) feeding program. In an effort to improve the feeding behaviors of preschool children with ASD, a community mental health preschool program implemented a variation of the SOS intervention to determine its effectiveness. The feeding intervention is an intensive 8-month program, consisting of 30-minute sessions, 4 days per week, in a school cafeteria setting.
Objectives: We report findings from a longitudinal archival dataset collected during the implementation of a feeding intervention as part of a community mental health preschool program children with ASD. We examined the relationship between feeding behaviors and other client characteristics including age, sex, autism symptom severity, and cognitive ability. Discrepancies between clinician and caregiver reports of symptoms were also analyzed.
Methods: Sixty children ages 35 to 59 months diagnosed with ASD received a feeding intervention from a community mental health preschool program for eight months. The archival dataset included monthly administrations of the Brief Autism Mealtime Behavior Inventory (BAMBI) from both caregivers and clinicians. Severity of autism symptoms (Clinical Autism Rating Scale) and general cognitive ability (Psycho-Educational Profile) were also collected at intake and post-treatment. We used Hierarchical Linear Modeling (HLM) techniques to model the changes in BAMBI scores across the 8 months of treatment to assess effectiveness of the feeding intervention. We also used HLM to examine autism severity, age, cognitive ability, and gender of the client as potential predictors of treatment outcomes. Differences between caregiver and clinician reports of feeding behaviors at intake and post-treatment were examined using t-tests.
Results: Caregiver reported BAMBI score indicated that at post-treatment, 3 of the 53 children with significant feeding problems at intake no longer had significant problems post-treatment. This finding was not corroborated on the clinician report. HLM analyses show that reported problematic feeding behaviors over the course of treatment decreased significantly on caregiver report, but not on clinician report. Food selectivity significantly decreased on both caregiver and clinician reports. Cognitive ability at intake significantly predicted decreased food selectivity on the clinician report. Age, autism severity, and gender did not significantly predict treatment outcomes. Clinicians rated the feeding problems as more severe at intake than the caregivers. There were no significant differences between reporters at post-treatment.
Conclusions: The intensive feeding program implemented at a community mental health preschool program for children with ASD showed minimal effectiveness. This study highlights the difficulty of effective implementation of feeding interventions in community mental health settings. Implications, limitations, and future directions for research will be discussed.

189 **109.189** Outcomes of a Low-Intensity Early Behavioral Intervention Among Japanese Preschoolers with Autism Spectrum Disorders: A 1-Year Follow-up

H. Haraguchi[1], *M. Inoue*[2], *F. Noro*[3], *A. Stickley*[4], *A. Miyake*[5] *and Y. Kamio*[6], *(1)National Institute of Mental Health, National Center of Neurology and Psychiatry, Japan, Tokyo, Japan, (2)Tottori University, Yonago, Tottori, JAPAN, (3)University of Tsukuba, Tsukuba, Japan, (4)Stockholm Center for Health and Social Change (Scohost), Södertörn University, Huddinge 141 89, Sweden, (5)National Institute of Mental Health, National Center of Neurology and Psychiatry, Japan, Yokohama City, JAPAN, (6)Department of Child and Adolescent Mental Health, National Institute of Mental Health, National Center of Neurology and Psychiatry, 4-1-1 Ogawahigashicho, Kodaira, Tokyo, Japan*

Background:
Studies suggest early intensive behavioral intervention (EIBI) can improve cognitive abilities, language, and adaptive behavior of young children with autism spectrum disorders (ASD). However, EIBI is unaffordable in many countries. Although it is essential to implement evidence-based early interventions for children with ASD with varied needs in community settings, evidence whether low-intensity early behavioral interventions (LBI) for ASD children contribute to improved outcomes compared to eclectic treatment-as-usual (TAU) in community settings is not well established.
Objectives:
This study aimed to examine whether LBI implemented in community settings helped to improve DQ and adaptive behavior of children with ASD compared to TAU.
Methods:
Sixty one preschool children diagnosed with ASD were recruited from several universities, private agencies, and regional public centers. After the exclusion of 8 children with a high DQ (DQ >84), the study sample consisted of 53 children: 27 participants (24 male) (mean age: 4.0 years; SD: 1.3; range: 2.1-6.7) receiving LBI (a mean of 3.8 hours per week; SD: 2.5; range: 0.8-8.0) and 26 participants (21 male) (mean age: 3.5 years; SD: 1.0; range: 2.3-5.9) receiving TAU (a mean of 18.2 hours per week; SD: 9.7; range: 0.5-25.3). Standardized tests were administered at baseline (T1) to assess mental age (DQ), adaptive behavior (VABS), ASD symptom severity (PARS), mental health problems, maternal parenting stress and depression, and again, 1 year later (T2). Intervention type, intensity and duration were also monitored after 6 months. There were no differences between groups for age, parental age or education at T1. A paired t-test was used to compare DQ and VABS scores for each group between T1 and T2. DQ at T1 in the TAU group was significantly higher than in the LBI group ($t = -2.284$ $p < .05$). Analysis of covariance was used to compare between-group changes in DQ and VABS scores.
Results:
Within the LBI group there was an increase in DQ ($t = -2.150$; $p < .05$), Language-Social DQ ($t = -3.221$; $p < .01$), and VABS Communication ($t = -2.267$; $p < .05$) score, and decreases in VABS Daily Living ($t = 2.758$; $p < .05$) and VABS Socialization scores ($t = 3.024$; $p < .01$) between T1 and T2. For the TAU group only Language-Social DQ ($t = -4.161$; $p < .01$) and VABS Communication ($t = -2.665$; $p < .05$) score increased. A between groups comparison revealed a greater increase in DQ in the LBI group than in the TAU group ($F = 4.129$; $p < .05$). There were no significant differences in the size of the score change between the groups for Cognitive-Adaptive DQ, Language-Social DQ, or the VABS scores.
Conclusions:
In this prospective observational study, preschool children with ASD receiving LBI, which included varied programs and a lower intensity intervention compared to in previous studies, had a greater improvement in DQ across a 1-year period compared to children receiving TAU, even though the mean intensity of the LBI intervention was less than the TAU intervention. RCTs involving larger samples are now needed to determine the evidence-based efficacy of LBI in community settings.

190 **109.190** Parent Training Via Telehealth for Children with Autism Spectrum Disorder and Disruptive Behavior: A Demonstration Pilot

K. Bearss[1]*, T. L. Burrell*[2]*, V. Postorino*[2]*, S. Gillespie*[3] *and L. Scahill*[2]*, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Atlanta, GA*

Background: As the number of cases of ASD has increased, so have the challenges of serving these children and their families. Telehealth is a potential solution to the problem of limited access to specialized services for children with ASD and families in rural areas. The Research Units in Behavioral Interventions (RUBI) PT program showed that a 24-week, structured parent training (PT) program was effective for reducing disruptive behavior in children with ASD when delivered 1:1 in a clinical setting. A promising expansion involves telehealth delivery of RUBI-PT, as this modality could increase access to care in rural and underserved communities.
Objectives: This open-label pilot study evaluated the feasibility and initial efficacy of the RUBI-PT program when delivered via telehealth to families of children with ASD and disruptive behaviors in rural areas. We define feasibility as evidence that the treatment is acceptable to families and therapists, that the outcome measures can be collected as scheduled, and that the treatment can be delivered reliably by trained therapists via telehealth. Efficacy was evaluated through change on the parent-rated Aberrant Behavior Checklist-Irritability subscale (ABC-I) and independent evaluator ratings of overall improvement on the Clinical Global Impression-Improvement (CGI-I) scale.
Methods: Parents of children ages 3-8 with a community diagnosis of ASD and disruptive behavior living in rural Georgia were enrolled in the 24-week study. The RUBI PT curriculum is based on principles of applied behavior analysis and provides parents with specific techniques to manage child behavioral problems and promote adaptive skills. Eleven core sessions and up to two supplemental sessions (e.g. toileting, feeding, sleep issues) were delivered over 16 weeks. Follow up telephone boosters were conducted at Weeks 18, 20, and 22 to promote skill generalization and maintenance. Assessments occurred at Baseline, Weeks 8 and 16 and 24.
Results: Fourteen children with a community diagnosis of ASD were screened and all met eligibility criteria. Families were recruited from 4 telehealth sites (2 schools, 1 primary care center, 1 regional medical center). Mean age was 5.8 ± 1.7 years; 64% were males; mean IQ = 69.4 ± 17.6. Thirteen of 14 families (92.9%) completed the 24-week treatment. Feasibility outcomes showed 98% therapist fidelity to treatment, high parental engagement in treatment (91.6% of core sessions attended) and 94.6% attainment of in-session goals. Despite the distance from the center, we were able to collect 95% of outcome data from parents and caregivers across the 24-week trial. Parents reported greater confidence in managing problem behaviors and both therapists and parents reported high levels of comfort with the telehealth technology. Regarding efficacy of the telehealth treatment, parents reported a 46.4% decrease in disruptive behaviors on the ABC-I at Week 24. Eleven of 14 (78.5%) participants were rated as much/very much improved on the CGI-I by an independent evaluator.
Conclusions: The delivery of PT via telehealth appears to be acceptable to parents and therapists. Preliminary efficacy findings are promising and suggest that delivery of the RUBI PT program via telehealth may produce notable reductions in parent-reported child disruptive and noncompliant behaviors.

191 **109.191** Parent-Based Intervention Therapy for Autism Spectrum Disorder

A. Deshpande[1]*, N. Ramamoorthy*[1]*, M. Bhargavi*[1]*, A. Jayaraman*[2] *and N. N. Mundkur*[3]*, (1)Sangamitra, Bangalore, India, (2)Center for Child Development and Disabilities, Bangalore, India, (3)Centre for Child Development and Disabilities, bengaluru, INDIA*

Background: Â In India, >10 million children are affected by autism spectrum disorder (ASD). With improvements in diagnosis, the number of cases is expected to greatly increase; however, there continues to be a deficit of professionals in the field of autism intervention. Several studies have shown that a structured intervention for children with ASD at an early stage significantly improves IQ levels, adaptive behavior, and diagnosis of autism compared to children receiving community-based intervention. In this regard, parent-implemented intervention has shown better outcomes for both children and parents compared to other forms of intervention for ASD, and has extended the benefits of intervention to the home environment.
Objectives: Â This study aimed to provide timely intervention in children with ASD by training parents to be interventionists themselves.
Methods: Â Twenty-three children with ASD (3–7 years) were first diagnosed using standardized tools, and then, evaluated using the Early Start Denver Model Curriculum Checklist (ESDM) in the areas of communication (receptive and expressive), social skills, and play skills pre-intervention, and the modified Indian version of the MacArther Communicative Development Inventory. A comprehensive intervention plan was then designed to begin from the child's basal level of functioning, based on the above assessments. This included enhancing the child's social, communication, and self-help skills through play therapy, language sessions, phonetics and early literacy program, toilet-training program, self-help development program, and sensory program; 3 h/day at the center and at least 2 h/day at home for 5 days, leading to a 25-h structured intervention program weekly. We also focused on sensitizing and empowering parents through weekly presentations and home program to facilitate intervention during child's daily activities. Plans were reviewed monthly by staff and parents. Evaluation using ESDM checklist was performed after each of the four post-intervention sessions at 6-month intervals.
Results: Â Based on our pilot results, most children showed significant improvements in communicative abilities, play, and social skills at the end of 1–4 intervention sessions (1st session: n = 17; 2nd to 4th session: n = 6) as per the ESDM check-list. By the end of the first intervention session, 12/17, 9/17, and 10/17 children showed improvements in communication, social skills, and play, respectively. Among the 6 kids who have completed all 4 intervention sessions so far, all showed significant improvements in communication, social skills, and play as compared to pre-intervention ($p < 0.05$).
Conclusions: Â Based on our results, we can conclude that our parent-based intervention therapy has successfully enhanced the developmental outcomes for children with ASD. It has made parents more tuned-in to their child's needs and show child-oriented responses, sensitive to the challenges their child faces, have appropriate expectations from the child, and be more optimistic. Our results support previous research that suggests that close cooperation between parents and professionals as well as parental involvement is key to the success of autism intervention programs. We believe that involving parents/primary caregivers will compensate for the deficit of professionals in the field of autism intervention and help in effective and timely intervention in children with ASD.

192 **109.192** Parent-Child Group Intervention for Young Children with ASD

C. Colombi[1] *and A. M. Fish*[2]*, (1)University of Michigan, Ann Arbor, MI, (2)Psychiatry, University of Michigan, Ann Arbor, MI*

Background: ASD affects approximately 1 in 68 children in the U.S., according to the Center for Diseases Control (Baxter et al., 2014). More children than ever are being diagnosed or identified as at-risk for ASD in the first years of life. Despite strong evidence for the positive impact of early intervention that begins immediately following diagnosis (Koegel et al., 2014), and despite evidence that intervention delivered in the first three years of life has higher impact on outcomes in comparison to later start (Vivanti et al., 2016), access to high quality treatment is quite limited, and this is particularly true for very young children. While we can identify early signs of ASD as early as 12 months of age, on average children with ASD in the U.S. start intervention after 3 years of age (CDC, 2016). Therefore, the majority of children miss an important developmental window shown to significantly improve children's outcomes. Barriers preventing very early access to intervention include a continuous increase in the number of children diagnosed, as well as scarcity of specialized providers. One way of increasing access to intervention is to teach intervention strategies to parents immediately after diagnosis.
Objectives: The aim of this project was to adapt an existing evidence based intervention, the Early Start Denver Model (ESDM) (Rogers and Dawson, 2010), to a parent-child group delivery in order to increase access to treatment in the period immediately following diagnosis, and thereby improve child outcomes.
Methods: The Parent-Child group ESDM was delivered to 5 young children with ASD, between 24 and 48 months of age, and their caregivers. Each family participating in the study received one 1-hour session per week of the treatment, delivered in a group of 5 child -caregiver dyads, for 12 weeks. During the first portion of each session the therapist covered an ESDM teaching strategy with the caregivers, while the children played under the supervision of student research assistants. During the last portion of the session, the caregivers joined their children and practiced the ESDM teaching strategies with the coaching of the therapist.
Results: Preliminary data indicated gains in social-communication behaviors in children. Acceptability of the program was very good as indicated by retention of all participants. Moreover, results from a five-point Likert-based scale survey indicated that the caregivers agreed or strongly agreed that the program was useful and satisfying.
Conclusions: Our preliminary results suggest that the ESDM delivered in group may be useful to teach intervention skills to parents and to increase social communication in young children with ASD.

193 **109.193** Parental Perspectives on Parent-Mediated Intervention for Toddlers Suspected of Autism Spectrum Disorder to Support Parent during the Waiting Period Surrounding the Diagnostic Evaluation

A. J. Beaudoin[1]*, M. Couture*[2] *and G. Sébire*[3]*, (1)Université de Sherbrooke, Québec, QC, CANADA, (2)Rehabilitation, Universite de Sherbrooke, Sherbrooke, QC, CANADA, (3)Pediatrics, McGill University, Montréal, QC, Canada*

Background: Â Knowing that interventions for children suspected of autism spectrum disorder (ASD), are most effective when offered as early as possible, interventions that are tailored to very young children presenting early difficulties in social interaction or communication is needed. Parents-mediated interventions may be a useful way to support developmental and functional outcomes in vulnerable young children and to bring benefits to the whole family by improving the parents' sense of competence and empowerment.
Objectives: The study aims to assess the effects of a 12-week parent-mediated intervention adapted from the Early Start Denver Model (ESDM) and the Social Communication Emotional Regulation Transactional Support (SCERTS) model for families with low-socioeconomic status (SES) having a toddler suspected of ASD on 1) parents' use of strategies, 2) parent-child interactions, and 3) parental well-being.
Methods: The proposed intervention offers 12 individual coaching sessions to parents of children suspected of ASD at their home on how to interact with their young children and thus stimulate their development through daily interactions. An experimental study was conducted with 19 families with low SES having a child with a suspicion of ASD aged between 15 and 30 months and at least one of their parents, randomly assigned to the group receiving the intervention right away (group 1) or having to wait 3 months before having access to the intervention (group 2).
Parental perspectives were collected three to four times; before waitlist (T0, only for group 2), pre-intervention (T1), post-intervention (T2), and three-month follow-up (T3) and analyzed using Mann-Whitney and Wilcoxon signed-rank tests. Parents' use of strategies and parent-child interactions were rated using respectively the ESDM Fidelity Checklist and Adamson's engagement rating scale via videotapes of a 10-minute free play period between the child and his parent at each assessment time. Parental well-being was assessed through two questionnaires completed by parents themselves, the Parental Stress Index – Short Form (PSI-SF) and the Parent Sense of Competence (PSOC).
Results: 18 of the 19 parent-child dyads participated in the 12 weekly parents coaching sessions. Data analysis shows significant improvement in parents' use of strategy and parent-child interactions during the intervention phase (T1 – T2), but no significant change before (T0 – T1) or after intervention (T2 – T3). Regarding parental well-being, no significant changes were noted in parental well-being at any time points.
Conclusions: This study shows promising results on proximal outcomes (parents' use of strategies and parent-child interactions). Knowing so, parent-mediated interventions may be an interesting alternative to increasing timely access to interventions, especially before children has any diagnosis, and thus very few services. In fact, this study shows that it helps parents to use strategies to promote their child's development and to interact adequately with their child during free play periods. However, parental support should be targeted more specifically to improve parental well-being. Also, more distal outcomes, such as child development and parental satisfaction toward the program should be assessed.

194 **109.194** Pilot Study of a Comprehensive Psychosocial Summer Treatment for Young Children with HFASD

C. A. McDonald[1], *M. L. Thomeer*[2], *C. Lopata*[2], *J. P. Donnelly*[2], *J. D. Rodgers*[2] *and A. K. Jordan*[3], *(1)Institute for Autism Research, Canisius College, Buffalo, NY, (2)Canisius College, Institute for Autism Research, Buffalo, NY, (3)Counseling, School, and Educational Psychology, University at Buffalo, SUNY, Buffalo, NY*

Background: The number of children diagnosed with autism spectrum disorder (ASD) has been increasing at an alarming rate, highlighting the need for effective treatments (Odom et al. 2014). The concentration of the increase among young high-functioning children with ASD (HFASD) poses a significant challenge, as specialized treatments for these young children are non-existent. While a growing body of evidence suggests that cognitive-behavioral treatments for youth with HFASD may yield positive outcomes (e.g. Laugeson et al. 2012; Frankel et al. 2010), their use with young children with HFASD has not been evaluated.
Objectives: This study examined the feasibility and initial outcomes of a comprehensive summer psychosocial treatment (summerMAX^{yc}) for 23 young children, aged 4-6 years with HFASD.
Methods: *Participants:* The sample included 23 children, aged 4-6 years with HFASD. Each child had a prior clinical diagnosis of ASD, an SB-5 abbreviated IQ >70 (at least 1 subtest >80), and a PLS-5 expressive or receptive language score >80. All diagnoses were confirmed using the ADI-R. *Measures:* Social Responsiveness Scale - Second edition (SRS-2), Adapted Skillstreaming Checklist for Young Children (ASC^{yc}). *Procedures:* The 5-week cognitive-behavioral treatment (5 days/week, 6 hours/day) included instruction and therapeutic activities targeting social/social-communication skills, facial-emotion recognition, and interest expansion. A behavioral system was also implemented to reduce ASD symptoms and problem behaviors and/or increase skills acquisition and maintenance. Rating scales were completed pre- and post-treatment by parents and staff clinicians.
Results: Feasibility was supported in high levels of treatment fidelity (all components >93%) and parent- and staff-reported satisfaction. Satisfaction ratings averaged 67.3 out of a maximum of 70 points (average item *M*=6.7 of a maximum 7) for parents and 45 out of a maximum of 49 points (average item *M*=6.4 of a maximum 7) for staff-clinicians. Average child satisfaction total was 14.5 of a possible 15 points (average item *M*=2.9 of a maximum 3). According to parent and staff-clinician ratings, children displayed significant reductions in ASD symptoms and gains in their use of targeted social skills. Pre-post comparisons indicated a significant decrease in parent (SRS-2 $p<.001$, $d=1.70$) and staff-clinician (SRS-2 $p<.001$, $d=1.29$) rated ASD symptoms, and increase in parent (ASC^{yc} $p<.001$, $d=1.68$) and staff-clinician (ASC^{yc} $p<.001$, $d=2.30$) rated social/social-communication skills.
Conclusions: Overall, results suggested that the comprehensive young child protocol (summerMAX^{yc}) can be conducted with a high degree of accuracy (fidelity), parents, children, and staff-clinicians find it quite acceptable, and participation is associated with significant symptom and skills improvements. These findings were considered especially promising as the effect sizes on the two parent and staff-clinician rating measures were large (*d*s 1.29 and 2.30). Results also suggested that cognitive-behavioral techniques/treatments may be appropriate for young children with HFASD. Despite these initial positive indications, the results must be considered suggestive and the summerMAX^{yc} protocol requires examination in an RCT.

195 **109.195** Real-World Conversational Turn-Taking: An Exploratory Study of Preschoolers with ASD, Teachers, and Peers

T. Liu[1], *S. Regan*[2], *E. Ferguson*[3], *L. Bateman*[3], *A. S. Nahmias*[4], *D. S. Mandell*[2], *R. T. Schultz*[5] *and* ***J. Parish-Morris***[6], *(1)Rice University, Houston, TX, (2)University of Pennsylvania, Philadelphia, PA, (3)The Center for Autism Research/CHOP, Philadelphia, PA, (4)University of California Los Angeles, Los Angeles, CA, (5)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background:
Early intervention (EI) has the potential to dramatically improve long-term outcomes in children with ASD (Howlin, Magiati, & Charman, 2009). Little is known about the influence of child-level characteristics on treatment gains in different EI settings, which could have important implications for how we match children to the most effective setting. Language may be an important moderator of individual gains. For example, a study of preschoolers with ASD revealed that children with higher standardized language scores at the beginning of the school year demonstrated steeper rates of cognitive growth in inclusion classrooms than in mixed disability or inclusion classrooms (Nahmias et al., 2014). In this study, we explore a hallmark of social communication: conversational turn-taking (Dykstra et al., 2013; Warren et al., 2010). Conversational turn-taking is a dynamic, ecologically valid measure of social communication that may vary across different EI settings. Defining child and classroom factors that facilitate conversational turn-taking could guide placement decisions, particularly if more turn-taking results in greater long term social and cognitive growth.
Objectives:
To assess conversational turn-taking in preschoolers with ASD, their teachers, and their peers during free play in three EI classroom settings (autism-only, mixed disability, inclusion), and compare profiles of children who engaged in peer conversations with children who did not.
Methods:
Twenty-four preschoolers with ASD (16 boys, M=4.1 years, 88% scored "very low" on the Mullen ELC) wore t-shirts with digital language recorders (LENA) in a child-safe chest pocket during a typical school day. All verbalizations produced by or directed at the target child during an unstructured "free play" sample were orthographically transcribed (M=19.0 minutes). We defined conversational turns as pauses of greater than 0 seconds and less than 4 seconds between utterances by different speakers (target child, peer, teacher). Dependent variables included turn-taking rates relative to total recording duration and inter-turn latency.
Results:
All 24 participants engaged in conversational turn-taking with teachers, but only 38% conversed with their peers. Children who engaged in peer conversational turn-taking (PC) were more likely than those who did not (N-PC) to be in inclusion classrooms (Chi-square = 7.22, $p<.05$), and in classrooms with more students ($p<.05$). PC and N-PC had statistically equivalent SCQ and ADOS severity scores, but PC had higher Mullen expressive and receptive language scores than N-PC ($ps<.05$). Rates of teacher-participant conversational turn-taking did not differ by setting, and teachers responded equally quickly to children in both groups.
Conclusions:
This exploratory study is part of a larger, longitudinal effort to examine mediators and moderators of intervention response in preschoolers with ASD, and is one of the first to analyze fine-grained measures of conversational turn-taking in different EI settings. Our finding that more peer conversations occur in inclusion classrooms suggests enriched opportunities for peer interaction in that setting compared with autism-only and mixed disability classrooms, but children in inclusion classrooms also had higher baseline standardized language scores. Future analyses with additional participants will assess the differential effects of child/classroom language variables (including conversational turn-taking) on cognitive and social growth over 9 months.

196 **109.196** Reduced Anxiety Following Pivotal Response Treatment in Young Children with Autism Spectrum Disorder

***J. Lei**, D. G. Sukhodolsky, S. M. Abdullahi, M. L. Braconnier, C. Kautz and P. E. Ventola, Yale Child Study Center, New Haven, CT*

Background: Up to 40% of children with ASD exhibit co-occurring symptoms of anxiety, further impairing social functioning. Despite recent successes in mitigating anxiety symptoms in school-aged children with ASD using adapted versions of Cognitive Behavioural Therapy, little is known about treatments for younger children. Pivotal Response Treatment (PRT) is a behavioural intervention that primarily aims to increase social communication skills in children with ASD by reinforcing social interactions in a naturalistic and contingent manner. To date, no studies have explicitly examined the therapeutic potential of PRT at reducing anxiety symptoms in young children with ASD.
Objectives: To explore changes in anxiety in young children (4-8 years) with ASD following a 16-week open-label trial PRT. We examined whether changes in anxiety may be independent from co-occurring changes in social communication skills, which is directly addressed by PRT, to hypothesise and evaluate whether any changes observed in anxiety may be driven by differential therapeutic elements of PRT.
Methods: Participants included 21 children (9 female, 12 male) with high-functioning ASD (M IQ=102, SD=16, measured by Differential Abilities Scale – 2nd Edition) between the ages of 4 and 8 years. Each child received three treatment sessions, with a total of 7 hours, on a weekly basis for 16 weeks. Parents completed outcome measures both before and after the 16 weeks of PRT. We conducted paired sample t-tests to evaluate changes in anxiety (Child and Adolescent Symptom Inventory – Anxiety Subscale, CASI-Anx), internalising symptoms (Child Behaviour Checklist – Internalising domain), and social communication (Social Responsiveness Scale, SRS) over the course of treatment. We conducted repeated-measures ANCOVA to evaluate changes in anxiety after controlling for changes social communication. Finally, we partitioned the variance of change observed in anxiety over the course of treatment, by including changes observed in social communication (SRS), IQ, and age in a step-wise hierarchical regression analysis.
Results: Participants showed significant reductions in anxiety (CASI-Anx) from pre-treatment to post-treatment (CASI-Anx Total; $p = .02$), internalising symptoms (CBCL; $p = .001$), and social communication (SRS; $p = .001$) (Table 1). After controlling for changes in social communication, participants still showed a significant reduction in anxiety, $F(1,19) = 6.13$, $p = .023$, partial $\eta^2 = .24$. Hierarchical linear regression model (Table 2) showed that residualised change in social communication accounted for little variance associated with change reported in anxiety, $R^2 = .02$, $p = .55$. Further addition of IQ and age, as covariates did not alter the model's ability to account for changes observed in anxiety over PRT.
Conclusions: This open-label study shows promising results for PRT to help reduce anxiety, and internalising symptoms more broadly, in young children with ASD. To our knowledge, this study is the first to address the gap in literature on evaluating anxiety reduction following intervention in young children with ASD, providing evidence supporting PRT's significant additional therapeutic potential in terms of reducing severity of anxiety. Future studies can evaluate whether current finding may hold using larger sample sizes, and translated to lower-functioning young children with ASD.

197 **109.197** Role and Predictors of Therapeutic Alliance in a Parent-Mediated Intervention for Autism

***C. A. Taylor**[1], R. Emsley[1], P. Callery[1], J. Marshall[2], J. Green[1] and .. PACT Consortium[3], (1)University of Manchester, Manchester, United Kingdom, (2)Manchester Metropolitan University, Manchester, United Kingdom, (3)United Kingdom*

Background: Therapeutic alliance is a measure of the quality of the working relationship between therapist and client. In psychiatry, meta-analyses have shown a small but consistent relationship between quality of alliance and outcome for both adult (Horvath, Del Re et al. 2011) and child/youth clients (Shirk, Karver et al. 2011), and a range of factors have been shown to associate with the quality of alliance. However, therapeutic alliance has been little researched in the context of parent-mediated interventions for children with autism.
Objectives: To investigate the relationship between parent-therapist alliance and a range of baseline and process variables, and the role of alliance as a post-randomisation effect modifier on parent and child outcomes, in a parent mediated intervention for autism.
Methods: Therapeutic alliance was rated at three time points by 77 parents and 6 therapists participating in the Pre-School Autism Communication Trial (Green, Charman et al. 2010). This was a randomised control trial of a parent-mediated intervention for autism (Pre-school Autism Communication Therapy; PACT), compared against treatment as usual (TAU). Baseline variables comprise parent demographic variables, parent causal belief variables, and an average therapist fidelity variable. Process variables comprise parent 'Expression' and therapist 'Integration' of parent perspectives, measured on the Parent Perspectives Coding Scheme (PPCS), developed specifically for the study. 120 sessions from a purposive high-low parent-rated alliance subsample of 20 cases were coded on the PPCS. Since alliance is not measurable in the TAU arm, we use significant predictors of alliance to predict the 'counterfactual alliance' that would have been observed in the PACT arm for those randomised to TAU. This forms latent classes of alliance, and we compare outcomes, including measures of parent synchrony, child initiations and symptoms, between PACT and TAU within each of these latent classes.
Results: Parent-rated and therapist-rated alliance did not correlate. Parents who cited MMR as a possible cause of autism in their child rated the alliance lower than those who did not ($p<.05$) and parents with no post-16 qualifications rated the alliance higher ($p<.05$); these two variables were independent. A multiple regression model including the two variables in a single step explained 18.3% of variance in parent-rated alliance (Table 1). PPCS Expression and Integration scores were higher in the high parent-rated alliance group but the difference was non-significant. Therapist-rated alliance associated positively with therapist fidelity ($p<.01$) and with PPCS Expression and Integration variables ($p<.01$). A multiple regression model containing fidelity, expression and integration explained 58.8% of variance in therapist-rated alliance (Table 2). The analysis of alliance and treatment effects is underway and results will be included in the presentation.
Conclusions: Therapists should be aware that parents may rate the alliance differently from themselves and that different factors associate with their ratings. Parents' causal beliefs and level of education may influence their ratings of alliance in specific interventions. In keeping with alliance theory, open discussion of disagreement may improve alliance in these cases, especially where the parents' views on causal beliefs are unlikely to be shared by the therapist.Â **Â**

198 **109.198** Scoping the Evidence of the National Autistic Society (NAS) Early Bird Parent Education Training Programmes

J. J. Dawson-Squibb[1]*, E. L. Davids*[2] *and P. J. de Vries*[1]*, (1)Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa,*

(2)Adolescent Health Research Unit, Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa

Background:
The EarlyBird (EB) programme is a Parent Education Training (PET) programme designed to assist parents and caregivers shortly after their child is diagnosed with an Autism Spectrum Disorder (ASD). The United Kingdom-based National Autistic Society (NAS) developed the twelve week group-based programme in 1997. Its broad aims are to 1) support parents immediately after diagnosis, 2) empower parents and encourage a positive perception of the child's ASD, and 3) help parents establish good practice. The EarlyBird Plus (EB+) course was designed in 2003 for parents of school-going children under the age of 9 years.
Both programmes are run internationally in many High Income Countries (HIC), and more than 20,000 families to date have attended the courses. Many clinical and research teams in low- and middle-income countries (LMIC) and other low-resource settings are seeking appropriate evidence-based parent education programmes to implement in these settings, where parent support is severely lacking. EB/EB+ may potentially fill such a need.
Objectives:
This study set out to perform a comprehensive scoping review of all peer-reviewed publications on the acceptability and outcomes of the EB and EB + programmes. We reviewed the context for programmes, study populations, design, outcome measures used, and overall evidence-base.
Methods:
A search was conducted between February and June 2016 using the following databases: EbscoHost, Sabinet, SAGE journals, Directory of Open Access Journals, BioMed Central, Scopus and Science Direct, as well as 'grey literature'. The searches were conducted using the following keywords: EarlyBird, EarlyBird Plus, Autism, Parent Skills Training, Psychoeducation, Parent Support, Parenting Programmes, and Parent Training. Two reviewers independently screened titles and abstracts of publications using the inclusion criteria.
Results:
The review identified 18 articles of which two were from New Zealand and 16 from the United Kingdom. No publications were identified from LMIC. Thirteen of the articles emphasised that the EB and EB+ programmes met their aims and parental satisfaction regarding the course was high. 72% of studies were non-randomized pre-post control in design and only one had a control group.
Acceptability of the programmes was reported on in 94%, and efficacy in 72%. Outcome measures included parental stress, parental perceptions severity of symptoms and of the intervention, parental knowledge and child adaptive behaviour. No randomized controlled trials or head-to-head studies with other parent education training programmes have been performed using of EB/EB+ to date.
Conclusions:
In spite of its widespread use, the evidence-base for EB/EB+ was surprisingly small, and was limited to findings from two English-speaking high-income countries. Whilst there is no doubt about the potential usefulness of these programmes, our findings suggest that much further research evidence may be required in order to determine the potential usefulness and appropriateness of these programmes in low-resource environments. Apart from the need for study designs other than pre/post designs, careful consideration should also be given to acceptability and cultural appropriateness, to outcome measures (including parent-child or child-specific), and to the potential scalability of such interventions.

199 **109.199** Social Responsiveness Gains and Predictors of Outcome Associated with Social Pivotal Response Treatment for Toddlers with ASD: Results of an Ongoing RCT

A. Barrett[1]*, A. Navab*[1]*, J. Ko*[1]*, E. McGarry*[1]*, J. Bradshaw*[2]*, T. Vernon*[1]*, E. J. Horowitz*[3] *and T. German*[3]*, (1)University of California Santa Barbara, Santa Barbara, CA,*

(2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)UCSB Department of Psychological and Brain Sciences, Santa Barbara, CA

Background: Â During the early years of life, the ability to orient one's attention to social cues of others, particularly parents, is imperative to development and social learning. Toddlers with autism spectrum disorder (ASD) demonstrate significant vulnerabilities in early engagement skills, such as social orienting and joint attention behaviors, which are found to be significant predictors of later language ability (Dawson et al., 2004). Specifically, known decreased sensitivity to visual and auditory social stimuli in their environment may lead to long-term negative effects on social, emotional, and language development (Dawson et al., 2002; McPartland et al., 2011). Early interventions that integrate social elements into reinforcement paradigms can dramatically improve collateral levels of interpersonal engagement (Vernon et al, 2012). This current investigation examined child responsiveness to parent engagement bids and its predictability of expressive language gains as a result of Pivotal Response Treatment.
Objectives: This investigation focused on evaluating toddler social responsiveness to parent social bids in naturalistic play probes. Additionally, the study investigated whether pre-intervention levels of engagement could both (1) function as an accurate outcome predictor of expressive language abilities and (2) be improved in a PRT paradigm that emphasized engaging social exchanges.
Methods: Participants were 19 toddlers (18-48 months) with ASD enrolled in an ongoing randomized controlled trial. Participants were age-matched and randomly assigned to a treatment (6 months of PRT focusing exclusively on social routines and reinforcers) or waitlist condition. At pre and post, all participants engaged in a five-minute structured laboratory observation (SLO) with their parent, in which parents were instructed to play with their child using a standardized set of toys. SLOs were coded for parent social play bids and the quality and frequency of child's social responses. Additionally, videos were transcribed as a naturalistic measure of expressive language abilities. A repeated measures analysis of variance was conducted to assess for child engagement and language skills between groups before and after intervention.
Results: Â When examining gains in global social responsiveness (verbal and nonverbal responses) to parent bids, results indicated a medium effect (ηp2=.06, d=.78) in the treatment condition compared to waitlist controls. Specifically for verbal social responsiveness, treatment participants exhibited improvements indicative of a large effect (ηp2 =.18, d=1.13) not observed in the waitlist condition. We can conclude that participation in a social PRT paradigm was associated with significant increases in social responsiveness and verbal engagement in response to parent social bids in naturalistic situations. Level of social responsiveness to parent bids at pre-intervention was correlated with several post-intervention language variables: number of total words (r^2=.59, *p*=.03), number of novel words (r^2=.67, *p*=.01), and average length of utterance (r^2=.78, *p*=.002). While responsiveness to parent bids only required participants to engage nonverbally, pre-existing levels of engagement were significantly associated with resulting expressive language abilities following intervention.
Conclusions: Low levels of engagement with parents are malleable to change as a result of social engagement intervention. Upon further exploration, this nonverbal naturalistic assessment may prove effective for predicting responsiveness to early intervention for minimally verbal children with ASD.

200 **109.200** Tailoring an Evidence-Based Practice to Parents Raising Preschoolers with Autism: Strengths, Challenges, and Future Research Directions

S. Dababnah[1]*, E. M. Olson*[2]*, S. Huntington*[3] *and M. Sermon*[1]*, (1)University of Maryland, Baltimore, Baltimore, MD, (2)Providence Autism Center, Providence Regional Medical Center Everett, Everett, WA, (3)Onslow County Partnership for Children, Jacksonville,, NC*

Background: Parent strain and burden are high in families raising children with Autism Spectrum Disorder (ASD). Parents of preschool children with ASD in particular are particularly vulnerable to stress and depression. Poor parent mental health is associated with several negative outcomes, including child social difficulties, strained parent-child attachment, and marital unhappiness. Yet, few interventions address the direct needs of this growing population of parents.
Objectives: The current study evaluated the outcomes of an existing evidence-based parenting program, The Incredible Years, adapted to caregivers of young children with ASD. The program focuses on improving child-parent communication, problem solving, stress management, and school readiness, as well as to reduce challenging child behaviors and poor family dynamics.
Methods: Seven groups of parents in two sites participated in a pilot trial with no comparison group of the 12-week intervention. Participants were recruited from a community convenience sample. Pre/post changes in parenting stress using the Parenting Stress Index, caregiver coping using Ways of Coping Questionnaire, and child behavior using the Aberrant Behavior Checklist were examined, as well as acceptability and fidelity measures available in the Incredible Years manual. Data were analyzed with two-tailed, paired t-tests ($p<.05$) and basic descriptive statistical procedures using SPSS.
Results: Of the 46 parents who completed baseline measures, 37 completed the program (80.4%). Most participants were mothers and married. The majority of caregivers identified as White (67%) or Latino/a (30%). Approximately two-thirds of the participants had a college degree or more. Participants reported a range of household income levels, with nearly a quarter of respondents noting a household income of less than $25,000. A minority of caregivers had mental health issues (15%).
Fidelity to the manualized intervention was maintained throughout the program period. Child-related parenting stress significantly declined at posttest, with a mean percentile decrease of 6 points (95% CI: .83, 11.02). Child irritability and agitation significantly decreased by 3 points (95% CI: .42, 6.17), and child lethargy and social withdrawal by 2 points (95% CI: .39, 4.20). While improvements in caregiver coping skills and child hyperactivity and non-compliance trended in the expected directions, the changes were not statistically significant. Acceptability was high among graduates of the program, particularly regarding the play-based approach of the program with specific skills in improving parent and child emotion regulation, as well as opportunities for social support and peer learning. Participants' most common recommendation for improvement was to extend the program's duration.
Conclusions: Â The Incredible Years is a promising practice for parents raising preschoolers with ASD. A randomized controlled trial is needed to rigorously test the intervention. Specifically, more research is necessary to investigate further intervention modifications to improve outcomes for young children with ASD and their parents.

201 **109.201** Teacher Perceptions and the Implementation of Jasper for Students with ASD

J. Panganiban[1]*, S. Y. Shire*[1]*, Y. C. Chang*[2]*, W. I. Shih*[3] *and C. Kasari*[3]*, (1)University of California Los Angeles, Los Angeles, CA, (2)California State University, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Â Children with autism spectrum disorder (ASD) are less likely to be jointly engaged with a play partner than typically developing children (Adamson, Bakeman, Deckner, & Romski 2009). Joint engagement during play provides educators an optimal environment to teach social communication skills. It is especially important for teachers to use strategies that promote engagement for students with ASD. However, teacher perceptions of their students' behavior may influence social interaction strategies.
Objectives: Â We aimed to investigate how teachers' perceptions about students with ASD influenced use of joint engagement strategies during dyadic play interactions. We examined how teachers perceived students' ability to control their ASD related behaviors, and how this perception relates to joint engagement strategies.
Methods: Â Data were analyzed from a study implementing a targeted social communication intervention (JASPER) in preschools (Chang, Shire, Shih, Gelfand, & Kasari, 2016). Participants included 66 preschool students with ASD (mean age = 48 months), 82% male, and from diverse ethnic backgrounds (12.1% African American, 30.3% Caucasian, 18.2% Latino, 15.2% Asian, and 18.2% other). Twelve teachers from six ASD preschool classrooms located around the Los Angeles area participated. The schools were randomized to receive teacher training or placed on a waitlist. Pre-intervention, teachers completed questionnaires rating their students' effortful control over behaviors associated with ASD:Â social interaction, non-verbal communication, repetitive interests/behaviors, and sensory seeking behavior. For these four domains, teachers read a description of behaviors associated with ASD, and rated each child (1-5) on their ability to control those behaviors. Scores across all four domains were totaled to create a composite score representing teachers' perceptions of each student's ability to control ASD related behaviors (M = 3.06, SD = .988). Teachers and students were filmed during a ten-minute play interaction, before and after receiving JASPER training. Videotapes were scored for use of strategies to promote joint engagement during play, resulting in overall teacher strategies scores.
Results: Â First, multiple regression analysis from pre-intervention was conducted on the entire sample. At entry, teachers' perceptions of a student's ability to control ASD behavior predicted overall teacher strategies scores, accounting for students' expressive language ability (β = .064, p = .01). Teachers' perceptions accounted for an additional 14% of variance in teacher strategies scores (ΔR^2 = .144). A separate regression analysis was conducted for the group that received JASPER. Teachers' perceptions were not related to changes in strategy scores after receiving JASPER training (β = -.029, p = .44, ΔR^2 = .034).
Conclusions: Â Teachers' perception of students' ability to control ASD behavior is associated with strategies used during play interactions. Prior to training, teachers tended to use strategies promoting joint engagement for students who were perceived to be better able to control their ASD behavior. However, these perceptions did not interfere with teachers' ability to learn and implement intervention strategies. Teachers made significant improvements in using intervention strategies across students (Chang et al., 2016), and these improvements were not related to their initial perceptions of students' ability to control ASD behavior.

202 **109.202** Telehealth Delivery of a Caregiver-Mediated Intervention for Minimally Verbal Children with ASD

R. Yosick[1], *W. Walton*[1], *B. Kansal*[1] *and C. Delfs*[2,3], *(1)Marcus Autism Center, Atlanta, GA, (2)Pediatrics, Emory School of Medicine, Atlanta, GA, (3)Language and Learning Clinic, Marcus Autism Center, Atlanta, GA*

Background: It is estimated that 25% to 30% of children with Autism Spectrum Disorder (ASD) remain minimally verbal (i.e., using fewer than five words on a daily basis; Tager-Flusberg & Kasari, 2013; Lord et al., 2004). Intensive behavioral interventions for children with ASD often focus on social initiations such as requests as initial targets for language development (Sundberg & Partington, 1998). Request training teaches individuals to initiate communication with others by incorporating behavioral techniques (e.g., environmental manipulations, prompting, and reinforcement) within naturalistic teaching opportunities (Paul, 2008), and can be implemented through direct services or delivered as a caregiver-mediated intervention (Loughrey et al., 2014). Several barriers to accessing evidence-based treatment for children with autism are common, including lengthy time commitment and geographical restrictions (Thomas et al., 2007). Parents of children with ASD have specifically recognized the need for greater access to applied behavior analysis services (Dymond et al., 2007). Prior studies have provided promising evidence of the utility of telehealth technology to deliver behavioral services to children with ASD (e.g., Wacker et al., 2013; Vismara et al., 2012 and 2013); however, research is limited.
Objectives: The current study aimed to evaluate the feasibility, caregiver satisfaction, and preliminary efficacy of a caregiver-mediated intervention delivered via telehealth to improve expressive language of 15 young children with ASD and severe language delays.
Methods: Fifteen minimally verbal children (ages 2 to 4 years) with autism were enrolled in a 12-week caregiver-mediated request training intervention. All participants were diagnosed with ASD using gold standard assessment procedures, and the average Mullen expressive language t-score of the sample was 23.72 (SD = 8.46; Mean AE = 13.63 months). The study utilized a within-group design and compared child vocalization outcomes at pre- and post-intervention, as well as at 1-month follow-up. Intervention procedures were based on Loughrey et al. (2014), and included didactic teaching, video modeling, practice, and feedback.
Results: Data were collected utilizing both direct and indirect measures that assessed feasibility, caregiver satisfaction, and preliminary efficacy. Out of 15 enrolled participants, the majority (66.67%) completed the entire study. Session attendance was high (M = 82.21%, SD = 13.66%), all participants (100%) reported satisfaction with the services their child received, and most (88.89%) reported that they would participate in telehealth services in the future. During a naturalistic observation from pre- to post-treatment, most children (80%) made gains in unprompted requests, and half (50%) made gains in spontaneous comments.
Conclusions: Our study provides preliminary support for the feasibility and efficacy of a caregiver-mediated intervention to increase language skills in minimally verbal children with ASD delivered entirely through the use of telehealth technology. Given that many young children with ASD do not develop functional communication skills without intervention (Eigsti et al., 2011) and that there are significant barriers to accessing evidence-based treatment, a time-limited and easily accessible intervention such as the one utilized in our study has the potential to make a large positive impact on this population.

203 **109.203** The Effectiveness of an Intensive Training Program on ORAL Productions on Children with Autism Spectrum Disorder

R. Loureiro*, A. L. Cunha Lopes, M. Lopes, F. Nunes, R. Vieira, S. Charrua and I. Costa, Instituto do Desenvolvimento, Oporto, Portugal*

Background: The development of speech in children with autism spectrum disorder is one of the top parental priorities and expectations. This development is not always predictable, being variable from child to child. Addressing this issue, it was developed an Intensive Training Program that integrates speech therapists that work on a daily or three times a week regimen this particular area of development. The aim of this study was to analyze, as a proof of principle, the evolution of portuguese phonemes productions of two children after the intensive training program.
Objectives: This study is descriptive and exploratory, based on two case studies of four years old male children, diagnosed with grade three autism.
Methods: They attended the intensive training for six months, one of them on a daily regimen and the other one three times a week, with four hours sessions. Quantitative data was collected by filling an evaluation table containing all portuguese phonemes that classified the productions based on their acquisition level. The evaluation was performed in a passive fashion, without interference in children's activities. The program took place in a structured environment after giving informed consent by children's parents.Â .
Results: Â the quantitative results showed an increase in verbal production in both cases. Regarding the types of vocalizations, there was a significant decrease of the stereotyped productions and an increase of the emerging productions. In recent months, the results showed that the children were starting to do specific productions after the therapists models. The results also showed significant differences between the two children, as it was noted a greater change in the case submitted to a daily training.
Conclusions: Â Future research should continue to focus on the influence of an intensive training in the development of speech and its communication functionality. It would also be important to compare different groups of children, one submitted to the program and the other submitted to weekly therapies.

204 **109.204** The Pediatric Developmental Passport: How to Ensure Our Families Are Accessing the Right Care

E. Young[1]*, R. Aiyadurai*[2]*, T. Jegathesan*[1]*, N. Bechard*[3]*, C. R. Brown*[4]*, U. M. Cellupica*[5]*, K. Dillon*[6]*, J. Huber*[7]*, R. Minhas*[2] *and J. Maguire*[2]*, (1)St. Michael's Hospital, Toronto, ON, CANADA, (2)St. Michael's Hospital, Toronto, ON, Canada, (3)University of Toronto, Toronto, ON, Canada, (4)University of Ottawa, Ottawa, ON, Canada, (5)Children's Treatment Network of Simcoe York, Richmond Hill, ON, CANADA, (6)Children's Treatment Network of Simcoe York, Richmond Hill, ON, Canada, (7)University of Toronto, Toronto, CANADA*

Background: The Pediatric Developmental Passport (passport) is an innovative tracking tool for families of children with autism spectrum disorder (ASD). It provides a mechanism for clearly communicating appropriate regional developmental services, an opportunity to track progress in accessing these developmental services and a valuable summary of the developmental care received by that child for the pediatrician. A qualitative study with parents and health professionals (developmental pediatricians, developmental nurses, pediatricians) lead to the design and iterative review of the passport.
Objectives: The objective of this study was to determine the generalizability and effectiveness of the passport compared to placebo in a multi-site pragmatic randomized control trial.
Methods: A pragmatic multi-site randomized controlled trial was conducted with families of children between 0-6 years of age diagnosed with ASD. Families from two different models of developmental care were enrolled into the study. One site was a community based developmental consultation clinic and the second site was an academic developmental practice that provides longitudinal follow up. All families included in the study were randomized to receive the passport or placebo. Regional agencies that provided publicly funded ABA and parent education services were contacted directly to obtain accurate contact and access status of recommended developmental services. The effectiveness of the passport at each site was measured via chi square test at a p value of <0.05.
Results: Forty children with ASD were included and followed in this study, 20 from each site. At the community site, 90% of families that were given the passport contacted ABA services, compared to the 40% in the placebo group (p value = 0.024). There was no significant difference in the proportion of families that contacted ABA services at the academic site (90% in both arms). Comparison of the passport and placebo groups at within each site indicated no significant difference in the proportion of families that contacted parent education services. A significant difference was found in the proportion of families that contacted parent education services between the academic and community sites (60% vs. 19%, p=0.011).
Conclusions: Families that receive a diagnosis from consultation clinics are expected to follow up with a primary care physician. The differences observed in this study indicate that families that receive a diagnosis from this model of healthcare may benefit from further support to contact and access developmental services. The Pediatric Developmental Passport shows evidence as an effective tool to support families post diagnosis in this pilot RCT. With the Passport, the proportion of families that accessed ABA services increased to be equal to those who were followed longitudinally within an academic developmental practice.
Larger trials are being developed to further evaluate the Passport within different types of practices and different populations.

205 **109.205** The Relationship Between Duration and Outcomes in Young Children on the Autism Spectrum Using a Specialised Intervention

A. Mazzoni[1]*, V. Eapen*[2] *and R. Grove*[3]*, (1)University of New South Wales, Sydney, Australia, (2)Academic Unit of Child Psychiatry South West Sydney (AUCS), Liverpool, Australia, (3)The University of New South Wales, Sydney, Australia*

Background: Previous research has shown that early intervention results in improved outcomes for children on the Autism Spectrum. However, there is limited data and mixed findings on the impact that duration of time spent in therapy has on treatment outcomes. While some studies have shown that minimal significant gains occur after one year of intervention, others have indicated that children receiving more specialised interventions demonstrated marked improvements with increased time spent in therapy (Cohen, Amerine-Dickens, & Smith, 2006; Howard, Stanislaw, Green, Sparkman, & Cohen, 2014; Virues-Ortega, Julio, & Pastor-Barriuso, 2013). These researchers argue that specialised interventions are generally focused on building foundational skills within the first year, while the second year helps to further develop and solidify these skills (Howard et al., 2014). Although there are a few interventions classified as specialised, to date, much of the research has focused on Applied Behaviour Analysis. Therefore, it is important to investigate whether this finding is limited to ABA or extends to other specialised therapies.
Objectives: The objective of the current study was to evaluate the relationship between duration of a specialised intervention, specifically the Early Start Denver Model (ESDM), and outcomes including symptoms of autism, cognitive ability and adaptive behaviours.
Methods: Children on the autism spectrum were aged two to five attending an autism specific preschool program receiving the ESDM early intervention program were evaluated at the beginning of the intervention program, and followed up every 12 months until they exited the preschool. Correlation and Regression analysis were used to assess the relationship between months children spend in therapy and outcomes in assessments. These included the Autism Diagnostic Observation schedule, the Mullen Scales of Early learning, Vineland Adaptive Behaviour Scales, Social Communication Questionnaire and the Repetitive Behaviour Scale.
Results: Increased time spent in therapy was associated with improved outcomes across a number of domains after controlling for potential moderators, including cognitive ability, age at enrolment, severity of symptoms and intensity of intervention. These included communication skills, daily living skills, interpersonal relationships, coping skills and adaptive behaviours. Interestingly, there was no association between improvement in receptive and expressive language and the duration of intervention.
Conclusions: Our findings demonstrate that early intervention is beneficial for preschool children on the autism spectrum, with increased duration of specialised intervention associated with improved outcomes across specific domains of functioning. These associations are in keeping with the domains that were the target of the intervention. However, further improvements in receptive and expressive language were not associated with the duration of intervention. It is unclear whether this finding indicates that children received the maximum benefit on receptive and expressive language skills after the first year of intervention or whether other factors outside of the ones accounted for played a role. Overall, this study supports the idea that increased time spent in specialised interventions improves specific outcomes.

206 **109.206** The Relationship Between Intervention Fidelity and Child Social Communication Gains in a Parent-Mediated Intervention.

K. M. Frost *and B. Ingersoll, Michigan State University, East Lansing, MI*

Background:
Parent-mediated naturalistic developmental behavioral interventions (NDBIs; Schriebman et al., 2015), teach caregivers to increase their responsiveness to their child's behavior and to elicit communication and play within child-directed activities. Previous research on a parent-mediated NDBI, Project ImPACT, has shown improvement in parent fidelity and rate of child language targets (Ingersoll & Wainer, 2013; Ingersoll et al., 2015); however, the relationship between parent use of specific fidelity components and broader child social communication outcomes is less clear. In this study, we examined the association between parent changes in Project ImPACT fidelity and child improvement on the Brief Observation of Social Communication Change (BOSCC; Grzadzinski et al., 2016).
Objectives:
We examined whether improvement in parent use of Project ImPACT intervention strategies was associated with improvement in child social communication on the BOSCC. We hypothesized that improvements in several key dimensions of parent fidelity (parent responsiveness, parent elicitation of child initiations, and parent prompting and reinforcement of child language) would be associated with improvements in child social communication on the BOSCC, whereas changes in other dimensions (parent modeling of language, parent prompting of child play skills) would be less closely associated with child improvements.
Methods:
Participants were drawn from two studies of online adaptation of Project ImPACT (Ingersoll & Dvortcsak, 2010). Parents of young children with ASD completed an online, interactive tutorial on Project ImPACT either on their own (n=21) or in combination with twice-weekly therapist assistance (n=21). Families completed lab-based assessments pre- and post- intervention, in addition to completing unstructured parent-child play interactions in the home. Video-recorded play interactions were then rated for parent intervention fidelity, as well as child social communication behaviors using the BOSCC.
Results:
Preliminary analyses were conducted with a subset of the pilot study participants (n = 15). Significant improvement was observed from pre to post on parent fidelity, $t(14) = 4.68$, $p < .01$, $d = 1.20$, and child BOSCC Social Communication (SC) total scores, $t(14)=3.885$, $p < .01$, $d = 1.00$ (Table 1).Â In addition, there was a significant association between improvements in parents' use of elicitation of child initiations and direct language prompting and improvement in child social communication skills on the BOSCC SC Total (Table 2). Additional analyses will confirm these findings in the full sample (n=42), as well as supplement findings using multiple regression to clarify the amount of variance in child BOSCC change scores that are accounted for by changes in the different parent fidelity dimensions.
Conclusions:
These data suggest that parent use of certain strategies, particularly elicitation of initiations and direct teaching of language, are associated with increased child social communication. Other strategies, such as parent responsiveness, parent modeling of language, and parent prompting of play, were not associated with child social communication behavior. However, it is possible that these behaviors support the interaction, and allow for the efficacy of teaching strategies. Further research should investigate potential "active ingredients" of parent-mediated treatments as they relate to child intervention response over time.

207 **109.207** Umbrella Review: Systematic Reviews of Psychosocial Interventions for Children with Autism Spectrum Disorder

E. Gange[1]*, K. Seatter*[2] *and V. R. Smith*[1]*, (1)Educational Psychology, University of Alberta, Edmonton, AB, CANADA, (2)Educational Psychology, University of Alberta, Edmonton, AB, Canada*

Background: Autism spectrum disorder (ASD) now affects approximately one in 68 children, making it one of the most prevalent neurodevelopmental disorders of childhood (Center for Disease and Control [CDC], 2016). Although there is no cure for ASD, there is a diverse range of interventions available that are designed to target the core deficits of the disorder and can improve a child's developmental trajectory (CDC, 2016).Â Over the past 20 years there has been an explosion of ASD intervention research, and as such, it is no longer feasible for individuals to read and retain the vast body of available information in this area (Interagency Autism Coordinating Committee, 2012). Indeed, it is an overwhelming and challenging task for physicians, clinicians, teachers, and policy-makers to determine which specific interventions should be recommended for each individual child. In response to this challenge, there has been a rise in production of systematic reviews (SRs). An umbrella review, which involves collating information from multiple SRs, makes it possible to better determine the effectiveness of ASD interventions and will facilitate evidence-informed decision-making.
Objectives: The present study is an umbrella review of SRs of psychosocial interventions for ASD. The review aims to summarize SRs from 2006 to 2016, evaluate their quality, identify predictive factors associated with quality, and determine best practice recommendations for intervention.
Methods: Studies were identified through comprehensive searches of six electronic databases. The search strategy consisted of keywords and medical subject headings for autism and related disorders and various psychosocial interventions. Eligible studies met the following criteria: systematic search description; participants aged 0-12 with a diagnosis of ASD; and review of a psychosocial intervention. The methodological quality of SRs was assessed using the AMSTAR tool (Shea et al., 2007) and descriptive data were extracted.
Results: The comprehensive search resulted in the inclusion of 159 SRs published between 2006 and 2016.Â In terms of participants, 77% of SRs included both preschool and school age children, 12% included only preschool age, and the remaining 11% included only school age. Sixty-five different journals published these SRs. Six dissertations were included. Additional characteristics of the SRs will be summarized descriptively. Evidence tables will be produced to synthesize the clinical findings and recommendations of the SRs. A backward elimination multivariable regression analysis will be conducted post-hoc to examine predictors of the methodological quality of reviews, as measured by the overall score on the AMSTAR. Review characteristics associated with the quality of reviews and several independent variables will be explored in the regression models.
Conclusions: The methodological strength of the SRs included in this umbrella review was greater than those included in Seida and colleagues' (2009) umbrella review, indicating that they are less vulnerable to bias. Further, Seida and colleagues' review found 30 SRs that met eligibility criteria and were published between 1996 and 2007 while the current umbrella review included more than five times as many SRs, indicating that there has indeed been an explosion of SRs focused on ASD interventions in recent years.

208 **109.208** Using Engaging Social Interactions within a Pivotal Response Treatment Framework to Improve Adaptive Communication Skills and Autism Symptom Severity in Toddlers with ASD: Evidence from a Randomized Controlled Trial

E. McGarry[1]*, L. Hughart*[1]*, A. Barrett*[1]*, J. Ko*[1]*, A. Navab*[1]*, J. Bradshaw*[2]*, E. J. Horowitz*[3]*, T. German*[3] *and T. Vernon*[1]*, (1)University of California Santa Barbara, Santa Barbara, CA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)UCSB Department of Psychological and Brain Sciences, Santa Barbara, CA*

Background:
Extensive research has examined the use of motivating stimuli to facilitate interventions for young children with autism spectrum disorder (ASD). Rewarding a child's communicative attempts via access to a preferred item has been demonstrated to foster expressive and receptive language development and reduce autism symptomatology (Koegel et al., 1987; Koegel et al., 2010). Considering these promising results, recent studies have evaluated if these benefits may be enhanced through the use of engaging social interactions in lieu of items (Vernon, 2014; Vernon et al., 2012; Koegel et al., 2009). Rather than foster developmental efforts through delivery of motivating stimulus items, this intervention encourages social engagement by capitalizing on social activities informed by child sensory preferences. Research suggests that this approach is particularly effective, leading to widespread gains in eye contact, directed positive affect, verbal initiations, and parent-child engagement (Vernon et al., 2012). The present investigation examines preliminary results of an ongoing RCT examining the impact of this social engagement intervention on language development and amelioration of autism symptoms.
Objectives: This study's objective was to investigate the impact of using embedded social interactions within a Pivotal Response Treatment intervention framework to improve the language skills and autism symptom severity of young children with ASD.
Methods: 19 toddlers with ASD, ages 18-48 months, participated in an ongoing randomized controlled trial. Participants in the immediate treatment condition received 6 months of a social engagement intervention in which language was reinforced with access to a motivating social exchange derived from each child's existing, but non-social preferred activities. A comprehensive battery of assessments was administered to participants at pre- and post-intervention, including measures of adaptive functioning (the Vineland Adaptive Behavior Scales, Second Edition) and autism symptom severity (the Autism Diagnostic Observation Schedule, Second Edition). A multivariate analysis of variance (MANOVA) was conducted to identify changes in language abilities and autism symptoms across groups.
Results: With the use of Wilk's criterion, multivariate analysis of Vineland scores revealed that the treatment group exhibited significantly greater gains in overall communication abilities in comparison to the control group: $F(1, 15) = 6.42$, $p=.023$. More specifically, the intervention was associated with significant improvement in participants' receptive language skills when compared to the control group: $F(1, 15)= 5.65$, $p=.031$. While expressive language scores exhibited a positive trend within the intervention group that was not present in the control group, this result was not yet statistically significant given the preliminary nature of the data and small n: $F(1, 15)= 2.92$, $p=.108$. Multivariate analysis of ADOS total scores revealed that participants in the treatment group exhibited a significantly greater improvement in autism symptoms than the control group: $F(1, 17)= 5.27$, $p=.035$.
Conclusions: These results support the benefits of using an embedded social interaction modification to established PRT procedures to improve the communication skills and autism symptoms of toddlers with ASD. The positive growth trend seen in the data suggest that the adaptive language skills of children with ASD move within the proximity of typically-developing peers following participation in this project.

209 **109.209** Visual Pattern As a Secondary 'Biologically-Oriented' Outcome in the Field of Early Intervention of the Autism Spectrum Disorder: Can the Eye-Tracker Provide Useful Suggestions ?

A. Narzisi[1], *L. Billeci*[2], *S. Calderoni*[3], *G. Campatelli*[4], *F. Fulceri*[3] *and F. Muratori*[5], *(1)IRCCS Stella Maris Foundation, Pisa, Italy, (2)IRCCS Stella Maris Foundation, Calambrone, Pisa, ITALY, (3)University of Pisa – Stella Maris Scientific Institute, Pisa, Italy, (4)IRCCS Foundation Stella Maris, Pisa, Italy, (5)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background: Eye tracking has the potential to characterize autism spectrum disorder at a unique intermediate level, with links 'down' to underlying neurocognitive networks, as well as 'up' to everyday function and dysfunction. Because it is non-invasive and does not require advanced motor responses or language, eye tracking is particularly important for the study of young children and infants (Falck-Ytter et al., 2013).
Objectives: A previously published studies indicated that the early intervention resulted in gains in developmental level, language and adaptive behavior of children with autism spectrum disorder. This work describes a secondary 'biologically-oriented' outcome: the visual pattern studied through eye-tracking.
Methods: Twenty 24 to 30 month old children at their first diagnosis of autism spectrum disorder were recruited and their visual pattern, in addition to the standard clinical protocol, was studied at T0 (time of the first diagnosis) and at T1 after 6 months of intervention. The eye-tracking tasks consisted in the presentation of short video sequences involving responding (figure 'a') and two initiating JA tasks (JA1 figure 'b' and JA2 figure 'c'). Gaze accuracy, transitions and fixations were analyzed. Age-matched typical children were also compared at T0 and T1.
Results: In responding JA task children with ASD improved their engagement with target object showing an increased fixation at T1 compared to T0 (p=.02). No significant difference with typical children was found at T0 while a slightly increase in looking at target was discover at T1 (p=.048). In initiating JA1 children with ASD significantly improved their ability of disengage and explore space: increased transitions from non-target object to target object (p=.01), tended to look more to non-target object (p=.06) and decreased fixations at face (p=.01). At T1 their still made more transitions at the target object compared to the non-target one (p=.02) respect to typical children (higher transitions score) while they did not show any more decreased attention at non-target object. As regards IJA2 ASD children did non show significantly improvement in visual pattern and they still made more transitions then typicals between target object and face. From a clinical point of view, at T1 children showed a significantly improved in terms of ADOS-2 comparison score (CS). Also developmental level, language and adaptive behavior showed significant gains.
Conclusions: For our knowledge this was the first trial that used the eye-tracking as out come measure to demonstrate that early intervention was associated with progressive normalized visual pattern and with improvements in social behavior in young children with autism spectrum disorder.

210 **109.210** Group-Based Interventions for Parents of Children with ASD: Impact on Psychological and Physiological Outcomes

S. Iadarola[1], *K. Mustian*[2], *M. Porto*[3] *and T. Smith*[3], *(1)University of Rochester Medical Center, Fairport, NY, (2)Surgery, University of Rochester Medical Center, Rochester, NY, (3)University of Rochester Medical Center, Rochester, NY*

Background: Parents of children with autism spectrum disorder (ASD) report exceptionally high levels of stress as compared to their counterparts, and parental stress exerts bidirectional effects on child outcomes. Caregiving stress likely results in poor health outcomes for parents, but we know very little about parental objective health profiles, given that most intervention studies rely on parental self-report outcomes. Parent-focused interventions (e.g., psychoeducation, behavioral education, mind-body interventions, social support) in ASD have been tested and demonstrated as helpful in addressing child outcomes, but the data on parent outcomes are equivocal.
Objectives: Evaluate the feasibility and preliminary efficacy of two group-based interventions (i.e., psychoeducation and mindfulness) for parents of children with ASD, with a focus on psychological and physiological outcomes.
Methods: Twenty-two parents of children with ASD (17 completers) with high baseline parental stress (i.e., above the 90thpercentile) were enrolled in a pilot, randomized clinical trial on parent-focused interventions. Participants were randomized to 8 weeks of either a group psychoeducation program (GPEP) or a group mindfulness-based intervention (MBI). Parental self-report on psychological outcomes (parental stress, caregiver strain, perceived health) and physiological health outcomes were collected at baseline and post-treatment. Physiological/clinical outcomes were assessed in a laboratory setting (heart rate variability, blood pressure) and in the participant's home environment (sleep, via actigraphy).
Results: Regarding feasibility outcomes, we met recruitment goals and had approximately 21% attrition, which is comparable to other parent training programs. Post-treatment, parents in GPEP demonstrated significant reductions in total stress (p=.04) and on the Parental Distress (p=.05) and Difficult Child Interactions (p>.01) domains. Parents in MBI improved only on the Difficult Child domain (p=.05). Between-group comparisons revealed that GPEP parents showed greater change post-treatment than MBI for parental stress (p>.01). In contrast, the MBI group showed significant improvement in perceived physical and emotional health (p=.02), whereas the GPEP group showed no change. Neither group demonstrated change in caregiver strain. No differences were observed in either group on physiological or clinical health outcomes.
Conclusions: Parent-focused interventions that are delivered in group formats and that are evaluated via multiple approaches to outcomes are important, but significantly understudied in ASD. The current study preliminary supports the feasibility of adapting individual intervention into group-based treatments and collecting objective data on functional and clinical health outcomes. In this small pilot sample, both psychoeducation and mindfulness effectively addressed different aspects of parental stress and perceived health. Along with previous research, this highlights the importance of including mediator and moderator analyses in parent interventions to identify what factors might influence treatment response. In this sample, no changes in physiological outcomes were observed, suggesting that parent perceptions of improved stress and health may not necessarily translate into change in objective health outcomes. This was a very small pilot sample, so the results are not conclusive. However, they do suggest the feasibility and importance of continuing parent-focused interventions that considers multiple outcomes.

211 **109.211** Child Outcomes and Behavioral Predictors of Treatment Response for Pivotal Response Treatment

G. W. Gengoux[1], *J. M. Phillips*[1], *C. Ardel*[1], *M. E. Millan*[1], *R. K. Schuck*[1], *T. W. Frazier*[2] *and A. Y. Hardan*[1], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Pivotal Response Treatment (PRT) is an evidence-based naturalistic behavioral intervention which is traditionally delivered via a parent training model. Support for its use in improving language abilities has historically come from single-case studies using primarily behavioral observation measures. There is a critical need for examination of outcomes from larger samples and from objective measures which can be more easily compared across trials and to normative developmental trajectories. Furthermore, identification of behavioral factors which predict treatment response will be essential for selecting the best treatment for an individual child.
Objectives: This presentation will review outcomes from a randomized controlled trial comparing a Delayed Treatment Group (DTG) to a PRT package treatment (PRT-P) which combines parent training with clinician-delivered in-home treatment. We hypothesize that the addition of clinician-delivered early intervention may help boost child language development while parents are learning the PRT techniques. Our aim is to highlight new data demonstrating how standardized measures of language and cognitive abilities can be used to assess and predict treatment response in clinical trials.
Methods: Participants include 48 children with ASD and significant language delay, ages 2-5 years. Children were randomly assigned to DTG or PRT-P, which involved weekly parent training and 10 hours per week of in-home therapist-delivered treatment for 3 months, followed by a less-intensive phase with 5 hours per week of in-home treatment and monthly parent training sessions. Dependent measures included Clinical Global Impression Improvement (CGI-I) ratings by trained raters blinded to treatment condition, as well as standardized parent questionnaires such as the MacArthur-Bates Communicative Development Inventories (CDI), as well as structured behavioral observations.
Results: Examination of changes with PRT-P reveal that children in the active group acquired greater vocabulary as evidenced by an average gain of 137 words between baseline (*M*=134 ± 113.5) and post treatment (*M*=271 ± 205) on the CDI, which was significantly greater than changes observed in the DTG (F=6.089; df(1:34); p=0.019). CGI-I ratings indicate that the PRT-P group is showing more improvement in communication compared to controls (X^2(3, N=40)= 17.50; p=0.001).Â Specifically, 4 children were rated as very much improved (0 in DTG), 10 children rated as much improved (2 in DTG), 4 children rated as minimally improved (14 in DTG) and one child rated "no change" (5 in DTG). In addition, greater change between baseline and post-treatment on the CDI was correlated with baseline Mullen Early Learning Composite (R: 0.716; p=0.009) and with Mullen nonverbal skills (R: 0.555; p=0.049) suggesting that better performance on tests of early cognitive skills may predict response to PRT.
Conclusions: These data suggest that the PRT package approach shows promise for addressing communication deficits associated with ASD. Potential benefits and challenges of a combined parent training and clinician-delivered early intervention approach will be discussed, with a focus on factors which may predict an individual child's response to treatment and aid clinicians in better personalizing care.

212 **109.212** Treatment Adherence and Dose As Predictors of Child Language Outcomes in Pivotal Response Group Parent Training

M. A. Minjarez[1], *J. Liang*[2] *and T. W. Frazier*[3], *(1)Seattle Children's Autism Center, Seattle, WA, (2)PGSP-Stanford PsyD Consortium, Palo Alto, CA, (3)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Behavioral interventions are robustly supported in ASD treatment, including those that are parent-administered. Previous research supports that group parent training in Pivotal Response Treatment (PRTG) results in gains in child language ability (Hardan et al., 2015). There remains a need, however, for better understanding of the relationship between parent fidelity of treatment implementation, dose of treatment, and child outcomes.
Objectives: To evaluate relationships between adherence to implementation, therapy dose, and child language outcomes from a randomized controlled trial of PRTG.
Methods: Participants included parents and their children, ages 2-6 years, with diagnoses of ASD and significant language delay. In the RCT, 53 participants were randomly assigned to either PRTG or a parent psychoeducation group (PEG). PRTG consisted of 12 weeks of parent training in the delivery of pivotal response therapy targeting language development. Parent adherence to PRTG implementation (defined as % fidelity to pre-defined therapy characteristics achieved) and dose (defined as the number of parent-implemented child learning opportunities) were coded at baseline, mid-point (week 6), and endpoint (week 12). The dependent measure was the number of child utterances at week 12 based on a structured laboratory observation. Linear regression and structural mediational models were used to evaluate relationships between PRTG treatment, parent fidelity, child learning opportunities, and child utterances.
Results: PRTG treatment substantially increased both fidelity and learning opportunities by week 6. At week 12, child learning opportunities was a significant independent predictor of child utterances, even after accounting for non-verbal ability. However, the relationship between parent fidelity and child learning opportunities was substantial (r=.66) and this shared variance was the biggest predictor of child utterances. Mediational models indicated that PRTG treatment resulted in early and ongoing improvements in parent fidelity, which lead to increases in the number of child learning opportunities, which, in turn, resulted in increased child utterances.
Conclusions: The present findings indicated the attention PRTG treatment provides leads to early and ongoing improvements in the quality of therapy provided by parents. These improvements in therapy quality coincide with improvements in the number of learning opportunities and together these enhancements in treatment adherence and dose improve child language outcomes. Results highlight the importance of therapy adherence and dose as crucial, consistent with findings from early intensive behavioral intervention studies. Parent-based behavioral intervention strategies should continue to emphasize treatment adherence throughout the delivery of treatment, as this is an important determinant of success via increasing the number of child learning opportunities. Additional research is needed to establish appropriate dosing of parent training to maximize child outcomes, but the present results suggest that 12 weeks is a useful lower bound.

213 **109.213** Structural Neuroimaging Predictors of Benefits from Pivotal Response Treatment

J. P. Hegarty II[1], *G. W. Gengoux*[1], *J. M. Phillips*[1], *S. Tanaka*[1], *T. W. Frazier*[2], *A. L. Reiss*[1] *and A. Y. Hardan*[1], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Cleveland Clinic Center for Autism, Cleveland, OH*

Background: Autism spectrum disorder (ASD) is a heterogeneous disorder and several neurobiologic measures have been examined to identify potential subgroups, with limited success thus far. Applying neuroimaging methodologies to identify prognostic markers or indicators of treatment response may be an alternative approach to address this heterogeneity. To date, no biomarker of treatment response has been identified for any biological or behavioral intervention in autism. Additionally, there is a growing need for innovative, efficient, cost-effective treatment models guided by biological markers of treatment response to optimize results and longterm outcome. This is particularly true for very young children with ASD when the brain is most plastic and time should not be wasted in implementing treatments that might not be beneficial.
Objectives: The goal of this investigation is to use a hypothesis-generating approach and apply multimodal imaging techniques to help identify biomarkers of treatment response. In this investigation, we aim at applying structural magnetic resonance imaging (MRI) and diffusion tensor imaging (DTI) to identify biomarkers of pivotal response training (PRT) treatment response. The development of biosignatures of treatment response is critical and the present study is the first step in providing evidence supporting the possibility of identifying biomarkers to predict response to behaviorally and biologically--based treatments.
Methods: The PRT intervention consisted of teaching parents behavioral techniques to facilitate language development. PRT training lasted at least 12 consecutive weeks with one session per week. Sessions included in vivo coaching of parent implementation of PRT techniques with their child, as well as review and feedback on videos of parents practicing PRT at home. Objective and subjective outcome measures were obtained at baseline and at the end of treatment. High resolution anatomical MRI and DTI scans are being obtained on children with ASD before and after their participation in PRT. Correlations between neuroimaging measures (volume and surface) and fractional anisotropy (FA)) in language areas (e.g. superior longitudinal fasciculus(SLF)) and changes in outcome measures were examined.
Results: Eighteen children with ASD have participated in this study to date. Anatomical MRI and DTI scans have been obtained on all individuals at baseline (prior to treatment). Five followup scans (post treatment) have successfullyÂ been collected.Â NeuroimagingÂ andÂ treatmentÂ dataÂ areÂ availableÂ on 8Â participantsÂ asÂ theÂ additionalÂ scansÂ andÂ behavioral informationÂ areÂ beingÂ processed.Â A relationship between the volume (n=8; r_s= -0.81, p= 0.015) and surface area (n=8; r_s= -0.82, p= 0.013) of the inferior frontal gyrus, which contains Broca's area, were significantly associated with changes in the number of utterances as assessed during structured laboratory observation (Figure 1). Cortical thickness was also associated with expressive communication (n=7; r_s= -0.88, p= 0.008) as assessed with PLS-5. Associations between FA in the SLF and changes in several language measures were observed including the number of utterances during structured laboratory observation and number of words produced out of 396 on the MacArthurBates Communicative Development Inventories.
Conclusions: Preliminary findings from this pilot study suggest that neuroimaging measures are potentially useful as predictors of treatment response. Additional analyses will be completed as more data become available. We will discuss these findings and highlight the advantages and challenges of using neuroimaging information in clinic trials to assess treatment response and biologic changes due to the intervention.

214 **109.214** Neural Predictors and Neural Pathway of Response to Pivotal Response Treatment in Young Children with Autism

D. Yang[1,2], *K. A. Pelphrey*[1,2], *D. G. Sukhodolsky*[3] *and P. E. Ventola*[3], *(1)Autism and Neurodevelopmental Disorders Institute, The George Washington University, Washington, DC, (2)Children's National Health System, Washington, DC, (3)Yale Child Study Center, New Haven, CT*

Background: Autism Spectrum Disorders (ASD) are common yet complex neurodevelopmental disorders, characterized by social, communication, and behavioral deficits. Behavioral interventions for young children with ASD have shown favorable results; however, significant obstacles exists in the development of precision medicine in ASD. Specifically, it remains largely unclear (a) what sensitive, objective pretreatment neurobiological markers can accurately forecast the response to treatment, and (b) what neural pathways mediate the treatment outcome. It is important to be able to predict or stratify subgroups of young children likely to respond to specific treatments because early childhood provides a sensitive window of opportunity for intervention, while unsuccessful intervention is costly to children, families, and society. It is also important to understand the neural mechanism of treatment responses because the pathways may provide a neural target for concurrent intervention to boost treatment effects during the course of treatment.
Objectives: To develop pretreatment neurobiological markers that can predict the response to an evidence-based behavioral treatment—Pivotal Response Treatment (PRT)—in young children with autism, and to examine the neural mechanism underlying treatment effects.
Methods: In a sample (*N*=20; 7 girls, 13 boys) of young (*M* age=5.90 years, *SD*=1.07), cognitively-able (*M* FSIQ=103.45, *SD*=17.03) children with ASD, who participated in a 16-week trial of PRT, we measured the change in autism symptom severity by modeling the delta change scores (that is, post minus pre) of the parent-report Social Responsiveness Scale (SRS) total raw scores, while our study participants viewed neuroimaging stimuli depicting point light displays of coherent biological (BIO) or scrambled (SCRAM) motion in a 3T scanner within 1 week before and after PRT. fMRI analyses were conducted with mixed-effects modeling and the results were thresholded at *Z*>2.33 (voxel) and *p*<.05 (cluster), while gender was controlled for as a covariate of no interest.
Results: First, with respect to neural predictors, we found that greater reduction in autism symptom severity from pretreatment to post-treatment was linearly associated with greater pretreatment levels of activity in response to biological vs. scrambled motion in the neural circuits that support social information processing (superior temporal sulcus, fusiform gyrus, amygdala, inferior parietal cortex, and superior parietal lobule) and social motivation/reward (orbitofrontal cortex, insula, putamen, pallidum, and ventral striatum) (**Figure 1A**). The predictive value of our findings for individual children with ASD was supported by a multivariate pattern analysis with cross validation. Second, with respect to neural pathways, we found that greater reduction in autism symptom severity was linearly associated with increase in activity in response to biological vs. scrambled motion in the action observation network (inferior parietal lobule, parietal operculum cortex, supplementary and pre-supplementary cortices located on the medial surface) (**Figure 1B**).
Conclusions: Predicting who will respond to a particular treatment for ASD and advancing the knowledge of neural pathways of treatment outcomes, the current findings provide key neural bases of behavioral response to treatment in young children with ASD. The implications of the findings are far reaching and should greatly accelerate progress toward more precise and effective treatments for core deficits in ASD.

215 **109.215** Outcomes for Children Receiving the Early Start Denver Model in a Mainstream Versus Autism-Specific Setting: A Pilot Randomized Controlled Trial

G. Vivanti[1]*, E. Duncan*[2]*, K. Hudry*[3] *and C. Dissanayake*[4]*, (1)AJ Drexel Autism Institute, Philadelphia, PA, (2)Community Children's Centre, La Trobe University, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, Melbourne, AUSTRALIA, (4)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Â The U.N. Convention on the Rights of Persons with Disabilities (United Nations, 2006) has articulated a human right for access to early intervention for young children with disabilities, which should be provided in the least restrictive environment suitable to meet children's needs, including consistent opportunities for interaction with typically developing peers. To date, there is little scientific research testing the benefits and disadvantages of providing early intervention within mainstream versus autism-specific settings. The aim in our study is to address this gap.
Objectives: Â To examine the outcomes of an evidence based early intervention program provided in a community childcare center for children in an autism versus mainstream setting.
Methods: We conducted a sequential multiple assignment randomized trial (SMART RCT) involving 32 toddlers with ASD. Half participants were randomly assigned to receiving an evidence-based early intervention program (the Early Start Denver Model) in a playroom that only includes children with ASD (autism-specific setting group), and the other half (social inclusion group) received the same intervention within a mainstream setting with neurotypical peers. Participants' communication, adaptive behaviour and autism symptoms was measured at baseline and after 1 year post-intervention.
Results: Preliminary analyses including 8 children in each group revealed that both groups equally improved in their communication from baseline to post-treatment, as assessed through the Mullen Scales (Repeated Measures ANOVA, $F(1, 14) = 8.3$, $p = .01$, $\eta_p2 = .37$), and experienced a reduction of ASD symptoms, as assessed through the Social Communication Questionnaire (($F(1, 14) = 9.73$, $p < .01$, $\eta_p2 = .40$). While both groups significantly improved in their adaptive behaviour as assessed through the Vineland (($F(1, 14) = 12.46$, $p < .005$, $\eta_p2 = .47$), there was a trend suggesting superior gains in the social inclusion group (($F(1, 14) = 3.11$, $p = .09$, $\eta_p2 = .18$).
Conclusions: Preliminary results suggest that receiving early intervention in a mainstream setting has the potential to be equally beneficial, and potentially more beneficial, than receiving the same intervention in an autism-specific setting. **Â**

216 **109.216** Preschool Early Intervention Outcomes in Different Community Based Settings

A. S. Nahmias[1] *and D. S. Mandell*[2]*, (1)University of California Los Angeles, Los Angeles, CA, (2)University of Pennsylvania, Philadelphia, PA*

Background: Despite the requirement in the United States to provide free and appropriate public education for young children with ASD in the least restrictive environment suitable for their needs, there is little research comparing the impact of settings of varying restrictiveness where interventions are delivered (Parsons et al., 2011). Consistent opportunities to interact with typically developing peers often are a recommended practice for young children with ASD (e.g., Koegel et al., 2009). Studies of inclusive preschool programs for children with ASD suggest that preschoolers with ASD can make gains in cognitive, academic, language, functional and social skills when placed with their typically developing peers. However, there is debate as to the appropriateness of inclusive settings for children with ASD. Most research to date of early interventions programs has investigated interventions delivered in more segregated settings (home and clinic based individual services or ASD specific classrooms). These settings do not routinely offer opportunities to interact with neurotypical peers, and have not compared inclusive to non-inclusive settings. However recent research has suggested that inclusive preschool intervention may be particularly beneficial for some children with ASD (Nahmias et al., 2012).
Objectives: To examine the main effects of receiving preschool early intervention in one of four educational settings that vary in their level of restrictiveness (Home, ASD-only, Mixed disability, or Inclusion).
Methods: Participants are 115 children with ASD (Mean age = 45.5 months, 80.9% Male, 46.1% Black/African American) that receive intervention services through a public preschool early intervention system. Participants are assessed at study enrollment and 9 months later with a standardized developmental assessment of cognitive and language skills (the Mullen Scales of Early Learning). Parents and teachers also completed questionnaires assessing the child's adaptive behavior and social skills (Adaptive Behavior Assessment System- 2nd Edition; Social Skills Improvement System). Data collection and analysis are ongoing. Preliminary results based on 60 participants are presented below, using repeated measures ANCOVA to assess for changes over time by setting, controlling for baseline differences.
Results: Based on adjusted analyses, groups did not differ in their improvement over time in their cognitive, expressive or receptive language, adaptive behavior, or social skills (all *ps* ³ .3, η_p2s £ .08).
Conclusions: These results suggest preschoolers with ASD on average may make equivalent gains across different types of early intervention settings. These findings provide substance to the argument that inclusive settings are well suited for children with ASD, suggested that children can do as well in inclusive settings as segregated settings. Moderator analyses are planned to assess whether there are child characteristics associated with increased benefit from attending a particular type of setting.

217 **109.217** Child and Parental Factors Associated with Preschool Placement in an Urban Early Intervention Setting

S. R. Crabbe[1]*, A. S. Nahmias*[2]*, H. J. Nuske*[1] *and D. S. Mandell*[1]*, (1)University of Pennsylvania, Philadelphia, PA, (2)University of California Los Angeles, Los Angeles, CA*

Background: Â Federal legislation requires that children with autism be placed in the least restrictive environment appropriate to their needs. Little research has been conducted on the predictors of where children with autism are placed in their early intervention placements. Child and family characteristics such as child age, social skills and Verbal IQ, as well as family income, have been found to predict educational placements in elementary schools; it is not clear if these same factors predict placements in preschools (Lauderdale-Littin, Howell & Blacher, 2013; Harris & Handleman, 2000). Initial findings from qualitative research indicate that inclusive vs. segregated placements is driven by parents' advocacy skills; however no quantitative studies have examined this question (Lalvani, 2012). Understanding of these factors in relation to early intervention settings that vary in their restrictiveness is the critical first step to supporting family and provider partnerships for early intervention planning in the community.
Objectives: Â To examine parent and child characteristics associated with placement in four early intervention settings (autism only, mixed disability, inclusion and home-based services).
Methods: Â Parents and teachers of 77 preschool aged children with ASD receiving early intervention services in Philadelphia (3–5 years, 80% male, 56% African-American) completed questionnaires about children's social skills and problem behaviors (Social Skills Improvement System Rating Scales),Â adaptive behaviors (Adaptive Behavior Assessment System 2nd Edition), cognitive and language development (Mullen Scales of Early Learning; MSEL). Parents also answered questions from the Early Intervention Placement Preference Survey about their perceived advocacy skills and their opinions of the relative benefits of different early intervention placements.
Results:
Data collection and analyses are ongoing. Preliminary analyses show that children in autism-only classrooms had lower adaptive behaviors than those in inclusion or home-based settings (F (3,85)=4.99, *p*=.003). There were no significant differences in problem behaviors and social skills among children in different setting types. Children in inclusive settings had greater expressive language (F (3,99)=4.36, *p*=.006) and receptive language (F(3, 99)=3.62, *p*=.02) than those in mixed disability or autism only settings. Parents of children in inclusion settings were more likely than parents of children in other settings to report that they rely on experts for placement advice (X^2 (12, 77) =23.66, p<.05). This 'expert reliance' was also marginally correlated with whether the parent's placement preference ever matched their actual placement setting (r(74)=.16, p=.09).
Conclusions: Â Results suggest greater adaptive behaviors and language skills are associated with being placed in inclusion preschool settings, which indicates that these child factors may be considered by professionals when placement decisions are made. Results also suggest that parents of children in inclusive settings consult providers in placement decision making more than parents of children in other settings. Though directionality cannot be determined from the current research design, this provides a future research direction to explore. Further analyses will include an extended sample as well as regression analyses to examine specific predictors for placement.

218 **109.218** Impact of Challenging Behavior, Inhibition, and Emotion Regulation Skills on Developmental Outcomes in Preschoolers with Autism

H. J. Nuske[1]*, A. S. Nahmias*[2]*, B. E. Yerys*[3]*, J. R. Bertollo*[3]*, L. Antezana*[4]*, S. R. Crabbe*[1]*, K. Rump*[1] *and D. S. Mandell*[1]*, (1)University of Pennsylvania, Philadelphia, PA, (2)University of California Los Angeles, Los Angeles, CA, (3)The Center for Autism Research/CHOP, Philadelphia, PA, (4)Virginia Tech, Blacksburg, VA*

Background: Three quarters of school-aged children with ASD present with emotional dysregulation and almost two thirds present with challenging behaviors. Decades of research has shown strong associations between emotional dysregulation and challenging behaviors; these behaviors affect academic outcomes in typically developing children and predict teacher burnout. Their effect in academic outcomes in preschoolers with ASD is not yet known.
Objectives: To examine the impact of challenging behaviors (i.e. aggression, bullying) and emotional regulation skills on developmental outcomes in children with ASD
Methods: A total of 44 preschoolers (3-5 years) with ASD receiving community based intervention services participated in the study, data on the first 20 are presented here (data collection is ongoing). Children were given a standardized developmental assessment (the Mullen Scales of Early Learning; Mullen) at baseline and then 9 months later. Teachers completed questionnaires assessing challenging behaviors (the Social Skills Improvement System: Problem Behaviors Scale) and emotional regulation (the Behavior Rating Inventory of Executive Function: Emotional Control scale), and children completed a novel task of "hot" (socio-affective) executive function skills, the Tongue Task. This task measured the time in seconds for which children resisted eating a candy, thus tapping inhibition skills with a rewarding stimulus that should invoke impulsive behavior, which may be relevant for emotion regulation capacity. Multiple linear regression analyses controlling for age and sex were conducted to examine the impact of emotion regulation and hot inhibition on Mullen developmental quotient (DQ) change scores over 9 months.
Results: Â In an adjusted analysis, only teacher-rated emotion regulation was statistically significantly associated with Mullen DQ change scores, *b*Â = .38,Â *t*(17) = 2.34,Â *p*= .03, with more difficulties in emotion regulation at baseline associated with *greater* cognitive and language gains. Hot Inhibition skills were marginally associated with developmental gains, *b* = .44, *t*(17) = 1.91, *p*= .07, such that stronger hot inhibition skills were also associated with greater gains in DQ. Teacher-rated emotion regulation was unrelated to hot inhibition skills (*r*(23) = .10, *p*= .64). Teacher-rated challenging behaviors did not predict developmental outcomes (*p*s > .28).
Conclusions: Results suggest that emotion regulation and hot inhibition skills have parseable moderation effects on cognitive outcomes in preschoolers with autism, with an unexpected negative relationship between emotion regulation and developmental outcomes. As expected, higher hot inhibition skills were related to greater developmental gains which fits with current knowledge on these as prerequisite skills for learning. This pattern of findings is indicative of a potential bootstrapping effect that hot inhibition skills may have on emotion regulation difficulties, to be tested in future research designs. Contrary to research in typical development, in this study challenging behavior did not impact outcomes. Results will be updated to include the final sample.

Poster Session
110 - Social Cognition and Social Behavior I
12:00 PM - 1:40 PM - Golden Gate Ballroom

219 **110.219** Parental Attitudes Towards Touch Screen Device Use in Children with an Autism Spectrum Disorder.

S. M. James[1]*, J. Kaufman*[1]*, C. E. Wood*[1] *and R. Giallo*[2]*, (1)Swinburne University, Melbourne, Australia, (2)Healthy Mothers Healthy Families Research Group, Murdoch Childrens Research Institute, Parkville, Australia*

Background:
Touch screen technology has increased significantly in usage amongst children and adults. Since 2012, families who own a smart phone, tablet and laptop have increased from 26% to 56% (Deloitte Media Consumer Survey, 2016). Parental and educational forums reveal children with Autism Spectrum Disorders (ASD) are amongst the high percentage of touch-screen device users. Despite the growing increase in touch screen use, it is unclear whether children with an ASD are benefitting from using a touch-screen device, e.g. using a touch-screen for socialising, or whether using a touch-screen is having any negative impact on their development, e.g. social isolation.
Mixed reviews on parent forums have indicated there may be a difference in opinion between parents of children with an ASD compared to parents of children who are TD. Therefore, suggesting parents of children with an ASD may be more accustomed to different apps and find more benefits to using touch screen devices that go unnoticed in parents of TD children.
Objectives:
1) Are there differences in attitudes and feelings (e.g. guilt) toward touch screen device use in parents of children with an ASD, compared to parents of children who are typically developing (TD)? If so, what are the nature of these differences?
2)Do parents find touch screen devices are facilitating or interfering with their child's development, such as their social skills?
Methods:
Data were collected from a survey that was advertised through Swinburne University, located in Melbourne, Australia. Situated in the university is a child research centre called the 'BabyLab', and the survey was advertised on the BabyLab webpage, Facebook page and shared by parents through mother and parent- group networks. Parents of children who have an ASD and parents of children who were TD aged between 2-12 years old were invited to participate. Data was collected in Australia, Canada, the UK and the U.S. A total of 203 parents have participated to date.
Results:
Parents of children with an ASD (n=111) reported touch screen devices were helpful in facilitating social, emotional and friendship skills, compared to parents of children who were TD (n=92), and did not report such benefits. A significant effect was found in parents of children with an ASD, who reported feeling less guilt about their child's use of a touch-screen device, when they reported the touch-screen device facilitated with their child's social, emotional, and friendship skills p <.05.
Conclusions:
The data from this survey indicates there are differences in attitudes from parents who have a child with an ASD compared to parents who have a child who is TD and their use of touch-screen devices. These data are important to help guide us in what areas children with an ASD are either benefitting from the use of touch-screen devices, or what could be problematic. With the increasing exposure of touch-screens it is beneficial for parents and practitioners to evaluate how children can be best supported with using such devices considering their high usage in the ASD population.

220 **110.220** Parental and Teacher Reports of Social Skills and Problem Behaviours in Children with Autism Spectrum Disorder

M. Clark[1]*, J. Barbaro*[2] *and C. Dissanayake*[3]*, (1)Kingsbury Drive Bundoora, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, School of Psychology & Public Health, La Trobe University, Melbourne, Australia, (3)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Cross-informant literature suggests that parents and teachers provide unique information on children's social competencies across settings. However, there is also considerable evidence to indicates that these informants often differ in their reports of child behaviours. Parents consistently report more problem behaviours at home in comparisons with teachers, both informants report similar social skills (Achenbach & McConaughy, 1987)
Objectives: This study compared parent (*n*=46) and teacher (*n*=44) ratings of social skills, problem behaviours and peer interaction in a sample of school-aged children with an Autism Spectrum Disorder (ASD). A second objective was to identify which social areas children are reportedly strongest and weakest according to parents and teachers.
Methods: Parents and teachers completed the Social Skills Improvement System (SSIS) to obtain a cross-informant perspective of positive and negative social behaviours. The Penn Interactive Peer Play Scale (PIPPS) was also completed to assess three dimensions of play across settings 'play interaction', 'play disconnection' and 'play disruption'.
Results: As expected, parents reported a higher occurrence of maladaptive behaviours in the home environment. Parent and teacher ratings of social skills were simiar across settings as expected. Parents and teachers also converged on two dimensions of the PIPPS: 'play interaction' and 'play disruption'. A significant difference in reports of 'play disconnection' was evident with parents reporting higher disconnection. Communication was identified as a social strength by both informants. Despite differences in the frequency of problem behaviours, informants agreed that hyperactivity/inattention and externalizing were the most common and challenging behaviours.
Conclusions: Understanding social weaknesses provides a benchmark for tailoring social skills interventions to support these areas of difficulty. Addressing challenging behaviours at school age may minimise subsequent disruption on later development and social engagement during adolescents and adulthood.

221 **110.221** Patterns of Visual Engagement Identify Distinct Subgroups of School-Age Children with ASD

J. R. Yurkovic[1]*, S. Gillespie*[2]*, W. Jones*[3]*, A. Klin*[3] *and S. Shultz*[4]*, (1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: The vast heterogeneity in Autism Spectrum Disorder (ASD) is an obstacle to advancements in identifying and treating causes of the disorder. Eye-tracking measures of atypical visual engagement with the social world—a quantitative metric that captures a defining symptom of the condition – provides a promising means for deriving more homogeneous subgroups (Rice et al., 2012; Campbell et al., 2014). Parsing heterogeneity in ASD by measuring visual scanning during dynamic social scenes may contribute to the identification of intermediate phenotypes for genetics research, and to the development of interventions optimized for individual children.
Objectives: To examine: (1) whether subgroups of children with ASD can be reliably identified based on patterns of variability in social visual engagement; and (2) whether the subgroups differ on standardized measures of social disability.
Methods: A heterogeneous sample of children with ASD (n=178, age=10.51(3.19)) watched age-appropriate, socially-relevant videos while eye-tracking data were collected. Percent fixation on eyes, mouth, body, and object regions was calculated for each child. The Hopkins index was used to assess whether clusters are reliably identifiable by variability in visual scanning. Unsupervised statistical learning methods, including Principal Components Analysis (PCA) and hierarchical clustering, were utilized to visualize and identify clusters of different visual fixation patterns. Analyses were performed on scaled data and inter-observation distances were calculated via Euclidean distances. A three-cluster solution was achieved through hierarchical clustering of fixations to eyes, mouth, body, and object in each participant pair.
Results: The Hopkins Index indicated the clustering tendency as appropriate (0.16<0.5). PCA and hierarchical clustering analyses identified three clusters of children with ASD (Figures 1a & 2b). As expected, ANOVA and post-hoc Tukey analyses revealed significantly different fixation patterns between clusters (Figures1a,2b), with Cluster 1 fixating more on eyes, Cluster 2 on mouths, and Cluster 3 on objects. Children in Cluster 1 had lower Vineland communication scores (p=0.051) compared to Cluster 2, suggesting that higher eye-looking may not be associated with greater adaptive skills in this subgroup of children. Consistent with previous reports that higher mouth fixation is associated with lower social disability (Rice et al., 2012) children in Cluster 2 had significantly lower ADOS symptom severity (p=0.051) than those in Cluster 3, and higher Vineland communication scores (p=0.051) than those in Cluster 1 (Figure 2b). Finally, children in Cluster 3 had higher ADOS symptom severity scores compared to those in Clusters 1 (p=0.098) and 2 (p=0.051), suggesting that high levels of object fixation are associated with greater social disability. Cluster 3 also had a significantly higher proportion of males (p=0.024) than Clusters 1 and 2 (Figure 2a).
Conclusions: Results demonstrate that variability in visual engagement during viewing of dynamic social scenes can be used to identify more homogeneous subgroups of children with ASD. These subgroups displayed distinct patterns of visual attention, and varied by gender and measures of social ability. Future analyses will examine whether the social adaptive value of visual scanning patterns vary for different subgroups of children with ASD, a critical step towards creating interventions optimized to the individual's learning style.

222 **110.222** Perceptions and Experiences of Friendship and Loneliness in Adolescent Males with High Cognitive Ability and Autism Spectrum Disorder

A. Berns[1]*, S. Assouline*[2]*, W. Liu*[1] *and G. Jones*[1]*, (1)University of Iowa, Iowa City, IA, (2)Belin-Blank International Center for Talented and Gifted Education, University of Iowa, Iowa City, IA*

Background: Many high-functioning individuals with autism spectrum disorder (ASD) have a desire for friendships, despite social deficits. In fact, these individuals experience loneliness in adolescence and into adulthood. While youth with high-functioning ASD have demonstrated less mature friendship qualities and motivation for friendship behaviors, no previous research has identified the experiences of loneliness, the friendship qualities and the motivation for friendship behaviors, along with the social deficits of youth with high cognitive ability (IQ > 120) and ASD. These twice exceptional youth have unique experiences, given their high intelligence, which may or may not facilitate their social-emotional functioning.
Objectives: This study identified the perceptions and experiences of friendships and loneliness in twice exceptional adolescent males with high cognitive ability and ASD. Additionally, this study described how friendship quality, motivation for friends, social skills, and intelligence may influence loneliness in these twice exceptional males.
Methods: This study employed a multiple case study design with 10 twice-exceptional adolescent males, ages 13-9 to 18-11, who have high cognitive ability (Full Scale IQ, Verbal IQ, or Perceptual IQ >120) and ASD. Adolescent, parent, and teacher interviews were completed, transcribed, and analyzed using Consensual Qualitative Research (CQR).
Results: Results describe friendship quality for these youth, with particular contributions to current understanding of companionship, security, help, closeness and balance. Findings inform friendship motivation, as well, and etiologies of amotivation are documented. Results indicate positive and negative influences of high intelligence on interpersonal functioning, and immaturity and symptoms of rigidity affecting friendships, as well. Pathway analyses reveal twice-exceptional youth with insecure friendships experience loneliness and introjected motivation for friendships, along with increase in peer dyadic relationships and decrease in loneliness. Those with insecure friendships and perseverative interest in peers also present with suicidal ideation and/or attempts.
Conclusions: Future research should expand the use of individual therapies (i.e., cognitive behavioral therapy for depression) for these twice-exceptional teens, particularly in middle school, with modifications to accommodate difficulties with perseveration on negative emotions, as well as explore coping strategies of engaging with fictional characters when lonely.

223 **110.223** Phenotype and Eye Tracking Heritability in Twin Pairs

M. Reid[1]*, J. N. Constantino*[2]*, A. Klin*[3]*, W. Jones*[3] *and C. Klaiman*[4]*, (1)Marcus Autism Center, Atlanta, GA, (2)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background:
Studying twin pairs can give valuable insight into genetic and environmental factors contributing to Autism Spectrum Disorder (ASD). Studies examining twins indicate about a 70-95% percent concordance rate for autism in monozygotic twins and about 30 percent concordance for dizygotic, same-sex twins (e.g., Hallmayer et al., 2011; Nordenbaek et al., 2014). In addition, symptom severity within twin pairs, based on parent questionnaires, concluded that extreme social and repetitive behavior symptoms of autism had high heritability (Frazier et al., 2014). Quantitative measures for reciprocal social behavior also indicate greater trait concordance for monozygotic twins than dizygotic twins (Marrus et al., 2015).
Objectives:
To investigate in a sample of twins, referred for diagnostic evaluation, whether there is high concordance in directly assessed, phenotypic profiles of monozygotic and dizygotic toddlers.
Methods:
Participants included 8 sets of twins ranging in age from 16 to 35 months (mean=28.75 months; SD=6.57) including 3 sets of monozygotic (MZ) twins and 5 sets of dizygotic (DZ) twins. Participants received a clinical evaluation and underwent an eye tracking session through a research study at the Marcus Autism Center. Diagnostic assessments included the *Mullen Scales of Early Learning and the Autism Diagnostic Observation Schedule, 2nd Edition* (ADOS-2) and a medical/developmental history was collected.
Results:
Of the MZ twins, all pairs were diagnosed with ASD. Of the DZ twins, 3 pairs were diagnosed with ASD, 1 pair with language delay, and one where one twin had no clinical features and the other had a subthreshold developmental delay. There was fair agreement on age of parental reported first concerns for MZ and DZ twins (ICC = 0.49; 0.38, respectively). Strong to almost perfect intraclass agreements, for both MZ and DZ twins on the ADOS-2 were found across total scores (ICC = 0.93; 0.91, respectively), social affect (ICC = 0.72; 0.84, respectively) as well as restricted and repetitive behavior (ICC = 0.85; 0.97, respectively). For the developmental measure, MZ twins had almost perfect and moderate agreement for visual reception and receptive language age equivalents respectively (ICC = 0.91; 0.69). DZ twins had moderate and almost perfect agreement for visual reception and receptive language (ICC = 0.63; 0.81). Expressive language levels showed the greatest heritability, with MZ twins showing strong agreement (ICC = 0.83) and DZ twins showing poor agreement (ICC = 0.29).
Conclusions:
Overall, in this small, pilot sample, we explored various behavioral traits which could shed light on differences in concordance between MZ and DZ twins. Both MZ and DZ twins showed strong agreement on autism symptomatology, precognitive abilities and receptive language. Expressive language skills show the greatest level of concordance, with MZ twins having significantly greater similarities than DZ twins. This language level difference could account for some of the differences we noted in age of first concerns. As our study is longitudinal, we expect to add about 30 more twin pairs to our sample as well as analyze eye-tracking to have another, objective measure to assess for concordance prior to the annual meeting.

224 **110.224** Play Ball!: Long-Term Sports Participation Is Associated with More Behavioral Regulation in Children with Autism Spectrum Disorder

J. N. Phung[1] *and W. A. Goldberg*[2]*, (1)University of California, Irvine, Irvine, CA, (2)Psychology and Social Behavior, University of California, Irvine, Irvine, CA*

Background: Physical activity patterns of children with Autism Spectrum Disorder (ASD) are disorganized and repetitive (i.e., pacing; Bandini et al., 2013). These restricted and repetitive behaviors (RRBs) that make up the diagnostic criteria of ASD have been linked to executive functions (EF), a host of interrelated processes that support behavioral and emotional regulation. RRBs have been associated with poorer behavioral inhibition (Boyd et al., 2009). Challenges in EF are problematic because they hinder daily functioning. Sports team involvement (e.g., baseball) could help increase physical activity and also improve EF. To date, there has been little research linking physical activity and EF in children with ASD. However, studies have documented these associations in children with ADHD. Physical activity lowered compulsive behaviors and improved EF in children with ADHD (Archer & Kostrzewa, 2012). Given these associations, physical activity could also aid in these areas in children with ASD.
Objectives: Â To examine associations between sports participation and executive functioning (behavioral and emotional regulation) in children with ASD.
Methods: Participants were 15 children (8-11 years, *M*=9.7 years, *SD*=1.18; 93% boys) with a clinical diagnosis of ASD (confirmed using the ADOS-2; Lord et al., 2000), and their parents. ADOS-2 comparison scores across modules fell into the "moderate" severity range (*M*=6.6, *SD*=1.45; range 4 to 9). Full-scale IQ scores (WASI-II; Wechsler, 1999) were "low average" (*M*=88.73, *SD*=15.66). Parents reported on whether children participated in organized sports teams and the duration of their participation. Parents also completed the Behavior Rating Inventory of Executive Function (BRIEF; Gioia et al., 2000), the gold standard in measuring multiple domains of EF. For the present study, we examined the behavior regulation (e.g., "Is fidgety") and emotion regulation (e.g., "Mood changes frequently") domains of the BRIEF. Each index had 2 subscales (Behavior Regulation Index (BRI): inhibit and self-monitor; Emotion Regulation Index (ERI): shift and emotional control).
Results: Analyses of covariance were conducted between the duration of sports participation (<1 year, 1-2 years, and 2-3 years) and the four subscales of the two indexes of the BRIEF, controlling for child IQ. The results indicated a difference between the duration of sports participation and self-monitoring (BRI). Posthoc comparisons revealed significant differences between sports participants of <1 year and 2-3 years; children who participated in 2-3 years of sports had significantly higher self-monitoring than children who participated <1 year of sports (Figure 1). No significant effects were observed with the Inhibit subscale (BRI) or with the two ERI subscales.
Conclusions: Associations between long-term sports participation and self-monitoring skills in children with ASD were found. Self-monitoring, or the awareness of the impact of one's own behavior on others (Gioia et al., 2000), in the context of a sports team could influence the outcome of a game (i.e., winning/losing). As such, children who are motivated to help their team win may exert more effort in monitoring their own behaviors, though it is also possible that children who are better at self-monitoring are more likely to pursue sports involvement for a longer duration of time.

225 **110.225** Poor Sleep Quality Is Associated with Discordant Peer Relationships Among Adolescents with Autism Spectrum Disorder

J. N. Phung[1,2] *and W. A. Goldberg*[3]*, (1)University of California Irvine, Irvine, CA, (2)University of California, Irvine, Irvine, CA, (3)Psychology and Social Behavior, University of California, Irvine, Irvine, CA*

Background: Individuals with Autism Spectrum Disorder (ASD) experience impairments in social communication and restricted and repetitive behaviors (RRBs) (Centers for Disease Control, 2016), and these deficits often make it difficult to form and maintain friendships with peers. For example, children with ASD who have deficient verbal abilities have fewer social interactions, have less satisfying relationships with peers, and feel lonelier (Bauminger & Kasari, 2000; Sigman et al., 1999). As children approach adolescence, there is typically a quantitative shift to the majority of leisure time being spent with peers (Larson, 2001), yet this is often not the case for adolescents with ASD, who spend a large amount of time with adults (Orsmond & Kuo, 2011). For individuals with ASD, the consequences of social impairments and compromised relationships may be compounded by other challenges associated with ASD, one of which is poor sleep quality. Between 32% to 71.5% of children and adolescents with ASD experience sleep problems (Deliens et al., 2015). Sleep problems include difficulty falling asleep, inconsistent sleep schedules, insufficient nighttime sleep, and daytime sleepiness that impairs daytime functioning (Goldman et al., 2012). Poor sleep quality and daytime sleepiness are common among adolescents with ASD, and consequences of poor sleep may make social interactions difficult. Connections between sleep quality and social relationships in ASD samples have been understudied.
Objectives: The goal of the present study was to examine the associations between nocturnal sleep problems and daytime sleepiness in relation to the quality of peer relationships among adolescents with and without ASD.
Methods: Participants were community samples of 19 adolescents with ASD (aged 11-20 years, *M*=16.88, *SD*=2.50; 84.2% boys) and 10 neurotypical (NT) adolescents without a family history of ASD (aged 13-18 years, *M*=15.73, *SD*=2.00; 60% boys). Clinical diagnoses for the group with ASD were confirmed using the ADOS-2 (Lord et al., 2012). Adolescents completed questionnaires about closeness and discord in relationships with a same-gender peer, and they reported on sleep-wake problems and daytime sleepiness using the Sleep Habits Survey (SHS; Wolfson & Carskadon, 1998). Adolescents also wore an actigraph sleep watch to bed for 7-nights and kept sleep diaries of bed/wake times.
Results: Pearson correlations revealed significant associations between adolescent-reports of sleep problems and discordant peer relationships; more sleep-wake problems and more daytime sleepiness were associated with more discord with peers in the sample with ASD, but not in the NT sample. The closeness aspect of peer relationships was not significantly associated with sleep quality.
Conclusions: Adolescents' reports of more sleep problems and daytime sleepiness, but not actigraph indicators of sleep, were directly associated with discordant peer relationships. Adolescents who are already challenged in social interactions due to ASD may be especially vulnerable to intense negativity in peer relationships when they also experience poorer nighttime sleep and more daytime sleepiness. NT adolescents may be better able to regulate social interactions despite poor sleep and feeling tired. Conflicts with peers and daytime sleepiness in addition to nighttime sleep quality are important issues for clinicians to address in sleep and behavioral interventions.

226 **110.226** Positive Correlation Between Global and Fine Social Perception in Children with ASD: An Eye-Tracking Study

E. Rechtman[1]*, E. Douard*[1]*, A. Vincon-Leite*[1]*, A. Philippe*[2]*, N. Chabane*[3]*, H. Lemaître*[4]*, J. M. Tacchella*[1]*, F. Brunelle*[1]*, N. Boddaert*[1]*, A. Saitovitch*[1] *and M. Zilbovicius*[1]*, (1)INSERM U1000, Institut Imagine, Paris, France, (2)UMR 1163, Institut Imagine, Paris, France, (3)INSERM U1000, Paris, France, (4)INSERM U1000, Institut Imagine, Université Paris Sud, Paris, France*

Background: Social perception deficits are one of the main clinical characteristics of autism spectrum disorder (ASD). During the last decade, eye-tracking methodology has allowed an objective and quantitative characterization of these deficits.
Objectives: In this study, we aimed to investigate the relationship between two levels of social perception in children with ASD; global social perception, measured using a preferential viewing eye-tracking paradigm (Pierce et al. 2011), and fine social perception, measured using a social scenes eye-tracking paradigm (Saitovitch et al. 2016).
Methods: Twenty-six children with ASD (five girls, age = 10.3 ± 3.3) and thirty-nine typically developing (TD) children (thirteen girls, age = 9.5 ± 2.4) participated in this study. ASD diagnosis was based on DSM-IV-R and ADI-R criteria. Tobii T120 eye-tracker was used to measure gaze behavior during two eye-tracking paradigms: a social scenes paradigm and a preferential viewing paradigm. In the social scenes paradigm, participants were presented with movie fragments displaying social scenes with characters engaged in peer to peer social interactions. The number of fixation to the face and eyes of characters was compared between groups, controlling for gender and age. In the preferential viewing paradigm, participants were presented with a movie consisting of dynamic geometric images (DGI) and dynamic social images (DSI) displayed side-by-side simultaneously on the screen. The number of fixation to the DSI was compared between groups, controlling for gender and age. Finally, a correlation analysis was performed between the number of fixation in the face and eyes of characters in the social scenes paradigm and the number of fixation in the DSI in the preferential viewing paradigm.
Results: In the social scenes paradigm, statistical analysis showed significant reduced fixations to the face ($p < 0.001$) and to the eyes ($p < 0.001$) in ASD group compared to TD group. In the preferential viewing paradigm, significant reduced fixations in DSI was observed in ASD group compared to TD group ($p<0.001$). Correlation analysis showed a significant positive correlation between the number of fixations in the face during the visualization of social scenes and the number of fixations in the DSI in the preferential viewing paradigm ($p<0.05$) in children with ASD. Indeed, ASD children who looked less to the faces of characters were the ones who presented less preference for social movement. No correlation was observed in the TD group.
Conclusions: Taken together, these new results seem to indicate that abnormalities in the global process of preference for social movement over geometric movement would be associated with abnormalities in the process of face perception in ASD. Furthermore, these results may suggest that the more fine and complex social perception deficits in ASD could be predicted by more global social perception deficits.

227 **110.227** Positive, Negative, and Other Emotions in Young Autistic Children: The Importance of Context

C. Jacques[1], *V. Courchesne*[2], *S. Mineau*[3], *C. Cimon-Paquet*[4], *J. Degré-Pelletier*[3], *S. Pelletier*[5], *G. Thermidor*[3], *L. Mottron, M.D.*[3] *and M. Dawson*[6], *(1)Université du Québec en Outaouais, Gatineau, QC, Canada, (2)University of Montreal, Montreal, QC, Canada, (3)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada, (4)Centre d'excellence en Troubles envahissants du développement de l'Université de Montréal (CETEDUM), Gatineau, QC, CANADA, (5)Centre d'excellence en troubles envahissants du développement de l'Université de Montréal, Montréal, QC, Canada, (6)Centre d'excellence en Troubles envahissants du développement de, Montréal, QC, CANADA*

Background: Â Young autistic children are claimed to have excessively negative and dysregulated emotions, with pervasively reduced positive affect (Zwaigenbaum et al., 2013; Hirschler-Guttenberg et al., 2015). However, in preliminary data from the Montreal Stimulating Play Situation (MSPS; Jacques et al., 2015), young autistic and age-matched typical children displayed similar positive and negative emotions. These pilot findings raise questions about the importance of context and about autistic emotions perceived as “unknown” by typical observers (Yirmiya et al., 1989).
Objectives: Â To assess larger groups of age-matched young autistic and typical children with MSPS, and to further document the context of their emotions.
Methods: Â 37 autistic (mean age=45.8 months, SD=10.5; MSEL=74.0, SD=27.7) and 39 typical (mean age=41.1 months, SD=14.1, $p=0.124$; MSEL=103.0, SD=24.8, $p<0.001$) children were assessed with MSPS. Four play periods (free-play 1, semi-free play, semi-structured play, free-play 2) with 40 objects of potential interest to autistic children were filmed by a trained cameraman. Two naïve typical raters coded positive, negative, neutral, and unknown emotions on Observer XT 11©. Duration, frequency, and proportion of children displaying each emotion were analysed for all play periods, and associated with object explorations and repetitive behaviors.
Results: For the full MSPS, there were no significant group differences in frequency, duration, and proportion of children displaying positive, negative, or neutral emotions (p’s>.09). Positive emotions were pervasive and negative emotions rare in both groups. However, emotions coded as unknown were observed in 43.2% of autistic vs 0% of typical children ($p<.001$). Autistic children thus displayed significantly greater frequency (mean=3.5, SD=9.0, $p=.018$) and duration (mean=14s, SD=37s, $p=.019$) of emotions coded as unknown, compared to their complete absence in typical children.
For individual play periods, there were no significant group differences for positive, negative, or neutral emotions (p’s>.12) except in semi-structured play, with greater duration of positive emotions in typical (mean=104s, SD=109s) vs autistic (mean=59s, SD=58s, $p<.05$) children. Unknown emotions were significantly more frequent in autistic children in semi-structured and free-play 2 periods (p’s<.05).
For emotions associated with objects explored by >75% of children, across both groups positive emotions were expressed 18.9-76.9% and negative emotions 0-5.1% of the time, with no significant group differences for any object (p’s>.06). Emotions coded as unknown, unique to autistics, were observed 2.7-13.5% of the time (p’s=.018-.301).
Finally, for emotions in autistic children associated with their most-observed repetitive behaviors, positive emotions were observed during arm movements, hand flapping, and close gaze at objects (16.2%, 24.3%, 16.2% of the time, respectively), as were unknown emotions (8.1%, 5.4%, 5.4%). Negative emotions were not observed during any of these behaviors.
Conclusions: In a novel context of potential interest to them, autistic children expressed many positive and few negative emotions, particularly when exploring objects freely. Characteristically autistic repetitive behaviors co-occurred with positive, not negative, emotions. We did not find evidence of emotional dysregulation in young autistic children, compared to age-matched typical children with significantly higher MSEL scores. Autistic children uniquely expressed a range of emotions coded as unknown, suggesting there is room to improve our understanding of their full emotional repertoire.

228 **110.228** Preliminary Evidence Suggests Specific Impairments in Explicitly-Evoked Social Inferences in Adults and Children with Autism

L. A. Harrison[1,2,3], *R. P. Spunt*[3], *E. Kilroy*[1,2], *A. Concha*[2], *E. J. Goo*[2], *C. Butera*[2], *R. Adolphs*[3] *and L. Aziz-Zadeh*[1,2], *(1)Brain and Creativity Institute, Dornsife College of Letters, Arts and Sciences, University of Southern California, Los Angeles, CA, (2)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)Division of Humanities and Social Sciences, California Institute of Technology, Pasadena, CA*

Background: Difficulties inferring others mental states may underlie social interaction deficits in Autism Spectrum Disorders (ASD). Behavioral studies (Chevallier et al., 2012) suggest that social inference deficits in autism are selective for implicit tasks. When cues are made explicit, people with autism may in fact be able to draw social inferences, but may fail to do so in everyday situations due to other attentional or perceptual shortcomings. Thus therapy may better target these different social cognitive processes.
Objectives: This study had two objectives. The first was to test whether social inference is intact in autism in an explicitly-cued task. If so, we then sought to determine whether this generalizes across two classes of social stimuli: hands and faces. The second objective was to corroborate behavioral findings with preliminary neuroimaging findings to explore whether behavioral similarities or differences between ASD individuals and matched controls are reflected in neural processing.
Methods: Behavioral responses were collected in 20 children (10 ASD) and 41 adults (22 ASD). Neuroimaging data were collected in 16 children (6 ASD) and 23 adults (2 ASD). All ASD subjects' diagnoses were confirmed with the ADOS. The Level of Inference (LOI) task (Spunt & Adolphs, 2014) tested explicitly-cued social inference. The LOI task asks subjects to make yes/no responses to how (low-LOI) and why (high-LOI) questions about pictures of people performing actions. Half of the stimuli featured faces; half hands. Responses were evaluated with respect to normative responses. All imaging data were collected in a 3T scanner. Adults performed the LOI task, while children completed a mentalizing task in which they "thought why" an actor performed an observed action in one of three conditions (emotional and nonemotional expressions, and hand actions).
Results: In the behavioral task, for Why-Hand trials, independent-samples t-tests showed that the percent correct for controls was significantly higher than for ASD subjects for both children ($p=0.019$) and adults ($p=0.002$). No other group effects were observed. Child neuroimaging preliminary results showed largely similar patterns across ASD subjects and controls in whole brain analyses. ROI analyses (independent samples t-tests) showed reduced left IFG activity ($p=0.039$) in the ASD group for non-emotional faces. ASD subjects tended to have less activation ($p=0.078$) in the right TPJ; in controls, LOI Why-Hand accuracy correlated with rTPJ responses to emotional stimuli ($r=0.798$, $p=0.005$) . Adult behavioral performance and brain activation maps were comparable to controls.
Conclusions: With the exception of hand stimuli, preliminary data indicate that both children and adults with autism can accurately perform tasks of explicitly-cued social inference. Small neural activation differences were observed in children, and will be further investigated with larger samples. Future work will explore which compensatory mechanisms might preserve explicit inferences about faces: stimuli with ambiguous facial expressions will test against the hypothesis that valence matching preserves Why-Face accuracy; and LOI and NEPSY-Theory of Mind accuracy will be compared. Our results indicate that to better understand everyday functioning in autism, the field should explore under what conditions implicit and explicit social inferences are impaired.

229 **110.229** Preservation of Emotional Awareness in ASD: A Preliminary Exploration Using the Leas-C

A. Keefer[1,2]*, V. Singh*[1]*, M. G. Pecukonis*[3]*, G. Gauthier*[4]*, S. H. Mostofsky*[1,2] *and R. A. Vasa*[1,2]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins School of Medicine, Baltimore, MD, (3)Department of Psychology, University of Maryland, College Park, MD, (4)Johns Hopkins University, Baltimore, MD*

Background:
Deficits in awareness of one's emotions and those of others are considered a fundamental weakness in ASD (Humphreys et al., 2007), and are a key target of psychosocial treatments for youth with ASD. Yet, hardly any studies characterize emotion awareness in ASD, and results from the extant literature are mixed. Some data show that youth with ASD perform comparably to TD controls when identifying situations associated with specific emotions (Capps et al., 1992), whereas other data indicate that youth with ASD have difficulty identifying emotional blends (e.g., "happy and sad") in emotionally evocative vignettes (Reiffe et al., 2006). The Levels of Emotional Awareness Scale for Children (LEAS-C; Bajgar et al., 2005) assesses a child's awareness of a broad range of emotions in oneself and others when presented with social vignettes. This scale has the potential to provide insight regarding capacity for emotional awareness in this population.
Objectives:
This study examines emotion awareness in ASD by exploring potential differences on the LEAS-C between youth with ASD and TD peers.
Methods:
Ninety-seven participants, 8 to 16 years, were enrolled from ongoing research studies. Two groups of children were examined: children with ASD and TD children without psychopathology. The ASD group was well-characterized using the ADOS-2, ADI-R and WISC-IV (VCI > 70). The LEAS-C was administered, which assesses children's awareness of their own and others' emotions in 12 real-life, social vignettes. The child reads each vignette and then writes the emotions s/he and a character in the story would feel. Time is unlimited. Responses are scored on a 5-point scale: 0 (unable to identify emotions; can identify cognitive states - "I'd feel confused"); 1 (can identify somatic features), 2 (can identify action or general emotional states - "I'd feel upset."), 3 (can identify unidimensional emotions - "I'd feel sad"), 4 (blends of emotions - "I'd feel relieved and disappointed"). A total score rates the emotional complexity of both responses. Group differences were analyzed using independent t-tests, and correlations were examined using Spearman-rank order correlations.
Results:
There were no significant differences between ASD and TD controls on Self [$t(95) = -1.026$, $p=.31$], Other [$t(95) = -1.710$, $p=.09$], or Total [$t(95) = -1.07$, $p=.29$] LEAS-C scores. Both groups averaged scores of "2" and "3" by item, indicating that responses focused on emotion related actions and reporting unidimensional emotions (e.g., "I'd feel sad"). Of note, scores in the TD group were comparable to previous studies using the LEAS-C (Veirman et al., 2011). LEAS-C scores did not correlate with age, gender, or IQ.
Conclusions:
Youth with ASD performed comparably to TD controls on a written measure of emotional awareness. This suggests that youth with ASD have the capacity to identify simple emotions when provided written descriptions and unlimited response time. This capacity, however, might be compromised in real world settings involving fast-paced reciprocal social interactions and reliance on deeper levels of emotional awareness including interoceptive processing. Interventions that can use these strengths to deepen emotional awareness in real world settings will be critical.

230 **110.230** Prevalence and Frequency of Online Sexual Activity in Adults with ASD

S. Nichols[1] *and S. Byers*[2]*, (1)ASPIRE Center for Learning and Development, Melville, NY, (2)Psychology, University of New Brunswick, Fredericton, NB, CANADA*

Background: Researchers have only recently begun to assess a broad range of aspects of the sexual well-being of cognitively able adults with ASD (CA-ASD) using methods that overcame many early limitations (e.g., Byers, Nichols, & Voyer, 2013; Byers, Nichols, Voyer, & Reilly, 2013; Gilmour, Schalomon, & Smith, 2012). The results of these studies paint an overall positive picture for both individuals in and not in a relationship. One area of the sexual functioning of individuals with CA-ASD that has received little attention is use of the Internet to engage in sexuality-related activities. Yet, such activities are very common among neurotypical populations (Carroll et al., 2008; Daneback, Månsson, Ross, & Markham, 2012; Döring, 2012; Shaughnessy, Byers, & Walsh, 2011). Given the social impairments associated with ASD, it is possible that individuals with CA-ASD are more comfortable expressing their sexuality through on-line sexual activities because these activities do not require in-person, real-time interactions.
Objectives:
To determine the extent to which men and women in different age groups with CA-ASD engage in a range of online sexual activities (OSA) including non-arousal OSA (seeking sexual information, chatting), solitary-arousal OSA (S-OSA), and partnered-arousal OSA (P-OSA).
Methods:
Participants were a community sample of 141 men and 190 women (ages 21 – 73 years) with CA-ASDÂ who met cut-off criteria on the Autism Spectrum Quotient (AQ), a brief screening questionnaire designed to measure degree of ASD symptomatology in adults (Baron-Cohen et al., 2001).Â Participants completed an online questionnaire that included measures of ASD symptomatology, and online sexual activity.
Results:
Almost two-thirds of participants had engaged in one or more OSA. The most commonly reported online activities were watching sexually explicit videos (48%), masturbating while doing so (32%), and reading erotic material (32%). 21% of the sample had visited an education or dating website in the previous month; 54% had engaged in at least one S-OSA activity; and, 12% had engaged in at least one P-OSA activity. Significantly more of the men than women had engaged in Information Seeking and S-OSA but the men and women did not differ in their likelihood of having engaged in Chatting or P-OSA Experience. Individuals in their twenties were significantly more likely to have engaged in information seeking (34%) than were those in their 30's 40's, or over 50 (14%, 18%, and 18%, respectively), $X^2 = 11.88$, $p = .008$. The age groups did not differ in their likelihood of having engaged in the other OSAs.
Conclusions:
Most adults with CA-ASD engage in online sexual activity, and for the most part the likelihood of engaging in OSA was the same regardless of age. Men were more likely than women to engage in solitary-arousal activities but not in other forms of OSA. Few participants reported a problematic use pattern suggesting that OSA is generally a positive sexual outlet for adults with CA-ASD. Sexuality education programs are needed that incorporate OSA as a good alternative for some but also teach internet safety and strategies to reduce vulnerability to engaging in illegal OSA.

231 **110.231** Probing Social Motivation Heterogeneity in Young Children

B. Thompson[1], *D. Baron*[2] *and C. Holland*[2], *(1)University of Southern California, Los Angeles, CA, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: There are vast knowledge gaps in understanding neurobiological mechanisms that contribute to the broad heterogeneity seen in social-affective behavior across human populations. This is particularly true for children with neurodevelopmental disorders whereby neural circuitry involving complex mental functions, such as social-affective processing, is disrupted. This processing, which can influence attention, motivation/reward, and emotional regulation, is a difficult construct to test in young children. While it is well documented that children with autism spectrum disorder (ASD) show disruptions in social behaviors, the underlying mechanisms driving those disruptions is less understood. Theories range in explanations that these social deficits arise from a lack of motivation for social interaction, to aversion to social interaction. These knowledge gaps in both understanding and measuring social-affective processes currently limits the design of effective and scalable interventions for improving disrupted social behavior. Strategies and tools are needed to better probe complex internal responses, such as feelings, drives, and motivations independent from language, and to decipher subtle behavioral consequences of these internal responses for low-verbal children including those with neurodevelopmental disorders.
Objectives: There were two goals of this study. The first was to build upon our previously established paradigm of conditioned place preference (CPP) for use in young typically developing (TD) children by adapting the task for use with a social unconditioned stimulus. The second goal was to use the social CPP task to probe whether the social interaction phenotype in children with ASD is due to an *aversion to* social interactions, or alternatively, *a lack of reward from* social interactions.
Methods: Typically developing children and children with ASD aged 36-60 months participated in this social CPP task. The task utilized Pavlovian conditioning methods in which a conditioned stimulus (CS) was repeatedly paired with an unconditioned stimulus (US), which elicited an unconditioned response (UR), and after successful conditioning, the CS elicited a conditioned response (CR) similar to the UR. Using a novel social experimenter as the US, and a custom-designed child-friendly arena, a castle, as the CS, the CS was paired with the US across four conditioning trials and we then measured place preference scores when the US was not present.
Results: Our results demonstrate that TD children display a robust social CPP ($p<0.05$) and that CPP scores correlate with sub-scales of the Mullen Scales of Early Learning. In comparison, the ASD group shows more heterogeneous conditioning scores in the social CPP task, revealing less preference for the social US in our preliminary data.
Conclusions: There is significant heterogeneity in the behavioral characteristics and genetic underpinnings of social behaviors in both TD children and children with ASD. The establishment of reliable and robust behavioral paradigms that can reveal differences in motivation, reward, and aversion for social stimuli, as utilized in this study, promises to transform approaches to assessment and intervention in young or low-verbal children, and to illuminate potential underlying neurobiological mechanisms responsible for the observed heterogeneity. This will allow for more precise interventions to target and reduce core social-affective symptoms of ASD.

232 **110.232** Quantifying the Dynamic of Visual Exploration of Complex Social Scenes in Children with Autism Spectrum Disorder (ASD) without Any a Priori: An Eye-Tracking Study

N. Kojovic[1], *M. Franchini*[2,3], *T. A. Rihs*[4], *R. K. Jan*[4], *H. F. Sperdin*[5], *S. Eliez*[6] *and M. Schaer*[3], *(1)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland, Geneva 1211, Switzerland, (2)Sensorimotor, Affective and Social Development Unit, University of Geneva, Geneva, Switzerland, (3)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland, (4)Functional Brain Mapping Laboratory, Dept. of Fundamental Neuroscience, University Medical school, Geneva, Switzerland, Geneva, Switzerland, (5)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland, Geneva, Switzerland, (6)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland, University of Geneva, Geneva, Switzerland*

Background: Numerous eye-tracking studies using predefined areas of interest (AOIs) have highlighted the atypical visual exploration pattern in individuals with ASD (e.g. tendency to look less at the eyes and faces compared to the group of typically developing (TD) individuals (for a review, see Klin et al. 2003)). The approach using AOIs is highly adapted for addressing specific research questions, like the one of relative dominance between different groups of AOIs (e.g. eyes vs. mouth). However, while it can inform us on what is more attracting for one group/person, it is less suitable for capturing the subtlety of the dynamic of visual exploration employed during viewing naturalistic social interactions, and how visual exploration of such scenes develops and changes with age.
Objectives: Our aim was to develop a method that will be able to define age-appropriate dynamic norms of visual exploration of complex social scenes, based on a group of TD children, for quantitative comparison with children with ASD.
Methods: A 3-minute "Trotro" cartoon was displayed on a Tobii eye-tracker device for 37 ASD males (aged 3.95±1.25) and 28 TD males (aged 3.10±1.30). Inspired by the concept of a *heatmap*, for each frame of the video we intended to create the "normative" gaze pattern distribution. This normative gaze distribution was obtained from TD subjects, employing kernel density distribution estimation on the raw gaze data of TD individual for each frame of the video (Botev et al., 2009). Once the "norm" was defined for each patient we calculated the "distance" of his/hers gaze coordinates form this "norm" in a frame-by-frame manner. For each patient we obtained one measure per frame of *Proximity from the "norm"*, and thus obtained measure was averaged for the duration of the video. Higher values indicate the visual exploration of the individual is being more similar to the one of TD subjects. The proximity measure was further correlated with direct measures of expressive, receptive language, cognition and imitation skills (PEP-3); indirect measures of communication and socialization skills (VABS-II) and severity of autistic symptoms (ADOS-2).
Results: We found positive correlation between proximity from the "norm" and direct measure of verbal & nonverbal cognition (R^2 = 0.19; p =. 008), language understanding (R^2 = 0.18; p =. 01), language expression (R^2 = 0.21; p =. 007) and imitation skills (R^2 = 0.15; p =. 02). We have also observed positive correlation between this measure and indirect measure of communication (R^2 = 0.24; p =. 004) and socialization skills (R^2 = 0.27; p =. 001), as parents reported them. Finally, a tendency toward negative correlation between the proximity from the "norm" and the severity of autistic symptoms was observed (p=. 0507).
Conclusions: Our results suggest that our method can be used as a valid measure for quantifying the dynamic visual exploration of complex social scenes based on a group of TD children, providing an age-appropriate manner to measure deviances in social cognition development in age-matched children with ASD. We further intend to use this measure in a longitudinal design.

233 **110.233** Ratings of Social Difficulties By IQ in Young Adults with ASD

K. Durica[1], *M. Murray*[1] *and A. Pearl*[2], *(1)Penn State College of Medicine, Hershey, PA, (2)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hummesltown, PA*

Background: Autism Spectrum Disorder (ASD) is a persistent and debilitating condition which frequently affects social ability. Despite increases in research examining social skills interventions for children and adolescents with ASD, few studies target social skills interventions for adults with ASD. Better understanding of areas of social deficit based on IQ would be helpful to understand how to design social skills interventions for young adults with ASD.
Objectives: This study examined the differences in self-report and other-report of social responsiveness of young adults with ASD when grouped by IQ.
Methods: Participants included forty-nine adults (77.6% male, 77.6% Caucasian) between the ages of 18- and 35-years-old (M = 23.19, SD = 4.13). Participants were divided into groups based on the median composite IQ score (<100, N = 24; >100, N = 25). Prior to beginning a social skills intervention, composite IQ was estimated using the Kaufman Brief Intelligence Scale, Second Edition (KBIT-2; M = 98.61, SD = 19.89). Participants and their elected reporters (parents or close family members) also each completed the Social Responsiveness Scale, Second Edition (SRS-2). Additionally, the participants completed the Achenbach Adult Self-Report (ASR) and a close family member completed the Achenbach Adult Behavior Checklist (ABCL).
Results: One-way ANOVAs revealed significant differences between the higher and lower IQ groups on the SRS-2 parent-report of social cognition (F=4.04, p = .05), SRS-2 self-report of social motivation (F = 5.91, p = .019), ABCL intrusive subscale (F = 4.15, p = .047), and ASR avoidant personality problems (F = 8.38, p = .006). Participants with higher IQs reported more problems with social motivation and avoidant personality problems, while participants with lower IQs had close family members report more problems with social cognition and intrusive behaviors. A significant correlation (r = .522, p = .007) was found between other- and self-report of social motivation as measured by the SRS-2 for the high IQ group only. A significant correlation (r = .435, p = .034) was found between other-and self-report of social cognition for the low IQ group only.
Conclusions: Participants with higher IQs experience more problems with social motivation (which participants and their elected reporters agreed on) and being avoidant of others, which may be a reflection of their difficulties with social anxiety. Participants with lower IQs experience more problems with social cognition (which participants and their elected reporters agreed on) and not understanding when they are being intrusive (e.g., not recognizing boundaries), which may be a reflection of their difficulties with understanding social cues. This reinforces the concept of having two slightly different tracks of the social skills intervention to give the two IQ groups a different experience that would be geared more toward what would help them succeed in social situations.

234 **110.234** Ratings of Social Difficulties By IQ in Young Adults with Autism Spectrum Disorder

K. C. Durica[1] *and M. Murray*[2], *(1)Penn State Hershey, Hershey, PA, (2)Psychiatry, Penn State College of Medicine, Hershey, PA*

Background: Autism Spectrum Disorder (ASD) is a persistent and debilitating condition which frequently affects social ability. Despite increases in research examining social skills interventions for children and adolescents with ASD, few studies target social skills interventions for adults with ASD. Better understanding of areas of social deficit based on IQ would be helpful to understand how to design social skills interventions for young adults with ASD.
Objectives: This study examined the differences in self-report and other-report of social responsiveness of young adults with ASD when grouped by IQ.
Methods: Participants included forty-nine adults (77.6% male, 77.6% Caucasian) between the ages of 18- and 35-years-old (M = 23.19, SD = 4.13). Participants were divided into groups based on the median composite IQ score (<100, N = 24; >100, N = 25). Prior to beginning a social skills intervention, composite IQ was estimated using the Kaufman Brief Intelligence Scale, Second Edition (KBIT-2; M = 98.61, SD = 19.89). Participants and their elected reporters (parents or close family members) also each completed the Social Responsiveness Scale, Second Edition (SRS-2). Additionally, the participants completed the Achenbach Adult Self-Report (ASR) and a close family member completed the Achenbach Adult Behavior Checklist (ABCL).
Results: One-way ANOVAs revealed significant differences between the higher and lower IQ groups on the SRS-2 parent-report of social cognition (F=4.04, p = .05), SRS-2 self-report of social motivation (F = 5.91, p = .019), ABCL intrusive subscale (F = 4.15, p = .047), and ASR avoidant personality problems (F = 8.38, p = .006). Participants with higher IQs reported more problems with social motivation and avoidant personality problems, while participants with lower IQs had close family members report more problems with social cognition and intrusive behaviors. A significant correlation (r = .522, p = .007) was found between other- and self-report of social motivation as measured by the SRS-2 for the high IQ group only. A significant correlation (r = .435, p = .034) was found between other-and self-report of social cognition for the low IQ group only.
Conclusions: Participants with higher IQs experience more problems with social motivation (which participants and their elected reporters agreed on) and being avoidant of others, which may be a reflection of their difficulties with social anxiety. Participants with lower IQs experience more problems with social cognition (which participants and their elected reporters agreed on) and not understanding when they are being intrusive (e.g., not recognizing boundaries), which may be a reflection of their difficulties with understanding social cues. This reinforces the concept of having two slightly different tracks of the social skills intervention to give the two IQ groups a different experience that would be geared more toward what would help them succeed in social situations.

235 **110.235** Reading Intention in Action: The Case of Autism Spectrum Disorder

C. Ansuini[1], *J. Podda*[1], *F. Battaglia*[2], *A. Cavallo*[3], *A. Koul*[1], *M. Pintaudi*[4], *E. Veneselli*[2,4] *and C. Becchio*[1,3], *(1)C'MON Unit, Istituto Italiano di Tecnologia, Genoa, Italy, (2)Child Neuropsychiatric Unit, G. Gaslini Hospital, Genoa, Italy, (3)Department of Psychology, University of Turin, Turin, Italy, (4)DINOGMI, University of Genoa, Genoa, Italy*

Background: Â Autistic traits span a wide spectrum of behavioral departures from typical function including impairments in communication, presence of restricted behaviors and difficulties in social interaction. It is a common experience that effective interaction with others often relies on the ability to decode others' intention. Recent evidence suggests that individuals with ASD have difficulties in anticipating the subsequent part of an action chain. To note, these anticipation difficulties emerge not only when performing the action (Fabbri-Destro et al., 2009), but also when observing someone else performing it (Cattaneo et al., 2007).
Objectives: Â The aim of the present study was twofold: 1. To test whether ASD children would be able to read someone else's intention from movement kinematics; 2. To test whether ASD children would be better at generating predictions about actions that are similar to their own.
Methods: Â Nineteen high functioning children with ASD (17 boys) as well as 17 TD children (13 boys) matched on age, IQ full scale and handedness participated in the study. The participants with ASD fulfilled DSM-5 (APA, 1994) criteria for autistic disorders. All participants were requested to observe video-clips of a hand reaching and grasping a bottle to either place it into a container or pour its content into a glass. Participants had to identify the intention underlying the observed movement. Crucially, video-clips were edited as to occlude the final part of the action, therefore participants could rely only on visual kinematics of the initial part of the action. To examine whether TD and ASD children use knowledge of their own kinematics to generate predictions, we manipulated the degree of similarity between the kinematics of the observer and the kinematics of the observed agent. Thus, in two separate blocks, we administered video-clips of movements performed by either TD or ASD children. In each block, video-clips for both pouring and placing action (50%-50%) were presented randomly. Block order was counterbalanced across participants. We assessed children's performance using t-tests on signal detection theory measures.
Results: Â The analyses revealed that ASD children's performance was at chance level in identifying the underlying intention. In contrast, a significantly above-chance identification rate was found for TD children (p<.05). Indeed, TD children were able to predict how the action would have unfolded even if presented only with its initial part. When contrasting performance for the two blocks separately, results indicated that neither TD nor ASD children were significantly better in predicting their own compared to others' movement (p_s<.05)
Conclusions: Â Overall, these findings are consistent with the idea that impaired social skills in ASD may - at least partially – be explained by anomalies in intention recognition from movement observation. Further analyses will test whether these anomalies correlate with motor execution abilities or with the severity of social symptoms in the attempt to shed light on the complex relationship between action execution, intention understanding and social skills in autism.

236 **110.236** Reading the Mind in the Eyes: Examining a Large Multicentre Dataset

R. Holt[1], *M. C. Lai*[2], *H. L. Hayward*[3], *E. Loth*[4], *A. N. Ruigrok*[5], *M. V. Lombardo*[5,6], *B. Auyeung*[7], *D. G. Murphy*[8] *and S. Baron-Cohen*[5], *(1)Autism Research Centre, University of Cambridge, Cambridge, UNITED KINGDOM, (2)Psychiatry, University of Toronto, Toronto, ON, CANADA, (3)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)University of Cyprus, Nicosia, Cyprus, (7)University of Edinburgh, Edinburgh, United Kingdom, (8)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Â Difficulties with aspects of social cognitive processing comprise a core symptom of Autism Spectrum Conditions (henceforth autism). Previous studies have identified differences in performance on the 'Reading the Mind in the Eyes' test (Eyes test) in individuals with autism (Baron-Cohen et al 1997, 2001 (JCPP), 2015 (PLoS ONE), Lai et al 2012 (PLoS ONE), Karlan et al 2008 (JADD), Lombardo et al., in press, Scientific Reports).
Objectives: Â Here we present data from the Eyes test collected as part of the EU-AIMS Longitudinal European Autism Project (LEAP), pooling data from 6 study sites. This study aimed to examine: 1) Categorical group differences (autism vs. controls and males vs. females) in performance (accuracy and reaction time). 2) The interaction between diagnosis and sex. 3) The effects of cross-sectional age on task performance. These differences were first considered in the complete sample, and secondly in separate age cohorts of children (6-11 years), adolescents (12-17 years) and adults (18-30 years).
Methods: Participants with a diagnosis of autism aged 6-30 years (N=329; 237 males, 92 females) and age matched typically developing controls (N=264; 174 males, 90 females) completed the Eyes task as part of a battery of cognitive tasks. Three versions of the task were administered using age appropriate mental state words and were translated into the native language of the different participating countries.
Results: Significant differences were identified for task accuracy between the autism and control groups ($F(1,588)=24.24$, $p<.001$, $r=0.2$), with fewer correct responses seen in the autism group. In addition, significant sex differences were identified ($F(1,588)=12.09$, $p=.001$, $r=.14$) with more correct responses seen in females. There was no significant interaction between diagnosis and sex and no differences in reaction time between the groups. A significant correlation was identified between accuracy and age, with an improved performance seen with increasing age ($r=.348$, $p<.001$). When examining the age groups separately, significant differences were identified between the autism and control groups in both the adult ($F(1,228)=6.15$, $p=.014$, $r=.16$) and adolescent ($F(2,203)=17.04$, $p<.001$, $r=.28$) samples, however there was no significant difference in the child group. Significant correlations between task accuracy and age were identified in the child ($r=.279$, $p<.001$) and adolescent groups ($r=.234$, $p=.001$) but were not seen in the adult group.
Conclusions: Performance differences were identified on this task, indicating impairment in complex emotion recognition associated with mental state attribution in individuals with autism. The finding of group differences is consistent with previous work, however in this case no interaction between diagnosis and sex was identified. Task performance was significantly associated with cross-sectional age, demonstrating improvements on the task with increasing age in children and adolescents but not in adults. Future work will examine the longitudinal data from this task to further examine the effect of development on task performance. Future work will also utilize an item level clustering approach to examining the data.

237 **110.237** Recounting Basic and Self-Conscious Emotional Experiences in Children with and without Autism Spectrum Disorders

D. Davidson[1], *E. Hilvert*[2], *J. Sherman*[3], *M. Giordano*[1] *and I. Misiunaite*[1], *(1)Loyola University Chicago, Chicago, IL, (2)Loyola University, Chicago, IL, (3)Psychology, Loyola University Chicago, Chicago, IL*

Background:
The ability to reflect on one's emotional experiences is central to emotional competence. Past research has shown that high-functioning individuals with ASD can discuss their experiences with basic emotions, but struggle with more complex emotions (Losh & Capps, 2006). This has important bearing on social functioning, as complex emotions, particularly self-conscious emotions, facilitate social relationships by motivating us to adhere to social norms (guilt) as well as personal standards (pride).
Objectives:
Most studies have focused on basic emotion processing in ASD using recognition paradigms (Uljarevic & Hamiliton, 2013). The purpose of this research was to examine children's verbal recounting of basic (happy, fear and sad) and self-conscious (pride, guilt, embarrassment) emotions that they have experienced. Relations between ASD symptomatology, Theory of Mind (ToM), cognitive skills, and recounting of emotions were also assessed.
Methods:
Twenty-three children with ASD and 36 neurotypical (NT) children were tested. Table 1 shows significant and non-significant differences between the groups. Children were asked to provide two different personal instances during which they experienced happiness, fear sadness, pride, guilt, and embarrassed emotions. Recounting was interspersed between other tasks not related to this study. Additional measures included ToM (Strange Stories and Faux Pas Detection), Child Autism Rating Scale-2, Social Responsiveness Scale-2, and the Wechsler Abbreviated Scale of Intelliegence-2. Children's recounts were coded using a system to gauge accuracy in responses, whether they included others in their recounts, and features related to specific emotions (e.g., presence of an audience with embarrassment).
Results:
The most compelling findings centered on the number of recounts provided: children with ASD gave significantly fewer recounts of each emotion than NT children, $t(56) = 2.49 – 3.80$, $p < .02$ (Table 2). Additionally, children with ASD gave significantly more recounts of happy, sad and pride experiences than fear, guilt or embarrassed experiences. Language ability, $r(21) < .17$, matrix reasoning, $r(21) < .41$, and FSIQ, $r(21) < .37$, were not related to the number of recounts children with ASD provided. These results correspond to statements made by children with ASD, including "I don't think I have ever felt guilty." or "I can't think of when I felt scared."
However, when providing a recount, children with ASD were strikingly similar to NT children (e.g., no significant differences were found in the accuracy of their recounts).Â Nevertheless, a few differences were found, to the extent that children with ASD made fewer connections to others in their recounts.Â ToM was positively related to number of emotion recounts in the ASD, but not in the NT group.
Conclusions:
The results showed that children with ASD struggled to recount personally experienced episodes of fear, guilt and embarrassment. These findings are consistent with research showing deficits in the understanding of fear (Tell et al., 2014), and research showing that individuals with ASD may be less prone to feelings of guilt (Davidson et al., 2015). These results were not due to differences in language or other intellectual abilities, although ToM skills were related to a number of findings in children with ASD, but not NT children.

238 **110.238** Relationship Between Executive Functioning and Adaptive Functioning within Autism Spectrum Disorder (ASD).

S. Barber[1]*, C. Rhoads*[1]*, M. Frye*[1]*, J. Gerdts*[2]*, A. Wallace*[1] *and R. Bernier*[2]*, (1)University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA*

Background: Autism Spectrum Disorder (ASD) is a heterogeneous disorder with varying abilities across domains such as cognition, executive functioning, and adaptive skills. Cognitive abilities range from impaired to well above average with approximately 31% of diagnosed children having an intellectual disability (ID; Baio, 2014). Deficits in Executive Functioning (EF) are also commonly observed, but EF abilities are varied (Hill, 2004). Prior research has explored the relationship between EF and adaptive functioning in individuals with ASD (McLean, Harrison, Zimak, Joseph, & Morrow, 2014), but there is little literature examining this relationship in individuals with ASD with intellectual impairment. In individuals with ASD and typical cognitive abilities, deficits in the EF skills of metacognition have been associated with deficits in adaptive functioning (Gilotty, Kenworthy, Sirian, Black, & Wagner, 2002). By examining the relationship between EF and adaptive functioning in a population with cognitive deficits, greater understanding of the relationship between EF and adaptive functioning can be gained.
Objectives: To 1) explore the relationship between EF and adaptive functioning in ASD and 2) expand our understanding of this relationship by incorporating children with ASD and cognitive impairment.
Methods: Participants were 82 children who met strict (ADOS, ADI) criteria for ASD participating in a study focused on the biological basis of ASD (64 male, M_{age} = 12.41, range = 5.33-17.67). Forty-six individuals had an IQ of 70 or greater, and 36 individuals had an IQ of less than 70. Correlations were conducted between composites of the BRIEF and the composite and subdomain scores of the VABS. A series of hierarchical linear regressions were also conducted to determine the amount of variance in each of the VABS composite and domain scores that was accounted by IQ, Metacognitive Index (MCI) scores, and Behavior Regulation Index (BRI) scores.
Results: Significant negative correlations were found between the BRI, MCI, and the four VABS measures for individuals with unimpaired cognitive functioning. Within this subgroup, MCI was a significant predictor of VABS Daily Living Skills ($\beta = -.439$, $t(42) = -2.507$, $p < .05$), and BRI was a significant predictor of VABS Composite ($\beta = -.416$, $t(42) = -2.451$, $p < .05$) and Socialization ($\beta = -.569$, $t(42) = -3.410$, $p < .01$). For individuals with IQs less than 70, significant negative correlations were found between the MCI and the VABS Composite, Communication, and Daily Living Skills. However, regression analyses indicated that only IQ significantly predicted performance on the VABS domains in this subgroup.
Conclusions: Â Our results support previous findings indicating that in individuals with ASD and typical cognitive abilities, EF abilities are associated with adaptive skills. However, we found that EF abilities in the realm of behavior regulation were greater predictors of adaptive functioning than metacognitive abilities. While moderate correlations are found between metacognition and adaptive functioning domains in individuals with cognitive impairment, it does not appear that metacognitive abilities are significant predictors of adaptive functioning. Overall, findings suggest that the relationship between EF and adaptive functioning differs in individuals with ASD and cognitive impairment than individuals with ASD with intact cognitive abilities.

239 **110.239** Relationships Between Engagement States and Early Functioning in Children with Autism and Typical Development

A. M. Abdelaziz[1]*, M. Wagner*[2]*, D. A. Fein*[3] *and L. R. Naigles*[3]*, (1)UCONN, Mansfield Center, CT, (2)University of Connecticut, Storrs, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

Background:
In both Typically Developing (TD) children and children with ASD, different engagement types have been found to influence language development (1). For example, Joint Attention (JA) and Supported Joint Engagement (SJE) have been shown to predict later vocabulary (3). More specifically, Bottema-Beutel et al. (2014) reported that after dividing SJE into 'Higher' and 'Lower' only HSJE predicted later social communication and expressive language in children with ASD. However, it is not clear which aspects of SJE are most relevant for language growth, nor whether participation in SJE is uniquely facilitative for children with ASD, as Bottema-Beutel et al., (2014) did not compare SJE and JA, nor did they compare children with ASD and TD children.
Objectives:
We extend the paradigm of Bottema-Beutel et al., (2014) to a new sample of children with ASD, compare them to TD children, and investigate how each of the different engagement states are related to the children's early language scores.
Methods:
Participants include 15 children with ASD (ASD_{MAge}=34.93 months, 12 males), and 15 TD children (TD_{MAage}=19.82 months, 13 males), recorded at 3 visits, 4 months apart, and initially matched on language level (raw scores) ($ASD_{MullenEL}$=16.44(6.22), $TD_{MullenEL}$=20.35(5.70)). Children and caregivers engaged in 30-minute play sessions, which were coded for episode types in two separate waves. First, three types of JA were coded, designated as when the child and caregiver alternated between looking at each other and an object, with the child either responding (RJA) or initiating (IJA), or JA being mutually established (JA). Second, two types of SJE were coded, designated as when the caregiver influenced the child's object play, but the child engaged with the caregiver without visually referencing him/her (1): Higher (HSJE) occurred when the child responded by reciprocating and collaborating with the caregiver and Lower (LSJE) occurred when the child responded without reciprocal or collaborative exchange with the caregiver. A seventh episode type, Passive Attention (PA) was coded when caregivers followed the child's attention with no behavioral response. Correlations were performed between children's durations of engaging in each episode type and their Mullen scores.
Results:
In the TD group, only Expressive language correlated significantly with joint activity; children with higher scores also engaged in longer episodes of JA (r=.5419, p=.0369). In contrast, in the ASD group four significant correlations were obtained: Children with better Receptive language engaged in longer RJA episodes (r=.5697, p=.0335) and shorter LSJE episodes (r=-.5593, p=.0376), and children with better Visual Reception engaged in longer HSJE episodes (r=.6618, p=.0099) and longer RJA episodes (r=.6233, p=.0172).
Conclusions:
These findings demonstrate different patterns of correlations in children with ASD and TD children, with joint activities being related to cognition as well as language in the ASD group but only language in the TD group. We next investigate whether the aspects that predict children's later vocabulary growth will also be different in the 2 groups, and compare which engagement states are predictive of later language development.

240 **110.240** Same Day, Different Gaze: Task Effects on Eye Gaze to Social Stimuli

***J. Mertens**, E. Zane and R. B. Grossman, FACE Lab, Emerson College, Boston, MA*

Background:
Atypical eye gaze is a canonical symptom of Autism Spectrum Disorder (ASD; Kanner, 1943), but attempts to use eye-tracking to analyze aberrant gaze patterns have produced mixed results (Papagiannopoulou et al., 2014). This variability may be due to different task demands, which are known to affect eye-tracking patterns in TD individuals (e.g., Triesch et al., 2003; Radun et al., 2014).
Many passive-listening studies have found that individuals with ASD look less at the eyes of unfamiliar actors than their neurotypical (TD) peers (Klin et al., 2002; Sterling et al., 2008; White, et al., 2015). However, emotion identification tasks often don't show these group effects (Bal, et al., 2010; Sawyer et al., 2012; Spezio et al., 2007). This variability in results may reflect differences between task-driven versus passive gaze in individuals with ASD.
Objectives:
To analyze the effect of task type (passive viewing versus emotion-identification) on eye gaze patterns to social stimuli in children and adolescents with and without ASD.
Methods:
Participants were children and adolescents ages 10-17, 19 with ASD (3 females) and 25 TD controls (8 females), who were not significantly different in language ability as measured by the CELF-5 (ASD M = 113, TD M = 114), IQ as measured by the K-BIT (ASD M = 117, TD M = 107), and gender.
Participants watched videos of human actors while eye gaze was recorded in two separate tasks. During one task, participants passively viewed adolescents talking about their lives. In the other task participants were asked to identify the emotion on a speaker's face.
We calculated emotion-identification accuracy in the second task as well as percent dwell times to the actors' face, eyes, and mouth in both tasks.
Results:
There was a main effect of diagnosis for gaze time to the face, with ASD participants looking less across both studies. We also found a significant interaction of task and diagnosis on gaze to the eye region. Post-hoc tests revealed that participants with ASD looked less to the eye region than TD participants during passive listening. In the emotion identification task, there were no differences in eye gaze or in accuracy rates across groups.
Conclusions:
Participants with ASD looked less at the eyes than their TD peers when passively watching a video, but both groups showed similar gaze patterns during emotion identification from faces. Reduced social motivation among individuals with ASD could explain reduced gaze to the eye region in the passive viewing task. It is possible that this lack of social interest is then overridden by a desire to successfully complete a task (McClelland, 1987), thereby eliminating the group difference in gaze pattern during the emotion identification task. In summary, our analysis shows that gaze patterns of adolescents with ASD to faces can change with the addition of a concrete task demand. Therefore, variability of results in previous eye-tracking studies may reflect effects of the tasks, rather than the natural propensity of individuals with ASD to gaze at faces.

241 **110.241** See No Emo, Hear No Emo, Feel No Emo? the Effect of Seeing Versus Hearing Emotions on Mood in Autism Spectrum Conditions

***D. M. Berry**, Stoke on Trent, Keele University, Staffordshire, England, United Kingdom*

Background: Â Observing an emotional display (e.g. another person laughing) often leads neuro-typical observers to mimic, recognise and 'catch' the underlying emotion themselves, resulting in a subjective change in mood. This emotional contagion is suggested to have evolved as a social mechanism to foster group cohesion by creating a bond between individuals engaged in the shared emotional display (Provine, 2004). Individuals with Autism Spectrum Conditions (ASC) reportedly demonstrate reduced emotional contagion when observing displays of emotions (e.g. Helt et al., 2010), but emotional displays contain visual and auditory information, and it is not yet known whether emotional contagion is driven primarily by visual or auditory sensory processing. Atypical auditory processing been noted previously in individuals with ASC, but contemporary emotion recognition interventions typically focus on visual processing, for example by training participants to read facial expressions. Understanding the relationship between sensory processing and emotion processing could improve emotion interventions for people with ASC.
Objectives: This study aimed to determine whether emotional contagion is driven primarily by hearing or by seeing displays of emotions, and whether this differs in people on the autism spectrum.
Methods: Forty-four adults with ASC and 49 neuro-typical adults participated in the study. Participants watched two video montages of strangers exhibiting realistic displays of emotions: one montage in audio-only format (sound files with a blank visual display) and another in visual-only format (muted video clips). The emotion depicted in the videos was a between-subjects factor, such that half of the participants watched video montages of laughter and half watched video montages of crying. Participants were asked to rate their mood before and after each video montage, so emotional contagion as a result of each video montage could be measured. The items in the mood rating scales were taken from the PANAS (Watson et al., 1988).
Results: Data were subjected to a 2 (Participant group: ASC, Control) x 2 (Sensory information: Audio, Visual) x 2 (Emotional expression: Laughing, Crying) ANOVA. A main effect of Participant group was found, with participants in the ASC group finding the emotions displayed in the videos significantly less contagious than Control participants. A significant interaction was also found between Sensory information and Emotional expression, driven by the absence of emotional contagion when seeing visual-only displays of laughter.
Conclusions: Participants with ASC found emotions less contagious than neuro-typical adults, but the impact of sensory information was the same for both participant groups. Rather, the impact of seeing versus hearing emotions was dependent on the emotion being expressed. Hearing others laughing and crying resulted in comparable emotional contagion, but without sound, the facial expressions involved in laughter failed to trigger any change in mood. Although the nature of contagion is yet to be studied for other emotions, this research suggests the auditory properties of laughter are particularly important for fostering a positive collective mood. This finding has implications for individuals with ASC who block out auditory stimulation in social situations, because this may create another barrier to inclusivity within a social group.

242 **110.242** Self-Perception and Friendship Relationships of Teenagers with High-Functioning Autism in Mainstream High Schools: A France – Quebec Study.

***M. Aubineau**, Université Toulouse Jean Jaurès, Toulouse, France*

Background: For a decade, an increasing number of students diagnosed with ASD (including Asperger syndrome) was able to attend mainstream high schools in both France and Quebec (Cappe, Smoke, & Boujut, 2014; Kalubi, Chatenoud, Guillemette, Larivée, & Leroux, 2015). Over the years, this increasing number of ASD youths has come to represent a greater proportion of all children with special educational needs in regular schools (French Ministry of Education, 2015). However, little is known about how the French and Quebecois teenagers with ASD cope with different aspects of inclusion. For these students, whose inherent difficulties lie in social interaction and communication, taking into account social challenges of mainstreaming experience is essential (Humphrey & Lewis, 2008; O'Hagan & Hebron, 2016).
Objectives: To examine self-perception and friendship relationships in teenagers with ASD attending mainstream high schools in France and Quebec and how these variables influence their experience of school inclusion.
Methods: 23 students with ASD (age range 12 – 16 years) participated in the study. All of them attended high school full-time, in France (n=15) and in Quebec (n=8). Written informed consent was obtained from each participant and his parents. Youths filled out the *Friendship Qualities Scale* (FQS; Bukowski et al. 1994) – 5 dimensions, and the *Self-Perception Profile for Adolescents*(SPPA; Harter, 1988) – 9 dimensions.
Results: Internal coherence of scales was satisfactory in both sets of data (Cronbach α > .70). Cluster analyses identified 3 groups on the FQS scales and 4 groups on the SPPA questionnaire. The FQS clusters were named *socially isolated* (N = 8), *sociable* (N=7) and *average* (N=8). SPPA clusters were labeled *school difficulties* (N=8), *school-work oriented* (N=5), *low self-esteem* (N=4) and *socially performing* (N=6). Cross-tabulation of these profiles revealed that 80% of *school-work oriented* youths considered themselves as *socially isolated*, with low scores in social and friendship self-evaluation. As expected, *sociable* youths did not consider themselves as *isolated.* Youths with *school difficulties* were equally distributed across the 3 self-concept profiles. Despite the identical mean score for *Global Self-Worth* in both *socially performing* and *school-work oriented* groups, the *socially performing*group shows higher mean scores in almost all dimensions measured by FQS and SPPA. This study was part of a larger doctoral research including semi-structured interviews with both teenagers with ASD and their parents, in order to provide a more comprehensive picture of the experience of school inclusion. Analyses of interviews realized with these participants illustrate specific problems of school adjustment as well as factors that facilitate mainstream inclusion for students with ASD.
Conclusions: These results underscore the importance of taking into account diversity in ASD adolescent profiles and social adaptation strategies. Despite the heterogeneity, the data suggest the importance of friendship relationships and their influence on a satisfying self-perception. The diversity of self evaluations of friendships and self concept suggest that self assertion and social skills training focusing on high functioning autistic youth's specific problems in high school mainstream programs might be an important pathway to successful inclusion and academic perseverance.

243 **110.243** Self-Perception of Academic Competency in Autism Spectrum Disorder

***R. Furlano** and E. A. Kelley, Queen's University, Kingston, ON, CANADA*

Background:
Self-perception is the ability to understand and reflect upon one's own competency to perform in the world. Although individuals with ASD struggle with certain areas, these individuals tend to overestimate their abilities when asked about their symptomatology, social functioning, and academic abilities. This lack of awareness may make it difficult for individuals to adjust their behaviours in accordance with feedback, leading to greater impairments over time. While there is a growing body of literature examining overestimations of competency in individuals with ASD, little research has focused on examining how different parameters influence this phenomenon.
Objectives:

1. To examine if self-perception of academic competency in children with ASD differs from typically-developing (TD) controls.
2. To examine if estimations of competency change after providing feedback on a task.Â

Â Methods:
Eighty participants, 40 with ASD and 40 TD controls (age range =10-15 years), will participate. Currently 14 participants with ASD, and 21 TD controls have been tested and data collection will be completed for the conference. Participants complete three conditions of an academic task: 1) Correct: participants are asked how many questions they think they answered correctly, 2) Incorrect: participants are asked how many questions they think they answered incorrectly, 3) Feedback: participants are provided with feedback after each question. Participants are asked how well they think they will do prior to completing the task (pre-prediction) and are asked how they think they did after completing the task (post-performance). Difference scores between actual and predicted performance are used in data analysis.
Results:
Preliminary results suggest that the ASD group ($M_{pre\text{-}prediction}$ = 6.14, $M_{post\text{-}performance}$ = 4.93) tends to overestimate their performance before ($t(33) = 2.31$, $p = .02$) and after ($t(33) = 3.50$, $p = .001$) completing the correct condition compared to TD controls ($M_{pre\text{-}prediction}$ = 3.10, $M_{post\text{-}performance}$ = 1.05). Results also suggest that the ASD group ($M_{pre\text{-}prediction}$ = 4.93, $M_{post\text{-}performance}$ = 5.43) tends to overestimate their performance before ($t(33) = 2.84$, $p = .008$) and after ($t(33) = 4.55$, $p < .001$) completing the incorrect condition compared to TD controls ($M_{pre\text{-}prediction}$ = 1.52, $M_{post\text{-}performance}$ = 1.23). No differences were found between the groups actual performance on all tasks. When comparing the conditions within groups, the ASD group was more accurate on the feedback condition ($M_{post\text{-}performance}$ = 2.29) compared to the correct ($t(13) = 3.58$, $p = .003$) and incorrect ($t(13) = 2.76$, $p = .016$) conditions. No differences were found between the feedback ($M_{post\text{-}performance}$ = 0.65) and the correct and incorrect conditions in the TD group.
Conclusions:
Examining how different parameters affect how children with ASD self-evaluate will further our understanding of mechanisms underlying this phenomenon. Preliminary results suggest that children with ASD tend to overestimate their competencies before and after completing objective tasks. The findings also suggest that the ASD group's estimation of competency is more accurate after receiving feedback on the task. A greater understanding of these mechanisms will not only help us understand more about the development of self-perception in ASD but about this population in general.

244 **110.244** Self-Regulation Strategies during a Delay of Gratification Task: Group Differences in Children with ASD and Typical Development

E. A. Bisi, *E. F. Geib, B. J. Wilson, R. N. Bassett and S. R. Payne, Seattle Pacific University, Seattle, WA*

Background:
Significant research with children with typical development (TD) has shown that the ability to delay gratification predicts positive outcomes such as improved school readiness and better social adaptation (Feldman & Klein, 2003; Mischel, Shoda, & Peake, 1988). Certain strategies involving self-distraction such as gaze aversion have been shown to facilitate children's ability to wait for a reward on the Delay of Gratification task (DoG; Cournoyer & Trudel, 1991; Mischel et al., 1988), a seven-minute assessment in which children are challenged to postpone immediate gratification in favor of a larger, more desirable reward. In contrast, temptation behaviors, including direct gaze toward and touching the reward, can interfere with successful performance on this task (Ostfeld-Etzion et al., 2015). Although one prior study found 6-7 year old children with autism spectrum disorder (ASD) were less able to delay gratification (Faja & Dawson, 2015), no research has investigated the self-regulation and temptation behaviors used during the DoG by these children.
Objectives:
One purpose of our study was to assess group differences (ASD vs. TD) in the ability to delay gratification using a young sample of children. We also wanted to investigate group differences in children's self-regulation strategies and engagement in temptation behaviors during this task by children with autism and typical development.
Methods:
Our sample included 104 children (ages 3:0 to 6:11), 57 (46% female) with TD and 47 children with ASD (17% female). Children completed a seven-minute Delay of Gratification task developed by Walter Mischel (1988) in a laboratory setting. Videotapes of the task were coded for total wait time, self-regulatory behaviors, which included gaze aversion, kinetic movement, and verbal mediation, and temptation behaviors including direct gaze and touching the food reward.Â Total wait time was used as an index of children's ability to delay gratification.
Results:
Using independent samples *t*-tests to assess group differences (ASD vs. TD) related to the DoG, we found ASD children had shorter wait times than children with TD ($t = -2.13$, $p = .03$). There were no significant group differences in percentage of time using any individual self-regulatory strategy: gaze aversion ($t = -.83$, $p = .41$), kinetic movement ($t = .67$, $p = .53$), and verbal mediation ($t = .15$, $p = .88$). However, children with autism spent a higher percentage of time engaged in touching behaviors ($t = 2.78$, $p = .007$) compared to their TD peers (see Table 1).
Conclusions:
These results support prior research on the reduced ability to delay gratification in children with ASD and extend this research to a younger sample. We also found that the time spent in self-regulation strategies by children with ASD did not differ significantly from their typically developing peers. However, children on the autism spectrum spent more time engaging in temptation behaviors such as touching the reward. We know of no other research that has investigated the unique behaviors of children with ASD during the DoG task. Future research should investigate whether specific self-regulatory behaviors are effective in helping these children successfully complete this task.

245 **110.245** Sequential Associations Between Caregiver Talk and Child Play in Autism Spectrum Disorder and Typical Development

K. Bottema-Beutel[1], *C. Malloy*[2], *B. Lloyd*[3], *L. Joffe Nelson*[4], *P. J. Yoder*[5] *and L. R. Watson*[6], *(1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Boston College, Chestnut Hill, MA, (3)Special Education, Vanderbilt University, Nashville, TN, (4)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA, (5)Vanderbilt University, Nashville, TN, (6)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: In the early phases of development, caregiver-child play often involves caregiver talk about children's play (McDuffie & Yoder, 2010; Siller & Sigman, 2008). Although originally studied to facilitate language, these types of utterances might elicit particular types of child play and visa versa. When children play at their most developmentally advanced level, this may prompt the caregiver to provide yet more talk related to the play experience, in a mutually reinforcing manner (Alessandri, 1992). These contingencies may be especially important to understand in children with autism spectrum disorder (ASD), to better support caregiver-child interactions within play contexts. We focused on two main types of caregiver talk: responsive talk that relates to the child's current focus of attention, termed *follow-in utterances*; and utterances that relate to the caregiver's focus of attention and *not* the child's focus of attention, termed *caregiver-focused* utterances. Follow-in utterances can be further parsed into *follow-in directives*; those that suggest or direct the child to do something different with a toy the child is already playing with, and *follow-in comments*; those that describe the state of affairs regarding the toy the child is already playing with but do not suggest or direct the child to do something new.
Objectives: Â To determine whether: (a) child functional play is more likely to elicit caregiver follow-in utterances than exploratory play, (b) follow-in utterances are more likely to elicit functional play than caregiver-focused utterances, (c) follow-in comments are more likely to elicit functional play than follow-in directives, and (d) any of the above sequential associations differed for children with ASD as compared to TD children.
Methods: Fifty children with ASD and 48 TD children who were group-wise matched on mental age (mean mental age ≈ 14 months across groups) were recorded during a free play interaction. Recordings were coded for caregiver talk and child play using 5 s partial-interval sampling. Sequential analysis methods were used to answer research questions. An index of sequential association was used as a dependent variable in mixed-effects models to account for nesting of behavioral sequences within caregiver-child dyads. Chronological age was used as a control variable in each mode.
Results: Analyses showed sequential associations between child play and caregiver follow-in utterances were stronger in the ASD group than the TD group, but did not differ according to play type. Follow-in utterances elicited functional play while caregiver-focused utterances had an inhibitory effect, and this distinction was more prominent for the ASD group than the TD group (Figure 1). Finally, across both groups of children, follow-in directives were more likely than follow-in comments to elicit functional play (Figure 2).
Conclusions: Our results indicate that, more so than TD caregivers, caregivers of children with ASD time their utterances to follow child play. Also, children with ASD may be particularly likely to benefit from caregiver's follow-in talk when engaging with toy play. Our findings also invite a reappraisal of the role of directives (previously considered 'asynchronous) in caregiver-child play, given our findings that follow-in directives elicit developmentally high-level play.

246 **110.246** Shared Mechanism for Emotion Processing in Adolescents with and without Autism

C. Ioannou[1]*, M. El Zein*[1]*, V. Wyart*[1]*, I. Scheid*[2]*, F. Amsellem*[3]*, R. Delorme*[3]*, C. Chevallier*[1] *and J. Grèzes*[1]*, (1)Ecole Normale Supérieure, Paris, France, (2)Robert Debre University Hospital, Paris, France, (3)Institut Pasteur, Paris, France*

Background:
Autism spectrum disorders (ASD) are characterised by significant deficits in social interaction and communication skills. Atypicalities in the affective domain are central to ASD and research suggests that individuals with ASD react to social cues differently from typically developing (TD) individuals. The roots of such difficulties are still debated but it has been suggested that difficulties in processing emotional cues play an important role in these social deficits. This hypothesis has led to a considerable amount of work pointing to emotion recognition difficulties, yet, a number of studies have found that people with ASD do recognise emotions accurately.
Objectives:
Here, we shift the focus to ask whether the *mechanisms*behind emotion processing are the same in ASD, irrespective of potential differences in accuracy between ASD and TD groups. To do so, we focus on the contextual impact of gaze on emotion recognition for two reasons: Firstly, we know that neurotypical adults better decode and rate as more intense anger paired with direct gaze and fear when coupled with averted gaze (labelled here Threat+), as compared to the other emotion-gaze combinations (threat-), and secondly, because it is theoretically possible to distinguish different mechanisms that may affect the integration of these social cues, using model-based analyses of participants' accuracy.
Methods:
20 adolescents (12-17 yrs) with ASD and 20 age-, gender-, IQ- matched TD controls participated in a two-choice emotion categorisation task (fear or anger). In each trial, participants were presented with a facial expression of anger or fear of varying intensity (7 levels of emotion strength), paired with direct or averted gaze, for 250ms, and had to categorise the expressed emotion (4 second response window).
To identify the computational mechanisms accounting for the influence of gaze direction on emotion categorization, we compared two models: model 1, where gaze direction would bias responses towards Threat+ combinations and model 2, where gaze direction would enhance the perceptual sensitivity to Threat+ combinations. We used Bayesian model selection and calculated the Bayesian information criterion (BIC) to determine which of the two models was more likely to explain the observed data.
Results:
Behavioural data revealed that the ASD group displayed lower overall performance (TD:86%; ASD:82%). Yet, gaze direction had a similar impact on emotion categorisation in both groups, i.e. improved accuracy for Threat+ combinations (figure 1a). Critically, computational modelling of participants' behaviour reveals that the same mechanism, i.e. increased perceptual sensitivity, underlies the contextual impact of gaze direction in both groups (figure 1b).
Conclusions:
Adolescents with ASD, while being overall less accurate in emotion recognition, are able to integrate gaze direction with facial expressions of emotion similarly to TD adolescents. Importantly, the mechanisms behind such integration are the same as in both TD adolescents and neurotypical adults (El Zein et al., 2015). We discuss the specific experimental conditions that may favour emotion processing and the automatic integration of contextual information in ASD.

247 **110.247** Shared Zones and Autism Spectrum Disorder

G. Cowan[1]*, R. Earl*[1]*, M. Falkmer*[2]*, **S. J. Girdler***[1]*, S. L. Morris*[3] *and T. Falkmer*[1]*, (1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Physiotherapy and Exercise Science, Curtin University, Perth, Australia*

Background: Shared zones present an alternative means of calming traffic whilst promoting active travel, and social civic engagement. Shared zones are characterized by the removal of markers traditionally delineating the road and footpath. They are regulated by basic traffic rules with design features encouraging informal social interactions between users to promote safe behaviours. Safe negotiation of a shared zone relies on an individual's ability to rapidly scan, assess and respond to ambiguous social stimuli. This ability may be impacted by impairments in cognitive processing, such as autism spectrum disorders (ASD), potentially compromising the safety of vulnerable users. There is a paucity of research examining the impact of shared zones on the visual scanning patterns of pedestrians with and without social difficulties.
Objectives: Â To compare the visual scanning patterns of pedestrians with and without ASD when crossing a shared zone, benchmarked against traditionally marked pedestrian crossings (zebra crossings).
Methods: Head-mounted eye-trackers were used to record participants' eye movements as they completed a series of crossings across in a shared zone and a zebra crossing. Eye movements were measured as number of fixations, fixation duration and location relative to predetermined areas of interest (AOI). AOIs were categorised as traffic relevant and not-traffic relevant. The eye movements of 40 adult pedestrians, 19 with ASD and 21 typically developing, were successfully recorded.
Results: A total of 3,287 fixations were analysed. The eye tracking data revealed that all pedestrians were less likely to look at traffic relevant objects in the shared zone (47.1%) compared to the zebra crossing (59.1%). There was no between group difference in relation to fixations on traffic relevant versus not traffic relevant objects between pedestrians with ASD and the control group. Pedestrians with ASD did, however, have 16msec shorter median fixation durations overall compared to the control groupÂ ($p<0.001$). The total number of fixations with eye contact were miniscule across both groups, showing no difference between the groups, neither in the shared zone, nor at the zebra crossing.
Conclusions: It has been proposed that shared zones increase the attention and care taken by users. However, both groups fixated more on traffic relevant objects at a zebra crossing suggesting that zebra crossings cue pedestrians to attend to traffic relevant objects to a higher degree than a shared zone regardless of impairments in cognitive processing. The clear lack of difference in visual scan patterns between the groups indicated that participants with ASD were no more at risk in the shared zone than pedestrians without ASD. Observed between group differences in fixation durations, with pedestrians with ASD exhibiting shorter fixation durations overall, suggest that those with ASD processed visual stimuli more rapidly or inadequately in comparison to their typically developed peers. This finding requires further investigation. Finally, the few fixations that could be classified as eye contact across both groups, potentially challenge the idea that shared zones increase social interaction between road users.

248 **110.248** Social Cognitive Profiles of Adults with Autism and Schizophrenia

N. J. Sasson[1]*, K. E. Morrison*[2] *and A. Pinkham*[2]*, (1)University of Texas at Dallas, Richardson, TX, (2)The University of Texas at Dallas, Richardson, TX*

Background: Severe social dysfunction is the principal impediment reducing quality of life and social outcomes in adults with autism spectrum disorder (ASD) and schizophrenia (SCZ). Investigations of the mechanisms underlying social dysfunction in SCZ and ASD have focused on impaired social cognition, and recent genetic, behavioral, and neuroimaging data suggest substantial overlap in the social cognitive phenotypes in the two disorders.
Objectives: No study to date has systematically examined social cognitive profiles in ASD and SCZ to elucidate patterns of similarity and distinction. Delineating patterns within matched samples on a common set of standardized tasks assessing multiple domains of social cognition is imperative for identifying areas of convergence and divergence that can inform treatment efforts for each disorder.
Methods: Adults with ASD (n=79), SCZ (n=95), and typically-developing (TD) individuals (n=128) completed eight tasks spanning 4 domains of social cognition: A) attribution style/bias was evaluated with the Ambiguous Intentions and Hostility Questionnaire (AIHQ); B) emotion recognition was assessed with the Bell Lysaker Emotion Recognition Task and the Penn Emotion Recognition Test; C) social perception was measured with the Relationships Across Domains test; d) mental state attribution was assessed with the Reading the Mind in the Eyes Test, The Awareness of Social Inferences Test, Part III, (TASIT), and the Hinting Task. Participants also completed the Trustworthiness Task, which does not fall cleanly into the four domains.
Results: Â The groups were comparable on IQ (group mean range: 102.07–105.30; p=.11), but differed on gender (90% male in ASD, 80% in TD, 74% in SCZ; p=.048), age (group mean range: 23.61-26.97; p<.01), and ethnicity (90% Caucasian in ASD, 76% TD, 64% SCZ; p<.01). Gender, age, and ethnicity were covaried in analyses.
A MANOVA of the group differences was significant, $F(16,564)=7.10$, p<.001, and follow up one-way ANOVAs indicated significant differences between the groups on all tests (*p's*<.04). TD individuals scored significantly higher than both clinical groups on emotion recognition, social perception, and mental state attribution tasks (*p's*<.001). TD individuals rated faces significantly more trustworthy than SCZ (p=.04), but not ASD individuals (p=.53). On the AIHQ, TD individuals trended towards significance compared to the SCZ group (p=.08), with the SCZ group rating more bias to blame others, but did not differ compared to the ASD group (p=.99)
When directly compared, the ASD and SCZ groups performed significantly different on TASIT (p=.01) and approached significance on the AIHQ (p=.06). The ASD group was less accurate in detecting lies and sarcasm, and individuals with SCZ showed a stronger attribution bias to blame others for negative outcomes. The clinical groups did not differ from each other on the other social cognitive tasks (*p's*>.50).
Conclusions: Although individuals with ASD and SCZ shareÂ significant social cognitive impairments, they also exhibit some disorder-specific distinctions, including a greater hostility bias in SCZ and reduced ability to detect lies and sarcasm in ASD. These may contribute to social dysfunction in unique ways, and treatment efforts may benefit from targeting these different profiles to improve quality of life and outcomes for adults with these disorders.

249 **110.249** Social Discounting in Autism Spectrum Disorder

K. R. Warnell[1]*, S. Maniscalco*[2]*, L. Hotz*[3]*, S. Baker*[4]*, L. C. Anderson*[2]*, H. Milhorn*[5]*, M. G. Pecukonis*[2]*, E. Sadikova*[2]*, R. Yi*[5] *and E. Redcay*[2]*, (1)Department of Psychology, Texas State University, San Marcos, TX, (2)Department of Psychology, University of Maryland, College Park, MD, (3)New York City Department of Health and Mental Hygiene, New York City, NY, (4)Department of Psychology and Neuroscience, University of North Carolina at Chapel Hill, Chapel Hil, NC, (5)Department of Health Education and Behavior, University of Florida, Gainesville, FL*

Background: In social discounting tasks, participants choose between a smaller monetary reward for themselves versus a larger reward for partners of varied social distance (e.g., a sibling versus an acquaintance; Jones & Rachlin, 2006).Â Participants' choices thus implicitly measure the subjective value of rewards given to others, capturing constructs such as social closeness or perspective taking. Indeed, variability in social discounting has been linked to externalizing disorders (Sharp et al., 2012), episodic thinking (Yi et al., 2016), and empathy (Olson et al., 2016). Quantifying social discounting rates in ASD may help explain and predict relationships with close and distant others, but, to date, no research has examined social discounting in autism.
Objectives: To assess social discounting in adolescents and adults with ASD.
Methods: Forty-four typical individuals (16 males, average age=20.23 years) and sixteen individuals with ASD (13 males, average age=20.08 years) participated. We also analyzed data from a subset of 16 typical participants matched on age, sex, and verbal IQ. Participants were first told to list four individuals that they knew personally: Partner 1 was the person they were closest to; Partner 2 was someone else they knew well; Partner 3 was a person they knew a little; and Partner 4 was a person who they would recognize, but did not know well. Participants then completed a computerized social discounting task for each partner, understanding the task to be hypothetical. On each of six trials, participants chose between $100 for their partner versus a lower variable amount (titrated between $1.57 and $98.44) for themselves (Figure 1). This algorithm revealed the value at which the participant considered a reward to him or herself to be equal to giving $100 to the partner. Lower values corresponded to increased discounting (e.g., valuing others' rewards less).Â As a control, participants completed a delay discounting task, in which they chose between receiving $100 at a future time point versus receiving a lower amount today. This ensured that effects were not driven by task comprehension, general discounting, or understanding of money.
Results: A repeated-measures ANOVA examining social discounting found a main effect of group membership, with ASD participants showing increased discounting. The interaction between group membership and social partner level was also significant (p=.041; Figure 2); ASD participants showed no difference in discounting for Partner 1, but increased discounting for more distant partners (i.e., showed less value for rewards given to these social partners; Partner 2, p=.002; Partner 4, p=.062). Delay discounting also revealed a main effect of group (p=.008), but no interaction between group and time point. Across both tasks, trends were similar but not significant for the matched typical group.
Conclusions: Overall, individuals with ASD showed no difference in social discounting for their closest social partner, but did show quicker drop-offs in the value of rewards given to individuals outside of this most intimate relationship. Additional data are being collected to examine the relation between social discounting and social cognitive abilities, to better assess the causes and consequences of social discounting.

250 **110.250** Social Inclusion of Children with ASD Who Have Moderate to Severe Intellectual Disabilities

A. Porthukaran[1], *J. M. Bebko*[2], *A. Perry*[3] *and B. L. Ncube*[4], *(1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, CANADA, (3)Psychology, York University, Toronto, ON, CANADA, (4)York University, York, ON, CANADA*

Background: For children with moderate to severe intellectual disabilities (ID), there are often barriers to participating in social situations. This issue may be particularly salient in those children who additionally have a diagnosis of autism spectrum disorders (ASD). Research has shown that children with ASD have fewer friends, are invited less frequently to peer events and generally experience more instances of exclusion than typically developing peers. However, among children with ASD with co-morbid ID, it is difficult to know whether the social isolation experienced derives from intellectual disability or whether the impairment in social skills found in ASD further exacerbates this issue. Although efforts are made by teachers and parents to integrate children with ASD in these situations, understanding the social needs and experiences of children with ASD, over and above those with moderate to severe intellectual disabilities, may allow for true inclusion in schools and the community.
Objectives: In this study, children with ID with and without ASD were observed at a social, community (e..g, sports, scouts) or school setting (i.e. at recess or during gym class) with a coding scheme designed for behavior observed. We measured the available opportunities for interaction and the rate of actual interactions "in situ", in order to assess the inclusion of these children in activities with peers and adults to determine the differential experiences of children with ASD and those without.
Methods: 10 children with ASD and ID and 13 children with an ID (ranging from 6.6 to 17.5 years of age; median IQ = 38.68) were observed in unstructured social settings. Total number of available interactions (defined as another person being in close proximity, or within 2 meters, during a social event), total interactions (spoken, play, physical contact, etc.) and who the interaction was with (typically developing peer, peer with a developmental disability or adult). To standardize for differences in observation length, all available opportunities and interactions were calculated as rates per 15 minutes.
Results: There was no difference between the ID and the ASD + ID groups in the overall proportions of interactions ($p > 0.05$). However, children with ASD + ID had fewer interactions with peers who had developmental disabilities (13% of available opportunities) compared with children with just ID (36%), $t(45) = 2.80$, $p < 0.01$). Within the ASD group, adults had significantly more frequent interactions (33% of available opportunities compared to 13%) than children with developmental disabilities ($t(37) = 2.35$, $p = 0.02$).
Conclusions: These results indicate that children with ASD and ID have fewer social interactions with children with developmental disabilities than children with ID alone in unstructured social situations. This lack of interaction with this key group of peers who face similar barriers can exacerbate the isolation experienced by children with ASD. Also, the increased interactions with adults compared to this group, may give caregivers a false impression of social inclusion. Further analyses examining differences in the proportion of interactions within groups, and relations to social and adaptive measures are ongoing.

251 **110.251** Social Pupillary Response in Children and Adolescents with Autism Spectrum Disorder

J. L. Guilfoyle[1], *L. N. Mooney*[1], *M. P. Hong*[1], *E. Pedapati*[2], *L. K. Wink*[3], *K. C. Dominick*[4], *R. Shaffer*[5] *and* ***C. A. Erickson***[3], *(1)Psychiatry, Cincinnati Childrens Hospital, Cincinnati, OH, (2)INSAR Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Division of Psychiatry, Cincinnati Children's Hospital Medical Center, CINCINNATI, OH, (5)Cincinnati Children's Hospital Medical Center, Harrison, OH*

Background: The neural mechanisms underlying autism spectrum disorder (ASD) have been found to vary significantly across the life span. For example, prior research has shown enlarged brain volume and neuronal overgrowth in individuals with autism up until they hit adolescence when abnormal degeneration occurs (1,3). Eye tracking and pupillometry have been used extensively in studies of social processing and autonomic response in ASD (2,6) and allow further investigation into the age-specific neurophysiologic differences associated with the progression of autism.
Objectives: The primary aim of this study was to utilize pupillary response to visual stimuli as a way to explore potential age-specific social processing abnormalities associated with ASD.
Methods: Individuals between the ages of 5 and 30 with a clinical diagnosis of ASD and age- and gender-matched typically developing controls (TDC) were recruited at Indiana University. Participants viewed a 60-second, side-by-side social scenes and geometric patterns eye tracking paradigm similar to those used in previous studies of social processing in ASD (4,5). The primary measures were average and maximum Social to Geometric Pupil Ratio ($SGPR_{avg}$, $SGPR_{max}$). All ASD participants underwent a battery of psychological testing and caregiver behavioral evaluations. Participants were further grouped into adolescent and child cohorts depending on whether they were older or younger than 12 years old.
Results: Thirty-seven ASD and twenty-six TDC provided evaluable pupillometry data. There was no difference between ASD and TDC individuals in pupillary measures nor was there a correlation between pupillary measures and age. Notably, there was a statistically significant interaction between ASD vs. TDC and adolescent vs. child on $SGPR_{avg}$ [$F(1, 63)=4.349$, $p=0.042$] with the child ASD group having an elevated social pupillary response and the adolescent ASD group having a decreased response compared to TDC.
Conclusions: The interaction between ASD vs. TDC and adolescent vs. child on social pupillary response indicates that changes in adolescence may have an effect on social responsiveness in individuals with ASD. Further investigation into the age-specific neural mechanisms underlying social processing in ASD is required.

252 **110.252** Social Visual Engagement during Dyadic Interaction in Infants with and without ASD

I. Stallworthy[1], *S. Glazer*[2], *P. Lewis*[1], *A. Klin*[3], *S. Shultz*[4] *and W. Jones*[3], *(1)Marcus Autism Center, Atlanta, GA, (2)University of Texas M.D. Anderson Cancer Center, Houston, TX, (3)Marcus Autism Center, Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background:
Infant-caregiver interactions are both the platform and the catalyst for subsequent development, as mutually-adapted infant and caregiver behaviors create cycles of contingency that scaffold infants' emerging abilities and facilitate further interaction (Fogel & Thelen, 1987). Given the importance of contingent social interaction in guiding typical development, this study investigates whether infants with Autism Spectrum Disorder (ASD) are sensitive to two critical aspects of social experience—contingency and familiarity—within the context of face-to-face dyadic interactions. Identifying aspects of early social experience that are disrupted in ASD may provide an early diagnostic marker of the condition, and may also inform our understanding of the developmental processes through which early atypical experiences culminate in symptoms of ASD.
Objectives:
This study examines sensitivity to social contingency and familiarity in typically developing (TD) infants and those with ASD by measuring infant social visual engagement with: (1) a *familiar* social partner interacting with them *contingently,* (2) a *familiar* social partner interacting with them *non-contingently*, and (3) an *unfamiliar* social partner engaging with them *non-contingently.*
Methods:
Participants were 2-5-month-old typically developing infants (typical outcomes confirmed at 24 months; n=14, mean age=4.40(0.23) months, 7 female), and 2-5-month-old infants with ASD (data collected prospectively, prior to diagnosis; diagnostic ascertainment performed at 24 months; n=8, mean age=4.33(0.20) months, 1 female). Eye-tracking and video data were collected monthly between 2 and 6 months while infants viewed: (1) a closed-circuit live video feed of their caregiver (*familiar/contingent*, Figure 1A); (2) pre-recorded clips of their caregiver (*familiar/non-contingent*); and (3) pre-recoded clips of unfamiliar actresses (*unfamiliar/non-contingent*) (Figure 1B). Regions of interest were coded in each video, and percentage of fixation time on eyes was compared between groups and conditions.
Results:
Consistent with prior analyses (Jones & Klin, 2013), eye-looking at this cross-sectional age point is present at levels that are similar between groups ($p<0.51$). In TD infants, eye-looking showed a trend towards increasing as a function of both contingency and familiarity: TD infants look most at the eyes when interacting contingently with their caregiver, less when viewing a non-contingent recording of their caregiver, and least when viewing pre-recorded non-contingent strangers (Figure 2A). By contrast, infants with ASD showed no modulation of eye-looking as a function of contingency (Figure 2B). They instead demonstrated a trend towards increased eye-looking when viewing familiar versus unfamiliar caregivers. Immediate next steps include further examination of these trends in a larger sample.
Conclusions:
Preliminary findings suggest that, from the earliest months of life, sensitivity to social contingency may be disrupted in infants with ASD. While TD infants look more at the eyes of those who are engaging with them contingently, levels of eye-looking were not modulated by contingency in infants with ASD. Instead, visual engagement in infants with ASD may be more strongly influenced by the familiarity of their social partner. Future analyses will examine the emergence and refinement of sensitivity to social contingency longitudinally, and will include measures of reciprocal social smiling and time-varying mutual gaze as further indices of sensitivity to social contingency.

253 **110.253** Sport Experiences for Youth with Autism Spectrum Disorder (ASD) and Intellectual Disabilities (ID)

S. Ryan[1] *and J. A. Weiss*[2], *(1)York University, Toronto, ON, Canada, (2)York University, Toronto, ON, CANADA*

Background: Youth with intellectual disabilities (ID) have lower sport participation rates than their typically developing peers (Westendorp et al., 2011) but little is known about patterns of sport participation in youth with Autism Spectrum Disorder (ASD). Grandisson and colleagues (2012) discuss a conceptual approach to understanding sport participation in individuals with ID using *personal* and *environmental* factors – an approach that is beneficial for assessing similar participation issues for those with ASD and ID.
Objectives: The present study aims to i) examine differences in positive sport experiences for youth with ASD and ID compared to youth with ID alone and ii) examine the relations among personal factors (adaptive behaviour, behaviour problems), environmental factors (available resources, coach relationship, parent support of sport), and positive sport experiences in youth with ASD.
Methods: As part of a larger study examining sport participation in youth with ID, parents of youth involved in Special Olympics (*N*=411) completed online questionnaires about personal and environmental factors, and sport experiences. Parents (81% mothers) were 34 to 67 years of age (*M*=49.39, *SD*=6.14) and children with ID (64% male) ranged in age from 11 to 23 years (*M*=17.20, *SD*=3.05), with 29% having a diagnosis of ASD. Parents reported on their support of sport and the child-coach relationship, as well as their child's sport experiences (Teamwork & Social Skills subscale, YES 2.0; Hansen & Larson, 2005), adaptive behaviours (SCA; Mazurek et al., 2012; W-ADL; Maenner et al., 2012), behaviour problems (SDQ; Goodman, 1997), and resources (PEMCY; Coster et al., 2012).
Results: A two-way ANOVA (gender X ASD status) was used to investigate differences in quality of the sport experience between youth with ASD and ID compared to youth with ID alone. There was no main effect of gender and no significant interaction, however, there was a trend towards a main effect of ASD status, such that youth with ID alone (M = 2.76, SE = .10) had greater positive sport experiences compared to youth with ASD and ID (M = 2.36, SE = .19), $F(1, 397) = 3.43$, $p = .07$. Mediation analyses using the PROCESS macro (Hayes, 2012) revealed significant pathways for personal and environmental factors. Specifically, sociocommunicative abilities, the quality of the coach relationship, and parent support of sport had significant indirect associations between ASD status and positive sport experiences.
Conclusions: The findings suggest that experiences may not be the same for all youth with ID involved in sport, such that youth with ASD and ID may have fewer positive sport experiences compared to youth with ID alone. Further, differences in personal and environmental factors may explain the relationship between ASD status and sport experiences. These findings suggest that additional supports may be required in sports for youth with ASD with social communication deficits or difficulties with support from their coach or parents. The present study contributes to our understanding of sport experiences in youth with ASD and ID, and may have implications for improving social supports in sport for all youth with ID.

254 **110.254** Task Related Differences in the Theory of Mind Profile of School-Aged Children with ASD

M. R. Altschuler[1,2] *and S. Faja*[1]*, (1)Boston Children's Hospital, Boston, MA, (2)Bates College, Lewiston, ME*

Background:
Impairments in social functioning in autism spectrum disorder (ASD) are theoretically linked to an underlying deficit in theory of mind (ToM)–the social cognitive ability to take another's perspective. Previous research has consistently documented ToM impairments in preschoolers with ASD (Baron-Cohen, Tager-Flusberg, & Cohen, 2000), but the investigations of ToM deficits in school-aged children with ASD and average IQ have produced mixed results (Scheeren et al., 2013).
Objectives:
To examine the pattern of individual differences in ToM in school-aged children with ASD and average IQ using a battery of ToM measures (e.g., precursors of ToM, first-order false belief, and second-order false belief). To compare ToM performance between children with ASD and typical development.
Methods:
To date, 41 children with ASD between the ages of 7-11 years have participated. All children had an ASD diagnosis (ADOS-2, ADI-R, DSM-5) and WASI-2 Full Scale IQ of 80 or higher. The ToM battery included tasks measuring: (1) precursors of ToM (TOM Test-Level 1 and Perception Knowledge task), (2) first-order false belief (Location Change False Belief task, Unexpected-Contexts False Belief task, and TOM Test-Level 2), and (3) second-order false belief (TOM Test-Level 3). The TOM Task (Muris et al., 1999) was presented on a laptop and all other measures were presented as videos with pre-recorded questions. We are currently collecting data from typically developing children (anticipated sample size of 30) and will compare the performance between groups. We are also collecting data from additional children with ASD (anticipated final sample size of 65).
Results:
ToM precursors were not significantly related. Instead, age related improvements were detected on Perception Knowledge, $r(41) = .34$, $p = .03$, whereas TOM-Level 1 related to language level, $r(29) = .44$, $p = .02$. Performance across first-order false belief tasks were related, Chronbach's a=.65; rs > 0.36, ps < .03. Within these measures, Location Change False Belief improved with age, $r(40) = .37$, $p = .02$, and TOM-Level 2 performance was associated with language ability, $r(29) = .40$, $p = .03$. Finally, the second-order false belief measure, TOM-Level 3, was sensitive to both age, $r(40) = .42$, $p = .01$, and language level, $r(29) = .50$, $p = .01$. Across all measures, nonverbal IQ was not related ToM. Finally, ADOS-2 severity scores were examined with respect to ToM. More severe symptoms related to worse performance only on the Unexpected Contents Task, $r(36) = -.40$, $p = .02$.
Conclusions:
Overall, our research has important implications for understanding the heterogeneity in social functioning and social cognition in school-aged children with ASD. First, variables within a ToM level were only moderately related at best. Second, some tasks in our battery measuring multiple levels of ToM continue to detect developmental changes in ASD–even among school-aged children without cognitive impairment (i.e., Perception Knowledge, Location Change, and TOM-Level 3). As with previous work (Steele, Joseph, & Tager-Flusberg, 2003), language level influenced performance, especially for the TOM Task. Finally, ToM performance was generally *not* related to ASD symptoms in this age range.

255 **110.255** The Association Between Theory of Mind, Executive Function and the Symptoms of Autism Spectrum Disorder

C. R. Jones[1]*, E. A. Simonoff*[2]*, G. Baird*[3]*, A. Pickles*[4]*, F. Happé*[4] *and T. Charman*[5]*, (1)Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom, (2)Institute of Psychiatry, London, UNITED KINGDOM, (3)Newcomen Children's Neurosciences Centre, Evelina London Children's Hospital at Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM, (4)King's College London, London, UNITED KINGDOM, (5)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
Many dominant theories of autism spectrum disorder (ASD) assert that atypical cognitive processes contribute to the expression of observed autistic symptoms. In particular, it is proposed that theory of mind (ToM) impairments relate to the expression of social and communication difficulties, and that poor executive functions associate with the presence of restricted and repetitive behaviours (RRBs). However, experimental evidence is mixed and comprehensive investigation has been limited by small and unrepresentative sample sizes and the absence of wide-ranging task batteries. Further, most previous research has focussed on a cognitive domain in isolation, meaning broader conclusions about the pattern of cognition-behaviour associations cannot be drawn.
Objectives:
We used structural equation modelling (SEM) as a parsimonious and statistically robust way of exploring the associations between ToM and executive function and parent-reported measures of social communication and RRBs.
Methods:
Participants were 100 adolescents (mean age = 15 years 6 months; SD = 6 months) with ASD from the Special Needs and Autism Project (SNAP). The mean full-scale IQ was 84 (SD = 18). Four tasks were used to measure ToM (False belief, Strange stories, Frith-Happé animations, Reading the Mind in the Eyes) and six tasks were used to measure executive functions (Opposite worlds, Card sort, Category fluency, Design fluency, Digit span, Planning drawing). Symptoms of ASD were obtained via parent-report, with the Social Responsiveness Scale (Constantino & Gruber, 2005) used to measure social communication behaviours and the Repetitive Behavior Scale-Revised (Bodfish et al., 2000) used to measure RRBs. SEM enabled different theoretical models of the interrelationships between the multiple measures to be tested and compared.
Results:
Our final model had acceptable model fit (CFI = .89; RMSEA = .05). ToM ability was associated with both social communication symptoms (standardized coefficient = -.41) and RRBs (standardized coefficient = -.42). In contrast, EF was a correlate of ToM but had no direct association with parent-reported symptom expression.
Conclusions:
Our data suggest ToM ability, but not EF, is related to autistic symptom expression in adolescents with ASD. This suggests that the previously held theoretical position that ToM is not relevant to RRBs needs reconsidering.

256 **110.256** The Broad Autism Phenotype, Emotion Recognition, and Romantic Relationships

R. Jamil *and M. N. Gragg, University of Windsor, Windsor, ON, CANADA*

Background: The broad autism phenotype (BAP), or subclinical features of autism spectrum disorder (ASD), has been identified in people both with and without relatives with ASD. Broad autism phenotype features include aloof personality, rigid personality, and pragmatic language deficits. People with higher levels of BAP features have more intimate relationship difficulties than those with lower levels of BAP features, whether or not they have a relative with ASD. People with higher levels of BAP also have difficulty understanding others' facial expressions, which may impede their ability to initiate and maintain romantic relationships.
Objectives: The purpose of the study was to explore the relationship between BAP features, emotion recognition skills, and romantic relationship functioning in emerging adults with and without relatives with autism.
Methods: Participants (*N* = 235, 80% female, mean age = 20) were in two groups: (1) emerging adults with no known relatives with ASD (No Relative Group; *n* = 115) and (2) emerging adults with relatives with ASD (Relative Group; *n* = 120). Relatives were most often siblings (*n* = 49) and cousins (*n* = 57) of people with ASD. Approximately 54% of the participants (*n* = 127) were in a romantic relationship at the time of the study. All participants completed an online survey, which included the Broad Autism Phenotype Questionnaire, the Reading the Mind in the Eyes Task, the Dating and Friendship Questionnaire, and the Social and Emotional Loneliness Scale.
Results: Participants with higher BAP scores had significantly fewer numbers of past romantic relationships compared to participants with lower BAP scores. Similarly, participants with higher BAP scores had significantly weaker emotion recognition abilities compared to people with lower BAP scores. Mediation analyses revealed that people with higher BAP scores experienced fewer numbers of romantic relationships, in part because of their weaker emotion recognition skills. There was no association between BAP scores and romantic loneliness, relationship satisfaction, and duration of current romantic relationships. Additionally, participants with the BAP (n = 60) and without the BAP (*n* = 175) did not differ in their current dating status. Participants in the Relative and No Relative group did not differ on their average number of past romantic relationships or on their scores of emotion recognition.
Conclusions: It is important for parents without the BAP to model strong emotion recognition skills (e.g., by emphasizing how others feel based on their facial expressions) for young adults who exhibit features of the BAP in order to promote healthy romantic relationships. It is also important to inform family members of people with ASD about the BAP so that relatives who exhibit more BAP features may recognize these features in themselves and can experience the benefits of romantic relationships by seeking help and resources. By improving the quality of life of relatives of people with ASD, these individuals will be empowered to provide better care and advocacy for their relatives with ASD.

257 **110.257** The Broader Autism Phenotype As It Relates to Interoception, Alexithymia, and Emotion Processing

C. A. Jennings[1] *and J. B. Wagner*[2]*, (1)Psychology, The College of Staten Island - CUNY, Staten Island, NY, (2)College of Staten Island, CUNY, Staten Island, NY*

Background: The ability to process information from our internal bodily state has been found to relate to socio-emotional competence (Ferri et al., 2013). Neurotypical adults who show high interoceptive accuracy (IA) in sensing and tracking bodily signals such as heart rate are found to experience emotions with heightened intensity (Pollatos et al., 2007), and work with individuals with ASD has also examined IA, though results are mixed. Some studies have found increased IA in ASD (e.g., Schauder et al., 2015), while others have found impaired IA (e.g., Garfinkel et al., 2016). Recent studies have suggested that alexithymia, a personality construct characterized by impairments in sensing, identifying, and describing one's emotions, might mediate associations between ASD and IA (Shah et al., 2016) as well as ASD and emotion processing (Cook et al., 2013). More work is needed to understand how the associations among these factors might relate to the broader autism phenotype (BAP).
Objectives: The present study investigated the relations between characteristics of the BAP, IA, alexithymia, and emotion recognition in the general population.
Methods: The present sample included 36 undergraduate students (14 male). Participants completed a heartbeat perception task, where they were asked to silently count their heartbeats without physically feeling their heart or pulse. Heart rate was recorded using a Biopac MP150WSW system. After this task, participants completed a series of questionnaires to measure aspects of socio-emotional competence. Characteristics of the BAP were measured through the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012); alexithymia was assessed with the Toronto Alexithymia Scale (TAS-20; Bagby et al., 1994); and emotion recognition was assessed using the Reading the Mind in the Eyes Test (RMET; Baron-Cohen, et al., 2001). Based on prior work by Pollatos et al. (2007), IA was calculated as the mean accuracy in heartbeat perception across three randomly-ordered time intervals.
Results: Characteristics of the BAP were found to be positively related to alexithymia, $r(33) = .648$, $p < .001$, and a trend towards a negative association with emotion recognition was also found $r(34) = -.321$, $p = .056$. Alexithymia was negatively related to emotion recognition, $r(33) = -.373$, $p = .027$, and on further analysis, when controlling for alexithymic traits, the marginal association between BAP and emotion recognition disappeared ($r(32) = -.113$, $p = .525$), consistent with previous work. When examining these aspects of socio-emotional processing in relation to IA, only the RMET was found to be significantly associated, $r(34) = .411$, $p = .013$, such that those who were more accurate in detecting their heartbeats also showed better accuracy in recognizing others emotions.
Conclusions: Consistent with past work in ASD, the present study found a) increased BAP characteristics were associated with higher levels of alexithymia, b) higher levels of alexithymia were associated with worse emotion recognition, and c) relations between BAP and emotion recognition were mediated by alexithymic traits. Further, better interoception related to better emotion recognition. Future work will expand the present sample to further explore the relationship between IA and socio-emotional competence as it relates to the BAP.

258 **110.258** The Development of Face Expertise in Autism and the Own Race Advantage

M. Hanley[1]*, D. M. Riby*[2]*, M. Hirai*[3]*, T. Yamagata*[4]*, N. Ikeda*[3] *and H. Shimoizumi*[5]*, (1)South Road, Durham University, Durham, England, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)Jichi Medical University, Tochigi, Japan, (4)Jichi Medical University, Shimotsuke, Japan, (5)International University of Health and Welfare, Tochigi, Japan*

Background: Â Face perception atypicalities have been well-documented in relation to autism spectrum disorders (ASD), for example, suggesting a lack of 'face expertise' (Schultz, 2005). These abnormalities are important to understand as they link to the defining social impairment in ASD. Studies in typical development (TD) show that adults and children are better at recognising faces of their own race than those of another race (own-race-advantage; ORA). The ORA demonstrates how experience (e.g. increased exposure to own race faces) shapes face perception and provides an interesting way of probing the role of experience/expertise in face perception in ASD. Two papers have explored the ORA in autism, but have provided inconsistent findings (Hui-Lin-Chien et al., 2014; Wilson et al., 2011).
Objectives: Â The aim of this study was to explore the development of the ORA in children with ASD compared to TD children in Japan. We hypothesized that the ORA would be reduced in children with ASD compared to TD children. Critically, we used a face recognition task with 4 different stimuli manipulations to explore how manipulating information from different areas of the face impacted upon recognition (e.g. eye vs. mouth). We hypothesized that children with ASD would have the most difficulty in the easy-eye and hard-eye condition, in line with the idea that difficulties with face expertise in ASD are linked with attention to the eyes.
Methods: 52 participants (7- 16 years, 24 ASD, 28 TD children, matched on age and non-verbal ability) completed a sequential face recognition task. The task was adapted from Hui-Lin Chein et al., 2014). Participants were shown a face (3s) followed by a blank screen with a fixation cross (1s), followed an image with two faces. From the two faces, participants had to identify the face they had previously seen. The additional face was either a completely different face (IC;identity change), or the same face as before with a manipulation: easy eyes (EE; eye change), hard eyes (HE; eye spacing change) or hard mouth (HM; change in spacing between nose and mouth). Half of the 64 trials contained Asian faces and half were Caucasian.
Results: A 2X4 factorial ANOVA revealed a main effect of condition whereby both groups found each manipulation increasingly difficult (IC < EE <HE <HM), but no interaction with group. Therefore children with ASD did not suffer an atypical decrement when recognition dependent upon changes in the eyes region. Although there was a trend towards significance, a main effect or interaction effect for the race of the face was not found (p = .07), therefore an ORA was not clearly demonstrated in either group
Conclusions: The current study lends support to the idea that children with ASD do not demonstrate an ORA. However, in this case neither did the TD children. Additionally, children with ASD showed the same pattern of performance across the conditions indicating they did not have particular difficulties in noticing changes dependent on the eye region. The implications will be discussed.

259 **110.259** The Effectiveness of Social Skills Treatment for Adolescents with Autism Spectrum Disorder

A. Pulido[1] *and A. J. Lincoln*[2]*, (1)Alliant International University, Gardnerville, NV, (2)Alliant International University, San Diego, CA*

The Effectiveness of Social Skills Treatment for Adolescents with Autism Spectrum Disorder. A. Pulido-Banner*1 and A. J. Lincoln2, (1) Alliant International University.

Background: Treatment options for social skill deficits in adolescents with Autism Spectrum Disorder (ASD) are limited. Throughout the lifespan, individuals must learn to conform to society's social expectations or face becoming isolated from peers (Dereli-Iman 2014).Â The PEERS program (Laugeson, 2014) was created to address the many complexities faced by treating adolescents with ASD and the unique hardships faced when attempting to learn social skills. The PEERS program is an evidence-based program for teen's with ASD and non-ASD teenagers with disorders that involve social skill deficits (Laugeson, 2014). Currently the sole source of information used to assess social skill ability has been informant report because it is inexpensive, quick, and easy and provides fairly reliable data (Matson & Wilkins, 2009). Some limitations to self-report are the lack of generalizable data and poor consistency across informants which can cause shared method variance (Kaugars et al., 2011). The CASS is currently the only published observational tool to measure ASD symptoms and can be used to increase external validity in evidence based social skills treatment programs (White et al., 2015)

Objectives: The aim of this study was to replicate the findings from the empirically supported PEERS program and to evaluate the effectiveness of a, social skills program for adolescents with ASD by comparing outcome results from informant report and an evidence based observational measure.

Methods: Participants to date are twenty-two 12:0 to 17;11 year-old adolescentsÂ with a diagnosis of ASD. ASD diagnoses were confirmed by the ADOS, ADI-R or a qualified mental health professional using the DSM-IV or DSM-V. All participants scored ≥ 70 on standardized measures of intellectual and language abilities. Participants were randomly assigned to either 10 group therapy PEERS sessions (n=22) or a 10- week waitlist (n=10). The participants from the waitlist group were then crossed over into the treatment group following the 10 week waiting period. Outcome measures included Social Communication Questionnaire (SCQ), Social Skills Improvement System Parent and Teacher (SSIS-P, SSIS-T), Quality of Play Questionnaire-Adolescent version (QPQ-A), Social responsiveness Scale Parent and Teacher (SRS-P, SRS-T), Test of Adolescent Social Skills Knowledge (TASSK), Symptom Checklist 90 Revised (SC-90), Friendship Qualities Scale (FQS), Social Anxiety Scale-Parent and Adolescent (SAS-P, SAS-A) and The Contextual Assessment of Social Skills (CASS).

Results: Preliminary findings suggest that adolescents who completed a 10-session PEERS program evidenced clinically significant improvements in social skill ability as measured by self-report, informant report and observational measures. Improvements in conversation skills were found in teens who completed PEERS treatment. Comparative outcomes for participants in the PEERS and waitlist groups will be presented.

Conclusions: Preliminary evidence suggests that the PEERS program demonstrates improvement in social skill ability for adolescents with ASD when measured via informant report or through direct standardized observation employing the CASS. However an unexpected post hoc finding suggested that levels of anxiety increased among adolescents with ASD who participated in the 10 week PEERS treatment group.

260 **110.260** The Effects of Diagnostic Disclosure, ASD Knowledge, and Peer ASD Symptomology on the Perception of Vignette Characters with ASD

C. M. McMahon[1] *and L. Arader*[2]*, (1)Department of Social & Behavioral Sciences, Miami University, Hamilton, OH, (2)Department of Psychology, Hamilton College, Clinton, NY*

Background: Few studies have examined what factors influence and/or increase the positive engagement of peers who interact with individuals with ASD. Given that individuals with ASD experience stigmatizing attitudes from peers (Humphrey & Lewis, 2008) and that peers themselves endorse such attitudes (Obeid et al., 2015), there is a need for further research in this area.

Objectives: The goal of this study was to examine three factors that may influence peer perception of individuals with ASD: (1) the peer's awareness of the individual's diagnosis, (2) the peer's knowledge of ASD, and (3) the extent to which the peer experiences symptoms characteristic of ASD.

Methods: 203 undergraduate students were randomly assigned to read a series of vignettes wherein the main character exhibited behavior characteristic of ASD and disclosed: (1) an ASD diagnosis, (2) an unrelated diagnosis (e.g., depression), or (3) no diagnosis. Participants' perceptions toward the vignette character were examined using the Openness Scale (Nevill & White, 2011) and the Affect, Cognition, and Behavior Subscales of the Multidimensional Attitudes Scale (Findler et al., 2007). Participants' knowledge of ASD was assessed by an author-created questionnaire, and the Autism Spectrum Quotient (Baron-Cohen et al., 2001) was used to evaluate participants' ASD symptomology. Four hierarchical linear regressions (dependent variables: Openness, Affect, Cognition, Behavior) were used to analyze the data.

Results: Across all regressions, participants had more positive perceptions of characters who disclosed an ASD diagnosis compared to those who did not disclose a diagnosis, Openness: $t(197) = -5.21$, $p < 0.01$, Affect: $t(196) = -2.33$, $p = 0.02$, Cognition: $t(200) = -3.47$, $p < 0.01$, Behavior: $t(198) = -4.07$, $p < 0.01$, but there were no significant differences in perception of characters who disclosed an ASD versus unrelated diagnosis. Greater knowledge of ASD was associated with more openness, $t(197) = 2.90$, $p < 0.01$, and positive affect, $t(196) = 4.90$, $p < 0.01$, toward vignette characters. Participants who endorsed having more symptoms of ASD reported more distancing behavior, $t(198) = -2.79$, $p = 0.01$, less openness toward vignette characters who revealed an unrelated diagnosis, $t(197) = -3.08$, $p < 0.01$, and more negative affect toward vignette characters who did not reveal a diagnosis, $t(196) = -2.48$, $p = 0.01$. See Table 1 and Figure 1.

Conclusions: Overall, peers responded more positively when vignette characters disclosed a diagnosis, regardless of the nature of that diagnosis. Diagnostic disclosure may provide peers with a cognitive explanation for odd social behaviors demonstrated by the vignette character and/or may lead peers to experience more empathy for the vignette character. Peer knowledge of ASD was associated with more positive perceptions of vignette characters, suggesting that further work should be done to educate peers about ASD. Finally, peers who endorsed ASD symptomology had more negative perceptions of vignette characters, particularly when the characters did not disclose an ASD diagnosis. These results may reflect social difficulties on behalf of the peer, as well as a potential affinity for others who openly endorse experiencing social difficulties.

261 **110.261** The Evaluation of Guidelines about How Teachers and Parents Can Use the Tablets Effectively for Supporting Children on the Autism Spectrum in the Area of Joint Attention Skills

C. Mangafa[1]*, L. Moody*[1]*, A. Woodcock*[1] *and A. Woolner*[2]*, (1)Faculty of Arts and Humanities, Coventry University, Coventry, United Kingdom, (2)Ads Reality, London, United Kingdom*

Background:
Despite the rapidly increasing use of tablets in schools and homes, and the children's motivation in using them, there is limited guidance on how to use the tablets to teach children with autism specific skills, such as joint attention skills.
Objectives:
This study was a follow up of four previous studies (teachers' and parents' interviews, classroom observations and focus groups) that led to the creation of guidelines for teachers and parents on how to use the mobile tablets with children with autism (aged 4-11) to support the development of joint attention skills. The aim of this study was to evaluate the content and structure of the guidelines as well as to investigate the usefulness of the documents and possible ways of disseminating them.
Methods:
Four group interviews were conducted in two primary schools and a HE institution comprised by researchers, teachers and parents. Each member of the group was given a copy of the two versions of the guidelines; one for parents and one for teachers.
Results:
Four major themes emerged from the analysis: 'The Content of the Guidelines', 'The Structure of the Guidelines', 'The Usefulness of the Guidelines for Parents and Teachers' and 'The Dissemination of the Guidelines'. The participants made recommendations on how the documents can be written to attract teachers' and parents' interest, what information they should include and how to be structured, and they also recommended activities that can foster joint attention skills in class and home. It was also mentioned that the guidelines can be a valuable tool for teachers to reflect on their practice and try new activities, as well as to use them with parents at school to build their confidence. Participants have not seen such a document before and mentioned that the guidelines can contribute to the teachers' professional development on how to use a tablet to teach joint attention skills to children with autism.
Conclusions:
The guidelines include recommendations based on the participants' input as well as evidence-based strategies on how to gain and maintain the child's attention, encourage sharing and turn-taking, initiate and sustain conversation, keep eye contact and empathise with others. It is argued that teachers can learn to use the tablets in an experiential, playful and intuitive way as long as they are aware of the purpose of using tablets in their classroom. The tablet has a supporting role to the learning and teachers as well as parents should use their expertise and knowledge of the child's needs and interests to teach them specific skills.

262 **110.262** The Impact of Socioeconomic Status and Parental Education on I-E Behaviors and Coping Skills in Children with ASD

G. Haidar[1] *and R. Bernier*[2]*, (1)University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA*

Background:
The presence of internalizing and externalizing (I-E) behaviors has been shown to negatively affect developmental trajectories in children (Slopen et al., 2013). Coupled with a diagnosis of Autism Spectrum Disorder (ASD), the presence of I-E behaviors in children may further complicate developmental milestones (Woodman et al., 2016). It has been reported that coping strategies and coping competence play a moderating role on I-E behaviors in neurotypical children (O'Leary-Barrett et al., 2013), suggesting coping may be an important intervention target. However, the relationship between coping skills andÂ I-E behaviors in children with ASD remains largely unexplored.
Objectives:
To explore the relationship between coping skills and I-E behavior presentation in children with ASD, while considering the moderating role of SES and parental education.
Methods:
Participants included 2,751 children (2,384 males, 375 females) aged 4 to 17 years, 11 months (M= 9.03, SD= 3.56) from the Simons Simplex Collection with data regarding coping skills and I-E behaviors. The coping scores from the Vineland Adaptive Behavior Scales -2nd Edition (Sparrow et al., 2005) were used as a measure of coping ability and Internalizing and Externalizing behaviors were captured with the Internalizing and Externalizing Symptoms T scores, respectively, from the Child Behavior Checklist (1.5-5 years and 6-18 years collapsed; Achenbach et al., 2001). SES and parental education were extracted from the demographic information for each family. Regression analyses were computed to assess the relationship between the child's coping skills and severity of I-E behaviors, with SES and parental education as potential moderating variables.
Results:
Similar to what is reported in the neurotypical literature, coping skills were negatively correlated with externalizing (r= -.306, p= <.01) and internalizing (r= -.052, p= <.01) behaviors in this large sample of individuals with ASD. SES was positively correlated with coping skills (r= .079, p= <.01), although parental education was not. SES was negatively correlated with I-E behaviors (internalizing r= -.095, p= <.01; externalizing r= -.129, p= <.01) and parental education was as well (maternal-internalizing r= -.064, p= <.01; maternal-externalizing r= -.085, p= <.01; paternal-internalizing r= -.056, p= <.01; paternal-externalizing r= -.059, p= <.01). When SES and parental education were entered into the regression equation, the significant relationship between coping and I-E behaviors both remained (internalizing r= -.052, p= .02; externalizing r= -.304, p= <.01), with SES playing a significant moderating role between coping skills and behavior (internalizing r= -.094, p= <.01; externalizing r= -.127, p= <.01). Parental education did not have a significant moderating influence.
Conclusions:
The observed relationship between coping skills and I-E behaviors in children with ASD, mirrors findings reported in neurotypical children. However, we found that SES plays a moderating role, such that at higher SES levels, the relationship between coping skills and I-E behaviors is stronger. Importantly, this observed relationship highlights the development of coping skills as a key target area of behavioral intervention that may benefit children with ASD and highlights that consideration of SES for interventions focusing on coping skills is essential.

263 **110.263** The Problem of Bullying: Parent, Teacher, and Layperson Perceptions

H. E. Morton[1]*, R. G. Romanczyk*[2] *and J. Gillis*[2]*, (1)Center for Autism Research, Binghamton, NY, (2)State University of New York at Binghamton, Binghamton, NY*

Background: Bullying is a common problem in school-age children, and children with Autism Spectrum Disorder (ASD) are victims of bullying more frequently than their typically-developing peers (Kloosterman, Kelley, Craig, Parker, & Javier, 2013; Zeedyk, Rodriguez, Tipton, Baker, & Blacher, 2014). Although bullying and victimization behaviors have been examined in children with ASD, definitions vary across studies (e.g., Bitsika & Sharpley, 2014; Cappadocia, Weiss, & Pepler, 2012). As there is no precise definition of bullying or list of criteria for its occurrence (Humphrey & Hebron, 2015), perception and understanding of bullying may vary widely in the population. Conceptualization differences contribute to discrepancies in the literature regarding prevalence estimates and variables associated with bullying and victimization experiences (Humphrey & Hebron, 2015).
Objectives: This study aims to establish a more comprehensive understanding of bullying perceptions by identifying scenarios that exemplify this behavior, and characterizing them according to different types of bullying (e.g., physical, verbal, interpersonal, cyber). Additionally, this project seeks to identify differences in perceptions across types of bullying and ages of children experiencing bullying. Finally, this study aims to compare severity ratings for and identification accuracy of bullying scenarios by parents of children with ASD, service providers for children with special needs, and laypersons.
Methods: This study presents written vignette scenarios in an online survey format that describe various bullying and victimization interactions, and non-examples, between two school-age children (i.e., 4-15 years old). Participants include parents of children with ASD, service providers for children with special needs and laypersons (e.g., undergraduate college students).
Results: Data collection is ongoing; preliminary results from laypersons (N=313) indicate that respondents are able to discriminate between bullying and non-bullying examples ($t(312)=67.15$, $p<.001$), and vary significantly in their severity ratings of different types of bullying presented in the vignettes (Physical > Cyber > Interpersonal > Verbal; $F(2.92,911.14)=120.67$, $p<.001$). Respondents are frequently able to correctly identify the presence of bullying (M=73.96% accuracy, SD=12.44%), and vary in their accuracy of identifying types of bullying (Cyber > Verbal = Physical > Interpersonal; $F(2.58,705.52)=23.53$, $p<.001$). Finally, respondents rate bullying behavior more severely in older children in comparison to younger children (4-6yrs < 7-9yrs < 10-12yrs < 13-15yrs; $F(2.92,875.56)=30.217$, $p<.001$). Additional planned analyses include comparison of severity ratings and accuracy of responses by participant group. Completion of data collection is anticipated by December 2016.
Conclusions: The broad abilities of participants to distinguish between examples of bullying and non-bullying, and also to accurately identify the presence of bullying are promising for implementation of interventions. However, variation in accuracy in identifying, and severity perceptions of, different types of bullying highlight the need for precision in assessment because it informs intervention for bullying in school-age children with ASD. Additionally, bullying behavior may be overlooked, especially in very young children. Further conclusions may be drawn according to hypothesized group-level differences, especially regarding perceptions of caregivers and service providers for children with ASD.

264 **110.264** The Relationship Between Executive and Social Functioning in Children with Autism Spectrum Disorders on Parent-Rated Measures

T. Torske[1], *T. Nærland*[2,3], *M. G. Øie*[4,5] *and O. A. Andreassen*[3], *(1)Child and Adolescents Psychiatric Outpatient Clinic, Vestre Viken Hospital Trust, Bærum, Norway, (2)Oslo University Hospital, Oslo, Norway, (3)NORMENT, KG Jebsen Centre for Psychosis Research, University of Oslo and Oslo University Hospital, Oslo, Norway, (4)The Psychology Department, University of Oslo, Oslo, Norway, (5)Research Department, Innlandet Hospital Trust, Lillehammer, Norway*

Background: Executive function (EF) deficits are common in children with Autism Spectrum Disorders (ASD), but not part of the diagnostic criteria. While both social and EF deficits in ASD have been extensively studied separately, there has been limited research on the *relationship between* EF and social function. Most research has focused on neuropsychological assessment of EF and/or how EF impairment is related to a diagnosis of ASD.
Objectives: The aim of the present study was to explore the relationship between social functioning and EF on parent-rated measures in a clinical sample of children with ASD. Furthermore we wanted to investigate how IQ, gender and age influence the relation between EF and social problems. Most research within the ASD field is done on males, but some evidence suggests that females exhibit greater EF and social impairments than their male counterparts and we would like to examine this further.
Participants and Methods: The current sample comprised 86 children with ASD recruited from outpatient clinics between 2013 and May 2016 and assessed at age 6-18 years. Thirteen of the children (15.1%) had childhood autism, 1 had atypical autism (1.2%), 41 (47.7%) had Asperger syndrome and 31 (36%) had unspecified pervasive developmental disorder. Male:female ratio was 2.7:1. Twenty-eight of the participants (32.6%) had an attention deficit/hyperactivity disorder (ADHD) diagnosis in combination with their ASD. Autistic symptoms were evaluated using Autism Diagnostic Interview-Revised (ADI-R) and/or Autism Diagnostic Observation Schedule (ADOS). In addition, the assessment included a full medical and developmental history, physical examination, and IQ assessment. For measurement of social function the parent version of the Social Responsiveness Scale (SRS) was used. In order to assess executive function parents completed the Behavior Rating Inventory of Executive Function (BRIEF).
Results: A multiple regression analysis was conducted to identify the relations between SRS total score and age, gender, total IQ, BRIEF Behavior Regulation Index (BRI) and BRIEF Metacognitive Index (MI). This model significantly explained SRS total; $F(5, 80)=12.57$, $p<.001$, $R^2=.440$. Only BRIEF MI had a significant independent contribution to the prediction, $p=.001$. This result remained when the children with comorbid ADHD where removed from the analysis. For the children with ASD without ADHD (n=58) the regression model with age, gender, total IQ, BRIEF BRI and BRIEF MI significantly explained SRS total; $F(5, 52)=10.31$, $p< .001$, $R^2=.498$. Only BRIEF MI had a significant independent contribution to the prediction, $p=.003$.
Conclusions: We report a relationship between parental reports of EF and social function in an everyday setting in children with ASD. We found that the metacognitive domain of EF has a significant association to many aspects of social function. These results may have implications for understanding the cognitive components in the social deficits that define ASD. The findings suggest that studies are needed to clarify if children with ASD will improve their social function through intervention programs designed to enhance EF in general and metacognitive function in particular.

265 **110.265** The Role of Callous- and Unemotional Traits in Emotional Face Processing in Adolescents with ASD or ODD/CD

C. C. Bours[1], *M. J. Bakker*[2], *J. Tramper*[3], *N. N. J. Rommelse*[4], *J. C. Glennon*[5] *and J. K. Buitelaar*[4], *(1)Department of Cognitive Neuroscience, Radboud University Medical Center, Nijmegen, The Netherlands, Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (2)Cognitive Neuroscience, RadboudUMC, Nijmegen, Netherlands, (3)Department of Artificial Intelligence, Radboud University, Nijmegen, The Netherlands, Donders Institute for Brain, Cognition and Behavior, Radboud University, Nijmegen, The Netherlands, Nijmegen, Netherlands, (4)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (5)Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

Background: Facial expressions are important for understanding others' emotions and feelings. Individuals with psychiatric disorders such as Autism Spectrum Disorder (ASD), Oppositional Defiant Disorder (ODD) and Conduct Disorder (CD) show deficits in the processing of emotional faces. A common factor in these psychiatric disorders is the lack of empathy (Decety & Moriguchi, 2007). More recently, evidence pointed to a potential role of callous- and unemotional traits (CU traits) in emotional processing deficits in ASD and ODD/CD (Dadds et al., 2006; Leno et al., 2015). In ASD half of the adolescents show high levels of CU traits (Leno et al., 2015). In this study we used eye-tracking and questionnaires to compare facial emotion processing in adolescents with ASD, ODD/CD and typically developing controls (TDC), and examined the modulatory role of CU traits.
Objectives: Investigate the role of CU traits in gazing behavior towards emotional faces in a large sample of male adolescents with ASD, ODD/CD or typical developing controls.
Methods: A total of 122 male participants (N=42 ODD/CD, N=52 ASD, and N=28 (TDC) were included in the current study (age range: 12-19 years, mean = 15.4, SD = 1.9). We took a novel non-parametric trial-based approach to investigate the time-wise proportionality of looking behavior to specific regions of interest (ROIs) in emotional faces. As ROIs we selected the eyes region (both eyes within the ROI), the mouth region and the rest of the image. For every ROI we investigated total fixation duration, percentage of first fixation to ROI, and time to first fixation to a ROI in miliseconds. We used Kruskal Wallis one-way ANOVA to examine eye tracking patterns across facial emotions (neutral, anger, fear, sadness and happiness) and diagnostic groups. Furthermore, we investigated the correlation between eye gazing for emotional faces with CU traits by using the parent rated total scores of the Inventory of Callous-Unemotional Traits *(ICU)*questionnaire and the Youth Psychopathic Traits Inventory (YPI).
Results: We observed significant group differences for the time to first fixation towards the eye region for fearful faces using a Kruskal Wallis One-way ANOVA (X^2 (DF=2, N=248) = 6.11, p=0.0471). Compared to controls, the ASD and CD/ODD group took significant longer time to fixate on the eyes of a fearful face. For the mouth region we did not find significant differences. Moreover, for the other emotions and neutral facial expression we did not find significant group differences. When examining the role of CU traits we observed a significant positive correlation between time to first fixation for fearful faces and CU traits in both the ASD and ODD/CD group.
Conclusions: Our findings correspond with previous findings from eye-tracking studies that report deficits in the processing of fearful faces in both adolescents with ASD or ODD/CD. We were able to pinpoint more precisely eye-tracking gazing behavior in these clinical groups. Our data suggest that callous and unemotional traits play a modulating role in fear processing in both male adolescents with ASD or ODD/CD.

266 **110.266** The Sense of Leading Gaze in Joint Attention

O. Grynszpan[1]*, J. Nadel*[2] *and J. C. Martin*[3]*, (1)CNRS UMR 7222, Institute of Intelligent Systems and Robotics, University Pierre et Marie Curie, Paris, FRANCE, (2)French National Centre of Scientific Research (CRNS), Paris, FRANCE, (3)LIMSI, Université Paris Sud, Orsay, France*

Background: Gaze plays a pivotal role in human communication, especially for coordinating attention. The Autism Spectrum Disorder (ASD) is considered to be strongly associated with impairments in joint attention. The ability to lead the gaze direction of others forms the backbone of joint attention. To be functional for interpersonal communication, this ability entails that the sensorimotor feedback yielded by the gaze reactions of others elicits a sense of leading gaze in the individual who initiates eye movements.
Objectives: This study investigates a specific aspect of joint attention in ASD, that is, the emergence of the sense that one is leading the attentional focus of others.
Methods: Using eye-tracking and virtual reality technology, we designed avatars that can follow the gaze of participants in real time. Seventeen adults with ASD and 17 typical adults matched on IQ participated. During a training phase, participants were alternately exposed to an avatar that followed their gaze and an avatar that moved its gaze independently from the participants. The avatars were surrounded by three objects that changed with each new trial (Figure). After each trial participants had to indicate what object they preferred and guess what object the avatar had preferred. In a subsequent test phase, they were facing the two avatars at the same time and three objects displayed around them. Again, one avatar was following their gaze while the other was not. The task was the same as before. Eye-tracking data served as measures of attention. Participants' responses regarding their preferred objects and the preferred objects of the avatars yielded a measure of their awareness that a link existed between them and one of the avatars, that is, the avatar following their gaze.
Results: Â During the final half of the training phase, typical participants selected the same preferred object for them and the gaze-following avatar more often than for the independently gazing avatar [*Z*Â =Â 2.08, *p*Â =Â 0.038]. By contrast, such an effect was not observed in the group with ASD. During the test phase, eye-tracking data yielded an interaction between the groups and the gaze behaviors of the avatars [*F*Â (1,Â 32)Â =Â 5.25, *p*Â =Â 0.029, η^2Â =Â 0.14]. Typical participants looked more at the independently gazing avatar than participants with ASD who were more focused on the gaze-following avatar.
Conclusions: Â Attentional measures suggest that participants with ASD continued to be intrigued by the gaze-following avatar during the test phase, while typical participants seemed to have already recognized the link between them and this avatar during the training phase. Impairments in joint attention could be linked to a failure in sensing oneself as an agent leading the attentional focus of others.
Figure: Snapshot of the virtual scene shown to each participant during the training phase. An avatar was displayed with three consumer goods located on its side and in front of it. The avatar either followed the gaze of the participant or displayed gaze patterns that were independent from the participant.

267 **110.267** Vicarious Effort-Based Decision-Making in Adults with Autism Spectrum Disorders

M. G. Mosner[1]*, J. K. Kinard*[2]*, S. McWeeny*[3]*, J. Shah*[3]*, C. Damiano*[4]*, M. R. Burchinal*[5]*, H. J. V. Rutherford*[6]*, R. K. Greene*[7]*, M. T. Treadway*[8] *and G. S. Dichter*[7]*, (1)University of North Carolina - Chapel Hill, Carrboro, NC, (2)Carolina Institute for Developmental Disabilities, University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of North Carolina, Durham, NC, (5)Data Management and Analysis Center, Frank Porter Graham Child Development Institute, Chapel Hill, NC, (6)Child Study Center, Yale School of Medicine, New Haven, CT, (7)University of North Carolina - Chapel Hill, Chapel Hill, NC, (8)Department of Psychology, Emory University, Atlanta, GA*

Background: There has been recent emphasis on examining motivational aspects of social deficits in ASD (Chevallier, Kohls, Troiani, Brodkin, & Schultz, 2012). The purpose of the present study was to evaluate vicarious effort-based decision-making to address one aspect of the social motivation hypothesis of ASD (i.e., the willingness to expend effort to win a reward for another person). Our research group recently reported that adolescents with ASD are characterized by impaired vicarious effort-based decision-making (Mosner, Kinard, Mcweeny, Shah, Damiano, Burchinal…& Dichter, 2016).
Objectives: As a follow-up to our prior study of adolescents with ASD, the present study explored vicarious effort-based decision-making in adults with ASD to examine potential developmental changes in vicarious effort-based decision-making in ASD between adolescence and adulthood.
Methods: Twenty-three typically developing controls (TDCs; age *M*= 21.32, IQ *M*=118) and 28 high-functioning adults with ASD (age *M*=20.00, IQ *M*=107) participated. Diagnoses of ASD were confirmed with the ADOS-2, and groups were matched on age and gender distribution (*p*'s<.05). A modified version of the Effort Expenditure for Rewards Task (EEfRT) was used as a behavioral measure of vicarious effort-based decision-making. In this task, participants are provided with the probability of receiving monetary rewards of various magnitudes on each trial and asked to choose between an "easy task" for a small, stable reward or a "hard task" for a variable but consistently larger reward (Treadway, Buckholtz, Schwartzman, Lambert, & Zald, 2009).Â Unlike the standard version of the task where participants work to earn money for themselves, in this version of the task, participants were working to win money for another person.
Results: There were no group differences (ASD vs. TDC) in the proportion of hard task choices across all levels of reward magnitudes and probabilities (*p*'s>.05, Cohen's *d*<.27). There were also no significant Group x Magnitude or Group x Probability interactions (*p's*>.05, Cohen's *d*<.50). Effect sizes of this magnitude suggest results would remain non-significant with samples sizes as high as 67-270, depending on the effect examined.
Conclusions: Â These findings suggest that adults with ASD did not differ in their willingness to expend effort for others across all levels of reward probabilities and magnitudes compared to TDC adults. Contrary to our previous findings with adolescents with ASD, adults with ASD did not differ in sensitivity to reward parameters when earning rewards for others. These findings also contrast with our previous findings with adults with ASD, in which we found greater effort expenditure across all reward parameters when earning rewards for themselves compared to TDC adults (Damiano, Aloi, Treadway, Bodfish, & Dichter, 2012). The difference in patterns of results between the present study with adults and our prior results from adolescents (Mosner et al., 2016) highlights the developmental differences in vicarious effort-based decision-making for others. Adolescence may be an especially vulnerable period of development for individuals with ASD during which deficits in social motivation differ compared to adults. Future studies in this area should include younger children with ASD to further explore the trajectory of vicarious effort-based decision-making across development.

268 **110.268** Web-Based Tool to Assess Social Cognition in Youth with ASD: Reliability and Criterion Validity

R. J. Weber[1]*, E. Kang*[1]*, E. Trimber*[1]*, A. Karls*[2]*, N. M. Russo-Ponsaran*[2]*, C. McKown*[2] *and M. D. Lerner*[1]*, (1)Stony Brook University, Stony Brook, NY, (2)Rush University Medical Center, Skokie, IL*

Background: Social cognitive deficits are a critical feature of autism spectrum disorder (ASD; Beauchamp & Anderson, 2010). However, no integrative, objective, psychometrically-sound tool to directly assess the multiple social-cognitive processes implicated in ASD is available. One such assessment, SELweb™, has demonstrated strong psychometric properties in large typically-developing (TD) samples (McKown et al., 2015). SELweb is an easy-to-use, web-based, modular assessment of self-control (SC), theory of mind (ToM), social problem solving (SPS), and emotion recognition (ER). If validated for youth with ASD, SELweb could complement outcome assessment batteries for intervention studies and provide a platform for a standardized social-cognitive assessment across settings.
Objectives: To evaluate (1) internal consistency of SELweb modules, (2) criterion validity of SELweb compared to existing social-cognitive measures, (3) SELweb performance in ASD youth compared to normative data, and (4) feasibility of using SELweb in this population.
Methods: Â Thirty-one youth with ASD (see Table 2 for demographics) completed the ADOS-2 (Lord et al., 2012), SELweb, and four validation tasks: Go/No-Go and Distractibility SC tasks (Zimmerman et al., 2005), an advanced ToM task (Happé, 1994), a SPS task (Kupersmidt et al., 2011), and a facial ER task (Tracy et al., 2009). Parents rated youth's social skills/problem behaviors (SSIS; Gresham & Elliot, 2008) and ASD severity (SRS-2; Constantino & Gruber, 2012). Cronbach's alpha was calculated to assess SELweb internal consistency. Pearson correlations examined associations of SELweb with demographic variables and scores on corresponding criterion measures and parent-reports. Independent-samples *t*-tests compared age-corrected SELweb scores to TD normative data. Qualitative feasibility data was collected during SELweb administration.
Results: Â Internal consistencies across SELweb modules were acceptable to excellent (α=.57–.91). SC, ToM, and SPS demonstrated convergent validity with criterion tasks (Table 1; all *p*<.011). SC correlation with the criterion SPS task evidenced discriminant validity (*p*=.188), as did ToM and SPS with criterion measures of all other SEL constructs (all *p*>.252). ER correlated with responses to angry faces on the criterion ER task (*r*=.398, *p*=.033). Youth who were older or male scored lower on ER and ToM (Table 2). Problem behaviors were associated with lower ER scores. IQ was positively correlated with SC, ToM, and overall SELweb scores. Youth who scored higher on SC or were younger took longer to complete SELweb. Youth with ASD scored significantly lower than the TD normative sample for SC, SPS, ToM, and overall (all *t*>2.35, *p*<.019). With one exception, all children completed SELweb and did so independently. As evidenced via comments and behavioral observations during testing, children were engaged with the assessment format. Only five children required one short break.
Conclusions: Promising psychometric properties and qualitative feasibility of SELweb support its utility as modular social-cognitive assessment for youth with ASD. SELweb performance corroborates well-established deficits among youth with ASD (SC, ToM, SPS) and converges with findings that ASD-specific differences in facial ER are inconsistent (Harms et al., 2010). Overall, SELweb demonstrates the capacity to acquire potentially treatment-sensitive, individual domain-specific profiles, in addition to overall, social cognitive functioning.

269 **110.269** Young Children's Understanding of Desires and Beliefs: Effects of Autism Spectrum Disorder and Modality on Theory-of-Mind

A. A. Hasni[1]*, L. B. Adamson*[1] *and D. L. Robins*[2]*, (1)Georgia State University, Atlanta, GA, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Â Theory-of-mind (ToM) abilities reflect a capacity to understand and react to thoughts and emotions in oneself and in others. Around age three years, many typically-developing (TD) children are able to reason about their own and others' mental states, particularly desires and beliefs. In contrast, children with autism spectrum disorder (ASD) and non-ASD developmental delays (DD) often show significant delays in mastering ToM skills (Baron-Cohen, Leslie, & Firth, 1985). However, there has been little research on the emergence of understanding desires and beliefs, the influence of modality on ToM performance, and the relationship of parent's perceptions of their child's ToM skills to ToM task-performance.
Objectives: Â We investigated 1) whether ASD and DD affect ToM performance in the auditory modality and the visual modality, and 2) whether parent's perceptions of their child's ToM abilities correspond with their child's performance on desire and belief tasks.
Methods: Â 42 three-year-old children (17 female) and parents were recruited for a larger project documenting the early development of communication and social understanding.Â There were three groups: ASD (*n*=13), DD (*n*=14), and TD (*n*=15) children.Â All children received four ToM tasks: two visual items adopted from Wellman and Liu's (2004) ToM scale assessing diverse desires and diverse beliefs and two newly-crafted auditory items also assessing desire- and belief-understanding.Â Parents completed the Theory of Mind Inventory (ToMI; Hutchins, Prelock, & Bouyea, 2014) from which we selected 6 items that focused on desires and beliefs. For each item, parents used a Likert scale ranging from 0 to 20 to indicate their child's ToM-understanding.
Results: Â Children with ASD (*M*=0.31, *SD*=.48) and with DD (*M*=0.50, *SD*=.76) passed significantly fewer ToM items than TD children (*M*=2.60, *SD*=1.06), $F(2,41)=35.13$, $p<.001$.Â The ASD and DD means did not differ significantly nor was there a significant effect of modality or a significant modality x group interaction. There was a significant association between group and the number of children who did not pass any ToM tasks, $\chi 2(2, N=42)=17.57$, $p<.001$. We found a significant difference in the average ToMI score by group, $F(2,41)=5.62$, $p<.007$, with no significant difference between parents of children with ASD (*M*=6.33, *SD*=4.94) or DD (*M*=7.18, *SD*=4.24), but significantly higher ToMI scores reported by parents of TD children (*M*=11.63, *SD*=4.49).Â ToM and ToMI scores were moderately correlated, $r(40)=.37$, $p=.018$.
Conclusions: Â Our findings suggest that three-year-old children with ASD or DD demonstrate significant delays in their desire-belief understanding compared to TD children across modalities, and that parent's perceptions of their child's understanding of beliefs and desires coincide with their child's performance on ToM tasks. Future studies should look at desire-belief understanding in older children with ASD and DD to document the developmental trajectories of these abilities and to investigate how children with ASD and DD might differ from TD children on other ToM constructs, such as knowledge/ignorance and false beliefs.Â Furthermore, additional research linking parent's perceptions of their child's ToM skills with children's performance on ToM tasks may inform the development of parent-mediated interventions that address social-cognitive developmental delays in children with ASD and DD

270 **110.270** "Friends Are Hard…but It Gets Better": An Examination of the Friendship Experiences of Adolescent Girls and Adult Women with and without Autism

F. R. Sedgewick[1]*, V. Hill*[2] *and E. Pellicano*[1]*, (1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)Psychology and Human Development, UCL Institute of Education, London, United Kingdom*

Background:
While much is known about the friendships and peer relationships of autistic children, these studies have focused largely on school-age boys on the autism spectrum. The very limited research on autistic girls' friendships intriguingly suggests, however, that they might be more similar to those of neurotypical adolescents than autistic boys.
Objectives:
This research sought to examine the friendship experiences of two cohorts of autistic females, adolescent girls and adult women, alongside their neurotypical counterparts, to elucidate the similarities and (subtle) differences across distinct stages of development.
Methods:
We conducted semi-structured interviews with 60 participants, including 30 from each age group (15 autistic girls, 15 neurotypical girls; M age = 14 years 2 months; M Social Responsiveness Scale (SRS) score = 83.8 autistic; 46.7 neurotypical) (15 autistic women, 15 neurotypical women: M age = 30 years 6 months; M SRS score = 78.3 autistic; 41.8 neurotypical). Thematic analysis was used to identify themes.
Results:
Almost all participants discussed having one or more secure friendship, although some autistic participants said that they had significant difficulty in maintaining relationships.
Â
Friendships online. Neurotypical girls used social media to display their offline friendships in the online environment, 'liking' friends' posts as a way of affirming the relationship. Autistic girls were at a severe disadvantage in terms of this 'friendship performance', as they often had limited access to social media and therefore could not engage in these reinforcing behaviours. In contrast, autistic women relied heavily on social media to enact their relationships, preferring written communication and often being active in online communities, making the internet an integral part of their social lives.
Â
*Competition.*Â Adolescents spoke of a sense of trying to 'be the best' in many different ways. This competition was within friendships as well as with wider peers. Autistic girls frequently described being unable to understand how to effectively engage in these behaviours, and therefore 'losing' social cachet. This competition during adolescence was mentioned by both autistic and non-autistic women in terms of past friendships, and that they actively avoid such people in adulthood.
Â
Conflict management. Â Autistic girls and women displayed a more 'extreme' social profile than their neurotypical peers, who generally sought to negotiate equitable outcomes when faced with conflict. In contrast, autistic adolescents felt they would either give up on the friendship or assume total responsibility for finding a solution, potentially leaving them vulnerable to manipulation. Similarly, autistic adults frequently said they would simply end a relationship that was difficult for them, leaving them happier and more satisfied with their social situation than they had been as a teenager.
Conclusions:
Despite identifying a wide range of challenges in the friendships of teenage autistic girls relative to neurotypical peers, these challenges tended to dissipate with age and maturity. Although adult autistic women acknowledged some continued social challenges, they generally described being highly satisfied with their friendships. Targeted interventions around self- and other-awareness may help autistic girls to identify and pursue the sort of relationships that would make them happiest.

271 **110.271** "My Brain Helps Me Think about Stuff": Autistic Children's Understanding of the Brain and Its Role in Behaviour

M. J. Bovis[1]*, E. Pellicano*[2,3] *and A. Alexander*[4]*, (1)55-59 Gordon Square, Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (3)School of Psychology, University of Western Australia, Perth, Australia, (4)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, UNITED KINGDOM*

Background: Very little is known about autistic children's knowledge of their own and other people's brains. The only existing study (Baron-Cohen 1989) suggested that autistic children have a relatively limited view of brain function, ascribing it with behavioural rather than mentalistic functions.
Objectives: Here, we sought to replicate Baron-Cohen's task and extend it to examine further children's perception of the brain and its role in shaping behaviour.
Methods: Cognitively able autistic (n=21) and neurotypical (n=39) children, aged between 6 and 11 years and of similar age and general cognitive ability, took part in structured interviews assessing knowledge of the functions of the brain and heart (cf. Baron-Cohen, 1989) and its perceived role in their own behaviour. We also used vignettes of neurodiverse children to prompt discussion (e.g., boys with possible autism, girl with possible autism, boy with possible ADHD) of the role of the brain in other people's behaviour.
Results: Contrary to Baron-Cohen (1989), we found no significant differences in the number of autistic and neurotypical children ascribing mentalistic functions to the brain. There was wide variability in children's responses, within both groups, ranging from full agency (e.g., "my brain was in control of making the right choice") to exerting influence (e.g., "it tells me to do things"). Both groups of children also identified the boys with possible autism and ADHD (but not the girl with possible autism) in the vignettes as not being personally responsible for their behaviour.
Conclusions: School-age children on the autism spectrum show a qualitatively similar conceptualisation of the nature of the brain and its functions to neurotypical children, contrary to previous suggestions. This study is the first stage of a fuller investigation of the way in which children on the autism spectrum understand their own brains and the role they play in shaping their distinctive identities.

272 **110.272** "If I Want to Live I Have to Camouflage": Social Camouflaging in Autism Spectrum Conditions (ASC)

L. Hull[1]*, K. V. Petrides*[1]*, C. Allison*[2]*, P. Smith*[3]*, S. Baron-Cohen*[2]*, M. C. Lai*[4] *and W. Mandy*[1]*, (1)University College London, London, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, University of Cambridge, Cambridge, UNITED KINGDOM, (4)Psychiatry, University of Toronto, Toronto, ON, CANADA*

Background: Â One potential aspect of the female ASC phenotype is the phenomenon of 'camouflaging' – using deliberate and/or automatic techniques to mask characteristics of ASC as a way of coping in social situations. Camouflaging at school, home and in clinical settings may account for the large numbers of women and girls with ASC who do not receive a timely diagnosis or are diagnosed later in life. However, there has been little empirical research into camouflaging to produce a standardised construct. In addition, no research has yet explored camouflaging amongst males with ASC.
Objectives: Â To assess the camouflaging experiences of adults with ASC. This is the first study to investigate camouflaging in a large sample of adults of all genders with ASC, using a systematic, data-driven, qualitative research approach to produce a conceptual model of camouflaging.
Methods: Â As part of a larger online survey, 55 women, 30 men, and 7 other-gendered individuals aged 18-79 with ASC completed a series of open-ended questions about their camouflaging experiences (or lack thereof). Thematic analysis of responses was used to identify key themes relating to respondents' attitudes to camouflaging and its impact on their lives.
Results: Â The vast majority of participants (n = 79) reported camouflaging their ASC in some situations. Respondents viewed camouflaging as a useful tool to help them navigate the social world, but many regretted the need to change themselves in order to fit in. Some viewed camouflaging as deceitful and manipulative, or felt they had little control over their camouflaging behaviours. Physical, emotional and mental exhaustion was the main consequence reported, and this in combination with the more negative attitudes to camouflaging was reported to lead to mental health issues such as anxiety and depression. Some respondents also described camouflaging as a gendered concept, citing the higher social standards set for typically developing women and the common misperception of ASC as a 'male condition'. These were reasons why some respondents felt that female-presenting individuals were more pressured to camouflage than ASC men. Some female respondents felt camouflaging had hindered their ASC diagnosis or access to support.
Conclusions: Camouflaging is a real, meaningful experience in the lives of adults with ASC of all genders. The possibility of camouflaging needs to be considered when assessing individuals for ASC, especially women and girls.

273 **110.273** Using Eye Tracking to Examine Attention to Social Stimuli and Circumscribed Interests in Girls with ASD

C. Harrop[1]*, S. Zheng*[1]*, S. Nowell*[1]*, D. Jones*[1]*, J. Parish-Morris*[2]*, B. Boyd*[1] *and N. J. Sasson*[3]*, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of Texas at Dallas, Richardson, TX*

Background:
Recent research suggests that girls with ASD may differ in important ways from boys with ASD. Two areas of possible distinction include (1) Fewer and/or different restricted and repetitive behaviors (RRBs), particularly with regards to the content of circumscribed interests (CI; Hiller et al., 2015; Frazier et al., 2015); and (2) Greater social motivation (Dean et al., 2014, Sedgewick et al., 2016). Eye tracking studies have examined attention to social scenes/images and images of common CI (Chevalier et al., 2015, Sasson et al., 2008, 2011, 2014), however these studies included predominantly male samples and did not consider the potentially different behavioral phenotype of girls with ASD.
Objectives: Three validated eye tracking paradigms were modified to examine whether social and nonsocial attention differ in boys and girls with ASD.
Methods: ASD girls and boys ages 6-10 and typically-developing girls and boys matched on age and sex are currently being recruited. This abstract details data from 8 girls with ASD on three modified eye-tracking paradigms: 1) a series of visual search arrays that were modified to include *male, female* and *neutral* interest items. We present data from *male vs. female* slides; 2) attention to social images (faces) in the presence of competing object images [either CI or non-CI] measured using a modified paired preference paradigm (Sasson and Touchstone, 2014); 3) a series of social scenes based on the interactive paradigm of Chevalier and colleagues (2015). Scenes were modified to include different levels of sociability (solitary, parallel and dyadic play) and male and female objects. Results for this third paradigm are not reported here, but are anticipated by Spring 2017.
Results: In paradigm one, girls with ASD spent 61.85% of their onscreen fixation time on *female* images compared to 38.15% on *male* images (t=-3.89, p=.01). Girls with ASD explored a greater number of unique *female* images (6.5) than *male* images (5.3; t=-2.96, p=.04). Although overall attention in girls with ASD was less perseverative and detail-oriented than reported in previous studies of males (*Figure 1;* Sasson et al., 2008, 2011), trends emerged for attention to be more perseverative (800ms vs. 430ms; t=-2.23, p=.08) and more detail-oriented (more fixations per image; 1.8 vs. 1.37; t=-1.96, p=0.1) on *female* than *male* images. In the paired preference paradigm, girls with ASD focused more on social stimuli than objects, even in the presence of CI images, a finding that contrasts with boys with ASD (*Figure 2;* Sasson & Touchstone, 2014).
Conclusions: Our data suggest that girls with ASD may be more socially motivated and drawn to *gender typical* images, with social attention comparable to prior typically-developing samples. Although the current sample size is small, data collection is ongoing with an expected sample size of 40 by May 2017. Our data has the potential to reveal different attention patterns in girls with ASD that may serve as protective mechanisms by promoting higher social motivation and reduced perseveration on nonsocial images.

274 **110.274** Social Seeking Behaviour and Its Neurobiological Correlates

I. Dubey[1]*, A. Georgescu*[1]*, K. Vogeley*[2]*, D. Ropar*[3] *and A. Hamilton*[1]*, (1)Institute of Cognitive Neuroscience, University College London, London, United Kingdom, (2)University Hospital Cologne, Cologne, GERMANY, (3)University of Nottingham, Nottingham, UNITED KINGDOM*

Background: Evidence suggests that social stimuli are innately rewarding. The reward value associated with social stimuli motivates us to make effort to seek social contacts. The extent to which social stimuli are able to evoke behavioural effort may vary depending on neuro-biological reward responsiveness and individual differences in value assignment to social stimuli. A recent theory suggests that people with autism spectrum disorders (ASD) differ from typical people in their motivation to engage with others (Chevallier et al. 2012). Neurobiological evidence suggests that people with ASD may have differential processing of social stimuli than typicals. The tasks used to measure social motivation in these studies either focus on anticipation or visual preference for social stimuli. However, anticipation or visual preference are conceptually different from social seeking which is described as the behavioural effort made to engage with social stimuli.
Objectives: This research aims to evaluate social motivation in ASD conceptualized as social seeking i.e. process of making effort to engage with social stimuli. Furthermore, we aim to identify the neurobiological correlates involved in the act of choosing to engage in social interactions.
Methods: Â Choose a movie (CAM) paradigm is used to quantify social seeking. CAM measures the behavioural effort (key-presses) people make to look at social or non-social movies. On every trial a choice between stimuli is presented with different levels of effort. Hence participants constantly evaluate the value of social stimuli against effort. In study 1, we evaluated group of adolescents with (N=37) and without ASD (N=31) on CAM paradigm. In study 2, we tested 24 typical adults (13 males) on CAM paradigm while their neural activation was recorded using fMRI.
Results: Â Logistic regression was used to predict the role of stimuli, effort and their interaction on participants' decision to seek social stimuli. Results from study 1 showed that the social seeking behaviour of the ASD group was significantly influenced by the effort and stimuli, but not by their interaction. These results are similar to study 2, in which typical adults were also influenced by the effort and stimuli, but not their interaction. Our imaging results show significant activation in superior-parietal cortex, the area responsible for information integration, while participant made the decision to seek social stimuli. Imaging findings also suggest a significant correlation between strength of effort made to view social stimuli and activation in middle occipital cortex and post central sulcus, indicating differential cognitive processing for effort levels.
Conclusions: We extend the evidence supporting reduced social motivation in ASD. While people with ASD have lower social motivation, their tendency to seek social interaction may reduce further when higher effort is required. We also present evidence for the differential neural processing in typical adults for effort while seeking social engagement. Overall, our findings indicate that social seeking is a complex process that involves integration of information from various sources such as the subjective reward values and external factors e.g. effort. Each of these factors can influence the social seeking behaviours in people with ASD.

275 **110.275** Lack of Privileged Access to Awareness for Rewarding Social Scenes in ASD

B. Chakrabarti*, H. L. Mihaylova, A. T. Haffey and K. Gray, School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background:
Reduced social motivation is hypothesised to underlie social behavioural symptoms of ASD (Chevallier et al., 2012). Evidence in support of this theory comes primarily from a) eye-tracking studies that commonly show reduced preferential looking to social compared to nonsocial stimuli, and b) differential neural responses to social rewards in individuals with and without ASD. Nearly all of these studies present stimuli above the threshold of awareness. This leads to an open question of whether such reduced preference for attending to social stimuli is seen if stimuli are presented below the threshold of conscious awareness. Continuous flash suppression (CFS) offers a method to test this possibility. A previous study has shown intact prioritisation of protofacial stimuli in autism using CFS (Akechi et al., 2015). However, this study does not explicitly test the difference between social and non-social stimuli, and uses schematic stimuli that are a) low in ecological validity and b) not rewarding.
Objectives:
To test whether individuals with and without ASD show earlier detection of social over nonsocial rewarding scenes that are closely matched for low-level stimulus features.. The measured variable is the time it takes for the target stimulus to overcome the interocular suppression induced by a dynamic mask. In line with the reduced social motivation hypothesis, it is predicted that neurotypicals will show a privileged access to awareness for rewarding social scenes, compared to ASD individuals.
Methods:
38 neurotypicals (11 males, mean age = 21.16) and 30 ASD adults (14 males, mean age =37.19) took part in the experiment. On each trial, a rewarding scene (social/nonsocial) was presented to one eye, and a high-contrast mask pattern updating at 10Hz was presented to the other eye. A control condition with inverted version of the same stimuli was similarly presented. Participants were required to indicate which side of fixation they 'detected anything other than noise'.
Results:
Mean response times were calculated from correct trials. The proportion of incorrect trials was comparable for both the two groups (3.46% for neurotypicals, 3.82% for ASD).
Since the groups were not matched on age, and in light of the known pitfalls of ANCOVA (Miller & Chapman, 2001), data from the two groups were analysed separately using Bayesian analyses (implemented in JASP). In neurotypicals, there was strong evidence for earlier detection of social reward over nonsocial reward stimuli (Bayes Factor [BF] = 839.87; this was not the case for the inverted condition, BF = 0.31). In ASD, there was moderate evidence for a null effect (BF = 0.23; also the case for the inverted condition, BF = 0.20).
Conclusions:
Strong evidence for a privileged access to awareness for rewarding social over nonsocial scenes was observed in neurotypical adults. No such privileged access was seen in ASD individuals, and moderate support for the null model was noted. These results suggest that the purported deficits in social motivation in ASD may extend to early attentional mechanisms.

Cumulative BF for upright social vs. non-social reward stimuli for neurotypicals (left) and ASD (right) individuals.

276 **110.276** Incentive Value of Social Signals in Typical Development and Autism.

A. Vernetti*, T. J. Smith and A. Senju, Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom*

Background: Â It has beenÂ proposed thatÂ typicalÂ development ofÂ social orientingÂ is based on theÂ learningÂ of theÂ association betweenÂ 'engaging' social signals,Â such as positive emotion andÂ gazeÂ cueing,Â and subsequentÂ positive outcomes such as an enjoyable interaction or theÂ opportunity for social learning.Â By contrast,Â atypical social orienting in autismÂ couldÂ result from the difficulty toÂ learn such association,Â resulting in not assigningÂ the rewardÂ valueÂ to 'engaging'Â social stimuli.
Objectives: Â A novelÂ interactiveÂ eye-trackingÂ task was developed to investigate visual orienting towards social signals associated with a rewarding stimulus in typicalÂ developingÂ toddlers, children and adults as well asÂ inÂ children with autism.

Methods: Â A group of typically developingÂ toddlers (n = 32, 3-4Â years old) and a group of typical adults (n = 32, 18-45Â years old) (study 1) as well as two groups of typical and autistic children (n = 58, 6-18years old, study 2) completed the interactive eye-tracking task. The participants observed a stimulus display consisting of two peripherally presented dynamic social signals (faces) and a centrally presented reward. Participants' eye movements were concurrently recorded with an eye-tracker, and the location of participant's fixation triggered the delivery of corresponding stimuli on-line. Fixation on each face triggered a dynamic sequence of signals and subsequent delivery of a reward, which was a popular animated cartoon, or a penalty, a blank screen. Two types of social signals were presented. An engaging social signal consisted in a person greeting and turning towards the centre of the screen while the other non-engaging social signal consisted in a person moaning and turning away from it. Engaging social signals triggered reward delivery for half the participants of each group, and non-engaging social signals for the other half of the participants of each group.
Results: Preliminary analyses revealed that both typically developing toddlers and adults (study 1) and both groups of children with and without autism (study 2) were able to learn the association between either of the social signals and the subsequent reward delivery, and preferentially orient to the reward-predictive cues. Importantly, all the groups acquired stronger preference when the reward-predictive social signal was engaging than when it was non-engaging.

Conclusions: These preliminary results show that typically toddlers, children and adults as well as children with autism were able to learn the reward value of social signals (either engaging or non-engaging) when such signals were associated with a rewarding stimulus. Moreover, these studies showed that the engaging nature of social signals facilitates the learning of social signal-reward association both in typically developing children and in adults, as well as in children with autism. The implications of these findings are discussed.

277 **110.277** Reward Modulates Mimicry-Related Neural Response in Neurotypical but Not Autistic Individuals

J. Neufeld[1,2,3]*, C. T. Hsu*[2,3,4] *and B. Chakrabarti*[3]*, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (2)Centre for Integrative Neuroscience and Neurodynamics (CINN), University of Reading, Reading, United Kingdom, (3)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (4)Brain, Language, and Computation Lab, Department of Psychology, Pennsylvania State University, University Park, PA*

Background: Autism Spectrum Disorders (ASD) are marked by difficulties in forming social bonds. It has been hypothesized that diminished motivation to attend social stimuli because they are not perceived as rewarding might be causal to the deficits in social cognition observed in ASD (Chevalier et al., 2012). Differential reward processing might further be linked to the deficits in spontaneous facial mimicry as widely reported in ASD. While people with low autistic traits have been shown to spontaneously mimic happy faces more if they were correlated with higher reward, individuals with high autistic traits did not show such differential mimicry (Sims et al., 2012). In a recent study we further found that reward value impacts on mimicry-related neural response and that autistic traits modulate this impact in neurotypical individuals (Sims et al., 2014). However, this relationship has not yet been tested within a clinical sample.
Objectives: In this study, we investigate whether the learnt reward value of faces impacts mimicry-related neural response in people with Autism similarly as in typically developing (TD) controls.
Methods: 26 adults with ASD and 25 neurotypical adults, matched for age, gender, and IQ took part in this experiment. Neutral faces were conditioned with high and low reward value outside the scanner where participants won money during a virtual card game in the presence of some faces (high reward) and lost money in the presence of other faces (low reward) (similar to Sims et al., 2012). Subsequently, participants passively viewed videos of the conditioned faces (high vs low reward) smiling at them in a 3T fMRI scanner. Differential BOLD response to high vs low reward faces in the inferior frontal gyrus (IFG) as indicator of mimicry-related response (cluster identified through an independent meta-analysis of mimicry (Caspers et al., 2010)) was tested for group differences. Further, individual differences in this contrast [high>low reward faces] was tested for an association with self-reported autistic traits as measured by Autism Spectrum Quotient (AQ).
Results: Multiple regression analysis contrasting the response to high vs low reward faces revealed lower response in left IFG, in the ASD group compared to the matched control group (β_{group} = -1.88, p (1-tailed) = 0.033). Further, t-value of this contrast was negatively correlated with AQ across the whole sample (β_{AQ}= -0.3, p = 0.02).
Conclusions: Our results suggest that for individuals with ASD and high autistic traits mimicry-related brain response to smiling faces is less modulated by learned reward value when compared to TD controls. The result suggest that the translation of liking to increased spontaneous imitation might be reduced in people with ASD. Further, another previous study from our lab showed that being imitated by a face lead to less VS activity in people with ASD as compared to controls (under revision), indicating that the link between reward and mimicry is affected in both directions in ASD. The latter could be a potential mechanism underlying difficulties in building social rapport.

278 **110.278** Reduced Looking at Imitative Actions in Young Children with ASD

L. Ruta[1,2]*, F. I. Fama*[1,3]*, L. M. Spadaro*[1,3]*, C. Carrozza*[1,3]*, E. Leonardi*[1,3]*, F. Marino*[1]*, G. Tartarisco*[1]*, G. Pioggia*[4] *and B. Chakrabarti*[5]*, (1)Institute of Applied Sciences and Intelligent Systems, "Eduardo Caianiello" (ScienceApp), National Research Council of Italy, Messina, Italy, (2)IRCCS Stella Maris Scientific Institute, Pisa, Italy, (3)University of Messina, Messina, Italy, (4)Institute of Applied Sciences and Intelligent Systems, "Eduardo Caianiello", National Research Council of Italy, Messina, Italy, (5)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background:
Imitation is a fundamental component of social behaviour, and noted from early stages of human development. Atypical imitation has been reported in ASD in clinical and observational accounts. One hypothesis suggests that imitation serves to build social rapport due to its inherently rewarding nature. The rewarding nature of imitation is noted from neuroimaging evidence that shows increased activity in reward-related neural regions when participants are being imitated, or watching imitative vs non-imitative interactions (Kuhn et al., 2010; Kuhn et al., 2011). A recent study using eye-tracking and self-report demonstrated that individuals with low trait empathy showed a reduced reward value for imitation (Neufeld & Chakrabarti, 2016). These lines of evidence lead to the question of whether imitation carries a similar reward value for children with and without ASD. Reduced reward value for imitation might manifest in reduced attention to imitative actions, which in turn can have long-term consequences, since many essential skills including language and social learning relies on and benefits from imitative actions.
Objectives:
To test, using an eye-tracking experiment, whether children with and without ASD attend equivalently to videos of naturalistic imitative play.
Methods:
Fifty-one children (22 ASD, 29 typically developing children (TD), aged 29-93 months (ASD mean=57.5, SD=17.5; TD mean=60.2, SD=8.1) were enrolled in the study. TD children were recruited in two mainstream nursery schools in Messina, Italy. ASD children were tested at the clinical facilities within the National Research Council of Italy (CNR), Messina. The Autism Diagnostic Observation Schedule - Second Edition (ADOS-2) and the Griffith's Mental Development Scale (GMDS) were used as part of the diagnostic assessment.
The experiment consisted of 6 trials (4 toy activity videos, and 2 gross motor imitation activity videos) of a child and an adult imitating each other (4 actions each video) in a naturalistic play interaction, presented on a computer screen. Each trial lasted 25 seconds and was presented in a random order. Gaze patterns were recorded with a SMI iView XTM RED dark-pupil 120Hz eye-tracking system (Sensomotoric Instruments, 2005) and exported using SMI **BeGaze 2.4** software. Statistical analyses were conducted using R (http://www.r-project.org/). A linear mixed effects model (package: lme4) was applied to explore the effect of group, gender and age to predict looking time (dwell time), accounting for the random effects of the different trials and the different regions of interest (adult and child activity, adult and child face, background). Results:
A main effect of group was observed on the looking time to imitative actions (Wald chi square= 6.1, p = .01), lowering it by about 1.15 sec(SE=0.45 sec) in the ASD group. No significant effect of age and gender was found (Wald chi square= 0.99, p = 0.3 and Wald chi square= 1.6, p = 0.2 respectively).
Conclusions:
We found a significant group difference in the amount of time spent attending to the imitative activities, with the ASD children attending less than the TD children to the videos. This provides preliminary evidence of a reduced reward value for imitative actions in ASD.

279 **110.279** Patterns of Individual Change in Response to Reciprocal Imitation Training

S. Malik[1], *C. Oliver*[2], *C. Stefanidou*[3], *J. Moss*[3], *B. Ingersoll*[4], *A. Wainer*[5], *L. Kossyvaki*[6] *and J. McCleery*[7], *(1)School of Psychology, University of Birmingham, Birmingham, UNITED KINGDOM, (2)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (3)University of Birmingham, Birmingham, UNITED KINGDOM, (4)Michigan State University, East Lansing, MI, (5)Rush University Medical Center, Oak Park, IL, (6)School of Education, University of Birmingham, Birmingham, United Kingdom, (7)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Reciprocal Imitation Training (RIT) is a naturalistic developmental behavioural intervention targeting social imitation skills. Previous research has shown RIT to be effective in increasing spontaneous object and gesture imitation. In a recent replication trial of a previous pilot-RCT of RIT, our RIT treatment group demonstrated a significant increase in spontaneous play-based object imitation skills compared with a wait-list control group (Malik, 2016). Alternatively, we did not replicate previously observed gains in elicited imitation skills.
Objectives: The aim of the present study was to evaluate whether individual children in the treatment group demonstrated reliable change in spontaneous and elicited imitation skills, and to further examine response to treatment in relation to child characteristics.
Methods: Twenty-four children with autism participated in the pilot randomized controlled trial. Stratified randomization led to two well-matched groups of 12 children: Treatment and Wait-List Control. Primary change measures included an Unstructured Imitation Assessment (UIA) and a Structured Imitation Assessment (SIA). These measures were administered pre- and post-intervention. Mullen Scales of Early Learning (MSEL) and Autism Diagnostic Observation Schedule (ADOS) were administered to characterize the children. Twenty sessions of RIT were delivered to the Treatment Group.
Results: Reliable Change Index (RCI) was calculated for both the Treatment and Wait-List groups to explore individual patterns of change that might be associated with RIT. On the UIA, 4 children showed Reliable Change in the Treatment group. Closer inspection of individual data revealed that these were also the only children in the entire dataset who did not exhibit any unusual sensory interests or complex mannerisms on the ADOS. One child exhibited reliable change in spontaneous imitation skills in the Wait-List Control group. No child exhibited skill deterioration in the Treatment group, whereas one child in the Wait-List Control exhibited skill deterioration. One child improved reliably on the SIA in the Treatment group while no child in the Wait-List group demonstrated reliable change on the SIA.
In order to examine child characteristics associated with response to treatment, correlation analyses were conducted between spontaneous imitation change scores (UIA) and chronological age, non-verbal mental age, and verbal mental age (MSEL), and all ADOS domains. In the Treatment group, total spontaneous imitation change scores were negatively correlated with ADOS Reciprocal Social Interaction (r_s = - 0.67, p <0.01), and ADOS Stereotyped Behaviours and Restricted Interests (r_s = - 0.61, p = 0.01). In the Wait-List group none of the child characteristics were associated with change in imitation scores.
Conclusions: A greater percentage of children showed reliable improvements in the RIT treatment group (33%) as compared with the Wait-List Control group (8%). Findings from both RCI and correlation analyses suggest that children who had fewer self-stimulatory behaviours were more likely to respond to RIT. These findings support the efficacy of RIT for children with ASD, but also suggest that children presenting with greater social difficulties and/or greater stereotyped, repetitive behaviours may be less likely to benefit from RIT.

280 **110.280** Intuitive Cooperation in Autism

M. Brosnan *and C. Ashwin, University of Bath, Bath, UNITED KINGDOM*

Background:
Dual Process Theory of Autism (Brosnan et al., 2016) proposes that slower, deliberative (Type 2) processing dominates in people with a diagnosis of ASD, whereas rapid, intuitive (Type 1) processing typically dominates in the general population. Rand et al. (2012) propose that cooperation, as assessed through a 'donating' task, is enhanced through Type 1 processing (e.g. when forced to make a fast decision) and diminished under Type 2 processing (e.g. with more time to deliberate on the decision).
Objectives:
There were three objectives: 1) To replicate the 'fast-cooperation' effect; 2) To examine if autistic-like traits in the general population relate to cooperation (assessed through amount donated) and the fast-cooperation effect; and 3) To examine if a group on the autism spectrum differed from a typically developing (TD) control group on cooperation (assessed through amount donated) and the fast-cooperation effect.
Methods:
1) 154 participants from a university open day volunteered to undertake a 5-minute online task, and were randomly allocated to either a fast (decide within 10 seconds) or slow (think about the decision for at least 10 seconds) condition. The decision was to identify how much of 40p would be donated to a collective pot to be doubled and distributed equally amongst all group members (and how much was to be kept for themselves, see Rand et al., 2012). 2) This task was repeated with 53 (33M, 20F), 17 year olds, who also undertook an assessment of autistic-like traits. 3) This task was repeated with 29 people with ASD (20M, 9F) and 32 TD controls (17M, 15F) aged 17.
Results:
1) Mean Fast condition (n=83) = 29.35 (SD 10.60); Mean Slow condition (n=71) = 26.06 (SD 13.00); $t(134.991)=1.71$, $p<.05$; Cohen's $d = .28$. The effect was significant, but small (around 8%), and in line with prediction.
2) A Linear Regression revealed that greater autistic-like traits were a significant predictor of a lower amount donated (Beta= -.34, $p<.02$) but condition (fast/slow – the effect was 5%) and sex (male/female) were not (both $p>.05$).
3) An ANOVA with amount donated as the dependent variable with Diagnosis (ASD/TD) and condition (Fast/Slow), and sex as a covariate revealed no significant relationships (all $p>.05$). Examining the insignificant trends, the ASD group donated around 8% less than the TD group in both conditions, see Figure 1.
Conclusions:
There is a relatively consistent effect in the manipulation of co-operation (around 8%) which may be affected by the speed of presentation (consistent with Rand et al.) or level of autistic-like traits (consistent with Brosnan et al.) – but these variables do not interact with each other. It would seem that those with ASD are as susceptible to the fast-cooperation effect as the TD group. Taken as a whole, the patterns in the data would suggest that higher autistic-like traits (including a diagnosis of ASD) are associated with less cooperation (8%, as measured by this task) and are as equally susceptible to the effects of time pressure as comparison groups.

281 **110.281** Preserved Socio-Economic Decision Making in Autism Spectrum Disorder: Evidence from the Ultimatum Game

***A. M. Acosta Ortiz**, S. Reimers and S. B. Gaigg, Psychology, City, University of London, London, United Kingdom*

Background: Game theoretical tasks have contributed significantly to our understanding of the role of intuitive and more deliberative reasoning processes in social decision making. One of these tasks is the Ultimatum Game (UG; Fehr & Schmidt, 2006), in which a proposer can decide how to split a given amount of money (£10) between themselves and a responder who then has the opportunity to either reject or accept the offered amount. If the responder accepts, the money is paid out as proposed; if s/he rejects neither participant receives any amount. The UG reliably demonstrates that social-economic decisions are primarily governed by relatively intuitive pro-social motives rather than rational thought. Thus, proposers commonly offer equal shares and responders tend to reject offers below 30%, when it would be rational for the proposer to offer the minimum amount possible under the assumption that a rational responder would accept something over nothing *(Fehr & Schmidt, 2000).* The difficulties that individuals with ASD demonstrate in various aspects of social cognition, coupled with their relative strengths in rule-governed and analytical thinking, would lead to the prediction that decisions on the UG by individuals with ASD would be based relatively more on deliberative thought than social-emotional intuition.
Objectives: To test the above prediction by examining the effects of time pressure on decision making in ASD on standard and modified versions of the UG that require either a standard reject/accept decision of offers or a calculation of whether more or less than 30% has been offered.
Methods: 23 ASD and 23 age and ability matched TD adults completed a multi-trail UG in which 48 offers were presented that varied across four levels of fairness (50%, 40%, 25% or 20% of varyingly sized pots). On two blocks participants needed to make standard accept/reject decisions, either under a 1.5 second time limit or no time-limit. On another two blocks, participants needed to indicate whether they were offered more or less than 30% of the total pot, again either under time pressure or not. Finally, participants completed the cognitive reflection task (CRT; *Frederick, 2005)*, which provides a measure of how likely people are to override instinctual responses with reflective thought.
Results: A significant Task x Time pressure interaction showed that time pressure significantly impacted on participants' ability to indicate whether offers were more or less than 30% without any significant effects on rejection rates. The absence of any group differences, suggests that both individuals with and without ASD reject offers more on the basis of an instinctual reaction rather than a rational calculation, which was further supported by inverse correlations between rejection rates and CRT even when overall accuracy on the mathematical calculation task was statistically controlled.
Conclusions: Contrary to predictions, the results suggest that individuals with and without ASD rely on similar intuitive, rather than deliberative processes to formulate decisions in the UG. The results will be discussed in light of additional evidence which suggests few differences in how individuals with and without ASD form decisions on the UG.

282 **110.282** How Accurate Are Adults with Autism in Gauging How Their Personality Traits Are Evaluated By Others?

***N. J. Sasson**[1], A. Pinkham[2], D. J. Faso[3], K. E. Morrison[2] and M. Chmielewski[4], (1)University of Texas at Dallas, Richardson, TX, (2)The University of Texas at Dallas, Richardson, TX, (3)University of Texas at Dallas, Allen, TX, (4)Southern Methodist University, Dallas, TX*

Background: Adults with autism spectrum disorders (ASD) are characterized by impairments in social cognition that contribute to social dysfunction (Sasson et al., 2011). Reduced understanding of the views and mental states of others in ASD (Happe, 1994) may result in a failure to adjust social behaviors depending upon the perceived expectations and knowledge of a social partner.
Objectives: The current study examines whether adults with ASD are less accurate than typically-developing (TD) controls at evaluating how their personality traits are viewed by others. We predicted that the ASD and TD groups would not differ on the self-perception (SP) of their personality traits or on how they expected others to perceive them (EOP), but they would differ on how unfamiliar others actually perceive them and on the accuracy of their EOP.
Methods: 412 undergraduates (294 female; M age = 20.2) rated videos of 11 adults with ASD (8 male; M age = 26.5) and 11 matched TD controls (8 male; M age = 25.9) on 20 personality traits drawn from the Big Five and autism-related questionnaires. The videos depicted ASD and control participants completing the "High-Risk Social Challenge Task" (Gibson et al., 2010) in which they make a one minute "pitch" for why they should be hired for a reality television program. ASD and control participants also rated themselves (SP), and how they thought someone would rate them upon their first meeting (EOP), on the same 20 personality traits.
Results: Averaged across the 20 traits, the ASD and TD groups did not differ in how they rated themselves ($F(1,20)=.17$, $p=.684$), or how they expected to be rated ($F(1,20)=.01$, $p=.937$). For individual traits, they differed only on the ASD group having a higher SP and EOP rating for creativity, and the TD group having a higher SP rating for being organized. However, undergraduates rated the ASD group less favorably than the TD group both overall ($F(1,410)=1823.56$, $p<.001$), and on every trait after correcting for multiple comparisons (corrected alpha=.0025) except for being quarrelsome. The ASD group was also less accurate at predicting how they would be rated. The discrepancy between their EOP and how they actually were rated was larger than for the TD group, both overall ($F(1,411)=1519.86$, $p<.001$), and on every trait after correcting for multiple comparisons, except for being more accurate on stubbornness and disorganization.
Conclusions: Although the ASD and TD groups largely did not differ on their self-perception of their personality traits or on how they expected others would perceive them, unfamiliar third party evaluators perceived the TD group more positively than ASD group. Further, the ASD group was far less accurate at predicting how they would be perceived than the TD group. Such inaccuracies may specify a potential mechanism through which reduced social cognitive ability may contribute to social impairment for adults with ASD.

283 **110.283** The Neural Bases of Social Motivation in Autism Spectrum Disorder during a Real-Time Peer Interaction

L. C. Anderson[1]*, E. Sadikova*[1]*, K. R. Warnell*[2]*, M. G. Pecukonis*[1]*, D. Moraczewski*[3] *and E. Redcay*[1]*, (1)Department of Psychology, University of Maryland, College Park, MD, (2)Department of Psychology, Texas State University, San Marcos, TX, (3)University of Maryland, College Park, MD*

Background: Difficulties with social communication and social interaction, including reduced interest in both approaching and sharing information with peers, are core features of autism spectrum disorder (ASD). Some hypothesize that reduced social motivation in ASD is one cause of these social communication deficits. However, functional magnetic resonance imaging (fMRI) studies investigating the neural correlates of social motivation in ASD reveal inconsistent findings. Critically, these past paradigms do not involve social *interactions*, which is a core area of dysfunction in ASD. Rather, participants are asked to passively and independently view images (e.g., static photos of smiling faces), which may not approximate real-world social communicative contexts. This lack of reciprocal social interaction and real-world applicability is troubling since individuals with ASD have the most difficulty in interactive social communicative contexts but may perform within normal limits on non-interactive laboratory tasks related to social cognition (Schilbach et al., 2013; Senju et al., 2009).
Objectives: Â The purpose of this study was to utilize a real-world interactive fMRI paradigm to investigate neural circuitry underlying social motivation in ASD.
Methods: Â Twelve children with ASD (ages 9-14, one female) and eleven gender-matched NT children (ages 8-12) were informed they would be chatting online both with a peer and a computer. The chat was simulated, but all children believed that the peer was real. Each trial had two phases: Initiation, in which participants disclosed information about themselves (e.g., "I like sushi") and Reply, in which participants received feedback from the peer ("Me too/neither!") or computer ("Matched!").
Results: Â During the Initiation period, neither NT nor ASD participants showed differences in activation between initiating a conversation with a peer versus a computer at the whole brain level (all whole-brain results are given at $p<0.01$, k = 20), potentially due to the high reward value of self-disclosure regardless of recipient. However, during the Reply period, NT participants showed greater activation in amygdala, ventral striatum (VS), orbitofrontal cortex (OFC), medial prefrontal cortex (mPFC), superior temporal sulcus (STS), and temporoparietal junction (TPJ) when they believed they were receiving a reply from a peer versus a computer, while participants with ASD showed no significant differences to peer versus computer replies. Between-group (NT versus ASD) whole-brain and region of interest (VS and amygdala) analyses revealed no significant differences between groups in neural activation to peer versus computer in either the Initiation or Reply phases; however, this may have been due to the current small sample size. These findings are preliminary, and data collection is ongoing.
Conclusions: In summary, preliminary results suggest that neurotypical children, but not children with ASD, show greater activation in classic reward and social cognitive brain regions when interacting with a same-aged peer (versus a computer control). The investigation of neural and behavioral correlates of social motivation within real-time social interactive contexts will help us better understand the core social deficits in ASD as well as typically developing children's drive to orient to and interact with the social world.

284 **110.284** Caregivers and Their Children with Autism Reading Together

V. Fleury[1]*, K. Young*[2] *and A. Boh*[1]*, (1)University of Minnesota, Minneapolis, MN, (2)University of Minnesota, Hastings, MN*

Background:
Experts have stressed the importance of including language and early literacy instruction as part of early intervention programming for children who are at-risk for reading difficulties but our understanding of literacy skill development for children with autism remains under-addressed in research and practice. Shared book reading interventions are well-studied approaches for bringing about change in language and early literacy with the additional benefit of being highly valued by both caregivers and early childhood professionals. To maximize the potential for shared reading, there is a critical need for research to be conducted in homes of children with autism to identify factors that can promote or inhibit shared reading experiences.
Objectives:

- To examine the extent to which children with autism actively participate in shared reading activities with their caregivers.
- Discuss challenges around participant recruitment and launching a program of research as a recently transplanted early career scholar.

Methods:
We used a quasi-experimental group design to study shared reading interactions of caregivers reading to their typically developing children (*N*=20) and caregivers reading to their children with autism (*N*=18). Caregivers read a total of nine books to their preschool-age child: preferred books selected by the child and/or caregiver from their personal library; unfamiliar fictional books; and unfamiliar non-fictional books. All reading sessions were videotaped to allow research assistants to code videos for the quality of joint engagement during book readings. Children's levels of engagement during book reading sessions were measured using continuous time sampling. Definitions of engagement have been adapted specifically for book reading from previous work on joint attention (Adamson, Bakeman, & Deckner, 2004; Wong & Kasari, 2012).
Results:
Our preliminary analyses reveal that children with autism spent more time unengaged (9.5%) in reading compared to typically developing children (3.4%). In addition children with autism demonstrated more frequent behaviors that disrupted reading sessions (3.3%) compared to their typical peers (1.7%). Typically developing children spent the majority of book reading in a passive engagement state (63.4%; e.g., listening to the caregiver read) followed by joint engagement (29.8%; e.g., making comments, responding to questions). Children with autism spent less time passively engaged (47.7%) and more time jointly engaged (38.1%) compared to typically developing children. Analyses of factors that may influence child engagement, specifically book type (familiar, non-fiction; fiction) and quality of parent book reading, are forthcoming.
Conclusions:
Shared book reading requires that children are able to sustain social interaction around a particular book, which can be challenging for many children with ASD due to difficulties with social communication and joint attention. These preliminary findings suggest that engagement in shared reading is both qualitatively and quantitatively different for children with autism compared to typically developing children. Additional analyses are forthcoming that will allow us to identify malleable factors that can promote or inhibit shared reading experiences, which may serve as targets for future intervention.

285 **110.285** Environmental Impacts on Language Development of Young Children with ASD

***J. B. Plavnick**, Michigan State University, East Lansing, MI*

Background:
Vocal language development of children with autism spectrum disorders (ASD) is an essential component of early intervention programs (Goldstein, 2002; Norrelgen et al., 2015), yet collecting representative language data can be difficult. Standardized direct assessments of children's language may be impacted by fluctuations on a given day, particularly for children with more severe ASD symptoms. Language samples obtained across time in the participant's natural environment provide a more complete account of language development and environmental effects on language (Kasari, Lord, & Tager-Flusberg, 2013; Tager-Flusberg et al., 2009). However, these samples require extensive time and money to collect.
Objectives:
The purpose of this study was to assess the language development and environmental impacts on language of young children with ASD enrolled in an early intensive behavioral intervention program. The Language ENvironment Analysis (LENA) system was used to collect and analyze weekly language samples of children with ASD. Gains in vocalizations and conversational turns will be assessed. In addition, correlations between environmental variables (e.g., instructional ratios, locations in center, activities) and vocalizations of children with ASD will be examined.
Methods:
Language samples of 16 children with ASD enrolled in an early intensive behavioral intervention program were collected twice a month over an eight-month period using the LENA Digital Language Processor and analyzed using the LENA software. Recording sessions lasted approximately 6.5 hr for each child at each time point. Child vocalizations, adult word count, and conversational turns between the child and adults were extracted for analysis. Paired samples t-tests were used to assess for differences in dependent measures at pre and post. Researchers also collected participants' daily activity schedules to correlate environments and activities with frequencies of child vocalizations, adult words, and conversational turns between adults and children.
Results:
Preliminary results indicate high within participant variability in frequency of vocalization and conversational turns between adults and child participants. During a given day, children appear to demonstrate higher vocalizations during group activities, with fewer vocalizations during one-to-one instructional programming. A complete description of correlations between environment and dependent variables will be presented.
Conclusions:
The results suggest variations in activities and instructional programming can impact the language of children with ADS. The LENA processor and software allow for an economical collection of language samples, which can reveal patterns in behavior across environments. By identifying environmental variables associated with high and low language levels, it may be possible to construct educational and therapeutic environments that are more meaningful for children with ASD.

286 **110.286** Function-Based Intervention with E-Coaching in Reducing Challenging Behaviors during Home Visits

***A. Fettig**, University of Massachusetts Boston, Boston, MA*

Background:
Challenging behaviors present a significant barrier to learning for children with disabilities and are a source of stress for families and practitioners. Extensive research has shown that function based interventions (FBI) are effective for reducing challenging behaviors and increasing pro-social behaviors in young children with disabilities, including Autism Spectrum Disorder (Duda et al, 2008; Fettig, Schultz, & Sreckovic, 2014). Studies that compared FBI to non-function based interventions have noted distinct advantages of this approach (Ingram, Lewis-Palmer, & Sugai, 2005). Research also demonstrated that follow-up coaching and support were *necessary* for ensuring high fidelity implementation (Barton & Fettig, 2013). Across this literature, coaching of FBI generally involved face-to-face meetings and multiple home visits. This is costly and time and resource intensive, which might limit the amount of support practitioners receive. Few have examined the use of web-based technology (videoconferencing, texting, emails) to support practitioners (Ludlow & Duff, 2002), and this might be a feasible approach. To date, no FBI studies have examined effects of videoconferencing to support interventionists to implement intervention during home visits. Given the need for cost effective and accessible approaches, a logical next step is to investigate effectiveness of e-coaching for supporting implementation of FBI with children with disabilities and challenging behaviors.
Objectives:
This study explored the effects of an e-coaching approach within FBI for an early interventionist working with a toddler with ASD and challenging behaviors. The research questions were: was e-coaching functionally related to the interventionist's implementation of FBI and was high fidelity of implementation of FBI related to a decrease in the child's challenging behaviors.
Methods:
The target behaviors for this study were: interventionist's implementation of FBI, missed opportunities for use of strategies and child challenging behaviors. The FBI was derived from the individualized behavior support plan (BSP) created with the parents and the interventionist. The BSP included strategies that supported interventionist in preventing challenging behaviors (e.g. visual cues for transition), teaching the child new skills (e.g., prompt child to ask for help) and responding to challenging and appropriate behaviors (e.g., redirection and praise).
Single subject, multiple baseline across behaviors design (Kazdin, 2011) was used to examine changes in the interventionist's use of FBI with the introduction of e-coaching. E-coaching via Facetime™ was introduced with the first set of FBI strategies (prevention) demonstrating baseline stability following the training sessions. Once the first behavior demonstrated stability with e-coaching, e-coaching commenced with the next set of strategies (teaching new skills and then responses to behaviors) to demonstrate baseline stability.
Results:
The results indicated that e-coaching was effective in supporting early interventionist's implementation of FBI and high fidelity of implementation resulted in reduced child challenging behaviors. Social validity data as well as research and practice implementations will also be shared.
Conclusions:
Given the study results and the need for cost effective and accessible approaches, educators should consider using e-coaching to support the implementation of FBI with children with ASD and challenging behaviors.

287 **110.287** The Transformative Learning Experiences of Parents during Parent Education Groups

T. Schultz[1] *and S. Kucharczyk*[2]*, (1)University of Wisconsin-Whitewater, Whitewater, WI, (2)Curriculum & Instruction, University of Arkansas, Fayetteville, AR*

Background:
Many parents of children with ASD have opportunities to participate in parent education groups. While focusing primarily on knowledge and skill acquisition (Schultz, Schmidt, & Stichter, 2011), these programs offer natural opportunities for dialogue and group support for parents with similar needs. Parent groups have potential for facilitating transformative learning through critical reflection on parent practices, discovering new perspectives and insights, and acting on new learning through changes in patterns of parenting (Wolfe, 2001; To, 2013). However, it is not yet understood how parents of children with ASD experience parenting groups and the potential for transformative learning within these contexts.
Objectives:
What were the potential and critical factors for fostering transformative learning experiences of parents of children with ASD participating in parent education groups?
Methods:
In order to better understand the transformative potential of such an education group, interviews were conducted with 17 parents who completed a parent education group (SCI-P) for parents of children with ASD. During the interviews, experiences of transformative learning and how group facilitation hindered or supported such learning were explored. Interviews were recorded and transcribed. Transcripts were coded through an iterative, collaborative process using a constant-comparative approach (Lincoln & Guba, 1985) that progressed from open coding using NVIVO (2012) software, to two additional passes across interviews using codes emerging from literature and research team discussions, to the development of matrices to further identify consistencies and discrepancies across participants (Huberman & Miles, 1994; Strauss & Corbin, 1998). Finally, themes were developed to answer the research questions and are described in the following section.
Results:
Two major themes emerged from the data. First, parents reported perspective shifts, which empowered them to act and think differently. Parents identified three areas in which they reframed how they thought: characteristics of ASD, their child's potential and parent actions, and being alone. The second major theme parents discussed was the impact the group characteristics had on their experience. Specifically, they were affected in positive ways by the openness of the group, the similarities they had with other parents, and the differences they had from other parents.
Conclusions:
Facilitators of parent groups are unlikely to recognize the potential for transformative learning for parents of children with ASD, given the limited research of transformative learning in informal, applied educational settings outside of higher education or the workplace (Taylor, 2007). Based on this study, facilitators should consider the value of promoting transformative learning given the various forms of perspective shifts and possible outcomes. They should incorporate ways to support the transfer of this learning into daily lives. The critical role relationships between and among the parents held for learning, suggest facilitators must integrate approaches to encourage and nurture relational spaces which are open and safe. Additionally, the importance of diversity in parenting experiences that resulted in disorienting questions and insights suggest facilitators should consider criteria for group participation (e.g., time since diagnosis).

Oral Session - 1A
112 - Prevalence, Trajectories and Treatment of Medical and Psychiatric Comorbidity
1:45 PM - 2:35 PM - Yerba Buena 3-6

Session Moderator: Bryan King, *UCSF Department of Psychiatry, University of California, San Francisco, San Francisco, CA*

1:45 **112.001** Medical Conditions in the First Years of Life Associated with Future Diagnosis of ASD in Children

L. A. Croen[1], *S. E. Alexeeff*[2], *V. Yau*[3], *Y. Qian*[2], *M. N. Davignon*[4], *P. M. Crawford*[5], *F. Lynch*[5] *and R. L. Davis*[6], *(1)Kaiser Permanente Division of Research, Oakland, CA, (2)Division of Research, Kaiser Permanente Northern California, Oakland, CA, (3)Kaiser Permanente, Berkeley, CA, (4)Kaiser Roseville Medical Center, Roseville, CA, (5)Center for Health Research, Kaiser Permanente Northwest, Portland, OR, (6)Department of Pediatrics, UTHSC, Memphis, TN*

Background: Many children with ASD have co-occurring medical conditions. However, large scale epidemiologic studies of health conditions emerging in the period preceding the first ASD diagnosis are lacking. Earlier ASD diagnosis and treatment can reduce the degree of impairment and improve function, thus identifying factors that precede a future ASD diagnosis could be immensely useful. If particular conditions are associated with future ASD diagnosis, ongoing surveillance of these conditions might aid in screening for ASD, enabling earlier identification and treatment.
Objectives: To examine medical conditions diagnosed prior to the first ASD diagnosis, assessing their prevalence and associations with subsequent ASD diagnosis.
Methods: The study population was drawn from the population of all children born from 2000-2009 and continuously enrolled in Kaiser Permanente (KP) in Northern California, Georgia, and the Northwest for the first two years of life. Data from electronic medical records (EMR) were reviewed through June 2012. We used a matched case-control design and included medical conditions documented prior to the first ASD diagnosis (N=3,911) or the matched age for controls (N=38,609). Over 1,000 ICD-9 codes were grouped into 79 medical conditions (e.g., constipation) within 19 domains (e.g., gastrointestinal). We fit conditional logistic regression models to estimate the odds ratio (OR) for the associations of medical conditions and subsequent ASD diagnosis. Adjusted models accounted for the matching by site and age and adjusting for sex, maternal race, maternal education, and household income. We also used the Conditional Inference Tree supervised clustering method to identify condition clusters associated with subsequent ASD risk.
Results: The average age of ASD diagnosis was 3.99 years. Of the 79 medical conditions tested, 38 were statistically significantly associated with subsequent diagnosis of ASD after adjusting for multiple testing. Developmental delay, mental health, and neurology conditions had the strongest associations with ASD diagnosis (ORs from 2.0 to 23.3). Within the developmental delay domain, language delays were the most frequently diagnosed among ASD cases during the pre-diagnostic period (49%) and most strongly associated with ASD risk (OR=23.3, 95% CI 21.4-25.4). Disruptive impulse conduct disorders (5.2%), attention-deficit/hyperactivity disorders (ADHD) (6.4%), and anxiety disorders (3.2%) were the most prevalent mental health conditions and had the strongest associations with ASD risk (ORs from 10-15). Moderately strong associations were observed for nutrition, genetic, ear nose and throat, and sleep disorder conditions (ORs from 2.1 to 3.2). Metabolic, musculoskeletal, ophthalmology, pulmonary, and many gastrointestinal conditions had weaker associations (ORs from 1.2 to 2.2). We identified several condition clusters associated with subsequent ASD diagnosis. Children with language delays in combination with mental health conditions had the highest risk of a subsequent ASD diagnosis. In the absence of developmental delay and mental health diagnoses, children with ophthalmology, ear nose and throat, and nutrition diagnoses were most likely to be subsequently diagnosed with ASD.
Conclusions: Children with ASD experience a higher prevalence of many medical conditions prior to their first ASD diagnosis. Using medical conditions as a predictive tool may speed the identification of children with ASD, leading to earlier intervention and improved outcomes.

1:57 **112.002** Pilot Randomized Control Trial of Cognitive Behavioral Therapy for Insomnia Modified for Families with a Child with Autism Spectrum Disorder

M. C. Souders[1], *J. E. Connell*[2], *R. Schaaf*[3], *C. M. Kerns*[4], *W. T. Eriksen*[5], *S. Zavodny*[6], *R. Sinko*[7], *L. Guy*[8], *B. A. Malow*[9] *and J. Pinto-Martin*[6], *(1)University of Pennsylvania/The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Thomas Jefferson University, Phhiladelphia, PA, (4)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (5)University of Pennsylvania School of Nursing, Philadelphia, PA, (6)University of Pennsylvania, Philadelphia, PA, (7)Thomas Jefferson University, Philadelphia, PA, (8)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (9)Vanderbilt University Medical Center, Nashville, TN*

Background: Chronic severe insomnia is one of the most common conditions in children with Autism Spectrum Disorder (ASD), affecting 60-80%. Insomnia in ASD have many possible biological, behavioral and cultural mechanisms. Scientists hypothesize that anomalies in the synaptic pathways of the brain may account for “arousal dysregulation” in ASD. Arousal dysregulation may produce a constellation of behavioral symptoms including anxiety, sensory sensitivities, hyperactivity and insomnia. Based on the idea that a subgroup of children with ASD are in a hyper-aroused state, we developed a calming module that included 12 relaxing and soothing activities that could decrease arousal levels. We modified Cognitive Behavioral Therapy for Insomnia (CBT-I) and included the calming module to address the internal factors and sensory sensitivities that threaten sleep. Currently, the standard care (SC) for behavioral insomnia in ASD is a 1-hour parent education session using a Sleep Tool Kit developed by the ATN and this may not be sufficient in all children with ASD to improve their sleep.
Objectives:
Therefore, the specific aims of this pilot Randomized Control Trial (RCT) were to:

1. determine feasibility and acceptability of implementing a CBT-I and SC vs. SC only RCT.
2. estimate the effects of CBT-I and SC vs SC only on sleep parameters and arousal/anxiety symptoms.

Methods: Sample: 40 parent-child dyads, children ages 6-10 years with insomnia, Two-groups: n=20 SC only (control) vs n=20 CBT-I and SC. SC group received a 1hour education session.. The intervention group received SC plus CBT-I, which included 8 weekly home visits to teach and tailor positive evening routines, calming module, and faded bedtime protocol. Data was collected for both groups using actigraphy, sleep diary, CSHQ, PARS, SCARED, RBS and sensory profile at baseline, week 4 and week 8.
Results: 97 % of families reported that the randomization process and interventions were very acceptable. All children were able to tolerate the actigraph. Baseline mean sleep latency using actigraphy in both groups was over 30 minutes, meeting criteria for insomnia (36.73 min vs. 40.11 min). Both groups’ mean CSHQ score was above 42, indicating sleep problems. After intervention, CBT-I group had greater decrease in wake minutes (-65.68 min vs. -18.69 min, p=0.037), increase in sleep minutes (46.13 min vs. 8.24 min, p=0.073) and increase in percent sleep (10.61% vs. 2.26%, p=0.034) as compared to SC only. Sleep latency decreased for both groups (SC and CBT-I, -17.01 min, p=0.001; SC, -7.53min, p=0.083), but CBT-I group experienced a clinically significant decrease, with the average post-intervention sleep latency falling below the cut-off for insomnia (19.71 min).CBT-I parents reported a greater decrease in night wakings on the CSHQÂ than SC parents (-1.32 vs. -0.19, p=0.046).
Conclusions: Â This pilot RCT was acceptable and feasible. The SC intervention was effective at decreasing sleep latency and is consistent with previously published data. CBT-I group had more consolidated sleep, shorter sleep latency and fewer wake minutes than SC only group. CBT-I was effective in significantly improving night wakings which has been a difficult problem to solve for families with ASD.

2:09 **112.003** Trajectories of Reported Challenging Behaviours Derived from the Aberrant Behavior Checklist in a Cohort of Canadian Children with Autism Spectrum Disorders

T. Bennett[1], *P. Szatmari*[2], *E. Duku*[3], *S. Georgiades*[3], *I. M. Smith*[4], *P. Mirenda*[5], *J. Volden*[6], *L. Zwaigenbaum*[7], *M. Elsabbagh*[8], *W. Ungar*[9] *and T. Vaillancourt*[10], *(1)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (2)Centre for Addiction and Mental Health, Toronto, ON, CANADA, (3)McMaster University, Hamilton, ON, CANADA, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (5)University of British Columbia, Vancouver, BC, CANADA, (6)University of Alberta, University of Alberta, AB, CANADA, (7)University of Alberta, Edmonton, AB, CANADA, (8)McGill University, Montreal, CANADA, (9)Sick Kids Research Institute, Toronto, ON, Canada, (10)University of Ottawa, Ottawa, ON, CANADA*

Background: Â Many children with Autism Spectrum Disorder (ASD) exhibit challenging behaviour that can interfere with child development and family well-being. Hyperactivity and irritability are common components of challenging behaviour. It is important to understand their developmental trajectories from time of diagnosis in order to effectively plan early intervention.
Â The Aberrant Behavior Checklist (ABC) was developed to measure the effects of intervention on challenging behaviour for people with intellectual disabilities (Aman, Singh, Stewart, & Field, 1985). The ABC is a 58-item caregiver-rated instrument with five subscales: Irritability, Lethargy, Stereotypy, Hyperactivity and Inappropriate speech, with higher scores indicating more severe problems. It has been used in several intervention studies among children with ASD (Kaat, Lecavalier & Aman, 2014).
Objectives: Â Using data from the longitudinal "Pathways in ASD" Study, we aim to examine: (a) the reliability and validity of the ABC in newly diagnosed children, (b) the stability of Hyperactivity and Irritability scores from (i) time of diagnosis at age 2-4 years to age 6 years, and (ii) after the transition to school (from age 6 years to age 12 years), (c) associations with parent- and teacher-reported aggression in participants at age 12.
Methods: Â Reliability of the ABC subscales was assessed using Cronbach's coefficient alpha and validity was assessed using correlations of subscales with the Child Behavior Checklist (CBCL) 1.5-5 and 6-18, Autism Diagnostic Observation Schedule (ADOS) and Vineland Adaptive Behavior Scales-II (VABS-II). Piecewise growth modeling was used to capture the trajectories during the preschool years and the transition at age 6 to and through the school context.Â Multiple regression was used to examine associations between Irritability and Hyperactivity scores at time of diagnosis with parent- and teacher-rated aggression as rated using the CBCL (controlling for baseline ASD symptoms and gender).
Results: Â Baseline data were obtained on 369 children, 84% boys, with mean age 40.8 months (SD 9.1 months).Â Internal consistencies for the subscales of the ABC varied between Cronbach's alpha of 0.8 and 0.9. Correlations between the ABC and CBCL subscales were 0.7 or greater, and correlations with the ADOS overall severity metric were low. Wave-to-wave correlations of the ABC Hyperactivity and Irritability subscales were 0.7 or greater. Correlations between the ABC Hyperactivity and Irritability subscales at each wave were 0.5 or greater. Examination of the Hyperactivity subscale trajectory showed relative stability in reported behaviours from time of diagnosis to age 6 years, after which reported Hyperactivity decreased over the school-aged period. However, for the trajectory of the Irritability subscale, a slight but constant decrease was seen from diagnosis to age 12. Parent-reported child Irritability and Hyperactivity scores at time of diagnosis were significantly associated with parent- and teacher-rated aggression problems at age 12.
Conclusions: The ABC shows adequate reliability and validity in this sample of children with ASD. Different trajectories were observed for Irritability and Hyperactivity subscales. Early childhood irritability and hyperactivity may predict higher levels of aggression at home and school during later childhood. Early intervention planning should explicitly assess child hyperactivity and irritability as important and potentially modifiable targets.

2:21 **112.004** Are Social and Communication Difficulties a Risk Factor for the Development of Social Anxiety?

H. Pickard[1], *F. Rijsdijk*[2], *F. Happé*[3] *and W. Mandy*[4], *(1)Social, Genetic and Developmental Psychiatry, King's College London, London, United Kingdom, (2)Institute of Psychiatry, KCL, London, UNITED KINGDOM, (3)King's College London, London, UNITED KINGDOM, (4)University College London, London, United Kingdom*

Background: Social Anxiety (SA) disorder is elevated in Autism Spectrum Disorder (ASD), a neurodevelopmental condition characterised by social and communication (SC) difficulties. In typically developing children, greater SC difficulties are commonly associated with heightened SA symptoms, both at a clinical and subclinical level. Whether SC difficulties place children at an increased risk of developing SA is unclear.
Objectives: Using a longitudinal design, this study aimed to disentangle the relationship between SC difficulties associated with ASD and SA symptoms in a population-based sample of children from the Avon Longitudinal Study of Parents and Children (ALSPAC).
Methods: Parent-reported data (n=9,491) on SC difficulties and SA symptoms was collected at age 7, 10 and 13. A cross-lagged panel design explored the stability and predictive relationship between latent SC difficulties and SA constructs over time. The specificity of these relationships was examined whilst controlling for generalised anxiety at all ages. Model comparisons were conducted to explore sex differences in these relationships.
Results: A significant relationship was observed between SA symptoms and SC difficulties at all ages. Earlier SC difficulties (age 7/10) predicted a significant amount of variance in later SA symptoms (age 10/13), but the reverse relationship from SA to SC difficulties was not observed. The relationship from SC difficulties to SA was strongest from 7 to 10 years old. The specificity analyses controlling for generalised anxiety revealed an identical pattern of results, with SC difficulties predicting SA, but not the reverse relationship. No sex differences in the directional relationships between SC difficulties and SA were observed.
Conclusions: The results indicate a directional and asymmetrical relationship with SC difficulties associated with ASD in mid-childhood predicting SA symptoms in late childhood. This suggests that SC difficulties may be an important and specific risk factor for the development of SA. A stronger contribution of SC difficulties to SA symptoms was observed in earlier childhood, suggesting that this may be a critical developmental period to target with earlier interventions. These findings indicate the importance of incorporating social skills training alongside effective interventions to alleviate symptoms of SA in children, as well as developing preventative approaches to foster SC development in those at a greater risk of developing clinical SA.

Oral Session - 1B
113 - New Directions in the Pharmacological Treatment of Social Disability in ASD
2:40 PM - 3:30 PM - Yerba Buena 3-6

Session Moderator: Bryan King, *UCSF Department of Psychiatry, University of California, San Francisco, San Francisco, CA*

2:40 **113.001** A Randomized Controlled Trial of Riluzole in Autism Spectrum Disorder

R. Nicolson[1], *T. Bennett*[2], *O. Akintan*[3], *C. Harvey*[4], *J. A. Brian*[5], *L. Capano*[6], *C. Hodgins*[7], *O. Kraus de Camargo*[3], *D. Mankad*[5], *A. Ahmad*[7], *M. Chalupka*[8], *L. Colli*[9], *L. Genore*[5], *A. Greco*[8], *T. Lui*[10], *A. Iaboni*[5], *I. O'Connor*[11], *D. Odrobina*[5], *K. Thorpe*[12] *and E. Anagnostou*[12], *(1)University of Western Ontario, London, ON, CANADA, (2)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (3)McMaster University, Hamilton, ON, Canada, (4)University of Western Ontario, London, ON, Canada, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (7)Lawson Health Research Institute, London, ON, Canada, (8)McMaster University, Hamilton, ON, CANADA, (9)Psychiatry and Behavioural Neuroscience, McMaster University, Hamilton, ON, CANADA, (10)Holland Bloorview, Toronto, ON, CANADA, (11)McMaster Universtiy-Offord Centre, Dundas, ON, CANADA, (12)University of Toronto, Toronto, ON, Canada*

Background: Medications currently indicated for children and adolescents with Autism Spectrum Disorder (ASD) are used to treat interfering behaviours often seen in ASD, but there are no medications with evidence supporting their use to treat the core symptoms of the disorder. Convergent evidence, however, suggests that ASD is associated with a shift in balance of neural excitation to inhibition. Riluzole is a glutamatergic modulator with neuroprotective and plasticity-enhancing properties, suggesting that it may play an important role in the treatment of neurodevelopmental disorders.
Objectives: The primary aim of this study was to investigate the safety and efficacy of riluzole in treating the core symptom domains in ASD. The effect of riluzole on interfering behaviours seen in children and adolescents with ASD was also examined.
Methods: 58 children and adolescents (mean age: 11.5±3.0 years) participated in a 12 week, randomized, double-blind, placebo-controlled trial of riluzole. Riluzole was started at 50mg daily and, for subjects 12 years of age and older, was increased after two weeks to 50mg twice daily. The primary outcome measure was the Aberrant Behaviour Scale – Social Withdrawal subscale [ABC-SW] score). Repetitive and ritualistic behaviors were evaluated by the Yale-Brown Obsessive-Compulsive Scale [YBOCS] total score, and the Repetitive Behaviour Scale [RBS] total score. Adverse effects were also assessed every two weeks using the Safety Monitoring Uniform Research Form (SMURF). Irritability, hyperactivity, and anxiety, common interfering behaviours in ASD, were evaluated using the relevant ABC subscales and the Spence Children's Anxiety Scale.
Results: 54 patients completed the trial. Four patients withdrew from the trial (two from each group), two due to adverse events and two due to the withdrawal of consent. Riluzole was well tolerated, with no serious adverse reactions reported.Â There were no significant differences between participants on placebo and those on riluzole with regards to social withdrawal, repetitive behaviour, or ritualistic behaviour (ABC-SW: p=0.3; YBOCS: p=0.1; RBS: p=0.1). However, subjects taking riluzole did have a significantly greater and clinically meaningful reduction in their scores on the ABC-Irritability (p=0.03) and ABC-Hyperactivity (p=0.03) subscales. None of the other outcome variables showed significant group differences.
Conclusions: Although riluzole was generally well-tolerated, it was not superior to placebo in terms of reduction in the core symptom domains of ASD. However, patients taking riluzole did show a significantly greater reduction in hyperactivity and irritability, both of which are interfering symptoms commonly associated with ASD.

2:52 **113.002** A Randomized Controlled Trial of Intranasal Oxytocin in Autism Spectrum Disorder

E. Anagnostou[1,2], *J. A. Brian*[1,2], *C. Campo-Soria*[3], *L. Capano*[1,4], *A. N. Esler*[3], *R. Hudock*[3], *D. Mankad*[1,2], *M. Penner*[1,2], *S. Francis*[3], *L. Genore*[2], *A. Iaboni*[2], *D. Odrobina*[2], *N. Peleg*[2], *D. Rambeck*[3], *E. L. Shankland*[3], *A. Dupuis*[1,5] *and S. Jacob*[3], *(1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)University of Minnesota, Minneapolis, MN, (4)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)The Hospital for Sick Children, Toronto, ON, Canada*

Background: There are currently no medications with evidence supporting their use to treat the core symptoms of the disorder. Convergent evidence, however, suggests a role for oxytocin in social cognition and reward.
Objectives: The primary aim of this study was to investigate the safety and efficacy of intranasal oxytocin in treating social withdrawal in autism spectrum disorder (ASD). The effect of oxytocin on social cognition as well as anxiety was also examined.
Methods: 60 children and adolescents (mean age: 12.4 ± 1.8 years) participated in a 12 week, randomized, double-blind, placebo-controlled trial of oxytocin, at 0.4 IU/kg twice a day. The primary outcome measure was the Aberrant Behavior Scale – Social Withdrawal subscale [ABC-SW] score). Adverse effects were also assessed every two weeks using the Safety Monitoring Uniform Research Form (SMURF). Aspects of social cognition as well as anxiety and quality of life were also evaluated.
Results: 54 patients completed the trial. 6 patients withdrew from the trial (5 active, 1 placebo), 1 due to adverse events and 5 due to the withdrawal of consent. Oxytocin was overall well tolerated, with no serious adverse drug reactions reported.Â There were no significant differences between participants on placebo and those on oxytocin on social withdrawal (ABC-SW: p=0.6). However, participants taking oxytocin did have a significant improvement in social recognition as measured by the Let's Face It! Battery (p=0.02). This was not seen in the case of object recognition as measured by the same battery (p=0.4) suggesting a specific social recognition effect.
Conclusions: In our sample, oxytocin was not superior to placebo in terms of reduction in social withdrawal. However, participants taking oxytocin did show a significant improvement in social recognition, suggesting that oxytocin may impact aspects of social cognition but may not be adequate to improve social function on its own.Â Implications for combination trials will be discussed.

3:04 **113.003** Intranasal Vasopressin Treatment Improves Social Abilities in Children with Autism

K. J. Parker[1], *O. Oztan*[1], *R. A. Libove*[1], *R. D. Sumiyoshi*[1], *D. S. Karhson*[1], *J. Summers*[2], *K. Hinman*[1], *K. S. Motonaga*[3], *L. K. Fung*[1], *D. S. Carson*[1], *J. M. Phillips*[1], *J. P. Garner*[4] *and A. Y. Hardan*[1], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Georgetown University, Washington, DC, (3)Pediatrics, Stanford University, Palo Alto, CA, (4)Comparative Medicine, Stanford University, Stanford, CA*

Background: There are currently no medications that target autism spectrum disorder (ASD)'s core social deficits. However, neurobiological systems that are critical for social functioning are arguably one of the most promising for ASD therapeutic target discovery. Arginine vasopressin (AVP) is one such candidate; it plays a critical role in promoting social behavior and experimental dysregulation of the AVP signaling pathway produces social deficits in animal models.
Objectives: We tested the safety and efficacy of 4-week intranasal AVP administration to improve social abilities in children with ASD using a double-blind randomized placebo-controlled trial design.
Methods: Participants were medically healthy outpatients (N=18 males, N=4 females), aged 6 to 12 years. Participants underwent comprehensive diagnostic and behavioral testing, and blood samples for safety monitoring and biomarker quantification were obtained. Participants were then randomized 1:1 to receive either AVP treatment (a maximum of 12 IU BID or 16 IU BID based on age) or placebo treatment. The primary outcome measure was change in social ability as assessed by parent ratings on the Social Responsiveness Scale 2 (SRS-2) between baseline and after treatment. Throughout the trial, drug safety was assessed. Upon completion of treatment, SRS-2 ratings and participants' blood samples were again obtained. Blood AVP levels and oxytocin receptor (OXTR) and AVP receptor v1a (AVPRv1a) gene expression levels were quantified via enzyme immunoassay and qPCR, respectively.
Results: Using a general linear model, including treatment (drug vs. placebo) and the biomarker measures, we found that treatment efficacy depended on pre-treatment AVP levels ($F_{1,9}=7.3544$; $P=0.0239$). Further analysis revealed that pre-treatment AVP levels predicted treatment response in participants receiving drug ($P=0.0099$), but not in those receiving placebo, suggesting that pre-treatment AVP levels may be useful in discerning children most likely to respond to AVP treatment. The treatment x AVP levels interaction therefore informed our comparison of drug-treated and placebo-treated participants. AVP-treated participants improved by an average of 12.8 ± 3.5 points on the SRS-2 Total Score ($P=0.0102$), but placebo-treated participants' SRS-2 Total Scores did not significantly differ from a 0 point improvement. We also observed a pre-treatment "biomarker signature" that predicted treatment efficacy. Thus, in addition to the effect of pre-treatment AVP levels, participants with lower OXTR gene expression, and higher AVPRv1a gene expression, showed greater improvement in SRS-2 Total Scores, particularly when relative expression was contrasted in each participant ($F_{1,9}=8.060$; $P=0.0194$). Finally, no differences in the rates of adverse events were observed between the placebo-treated and AVP-treated groups, and there were no changes from baseline in patients' electrocardiogram, vital signs, or clinical laboratory measurements during AVP treatment.
Conclusions: This is the first study to show that intranasal AVP treatment is well tolerated and improves social abilities in individuals with ASD. Findings from this pilot study also suggest that pre-treatment neuropeptide measures may help identify patients most likely to benefit from AVP treatment. This research has high potential to lead to development of the first effective and personalized medication to treat ASD's currently intractable social deficits.

3:16 **113.004** Results of a Phase 2 Randomized Double-Blind Placebo Controlled Study (VANILLA) Investigating the Efficacy and Safety of a V1a Antagonist (RG7314) in Adult Men with ASD

Background: The neuropeptide vasopressin (AVP) acts both as an endocrine hormone in the periphery and locally in the brain where it modulates social behaviors. Several lines of evidence suggest that inhibition of the vasopressin 1a receptor (V1a) could be beneficial for the treatment of core symptoms of Autism Spectrum Disorder (ASD). In the valproic acid rat model of ASD, V1a inhibition has been shown to improve social deficits in a dose-dependent manner. In a recently conducted proof-of-mechanism study we have shown that a single i.v. dose of a V1a inhibitor (RG7713) leads to subtle improvements of biomarkers of social communication in male adults with high-functioning ASD. RG7314 is an orally available V1a competitive antagonist with high specificity for V1a over V1b, V2, and oxytocin receptors that has demonstrated a favourable safety profile and pharmacokinetic parameters in healthy volunteers.
Objectives: The primary objectives of the VANIILA study were to evaluate: 1) the efficacy of 12-week treatment with RG7314 in treating social and communication deficits in adult men with high functioning ASD and 2) the safety and tolerability of RG7314. Secondary and exploratory objectives included the evaluation of effects of RG7314 on aberrant, adaptive, and repetitive behaviours, anxiety and mood as well as the estimation of pharmacokinetics parameters.
Methods: A staggered parallel-group, randomized, double-blind, placebo-controlled study was conducted with three doses of RG7314 (1.5, 4 or 10 mg PO per day). The treatment duration was 12 weeks and the study proceeded sequentially through four stages. Transitions from one stage to the next were decided by an Internal Monitoring Committee and an external Scientific Oversight Committee and the decisions were based on safety data review. Stage 1 tested placebo and 1.5 mg; Stage 2 placebo and 4 mg; Stage 3 placebo and 10 mg; and Stage 4 placebo, 1.5 mg, and 10 mg. The primary outcome measure was the caregiver rated SRS-2 scale. Secondary and exploratory measurements included the Vineland Adaptive Behavior Scales, second edition (VABS-II), the Aberrant Behavior Checklist (ABC), the Repetitive Behavior Scale-Revised (RBS-R), CGI-I, the State-Trait Anxiety Inventory (STAI), and the Anxiety, Depression and Mood Scale (ADAMS), amongst others. ClinicalTrials.gov Identifier: NCT01793441.
Results: A total of 223 subjects were enrolled in the four Stages (Stage 1 = 17; Stage 2 = 111; Stage 3 = 24; and Stage 4 = 71 and the dropout rate was 16.6%. At baseline, mean age was 25 years (SD = 6.53), mean FSIQ was 98.03 (SD=16.52), mean SRS-2 t-score was 77.52 (SD=7.26), mean CGI-S was 4.39 (SD=0.55), and mean Vineland-II™ Standard Composite Score was 60.8 (SD=13). Age, IQ, and ASD severity measures at baseline were generally well-balanced across treatment groups. Based on a blinded preliminary interim assessment, RG7314 appears to be safe and well tolerated. The final primary, secondary, and exploratory outcome measures results will be presented at the meeting.
Conclusions: The VANILLA study provides valuable data to understand the safety, pharmacokinetics, and the effects of RG7314 on social, communication and repetitive behaviours.

Oral Session - 2A
114 - Brain Structure in ASD Across the Lifespan
1:45 PM - 2:35 PM - Yerba Buena 7

Session Moderator: Declan Murphy, *Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

1:45 **114.001** Altered Structural Connectivity of Language Tracts in 6-Week-Old Infants at High Risk for ASD

J. Liu[1], *T. Tsang*[1], *L. P. Jackson*[2], *C. Ponting*[3], *S. S. Jeste*[4], *S. Y. Bookheimer*[1] *and M. Dapretto*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Semel Institute, UCLA, Los Angeles, CA, (3)Clinical Psychology, UCLA, Los Angeles, CA, (4)UCLA, Los Angeles, CA*

Background: Altered structural connectivity has been identified as a possible biomarker of autism spectrum disorder (ASD) risk in the developing brain. Several studies using diffusion tensor imaging (DTI) have shown reduced integrity of major white matter tracts in infants and toddlers who later developed ASD (Conti et al., 2015). Moreover, infants eventually diagnosed with ASD showed slower development of white matter tracts from 6 to 24 months (as indexed by fractional anisotropy (FA) values; Wolff et al. 2012), suggesting that altered or delayed structural connectivity in the early infant brain may be a useful biomarker of ASD. Examining white matter tracts specifically associated with social communicative functions (i.e., language) may lend further insight into early signs of ASD risk. For instance, the arcuate fasciculus (AF), connecting posterior temporal to premotor cortex, and the superior longitudinal fasciculus (SLF), connecting posterior temporal cortex to the inferior frontal gyrus, are two dorsal fiber tracts that connect key language regions of the brain. The AF is myelinated before the SLF, suggesting that the integration of sensory and motor representations must precede more advanced aspects of language processing (Perani et al., 2011). As such, structural connectivity in these tracts could also be used as a predictor of language outcome and ASD diagnosis.
Objectives: Here we investigated key white matter pathways of the dorsal language network in 6-week-old infants at high (HR) and low risk (LR) for ASD to identify atypicalities in structural connectivity that may predict altered developmental trajectories prior to overt language delays and the onset of ASD symptomatology.
Methods: DTI data were collected while infants underwent MRI during natural sleep. Preprocessing was conducted in FSL. Probabilistic tractography was used to examine the AF and SLF in both hemispheres. Indices of white matter integrity (including average fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD)) were extracted from probabilistic tractography and subsequently related to behavioral indices of language development and ASD symptomatology.
Results: Average FA in the AF was significantly higher in the LR group compared to the HR group, but only in the left hemisphere. In contrast, no significant between-group differences were observed for the SLF. Interestingly, however, indices of white matter integrity significantly correlated with later behavioral outcome as indexed by the Autism Observation Scale for Infants (AOSI) at 12 months of age.
Conclusions: These data suggest that early patterns of structural connectivity in the developing brain are measurably different in infants at high risk for developing ASD as early as 6 weeks of age. In line with prior evidence indicating that the SLF matures at a slower rate than the AF, significant differences were observed in the AF but not in the SLF. Specifically, LR infants show higher FA in the left AF, indicating a more mature pattern relative to HR infants. Furthermore, measures of white matter integrity relate to ASD symptomatology. These findings indicate that early differences in language-relevant white matter pathways may predict future language development and provide an early biomarker of ASD risk.

1:57 **114.002** Girls and Boys with Autism Spectrum Disorder Relative to Same-Sex Typically Developing Peers Exhibit Distinct Cortical Folding Abnormalities during Late Childhood and Adolescence

D. Yang[1,2], *S. M. Abdullahi*[3], *A. Jack*[1], *P. E. Ventola*[3], *E. H. Aylward*[4], *M. Dapretto*[5], *D. H. Geschwind*[5], *J. Duncan*[6,7], *S. J. Webb*[8], *S. Y. Bookheimer*[5], *L. Kenworthy*[2], *J. D. Van Horn*[9] *and K. A. Pelphrey*[1,2], *(1)Autism and Neurodevelopmental Disorders Institute, The George Washington University, Washington, DC, (2)Children's National Health System, Washington, DC, (3)Yale Child Study Center, New Haven, CT, (4)Seattle Children's Research Institute, Seattle, WA, (5)University of California, Los Angeles, Los Angeles, CA, (6)Department of Radiology & Biomedical Imaging, Yale University School of Medicine, New Haven, CT, (7)Department of Biomedical Engineering, Yale University, New Haven, CT, (8)University of Washington, Seattle, WA, (9)Laboratory of NeuroImaging, University of Southern California, Los Angeles, CA*

Background: Anatomical imaging studies have revealed pronounced and widespread reductions in gyrification during adolescence in healthy subjects, reflecting a late period of brain maturation. It is not known whether males and females with Autism Spectrum Disorder (ASD) relative to same-sex peers without ASD exhibit cortical folding abnormalities during this developmental period, and how much theÂ abnormalities may overlap.
Objectives: To examine and compare cortical folding abnormalities as measured by an index of local gyrification in girls and boys with ASD during late childhood and adolescence.
Methods: The sample included 219 children and teens (age: M = 13.01y, SD = 2.91y, range = 8.03 – 17.99y; IQ: M = 107.50, SD = 17.87, range = 75 - 167) recruited from five research sites (Yale, Harvard, UCLA, Seattle-1, Seattle-2). There were 54 ASD females, 52 TD females, 59 ASD males and 54 TD males. The four groups were well-matched on age and IQ. Females and males with ASD were well-matched on ASD symptom severity, language ability and adaptive behaviors. F-ASD and F-TD were well-matched on intracranial volume, so were M-ASD and M-TD. All participants underwent a T1-weighted structural scan. Cortical folding was estimated using FreeSurfer v5.3.0 with an additional flag of local gyrification index. Quality of the sMRI images were independently blind-rated by two authors (DY and SA); 30 subjects (6 F-ASD, 5 F-TD, 17 M-ASD, 2 M-TD) exhibiting obvious head motion were discarded. Age was centered before entered into analysis. Results were thresholded at $Z>1.96$ (vertex-level) and $p<.05$ (cluster-level) (two-sided).
Results: While across all participants, there were widespread age-related reductions in cortical folding, ASD males relative to TD males exhibited lower mean levels of cortical folding in the right insula and right postcentral gyrus, combined with abnormally accelerated age-related reductions in cortical folding in the right pars triangularis and the left lateral orbital frontal gyrus. In contrast, ASD females relative to TD females exhibited lower mean levels of cortical folding in the left superior parietal gyrus, and abnormally accelerated age-related reductions in cortical folding in the left rostral middle frontal gyrus.
Conclusions: Our results reveal that females and males with autism relative to their same-sex healthy control counterparts exhibit cortical folding abnormalities during late childhood and adolescence, suggesting abnormally accelerated brain maturation during this period in autism. The specific brain regions exhibiting abnormalities vary by sex, revealing different neurodevelopmental signatures of autism in girls vs. boys.

2:09 **114.003** Longitudinal Pre- and Postnatal Brain Growth Trajectory in ASD: Evidence for a Late Gestation Critical Time Window

F. Bonnet-Brilhault[1], *T. Rajerison*[2], *A. Saby*[3], *M. Guimard-Brunault*[3], *E. Houy-Durand*[1], *S. Roux*[4] *and J. Malvy*[1], *(1)UMR930, INSERM, Université François –Rabelais de Tours, Tours, France, (2)Child Psychiatry, CRA Aquitaine, Bordeaux, France, (3)CRA Centre Val de Loire, CHRU de Tours, Tours, France, (4)Université François Rabelais de Tours, INSERM U930, Tours, France*

Background:
Longitudinal pre- and post-natal brain growth trajectory in ASD remains unexplored despite severalÂ pathophysiological findings targeting both gestational period and early post-natal life. Furthermore early brain overgrowth has been largely reported but more recent studies on large populations do not replicate this result, highlighting both physiopathological and clinical heterogeneity in ASD.
Objectives:
The aim of this study was to characterize longitudinal brain growth trajectory in ASD in both prenatal and postnatal periods to identify the critical time window forÂ pathological neurodevelopmentalÂ processes.
Methods:
Prenatal and postnatal biometric parameters were collected in fetal Ultrasound records and medical records of 94Â patients with ASD (87 males/7 females; meanâ€‰age ±â€‰standard deviation 7.5 ±3.5 years) recruited and fully examined at the Center of Excellence in Autism in Tours (France).Â Diagnosis was made according to DSM-IV-R and DSM-5 criteria (American Psychiatric Association, 2000, 2013) and by using the Autism Diagnostic Interview or the Autism Diagnostic Observation Schedule-Generic. Diagnosis was complemented by the Childhood Autism Rating Scale, Behavioral Summarized Evaluation scale and Developmental Quotients using standardized tools. In utero parameters at 2nd and 3rdtrimester of gestation included Biparietal Diameter (BPD), Femur Length (FL) (N = 94: 87M / 7F) and Head Circumference (HC) (N = 70: 66M / 4F). Postnatal parameters included, HC, body length and birth weight (N = 70: 66M / 4F), HC at 1 year and 2 years (N = 54: 52M / 2F).
Results:
Compared to a French nationally recognized, normative database, ASD patients exhibited greater increase in HC between the 2nd (t= 2.58; p=0.01) and 3rd(t=3.37; p=0.001) trimesters of gestation, whereas BPD and femur length were not significantly increased. At birth, normal HC and weight were observed whereas body length was significantly larger (t=5.01; p<0.001). No brain overgrowth was observed during the first two years of life.
Conclusions:
This first longitudinal pre- and postnatal brain growth study in ASD suggests atypical neurodevelopmental processes during a critical time window between the 2nd and 3rd trimesters of gestation. This result opens discussions on pathophysiological tracks including genetic, inflammatory and structural pathways during this period. Accelerated postnatal brain growth seemed to be inconsistent and illustrates the clinical heterogeneity of ASD.

2:21 **114.004** Amygdala Neuron Number in ASD Is Increased at Pediatric Ages but Decreased By Adulthood

T. A. Avino[1], *N. Barger*[1], *M. V. Vargas*[1], *M. Bauman*[1], *D. G. Amaral*[2] *and C. M. Schumann*[1], *(1)Psychiatry & Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)Department of Psychiatry & Behavioral Sciences, University of California-Davis, Sacramento, CA*

Background: The amygdala is a complex cluster of nuclei located in the rostral portion of the temporal lobe. It plays a prominent role in modulating socioemotional processing, yet little is known about the postnatal neuronal development of this structure in humans. Structural and functional imaging studies have demonstrated an altered age-related growth trajectory and activation of the amygdala across the lifespan in individuals with autism. However, the cellular substrates that underlie this aberrant growth and function are not well understood.
Objectives: Our goal was to quantify the number of mature neurons within subregions of the amygdala in both typical development and autism across the lifespan. We also examine the number of immature neurons within the basal complex of the amygdala using immunohistochemistry as a function of both age and diagnosis.
Methods: We performed a stereological analysis of neuron number and size in subregions of the amygdala utilizing postmortem tissue from 50 human brains (28 Autism, 22 Typical; ages: 2-48 years old) representing the largest study of its kind to date. Additionally, we performed immunohistochemistry for B-cell lymphoma 2 (bcl-2) to examine the number of immature neurons within the basal complex of the amygdala.
Results: The ANOVA analyses demonstrate a significant main effect of diagnosis for lateral nucleus mature neuron number ($F(1,39) = 5.24$, $p < .05$), and significant interactions between age and diagnosis for the total amygdala ($F(2,41) = 5.69$, $p < .01$), basal nucleus ($F(2,41) = 7.13$, $p < .01$), accessory basal nucleus ($F(2,41) = 6.85$, $p < .01$), and central nucleus ($F(2,39) = 4.23$, $p < .05$). *Post hoc* comparisons show that within the pediatric group, individuals with autism have more mature neurons than neurotypical individuals in the basal and central nuclei. In adult cases, individuals with autism have significantly fewer mature neurons relative to neurotypical adults in the total amygdala and in the lateral, basal, and accessory basal nuclei. Preliminary examination of immature neurons shows significant age-related reductions of bcl-2 immunoreactive neurons in the basal complex of the amygdala.
Conclusions: These findings provide the first evidence of the normal pattern of lifelong neuronal development and maturation in the postnatal human amygdala. Furthermore, we demonstrate that these typical processes are disrupted in autism, resulting in an age-related loss of neurons across amygdala nuclei in adults with autism. Our results implicate altered neuronal maturation of the amygdala at early ages in autism with potential subsequent degeneration of this structure in adulthood.

Oral Session - 2B
115 - Neuropathology, Imaging Genetics, and Imaging-behavior Correlations
2:40 PM - 3:30 PM - Yerba Buena 7

2:40 **115.001** Sex-Specific Alterations in Motor Network Morphology in Relation to Repetitive Behaviours: A Twin Study

E. Cauvet[1], *A. Van't Westeinde*[2], *J. Neufeld*[1], *K. Mevel*[3,4], *R. Kuja-Halkola*[5], *R. Toro*[6] *and S. Bolte*[1,7], *(1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institute, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, SWEDEN, (4)Laboratory for the Psychology of Child Development and Education (LaPsyDÉ), CNRS UMR 8240, Sorbonne Paris Cité, GIP Cyceron, Université de Caen Normandie, Université Paris Descartes, Paris, France, Paris, France, (5)Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, (6)Institut Pasteur, Paris, FRANCE, (7)Stockholm County Council, Stockholm, Sweden, Division of Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm, Sweden*

Background:
Restricted and repetitive behaviors and interests (RRBI's) are core symptoms of autism spectrum disorder (ASD) (DSM-5) that are thought to be less prevalent in females than males (Van Wijngaarden-Cremers et al., 2014). Differences in the phenotypic expression and etiology of ASD, including structural morphology of the brain, might underlie this prevalence difference (Supekar and Menon, 2015, Lai et al., 2015). However, for results to be generalizable, the heterogenous expression of ASD, related to variability in environmental and epigenetic factors, needs to be controlled for.
Objectives:
The current study, within the Roots of Autism and ADHD Twin Study Sweden (RATSS) (Bölte et al., 2014), implemented a within-twin pair design to investigate sex differences in the relation between RRBI's and detailed structural morphology of neocortical motor networks.
Methods:
T1-weighted images from 29 female and 39 male MZ and DZ twin pairs (i.e. 134 participants including neurotypicals and individuals across the whole ASD spectrum), aged 9-24 years, were analysed using surface-based morphology software (Freesurfer) to obtain estimates of cortical volume, surface-area and thickness of gyri and sulci involved in the motor network: central, pre-and post-central, superior frontal (including the supplementary motor area), supramarginal, angular, intra-parietal and superior parietal areas. RRBI's were assessed using the subscale from the Autism Diagnostic Interview – Revised (Rutter et al. 2003). Within-pair differences in surface-based estimates were correlated to differences in RRBI's using generalized estimating equation linear models, while controlling for total brain volume and handedness (Edinburgh handedness inventory).
Results:
Behaviourally, males and females did not differ in within-twin pair differences in RRBI's (Kruskal-Wallis $\chi2(1) = 0.007$, $p = 0.9$). Neuroanatomically, RRBI scores were primarily associated with alterations in bilateral primary motor cortex, left SMA and intraparietal sulcus in females, but with alterations in left sensory cortex and the corresponding sensory associative parietal region in males. In females, the associations were mostly negative, indicating that an increase of RRBI symptoms was related to a decrease in brain morphological features. In males, the findings were differentially positively or negatively related to RRBIs. The details of the within-pair association between brain estimates and symptom is reported in table 1.
Conclusions:
Although females did not differ from males on RRBI symptoms, we report different and more regions of the neocortical motor network to be associated with RRBI's in females, supporting the female protective hypothesis. Females were particularly affected in primary motor and SMA in accordance with previous research showing that gray matter in these regions was related to RRBI's in girls, but not boys with autism (Supekar and Menon, 2015). Moreover, we show that RRBIs are associated with anatomical differences of the neocortical motor network even while controlling for genetic and shared environmental factors, indicating that these effects are partly due to non-shared environmental factors. Taken together, our findings suggest that the autistic phenotype is associated with different underlying neurobiology in females.

2:52 **115.002** Autism Risk Gene CNTNAP2 Was Associated with Cingulate Anatomy in Individuals with Autism Spectrum Disorder

Y. L. Chien[1], *S. S. F. Gau*[2] *and Y. J. Chen*[3], *(1)National Taiwan University, Taipai, Taiwan, Taiwan, (2)National Taiwan University Hospital & College of Medicine, Taipei, TAIWAN, (3)National Taiwan University Hospital, Taipei, Taiwan*

Background:
Contactin Associated Protein-Like 2 (CNTNAP2) has been implicated in neurodevelopmental disorders such as autism spectrum disorder (ASD). In addition to being associated with impaired development of language, CNTNAP2 may turn out to be a central node in the molecular networks controlling neurodevelopment. Evidence has shown that carriers of common variants of CNTNAP2 may have altered brain connectivity. Whether the genetic variants of CNTNAP2 are associated with cingulate structure that shows abnormal structure and function in ASD is not yet studied.
Objectives:
This study aims to investigate the association between CNTNAP2 variants and the anatomical structure of cingulate gyrus.
Methods:
We recruited 122 patients with ASD and 118 typically-developing controls. All the participants underwent brain MRI imaging. Brain volume, white matter volume, cortical thickness, and gyrification of cingulate gyrus were analyzed by FreeSurfer software with 74 automatic parcellation. Cingulate gyrus was divided into anterior, middle (anterior and posterior), and posterior cingulate (dorsal and ventral) when comparing volume, gyrification, and cortical thickness. For white matter volume comparison, cingulate gyrus was divided into rostral anterior, caudal anterior, and posterior cingulate. Five SNPs of CNTNAP2 that has been reported to be associated with ASD were genotyped. Main effect of each SNP and group*SNP interaction were examined for each region of cingulate gyrus.
Results:
Preliminary analysis showed that some candidate SNPs of CNTNAP2 may be associated with the gyrification and cortical thickness of anterior part of middle cingulate gyrus and ventral part of posterior cingulate gyrus, with significant age by SNP interaction as well as age by SNP by diagnosis interaction. There was no difference on the regional volume or white matter volume. After Bonferroni correction, the SNP main effect and age interaction remained significant on gyrification of anterior part of middle cingulate gyrus. When ASD and TD were separated, age interaction was still shown in ASD but not in TD, on the gyrification of both regions and on the cortical thickness of ventral part of posterior cingulate gyrus. However, the CNTNAP2 variants we selected were not associated with clinical severity of autistic symptoms in either ASD or TD group, measured by Social Responsiveness Scale and Social Communication Questionnaire.
Conclusions:
Our findings suggest that CNTNAP2 variants might be associated with the gyrification and cortical thickness of middle and posterior cingulate structure, particularly in ASD. These findings need validation in independent samples.

3:04 **115.003** GABA Receptor Binding Density in the Striatum of Individuals with Autism: Novel Findings for Consideration When Designing Human Clinical Autism Studies with Inhibitory Modulators

K. Subramanian[1], *C. Brandenburg*[2] *and G. J. Blatt*[2], *(1)Hussman Institute for Autism, Baltimore, MD, (2)Hussman Institute for Autism, Inc., Baltimore, MD*

Background:
The basal ganglia (BG) is a collection of sub-cortical nuclei that contain inhibitory GABAergic spiny projection neurons (SPN's). The BG projects to the thalamus and has reciprocal connections with multiple cortical regions and the cerebellum. The BG nuclei are implicated in OCD, habit formation, motor, speech, and language disorders. Thus, the BG is an ideal region of interest to examine the neurochemical basis of repetitive, stereotyped behavior and social communication difficulties observed in autism. Prior clinical trials using GABA receptor modulators as treatment in autism have yielded mixed results due to poor behavioral endpoint design. Therefore, the current investigation specifically examines the role of $GABA_A$ receptor changes compared to $GABA_B$ in select regions of the BG in postmortem cases from individuals with autism compared to typically developing controls. Previously, Wegiel et al. (2014) reported volumetric and neuronal density changes in specific BG regions in postmortem autism cases, and Oblak et al. (2011) found a decrease in $GABA_B$ receptor binding in the cingulate cortex, a source of diffuse limbic input to the dorsal striatum.
Objectives:
To determine the binding density of inhibitory $GABA_A$ receptors compared to $GABA_B$ in the BG, specifically, the dorsal and the ventral striatum in autism cases versus controls.
Methods:
Forty-one post-mortem cases were examined in select regions of the BG in age- and PMI-matched cases (n=20 control and n= 21 autism). Sampled regions in the dorsal striatum included caudate and putamen and sampled regions in the ventral striatum included the NAcc core and shell. Cryostat cut 20 µm sections from these regions were incubated with either [^{3}H]-Flunitrazepam 5 nM ($GABA_A$) or [^{3}H]-CGP 54626 3 nM ($GABA_B$) then loaded into X-ray cassettes with tritium standards and apposed to tritium-sensitive film for twelve weeks and fourteen weeks respectively. Two sections per case were used for determining total binding with the tritiated ligand and one section was used for non-specific binding with a competitive displacer. After exposure, the films were developed and digitized on a MCID platform to quantify measurements of binding in femtomoles per milligram of tissue for the ligand. Analysis was performed using student's t-test.
Results:
Significantly high $GABA_A$ expression revealed by [^{3}H]-Flunitrazepam binding was observed in dorsal striatum ($p=0.0024$) and ventral striatum ($p=0.0103$) in autism. In contrast, $GABA_B$ expression revealed by [^{3}H]-CGP 54626 binding was found to be unchanged in the dorsal striatum as well as the ventral striatum in subjects with autism compared to controls ($p>0.05$).
Conclusions:
Since $GABA_A$ receptors are present mainly post-synaptically, increased $GABA_A$ receptors with unchanged $GABA_B$ receptors implies postsynaptic alteration, which adds evidence to excitatory/inhibitory imbalance in select regions of the autism brain. Increased expression of $GABA_A$ receptors is a possible compensation to increased excitatory cortical inputs. Understanding the consequences of GABA receptor alterations in the BG is important for dissecting BG circuitry and its effects on cortical and BG related behaviors. Future human studies using inhibitory modulators should consider changes to GABA receptor targets in the striatum when designing experiments and planning end point outcome measures for clinical trials.

3:16 **115.004** Shared Differences Across Cortical Morphometry Features Associated with Autism Spectrum Disorder

D. Andrews[1], *A. Llera*[2], *M. Gudbrandsen*[1], *E. Daly*[1], *A. Marquand*[2,3], *C. M. Murphy*[1,4], *M. C. Lai*[5,6,7], *M. V. Lombardo*[5,8], *A. N. Ruigrok*[5], *M. Consortium*[9], *S. C. Williams*[3], *E. Bullmore*[10], *J. Suckling*[10], *S. Baron-Cohen*[5], *M. C. Craig*[1,4], *C. Beckmann*[2,11], *D. G. Murphy*[1,4] *and C. Ecker*[1,12], *(1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (3)Centre for Neuroimaging Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)National Autism Unit, Bethlem Royal Hospital, South London and Maudsley NHS Foundation Trust, London, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Child and Youth Mental Health Collaborative at the Centre for Addiction and Mental Health and The Hospital for Sick Children, Department of Psychiatry, University of Toronto, Toronto, Canada, (7)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (8)University of Cyprus, Nicosia, Cyprus, (9)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (10)Brain Mapping Unit, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (11)Centre for Functional MRI of the Brain, University of Oxford, Oxford, United Kingdom, (12)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychiatry, Goethe-University Frankfurt am Main, Frankfurt, Germany*

Background: Aspects of cortical structure such as cortical thickness, surface area, gyrification, and grey-white matter boundary integrity may represent different biological pathways underlying Autism Spectrum Disorder (ASD). Often these anatomical features are investigated in isolation. However, the identification of between-group differences that are shared across modalities could aid in identifying underlying neural mechanisms common to different anatomical features in ASD.
Objectives: We aimed to (1) identify multimodal components representing the inter-relationship between different *in vivo* MRI morphometric measures of cortical anatomy and to (2) relate these components to the ASD phenotype.
Methods: 98 adults with ASD (49 males and 49 females; diagnosed using the ADI-R and ADOS) and 98 matched typically developing controls (51 males and 47 females) aged 18-42 years received structural MRI scans at the Institute of Psychiatry, Psychology and Neuroscience, London, and the Autism Research Centre, Cambridge. Freesurfer software (http://surfer.nmr.mgh.harvard.edu/) was used to derive a set of eight morphometric features describing cortical surface anatomy for each participant (i.e. cortical volume, thickness, surface area, sulcal depth, mean radial curvature, metric distortion, local gyrification index, and grey to white matter signal intensity ratios). A multimodal fusion technique, linked independent components analysis (linked ICA) (Groves et al. 2011, 2012), was used to identify components comprised of shared inter-subject variation between the different cortical measures. Relationships between individual multi-modal components and ASD diagnosis and Autism Spectrum Quotient (AQ) scores were assessed through correlation analysis.
Results: We found one component representing increased cortical thickness and grey-white matter signal intensity ratio (GWR) in temporal and parietal regions as well as decreased gyrification in the cingulate gyrus, which was significantly negatively correlated with a diagnosis of ASD ($p=6.6^{e-5}$) and AQ scores ($p=4.2^{e-4}$). A second component representing (1) increased GWR across the entire cortex, (2) increased cortical thickness and surface area in frontal-temporal regions and (3) decreased cortical folding and gyrification in temporal regions also had a significant negative correlation with AQ measures ($p=3.3^{e-2}$).
Conclusions: We found significant correlations with ASD diagnoses and components comprising of reductions in grey-white matter boundary integrity and cortical thickness as well as increased gyrification. Our findings enrich understanding of the relationship between cortical features, and may aid in identifying neurobiological pathways that contribute to the cross-modal pattern of atypical cortical structure observed in ASD.

Oral Session - 3A

116 - Interventions with Young Children and Parents

1:45 PM - 2:35 PM - Yerba Buena 8

Session Moderator: Connie Kasari, *University of California, Los Angeles, Los Angeles, CA*

1:45 **116.001** Randomised Trial of a Prodromal Intervention for Infants at High Risk for Autism: Longitudinal Outcomes to Age Three Years

J. Green[1], *E. Jones*[2], *T. Gliga*[3], *M. W. Wan*[4], *A. Pickles*[5], *V. Slonims*[6], *G. Pasco*[7], *M. Elsabbagh*[8], *R. Bedford*[9], *T. Charman*[10] *and M. H. Johnson*[3], *(1)University of Manchester, Manchester, England, United Kingdom, (2)Birkbeck, University of London, London, UNITED KINGDOM, (3)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (4)University of Manchester, Manchester, UNITED KINGDOM, (5)King's College London, London, UNITED KINGDOM, (6)Evelina Children's Hospital Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM, (7)Institute of Psychiatry, London, UNITED KINGDOM, (8)McGill University, Montreal, CANADA, (9)Kings College, London, UNITED KINGDOM, (10)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Â There has been increasing interest in the potential for pre-emptive (pre-diagnostic) interventions in the infancy prodrome of autism, but little investigation as to their effect.
Objectives: To determine the longer term developmental outcomes to age 39 months of a parent-mediated video-aided intervention between 9-14 months for infants at familial risk for autism.
Methods: Â Two-site, two-arm assessor-blinded randomised controlled trial a 12-session therapist-delivered, parent-mediated social communication intervention delivered between 9 and 14 months of age (iBASIS-VIPP), against no intervention. iBASIS-VIPP is a modification for the autism prodrome of the Video Interaction for Promoting Positive Parenting (VIPP) programme. The home-based intervention uses video-feedback to help parents understand and adapt to their infant's individual communication style so as to promote optimal social and communicative development. iBASIS-VIPP extended the original 6 session VIPP program by adding up to six planned booster sessions according to need in discussion with family, and added therapeutic procedures to address any emerging developmental atypicality.Â The sample was 54 infants (28 intervention, 26 non-intervention) at familial risk of autism but not otherwise selected by developmental difficulty. Assessments were at 9-month baseline, 15-month treatment endpoint, and 27 and 39-month follow-up. Primary outcome was the level of emergent autism-related behaviour ('prodromal symptoms'), blind-rated on Autism Observation Schedule for Infants **(**AOSI) or Autism Diagnostic Observation Schedule (ADOS-2) across the four assessment points. Secondary outcomes were: blind-rated parent-child interaction (parent non-directiveness on the Manchester Assessment of Caregiver-Infant Interaction (MACI), parent synchrony on Dyadic Communication Measure for Autism (DCMA), child attentiveness on MACI and child initiations on DCMA). Other outcomes were child language (Mullen); non-blind parent-rated communication and socialisation (Vineland). Pre-specified intention to treat analysis combined estimates from repeated measures within correlated regressions to give an estimate of the overall effect of the infancy intervention. To summarize the treatment group differences in a principled fashion, the multiple point estimates were combined into an estimated area between the curves over time (sum of trapeziums, Figures 1 and 2). Trial registration: ISRCTN 87373263.
Results: Effect estimates for the autism prodromal symptoms, largest at 27 months, had confidence intervals at each separate time point including the null, but showed a significant consistent reduction when considered over time (ES=0.32; 95% CI 0.04, 0.60; p=0.026; Figure 1a). Significant overall effects through time were also seen on proximal intervention targets of parent non-directiveness/synchrony (ES=0.33; CI 0.04, 0.63; p=0.013; Figure 1c) and child attentiveness/communication initiation (ES=0.36; (95% CI 0.04, 0.68; p=0.015; Figure 1b). There was no effect on categorical diagnostic outcome, nor on other developmental or language measures (Figure 2a-d).
Conclusions: To our knowledge this is the first study of prodromal intervention for infants at risk, which has focused on emerging autism-related prodromal symptom trajectories and other dyadic treatment targets through 3 years. We demonstrate evidence of a treatment effect, extending after intervention, consisting of significant reduction in the overall level of emergent autism-related behaviours over time and enhanced parent-child dyadic social communication. The study highlights the value for early intervention trials of extended follow-up and repeated assessments within extended follow-up.

1:57 **116.002** Randomized Controlled Trial: Joint Attention Mediated Learning

H. Schertz[1], *S. L. Odom*[2], *K. Baggett*[3] *and J. Sideris*[4], *(1)Indiana University, Bloomington, IN, (2)University of North Carolina, Chapel Hill, NC, (3)Mark Chaffin Center for Healthy Development, School of Public Health Division of Health Promotion and Behavior, Georgia State University, Atlanta, GA, (4)Frank Porter Graham Child Development Institute, Chapel Hill, NC*

Background: Our primary aim was to determine the efficacy of the Joint Attention Mediated Learning (JAML) intervention for promoting joint attention between toddlers with autism spectrum disorders (ASD) and their caregivers and to determine maintenance effects. The JAML program is a parent-mediated, relationship-based, developmentally oriented intervention focused primarily on supporting joint attention learning. The research was conducted from sites in Indiana, Kansas/Missouri, and North Carolina.
Objectives: Our objectives were to assess JAML's: (a) effects on preverbal social communication for toddlers with ASD (b) social validity, and (c) maintenance of effects across time.
Methods: 127 toddlers, aged 16 to 30 months, and their parents participated in a randomized controlled trial to assess effects of JAML on four preverbal social communication outcomes: focusing on face (FF), turn-taking (TT), responding to joint attention (RJA), and initiating joint attention (IJA). Eligibility was determined by the ADOS-T. Principles of mediated learning supported parents' conceptual learning and their promotion of preverbal social communication targets for their toddlers. Experimental group participants received 32 weeks of individualized home-based support to promote their toddlers' social communication. Following post-assessment, control participants received instruction on the independent use of JAML materials. Using the Precursors of Joint Attention Measure (for which reliability had been established), coders blinded to group assignment observed intervals of parent-child interaction videos for the occurrence of targeted outcomes.
Results: Experimental and control groups showed no significant differences on pre-intervention measures; however, strong evidence of differential change between groups over time (in favor of the experimental group) was found from pre- to post-test for all four outcomes. These differences remained at six-month follow-up for FF, TT, and RJA. Post-assessment differences showed effect sizes of 1.24 post-intervention and 1.06 at 6-month follow-up for FF, .95 and 98, respectively, for TT, 2.80 and 4.71, respectively for RJA, and .85 and .57, respectively, for IJA. Inter-observer agreement (Kappa) reliability from blinded coders was .81 for FF, .72 for TT, 69 for RJA, and .74 for IJA. Parent and interventionist implementation fidelity with their intervention protocols was 98.6 and 99.5%, respectively, for ratings of satisfactory or better quality. Inter-observer agreement was 99% on both parent and interventionist fidelity measures. In an assessment of social validity (acceptability to parents) for those receiving JAML, a large majority strongly agreed with the acceptability and importance of JAML's goals, the parents' active role in the intervention, the support received to promote their toddlers' learning, their toddler's progress in the intervention, and their hopefulness about the child's future and confidence in their own ability to promote their children's learning. Descriptive data on other services received will be presented.
Conclusions: Joint attention, a competency associated with later language, social, and cognitive competence, is an achievable goal for toddlers with autism. Parents were able to translate key content and process components into everyday interactions. JAML's developmental focus, beginning with social regard for others' faces and proceeding to more advanced forms of preverbal social communication, maps onto emerging findings on early differences in social orientation in autism.

2:09 **116.003** Strengthening the Effects of Parent-Delivered Early Start Denver Model: A Randomized Controlled Multisite Trial

S. J. Rogers[1]*, A. Estes*[2]*, L. A. Vismara*[3]*, D. Senturk*[4]*, F. Whelan*[5]*, J. Munson*[6]*, G. Dawson*[7]*, M. R. Talbott*[8]*, J. N. Greenson*[6]*, C. D. Zierhut*[9] *and G. S. Young*[10]*,*

(1)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)University of Washington Autism Center, Seattle, WA, (3)Psychiatry and Behavioral Sciences, Emory University, Atlanta, GA, (4)University of California Los Angeles, Los Angeles, CA, (5)Univ. Cal. Los Angeles, Los Angeles, CA, (6)University of Washington, Seattle, WA, (7)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (8)Psychiatry, MIND Institute UCDavis, Sacramento, CA, (9)UC Davis MIND Institute, Sacramento, CA, (10)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA

Background: A previous RCT of parent implementation of ESDM (P-ESDM), did not demonstrate an ESDM advantage compared to community treatment. The design was confounded by significantly more outside treatment in the community group. The current study was designed to contrast two groups receiving active ESDM treatment to increase the likelihood that amount of outside treatment families took up would be similar. We compared standard P-ESDM (one clinic visit per week, written and verbal materials) to an enhanced approach involving two visits per week, clinic and home, and multimodal teaching methods).
Objectives: Compare effects of the standard and enhanced versions of P-ESDM on parent skills over the treatment period; examine longitudinal relationships between parent acquisition of ESDM skills and child developmental change .
Methods: A multisite RCT enrolled 48 children ages 12-30 months diagnosed with ASD, without other medical diagnoses, with DQs above 35. Thirty children completed the study, 13 in the standard and 17 in the enhanced group. Both groups received 12 weeks of parent coaching and 12 weeks of follow-up. The ESDM Parent Fidelity Implementation measure and an adapted version of the ESDM Curriculum Checklist were administered and scored 8 times by trained staff naïve to group assignment and hypotheses.
Results: Generalized linear mixed models (GLMM) were used to model longitudinal trajectories of outcomes, with main effects of treatment group and time, treatment by time interactions and subject level random intercepts and slopes. We found a significant interaction effect between treatment group and time on parent fidelity scores ($t(160)=3.23$; $p=0.0015$; Enhanced group: Estimated Mean Baseline: 3.28, Estimated Mean at End of Treatment: 3.81; standard group: Estimated Mean Baseline: 3.37,Estimated Mean at End of Treatment: 3.20). Improving parent fidelity scores occurred only in the enhanced ESDM group (See Figure 1)
Using the same GLMM approach, we found that both groups of children showed improvements in child checklist score ($t(217)=12.01$; $p<.0001$) (enhanced group: Estimated Mean Baseline: 0.35; Estimated Mean at End of Treatment: 0.51; standard group Estimated Mean Baseline: 0.38, Estimated Mean at End of Treatment: 0.50). Baseline ADOS ($\beta=-.057\pm.0012$ $t=-4.65$ $p<.0001$) and Mullen scores ($\beta=.0076\pm.0015$ $t=5.18$ $p<.0001$) were significant covariates. Covariates of mother's education level, age of subject, and average hours of outsideintervention were not significant . Group and time interaction for child change on the checklist wasÂ not significant ($t(215)=1.55$; $p=0.122$).
Â To examine relationships between parent and child change, we regressed the GLMM predicted subject-specific checklist slopes on the predicted subject-specific parent fidelity slopes. A significant association was found ($\beta=.051\pm.015$, $t=3.35$, $p=.0021$).Â
Conclusions: Â Parents in the enhanced P-ESDM demonstrated significantly faster rates of learning and greater fidelity than did parents in standard ESDM. The significant association between parent and child slopes suggests that the children of parents who showed improvement over time (enhanced group) show more rapid improvements on checklist scores over time, than did children whose parents do not show fidelity improvement over time (standard group). However the association between parent and child improvement was not as strong within the standard ESDM and enhanced ESDM groups.

2:21 **116.004** Enhancing Social Motivation in Inclusive Settings: Outcomes from a Randomized Controlled Trial for Preschool Children with Autism Spectrum Disorder

G. W. Gengoux[1]*, J. M. Hopkins*[2]*, R. K. Schuck*[1]*, M. E. Millan*[1] *and A. Y. Hardan*[1]*, (1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)PGSP-Palo Alto University, Palo Alto, CA*

Background: Studies of children with autism spectrum disorder (ASD) have repeatedly documented low rates of social initiations especially to peers, even among children without intellectual disability. Given existing support for motivation-based interventions in improving communication and reducing problem behavior, an important next step is to investigate how these techniques can be applied during social skills treatment to increase initiations with peers.
Objectives: This presentation reviews data from a randomized controlled pilot trial of a social group intervention aimed at motivating children with ASD to initiate interactions with peers.
Methods: Participants included 32 children with ASD (30 males; 2 females) ranging from 4-6 years old (M=5.16) assigned to one of two conditions: Social Initiation Motivation Intervention (SIMI; n=18) or Delayed Treatment Group (DTG; n=14). Participants in the SIMI condition participated in 8 weekly 75-minute social group sessions with typically-developing peers. Adult facilitators arranged cooperative play activities so that children with ASD received frequent reinforcement of social initiations directly from peers. Participants in the DTG continued community treatment for the duration of the 8-week trial and were compared to participants in the SIMI condition at post-treatment.
Results: Group differences between participants in SIMI and DTG were assessed on five outcome measures following treatment: Clinical Global Impressions-Improvement Scale (CGI-I), Social Responsiveness Scale-2 (SRS-2), Quality of Play Questionnaire (QPQ), Vineland Adaptive Behavior Scales-II (VABS-II), Social Skills Improvement System (SSIS), and Aberrant Behavior Checklist (ABC). On the SRS-2, significant group differences were observed on the Severity of Symptom category ($F=4.249$, $p<0.05$), such that participants in the SIMI condition exhibited significantly lower overall ASD severity scores (M=2.00 Mild, SD=1.4) than participants in the DTG condition (M=3.25 Moderate, SD=0.97) following treatment. On the CGI-I, significantly greater improvement was observed in the SIMI group compared to DTG in the areas of Communication ($F=4.308$, $p<.05$), Social Communication Integration ($F=4.376$, $p<.05$), and Maladaptive Behaviors ($F=34.286$, $p<.05$). On the QPQ, significant group differences were observed in the number of playdates to which participants were invited by others ($F=5.534$, $p<.05$). Specifically, participants in the SIMI condition exhibited greater treatment gains in joint activities with peers such as computer/video games ($F=7.963$, $p<.05$), playing cards ($F=3.867$, $p<.10$), and watching tv/movies ($F=3.445$, $p<.10$), and exhibited decreased arguments ($F=5.264$, $p<.05$) and teasing ($F=7.004$, $p<.01$) during playdates than participants in the DTG condition. On the SSIS, participants in the SIMI condition exhibited greater change from baseline to post treatment in self control skills ($F=5.416$, $p<.05$) and overall socialization standard score rating ($F=8.394$, $p<.01$). Results did not reveal significant differences between groups on the ABC or VABS-II following treatment.
Conclusions: Findings from this pilot investigation suggest that the SIMI treatment focused on enhancing motivation to initiate to peers was effective in augmenting broad aspects of social functioning including improved social communication skills, reduced symptom severity, and greater frequency of joint play with peers during playdates. Implications for design of effective inclusive social skills programming and future research directions for improving meaningful social outcomes will be discussed.

Oral Session - 3B

117 - Important Factors in Early Interventions: Predictors, Sustainability and Follow up

2:40 PM - 3:30 PM - Yerba Buena 8

Session Moderator: Connie Kasari, *University of California, Los Angeles, Los Angeles, CA*

2:40 **117.001** Long-Term Symptom Reduction Following the Preschool Autism Treatment Trial RCT (PACT)

J. Green[1], *A. Pickles*[2], *T. Charman*[3], *A. Le Couteur*[4], *K. Leadbitter*[5], *E. Salomone*[6], *R. Cole Fletcher*[7], *H. Tobin*[5], *I. Gammer*[8], *J. Lowry*[9], *G. Vamvakas*[10], *S. Byford*[11], *C. R. Aldred*[5], *V. Slonims*[12], *H. McConachie*[13], *P. Howlin*[14] *and J. Parr*[15], *(1)University of Manchester, Manchester, United Kingdom, (2)King's College London, London, UNITED KINGDOM, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, UNITED KINGDOM, (5)University of Manchester, Manchester, UNITED KINGDOM, (6)Institute of Psychiatry, London, UNITED KINGDOM, (7)University of Durham, Durham, United Kingdom, (8)Institute of Psychiatry, King's College London, London, UNITED KINGDOM, (9)Newcastle University, IHS, Newcastle Upon Tyne, UNITED KINGDOM, (10)Kings College London, London, United Kingdom, (11)Kings College, London, UNITED KINGDOM, (12)Evelina Children's Hospital Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM, (13)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (14)King's College London, Institute of Psychiatry, London, UNITED KINGDOM, (15)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Â It is not known whether early intervention can improve long-term autism symptom outcome.
Objectives: Â To determine long-term outcomes of the Preschool Autism Communication Trial (PACT). We hypothesised enhanced intervention effect on autism symptom outcomes, and continuation of effects on parent and child social interaction.
Methods: Â PACT tested a 12-month parent-mediated social communication intervention for children aged 2 - 4 years with severe autism (18 therapist-parent video-aided sessions and daily parent home-practice), randomized 1:1 against Treatment as Usual. We undertook follow-up ascertainment at all original trial sites (Manchester, Newcastle, and London, UK) at median 5·75 years (IQR 5·42–5·92) from the original trial endpoint. Pre-specified blinded primary outcomes were the Autism Diagnostic Observation Schedule Combined Severity Score (ADOS CSS); proportion of child dyadic initiatiations with parent from the Dyadic Communication Assessment Measure for Autism (DCMA), and an expressive-receptive language composite. Secondary outcomes included non-blinded parent-ratings of autism symptoms (SCQ), repetitive behaviours (RBQ), adaptive behavior (Vineland), and peer relationships (SDQ); teacher-ratings of adaptive behavior (Vineland). All analyses were by intention-to-treat. Study registration ISRCTN 58133827; funding UK Medical Research Council.
Results: Â 121 (80%) of the 152 trial participants (59 [77%] of 77 assigned to PACT intervention vs 62 [83%] of 75 assigned to treatment as usual) were traced and consented to be assessed. Mean age at follow-up was 10·5 years (SD 0·8). Group difference in favour of PACT on ADOS CSS was logodds effect size (ES) 0·64 (95% CI 0·07 to 1·20) at treatment endpoint and ES 0·70 (95% CI –0·05 to 1·47) at follow-up, giving a significant overall reduction in symptom severity over the course of the whole trial and follow-up period (ES 0·55, 95% CI 0·14 to 0·91, p=0·004; Figs 1 and 2). Figure 2 shows group time paths in relation to baseline (left) and TAU (right). DCMA child initiations at follow-up showed a Cohen's d ES of 0·29 (95% CI –0.02 to 0.57) in favour of PACT and was significant over the course of the study (ES 0·33, 95% CI 0·11 to 0·57, p=0·004). Non-blind parent-rated autism symptoms (ES 0·40, 95% CI 0·05, 0·77) and repetitive behaviours (ES 0·87, 95% CI 0·47, 1·35) showed comparable treatment effects (Fig 1). There were no group differences in the language composite (ES 0·15, 95% CI –0·23 to 0·53) or comorbid mental health problems.
Conclusions: Â This study supports the clinical value of the PACT intervention. It advances previous work by showing for the first time that a theoretically derived, developmentally targeted early intervention can have a sustained effect on autism symptom outcomes nearly 6 years after the end of treatment in a randomised trial. Such a sustained effect after time-limited intervention has implications for developmental theory and further research is needed to elucidate the developmental mechanisms. Strengths are the pre-specified ITT analysis on standard blinded outcomes and nearly 80% follow-up of one of the largest autism treatment cohorts. We cannot be sure how the results would generalized to milder autism spectrum disorder.

2:52 **117.002** Exploration of Prognostic and Predictive Factors of Outcome in Participants in the Preschool Autism Communication Trial (PACT)

V. Slonims[1], *A. Le Couteur*[2,3], *H. McConachie*[3], *K. Hudry*[4], *B. Barrett*[5], *P. Howlin*[6] *and .. PACT Consortium*[7], *(1)Evelina Children's Hospital Guy's and St Thomas' NHS Foundation Trust, London, England, United Kingdom, (2)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, UNITED KINGDOM, (3)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Olga Tennison Autism Research Centre, Melbourne, AUSTRALIA, (5)King's Health Economics, Institute of Psychiatry, London, UNITED KINGDOM, (6)King's College London, Institute of Psychiatry, London, UNITED KINGDOM, (7)United Kingdom*

Background: Recent systematic reviews and meta-analyses suggest benefits from various interventions for children with autism. However heterogeneity is a major barrier in evaluating treatment effectiveness and identifying what works for whom presents a continuing challenge.
Objectives: To explore this issue we exploited data from the large Pre-school Autism Communication Trial (PACT) (Green et al., 2010) which had treatment sites in three UK locations. Families were randomised to receive PACT or Treatment as Usual (TAU). We wanted to identify which baseline child and family factors might differentiate between children who improved on a measure of autism symptoms (ADOS-G) and those who did not, over the period of a year. A further aim was to attempt to distinguish between factors that influence outcome for all children (i.e. prognostic factors) from those due to the intervention (predictive factors).
Methods: Data from 152 families who were randomised to receive PACT or TAU at three UK sites were analysed. ADOS scores (Lord et al 2000) from baseline to end of study (146 children) were used to assess changes in autism symptomatology over time. Jacobson and Truax's (1991) Reliable Change Index (RCI) was used to identify children whose improvement or deterioration could be considered psychometrically reliable. The sample was divided into those children (n=43) who had made reliable improvement in ADOS scores over the trial period and those (n= 41) who had not.
Results: Baseline non-verbal ability was a significantÂ prognostic indicator, being greater among Improvers than Non-Improvers, irrespective of randomisation with moderate effect size (*d*=.46). No other child factors were prognostic or predictive of treatment outcome. Contingency analysis indicated that treatment group x outcome status varied by trial site (see table). TAU families in London site were less likely to have child Improvers than Non-Improvers, compared with London families receiving PACT or families at the other trial sites, irrespective of randomisation. Exploration of parent variables suggested that lower levels of parent synchrony during parent-child interaction was associated with a poorer outcome on ADOS score for children in the TAU group, especially in London, but this was not the case for the children receiving the PACT treatment.
Conclusions: Our data indicate the importance of separating prognostic from predictive factors when analysing intervention effects. Although non-verbal ability was related to prognosis more generally, it was not specifically associated with treatment outcome. No other significant factors were identified although analysis of family factors suggested that, for parents with more limited synchronous communication, PACT therapy – with its focus on supporting parent sensitive interaction with the child – may mitigate the odds of children with autism maintaining or increasing their levels of symptom severity. Continuing research in this area and the need to distinguish carefully between prognostic and predictive factors in intervention research is important if clinicians are to be able to make reasoned decisions regarding for whom a specific therapy might be more or less beneficial.

3:04 **117.003** Comparative Effectiveness of Two Province-Wide Intervention Models for Preschoolers with Autism Spectrum Disorder

I. M. Smith[1], *W. Ungar*[2,3], *H. Flanagan*[4], *B. D'Entremont*[5], *N. Garon*[6], *C. Waddell*[7], *S. E. Bryson*[8], *P. McDonnell*[9], *J. den Otter*[10], *F. Vezina*[11] *and N. Leger*[10], *(1)Autism Research Centre, Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (2)Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, (3)Sick Kids Research Institute, Toronto, ON, Canada, (4)IWK Health Centre, Halifax, NS, CANADA, (5)University of New Brunswick, Fredericton, NB, CANADA, (6)Mount Allison University, Sackville, NB, CANADA, (7)Simon Fraser University, Vancouver, BC, V6B 5K3, CANADA, (8)Dalhousie University, Halifax, NS, CANADA, (9)Psychology, University of New Brunswick, Fredericton, NB, Canada, (10)Education and Early Childhood Development, Gov't of NB, Fredericton, NB, Canada, (11)Health and Wellness, Gov't of NS, Halifax, NS, Canada*

Background: Many jurisdictions offer comprehensive early intensive behavioural intervention (EIBI) programs to families of preschoolers with ASD, with that diagnosis as the only eligibility criterion. Children in these programs receive many hours of individual intervention per week for extended periods. Many make significant gains, although there is ample evidence of variable outcomes, and high costs are associated with sustaining these intensive services in public systems. Little comparative information exists from either research or community contexts regarding alternative models of EIBI.
Objectives: To compare pre-intervention characteristics and post-intervention outcomes for preschoolers with ASD in two demographically similar provinces with ASD service models differing in intensity, duration, and treatment methods. Distinct from the comprehensive EIBI model followed in New Brunswick (NB), the Nova Scotia (NS) program relies on Pivotal Response Treatment as its foundation, is less intensive, and of shorter duration.
Methods: Â Participants were families of 311 children with ASD recruited from publicly funded EIBI in the Canadian provinces of NB (n = 134) and NS (n = 177). Parents rated their children's adaptive behaviour (Vineland Adaptive Behavior Scales-2), ASD symptoms (Social Responsiveness Scale-2), and maladaptive behaviour (Scales of Independent Behavior-Revised) at Time 1 (T1; pre-intervention) and / or Time 2 (T2; after a year of service); 42% contributed data at both times. Intervention providers documented services delivered to children.
Results: Â Compared to the NB group, NS children were older (55 vs. 48 mos) at T1, and had significantly lower levels of adaptive functioning (mean VABS-2 score of 74.2 vs. 80.6), higher levels of ASD symptoms (mean SRS Total of 72.0 vs. 66.3) and more frequent / severe maladaptive behavior (SIB-R Asocial Index of -7.79 vs. -3.58). Differences between VABS-2 scores at T1 and T2 for both provinces were examined in a multilinear mixed analysis (MLA). Independent variables were time, province, and province X time. Test age was covaried and was not significant, F (1, 469.63) = .160, p = .689. As expected, VABS-2 scores were higher at T2 than at T1, F (1, 451.375) = 5.143, p = .024. The interaction of Time X Province was not significant, F (1, 238.488) = 1.809, p= .180, suggesting no difference between provinces in mean degree of improvement from T1 to T2 (both gain approximately 5 standard score points, i.e., ½ SD). Both groups also showed improvements on some ASD symptoms and problem behaviour symptom measures (SRS-2 and SIB-R, respectively), with no significant differences in improvements between provinces.
Conclusions: Developmental and behavioural changes over one year of preschool ASD intervention services were similar in two adjacent Canadian provinces, with mean gains of about .5 SD in adaptive behaviour in both groups. These results were observed despite different treatment and service delivery models, as well as significantly different pre-intervention characteristics of the children served. These findings contribute to literature suggesting that the common elements of ASD interventions have important effects that may outweigh differences between models. Implications for policy, including cost-effectiveness, will be discussed.

3:16 **117.004** Sustaining Quality Implementation of a Targeted Social Communication Interventions in Authentic Community Settings: Paraprofessional Implemented Jasper with Toddlers

S. Y. Shire[1]*, W. I. Shih*[2]*, Y. C. Chang*[3]*, S. Bracaglia*[4]*, M. Kodjoe*[4] *and C. Kasari*[2]*, (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)California State University, Los Angeles, CA, (4)New York Center for Child Development, New York, NY*

Background: Â Due to the gap between known efficacious interventions for young children with ASD and routine daily care, implementation science studies address questions about intervention acceptability, feasibility, and fidelity by community practitioners. While these studies are increasing in the literature, examination of the sustainability of such programs in ongoing real-world contexts is not often reported. The present project explores the sustainability of a targeted social communication intervention for toddlers with ASD when implemented and supervised by public early intervention providers.
Objectives: Â First, to explore maintenance of Teaching Assistants' (TAs') intervention implementation delivered to a second cohort of toddlers in an authentic early intervention setting with on-site community support and no support from the research team. Second, to compare change in children's initiations of joint attention (IJA) between the first supported year of the study and the second unsupported year of the study.
Methods: As part of a randomized trial, 78 children with ASD age 2-3 years (*M*age=31.71 months) received JASPER intervention in project Year 1 (Yr1). An additional 63 toddlers with ASD (*M*age=32.15 months) received JASPER in a second randomized trial- Year 2 (Yr2). Twenty-two TAs delivered JASPER in both YR1 and YR2. All TAs and all but 7 children were members of an ethnic minority group.
Intervention. In YR1, TAs were provided with intensive supports from the university team including two weeks of in-vivo training plus weekly feedback and support to deliver the Joint Attention, Symbolic Play, Engagement, and Regulation intervention (JASPER: Kasari et al., 2008; 2014; 2015). Significant effects on joint engagement, joint attention gestures, play skills, and language were demonstrated for JASPER over usual treatment (Shire et al., in press). In YR2, TAs were provided with on-site community supervision and no external support from the research team. Each child received JASPER for 30 minutes a day for 10 weeks in both YR1 and YR2. This is the first examination of the sustainability of community supervised, and community implemented JASPER with toddlers in center-based care (YR2).
Measures. Ten-minute TA-child interactions at 10-week exit were coded for TAs' JASPER implementation. Independent assessors also administered an assessment of children's spontaneous joint attention skills including gaze, gesture, and language (Short Play and Communication Evaluation: Shire et al., in press). The total number of spontaneous initiations of joint attention (IJA) was obtained from video coding of this assessment.
Results: Â In YR1, TAs' average JASPER implementation was 80.90% (*SD*=16.31%) by treatment exit. At YR 2 exit, TA's average implementation was 71.21% (*SD*=11.74%). Children's gains in IJA skills over treatment were significant in both YR1 (f(1,88)=40.84, p<.001) and YR2 (f(1,88)=33.74, p<0.001). Gains in IJA were not significantly different between Yr1 and Yr2 (f(1,88)= 0.02, p=0.89).
Conclusions: Through on-site community supervision, TAs maintained quality implementation of JASPER intervention with a new cohort of toddlers with ASD where toddlers in YR2 made comparable IJA gains to toddlers in YR1. This is one of the first studies to examine long-term implementation outcomes for an evidence-based social communication intervention with toddlers with ASD implemented by community paraprofessionals.

Oral Session - 4A
118 - Community-based Screening and Detection Methods
1:45 PM - 2:35 PM - Yerba Buena 9

Session Moderator: Celine Saulnier, *Children's Healthcare of Atlanta, Emory University, Marcus Autism Center, Atlanta, GA*

1:45 **118.001** Development of a Video-Based Instrument for ASD Screening in Infancy

S. Ozonoff[1]*, G. S. Young*[1]*, A. Belding*[2]*, S. Dvorak*[3]*, A. M. Hill*[2]*, M. M. Hill*[2]*, A. J. Schwichtenberg*[4] *and J. N. Constantino*[5]*, (1)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Instructional and Educational Technology, UC Davis, Davis, CA, (4)Purdue University, West Lafayette, IN, (5)Department of Psychiatry, Washington University School of Medicine, St. Louis, MO*

Background: The most widely used method for ASD screening is parent report but recent studies have demonstrated low agreement with more objective measurements of ASD symptoms. Major sources of error in parent report are comprehension and interpretation errors, such as limited understanding of the constructs or knowledge of developmental milestones. The use of videos has been shown to dramatically increase clarity in other fields, from music instruction to motor vehicle repair; in this study we examined whether video also improves ASD screening.
Objectives: We developed the Video-Referenced Infant Rating System for Autism (VIRSA), a low-cost, low-burden, web-based ASD screening measure, and examined its psychometric properties and ability to predict autism outcomes.
Methods: The VIRSA consists of a large library of 20-second video clips of parents interacting with infants, distributed along a continuum from high to low social competence. Parents are shown a pair of videos and asked to choose the one most like their child. Depending upon which video is chosen, the next pair of videos is selected to narrow the search space, and this process is repeated until the ratings converge on a stable score. The VIRSA was administered at 6, 9, 12, and 18 months to parents of 90 infants at familial risk for ASD and 45 infants with no family history of ASD. The infants are followed to 36 months of age to determine diagnostic outcomes. Parents complete the VIRSA from home, immediately before the visit and one week later. Examiners complete the VIRSA immediately after the visit. Finally, parents complete the Infant Toddler Checklist (ITC), a screening instrument that uses written descriptions of behavior, providing a measure of convergent validity.
Results: Split-half reliability is good to excellent (*r*=.63 for parents, *r*=.86 for examiners). One-week test-retest reliability is good (*r*=.61), with parents selecting the same videos as the week earlier on 71.9% of paired comparisons. Inter-rater reliability is lower (*r*=.28) which was not unexpected, given the different contexts and expertise across parents and examiners. There is a significant main effect for the VIRSA as a predictor of the ITC,**Â** χ^2=579.64, p<.001. This suggests acceptable convergent validity, with the VIRSA indexing many of the same behavioral constructs as the ITC. To examine predictive validity we compared VIRSA scores of participants who are typically developing (n=135) to those with an ASD diagnosis (n=16) or for whom developmental concerns have been raised (Atypical group, n=18). As seen in Figure 1, VIRSA scores of the ASD group worsen over time, while those of the Typical and Atypical group are stable or increase with age (main effect of group,Â χ^2= 6.68, p<.05; group x time interaction, χ^2=6.41, p<.05. The ASD group differs significantly from the Typical group by 9 months and from the Atypical group by 18 months.
Conclusions: 1) The VIRSA has good psychometric properties. Parents provide consistent ratings over time, demonstrate moderate agreement with expert examiner ratings, and detect changing behaviors as their infants develop ASD. 2) These findings replicate the pattern of declines in development as ASD emerges that have been documented using other measures.

1:57 **118.002** Universal Screening for Autism in a Large Healthcare System: Diagnostic Outcomes after Age Four

W. Guthrie[1]*, M. Gerdes*[2]*, S. E. Levy*[3]*, J. Pandey*[1]*, R. T. Schultz*[1] *and J. Miller*[1]*, (1)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Large-scale autism screening studies have yielded empirical support for early screening for ASD. However, they have not accurately estimated sensitivity, specificity, and negative predictive value (NPV), because children who screen negative have not been systematically followed through the risk period.Â The Children's Hospital of Philadelphia (CHOP) implemented universal screening for ASD documented in the Electronic Health Record (EHR) in 2009. As these children age and continue to be served within our healthcare system, we have the opportunity to follow children screened for ASD and fill important gaps in the screening literature.
Objectives: Estimate sensitivity, specificity, positive predictive value (PPV), and NPV in a large sample of children screened for ASD in primary care and followed until age 4-6 years using data from the EHR.
Methods: Universal screening of children age 16-30 months was conducted using the Modified Checklist for Autism in Toddlers (M-CHAT; Robins et al., 2001) at CHOP primary care clinics. Parents completed the M-CHAT and pediatricians were asked to complete the Follow-Up Interview when appropriate and document results in the EHR. Children were included if (1)the M-CHAT was completed between 16-30 months, and (2)the child presented to primary care for follow-up at ≥4 years. Diagnostic outcomes were abstracted from EHR records from pediatricians, developmental behavioral pediatricians, psychologists, psychiatrists, and neurologists within the CHOP system.
Results: 21,543 children were screened using the M-CHAT during routine clinical between 2010-2012. 77.96% had complete data recorded in the EHR and 59.44% returned for a subsequent CHOP primary care visit at ≥ 4 years. Of the 7,602 children with follow up information available, 6.77% screened positive for ASD on the M-CHAT and 2.10% had a documented diagnosis of ASD by age 4. Sensitivity was estimated at 38.12% and specificity was 93.90%. PPV was 11.84%, while NPV was 98.60%. When outcome was broadened to include any neurodevelopmental or psychiatric diagnosis (i.e., developmental/language delay, intellectual disability, ADHD, other behavior disorder, anxiety), PPV was 58.83% and NPV was 76.18%. The effect of child and family characteristics (i.e., age at screening, race, ethnicity, prematurity, SES, primary language spoken) on screening accuracy will be discussed.
Conclusions: This study is among the first to examine universal autism screening and subsequent outcomes within a large pediatric healthcare system. Important differences from previous large-scale screening studies include follow-up data after the primary risk phase on large numbers of children, andÂ “real world” use of the M-CHAT with diagnoses made by CHOP providers (or community diagnoses documented in the EHR by pediatricians) rather than assessments in the research lab. Our data suggest a substantial proportion of children with ASD were missed by universal screening at 16-30 months. Just as there is no single cause or effective treatment across the entire autism spectrum, there is likely not a single screening measure or screening age that will identify all individuals with ASD. Future research should determine the type of child best identified through traditional early screening, and what additional methods would enhance classification accuracy.

2:09 **118.003** Examining Disparities in Duration of Screening-to-Diagnosis Time in aÂ Multistage, Early Intervention-BasedÂ Screening Protocol for ASD

M. Feldman[1]*, L. Buitrago Sandoval*[1]*, A. Eisenhower*[1]*, R. C. Sheldrick*[2] *and A. S. Carter*[1]*, (1)University of Massachusetts Boston, Boston, MA, (2)Tufts Medical Center, Boston, MA*

Background: There are long-standing health disparities in early diagnosis of autism spectrum disorder (ASD) for children from poor, racial and linguistic minority families (Durkin et al., 2010; Mandell et al., 2009; Zuckerman et al., 2013). The implementation of universal screening protocols is one attempt to overcome these inequalities by engaging in regular developmental screening of all children, a practice recommended by the American Academy of Pediatrics (2006) and Centers for Disease Control (2012). It is not known whether the implementation of multistage universal screening procedures reduces health disparities in the duration of the screening, referral, and diagnostic evaluation process.
Objectives: To determine whether the implementation of a multistage universal screening and assessment procedure in Early Intervention (EI) settings will reduce disparities in age of receipt of ASD diagnosis by shortening the time between the onset of screening and the receipt of diagnosis.
Methods: Participants are families of children enrolled in EI who are between ages 14-33 months (N = 125, M_{age}= 24.7 months at Stage 1 of screening, 83% male). Children were evaluated as part of a 2-stage screening procedure administered by their EI specialists to identify children at risk for ASD; those at risk were referred for diagnostic assessment. Parents self-identified as racially (57% identify as racial minorities), linguistically (46% Non-English primary language) and economically (66% of families earn <$45,000/year) diverse. Parent demographics including self-identified race, English language proficiency, and household income were of interest. Duration of the screening and assessment process was measured as the time in days required to proceed from Stage 1 (parent completion of EI-administered ASD screening questionnaires), through Stage 2 (EI-administered play-based observation screener for ASD), and ending at Stage 3 (diagnostic evaluation). Analyses examined whether demographics predicted duration of screening protocol from Stage 1 to diagnostic evaluation.
Results: Mean duration of the screening and assessment process was 2.8 months (*SD* = 2.0). A linear regression was conducted to predict duration of the screening and assessment protocol based on demographic factors of race (dichotomized into White and non-White), English language proficiency (5-point scale), and household income (10-point scale). The overall model was significant, $F(3,121)=3.08$, $p=.03$, $R^2 = .07$. Income was the only significant predictor ($ß=-.215$, $t=-2.26$, $p=.03$); parent race and English proficiency did not predict duration. For families with incomes ≤$45,000, mean duration was 3.2 months, whereas for families with incomes >$45,000, time between initial screening and diagnostic evaluation was 2.1 months.
Conclusions: In a diverse, urban sample, children from lower income households were found to be at particular risk of delayed diagnosis, even after being identified at-risk. Despite utilization of a free, universal screening and diagnostic assessment procedure, inequity still exists within the screening system. Nonetheless, for poor families, overall duration was markedly shorter than the nearly eleven-month delay reported in other studies (Mandell, Novak, & Zubritsky, 2005). This finding has implications for professionals engaging in screening of young children, as professional biases and/or family stressors may be impacting fair and equitable use of universal screening protocols.

2:21 **118.004** Efficacy of the Social Communication Questionnaire in a Community-Based Sample of Toddlers

T. N. Day[1]*, W. Guthrie*[2]*, C. Nottke*[3] *and A. M. Wetherby*[3]*, (1)Clinical Psychology, Florida State University, Tallahassee, FL, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Florida State University Autism Institute, Tallahassee, FL*

Background: Â Previous research has demonstrated that ASD can be diagnosed in children younger than 2 years of age (Zwaigenbaum et al., 2015), yet the median age of diagnosis is currently over 4 years (Christensen et al., 2016).Â Given the AAP's recommendation for routine screening at 18-24 months (Johnson & Myers, 2007), most early screening measures target that age range (e.g., M-CHAT-R/F assesses children 16-30 months [Robins, Fein, & Barton, 2009]). There are limited screening measures for 2- and 3-year-old children, further contributing to the under identification of ASD before age 4. While the Social Communication Questionnaire (SCQ; Rutter, Bailey, & Lord, 2003) was intended for children 4+ years, its effectiveness has been examined in children under 4. When prioritizing the accuracy of identifying ASD (i.e., sensitivity≥80%), the rate of false positives was extremely high (i.e., specificity at 25% for a cut-off of 11) in children at-risk for ASD (Oosterling et al., 2010). The SCQ does not appear to perform optimally in young children, but further investigation is warranted.
Objectives: Â (1) Examine the effectiveness of the SCQ in a community-based sample of toddlers; (2) Maximize its efficacy for 2-3 year olds
Methods: Â Children were ascertained through screening in primary care using the Infant Toddler Checklist (Wetherby & Prizant, 2002) or Early Screening for Autism and Communication Disorders (Wetherby et al., 2015). Both negative and positive screens were included in the current sample (*N* = 384). Parents completed the SCQ–Lifetime Form when their child was 24-47 months; on items probing about ages 4-5, parents were asked to consider the last 12 months. Children received a concurrent diagnostic battery to determine a best-estimate diagnosis of ASD (*n*=181), DD (*n*=91), or TD (*n*=112).
Results: A receiver operating characteristic (ROC) curve analysis resulted in an area under the curve (AUC) of .694. At the recommended cut-off of 15, sensitivity for ASD was 40.9% and specificity was 85.7%. Prioritizing sensitivity in this sample (i.e., 81.2%) resulted in a cut-off of 7 and specificity of 42.9%. ROC curves were also conducted on individual items and 6 items had an AUC>.60, which assessed reciprocal conversations (item 2), unusual hand and body mannerisms (15-16), nodding head for 'yes' (24), offering comfort (31), and reciprocal imaginative play (39). These 6 items were summed, which resulted in an AUC of .757. A cut-off of 1 had a sensitivity of 88.9% and specificity of 39.1%.
Conclusions: Results indicated that a lower cut-off is needed for young children and demonstrated a shortened version of the SCQ may be more effective for children 2-3 years. A 6-item composite exhibited moderately better sensitivity and comparable specificity than all 40 items at a cut-off of 7, and was substantially better than the known cut-off of 15. Both versions of the SCQ demonstrated a high rate of false positives indicating further assessment of ASD is warranted, but suggested utility for identifying ASD. Confirmatory factor analyses and examination of measure performance by developmental level and age will provide more insight into the most useful SCQ items in toddlers.

Oral Session - 4B
119 - Gender Differences in ASD
2:40 PM - 3:30 PM - Yerba Buena 9

Session Moderator: Celine Saulnier*, Children's Healthcare of Atlanta, Emory University, Marcus Autism Center, Atlanta, GA*

2:40 **119.001** Gender Differences in ASD through a Developmental PRISM

C. Shulman*, The School of Social Work, Hebrew University of Jerusalem, Jerusalem, Israel*

Background: In both Kanner's and Asperger's original samples, males were dominant: eight of the eleven children Kanner described and all four of Asperger's children were male. Over the past two decades, a trend towards decreasing male-predominance has emerged (Jensen, Steinhausen, & Lauritsen, 2014), with recent epidemiological studies showing a 3:1 male-female ratio (Werling & Gerschwind, 2015). Females with autism may be under-identified and underrepresented, resulting in a possible male-biased understanding of autism. The present research is an attempt to understand ASD characteristics in young females, and to specify cognitive profiles and ASD symptomatology at the time of diagnosis and three years later.
Objectives: This longitudinal study compares cognitive and ASD profiles of boys and girls in their third year of life and again at age six in order to address gender similarities and differences over time.
Methods: Sixteen girls and 50 boys with suspected ASD were assessed before age three (girls' ages in months: M = 26.377, SD = 3.224; boys' ages in months; M = 27.127, SD = 2.873) and again at around age six (girls: M = 69.382, SD = 4.538; boys: M = 72.452, SD = 4.296). At first assessment, before age three, cognitive abilities of all participants were assessed with the Mullen Scales of Early Development and the ASD profile was assessed with the ADOS toddler module. Cognitive abilities around age 6 were assessed with either the Wechsler Preschool and Primary Scales of Intelligence or the Mullen Scales of Early Development, and ASD profiles with the appropriate ADOS Module.
Results: Although there were no significant differences between the males and females at the initial assessment (girls' DQ: M = 66.21, SD = 12.74; boys' DQ: M = 62.968, SD = 14.673), a difference emerged around the age of six, with the girls' IQ being significantly lower than that of the boys (girls: M = 77.987, SD = 22.158; boys: M = 103.442, SD = 31.945). Similarly, differences emerged in autism symptomatology around age six, although no significant differences appeared before age three. By age six, the ADOS profiles of girls revealed fewer social-affective symptoms and fewer restricted and repetitive behaviors.
Conclusions: By age six, the gender differences evident in cognitive profiles and ASD symptomatology are similar to those documented in previous research despite the fact that no gender differences emerged around age three. Incorporating language, behavioral and cognitive factors in the longitudinal study of gender in ASD may shed light on diverging developmental trajectories in males and females with ASD. In order to understand ASD it is important to recognize the implications of a possible male bias, which may make it difficult to identify females with ASD, particularly at an early age.

2:52 **119.002** Differences By Gender in Rate of Autism Recurrence

I. A. Cox[1], *J. A. McGillivray*[2], *J. Manjiviona*[3], *D. T. Bulhak-Paterson*[4] *and M. A. Stokes*[5], *(1)Schol of Psychology, Deakin University, Burwood, AUSTRALIA, (2)School of Psychology, Deakin University, Burwood, AUSTRALIA, (3)Private Practice, Melbourne, AUSTRALIA, (4)Private Practice, East Malvern, Australia, (5)School of Psychology, Deakin University, Melbourne, Australia*

Background: Â Males with Autism Spectrum Disorder/Condition (ASD/ASC) outnumber equivalent females. Reasons for the gender disparity remain speculative. The historical conceptualisation of autism has shaped current diagnostic criteria and assessment tools, which may be insensitive in detecting female characteristics. Socialised gender roles and mechanisms adopted by females with ASC that obscure symptoms and underpin the 'camouflage hypothesis', may influence the sex skew. Such factors may lead to under diagnosis, misdiagnosis, or delayed diagnosis of ASC in females, precluding early intervention benefits and enhancing risk of adverse outcomes.
Objectives: This prospective investigation of school-aged children sought to explore the camouflage hypothesis by determining whether previously unidentified (PU) children with at least one older or younger sibling diagnosed with ASC show differential rates of diagnosis by gender. If more PU female siblings than PU male siblings of child probands with ASC screen positive for ASC traits, this would add support to the camouflage hypothesis.
Methods: Clinicians with expertise in ASC in the state of Victoria, Australia, were asked to identify potential participants from their case files and forward research invitations to them. Advertising through ASC agencies also facilitated recruitment. Forty siblings (*females*=20) aged 6 to 17 years of child probands with a clinical diagnosis of ASC, and their parents, participated in the study. Child participants were assessed on cognitive ability (WASI-II), language (CELF-IV: Screener), behavioural presentation: *Immediate* (ADOS-2); *Recent* (AQ), and *Lifelong* (developmental history), adaptive functioning (VABS-II: Parent or Caregiver Rating Form), and female ASC attributes (GQ-ASC). Questionnaires were parent reported. Positive screens for ASC were determined by above cut-off scores on measures and clinical judgement, aligned with DSM-5 criteria for ASD.
Results: Based on previous literature it was expected that 18.7% of siblings, 26.2% of male siblings and 9.1% of female siblings of child probands with ASC would screen positive for the condition. Compared to expected estimates, the recurrence rate almost doubled for siblings of child probands with ASC in this study, with no difference in recurrence rate found for PU male siblings (30%), z =.376, *p*=.353, yet a highly significant difference in recurrence rate identified for PU female siblings (40%), z=4.26, *p*=<.001. The recurrence rate for PU males did not differ significantly from that of PU females (*z*=0.66, *p*=0.51).
Conclusions: In families with ASC probands, the sibling recurrence rate of ASC in school aged children is higher than previously reported in infant siblings. More PU female siblings screened positive for ASC than PU male siblings, unexpectedly resulting in a narrower and reversed sex ratio. The recurrence rate for PU males corresponds with existing research, whereas, the recurrence rate for PU females reflects a four-fold increase from the earlier estimate, endorsing the camouflage theory. Implications of these findings regarding developmental manifestation of ASC, sibling assessments, and diagnostic considerations will be discussed.

3:04 **119.003** Sex Differences in Children Referred for Assessment: Utilizing the Autism Mental Status Exam (AMSE)

R. A. Oien[1,2], *S. Vambheim*[1], *A. Nordahl-Hansen*[3], *L. A. Hart*[2], *M. Eisemann*[1], *F. Shic*[4] *and D. Grodberg*[2], *(1)Psychology, The Arctic University of Norway, Tromso, Norway, (2)Child Study Center, Yale School of Medicine, New Haven, CT, (3)Special Needs Education, Oslo University, Oslo, NORWAY, (4)Seattle Children's Research Institute, Seattle, WA*

Background:
Several studies have noted that female diagnosed with ASD exhibit a higher severity of symptoms than males (e.g. Øien et al. 2016). One suggestion for this difference is that females with the same levels of autistic traits as males might fail to meet diagnostic criteria due to sex-specific differences in trait expression (Dworozynski et al. 2012). Recently, we have found that female toddlers with ASD express a relative strength in joint attention, but a relative weakness in imitation compared to male toddlers with ASD (Øien et al., 2016). In the present study we address sex differences in observed behavioral symptoms utilizing the Autism Mental Status Exam (AMSE). The AMSE is a free (brief) standardized diagnostic assessment that structures the observation and documentation of eight items comprising social, communicative, and behavioral signs and symptoms of ASD that typically emerge throughout a neuro- developmental evaluation (Grodberg, Weinger, Kolevzon, Soorya, & Buxbaum, 2012; Øien, Weinger, Kolevzon & Grodberg 2016).
Objectives:
To evaluate sex differences in parent and clinician reported ASD specific symptoms in a sample of children referred to clinic for ASD assessment.
Methods:
The source population for this study included all patients receiving comprehensive autism-focused diagnostic evaluations, as part of the Assessment Core protocol at the Seaver Autism Center for Research and Treatment from September 2013 through December 2014. The total sample comprised of N=123 children with a mean age of 5.74 years (S.D.= 2.88). Sixty-two males and 23 females received a DSM-5 guided consensus diagnosis of ASD. The AMSE was administered in children first, before they were administered the reference standard (ADOS, ADI-R). ANOVA was used to compare the proportion of total scores on the AMSE between males and females in the groups. Mann-Whitney U non-parametric tests were used to analyse which items most frequently failed by males and females receiving an ASD diagnosis.
Results:
A one-way ANOVA revealed no differences on total AMSE score between males and females. Mann-Whitney U tests were conducted to ascertain differences on item level between male and female toddlers receiving an ASD diagnosis. The analysis revealed that ASD females performed worse than males on language (P=.005). Furthermore, the analysis showed that ASD females had fewer problems related to oversensitivity than ASD males (P=.025)
Conclusions:
The present study found that females performed worse than males on language, and thus it may be the case that females with the same level of general language difficulty as male peers fall under the diagnostic thresholds for ASD due to the presence of fewer sensory issues disrupting social interaction. It is important to stress that this viewpoint is still highly theoretical, and that nuanced patterns of behavioural differences are present in girls with ASD as compared to males through childhood. Results suggest that nuanced patterns of behavioral differences are present in girls with ASD as compared to boys with ASD through childhood.

3:16 **119.004** Sex Differences in Cognitive and Reasoning Abilities Among Preschool and School-Age Autistic Children

V. Courchesne[1]*, D. Girard*[2]*, C. Jacques*[3] *and I. Soulières*[4]*, (1)University of Montreal, Montreal, QC, Canada, (2)Université du Québec à Montréal, Montreal, QC, CANADA, (3)University of Quebec in Outaouais, Gatineau, QC, Canada, (4)University of Quebec in Montreal, Montréal, QC, Canada*

Background: The estimated IQ of individuals on the autism spectrum (AS) differs depending on the intelligence test used. The most replicated finding is the discrepancy between Wechsler Intelligence Scales and Raven Progressive Matrices (RPM), in favor of the latter. Some authors also suggested that IQ in AS children differs between girls and boys, girls tending to have more intellectual impairment than boys (Volkmar et al. 1993). However, other authors reported no discrepancy between the IQ of girls versus boys with autism (Mandy et al. 2012). It is therefore unclear whether the Wechsler-RPM discrepancy characterizes the cognitive profile of both AS girls and boys.
Objectives: 1) To examine whether there are sex differences in performance on Wechsler and on RPM within an AS and a typically developing (TD) group. 2) To compare the discrepancy between Wechsler and RPM between sexes and groups.
Methods: 48 AS children (25 males, 23 females) aged from 4 to 12 years old (*M*=7.54) and 66 TD children (37 males, 29 females) aged from 4 to 12 years old (M=6.15, *p*=.13) were assessed using the colored version of the RPM and either the WPPSI-IV (n=18 AS and 29 TD) or the WISC-IV (n=32 AS and 37 TD) depending on their age. A "Wechsler IQ" variable was computed by taking the score of either the WPPSI-IV or the WISC-IV depending on which test the child completed. A discrepancy variable was computed by calculating the difference between Wechsler and RPM in percentiles.
Results:
Regarding results on the Wechsler, an ANOVA showed a main effect of group ($p<.001$), AS children having a significantly lower performance (*M*=16.66, *SD*=25.37) than TD children (*M*=60.80, *SD*=30.87). There was no main effect of sex ($p=.14$) and no interaction effect ($p=.15$). On the RPM, the ANOVA showed no main effect of group ($p=.13$) or sex ($p=.29$). There was a significant interaction ($p<.05$), autistic boys (M=82.00, SD=27.00) performing better than autistic girls (M=66.42, SD=32.37; $p<.05$), while no difference was found between TD girls and boys.
Furthermore, for the discrepancy variable, there was a main effect of group ($p<.001$) and sex ($p<.01$), with no interaction effect ($p=.52$). The discrepancy between Wechsler and RPM was greater in the AS group (*M*= 57.42, *SD*=3.58) than in the TD group (*M*=19.54, *SD*=3.07), and that discrepancy was greater in boys (*M*=44.88, *SD*=3.21) than in girls (*M*=32.08, *SD*=3.46) from both groups.
Conclusions: The present results first replicated Mandy et al. (2012) findings that boys and girls on the AS do not differ in terms of Wechsler IQ in a sample of preschool and school-aged AS children. In addition to the existing literature, the results show that the difference between boys and girls with autism might be different depending on the test used. Finally, the investigation of sex differences in the RPM-Wechsler discrepancy suggests that this discrepancy characterizes the cognitive profile of AS children of both sexes, but might be smaller among girls (both TD and AS).

Oral Session - 5A
120 - Services and Systems for Children and Adults with ASD
1:45 PM - 2:35 PM - Yerba Buena 10-14

Session Moderator: Lauren Brookman-Frazee*, University of California, San Diego, La Jolla, CA*

1:45 **120.001** School and Employment Effects on Pathways to Service Use in Emerging Adults with ASD

J. Lai[1] *and J. A. Weiss*[2]*, (1)Psychology, York University, Montreal, QC, CANADA, (2)York University, Toronto, ON, CANADA*

Background:
With a large cohort of individuals with ASD reaching adulthood, there is pressing need to understand the dynamics of service utilization through the emerging adulthood period. This age cohort has high unmet service need and access to these services is an important predictor of quality of life for adults with ASD. Various clinical and systemic factors are known to contribute to service receipt across the lifespan, but to date, no one has investigated the dynamics of service use in this specific age group. Further, it is unclear how participation in further education or securing employment impacts service receipt through these factors.
Objectives:
In this study, we report on differences in service receipt in young adults with ASD-only compared to ASD+ID and examine if continuing in school/having employment moderates the relationship between having an ID in addition to ASD on service receipt and if so, by what mechanism.
Methods:
An online survey was administered across Canada through the Canadian Autism Spectrum Disorders Alliance, completed by caregivers reporting on young adults (ages 18-25) with ASD-only (n=251) or ASD+ID (n=333). We collected sociodemographic data (including current schooling/employment status), clinical need (including mental health, behavioural problems, overall function), and systemic variables related to service receipt (including barriers to services, caregiver-directed services). Current service use was operationalized as any service used in the last 6 months. We used a moderated mediation model to investigate the impact of having schooling and employment, after high school, on factors that influence service receipt.
Results:
Our results show that young adults with ASD+ID receive more services (ASD-only: 1.82 SD=1.87, ASD+ID: 3.28 SD=2.74; t=7.29, p<.001). There was a direct effect of having ID on the number of services received (Beta=1.23, SE=.2, CI: .84, 1.62, p<.001), while there was no direct effect of being in school or having employment (Beta=.21, SE=.21, p=.32). In the model, the increase in services was partially mediated by higher rates of both behavioural concerns (t=5.35, p<.001) and caregiver-directed services (t=2.83, p=.005) in those with ASD+ID compared to those with ASD alone. However, being in school or having employment moderated those factors, such that when one is in school/employed, only behavioural concerns was related to more services (Beta=.13, SE=.07, CI: .02, .30) and when one was not in school/employed, caregiver-directed services mediates the increase in service receipt for those with ASD+ID (Beta=.21, SE=.13, CI: .03, .57).
Conclusions:
These results suggest that contextual factors play a role in explaining why adults with ASD+ID may receive more services than young adults with ASD alone. When adults with ASD+ID remain in school or in an employment setting, higher rates of behavior problems can trigger referrals to additions supports. When a young adult with ASD+ID is not in school or employed though, caregiver-directed services explain why they access more services compared to individuals with ASD alone. Once individuals with ASD+ID transition out of school and are not yet involved in a vocational setting, parent support services becomes a pathway to service receipt.

1:57 **120.002** Access to Justice: Legal Professionals' Experience and Knowledge of Autism in Family Courts in England.

A. Remington[1], *L. Crane*[2] *and R. George*[3], *(1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)Goldsmiths, University of London, London, UNITED KINGDOM, (3)Faculty of Laws, University College London, London, United Kingdom*

Background:
Access to justice is a key issue for many sectors of society, but can be particularly problematic for autistic individuals. This is because many aspects of the condition (e.g., inability to decode non-verbal cues, difficulties understanding non-literal language and subtext) render autistic people vulnerable to being taken advantage of in negotiation or dispute settings. In addition, a departure from daily routine, and lack of control of the situation can cause autistic individuals a great deal of distress. The family court and the wider family justice system (i.e., the lawyers, judges and others responsible for assisting families and resolving legal disputes within families) makes a particularly strong example of these issues because interpersonal relationships are often the foundation of the dispute, while the processes involved have strict (but socially unusual) rules about behaviour, language, and the roles of the individuals within the system.
Objectives:
Research highlights high levels of dissatisfaction amongst autistic people and their families who have experienced the criminal justice process, and a number of service providers offer autism-specific guidance on navigating the criminal justice system. However, criminal court processes are quite different from other areas of the justice system, making it questionable the extent to which lessons learnt from that area are directly translatable to other contexts such as family law. To address this, the present study aimed to examine the current autism knowledge and experiences of legal professionals in the English family justice system.
Methods:
Questionnaires (online and paper versions) were distributed to legal professionals across England, asking about 1) their professional background and experience working with autistic individuals, 2) knowledge of autism (diagnostic criteria of autism, descriptive characteristics and co-occurring behaviours) and 3) their perceived self-efficacy (their confidence in their ability to identify and work with autistic clients). A small follow-up study was conducted with 10 family justice professionals, using qualitative interviews to explore their experiences of cases involving autistic litigants.
Results:
197 legal professionals (barristers, solicitors, judges) from across the UK completed all parts of the survey. 58% of respondents reported that they had knowingly worked with autistic individuals, yet 91% indicated that they had never received training regarding the condition. Scores on the autism knowledge questionnaire were high: with an average score of 84% correct, and were slightly higher for the 44% of respondents who had a personal connection with autism. Despite the high levels of knowledge, legal professionals reported low levels of confidence in their ability to support autistic individuals in their practice. Interview data revealed a range of concerns and best practice suggestions.
Conclusions:
Our findings suggest the need for targeted training materials to help legal professionals work more effectively with their autistic clients. Specifically, the current study highlights the discrepancy between low practical confidence and high theoretical knowledge, a finding that can be used to inform the creation of best-practice resources to help bridge that gap.

2:09 **120.003** Examining Part C Early Intervention Services for Families with Children at Risk- or with Autism Spectrum Disorder

A. Aranbarri[1], *M. E. Miller*[1], *A. C. Stahmer*[2] *and S. J. Rogers*[1], *(1)University of California, Davis. MIND Institute, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background: Â As the rates of AutismÂ Spectrum Disorder (ASD) continue to increase and ASD pediatric screening efforts intensify, more infants and toddlers are entering the Part C system (e.g., Corsello, Akshoomoff, & Stahmer, 2012). Part C service delivery to toddlers with ASD varies greatly across states, rural/urban settings and family resources (Stahmer & Mandell, 2006). Research recommends receiving 20 or more hours per week of specialized evidence-based intervention for young children with ASD to achieve optimal outcomes—reducing intellectual impairment, improving social communication/skills and language development— (e.g., Dawson et al., 2010, Lord and McGee, 2001). However, Part C providers tend to use general developmental guidance which is not effective for ASD (Ingersoll et al., 2012). It is assumed that evidence-based practices are not the norm, and are especially difficult to access in low resourced areas. To improve community services to under resourced children with ASD, a better understanding of the current Part C system service delivery is needed.
Objectives: Â To obtain a comprehensive understanding of the early intervention delivery system for children with or at-risk for ASD at multiple levels of the Part C delivery system, across states and family income level.
Methods: Â Participants include 5 state Part C coordinators, that nominated 10 agency administrators serving mainly low resource areas, whoÂ nominated 20 early intervention providers within those agencies, that finally nominated 32 caregivers of children with or at-risk for ASD. A semi-structured on-line survey was conducted at these multiple levels. Descriptive and contingency analyses were conducted to explore the objective of the study.
Results: Â Lower income families report receiving one-third of the intensity of higher income families, with less access to specialized treatments. Despite this, lower income families report higher rates of satisfaction. Agency Administrator's and Provider's reports of service intensity are consistent with the caregiver's reports, while Part C coordinators overestimated the service intensity and quality provided to lower resources areas. Both Part C coordinators and Agency Administrator showed very little training in ASD. The home setting was consistent among the 3 administrative levels to be the principal delivery setting. In general, there were neither specific methods used for early intervention in ASD nor for parent training. These results highly vary among states.
Conclusions: Â Results suggest that special efforts are needed to increase evidence-based ASD training for Part C providers serving low income families and low resource areas to improve care for this population. Results also showed the need of stronger advocacy for lower income families, both in service quality and intensity needed. Data will be used to adapt an evidence-based practice that has previously shown efficacy in a randomized clinical trial. The adaptation will target the needs of rural and low resourced areas and will fit within the frame of the current Part C delivery system.

2:21 **120.004** Impact of State Autism Insurance Mandates on Healthcare Utilization and Insurance Expenditures Among a Commercially Insured Population with Autism Spectrum Disorder in the United States, 2008 – 2012.

***P. Nichols**, C. J. Alverson, D. Christensen, M. Yeargin-Allsopp, K. Nyarko, N. Dowling and S. Grosse, Centers for Disease Control and Prevention (CDC), Atlanta, GA*

Background: Â Insurance mandates for autism services are legislated in 46 states. Despite concerns about impact on costs to insurers, no research has evaluated the financial impact of these mandates on health plans.Â
Objectives: To identify differences in healthcare utilization and insurance expenditures for children with autism spectrum disorder (ASD) attributable to insurance mandates, overall and for the following service types: general outpatient, behavioral and mental health outpatient, inpatient, emergency department (ED), and prescription medications.
Methods: We performed a quasi-experimental analysis to compare pre-post mandate changes in healthcare utilization and expenditures for children aged 3–18 years in five states with mandates adopted during 2010 relative to five states without mandates throughout the study period. We compared these changes for children with ASD (≥2 outpatient ASD claims ≥7 days apart) and without ASD. We estimated changes separately for fully-insured plans (state-regulated, subject to insurance mandates) and self-insured plans (federally-regulated, not subject to insurance mandates). We used data from MarketScan Research Databases comprised of employer-sponsored insurance claims for 2008-2009 (pre-mandate) and 2011-2012 (post-mandate). We defined encounters for non-medication service types as separate days on which a child had ≥1 claim. Prescription fills were defined as the number of pharmacy claims. Expenditures were accumulated across all claims within a year.Â We computed aggregate counts (encounters or prescription fills) and expenditures for children with ASD and all enrolled children pre-post mandate. Subsequently, we computed the ratios of the aforementioned pre-post mandate ratios (ratios of ratios) of counts and expenditures for children with ASD relative to all enrolled children in mandate compared to non-mandate states, and the percent changes in the final ratios.Â
Results: For fully-insured plans, increases in ED expenditures and visits were 25% and 12% lower, respectively, for children with ASD relative to all children in mandate compared to non-mandate states. For these same groups, increases in inpatient expenditures and admissions were lower by 31% and 21%, and increases in medication expenditures and number of prescriptions were lower by 22% and 12%, respectively. For fully-insured plans, increases in outpatient and behavioral/mental health expenditures and visits were higher by 28% and 7%, respectively, in mandate states, and increases in "other" outpatient expenditures and visits were higher by 10% and 11%. Total expenditures for children with ASD in fully-insured plans in mandate states relative to non-mandate states were unaffected. In contrast, expenditures among children with ASD relative to all children were higher for all service types for self-insured plans in mandate compared to non-mandate states: by 13% for ED, 6% for inpatient, 8% for behavioral, 10% for other outpatient, and 3% for medication expenditures.
Conclusions: These data suggest that state mandates were associated with greater increases in behavioral/mental health visits and smaller increases in ED and inpatient care and filled prescriptions for fully-insured plans only. There was no overall cost increase to the fully-insured plans as a result of state mandates, as lower non-outpatient and medication expenditures fully offset higher expenditures for outpatient care. Further analysis with additional states and more recent mandates is warranted.

Oral Session - 5B
121 - Experiencing Autism as a Family
2:40 PM - 3:30 PM - Yerba Buena 10-14

Session Moderator: Aubyn Stahmer, *Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

2:40 **121.001** An Update on the Interagency Autism Coordinating Committee and the National Institutes of Health

***S. Daniels**, Office of Autism Research Coordination, Rockville, MD*

Background:
In this talk, the Office of Autism Research Coordination (OARC), which coordinates and manages the Interagency Autism Coordinating Committee (IACC), will provide an update on the IACC and its recent activities. The Interagency Autism Coordinating Committee (IACC) is a federal advisory committee established by Congress to coordinate activities concerning autism spectrum disorder (ASD) within the U.S. Department of Health and Human Services (HHS) and among member federal agencies. The committee, composed of 31 federal officials and public stakeholders representing diverse perspectives, provides advice to the Secretary of HHS on issues related to ASD.
Objectives:
The talk will cover background information about the committee and a description of the latest updates to the IACC Strategic Plan, which serves as a guide to federal funders of ASD research and services activities. An update on U.S. federal funding of autism research and recent ASD-related initiatives from the NIH will also be discussed.
Methods: NA
Results: NA
Conclusions: NA

2:52 **121.002** Through Their Eyes: Sisters' Experiences Growing up with a Preverbal Sibling with Autism.

G. Pavlopoulou[1] *and D. Dimitriou*[2]*, (1)Lifespan Learning and Sleep Lab, UCL, Institute of Education, London, UNITED KINGDOM, (2)UCL, Institute of Education, London, United Kingdom*

Background: Â Being the sister of a child with Autism Spectrum Disorder (ASD) can be both a challenging and enriching experience. Siblings' experiences can be complex and often difficult to capture using traditional methods, as they are often habitual and taken for granted. Many everyday activities are likely to be left unquestioned.Â Siblings in early adolescent years growing up with a sibling with ASD have been the subject of little previous research, especially in terms of sisters' experiences.
Objectives: The main goal of the current study was to explore and describe relationships and environmental settings in the life of the typically developing (TD) sisters growing up with a preverbal sibling with ASD.
Methods: The current study takes a phenomenological approach supported by written diaries, photo logs and Photovoice groups along with background testing and 1-1 interviews. Sisters were actively involved by: i) collecting photo data by themselves, ii) determining the content of the data and categorising, and iii) analysing and interpreting the data that consists of their observations, experiences and reflection. This is the first study to use longitudinal Photo-voice methodology in order to give TD sibs an active participatory role, a rare methodological approach in the current field of research. Each interview was audio-recorded and transcribed following the guidelines of interpratative Phenomenological Analysis.
Results: The average age of the sisters was 12.27 years old (SD=1.33) and the average age of the siblings with ASD was 11.6 years old (SD=1.62). Sister-driven content analysis identified eight major categories: birthday parties (22.06%), school assemblies (15%), siblings sharing time together (13.79%), lunch routines (13.79%), sleep routines (11.7%), sensory/self-stimulating behaviours (9.9%), supportive family members (8.14%) and hobbies/talents (4.15%). Four master themes emerged from our analysis: (i) the impact in education; (ii) the uncomfortable position of being different; (iii) need for respite; and (iv) acceptance and advocacy. Sisters' photos are also revealing in terms of the things they chose not to photograph that might have been expected to feature such as their fathers and members of extended family.
Conclusions: Innovative strategies in both research and intervention may shift the balance between vulnerability and resilience. As experts of their own lived experience, sisters shed light on their day-to-day experiences. The findings highlighted the feelings, needs and thoughts the sisters experienced as siblings and carers of children with autism, but also as students and young females with limited networking and support in the community. A strong sense of love and pride of living with autism was expressed throughout the interviews, and this builds into an optimism that can be a crucial part of interventions that help to lift and further develop resilience, wellbeing and a life that is possible while planning for what remains to be difficult. Such information around contemporary and lifecycle issues in the life of siblings is central to the goal of designing proactive empowering interventions by clinicians, communities such as school and other agencies, and by policymakers in relation to both quality improvement and cost containment.

3:04 **121.003** Wellbeing of Parents of Children with Autism Spectrum Disorder: Gender Difference within an Australian Population-Based Sample.

M. Seymour[1,2]*, R. Giallo*[2] *and C. E. Wood*[1]*, (1)Swinburne University of Technology, Hawthorn, Australia, (2)Healthy Mothers Healthy Families Research Group, Murdoch Childrens Research Institute, Parkville, Australia*

Background: Research has focused predominately on the experiences of mothers of children with Autism Spectrum Disorders (ASD). Yet, there are studies showing that fathers and mothers experience mental health difficulties and parenting differently[1]. Fathers may experience and express psychological distress differently than mothers; possibly through externalizing disorders (e.g., physical illness, drug and alcohol misuse)[2].
Objectives: To explore differences in experiences of psychological distrss and physical health (i.e., global health, chronic pain, weight, smoking, problematic alcohol consumption) between fathers and mothers of children with an ASD.
Methods: Data were drawn from the *Longitudinal Study of Australian Child* (LSAC)[3]; a large nationally representative study of Australian children and their families. LSAC comprises two cohorts of children, with six waves of data currently available. The present study draws on data from overlapping cohorts when children were aged eight to nine years (Baby-cohort wave 5; Kindergarten-cohort wave 3). Biological or adoptive fathers (n = 156) and mothers (n = 156) of children with an ASD from the same family were identified. Missing data were minimal (<20%) and were addressed by multiple imputation in SPSS 24.0[4], pooled across 20 parallel imputed datasets[5]. A series of bivariate logistic regressions were used to estimate the adjusted risk when controlling for known contextual variables which influence psychological and physical health (e.g., socio-economic position, country of birth, parent age, child gender, ASD severity).
Results: The majority of fathers and mothers were not experiencing elevated levels of psychological distress and reported good physical health (i.e., global health, not experiencing chronic pain, not consuming problematic amounts of alcohol, not smoking). However, the majority of fathers and mothers were categorised within an unhealthy weight category based on the Body Mass Index. Compared to mothers, fathers of children with ASD were at greater risk of: engaging in problematic alcohol consumption, adj. OR = 3.13, 95% CI [1.02-9.61]; being classified as underweight, adj. OR = 7.33, 95% CI [2.99-17.93]; and overweight, adj. OR = 2.29, 95% CI [1.13-4.67] on their Body Mass Index.
Conclusions: The results shed important light on the differences in the psychological and physical health of fathers and mothers raising children with an ASD. Fathers were at greater risk of experiencing physical health problems (i.e., problematic alcohol consumption, unhealthy Body Mass Index) than mothers. Parents of children with an ASD often face many stressors and demands, however they often report that there is not enough support directed to their wellbeing[6]. Continued research and support relating to these difference will improve service capacity to provide quality care to the unique needs of mothers and fathers raising children with ASD.

3:16 **121.004** Compass for Hope: Evaluating the Effectiveness of a Parent Training and Support Program for Children with ASD As a Telehealth Tool

G. M. Kuravackel[1], *L. A. Ruble*[2], *A. D. Rodgers*[2], *A. P. Ables*[3], *R. J. Reese*[4] *and M. D. Toland*[5], *(1)University of Louisville, Louisville, KY, (2)University of Kentucky, Lexington, KY, (3)University of Louisville Autism Center, University of Louisville, Louisville, KY, (4)Educational, School and Counseling Psychology, University of Kentucky, Lexington, KY, (5)Department of Educational, school and Counseling Psychology, University of Kentucky, Lexington, KY*

Background:
The impact of disruptive behaviors in ASD extends to parents and caregivers. Caregivers of children with ASD report higher stress compared to parents of neurotypical children and parents of children from other disability groups (Hayes & Watson, 2013).Research has demonstrated effectiveness of parent focused interventions through rigorous evaluation over the past 30 years (Zisser & Eyberg, 2010). Unfortunately for most families in rural areas, access to interventions that address disruptive behaviors is limited and physical access to services can be a barrier for many families (Bearss et al., 2013; Hodgetts, Zwaigenbaum, & Nicholas, 2015). One solution for access is the use of telehealth technologies to deliver specialized services in real time over a geographical distance (Dudding, 2009; Turner, 2003). COMPASS for Hope (C-HOPE) is an 8-week parent intervention program that was tested via telehealth (TH) and face-to-face (FF) delivery and is adaptable to rural settings. Developed from an existing framework called the Collaborative Model for Promoting Competence and Success (COMPASS; Ruble & Dalrymple, 2002), C-HOPE showed preliminary effectiveness. when comparing pre- and post-ratings of parent stress, parent efficacy, and problem child behaviors with a wait-list control (Rodgers, Ables, Ruble, Kuravackel & Reese, 2015).
Objectives:
The purpose of this study was to establish the efficacy of C-HOPE with families of children with ASD (ages 3 to 12) and its effectiveness as a tele-health tool to support families of children with ASD in underserved communities. Adaptive child behavior (Eyberg Child Behavior Inventory (ECBI; Eyberg & Pincus, 1999), parent self-efficacy (Being a Parent Scale (BPS; Johnston & Mash, 1989), and parenting stress (Parental Stress Index - Third Edition (PSI; Abidin, 1995) were evaluated using a pretest-posttest partially nested design and outcomes were evaluated based on type of delivery format (telehealth vs. face to face).
Methods:
Participants were assigned to one of three conditions: waitlist control (WLC; *n* = 10), C-HOPE delivered via TH (*n* = 10), and C-HOPE delivered FF (*n*= 13). FF was delivered over 4 cohorts and TH was delivered over 3 cohorts.
Results:
Due to the partially nested design and small number of cluster (therapy groups) a multilevel modeling approach for handling partial nesting could not generate stable results; therefore, single-level analyses were conducted correcting for the non-independence using the Type = Complex option in M*plus* to get unbiased estimates of the inferential statistics. Analyses of pretest-posttest differences showed significant improvement in all three outcomes (see Table 1).
Planned comparison analyses of differences on outcomes using pretest scores as a covariate (see Table 2) showed those in the TH condition had significantly lower adjusted child behavior posttest (ECBI) scores than those in the WLC condition (d = 0.99). The combined treatment modality (TH+FF) had significantly better child behavior outcomes (ECBI) than the WLC. condition. Small to moderate effect sizes were obtained on parent efficacy (BPS) and parent stress (PSI).
Conclusions:
C-Hope shows promise as a parent intervention that targets child behavior, parent skill and stress. Moreover, preliminary data suggest that C-Hope can be delivered effectively using telehealth technology.

1 **124.001** Adults with Autism Spectrum Disorder and the Criminal Justice System: An Investigation of Prevalence of Offending, Risk Factors and Gender Differences.

C. E. Blackmore[1,2], *E. L. Woodhouse*[1,2], *G. M. McAlonan*[2,3], *C. E. Wilson*[1,2], *V. Stoencheva*[1,2], *D. Robertson*[1,2], *E. Daly*[1,2], *P. Q. Deeley*[1,2], *M. C. Craig*[1,2], *J. Zinkstok*[1,2], *D. Spain*[1,2], *G. Roberts*[1,2], *N. Gillan*[1,2], *J. E. Faulkner*[1,2], *R. H. Wichers*[1,2], *K. L. Ashwood*[1,2], *D. G. Murphy*[1,2] *and C. M. Murphy*[1,2], *(1)Sackler Institute for Translational Neurodevelopment and Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (3)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: The behavioural and cognitive difficulties of some adults with autism spectrum disorder (ASD) may increase their risk of contact with the Criminal Justice System (CJS) either as offenders or victims of crime. There has been limited investigation of ASD and offending. However, available evidence is mixed; some studies report an increased prevalence of ASD in offending populations, an increased risk of committing specific crimes (assault and arson) or that people with ASD are no more likely to commit offences than non-ASD people.
Objectives: To compare prevalence of offending between adults with ASD and adults without ASD and to investigate between-group differences in types of offences. Further, to investigate gender differences and identify potential risk factors for offending in adults with ASD.
Methods: A retrospective review was completed of the medical records of 1275 adults who attended the Behavioural Genetics Clinic Adult Autism Service, the Maudsley Hospital, for assessment of possible ASD between April 2003 and January 2016. Participants ranged in age from 17 – 75 years of age (M = 32 years, SD = 12); 960 males and 305 females. 880 adults were diagnosed with ASD (660 males, 200 females) and 395 adults were not diagnosed with ASD (non-ASD group; 290 males, 105 females). The presence or absence of ASD and psychiatric co-morbidity was determined by consultant led multidisciplinary expert consensus, according to ICD-10 research criteria and confirmed with either an ADI-R and/or ADOS where possible. The presence of offending behaviour and type of offence (violence, sexual crime, arson, criminal damage, stalking/harassment, theft/burglary, substance misuse and other offences) was identified from medical reports. Forensic history was defined as contact with the CJS; this could include contact with the CJS both as offenders or victims of crime. Qualitative data from medical reports was transformed into nominal data in SPSS and between-group comparisons were made using chi-square tests.
Results: Non-ASD adults were significantly more likely to have a forensic history than adults with ASD (32% vs. 26%; χ^2=5.27, *p*=.02; figure 1). Non-ASD adults were more likely to have committed theft/burglary (9% vs. 5%; χ^2=6.05, *p*=.01) and substance offences (6% vs. 3%; χ^2=6.19, *p*=.01) than adults with ASD. Regarding risk factors, adults with ASD and comorbid ADHD were significantly more likely to have a forensic history than adults with ASD who did not have ADHD (32% vs. 24%; χ^2=4.16, *p*=.04). Adult males with ASD were significantly more likely to have a forensic history than adult females with ASD (30% vs. 13%; χ^2=23.56, *p*<.001).
Conclusions: Adults with ASD were less likely to offend and no more likely to commit any offence than non-ASD adults referred for clinical assessment of ASD. However, 26% of adults with ASD had a forensic history (either as perpetrators or victims of crime). Comorbid ADHD and male gender were risk factors for offending in adults with ASD. Health services research for adults with ASD is warranted, including liaison between CJS and mental health services to reduce the risk of adults with ASD becoming offenders or victims of crime.

2 **124.002** Age-Related Changes in Effortful Processing in Adults with ASD

P. S. Powell[1]*, L. G. Klinger*[2] *and M. R. Klinger*[2]*, (1)School of Psychology, Georgia Institute of Technology, Atlanta, GA, (2)UNC TEACCH Autism Program, Chapel Hill, NC*

Background: Little is known about age-related changes in cognitive functioning in adults with ASD. However, three previous studies of cognitive aging in ASD show similar or reduced age-related changes in cognitive functioning compared to adults with typical development (Geurts & Vissers, 2012; Lever & Geurts 2015; Lever et al., 2015).
Objectives: The primary objective of this study was to further examine age-related effects on cognition using measures sensitive to age-related decline while controlling for moderating variables (e.g., IQ, baseline motor abilities) that might obscure the relationship between age and cognitive functioning.
Methods: Twenty-nine adults with ASD and 30 adults with typical development were recruited for this study.Â Participants were group-matched on age (range: 30 – 67), gender, and IQ (range: 92-130), all *p*-values > .42. ASD diagnoses were confirmed via the self-report adult version of the SRS-2 and the ADOS-2. Participants completed several measures of cognitive functioning including measures of processing speed (Trail Making Test A), explicit memory (RAVLT Free Recall), executive functioning (Trail Making Test B, MoCA), and category learning (Woodcock-Johnson Concept Formation subtest).
Results: To assess diagnostic and age-related effects on measures of cognitive functioning a multivariate regression was conducted including Z-scores taken from standardized assessments of explicit memory, concept formation, executive functioning, and processing speed as dependent variables. Results revealed significant main effects of IQ [Wilks' λ = .467, $F(10, 43) = 4.91$, $p < .001$, $\eta_p^2 = .53$], age [Wilks' λ = .567, $F(7, 46) = 5.02$, $p < .01$], and diagnosis [Wilks' λ = .532, $F(7, 46) = 5.78$, $p = .01$, $\eta_p^2 = .47$], were qualified by a significant age by diagnosis interaction [Wilks' λ = .710, $F(7, 46) = 2.70$, $p = .02$, $\eta_p^2 = .29$]. Results suggest age may have a larger impact on cognitive functioning in older adults with ASD than older adults with typical development. The significant age by diagnosis interaction was primarily driven by performance on three measures thought to reflect components of working memory/executive function (e.g., Trail Making Test B, MoCA, Free Recall), Wilks' λ = .800, $F(3, 53) = 4.34$, $p < .01$, $\eta_p^2 = .20$.
Conclusions: Â Closer inspection of measures of cognitive functioning revealed greater age-related decline in ASD was not present across all cognitive domains, instead evidence points to accelerated cognitive aging in adults with ASD on tasks related to working memory. To the best of our knowledge, these findings are the first to document specific cognitive domains that are more disrupted by the aging process in adults with ASD compared to adults with typical development. Although findings are somewhat in contrast to previous studies of aging in ASD, which may be due to differences in sample characteristics (i.e., inclusion of individuals diagnosed in childhood) or analytic methods (i.e., controlling for IQ), they provide insight for the development of cognitive training interventions targeting specific cognitive difficulties faced by older adults with ASD. Yet, given that this study used a cross-sectional design, it is important that future studies replicated findings with a longitudinal sample.

3 **124.003** An Assessment of the Writing Skills and Writing Self-Efficacy of Autistic College Students and Their Mentors

K. Gillespie-Lynch[1]*, D. DeNigris*[2]*, M. C. Zajic*[3]*, A. Riccio*[4] *and N. Gaggi*[5]*, (1)College of Staten Island and The Graduate Center, CUNY, Brooklyn, NY, (2)The Graduate Center, CUNY, Jersey City, NJ, (3)University of California at Davis MIND Institute, Davis, CA, (4)Department of Psychology, College of Staten Island and The Graduate Center, CUNY, New York, NY, (5)College of Staten Island; City University of New York, Staten Island, NY*

Background:
Discrepancies between high cognitive and variable writing skills have been documented since the earliest accounts of autism (Asperger, 1991). Although writing skills are essential in college, the writing skills and self-efficacy of autistic college students have received almost no empirical attention (Gerstle & Walsh, 2010). Jurecic (2007) described difficulties one autistic college student faced writing for an audience and speculated that they might be attributable to Theory of Mind (ToM) challenges. The few studies that have examined writing skills among autistic children/adolescents suggest that they produce fewer written words and have more variable writing skills but do not differ overall in standardized writing scores relative to non-autistic youth (Griswold et al., 2002; Myles et al., 2003).
Objectives:
1) To compare writing skills, self-efficacy, and ToM among autistic and non-autistic college students.
2) To examine associations between measures among autistic students.
Methods:
Autistic college students in a mentorship program (n = 19) and non-autistic mentors (n = 6) completed pre-test assessments: the Social Responsiveness Scale-2 (SRS-2); Woodcock-Johnson Word Comprehension; Reading the Mind in the Eyes (RMIE), a nonverbal ToM measure; a writing self-efficacy measure (MacArthur et al., 2016); the Test of Nonverbal Intelligence (TONI); and a writing activity, wherein they were asked to share something interesting they had learned recently.
Results:
Autistic students reported heightened autistic traits and belief in writing conventions (a subscale of the self-efficacy scale; e.g., “Good writers don’t make errors in grammar”), wrote fewer words and sentences, and had lower RMIE scores (ps< .05) relative to mentors (see Table 1). Word comprehension, NVIQ, nonverbal ToM, other subscales of the self-efficacy measure (self-efficacy, goal-oriented avoidance, performance and mastery, beliefs about content and writing affect), errors, examples and perspective taking in writing did not differ.
Among autistic students, higher SRS-2 scores were positively associated with word comprehension and negatively correlated with goal-oriented performance (ps< .03). Nonverbal intelligence was associated with nonverbal ToM; word comprehension was associated with RMIE (ps< .02). No associations between writing volume, writing self-efficacy subscales, or ToM measures were observed.
Conclusions:
Replicating findings with autistic children/adolescents, autistic college students produced shorter texts than non-autistic mentors despite no group differences in NVIQ and word comprehension. This is consistent with our observations during mentorship; a number of autistic students encounter pronounced difficulty initiating and elaborating on their ideas through writing despite often high grammatical skills. Heightened belief in writing conventions (perfectionistic/rigid beliefs about writing) may contribute to these difficulties. However, no associations between writing self-efficacy subscales and writing performance were observed. The new writing self-efficacy measure used in this study had not previously been used with autistic students; it was highly reliable in this sample (α= .92). AutisticÂ students’ provided heterogeneous accounts of their writing self-efficacy, warranting further examinations of predictors of writing self-efficacy in a broader sample. Consistent with evidence that associations between ToM and spoken narrative skills among autistic children are apparent only for children with below average IQs (Capps et al., 2000; Losh & Capps, 2003), ToM was unrelated to writing skills among autistic students with average IQs.

4 **124.004** An Examination of Community Participation in Adults Diagnosed with ASD

S. L. Brown[1]*, A. Pearl*[2]*, M. Murray*[3] *and M. Salzer*[4]*, (1)Penn State College of Medicine, Hershey, PA, (2)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hummesltown, PA, (3)Psychiatry, Penn State College of Medicine, Hershey, PA, (4)Temple University, Philadelphia, PA*

Background: Â Research suggests participation in the community greatly decrease as an individual with ASD transitions into adulthood. This may be, in part, due the many barriers adults with ASD face. These barriers include lack of resources, limited opportunity, and limited self-determination or self-efficacy skills. Self-determination, in particular, is important when considering an individual’s community integration as it can inform treatment planning and can provide more meaningful opportunities for community participation. Providing the individual with opportunities to determine for themselves important activities may increase self-efficacy and meaningful community participation for adults with ASD.
Objectives: Â The current study examined differences in community participation in adults diagnosed with an ASD and neurotypical (NT) individuals. The study also obtained a subjective measure of the importance of the activities within the community (i.e., grocery shopping, attending a social gathering). Implications of independent community engagement will be explored. Additionally, the paper presentation will discuss the role and importance of self-determination in community participation for treatment planning.
Methods: Sixty-one adults, recruited from larger research projects, completed the Temple University Community Participation (TUCP) measure. Of the sixty-one individuals, 33 adults were diagnosed with an ASD. Symptoms of an ASD were confirmed by an informant report using the Social Responsiveness Scale- Second Edition (SRS-2; *M* = 66.50, SD = 10.32). Individuals in the study completed the TUCP measure, a measure of community engagement across various domains, to assess frequency of community participation as well as a subjective measure of importance of these activities to the individual.
Results: An independent samples t-test was conducted to compare self-reported measures of community participation. Individuals with ASD reported significantly fewer community participation days (M = 36.73, SD = 31.73) than NT individuals (M = 89.18, SD = 29.43) $t(59) = -.6.65$, p = 0.000. Significant differences were also observed in the number of activities that individuals with ASD (M = 6.48, SD = 4.09) engaged in compared to NT individuals (M = 12.50, SD = 3.04), $t(59) = -.6.42$, p = 0.000. When asked to rate the importance of activities, significant differences were also observed with individuals with ASD reporting fewer important activities (M = 11.97, SD = 5.81) than NT individuals (M = 15.32, SD = 3.50) $t(59) = -.2.67$, p = 0.01.
Conclusions: Results of the analyses supported the hypotheses that individuals with ASD report less independent engagement in the community and identified fewer important activities when compared to individuals without ASD. The results suggest a continued need to support adults in independent community engagement for a successful transition as well as integration of the individual’s self-identified important and meaningful activities when encouraging community inclusion. Results of the current study raise important questions regarding implicit biases that caregivers and treatment providers may have regarding the amount and type of participation that is sufficient for individuals with ASD. In addition, the data suggests that there may also be other factors impeding the individual’s ability to participate in the community, including low self-efficacy, social avoidance, or limited opportunities or access to the community.

5 **124.005** Association Between Affective Symptoms and School Bullying Experiences in Adults with Autism Spectrum Disorders

B. K. Woodruff[1]*, J. B. Adams*[2]*, M. Temkit*[3] *and K. Yost*[4]*, (1)Mayo Clinic Arizona, Scottsdale, AZ, (2)Arizona State University, Tempe, AZ, (3)Research Biostatistics, Mayo Clinic Arizona, Scottsdale, AZ, (4)Health Sciences Research, Mayo Clinic, Rochester, MN*

Background: Affective symptoms such as anxiety and depression are common in individuals with autism spectrum disorders (ASDs), as is a history of being bullied. Though it stands to reason that bullying experiences could contribute to affective symptomatology in adults with ASDs, it is unclear which bullying variables are most strongly associated with affective symptomatology.
Objectives: To describe affective symptomatology endorsed by adults with autism spectrum disorders and determine what relationship those symptoms have to bullying experiences.
Methods: A survey evaluating current affective symptomatology (depression, anxiety and anger) as well as details about school bullying experiences was completed anonymously by 48 adults (36 male) with ASDs. 58.4% had attended at least some college. Subjects were recruited at local autism community meetings or were mailed the instrument after expressing interest in participation. The latter subjects were identified from a database maintained by the Arizona State University Autism/Asperger's Research Program. Comparison between the groups was conducted using the non-parametric Kruskal Wallis test for population mean shift between the groups for continuous variables. The Pearson Chi-Squared and the Fisher's exact tests were used to test for group proportion differences for categorical variables.
Results: Â The majority of respondents reported depression (85.1%), anxiety (87.2%) and anger (68.8%). Depression severity reported by respondents was: "Not at all" (14.9%), "A little bit" (27.7%), "Somewhat" (25.5%), "Quite a bit" (17.0%), and "Very much" (14.9%). Anxiety severity reported was: "Not at all" (12.8%), "A little bit" (23.4%), "Somewhat" (23.4%), "Quite a bit" (25.5%), and "Very much" (14.9%).Â Anger severity reported was: "Not at all" (31.3%), "A little bit" (31.3%), "Somewhat" (12.5%), "Quite a bit" (20.8%), and "Very much" (4.2%). Of those reporting depression or anxiety, 51.2% were not receiving treatment. Only 6 respondents reported no history of bullying. Bullying experiences during college were associated with more severe depression (p=.0485), while bullying during preschool/kindergarten (p=.0323) and high school (p=.0261) were associated with *any* depression. Bullying experiences during elementary school were associated with more severe anxiety (p=.0350) as well as *any* anxiety (p=.0037). Bullying experiences during graduate school were associated with more severe anger (p=.0404). Prolonged bullying during elementary school was associated with *any* anger (p=.0490). Those respondents experiencing the greatest bullying frequency across *all* school levels were more likely to endorse depression (p=.0276) and anxiety (p=.0194). Cyber bullying in school settings was associated with more severe depression (p=.0042), anxiety (p=.0467), and anger (p=.0219).
Conclusions: Bullying experiences reported by individuals with ASDs appear common across multiple school settings and are associated with a significant burden of affective symptomatology in adulthood. The school level at which bullying occurred and variables describing the type and intensity of bullying experiences may predict the types of affective symptomatology impacting adults with ASDs. Such symptomatology appears undertreated.

6 **124.006** Augmenting Primary Health Care for Adolescents and Adults on the Autism Spectrum with Intellectual Disability

A. Urbanowicz[1,2] *and N. G. Lennox*[1,2]*, (1)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, The University of Queensland, South Brisbane, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia*

Background: Adults on the autism spectrum with intellectual disability experience unique health-related needs, difficulties accessing adequate health care and exhibit poorer physical and mental health outcomes in comparison to the general population. The Comprehensive Health assessment Program (CHAP) was developed by Prof Nick Lennox for adults with intellectual disability to improve access to healthcare, enhance communication between adults with intellectual disability, their families/caregivers and their general practitioner (GP), improve integration of healthcare and educate all those involved in the process. Three randomised controlled trials have shown this process significantly increases health screening and promotion and the identification of new disease in adults and adolescents with intellectual disability.
Objectives: The objective of this project was to develop a comprehensive health assessment program for adults on the spectrum with intellectual disability.
Methods: This project adapted the CHAP for adults and adolescents on the autism spectrum. It was informed by a review of the literature and feedback from an advisory group comprised of adults on the spectrum and their caregivers, health professionals and researchers working with adults and adolescents on the spectrum with intellectual disability.
Results: The review of the literature identified additional items and resources to be included in the adapted CHAP. This included the inclusion of a section about the sensory experiences of the person on the spectrum, information about their diagnosis of autism, additional questions about their gastrointestinal health, unusual eating patterns and additional information about strategies for working with adults on the spectrum with intellectual disability for the GP and health practice nurse.
The CHAP was adapted to reflect the inclusion of these items and resources, and then provided to the advisory group for feedback. These suggestions resulted in a number of changes, most noticeably; the change of language to first person language, the wording of questions regarding sexuality and human relations to illustrate that individuals may be transgender or identify with another gender and re-wording the mental health questions to include a question about self-harm. Feedback from advisory group members suggests the adaptation is appropriate and feasible for use with adults and adolescents on the spectrum with intellectual disability.
Conclusions: The adapted CHAP will be trialled with Australian adults and adolescents on the autism spectrum with intellectual disability. Feedback will be sought from the individual, their support person/s and health professional. This health assessment tool has the potential to improve health outcomes for adults and adolescents on the spectrum with intellectual disability.

7 **124.007** Autism Spectrum Conditions in People Who Died By Suicide in the UK.

S. A. Cassidy[1,2,3]*, L. Bradley*[1]*, G. Richards*[2]*, C. Allison*[4]*, R. O'Connor*[5]*, D. Heming*[6]*, D. Mosse*[7] *and S. Baron-Cohen*[4]*, (1)Coventry University, Coventry, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Newcastle University, Newcastle, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)University of Glasgow, Glasgow, United Kingdom, (6)Coroners Office, Cambridgeshire and Peterborough, Cambridge, United Kingdom, (7)University of London, London, United Kingdom*

Background: There is a significantly increased risk of suicidal ideation, suicidal behaviours (Cassidy et al. 2014) and death by suicide (Hirvikoski et al. 2015) in people with Autism Spectrum Conditions (ASC) compared to the general population. However, previous research has focused on prevalence of suicidality in clinic-based ASC samples. No research has yet explored suicide in general population samples, or compared the characteristics of suicide in those with and without ASC. This is key to understanding and thus preventing suicide among those with ASC.
Objectives: 1) To establish whether ASC diagnoses are over-represented among people who died by suicide in the UK; and 2) To compare the characteristics of suicide in those with and without ASC.
Methods: The first wave of data collection from a UK psychological autopsy study is presented. Coroners' inquest records for the period 2014-2016, ruling a suicide or open verdict, were requested from two UK cities. These records were scrutinised for evidence of ASC diagnoses; *Definite Diagnosis* (where the individual had a formal diagnosis of an ASC); *Strong Evidence* (where two independent judges agreed that the individual met all the criteria for ASC but had no formal diagnosis); *Probable Diagnosis* (where the two independent judges agree there are many signs, but there are gaps in the evidence); and *No Evidence* (where the person had no clear signs of ASC, even if other diagnoses were present and which were noted). Characteristics of those who died by suicide were also noted (gender, age at death, previous suicide attempts, suicidal ideation, mental and physical health conditions, environmental stressors, recent access to services).
Results: 219 coroners inquest records were assessed, 153 of which were ruled a likely suicide according to ICD-10 criteria. Of these, 11.76% had evidence of ASC, significantly higher than the rate of ASC in the general population in the UK (1%); 0.7% were classed as *Definite Diagnosis*; 1.3% as *Strong Evidence*; and 9.8% as *Probable Diagnosis*. There were no significant differences between the groups in terms of age, gender, number of physical or mental health conditions, presence of environmental stressors or previous suicidal ideation/attempts.
Conclusions: A significant minority of cases of death by suicide in the UK general population show evidence of the person having previously undiagnosed ASC. Preliminary analysis from the first wave of data collection so far suggests that individuals with and without evidence of ASC diagnosis did not significantly differ in terms of their broad characteristics (age at death, gender, number of physical or mental health conditions, presence of environmental stressors, likelihood of experiencing suicidal ideation or attempts, and recent access to services). Considering that many adults remain undiagnosed with ASC (Lai and Baron-Cohen, 2015), it is important for clinicians to be aware of increased suicide risk in ASC, and where ASC diagnosis is suspected, consider screening for suicidal thoughts and behaviours. These results will inform training for medical and allied professionals in an effort to improve suicide prevention, and highlight ASC as a particularly vulnerable group in the population.

8 **124.008** Autistic Traits and Suicidal Thoughts, Plans and Self-Harm in Late Adolescence: Population Based Cohort Study

I. Culpin[1], *B. Mars*[1], *R. M. Pearson*[1], *J. Golding*[1], *I. Bubak*[2], *P. Carpenter*[3], *C. Magnusson*[2], *D. Gunnell*[1] *and D. Rai*[1], *(1)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (2)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, (3)BASS Autism Services for Adults, Avon & Wiltshire Partnership NHS Trust, Bristol, United Kingdom*

Background:
The potential role of suicide as a contributor towards the excess premature mortality in people with autism has been highlighted recently. However there is relatively little understanding about which features of autism may lead to suicidal thoughts and behaviours and whether there are any potentially modifiable mediators. Existing research is largely limited to case reports or small clinical samples and there is a need for longitudinal, population based studies to provide further insights into the burden and pathways of suicidal thoughts and behaviours in autism.
Objectives:
Study objectives were two-fold: i) to examine the association of trait measures of autism with suicidal and self-harm behaviour at age 16 years; ii) to examine whether any associations could be explained by depression in early adolescence at age 12 years.
Methods:
Participants were 5,034 members of the Avon Longitudinal Study of Parents and Children (ALSPAC), a UK population-based birth cohort who completed a postal questionnaire on self-harm with and without suicidal intent, as well as suicidal thoughts and plans at age 16 years. Four autistic trait measures were analysed. These included the coherence subscale of the Children's Communication Checklist (assessed at 9 years), the Social and Communication Disorders Checklist (measured at 8 years), a repetitive behaviour measure (assessed at 6 years), and the sociability temperament subscale of the Emotionality, Activity and Sociability scale (measured at 3 years). These measures were dichotomised, with approximately 10% defined as the autism 'risk' group. Multinomial and modified poisson regression analyses were used to examine the associations between autistic trait measures and suicidal and self-harm behaviour at age 16 years. Structural equation modelling (SEM) was used to examine whether depression in early adolescence, as measured by the moods and feelings questionnaire (SMFQ) at 12 years, may explain this association. Analyses were adjusted for a range of child, parental and familial confounding factors.
Results:
Impaired social cognition at age 8 years was associated with increased risk of suicidal (adjusted OR=2.14, 95% CI 1.28 to 3.58, p=0.004), but not non-suicidal self-harm (adjusted OR=1.02, 95% CI 0.62 to 1.67, p=0.943) at age 16 years. Impaired social cognition was also associated with suicidal thoughts (adjusted OR=1.43, 95% CI 1.06 to 1.92, p=0.019) and plans (adjusted OR=1.95, 95% CI 1.09 to 3.48, p=0.024). There was no evidence for an association between the other autistic traits and self-harm with or without suicidal intent, suicidal thoughts and/or plans. Approximately 40% of the total estimated association between impaired social cognition and self-harm with suicidal intent was explained by depression in early adolescence.
Conclusions:
Impairments in social communication were strongly associated with suicidal thoughts, plans and behaviours at age 16 years. A substantial proportion of this effect was explained by depressive symptoms. These findings suggest that the social impairments associated with autism may be important in relation to suicidality, and that identification and treatment of depression may have the potential for preventative action.

9 **124.009** Barriers and Enablers to Success at Work: The Dandelion Program

D. Hedley[1], *R. Y. Cai*[2], *M. Uljarevic*[2,3], *M. Wilmot*[1], *J. Spoor*[4], *A. L. Richdale*[2] *and C. Dissanayake*[1], *(1)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia, (4)Department of Management & Marketing, La Trobe Business School, La Trobe University, Melbourne, Australia*

Background: Individuals with Autism Spectrum Disorder (ASD) are overrepresented when it comes to both unemployment and underemployment (Shattuck et al., 2012). Organizations can potentially improve employment opportunities for individuals with diverse needs by making reasonable adjustments and creating supportive workplace environments (Cavanagh et al., 2016; Yang & Konrad, 2011). However, there has been sparse research to date specifically aimed at identifying the factors associated with success at work from both the perspectives of the individual, and those who work with or support them.
Objectives: Our aim was to gain a better understanding of the factors that promote workplace success, the barriers to success, and program-related outcomes, for individuals with ASD participating in the Dandelion Program. The program is a three-year traineeship for adults with ASD developed by Hewlett Packard Enterprise (HPE), Australia, which provides an alternate pathway into employment in the information technology sector. Participants work within the Australian Federal Government. The program provides additional workplace supports to accommodate participants' diverse needs.
Methods: We used qualitative methodology (focus groups) to identify barriers and enablers to success at work in the context of the Dandelion Program. Participants comprised 28 adults: nine adults with ASD (89% male; M_{age}= 23.97 years, SD_{age}= 3.00) who were employed as software testers within the Dandelion Program; six of their family members (33% male; M_{age}= 43.92 years, SD_{age}= 13.89); seven support staff (29% male; M_{age}= 36.83 years, SD_{age}= 8.52); and six coworkers (67% male; M_{age}= 42.21 years, SD_{age}= 6.46). Focus groups were recorded, transcribed and coded. We adopted an inductive approach to content analysis (Thomas, 2006) conforming to COREQ guidelines (Tong, Sainsbury, & Craig, 2007) to analyze the data. From this process we developed a framework consisting of three main themes and 10 subthemes.
Results: The main themes identified were barriers, enablers, and general work outcomes. Overlapping themes were identified between all participant groups; however there were also subtle differences that emerged between them. For example, family members noted improved relationships at home that were not identified by the individuals with ASD themselves. Organisational support, advice from co-workers, supportive leadership, environmental modifications, and, in particular, the presence of an autism consultant, were identified as factors that facilitated success at work.Â Barriers to success included task related difficulties, individual factors, social difficulties and distractions, not managing work related stress, and being blunt ('too honest'). Overall, the program was positively appraised by participants. Positive outcomes of the program included trainees having a sense of purpose, financial and personal independence, and improved social relationships.
Conclusions: One of the most significant outcomes of this study was the identification of the positive attitudes of co-workers who worked closely with the trainees. The findings from this research provide evidence for the feasibility of implementing employment programs to support individuals with ASD, and identification of factors that promote, and also impede, workplace success, from the perspectives of the individuals involved.

10 **124.010** Building Employer Capacity to Support Meaningful Vocation for People with ASD: A Grounded Theory Study of Multi-Stakeholder Perspectives

M. Rashid[1], *S. Hodgetts*[2], *D. B. Nicholas*[3], *B. M. Di Rezze*[4], *J. A. Roberts*[5], *W. Nagib*[6] *and J. Leo*[7], *(1)University of Alberta/University of Calgary, Edmonton, AB, Canada, (2)University of Alberta, Edmonton, AB, Canada, (3)University of Calgary, Edmonton, AB, CANADA, (4)McMaster University, Hamilton, ON, CANADA, (5)Blavatnik School of Government, University of Oxford, Oxford, United Kingdom, (6)McMaster University, Hamilton, ON, Canada, (7)Abilities Centre, Whitby, ON, Canada*

Background: Little is known about best practices for helping employers support individuals with autism spectrum disorder (ASD) in attaining and retaining meaningful employment. An understanding and evaluation of specific employment and employer practices that foster employment success (i.e., job access, retention and advancement), and conversely existing gaps that require further development, is needed. As such, there is an urgent need for an evidence-informed theoretical base upon which salient variables (processes and outcomes) can be identified and examined for further evaluation within observational, interventional and longitudinal studies. This field is largely impeded until such a theoretical base is developed, and salient components of employer need to support meaningful employment for individuals with ASD are available.
Objectives: This research systematically explored strategies for building employer capacity to support meaningful employment opportunity for individuals with ASD.
Methods: Given the need for theoretical understanding to inform and advance vocational opportunity for individuals with ASD, a grounded theory design was used. Grounded theory is well established for the investigation of complex, multi-faceted human experiential phenomena, offering a theoretically rich understanding of processes and perceived outcomes. Purposeful and theoretical sampling was used to recruit participants across two Canadian provinces, Ontario and Alberta. Data collection to date has involved individual and group interviews with adults with ASD (N=25), their caregivers (N=12), employment supports (N=32), and employers (N=5). Recruitment, data collection and analysis is ongoing until data saturation is reached. We anticipate closing recruitment by the end of 2016. In line with grounded theory methods, data analysis is an iterative process. Therefore, verbatim (identifiers removed) transcripts and associated field notes are subjected to qualitative data analysis as they are completed. Data management and analysis are supported by N-Vivo11 software.
Results: Preliminary data analysis reveals five emergent themes related to building employer capacity to support vocational development for adults with ASD: (1) Accommodation; (2) Education and understanding disability; (3) Employment supports as vital; (4) Equal treatment and provision of equal opportunity for people with ASD in the workforce; and (5) Perception of visible versus invisible disability in the workforce.
Conclusions: This research is novel is its focus on building employer, rather than employee, capacity to support meaningful employment for individuals with ASD. Identified gaps and potential solutions, from the perspectives of multiple stakeholder groups, will be discussed.

11 **124.011** Building Employers' Capacity to Support Vocational Opportunities for Adults with ASD: A Synthesis Review of Practices, Strategies and Perceptions

M. Rashid[1], *S. Hodgetts*[2] *and D. B. Nicholas*[3], *(1)University of Alberta/University of Calgary, Edmonton, AB, Canada, (2)University of Alberta, Edmonton, AB, Canada, (3)University of Calgary, Edmonton, AB, CANADA*

Background: Â There is a significant body of literature on the value of supported employment and its significance for employers, and perceived potential challenges in employing individuals with autism spectrum disorder (ASD). Despite examples of successful and supportive interventions and vocational experiences for adults with ASD, substantial gaps remain. For example, the existing literature has largely focused on employment preparation and attainment, but has neglected job maintenance, and strategies to support employers' capacity development (Nicholas, Attridge, Zwaigenbaum & Clarke, 2014). The role and practices of employers seem central to job access and retention for people with ASD. To our knowledge, there has been no knowledge synthesis related to building employer capacity; however, such information has the potential to advance the field by identifying both existing capacity and knowledge gaps in this area.
Objectives: Â The purpose of this synthesis review was to identify studies focusing on services and supports that foster employers' capacity to support employment for adults with ASD.
Methods: Â A literature search was conducted with the assistance of a research librarian to identify studies addressing services and supports reported to build employer capacity to support vocational opportunities for adults with ASD. The search was conducted in EBSCO UAlberta Library search, which automatically includes more than 50 electronic bibliographic databases. Some of the major databases include are: MEDLINE, EMBASE, CINAHLplus, PsycINFO, Family Studies Abstracts, Web of Science, Scopus, Academic OneFile, Canadian Points of View Reference Centre, Business Source Complete, Canadian Reference Centre, SocINDEX. Key terms such as (employer* or company or companies or organization* or supervisor*) AND (hire or hiring or employ* or "vocational opportunit*") AND (autis* or ASD) were used. Two reviewers independently screened for inclusion, extracted data, and assessed study quality. Inclusion criteria were: (1) peer-reviewed literature, (2) English-language, (3) individuals with DD, and (4) employers and colleagues' perspectives.
Results: Fourteen studies met inclusion criteria and were included in the review. This synthesis review reveals several key findings. Involvement of support workers was conveyed as a core strategy for building employer capacity to support employees with ASD. In addition, disability awareness training, education, and acknowledgment of the benefits associated with of employing individuals with ASD were identified as supports. Employer concerns about required accommodation for employees with ASD were also identified. Collectively, these findings highlighted evidence gaps and future research directions in the field of building employer capacity to ultimately improve vocational outcomes for individuals with ASD.
Conclusions: There is a significant body of literature on the value of supported employment and its significance for employers, as well as a few studies addressing perceived challenges associated with employing individuals with ASD. Findings from this synthesis review notably indicate a lack of research focused on understanding employer's perspectives of what is vital to develop their capacity to support vocational opportunities for adults with ASD.

12 **124.012** Characteristics and Health Conditions of Publically-Insured Autistic Young Adults

T. W. Benevides[1,2], *H. J. Carretta*[3] *and K. Y. Graves*[4], *(1)Thomas Jefferson University, Philadelphia, PA, (2)Occupational Therapy, Augusta University, Augusta, GA, (3)Florida State University College of Medicine, Tallahassee, FL, (4)Behavioral Sciences and Social Medicine, Florida State University College of Medicine, Tallahassee, FL*

Background:
As increasing numbers of autistic adolescents age into adulthood, a primary concern is whether adult healthcare needs are recognized and treated appropriately (Nicolaidis et al., 2012). Croen et al. (2015) found that adults with ASD were more likely to have psychiatric, immune, cardiovascular, metabolic, endocrine, neurologic, gastrointestinal, and other conditions than same-age adults without ASD. Public insurers may be used by adults with autism to meet their healthcare needs. Although Medicaid is the most well-known public payer, persons younger than 65 can obtain access to Medicare. Young adults with autism may be eligible for Medicare due to eligibility through SSDI or old-age and survivors benefits. Due to the increasing prevalence and public health burden of increasing care needs of aging adults with ASD, it is imperative to identify utilization among a publically insured sample of adults with ASD.
Objectives:
This presentation will describe differences in comorbid conditions among young adult Medicare beneficiaries aged 18-25 years with ASD and no intellectual disability (ASD-only), as compared to beneficiaries with ASD and ID (ASD+ID) and adults with ID only. Subgroup analyses by race/ethnicity and gender will be presented.
Methods:
We conducted a retrospective analysis of existing national Centers for Medicare and Medicaid (CMS) claims Limited Data Sets (LDS) for 2008-2010. Claims associated with beneficiaries with ICD-9 codes of 299.xx were flagged as ASD, and 317.xx, 318.xx or 319.xx represented beneficiaries with ID. Analyses were conducted on all extracted claim files for eligible beneficiaries (inpatient, outpatient, home health, hospice care, skilled nursing facility services and professional services). We used the Agency for Healthcare Research and Quality H-CUP Clinical Classification Software (CCS)® to create condition flags from each claim (AHRQ, 2015). CCS uses standard ICD-9-CM codes to flag claims. Additional confirmation of CCS condition flags with ICD-9 code classification is underway. Chi-square statistics were used to identify differences in rate of occurrence of each condition between groups. Bonferroni correction for multiple comparisons resulted in differences between groups with *p* less than .003 as considered statistically significant.
Results:
Due to space, only 2008 results are described below; presentation data will contain all three years. Table 1 displays rates and 95%CI for specific conditions between the three groups. Seizure disorder occurred more frequently among young adults with ASD+ID than the other two groups; this difference was observed in 2009 and 2010 claims. Parkinson's disease was more prevalent among adults with ASD+ID than those with ID-only in 2008; this difference was not observed in other claim years. Adults with ID-only were significantly more likely than adults with ASD to experience 10 of the 17 conditions examined.
Conclusions:
Observed rates of psychiatric and medical conditions were significantly greater among young adults with ID than those with ASD for most conditions. Findings of greater rates of seizure disorder mirror those of other research. Additional analyses are ongoing to adjust for demographic characteristics that differ between groups. Practitioners, researchers and policymakers should attend to the impact that developmental disabilities, generally, have on health and health maintenance.

13 **124.013** Characteristics of Adult Females with Autism Spectrum Disorders in a Large Multicultural Sample

M. Merino Martinez[1,2], *L. Perez de la Varga*[3], *L. Garrote Petisco*[4], *C. D'Agostino*[5,6], *C. Amat*[7], *A. Vidal*[8], *O. Camba*[1] *and L. Peran*[7], *(1)Autismo Burgos, Burgos, Spain, (2)AETAPI Asociacion de Profesionales de Autismo, Madrid, Spain, (3)Federación Autismo Castilla y León, Castilla y Leon, Spain, (4)Director, Cedin, Valencia, Spain, (5)Yoenfoco, Buenos Aires, Argentina, (6)Mujeres Tea, Buenos Aires, Argentina, (7)Associacio Sindrom d'Asperger, Barcelona, SPAIN, (8)Hospital Clinic Barcelona, Barcelona, Spain*

Background:
Female Autism has been generating increasing efforts in research still most adult females studies of ASD has targeted neuro anatomical differences or specific cognitive profiles, but little efforts have been made to understand and describe the characteristics of adult women with ASD in depth and in large cross-cultural Spanish speaking sample.
Objectives:
The aim of the study was to design an online questionnaire and analyze in depth a large sample of woman with ASD in diagnostic routes, comorbidity, socialization strategies, special interests, sensory profile, developmental history, self-regulation and personal autonomy.
Methods:
After a period of exhaustive literature revision, an online Spanish questionnaire was designed and completed voluntarily by 265 woman of whom 188 had a formal diagnosis from a reliable and traceable source and were older than 18 years old. Statistical data was analyzed with SPSS for descriptive results n=188.
Results:
Participants were from 22 countries, most of them from Spain, México, Argentina, Venezuela and Chile aged from 18 to 73. The average delay for diagnosis was 5 years. Half of the women were mothers. Previous diagnosis and comorbidity were similar depression (40%, 34%) anxiety (36% 46%) eating disorders (11%, 20%) among others. Most women reported to have one or two friends, and many used socializing strategies as observation (63%) social scripts planning (58%), imitation, back analysis, (47%) and analysis of films and movies (40%). Memory and vocabulary were perceived as strengths by a large part of the sample (70%).Most woman reported social related hiper sensitivity (crowded places, physical contact, and sounds 65-70%). Anger behavior were explosive in many cases (57%) or blockage (54%).Interest in infancy were perceived as different from peers (70%) but more conventional in adulthood with striking interest in reading (63%) human behavior (35%) and psychology (39%) In their development they reported to had challenges in group play as girls (61%) and public speaking (60%).
Conclusions:
Though many limitations, for the size and depth of the study results has many implications. Diagnosis and identification of woman with autism is still late and a challenge in many countries, women are first treated for their comorbidities. Most of diagnosis routes resulted in comorbid conditions and more effort should be done for screening and diagnosis instruments design to clinical judgement and training.
Very few women did not have friends, and that support literature that woman might have better socials skills than males, their accommodation is less intuitive and more cognitive than neurotipicals, and indicate that camouflage strategies from literature do exist, however they might mask symptoms. In addition, emotional regulation is not always successful as might be polarized. Results on development history support the subtle presentation hypothesis during childhood, and more evidence during adolescence. In depth analysis of results might be helpful for identification and program design, an urgent need to guarantee appropriate diagnosis and treatment across different community and countries.

14 **124.014** Childhood Theory of Mind and Cognitive Flexibility and Early Developmental Change in Planning Skills Predict Later Behavioural Outcomes in Autistic Adolescents: A 12-Year Prospective Study.

L. Kenny[1]*, S. J. Cribb*[2] *and E. Pellicano*[1,2]*, (1)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (2)School of Psychology, University of Western Australia, Nedlands, Australia*

Background: Longitudinal studies of autistic people show that the behavioural features of autism generally endure into adulthood. It remains unclear, however, whether individual differences in early cognitive skills are longitudinally related to individual differences in specific behavioural outcomes.
Objectives: Here, we test the predictive utility of measures of childhood theory of mind (ToM) and executive function (EF) as well as the role of early developmental change in these cognitive constructs on emerging autistic symptomatology and adaptive behaviour in a cohort of autistic youth over a 12-year period.
Methods: Twenty-six cognitively able young autistic people (2 female) took part in a prospective longitudinal study. Participants were assessed on two key components of EF (planning and set shifting) and on a battery of ToM tasks (1st- and 2nd-order false belief) at Time 1 (*M*=5 years; 7 months, *SD*=11 months) and again at Time 2, 3 years later (*M*= 8 years; 4 months, *SD*= 12 months). We also measured participants' core autistic features (as indexed by the ADOS-2) and adaptive behaviour (as indexed by the Vineland-II) at Time 3, 9 years later (*M*=17 years; 10 months, *SD*= 14 months). Regression analyses were conducted to test whether early levels of cognitive skills (Time 1 ToM and EF) and the rates of developmental change in ToM and EF (between Time 1 and Time 2) could explain unique variance in (1) autism symptomatology and (2) adaptive behaviour in late adolescence.
Results: With regard to predicting autistic symptomatology, individual differences in Time 1 age, verbal and non-verbal ability failed to significantly predict variance in adolescents' ADOS-2 scores, $F(3,18)=.02$, $p=.99$, $R^2=.003$. The addition of Time 1 set-shifting ability and ToM significantly improved the fit of the model, $F(5,16)=5.26$, $p=.004$, $R^2=.50$. Finally, developmental change in planning ability between Time 1 and 2 explained a further 18% of unique variance in core autistic features, $F(6,15)=5.26$, $p=.004$, $R^2=.68$. With regard to adaptive behaviour, Time 1 age, verbal and non-verbal ability failed to significantly predict variance in adolescents' Vineland-II scores, $F(3,18)=1.96$, $p=.16$, $R^2=.25$. When we entered the early cognitive variables into the model, only Time 1 set-shifting ability significantly improved model fit, explaining an additional 20% of the variance in adolescents' adaptive behaviour, $F(4,17)=3.43$, $p=.03$, $R^2=.45$.
Conclusions: We show for the first time that both ToM and EF measured in childhood – and critically, early developmental changes in EF – predict specific aspects of autistic adolescents' behavioural outcomes 12 years later. These findings suggest that early-emerging cognitive atypicalities could cause behavioural disruptions that persist into early adulthood, possibly even persisting beyond the cognitive atypicalities themselves. The predictive power of these cognitive variables both adds weight to the veracity of these models as explanatory tools in autism research and underscores the importance of childhood cognition as a candidate target for early intervention.

15 **124.015** Clinical Characteristics of Female Adult Autism Spectrum Disorders (ASD): (I) Development of the Adult ASD Self-Rating Scale (A-ASD)

I. Fukunishi*, Minato-ku, Minami-Aoyama Antique Street Clinic, Tokyo, Japan*

Background: The assessment of the Adult Autism Spectrum Disorders (ASD) is so important.
Objectives: We developed the Adult Autism Spectrum Disorders Self-Rating Scale (A-ASD) and examined the reliability and validity of the A-ASD. At the same time, we also specified clinical characteristics of female adult ASD patients without intellectual disabilities.
Methods: The subjects were 29,525 psychiatric outpatients in Minami-Aoyama Antique Street Clinic (recent 13 years). Among them, we drew 246 ASD patients (178 males and 68 females) without intellectual disabilities. After obtaining their informed consent, we administered the A-ASD. It consists of 35 items. It has three factors, autism spectrum disorders (Factor 1), psychiatric comorbidity (Factor 2), and other neurodevelopmental disorders including ADHD (Factor 3)
Results: Cronbach alpha was approximately 0.9, indicating that internal consistency was adequate. There were significantly positive rest-retest correlations. Both the sensitivity and specificity were more than 80%. Thus, the reliability and validity were supported although we could not examine all types of the reliability and validity. However, both the sensitivity and specificity in females were less than 70%. We added 3 items on feminine emotions and behaviors to the same-sex women and reexamined the reliability and validity in female adult ASD patients. As a result, they were 78% and 80%, respectively. Finally, two different versions by gender were completed.
Conclusions: We have to pay close attention to female-specific characteristics to same-sex women when we perform a psychiatric diagnosis of female adult ASD without intellectual disabilities.

16 **124.016** Community and Facility-Based Employment of Adults on the Autism Spectrum

J. Rast[1], *A. Roux*[1], *K. A. Anderson*[2] *and P. Shattuck*[1], *(1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Approximately half of young adults with autism experience employment at least once between high school and their early twenties. The Workforce Innovation and Opportunity Act of 2014 and Employment First philosophy guide policy for people with disabilities in the U.S. and focus on increasing opportunities to experience community-based jobs with sustainable wages. However, we know little about the employment settings that adults with autism experience, particularly as they age further into adulthood.
Objectives: To describe the paid employment experiences of 1,991 adults, ages 30 to 65 years, on the autism spectrum who receive services through a state ID/DD service agency. Additionally, we explored factors associated with paid community-based employment and compared them to those associated with paid facility-based positions.
Methods: We analyzed findings from the National Core Indicators Adult Consumer Survey of adults with intellectual disability (ID) or a developmental disability (DD) who receive at least one service in addition to case coordination through their state ID/DD agency. There were 4,000 participants with autism in the 2014-15 ACS representing 32 states and one region. We used bivariate statistics and logistic regression to identify correlates of paid employment of each type.
Results: Most respondents were white (70%), non-Hispanic (89%), male (72%), with co-occurring ID (87%). One-fifth and had a co-occurring DD (21%). About half (59%) primarily used spoken language; had a legal guardian (53%); took medication to treat mood disorders, anxiety, or psychotic disorders (59%) or for behavioral challenges (47%); and received any Home and Community Based Services funding (56%). A small percentage received ICF/ID funding (8%). Overall, 29% held paid employment in the two weeks prior to the survey. In total, 12% worked for pay in the community - averaging 29 hours and earning $231/biweekly – and 18% worked for pay in a facility-based position- averaging 34 hours and earning $73/biweekly.
Community-based employment was significantly less likely for those who were black (OR: 0.40); female (0.56); used primarily non-spoken expression (0.19); took medication for behavior problems (0.64); or had moderate (0.38), severe (0.23), or profound ID (0.23). Community-based employment was significantly more likely for those with co-occurring DD (1.71). Adults with mild ID were more likely than adults who have no ID to have facility-based employment (OR: 1.74), while adults with profound ID were less likely (0.44). Adults who received ICF/ID funding were more likely to have a facility-based position (3.66).
Conclusions: This study describes the low employment rates and the associations with community versus facility-based paid employment for a sample of adults with autism in a large state-based survey. Future study might explore how services and supports such as Vocational Rehabilitation and Social Security Benefits influence community-based versus facility-based outcomes.

17 **124.017** Comparing Perceptions of Young Adults with Autism and Their Caregivers on Employment and Vocational Rehabilitation Needs

J. Albright[1], *D. Swain*[2], *A. Goldstein*[1], *G. Scalzo*[1], *S. W. White*[1], *J. Ernst*[3], *A. P. Azano*[4] *and A. Scarpa*[2], *(1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Department of Education, Virginia Polytechnic Institute and State University, Blacksburg, VA, (4)School of Education, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: It is estimated that 50-75% of adults with Autism Spectrum Disorder (ASD) are unemployed (Hendricks, 2010). ASD symptomology has been found to interfere with the ability to obtain and maintain employment (Seaman & Cannella-Malone, 2016). Vocational Rehabilitation (VR) programs are intended to assist individuals with ASD with job searches and the acquisition of necessary skills to obtain employment. However, adults with ASD report difficulty accessing effective VR services (Lawer et al., 2009).
Objectives: Caregivers and young adults (YA) with ASD were recruited to provide insight into accessibility and helpfulness of VR services, as well as perceived importance of specific employment factors.
Methods: Sixty-one caregivers and their YA children (ages 18-26) with an ASD diagnosis were recruited via the Interactive Autism Network (IAN) Research Database at the Kennedy Krieger Institute and were asked to complete an online survey. Survey items covered skills necessary for employment, future plans, and goals related to employment. Frequency analyses were conducted to determine accessibility and helpfulness of specific VR programs. A paired samples t-test was used to compare YA and caregiver reports.
Results: Both caregivers and YAs reported having access to a variety of VR services. Caregivers reported diagnostic/medical services to be the most helpful (endorsed by 14.8%), whereas YAs reported vocational evaluation and training to be the most helpful (endorsed by 11.5% each). Over 50% of the sample did not list VR services as being available or helpful.
Caregivers had significantly different perspectives than YAs regarding the perceived helpfulness of several VR services, including practice interviewing, guidance on self-disclosure, support to increase self-determination, trying out different jobs, interviewer education about ASD, practical skills related to the career field, social skills involving coworkers and strangers ($p<0.05$), and VR representatives having special training in ASD ($p<0.01$). On average, caregivers rated practicing skills related to career field as the most helpful service ($M=3.73, SD=0.55$), while YAs rated practice interviewing ($M=3.42, SD=0.84$) as the most helpful.
Caregivers also had significantly different perspectives than YAs regarding the perceived importance of specific employment factors, including enjoyment of the job, friendly work environments, advancement into long-term careers, and bosses and coworkers who understand the effects of ASD ($p<0.01$). On average, caregivers rated friendly working environment as the most important employment factor, ($M=3.92, SD=0.33$), while YAs rated enjoyment of the job ($M=3.49, SD=0.92$) as the most important.
Conclusions: Findings regarding the helpfulness of specific VR services indicate that applied practice of skills would be most beneficial to individuals with ASD who are seeking employment. Findings regarding the perceived importance of employment factors indicate that ASD-friendly workspaces are crucial, as is enjoyment of the job itself. Finally, with over one half of the sample neglecting to report access to effective VR services, it is important for future research to focus on improving access to helpful services.

18 **124.018** Contested Family Perspectives: Implications for Independent Living of Adults with ASD

V. D'Astous[1], *K. F. Glaser*[2] *and K. Lowton*[3], *(1)King's College London, London, England, United Kingdom, (2)King's College London, London, UNITED KINGDOM, (3)University of Sussex, Brighton, United Kingdom*

Background:
Adults with ASD have multiple abilities and disabilities across a wide range of social and functional areas of daily living which influence their support needs. Many continue to be supported by their ageing parents. While independent living may be an expectation and desired goal for adults with ASD, outcome studies report few achieve independent living, with most requiring continued support. Additionally, the timing of independent living for adults with ASD may occur in middle age and beyond, often when parents are unable to continue providing support. Few studies have explored the essential capabilities and support needs of adults with ASD for the achievement of independent living. This study underscored how contested perceptions of capabilities and needs may have implications for how and with whom support needs assessments are conducted and how support is provided.
Objectives:
To explore the current daily living capabilities and anticipated future support needs for independent living of adults with ASD, from theirs and family members' perspectives.
Methods:
Using a cross-sectional mixed methods research design, 74 adults with ASD (19-65 years of age), recruited from a London clinic completed the Camberwell Assessment of Need for Adults with Developmental and Intellectual Disabilities (CANDID) and 49 family members participated in semi-structured, face-to-face interviews to explore the capabilities and support needs of adults with ASD. SPSS was used to analyse quantitative data and thematic analysis conducted on qualitative information.
Results:
Findings revealed conflicting perceptions of the capabilities and support needs of adults with ASD reported by adults themselves and by family members. On quantitative measures adults with ASD self-reported higher support needs which contradicted what they expressed in qualitative interviews. Adults with ASD stated it was difficult for them to know, describe and express what they needed. In comparison with family members, adults with ASD frequently described their capabilities and expectations of independent living to be higher and support needs lower than what family members perceived them to be. Family members expressed concerns for the safety and wellbeing of adults with ASD and the need for support to achieve independent living.
Conclusions:
While not implying one perspective is better or more 'truthful' than another, findings highlight discrepancies between the expressed abilities and support needs of adults with ASD which may require consideration for how needs are assessed, and support provided. Face-to-face, detailed closed ended questions may provide a more accurate assessment of the abilities and support needs of adults with ASD than open ended questions. Deficits in executive function may make it difficult for adults with ASD to anticipate the future, inevitable changes that may occur and the tasks with which they may need support. Adults with ASD may underestimate their future support needs and parents may over estimate them. Social services may not appreciate the gravity of adults with ASD's need for support and possible consequences of its absence. Under or over estimating competencies and support needs of adults with ASD may impact their wellbeing and safety

19 **124.019** Convergence of Self-Report and Informant Measures of Executive Function for Adults with ASD

R. K. Sandercock[1,2], *L. G. Klinger*[2,3], *K. M. Dudley*[1,2] *and M. R. Klinger*[2,4], *(1)Department of Psychology & Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)Department of Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: The number of adults with Autism Spectrum Disorder (ASD) is rapidly increasing, and with it, the need for appropriate assessment instruments to better understand this population. Self-report measures are widely used for both research and clinical assessment of adults with ASD, though there is little research examining the convergence of self- and informant-report in this population.
Objectives: This research capitalized on a unique dataset of adults diagnosed with ASD as children by the TEACCH Autism Program from 1970-1999. The present study examined agreement between Caregiver- and Self-Report on the Behavior Rating Inventory of Executive Functioning–Adult Version (BRIEF-A; Roth & Gioia, 2005).
Methods: Caregiver surveys were completed for 274 adults with ASD in middle adulthood. Of this sample, 25 adults with ASD (age range: 27-57, M = 35.1) and their caregivers completed the Self- and Informant-Report versions of the BRIEF-A during in-person follow-up testing. The self-report form of the BRIEF-A was only administered to individuals with a full-scale IQ (FSIQ) of 70 or higher (FSIQ range: 73-120, M = 92.24).
Results: Caregiver and Self-Report t-scores on the BRIEF-A Global Executive Function Composite (GEC) were significantly correlated (r = .73, p < .01). Scores on the Behavioral Regulation and Metacognition indices also demonstrated significant, positive correlation (r = .75, p < .01; r = .64, p < .01, respectively). There was not a significant difference between Caregiver and Self-Report t-scores for the GEC (Caregiver M=56.28; Self-Report M=54.92). However, for two subscales, Self-Monitoring and Organization of Materials, Self–Report t-scores were significantly lower than Caregiver t-scores (t = 2.00, p < .05; t = -2.49, p < .05, respectively). Discrepancy scores were calculated by subtracting Self-Report t-scores from Caregiver t-scores on the GEC and on each subscale. Discrepancy size was significantly negatively correlated with the FSIQ of the adults with ASD. Larger discrepancies between Caregiver and Self-Report were associated with lower FSIQ scores (r = -.58, p < .01). Discrepancies were largest for individuals with FSIQs below 85, with the adults with ASD reporting significantly fewer executive function impairments than their caregivers reported about them.
Conclusions: The BRIEF-A demonstrated acceptable levels of inter-rater agreement when used to measure executive functioning for adults with ASD and did not show overall differences in t-scores for Caregiver and Self-Report version. However, cognitive ability was significantly related to the size of difference between Caregiver and Self-Report. Because individuals with lower FSIQs may have more difficulty accurately reflecting on their own impairments, under-reporting executive function issues may result in disqualification from services and, more broadly, an inaccurate understanding of executive function abilities in this population. For individuals with lower cognitive abilities, gathering information from multiple sources is important for a more complete assessment of functioning than gathering information from an adult or caregiver alone.

20 **124.020** Correlation of Medical Comorbidities and Medication Use in Adolescents and Adults with Autism Spectrum Disorder

D. J. Barnette[1,2], *K. Porter*[3] *and* ***C. Hanks***[4], *(1)Pharmacy Practice and Science, The Ohio State University, College of Pharmacy, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)Statistics, The Ohio State University, Columbus, OH, (4)Internal Medicine, The Ohio State University Wexner Medical Center, Hilliard, OH*

Background: The prevalence of adults with autism spectrum disorders (ASD) is increasing. However, little is known about the frequency of medical comorbidities and related medication use in adults with ASD. Psychotropic medications are often used in patients with ASD, but the pattern of use is poorly understood. Here, we report the on the frequency of medical comorbidities and medication use in a primary-care based population of adolescents and adults with autism.
Objectives: To examine medication use patterns in adolescents and adults with autism
Methods: The Center for Autism Services and Transition (CAST) is a primary care based effort to improve medical care for adolescents and adults with ASD. A retrospective chart review was done of all patients seen in the CAST clinic between April 2014 and April 2015. Data collected included demographics, diagnoses, and medications at the time of initial clinic presentation. Associations between comorbidities and medication classes were assessed by chi-square tests. All statistical tests were evaluated at the α=0.05 significance level.
Results: Â We reviewed 143 charts. Age ranged from 7 to 45 years (mean = 20) with the majority of patients (81%) between the age of 15 and 29 years old. Frequency of medical diagnoses included: 47% (n=67) with intellectual disability(ID), 52% (n=74) with ADHD, 51% (n=73) with anxiety, 37% (n=53) with obesity (BMI >30), 32% (n=46) with a history of aggressive behavior, 29% (n=41) with depression, 22% (n=32) with seizures and 8% (n=11) with hypertension. Medication use at the time of the initial visit included 59 (41%) on SSRIs/SNRIs, 51 (36%) on atypical (2nd generation) antipsychotics, 42 (29%) on antiepileptics, 35 (25%) on non-stimulant ADHD treatments, 36 (25%) on sleep aids, 34 (24%) on stimulants, 31 (22%) on benzodiazepines, 19 (13%) on stool softeners, 12 (8%) on non-SSRI/SNRI antidepressants, 12 (8%) on 1stgeneration antipsychotics, and 9 (6%) on antihypertensives (refer to Table 1. Additionally, 48 patients (34%) reported current use of complementary and alternative medicines with an additional 15 patients (11%) reporting previous use of complementary and alternative medicines. The average number of different medication classes was 3.0 for patients with ID and 1.9 for patients without ID. Further statistical analysis was performed to better understand the relationships of different comorbidities with specific medication class usage with a particular focus on ID, seizures, and history of aggressive behavior. These data are provided in Table 2.
Conclusions: In our primary care-based population of adolescents and adults with ASD, medication use is common with many patients being on multiple medications. We found higher rates of psychotropic medication use in patients with ID, seizures, anxiety, and a history of aggressive behavior. It is likely that patients with ASD are less able to self-advocate their needs than the general population, thus putting them at higher risk for complications related to medication use and polypharmacy. These data highlight the need for careful monitoring and awareness of risks of polypharmacy in adolescent and adult patients with ASD, particularly if they have intellectual disability, seizures, or a history of aggressive behavior.

21 **124.021** Criterion-Related Validity of the Theory of Mind Inventory-2 Self-Report Form for Adults with Autism Spectrum Disorder

E. T. Crehan[1]*, R. R. Althoff*[2]*, P. A. Prelock*[3] *and T. L. Hutchins*[4]*, (1)AARTS Center, Rush University Medical Center, Oak Park, IL, (2)Psychiatry, University of Vermont, Burlington, VT, (3)College of Nursing and Health Sciences, University of Vermont, Burlington, VT, (4)Communication Sciences & Disorders, University of Vermont, Charlotte, VT*

Background:
From identifying areas of strengths and challenges to assessing intervention efficacy, detailed social functioning measures are needed to best support individuals with ASD across the lifespan. Self-report tools in particular empower individuals to share their experiences in a meaningful way. The Theory of Mind Inventory-2, originally developed as a caregiver-report measure of theory of mind, has been adapted to a self-report format. Limited theory of mind is characteristic of ASD which has implications for a range of social skills, including gaze perception. To understand the utility of this measure, we compare the ToMI-2-SR to other self-reports of social skills as well as to eye tracking outcomes in a population of young adults.
Objectives:
1) To examine how the self-report form of the ToMI-2 is comparable to other social skills measures and eye tracking outcomes
2) To examine whether the ToMI-2-SR adds unique variance above and beyond existing measures of social functioning
Methods:
A total of 36 young adults (M_{age}*(SD)*= 20.5 (*2.2*), Average brief IQ = 113.0 (*13.5*), 41.7% female, 42% with a diagnosis of ASD or PDD) completed an eye tracking task and self-report questionnaires: Theory of Mind Inventory-2- Self Report (ToMI-2-SR), Social Responsiveness Scale (SRS), and Adult Self-Report (ASR). Four eye tracking conditions mimicking different gaze detection scenarios (averted gaze, mutual looking, getting caught staring, and catching another staring) were presented and four eye tracking outcomes are examined. Between group effects and bivariate correlations were conducted to explore theoretically-based tests of construct validity. More specifically, Pearson correlations were calculated between the ToMI-2-SR Advanced subscale, the SRS (Social Cognition and Social Communication subscales), ASR (Withdrawn and Thought Problems scales), and eye tracking outcomes (interest area (IA) dwell time, trial dwell time, IA first and second fixation duration).
Results:
A significant group difference emerged between the ASD/PDD group and the typically-developing group ($t(34) = 4.53$, $p<.001$ on what?. The ToMI-2_SR Advanced subscale was significantly correlated with the Social Cognition ($r=-.67$, $p<.001$) and Social Communication ($r=-.72$, $p<.001$) subscales of the SRS, as well as the Withdrawn ($r=-.50$, $p<.005$) and Thought Problems ($r=-.52$, $p<.005$) scales of the ASR. IA and trial dwell time were significantly correlated with ToMI-2-SR across all conditions except 'averted.' First fixation duration was significant in the averted condition ($r=-.44$, $p<.01$). Second fixation duration was significant in the 'getting caught staring' condition ($r=.36$, $p<.05$).
Conclusions:
Correlations between the ToMI-2-SR and other ASD-related scales were significant (and consistent with previous results using the caregiver version of the ToMI), providing evidence of criterion-related validity of the self-report form. Of particular interest is that correlations between eye tracking outcomes and the ToMI-2-SR followed a different pattern of correlations than between eye tracking outcomes and other measures of social skills. The unique contribution of the ToMI-2-SR has important implications for understanding gaze detection and social functioning. As adults with ASD continue to advocate for themselves (nothing about us without us!), well-established self-report measures will serve an increasingly key role in including individuals with ASD in their own care.

22 **124.022** Does Baseline Rsa Play a Role in Social Skills and Sensory Sensitivity in Adults with Autism Spectrum Disorders?

M. W. Kuiper[1]*, H. M. Geurts*[2] *and L. Verhoeven*[3]*, (1)University of Amsterdam, Doorwerth, Netherlands, (2)University of Amsterdam, Amsterdam, NETHERLANDS, (3)Dr Leo Kannerhuis, Doorwerth, NETHERLANDS*

Background:
There is increasing scientific attention for the possible relationship between autonomic functioning and ASD symptoms. The evidence is rather mixed. Some find no differences between people with and without ASD in autonomic functioning during sensory or social stimulation, whilst others find atypical reactions in people with ASD (see review of Klusek et al., 2015). The major focus, so far, was on autonomic responses. However, some suggest that baseline levels of autonomic functioning might be more important (e.g., Porges et al., 2013).
Objectives:
We examined whether baseline respiratory sinus arrhythmia (RSA) is related to social skills and sensory sensitivities in adults with and without ASD.
Methods:
38 ASD and 39 typically developing (TD) males (aged 18-45, mean=31.4; IQ>70, mean=104.5) were included. Baseline RSA was measured with an electrocardiogram and the VSRRP98 of the local university. Social skills were measured with a Dutch self-report social skills questionnaire ('Inventory of Interpersonal Situations'). Sensory sensitivities were measured with the Adolescent/Adult Sensory Profile. For the current analyses a sensory sensitivity total score was calculated. We performed two multiple regression analyses with, respectively, sensory sensitivity and social skills as dependent variables. In both analyses, the predictors were baseline RSA and Group (ASD vs. TD) in step one and an interaction (Group*Baseline RSA) in step two.
Preliminary Results:
The groups did not differ in age or IQ. Regarding sensory sensitivity, the preliminary results showed that in step one the model explained 35.4% of the variance. After adding the interaction, the model explained a similar amount of variance (R^2 *change*=.00) and did not result in significant additional explained variance. Only group was a significant predictor (ASD>TD; β=-29.80, p=.00). Regarding social skills, similar findings were observed as the model explained 37.4% of the variance in step one and adding the interaction did not result in a significant increase in explained variance (R^2 *change*=.001). Again, only group was a significant predictor (ASD<TD; β=21.72, p=.00).
Conclusions:
These preliminary findings suggest that baseline RSA is not related to social skills and sensory sensitivity in adults with or without ASD, over and above group. Group is a relevant factor, which was to be expected as altered social skills and sensory sensitivities are at the core of ASD. Future research needs to determine whether an altered physiological ability to adapt to the environment is a better candidate to elucidate the potential relationship between autonomic functioning and ASD symptoms.

23 **124.023** Driving Anxiety in Individuals with Autism Spectrum Disorder

H. J. Bishop *and D. Stavrinos, Psychology, University of Alabama at Birmingham, Birmingham, AL*

Background: Compared to 87% of the general population, only 25% of adults with Autism Spectrum Disorder (ASD) consider themselves independent drivers. Despite this low frequency of driving and its importance to overall quality of life, current transportation safety research among drivers with ASD is sparse and limited to survey data. These survey data have identified driving anxiety as a commonly reported driving barrier for individuals with ASD. Anxiety response comprises three components: physiological (i.e., increased heart rate), cognitive (i.e., anxious thoughts), and behavioral (i.e., avoidance of feared situations).
Objectives: The current study examined each of these components in individuals with ASD and the ability of anxiety to predict simulated driving performance.
Methods: Sixteen drivers with clinical diagnosis of ASD and sixteen drivers with typical development (TD) matched on age (M_{age} = 22.94, SD = 4.25), gender (94% male), and driving experience (months since permit received; M = 93.41, SD = 50.39) were recruited. Participants wore a Polar activity sensor band to record average heart rate (AHR) – a physiological measure of anxiety – as they completed a 10-mile simulated drive. The simulator automatically collected driving performance outcomes. Participants also completed questionnaires assessing demographic characteristics, driving frequency (behavioral), and the Scale of Apprehensive Driving (SAD) assessing driving anxiety (cognitive). Independent samples t-tests were conducted to examine group (ASD vs TD) differences in driving frequency, as well as cognitive and physiological driving anxiety. Full factorial linear regressions were also conducted to examine diagnostic group, physiological and cognitive driving anxiety, and the interaction of anxiety and group (GroupxAHRxSAD) as predictors of driving performance. The continuous predictors (AHR, SAD) were centered to reduce multicollinearity when including the interactions in the model.
Results: Drivers with ASD (M = 4.31, SD = 2.75) drove fewer days per week (M = 6.19, SD = 1.52), t(30) = -2.39, p < .01, and showed higher self-reported driving anxiety (M = 23.88, SD = 3.70) compared to TD drivers (M = 23.88, SD = 3.70), t(30) = 2.14, p = .03. No group differences were found for AHR, t(30) = -.844, p = .95. Higher self-reported driving anxiety (F(4,29) = 3.24, p = .03) predicted slower driving speed. The linear regression indicated that neither group, AHR, nor GroupxAHRxSAD predicted other simulated driving performance outcomes (i.e., motor vehicle collisions, reaction time, lane deviation).
Conclusions: Drivers with ASD reported higher levels of driving anxiety, but showed no differences in AHR compared to TD drivers. Diagnostic group was not a predictor for driving performance; however as psychological anxiety symptoms increased, drivers tended to drive more slowly, possibly as a compensatory mechanism. These finding may suggest that drivers with ASD can regulate their physiological anxiety symptoms while driving, but may drive less often than TD drivers due to their anxiety's psychological component. Study findings indicate diagnosis of ASD does not predict decrements in simulated driving performance. The current study suggests that targeting the psychological component of driving anxiety through evidence-based interventions (i.e., cognitive behavioral therapy) in the ASD population may increase rates of independent driving.

24 **124.024** Driving Performance of Drivers with Autism Spectrum Disorders: A Simulator Study

D. Chee[1]*, H. Lee*[1]*, A. H. Patomella*[2] *and T. Falkmer*[1]*, (1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Department of Neurobiology, Karolinska Institutet, Stockholm, Sweden*

Background: Driving is an important step for transitioning into adulthood as it cultivates a sense of autonomy and can help secure employment and social relationships. In order to be safe on the road, drivers are required to demonstrate a range of driving knowledge and skills related to traffic regulations, speed control, lane positioning, vehicle control, safe distance to others, anticipation and management of hazardous situations. Individuals with ASD often have more difficulties with executive functioning, which include processing speed, working memory, attention, mental flexibility, planning, and also difficulties in the ability to anticipate events. Due to the characteristics of autism and the nature of driving, driving can be challenging for drivers on the autism spectrum.
Objectives: This study aims to examine how drivers with Autism Spectrum Disorder perform during an unanticipated driving scenario in comparison with neurotypical drivers using a driving simulator.
Methods: Seventeen drivers with Autism Spectrum Disorder and 18 drivers without underwent a driving simulation (STISIM M300WS) in an urban setting consisting of a critical driving scenario. Driving mistakes and performance outputs on the driving simulator and the self-reported driving history on the Driving Behaviour Questionnaire were analysed.
Results: Drivers with Autism Spectrum Disorder reported significantly more lapses on the Driving Behaviour Questionnaire and committed more driving mistakes on the driving simulator than drivers without. Drivers with Autism Spectrum Disorder were also slower to react to the abrupt changes in traffic lights. However, drivers with Autism Spectrum Disorder drove less closely to vehicles in front, measured by time to collision (TTC), and were less likely to tailgate other vehicles.
Conclusions: Drivers with Autism Spectrum Disorder may be less efficient in responding promptly to critical driving scenarios that require prompt identification of and reaction to hazards but they appear to be safe drivers with respect to keeping distance to cars in front. Driver education should emphasise on the critical response of drivers with Autism Spectrum Disorder in different driving scenarios.

25 **124.025** Evaluating a University Mentoring Program: Outcomes for Students with ASD and Other Disabilities.

E. Byrne[1]*, A. Hillier*[1]*, J. Goldstein*[1]*, L. Tornatore*[1]*, A. Diaz*[1]*, H. Johnson*[1]*, S. Ratliff*[1]*, K. Silva*[1] *and S. M. Donnelly*[2]*, (1)University of Massachusetts Lowell, Lowell, MA, (2)University of Massachusetts Lowell, Lawrence, MA*

Background: Increasing numbers of students with autism spectrum disorder (ASD) are entering higher education. Their success can be jeopardized by organizational, social/emotional, and academic challenges if appropriate supports are not in place. Mentoring as an intervention strategy has received increasing attention in the literature. While the majority of previous work has focused on at-risk youth populations, students with ASD and other disabilities may be particularly responsive to a mentoring model.
Objectives: The present study examined the outcomes of a mentoring program for students with ASD and other disabilities. We were interested in how and to what extent having a mentor impacted the participants. For a subset we also compared academic outcomes (retention, credits earned, GPA) with a matched comparison group who did not receive mentoring.
Methods: Participants were 46 first year students registered with Student Disability Services (SDS), 36 were male and 10 were female with an average age of 21 years. All participants provided documentation of a disability prior to their eligibility for SDS services and the majority had an ASD diagnosis. Mentors were upperclassmen and were matched with mentees based on availability schedules and major. A subset of participants were matched with a comparison group registered with Disability Services who did not participate in the mentoring program.
Pairs met once a week for an hour for 14 weeks and followed a program curriculum focused on time management, stress management, accessing resources, study skills, dorm life, classroom etiquette, communicating with peers and professors, and working in groups.
Mentees completed a “Program Questionnaire” pre and post intervention designed to measure the effectiveness of the program curriculum. Questions focused on how prepared for university the mentees felt, whether they understood how things work at university, how confident they felt, etc. The post-measure also asked participants to rate how much they attributed any changes specifically to having a mentor.
Results: Significant changes were seen in feeling less worried about being successful, understanding academic expectations, knowing how things work at the university, knowing how to access supports, and where to find opportunities to meet others. Mentors had the most impact in knowing how things work at the university, knowing how and where to find opportunities to meet others, and managing time and organization.
There were no significant differences between a subset of those in the mentoring program and a matched comparison group for number of credits earned or GPA. Four students in the mentoring program had dropped out compared to two in the comparison group.
Conclusions: Â Mentoring programs can be an effective support mechanism for university students with ASD. However, mentoring might be limited in its impact. Whereas meeting regularly with a peer mentor may enhance students’ ability to manage workload and access resources, it less likely to effect retention, or significantly affect academic performance.

26 **124.026** Evaluation Adults with an Asd's Perceptions of Employment and Educational Supports

L. A. Lowery*, Occupational Therapy, University of Missouri, Columbia, MO*

Background: Recent studies indicate the lifetime costs of supporting individuals with an ASD at $2.4 million for individuals with an ID and $1.4 million for individuals without an ASD (Buescher, Ciday, Knapp & Mandell, 2014). These estimates strongly suggest that improving educational and employment outcomes for adults with an ASD is imperative. Rates of participation in higher education and competitive employment continue to be low (Shattuck et al. 2012, Renty and Roeyers, 2006). Many higher education institutions are beginning to explore development of supports for this growing population, but limited information regarding what supports are most beneficial for retention of students with an ASD and transition to work after graduation is known (Zager & Alpern, 2015, Camarena & Sarigiani, 2009). With regard to employment, federal legislation now requires agencies seek employment opportunities for individuals with disabilities at the highest level, i.e competitive employment (https://www.dol.gov/odep/topics/EmploymentFirst.htm). Input from consumers and collaboration with employers is an essential component of determining which supports are most helpful in the work setting.
Objectives: Evaluate the perceived effectiveness of common supports provided to individuals with an ASD in school and work settings and factors which positively or negatively influenced participation.
Methods: Descriptive survey (n=59), adults with an ASD, ages 18-35. Likert scale (5 and 4 point, very helpful-not helpful, strongly agree-disagree or neutral) for perceived effectiveness of educational and employment supports, respondents perceived feelings of success in the work setting and demographic information, e.g. educational level, living situation. Additional data gathered regarding selection of PSE institutions, types of employment and outside hobbies and interests was also included.
Results: Basic supports such as faculty and boss/supervisor mentoring were rated most favorably (44% and 63% respectively), indicating low cost or free supports may be of most benefit above more specialized supports.Â Academic specific supports such as tutoring and extended testing time were also rated as “very helpful” by 29% and 41% respectively by college participants.Â Of respondents, 52% attended college and 71% percent indicated that they been employed at least once. Six percent of respondents who attended college reported that they obtained work in their area of study after graduation indicating that ability to obtain competitive and meaningful employment is still a concern. Management of anxiety and social relationships were most frequently reported as negative aspects of work. Commonly recommended supports such as vocational rehabilitation were noted as least helpful by respondents. Low rates of participation with career counseling, resume writing and interview preparation were noted and indicate that that adults with an ASD may not be accessing important resources.
Conclusions: Individuals with an ASD may benefit most from non-disability supports in the educational and work setting such as faculty and employer mentoring, flexible work schedules and opportunities to work from home. Addressing consumer specific challenges such as anxiety and social relationships are an important component of programming. Continued input from consumers regarding supports is an important component of program evaluation.

27 **124.027** Examining Daily Living Skills in Adults with Autism Spectrum Disorder

N. Bagatell[1]*, M. R. Klinger*[2]*, E. Lamarche*[3] *and L. G. Klinger*[2]*, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)TEACCH, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Daily living skills (DLS) are the often taken-for-granted everyday activities needed for independent adult life. For adults with autism spectrum disorder (ASD), DLS are a predictor of employment success and post-secondary education (Gray et al., 2014; Klinger, et al., 2015). Across the life span, DLS for individuals with ASD lag behind non-disabled peers regardless of intellectual ability (Bal et al., 2015), with adults having the most significant deficits in community skills (Matthews et al., 2015). However, studies investigating DLS in adults are limited and lack detail regarding specific strengths and challenges.
Objectives: The objectives of this study were to examine the factor structure of DLS and to identify areas of strengths and needs at the factor and item level for adults with ASD based on conversational ability to inform the development of targeted interventions.
Methods: Caregivers of 274 adults diagnosed with ASD completed the Waisman Activities of Daily Living Scale (W-ADL), a 17-item scale developed for individuals with developmental disabilities. An exploratory factor analysis of the W-ADL using a varimax rotation was completed. The mean score for each subdomain and each item were calculated. In addition, the level of independence was calculated for each item. A one-way ANOVA was conducted to compare the effect of conversation ability on DLS. Within each conversation group, mean scores for each subdomain and level of independence on each item was calculated.
Results: Results of the factor analysis revealed a three-factor solution: Instrumental Activities of Daily Living (IADL), Self-Care and Simple Domestic Skills (SC), and Eating. Mean scores were: IADLs: 5.87 (Max score = 14), SC: 11.82 (Max score = 16), and Eating: 3.88 (Max score = 4). Only 8% percent (*N*= 22) of the sample received the maximum total score of 34, which reflects skills of a typical adult. Nearly all adults (95%) were independent in Eating. In the subdomain of SC, over 75% were independent with toileting and dressing but only 44% completed simple household tasks independently. In the IADL subdomain less than 20% were independent preparing a complete meal, doing basic home repairs, and managing finances. There was a statistically significant difference between conversation groups on SC and IADLs but not Eating, with those in the “good conversation” group showing the most independence, and those in the “no conversation” group being the most dependent across subdomains (see Table 1). However, those in the “good conversation” group still had significant deficits in IADLs (*M*= 9.3; Max score = 14) and less than 40% being independent in more complex activities.
Conclusions: As expected, conversation ability predicted DLS. Those with good conversation ability demonstrated strengths in Eating and SC but continued to have significant challenges with IADLs, skills considered essential for independent living. Results indicate a need for individually tailored interventions for individuals across the life span and across the spectrum. Programs designed to address IADLs of those with good conversation skills are crucial while interventions aimed at increasing independence in SC should be targeted for those with more significant conversation challenges.

28 **124.028** Examining Environmental Predictors of Social Participation and Service Use for Adults with ASD Using Geographic Information Systems (GIS)

D. V. Chan[1], *M. R. Klinger*[2], *K. Adkisson*[3] *and L. G. Klinger*[2], *(1)Allied Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)Duke Behavioral Health and Technology Laboratory, Durham, NC*

Background: Limited research on adults with ASD reports poorer community participation and social interaction compared to both typically developing peers and those with other disabilities (Liptak et al., 2011, Orsmond et al., 2013; Roux et al., 2013). Where adults live, including size of community and proximity to resources may be important environmental factors influencing participation and service use, but are rarely studied in this population (Badia et al., 2011).
Objectives: A geographic information systems (GIS) approach was used to systematically examine whether size of community and distribution of community resources contributed to community participation and service use outcomes for adults with ASD.
Methods: Outcomes were reported by 124 caregivers of adults (aged 21-54, M = 34.8) who were diagnosed with an ASD as children. Caregivers completed the TEACCH Autism in Adulthood Survey assessing adult outcomes, including community participation and service use. GIS mapping determined the population density where the adult lived, as well as how accessible it was to various features, including bus stops, grocery stores, coffee shops, religious organizations, and health care (see example in Figure 1). Accessibility was measured by both proximity to and density of features relative to the home location. Regression analyses examined whether these GIS measures predicted adult outcomes and service use, while also accounting for adult age, conversation ability, childhood IQ, and activities of daily living (ADL) skills.
Results: Results indicated that while person factors of better conversation ability and greater ADL skills significantly affected outcomes, community size was not significantly related to outcomes. Specifically, those from more and less densely populated areas had similar outcomes across a variety of domains including employment, social activity, adult well-being, and access to services. However, accessibility to specific features in the community such as public transportation and religious organizations were significant predictors of outcomes; those with better access to these features had better outcomes than those with poorer access. For example, greater access to religious organizations in the community was related to more frequently getting together with friends outside of organized activities or groups ($p < .001$) and increased involvement in community activities (volunteering and attending religious services) ($p = 0.02$; $p = .01$, respectively). Similarly, greater access to public transportation was related to use of a greater number of services in the last two years ($p < .001$). Accessibility to public transportation was also a significant predictor of increased satisfaction with services overall ($p = .008$) and was one of the significant predictors of better wages from employment ($p< .001$).
Conclusions: These findings suggest it is not the size of the community but access to specific community features such as public transportation and religious organizations that are important environmental considerations impacting social participation and service use for adults with ASD. As the numbers of adults with ASD increases and families focus on identifying factors associated with improved quality of life, these findings suggest that communities that provide opportunities for community integration via public transportation and religious organizations are important components in supporting positive adult outcomes.

29 **124.029** Executive Function Abilities in Individuals Receiving an Autism Spectrum Diagnosis in Adulthood

R. A. Charlton[1], *P. Abbott*[2], *H. Mansour*[1] *and F. Happé*[3], *(1)Goldsmiths University of London, London, United Kingdom, (2)Autism Diagnostic Research Centre, Southampton, United Kingdom, (3)King's College London, London, UNITED KINGDOM*

Background: Little is known about cognition in autism spectrum disorder (ASD) across adulthood, especially in later-life. In typical ageing, executive functions are particularly sensitive to age-related decline. Difficulties in some domains of executive function have been observed in ASD, but it is unclear whether older adults with ASD will show the same pattern of age-related change as typical adults.
Objectives: To examine executive function abilities in adults with ASD, including both gender differences and associations with age.
Methods: We examined the profile of cognitive abilities and autism traits in a group of 134 adults (97 males) receiving a first diagnosis of ASD in adulthood according to DSM IV or V criteria. Participants were assessed in a specialist adult diagnostic clinic, were aged between 18 and 75 years and all had abilities within the normal range on neuropsychological assessment. Executive function abilities were measured using age-normed scores for: Digit Symbol and Digit Span (Wechsler Adult Intelligence Scale-III or IV), Brixton, Hayling, Trails A and B, Key Search and Zoo Map (Behavioural Assessment of the Dysexecutive Syndrome). A composite score for executive function (Mean EF) was computed. Autism traits were measured using the self-report Autism Spectrum Quotient (AQ), Empathy Quotient (EQ), and Systemising Quotient (SQ).
Results: Few gender differences in ASD were observed across the measures. Women scored significantly higher than men on the Digit Symbol task, and reported higher AQ scores but this did not reach statistical significance. Correlations between age and executive function measures were calculated using age-corrected test scores; therefore one would not expect a significant correlation with age if individuals with ASD show the same age-related differences as typical adults. Results demonstrate a significant positive correlation between age and Digit Symbol as well as both Trails A and Trails B, indicating that as age increases performance on these measures is improving beyond typical adult performance. Age correlated significantly with self-rated scores on both AQ and SQ, indicating that self-rated scores increased with age.
Conclusions: In a group of adults without intellectual disability receiving a first ASD diagnosis in adulthood, few gender differences in executive function were observed. In some but not all executive function tasks, significant correlations were observed between age and performance. Results suggest that for some abilities relying on speed and sequencing, late-diagnosed individuals with ASD may demonstrate better performance than typical age-matched peers. Although these results are in keeping with ASD being protective against typical age-related decline, longitudinal studies are required to investigate this fully.

30 **124.030** Executive Function and Its Relation to Outcomes in Middle Adulthood

K. M. Dudley[1]*, M. R. Klinger*[2]*, J. L. Mussey*[3] *and L. G. Klinger*[2]*, (1)Department of Psychology & Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)UNC, Greensboro, NC*

Background: Â Executive function (EF) is defined as one's ability to manage oneself and one's resources including planning, monitoring, and cognitive flexibility (Welsh & Pennington, 1988). The literature documents EF deficits for those with ASD throughout childhood and adolescence (Kenworthy et al., 2008), but little is known about how EF manifests in middle adulthood and its relations to adult outcomes. This is of critical importance because over 50,000 individuals with ASD turn 18 each year suggesting the need to better understand predictors of adult outcomes.
Objectives: The current study investigated EF abilities and its relation to outcomes in adults diagnosed with ASD as children between 1970 and 1999 at the UNC TEACCH Autism Program.
Methods: Participants included 50 adults with ASD (age range 27-57; *M* age=37.2) who completed assessments measuring IQ (Stanford Binet-5; FSIQ range 40-120; *M* FSIQ=69.7) and confirm autism diagnosis (ADOS-2). Caregivers of adults with ASD completed measures assessing their adult's EF (BRIEF-Adult Version), quality of life (QOL-Q), adaptive behavior (Vineland-II), internalizing symptoms (ADAMS), and social functioning (SRS-2). Analyses were conducted to examine the relation of EF to areas of adult functioning.
Results: Bivariate correlations were conducted to assess the relationship between EF and nonverbal IQ (NVIQ), as the literature suggests a connection between these domains. When including the whole sample, there was no significant relationship between EF and NVIQ (r=-.06, p=.69). Because our sample had a large range in NVIQ standard scores (range=42-114; *M* NVIQ=71), we further probed this relationship by dividing the sample into those with NVIQ>70 (N=27) and NVIQ<70 (N=23). For those with NVIQ>70, there was a significant negative correlation between NVIQ and EF, with those with lower NVIQ scores demonstrating poorer EF (r=-.39, p=.05). However, NVIQ was not related to EF for those with NVIQ<70 (r=-.24, p=.28). Indeed, some individuals with low NVIQ were rated as having no problems with EF. Individuals with NVIQ<70 seemed to be driving the lack of relationship of NVIQ to EF in the full sample, suggesting the BRIEF-A may not be valid for adults with intellectual disability (ID). Thus, we examined the relations between EF and measures of adult outcome only for those with NVIQ>70. In this subsample (N=27), EF was significantly negatively related to overall QOL (r=-.57, p=.002), satisfaction with one's life (r=-.71, p<.001), adaptive behavior (r=-.55, p=.003), depression (r=-.73, p<.001), anxiety (r=-.69, p<.001), and social functioning (r=-.65, p=.001). All relationships indicate those with poorer EF were reported to have more problems in each of these domains.
Conclusions: Â These data indicate that the BRIEF-A may not be an appropriate measure of EF for adults with comorbid ASD and ID. For adults with ASD without ID, results suggest that EF is an important factor in adult functioning and those with poorer EF were rated to have poorer outcomes across all areas assessed. Because EF is considered a domain in which interventions can lead to improved EF abilities (Kenworthy & Anthony et al., 2013), these results support the idea that adult EF programs may facilitate improved adult outcomes.

31 **124.031** Experiences of College Students with Autism Spectrum Disorder: Successes, Struggles, and Needs

S. L. Jackson[1]*, L. A. Hart*[1]*, C. Beyer*[1]*, Z. J. Williams*[1]*, J. T. Brown*[2] *and F. R. Volkmar*[1]*, (1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)College Autism Spectrum, West Hartford, CT*

Background: Despite the growing number of college students with autism spectrum disorder (ASD; Shattuck et al., 2012), our understanding of their experiences/needs is surprisingly limited. Difficulties with anxiety, loneliness, and depression are the most commonly reported experiences of students with ASD (Gelbar, Smith, & Reichow, 2014), often stemming from non-academic aspects of college (e.g. living arrangements, social relationships, and structuring time). As a result, despite academic proficiency, students with ASD are less likely to graduate (39%) than the general student-body (52%), and students with other disabilities (41%; Gelbar, Shefcyk, & Reichow, 2015). As successful completion of a college degree is significantly related to positive adult outcomes in ASD (Newman et al., 2011), further research on this topic is needed.
Objectives: The current study aims to expand our knowledge of the academic/social experiences and mental well-being of college students with ASD, with the goal of using this information to help schools understand how to best support these students.
Methods: The current sample consists of 33 college students with ASD (48% male; age 18-57, *M*=23.0, *SD*=7.45). Using an anonymous, online survey, data was collected on participant demographics, academic/social experiences, and physical/mental health. Survey design was based on collaborations between Yale, College Autism Spectrum, and current/former college students with ASD. Data collection is ongoing.
Results:
Academic: Participants were primarily undergraduates (87.9%), studying at 4-year universities (93.1%). The majority stated being comfortable with their academic workload (69.7%). On average, participants utilized 2.5 support services, with academic advising (67%), exam accommodation (45%), and counseling/psychological services (36%) being the most commonly reported. Nearly one-third of participants desired additional/adjusted services, with housing accommodations, and improved counseling/psychological services being suggested most frequently.
Social:Â Participants reported an average of 1-2 close friends at school, with the majority (60.6%) stating that they were satisfied with their number of friends. However, most of the participants also reported feeling isolated (75.7%) or lacking companionship (87.9%) 'some of the time' to 'often'. Bullying at college was experienced by 24.2% of the sample, with the most common forms being exclusionary (18.2%), or verbal/provocative (12.1%).
Mental Health: Co-occurring psychiatric diagnoses were present in 45.5% of participants, with the most common being GAD (27.3%), SAD (18.2%), and depression (18.2%). Based on DASS-21 scores, participants reported 'severe' symptom levels of depression (*M*=13.2, *SD*=11.4), anxiety (*M*=9.6, *SD*=7.5), and stress (*M*=i5.0, *SD*=8.1) on average. Perhaps of greatest concern, 68.8% of participants reported lifetime occurrences of suicidal ideation (37.5% in the past year), including 46.9% who made plans for an attempt, and 9.4% who made a suicide attempt.
Conclusions: Similar to previous findings, the difficulties faced by college students with ASD in this study generally stemmed from non-academic aspects of collegiate life. Of particular concern were the elevated levels of loneliness, depression, anxiety, stress, and suicidal behaviors. Mirroring suggestions of the study participants, these findings would suggest colleges could help these students improve their experiences at school with support programs designed to build social skills/networks (e.g. peer-mentor programs, ASD housing/clubs), and by improving the availability and quality of counseling/psychological services.

32 **124.032** Experiences of Driving in Adults with and without ASD and Their Relationship with Self-Reported Autistic Traits

E. Sheppard[1]*, E. Van Loon*[2] *and D. Ropar*[2]*, (1)University of Nottingham, Nottingham, England, United Kingdom, (2)University of Nottingham, Nottingham, UNITED KINGDOM*

Background: There is increasing recognition that individuals with Autism Spectrum Disorders (ASD) may experience some challenges when driving. A number of studies have reported that young adults with ASD may experience difficulties with certain aspects of driving (e.g. Cox et al., 2012; Ross et al., 2015; Sheppard et al., 2010). However only one previous study (Daly et al., 2014) has surveyed adults with ASD about their experiences when driving and that study focused only on those who were regular drivers.
Objectives: This study surveyed a large sample of adults with ASD (both drivers and non-drivers) to understand further the difficulties they face when driving and to determine how they relate to self-rated autistic traits. Individuals without an ASD diagnosis were also surveyed as a comparison group.
Methods: An online survey was created which asked about respondents' diagnostic status, age, driver status, difficulties they face while driving/ barriers to learning to drive. The Autism Spectrum Quotient (AQ, Baron-Cohen et al., 2001) was included as a measure of autistic traits. 170 individuals who reported having a diagnosis of ASD (83 female, mean age 30.4) and 204 individuals with no diagnosis (106 female, mean age 28.7) responded. Respondents were recruited through a range of online autism forums/support groups as well as other research participant recruitment websites, and local and international online communities.
Results:
Respondents with ASD were less likely to hold a driving license and to own a car than comparison individuals, and were more likely to have tried to learn but given up. However drivers with ASD did not report being involved in more accidents over the past year. Current drivers with ASD reported more difficulty than comparison individuals on every aspect of driving surveyed, including multitasking, feeling anxious, judging positions of other vehicles, interpreting other road users' behaviour, managing unexpected changes and predicting upcoming events. Non-drivers with ASD who had previously learned but given up also reported more difficulties than non-drivers without an ASD diagnosis who had given up.
AQ scores positively correlated with reported driving difficulties both in the group with ASD and the comparison group. In drivers with an ASD diagnosis, high scores on attention switching, attention to detail and communication subscales were associated with difficulties in specific components of driving. In drivers without an ASD diagnosis, high scores on the social, communication and attention switching subscales were associated with having difficulty more broadly, across multiple aspects of driving.
Conclusions: Having an ASD or high levels of sub-clinical autistic traits may be associated with difficulties when driving, both during learning and after having obtained a license. Aspects of driving that an individual finds particularly challenging may relate to their specific profile of autism features.

33 **124.033** Experiences of Individuals with Autism Spectrum Disorder Who Identify As Lesbian, Gay, Bisexual, Transgender, Queer, Questioning, or Intersexed.

A. Hillier[1]*, N. Gallop*[1]*, E. Mendes*[2]*, A. Nizami*[1] *and D. OToole*[1]*, (1)University of Massachusetts Lowell, Lowell, MA, (2)Eva Mendes LHMC, NCC, Arlington, MA*

Background: While widely recognized as a serious omission, a lack of research focused on sexuality and ASD remains, and particularly the experiences of those who identify as LGBTQI. This results in minimal information available for individuals, family members, and professionals, and thus inadequate service provision for this population.
Objectives: The objective of this study was to gather preliminary data on the experiences of those who identify as LGBTQI and ASD, particularly the challenges they face stemming from these dual identities. We used a focus group qualitative analysis approach as a critical first step in exploring relatively uncharted ground, with the aim of identifying key themes and areas of need which might inform future research.
Methods: Four participants aged between 20 and 38 years with autism spectrum disorder (ASD) took part in the focus group. Participants' gender identities included male, transgender; agender/nonbinary; agender; lesbian/queer. All participants were Caucasian. Participants provided proof of a DSM-IV ASD diagnosis. An initial pilot study utilized an online questionnaire to explore issues around the experiences of those who identify as ASD and LGBTQI. Responses (n=10) were used to inform the development of questions for the focus group. The focus group included eight questions and took around 90 minutes. Two coders independently coded the entire transcription using NVivo software and identified the key themes.
Results:
Four main themes emerged from the focus group including 1) the intersectionality between ASD and LGBTQI did not present problems for the group in terms of understanding their gender identity and sexual orientation. They saw these as two separate identities. They did not endorse the hypothesis that having ASD might hinder or impair their understanding of their gender identity. They did note that one of the biggest challenges was not having the vocabulary for how they identified. This may be in part due to sparse opportunities to explore gender and sexual identity; 2) Challenges stem from others accepting their dual identities. Others, including professionals and family members, may believe the individual is confused about their gender and sexual identities because they have ASD; 3) Lack of understanding of the autism spectrum presents numerous barriers and contributes to isolation, particularly from others in the LGBTQI community. Members of the LGBTQI community, as well as professionals, often have stereotypical views of ASD presentation, thus discrediting the individual and invalidating what they say. 4) Appropriate service provision is almost nonexistent with many professionals at a loss for how to support them. In certain cases participants were shuffled from one provider to another, delaying treatment for years.
Conclusions: While some positive aspects of identifying as LGBTQI and having an ASD diagnosis were mentioned, our participants mostly described obstacles. These preliminary findings identify some key target areas for future research and programming. There is a clear need for better support, understanding, theories and practices regarding the intersection between ASD and LGBTQI issues.

34 **124.034** Facilitating Success for Students with Autism Spectrum Disorder at University

C. Thompson[1,2], *T. Falkmer*[1,2], *S. Bolte*[1,3,4] *and S. J. Girdler*[1,5], *(1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (4)Stockholm County Council, Center for Psychiatry Research, Stockholm, Sweden, (5)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia*

Background:
While many adults with Autism Spectrum Disorder (ASD) have average to high intellectual capacities they still experience numerous challenges which impact on their ability to negotiate everyday life. Despite recognition of their challenges there remain few evidence-based interventions targeting the needs of this group who continue to experience poor outcomes in important life areas such as employment, education and interpersonal relationships.
Objectives:
The aim of this research was to describe the viewpoints on factors impacting on the success at university for students with ASD from the perspectives of university students with ASD, their parents and their mentors.
Methods:
Q-methodology identified the viewpoints of the 57 participants. Twenty-two students with ASD participated (15 male and seven female; mean age=24.6; SD=9.7). Eleven of the participants were mothers and three were fathers of university students with ASD (mean age=54.0 years; SD=8.7). There were six male and 15 female mentors of university students with ASD (mean age=30.9 years; SD=7.9). The analysis employed a by-person varimax rotation factor analysis.
Results:
Three distinct factors were defined by 17 sorts from all three groups; factor one accounted for 23%, factor two accounted for 15% and factor three accounted for 8% of the variance, respectively. Viewpoint one *Individualised support* was characterised by the supports that facilitate success at university for individuals with ASD at university. Viewpoint two *Contextual support* was distinguished by the supports enabling participation in a university environment. This viewpoint also highlighted the logistical issues faced by students with ASD such as time management and transportation. Viewpoint three *Social support* was defined by the supports required for students with ASD to facilitate personal interactions within the university environment. This viewpoint identified consistent support as a mechanism for managing social interactions, recognising the difficulty that bullying can pose.
Conclusions:
The unique approach of the current study, has in part addressed the noted limitations in previous literature which has called for further research into the needs of university students with ASD. While young people with ASD aspire to succeed in post-secondary education they struggle negotiating the necessary steps in achieving this goal. This study highlighted that supports need to be individualised and that university services should broaden their interventions for students with ASD, and provide both social and academic support. The environment has been proposed as a potential intervention target in ASD with approaches such as peer mentoring likely to be particularly effective. Peer mentoring may be particularly suited in supporting university students with ASD given its potential to be tailored to meet individual needs. While traditionally, peer mentor programs have focused on providing academic supports, this study suggests that this focus should extend to include social, emotional and psychological support.

35 **124.035** Gender-Identity in High-Functioning Individuals with Autism Spectrum Disorder

R. M. George[1] *and* ***M. A. Stokes***[2], *(1)Victoria, Deakin University, Burwood, VIC, Australia, (2)School of Psychology, Deakin University, Melbourne, Australia*

Background: Â Clinical impressions indicate that within the Autism Spectrum Disorder (ASD) population that there is an overrepresentation of gender-dysphoria. However, little is presently known about the demographics of gender-identity issues in ASD.
Objectives: Â We hypothesized that there would be an increased prevalence of gender-dysphoria among those with ASD when compared to a typically developing (TD) population.
Methods: Â We surveyed gender-dysphoria with the Gender Identity and Gender Dysphoria Questionnaire in an international sample of individuals with ASD (*N*= 309, *M*=90, *F*= 219), aged (*M*=32.30 years, *SD*=11.93) and compared these rates to those of typically-developing individuals (*N*=261, *M*= 103, *F*= 158), aged (*M*=29.82 years, *SD*=11.85).
Results: Â When compared to TD individuals, individuals with ASD reported increased gender diversity ($\chi 2$= 34.06, p< 0.001, φ=0.25). Furthermore, individuals with ASD reported a higher number of gender-dysphoric traits ($t_{(569)}$ =8.6, p< 0.001, d= 0.73). Rates of GD in the group with ASD were significantly higher than reported in the wider population (OR=304.91, p<0.001). Relative to TD individuals, individuals with ASD prioritized personality aspects over gender in their romantic partner (χ^2= 52.48, p< 0.001, φ=0.56), expressed an androgynous self-concept (χ^2= 22.99, p< 0.001, φ=0.50) and reported gender as being unimportant to personal identity ($\chi 2$= 101.07, p< 0.001, φ=0.78). The ASD group reported poorer mental health than controls and belonging to a sexual or gender-diverse group worsened this effect.
Conclusions: Â Results suggest that ASD presents unique challenges to the formation and consolidation of gender identity. It is important that clinicians working with ASD are aware of the gender-diversity in this population, so that the necessary support for healthy socio-sexual functioning and mental well-being is provided.

36 **124.036** Getting Autistic People into Work: Evaluation of a Paid Internship Programme for Autistic Graduates

***A. Remington**, E. Roy, R. Sealy and E. Pellicano, Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom*

Background:
Autistic individuals often face significant challenges to obtaining and maintaining meaningful employment – more so than other disability groups. Aside from the clear economic impact of this gap, the failure to get autistic people into work has a demonstrably negative effect on quality of life in a group of people who commonly have unique and valuable skillsets. In addition, those autistic individuals who *are* in full-time work are often in poorly paid, low-skill jobs that do not reflect their competencies. The UK autistic community has identified that understanding effective ways to deliver appropriate employment support is one of their top ten research priorities. Consequently, employers are beginning to offer paid work placement opportunities for individuals on the autism spectrum.
Objectives:
This research seeks to understand the benefits and pitfalls of one such British scheme implemented by Deutsche Bank, a large German global banking and financial services company, and to determine its impact on the confidence and future employability of the interns. By better understanding autistic adults' workplace experiences, and the perspective of their co-workers, we aim to highlight both challenges to address, and also factors associated with successful transition to work.
Methods:
Semi-structured interviews were carried out with 8 autistic interns (aged 21 – 27 years), all with undergraduate degrees, and their hiring managers before the start of the programme and again immediately after its completion. Before commencing the programme, interviews focussed on previous employment experiences (interns) and expectations of the upcoming programme: opportunities, possible challenges and, in particular, how they might address these challenges (interns and managers). Following the internship, interviews with both interns and managers focussed on their experiences of the internship: aspects that went well, issues that arose, and ways they were overcome. Six team members who worked alongside the interns were also interviewed following the programme. They were asked about the perceived benefits and challenges of the scheme, both for the interns and for themselves as a team.
Results:
Interviews were recorded and transcribed verbatim, and resulting data was analysed using thematic analysis. Analyses are on-going, however preliminary results from initial interviews suggest a number of key themes. Both interns and managers saw great value in the scheme, identifying benefits for the organisation (original ways of thinking, high quality of work) as well as the individuals themselves (training in key areas, experience of office environments). Managers' concerns often focussed on social aspects of the workplace, whereas the autistic interns commented on performance-based worries such as whether they have the necessary skills for the role. Managers also highlighted a range of accommodations they had made, both with respect to workplace environments and their own leadership style, to facilitate the success of the internship programme.
Conclusions:
In light of the minimal existing literature, the current study contributes to a better understanding of the experiences of skilled autistic individuals currently in work. The findings also offer suggestions that can be used to inform the creation, and successful implementation, of subsequent programmes aimed to promote employment opportunities in autism.

37 **124.037** Health Service Use and Health Seeking Behaviours of Australian Adults on the Autism Spectrum

***A. Urbanowicz**[1,2], N. G. Lennox[1,2], J. Trollor[2,3] and K. R. Foley[2,3], (1)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, The University of Queensland, South Brisbane, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Department of Developmental Disability, Neuropsychiatry (3DN), School of Psychiatry, The University of New South Wales Australia, Sydney, Australia*

Background: Adults on the autism spectrum have unique health needs and frequently experience barriers to accessing healthcare related to emotional regulation, sensory sensitivity and healthcare system navigation. Many adults on the spectrum report low satisfaction with patient-provider communication and high levels of unmet healthcare needs. Difficulties with accessing healthcare may contribute to adults on the spectrum often exhibiting poorer physical and mental health outcomes in comparison to the general adult population.
Objectives: To describe the health service use and health seeking behaviours of Australian adults on the autism spectrum.
Methods: The Australian Longitudinal Study of Adults with Autism is a questionnaire-based study which aims to describe the physical and mental health, productivity, wellbeing and health service use of autistic adults in Australia aged 25 years and older. Rolling recruitment has occurred since July 2015. Participants are screened for inclusion and either emailed a link to the online version or mailed a paper copy of the questionnaire. Descriptive statistics and chi square analysis were performed. Further analysis will be conducted to account for demographic differences between groups.
Results:
Questionnaires were completed by 184 autistic adults and 129 non-autistic adults. Autistic participants were aged 25-80 years (mean 42.6 SD12.2) and non-autistic participants 25-79 years (mean 43.6 SD13.6). Over half (56.8%) of autistic respondents were female, 38.3% were male and 4.9% identified their gender as 'other'. The majority of non-autistic respondents (79.0%) were female.
The average length of visit to the general practitioner (GP) did not differ between autistic and non-autistic participants with the most commonly reported length of GP visit being 5-10 minutes (30%, 32%, respectively) and 10-15 minutes (33%, 35%, respectively). There were no differences in satisfaction with GP services between participant groups (p<0. 248) with more than 70% of both groups reporting they were satisfied or very satisfied. However when asked about the amount of help received from the GP, a larger proportion of autistic participants reported receiving ‘a little’ (21%) or ‘none at all’ (6%) in comparison to non-autistic participants (12%, 2% respectively) (p=0.033).
Autistic and non-autistic participants had different motivations to attend an appointment with a health professional (p<0.001). The majority (72%) of non-autistic participants attended a health professional because they wanted to go; compared to 57% of autistic participants. Twenty percent of autistic participants attended for both wanting to go themselves and being persuaded to go by someone else. Just over a third of autistic participants reported having delayed seeing a health professional for at least four weeks in comparison with only 15% of non-autistic participants. The reasons autistic participants delayed seeing a health professional included financial restraints, being unable to get an appointment and anxiety.
Conclusions: Generally, autistic and non-autistic adults reported similar lengths of GP visits and were satisfied with GP services in Australia. Less autistic adults attend a health professional because they want to and more autistic adults delay seeing a health professional due to a variety of reasons including anxiety. This study has important implications for the healthcare system in Australia.

38 **124.038** Impact of Anxiety and Autism Symptomatology on Pragmatic Language in Young Adult Males with Fragile X Syndrome

S. M. Matherly[1], *J. Klusek*[2], *J. Roberts*[3] *and L. Abbeduto*[4], *(1)University of South Carolina, Columbia, SC, (2)Communication Sciences and Disorders, University of South Carolina, Columbia, SC, (3)Department of Psychology, University of South Carolina, Columbia, SC, (4)M.I.N.D. Institute, UC Davis, Sacramento, CA*

Background: Fragile X syndrome (FXS) is the leading inherited genetic cause of autism spectrum disorder (ASD). It is also characterized by high rates of anxiety, with up to 84% meeting criteria for a disorder, resulting in reduced quality of life and increased impairment. It is speculated that anxiety interferes with language learning, particularly during social-interactive contexts resulting in pragmatic language (i.e., social language) impairments. Pragmatic impairments are highly associated with ASD, and investigation into the role of autism and anxiety in FXS on pragmatic language helps address the heterogeneity of behaviors and impairments based on a specific etiology.
Objectives: This is the first study to examine the effects of autism and anxiety symptoms on pragmatic language in young adult males with FXS using a semistructured, dynamic, conversational assessment. This study will identify specific language vulnerabilities in a syndromic, FXS population with high ASD comorbidity and will provide translational evidence for future treatment to optimize language development in males with FXS with findings relevant for different etiologic groups with ASD.
Methods: Participants included 25 young adult males (M_{age} 19.6, *SD* 2.1) with FXS. The Yale in Vivo Pragmatic Protocol (*YiPP*; Simmons, 2015) was administered to characterize use of appropriate pragmatic language and the level of contextual scaffolding from the examiner needed to elicit the target skill through error and cue scores. Error scores ranged from 0, appropriate spontaneous, to 2, completely inappropriate responses, and higher error scores are indicative of greater impairment. Cue scores ranged from 0, no response, to 6, spontaneous appropriate answer, and higher cue scores are indicative of better performance and less contextual scaffolding. Autism Diagnostic Observation Schedule-2 (ADOS-2) provided an autism severity index. Two subscales, socially avoidant and generalized anxiety, from the Anxiety, Depression and Mood Scale (ADAMS) assessed dimensional aspects of anxious behaviors to determine if deficits are related to generalized anxious states or isolated to social anxiety. Autism severity, generalized anxiety and socially avoidant behaviors were examined as predictors of language impairment.
Results: Â Participants had a mean error score of 1.44 (*SD* .39) reflecting language responses that tended to be mildly to completely inappropriate and cue scores of 2.41 (*SD* 1.30) indicating appropriate responses were elicited after greater scaffolding of conversational probes through nonspecific or specific verbal repetition or cues. Higher rates of social avoidance predicted greater language impairments (B=.04, *p*=.025, R^2=.48) and greater need for conversational scaffolding (B=-.11, *p*=.046, R^2=.47) after covarying for expressive vocabulary. Neither autism severity nor generalized anxiety symptoms predicted pragmatic impairments (*p*’s>.091) or contextual scaffolding (*p*’s>.159).
Conclusions: Â These findings highlight a complex relationship between anxiety and pragmatic language impairments in males with FXS. Results are consistent with a multifaceted interplay of dynamic systems involving language development in that socially avoidant behaviors, but not a pervasive anxious state, negatively impact pragmatic skills. Avoidant behaviors likely reduce environmental opportunities for learning, likely hindering social language development and augmenting avoidance. Continued research on the effects of autism and anxiety on pragmatic language is needed to comprehend similarities and differences across etiologies.

39 **124.039** Job Satisfaction and Quality of Life in Adults with Autism Spectrum Disorder (ASD) Participating in the Dandelion Program

D. Hedley[1], *M. Uljarevic*[2,3], *M. Wilmot*[1], *J. Spoor*[4], *A. L. Richdale*[2] *and C. Dissanayake*[1], *(1)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia, (4)Department of Management & Marketing, La Trobe Business School, La Trobe University, Melbourne, Australia*

Background: Adults with Autism Spectrum Disorder (ASD) face disproportionately high rates of unemployment (Shattuck et al., 2012). Organizations can potentially improve employment rates in individuals with diverse needs by making reasonable adjustments and creating supportive environments in the workplace (Cavanagh et al., 2016; Yang & Konrad, 2011). When individuals are employed and experience job satisfaction this generally leads to positive outcomes, including improved quality of life (QoL). Job satisfaction predicts a range of positive outcomes including improved work performance, lower absenteeism, lower turnover, and higher overall life satisfaction (Judge & Klinger, 2008), but the research on job satisfaction among individuals with disabilities and/or ASD is sparse and has produced mixed results (Baumgartner et al., 2014).
Objectives: The present longitudinal study examined QoL and job satisfaction, as well as the relationship between these factors, in adults with ASD participating in the Dandelion Program. This program, an initiative of Hewlett Packard Enterprise (HPE), Australia, is a three-year traineeship providing a pathway into employment for people with ASD, with additional workplace supports to accommodate their diverse needs. Individuals are placed in information technology positions within the Australian Federal Government.
Methods: Participants were 20 males with ASD aged 20 to 45 years (M = 25.15, SD =7.74 years) who were employed as software testers by HPE and placed at two federal government locations in Australia. Participants completed the Minnesota Satisfaction Questionnaire, short-form (MSQ; Weiss, Dawis, England, & Lofquist, 1967), a widely reported job satisfaction questionnaire, and the World Health Organization Quality of Life-BREF (WHOQOL-BREF; WHO, 1996), at three time-points, corresponding to 6, 12, and 18 months of employment respectively. Data from co-workers were included for comparison purposes.
Results: General, intrinsic and extrinsic job satisfaction was higher than that of co-workers ($p < .05$), yet significantly decreased over time in participants with ASD. QoL of participants with ASD did not differ significantly from co-workers at the three time-points ($p > .05$), and remained stable over the 18-month period. We did not identify a significant association between job satisfaction and QoL ($p > .05$).
Conclusions: This study identified a relatively high but decreasing level of job satisfaction in adults with ASD employed as software testers in a supported employment program. This decrease was not reflected in a corresponding change in QoL, which remained stable over the same 18-month period. The lack of a significant relationship between quality of life and job satisfaction was unexpected – we predicted that satisfaction at work would be reflected in life satisfaction, as has been reported elsewhere in individuals with developmental disabilities (Noonan-Garcia, 2003). Similarly, we expected quality of life to improve over time, as has also been demonstrated previously in individuals employed in a supported work environment (García-Villamisar, Wehman, & Navarro, 2002), yet it did not. Further work is required to unpack the relationship between work and quality of life in working adults with ASD.

40 **124.040** Life after School: Understanding the Transition to Adulthood from the Perspectives of Young Autistic People and Their Parents

S. J. Cribb[1]*, L. Kenny*[2] *and E. Pellicano*[3]*, (1)School of Psychology, University of Western Australia, Nedlands, Australia, (2)Centre for Research in Autism and Education (CRAE), London, UNITED KINGDOM, (3)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom*

Background: The majority of autism research focuses on understanding autism in childhood, which means that very little is known about the life chances of young autistic people as they transition into adulthood. The existing studies on this issue have consistently highlighted the striking variability in long-term outcomes of autistic individuals, even in individuals considered to be cognitively able. But the measures used to index a 'good outcome' are often quite crude in nature (e.g., proportion of individuals living independently, in paid employment etc.). Rarely has research sought to examine what a good outcome means from the perspectives of the individuals themselves or the people that support them.
Objectives: This study sought to understand the views and experiences of transition in a group of cognitively able young autistic people on the cusp of adulthood.
Methods: Twenty-eight cognitively able young autistic people took part in a 12-year prospective longitudinal study. In addition to standardized instruments, we conducted semi-structured interviews with 26 young people (M age = 17 years; 10 months; SD = 1;2) and 28 of their parents to elicit their views and experiences of school and their hopes and aspirations for their future lives. Thematic analysis was used to identify key themes.
Results: We identified three themes common to both young people and their parents' interviews, including (1) challenges that young autistic people face during this period of their lives, (2) autism and "autistic" identity, and (3) factors facilitating positive outcomes. Parents highlighted several concerns, including about anxiety, difficulties with organization, problems with motivation and potential vulnerability. Parents also expressed considerable concerns about lack of friends and romantic relationships. The young people themselves were less worried about not having friends, as many were often keen to keep to themselves. Nevertheless, they all had clear ambitions and appeared to have an age-appropriate desire for increased independence. Indeed, many astutely noted the importance of "getting the right amount of support" – that is, the need to strike a balance between providing support and building capacity for being able to manage flexibly in a variety of contexts, especially important for life after school. Young people varied considerably, however, with regard to their views on being autistic and the role it had to play in their lives, with some identifying it as a challenge, others distancing themselves from the diagnosis ("I try to be as normal as possible") and others still seeing it as a positive difference. There was agreement between parents and young people that "likeability", strengths and interests and a drive to reach goals were key factors in promoting young people's outcomes.
Conclusions: These findings shed light on the challenges faced by cognitively able young autistic people as they move on up into adulthood, especially the pressures – including from their parents – to conform to societal norms. The results further highlight the need to establish the most effective ways to prepare young autistic people for the potential obstacles they face as they make the transition to adulthood.

41 **124.041** Lifelong Learning in Autism: A Life History of an Autistic Woman's Learning Journey in Formal and Informal Learning Contexts

T. W. Henderson*, Giant Steps Montreal, Montreal, QC, Canada*

Background: Learning in autism remains underexplored in the literature and little is known about the lifelong learning experiences of adults on the spectrum or ways in which adult education can be inclusively designed to support and promote success. What we do know about learning in autism is that learning is atypical. Additionally, there is also resistance to learning in typical ways from typical approaches and therefore, a non-normocentric approach to evaluating and teaching autistic people is recommended. As incidence rates of autism diagnosis increase across society, more adults diagnosed with ASDs are enrolled in adult education. As such, this study seeks to richly describe the lived experience of one adult learner with autism and discover themes that suggest directions for autism-inclusive adult education design.
Objectives: The purpose of this study is to understand what lifelong learning looks like for an individual with autism. By exploring the life story of one elderly autistic woman, the barriers and facilitators to learning across the lifespan of an individual with ASD are revealed. Four sub-questions are examined: 1. How is learning for people with autism parallel to, different from, and complementary to non-autistic learning? 2. How does formal and informal learning occur? 3. What does this tell us about the transformative potential of self-directed learning for adults with autism? 4. What are some of the facilitators and barriers to learning?
Methods: The study used a qualitative life-history methodolgy. The life-history was established through a series of narrative interviews. The narratives collected and composed in this study were analysed using thematic analysis.
Results: This study examines the life history of a 72-year-old Deaf woman with an autism. By analysing her life experiences and narrative, questions of identity- and ability-diversity are highlighted and barriers and facilitators to learning and inclusion are discovered. The participant's story highlights the complex interrelationship between learning, identity, neurodiversity, legitimacy and agency, and the mediating roles of inclusion and accessibility. The findings contribute to developing a deeper understanding of the meaning and importance of formal and informal learning in the life of a person with autism and indicate ways in which the learning of adults with ASDs can be supported and enhanced.
Conclusions: Â Learning for the participant, across her lifespan, can be characterized as profoundly atypical from both a developmental and educational perspective. Her learning trajectory does not map easily onto a non-autistic learning history. Her story is rich from an educational biography perspective, giving voice to an exceptional person's life experience within a specific historical context. Her story strongly suggests the importance of using a non-normocentric approach that appreciates the unique and complimentary strengths, skills, and needs of adult learners on the autism spectrum. Her descriptions of learning demonstrate that she learns from often atypical types and sources of information and has a preference for self-education. Her story also powerfully highlights the importance of self-determination and the transformative potential of self-direction for learners like her and emphasizes the potential impact of leveraging technology to support learning, communication, engagement and autonomy.

42 **124.042** Loneliness and Quality of Life for the Broader Autism Phenotype

L. Graham Holmes[1,2], *C. J. Zampella*[2,3], *A. A. Gillespie*[1] *and M. B. Himle*[1], *(1)Department of Psychology, University of Utah, Salt Lake City, UT, (2)Child and Adolescent Psychiatry and Behavioral Sciences, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Clinical & Social Sciences in Psychology, University of Rochester, Rochester, NY*

Background:
Autism-related traits vary along a wide severity continuum, including subclinical traits that are continuously distributed among the general population (commonly referred to as the broader autism phenotype; BAP). Recognition of the BAP has led to increased interest in how these milder autism characteristics may influence functional outcomes in nonclinical populations. A small body of research has found that the BAP is related to fewer and lower-quality interpersonal relationships, as well as increased loneliness. This study investigated specific associations between the BAP and relationship quality and outcomes. Clarifying these associations is critical for identifying factors impacting quality of life in individuals with both subclinical and clinically significant symptoms of autism.
Objectives:
(1) Compare loneliness, distress, quality of life, relationship status, and social support among college students with and without BAP traits. (2) For the BAP group, investigate whether loneliness is associated with negative mental and physical health outcomes, and whether it accounts for a relationship between BAP traits and lower quality of life. (3) Test whether quantity and quality of relationships influences the impact of BAP traits on loneliness.
Methods:
Participants were 736 students (18-30 years, M=20.9, 65% female, 44% in a relationship) at the University of Utah. Participants completed the Broader Autism Phenotype Questionnaire (subscales: aloofness, pragmatic language, rigidity), the UCLA Loneliness Scale, the Depression Anxiety and Stress Scale, the MOS Social Support Survey, and the WHO Quality of Life-Bref (subscales: physical health, psychological, social, and environmental).
Results:
Individuals who met criteria for BAP (n = 95) rated themselves as experiencing more loneliness (p<.001) than their non-BAP peers. Additionally, the BAP group reported higher levels of stress, depression, and anxiety (p's<.001), and poorer quality of life across all domains (p's<.001). Within the BAP group, greater loneliness was correlated with increased stress (p=.001), depression (p=.001), and anxiety (p=.036). Furthermore, loneliness mediated the relationship between BAP and quality of life (p<.001). The BAP group was as likely as the non-BAP group to report a current romantic relationship (p=.473), yet reported lower overall levels of social support (p=.001). Both number of significant relationships and the perceived social support provided by those relationships were predictors of loneliness (p's<.001) within the BAP group. Of the BAPQ subscales, aloofness uniquely predicted loneliness within the BAP group, including when controlling for relationship status and gender.
Conclusions:
Individuals with subclinical autism-related traits are more likely to experience loneliness, resulting in poorer health outcomes and perceived quality of life. Quality of significant relationships predicts levels of loneliness in individuals with BAP. Additionally, the BAP trait of aloofness appears to be specifically related to loneliness. Together, these findings indicate that people with subclinical autism symptoms experience difficulty with relationships, and this difficulty is reflected in their health and quality of life. The importance of supporting healthy relationships is underscored for individuals across the autism spectrum.

43 **124.043** Measuring Work Adjustment in Adolescents with ASD

L. G. Klinger[1], *K. M. Dudley*[2], *R. K. Sandercock*[2] *and M. R. Klinger*[1], *(1)UNC TEACCH Autism Program, Chapel Hill, NC, (2)Department of Psychology & Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Adults with ASD often have poor outcomes including difficulty gaining and keeping employment. Research shows the current employment rate for young adults with ASD is 35% (Roux et al. 2013). Because employment is a pivotal experience that typically leads to better daily living skills (Taylor et al., 2015) and higher quality of life (Klinger et al., 2015), it is important to develop instruments that assess individuals' workplace readiness skills to identify individualized intervention goals. A common brief (i.e., 15 minutes) Vocational Rehabilitation assessment measure is the Becker Work Adjustment Profile (BWAP). The BWAP is composed of four subscales: Work Habits, Interpersonal Relations, Cognitive Skills, and Work Performance. It has been validated for persons with a wide variety of physical, developmental, and psychiatric disabilities but has not been previously validated with adults on the autism spectrum.
Objectives: The goal of this study was to examine the validity of the BWAP for adults with ASD. Specifically, we examined the relation between the BWAP and other measures associated with employment outcomes in adults with ASD: ASD symptom severity, intellectual functioning, and executive functioning.
Methods: Participants were 42 adolescents with ASD (14-19 years of age, M = 16 years,10 months) who participated in an employment and college readiness intervention. Measures were collected during a baseline assessment prior to beginning the intervention. All participants had their diagnosis confirmed by the ADOS-2, and all had intellectual functioning within the average range on the Wechsler Abbreviated Scale of Intelligence-II (WASI-II; range: 85-135; M=104). Parents completed the BWAP, the Social Responsiveness Scale-2 (SRS-2), and the Behavior Rating Inventory of Executive Functioning Adult Version (BRIEF-A). Teachers also completed the BWAP.
Results: Parent and teacher BWAP total scores were highly correlated (r=.65, p<.001) supporting convergent validity across raters. Multiple regression analyses were conducted to investigate the relation of each BWAP subscale to ASD symptom severity (SRS-2), intellectual functioning (WASI-II), and executive functioning (BRIEF-Global Executive Composite). For parent completed BWAP, Work Habits and Work Performance were significantly predicted by the BRIEF-GEC (β=-.71, p<.001 and β=-.78, p<.001, respectively). BWAP Interpersonal Relations was predicted by SRS-2 (β=-.37, p=.02) and BRIEF-GEC (β=-.32, p=.04). Finally, BWAP Cognitive Skills was predicted by WASI-II (β=+.48, p=.001) and SRS-2 (β=-.44, p=.001). Similar results were seen for the teacher completed BWAP.
Conclusions: Each of the subscales of the BWAP was strongly related to measures of functioning in adolescents with ASD. BWAP Interpersonal Relations was strongly related to autism symptom severity, BWAP Cognitive Skill was strongly related to intellectual functioning, and BWAP Work Habits and Work Performance was strongly related to executive functioning. These results suggest that the BWAP provides a relatively brief measure of employment skills that capture the range of interpersonal, intellectual functioning, and executive functioning difficulties experienced by adults with ASD in work settings. Research examining the utility of this measure in documenting intervention effectiveness is ongoing.

44 **124.044** Money Matters: Risks of Limited Money Understanding Among Adults with ASD

*K. F. Glaser[1], **V. D'Astous**[1] and K. Lowton[2], (1)King's College London, London, UNITED KINGDOM, (2)University of Sussex, Brighton, United Kingdom*

Background:
Money management is a unique adulthood need for some individuals with ASD. Money appears to be a difficult concept for many adults with ASD to understand and manage with extensive consequences of incompetence, and yet it remains largely unrecognised on the evidence base of supportive services. Patterns of money spending and financial management of adults with ASD including impulsive spending, poor planning, and obsessive saving and monitoring of money may be associated with repetitive patterns of behaviour characteristic of autism, executive function deficits and mental health comorbidities. However, individual personalities, experiences and media influences may also contribute to financial habits with learned money skills and changes in monetary patterns possible with effective support. Currently, informal support efforts from family members may be meeting the financial and money management needs of adults with ASD. Formal support services may be essential when family support is unavailable. Limited understanding of money and the inability to manage it may place adults with ASD at risk of harm.
Objectives:
To explore the monetary competencies and financial patterns of behaviour of adults with ASD.
Methods:
Using mixed methods, 74 adults with ASD (19-65 years of age), recruited from a London clinic, completed the Camberwell Assessment of Need for Adults with Developmental and Intellectual Disabilities (CANDID) and 49 family members participated in semi-structured, face-to-face interviews to explore the capabilities and support needs of adults with ASD. SPSS was used to analyse quantitative data and thematic analysis conducted with qualitative information.
Results:
Money budgeting difficulties were reported by adults with ASD as a high and unmet need on the CANDID, and monetary limitations and consequences were widely expressed and described in interviews. Problems with financial literacy and skills ranged from basic understanding of the monetary value of paper money and coins, difficulty with maths and counting change, to the inability to accomplish routine tasks of bill paying, to complex tasks such as budgeting and banking. Money management difficulties included the inability to budget or pay bills, over or underspending, lending or giving money away, and difficulty understanding credit cards and money. Some adults with ASD had experienced financial abuse and exploitation. Many had their money and spending monitored or managed by family members. The inability to think ahead, or to anticipate future needs, and difficulties in prioritising and decision-making, were key concerns of family members for adults with ASD who had some control over their finances. The need for financial support and money management, particularly with reference to the future, was frequently stated by, and about adults with ASD. However, who would assume this responsibility, family or formal support services was vague.
Conclusions:
Limitations in financial understanding may impede adults with ASD from making decisions as informed consumers, and place them at risk of harm and exploitation without adequate and effective support. An unmet need in the area of money management may significantly impact the safety and wellbeing of an adult with ASD.

45 **124.045** Mortality and Cause of Death in People on the Autism Spectrum: An Exploration of State-Based Administrative Data.

***Y. I. (. Hwang**[1,2], K. R. Foley[1,2], P. Srasuebkul[1] and J. Trollor[1,2], (1)Department of Developmental Disability, Neuropsychiatry (3DN), School of Psychiatry, The University of New South Wales Australia, Sydney, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia*

Background:
Examination of mortality and cause of death is of central importance for understanding the extent and nature of health inequalities for adults with autism spectrum disorder (ASD). Previous studies indicate that this population experiences 2 to 5.6 times higher mortality rates than the general population. Whilst respiratory disease and nervous system disorders are leading causes of death, unnatural and avoidable events, such as accidents and suicide, are also notable causes. In addition to the general paucity of information regarding health and wellbeing outcomes for adults on the autism spectrum, there has been limited investigation of mortality and cause of death.
Research concerning mortality and cause of death is of key importance for the evaluation and planning of health services and policy. Robust analysis of large linked data sets provides representative and timely information for such evaluation and planning.
Objectives:
To examine mortality rates and cause of death for adults with ASD, intellectual disability and both in comparison to the general population in New South Wales (NSW), Australia.
Methods:
Nine NSW state-based retrospective datasets have been linked as part of a larger project exploring the health and wellbeing of people with intellectual disabilities. These datasets cover the period of 2005/06 to 2011/12. We expect to have extended datasets (up to 2015/16) available for analysis and presentation by early 2017. For the current study, the ASD cohort was identified primarily through the Disability Services Minimum Dataset. Mortality and cause of death data were obtained from the NSW Attorney General and Justice Register of Births, Deaths and Marriages (RBDM) and from the Australian Bureau of Statistics (ABS). Population size, mortality and cause of death in the general population in NSW were accessed via the ABS data.
We will compare data for four groups: (i) ASD only, (ii) intellectual disability only, (iii) ASD and intellectual disability; and (iv) the general population in NSW. Descriptive statistics will be used to describe causes of death. Other analyses will include age-specific crude death rates, standardised mortality rates and Comparative Mortality Figure (CMF) and years of potential life lost (YPLL).
Results:
In our existing data n=15,983 adults with ASD only, n=42,243 adults with intellectual disability only, and n=7,497 adults with both ASD and intellectual disability were identified to have accessed disability services in NSW between 2005/06-2011/12. We anticipate that for the extended dataset, this cohort will increase substantially (at least n=20,000 adults with ASD only, n=60,000 adults with ID only and n=10,000 adults with both ASD and intellectual disability).
Conclusions:
This study will provide the most reliable and current information on mortality and cause of death in adults on the autism spectrum in Australia. Due to the nature of the data, it will include a wider sample of individuals on the autism spectrum than any other Australian study. This information will be of intense interest to health professionals, service providers and families, and will help shape efforts to address premature death for this population.

46 **124.046** New Age Vocational Training Program for Adults with Autism: Integration of Soft Skills Training and Software Testing

M. Baker-Ericzen[1], *M. Fitch*[2], *M. M. Jenkins*[2], *R. T. Trefas*[3], *E. Velazquez*[4], *M. Kinnear*[5] *and J. Leon*[6], *(1)Child and Adolescent Services Research Center, Rady Children's Hospital San Diego, San Diego, CA, (2)Rady Children's Hospital San Diego, San Diego, CA, (3)Research Resources, Rady Children's Hospital San Diego, La Jolla, CA, (4)Child and Adolescent Services Research Center, Rady Children's Hospital, San Diego, CA, (5)San Diego State University, San Diego, CA, (6)Technical Skills Training, National Foundation for Autism Research, San Diego, CA*

Background:
Longitudinal studies of intellectually able adults with autism have shown consistent and persistent deficits across cognitive, social, and vocational domains, indicating a significant need for effective treatments for these functional disabilities (Howlin, 2000). The cognitive and social skill deficits, "Soft Skills" which predict vocational outcomes, have been identified as major challenges to employment success for these adults (Hillier et al, 2007; Kautz et al, 2014). Additionally, individuals with AS gravitate to technology fields more than general population (Wei et al, 2013), providing a well-suited career choice.
Objectives:
This study tested a novel, community-based intervention that combines a soft skills manualized intervention, **Su**pported employment, **C**omprehensive **C**ognitive **E**nhancement & **S**ocial **S**kills (SUCCESS) with a software testing training program for adults with ASD. An open trial pilot study was conducted to obtain estimates of effects of multiple outcomes: cognitive skills, social skills, technical skills, vocational skills and satisfaction.
Methods:
A total of 25 adults (μ= 24 SD=4.64 yrs) participated and received the combined SUCCESS & Technical Skills program. Participants participated in the program 3 days a week for 3 hours each day totaling 9 hours a week over 6 months. The SUCCESS curriculum was delivered weekly for 90minutes via active group participation during a work meeting. Skills taught include executive functioning: attention, learning, memory, prospective memory, cognitive flexibility, problem solving, goal oriented thinking and contextual awareness and social cognition: social conversation (giving and receiving compliments, feedback and help), social relationships, initiations, social media and social networking. The technical skills curriculum prepares the participant for a position as an entry level Software QA Tester in the high tech industry, and also prepares the student to obtain a Certificate in Software Testing (from ISTQB). Pre and post assessments include a full battery of assessments with the Behavior Rating Inventory of Executive Function- Adult Version (BRIEF-A) ,Social Responsiveness Scale-2 (SRS-2), technical skills performance (completion rates, accuracy of bug detection, program proficiency), work skills (attendance, dress code, productivity) and vocational outcomes (employment). Data was gathered from standardized measures (participant and parent report), records, computer program reports and program staff ratings. The majority of participants were male (90%), white race/ethnicity (84%) and all graduated with a high school diploma.
Results:
Analyses consisted of calculating paired sample t-tests and Cohen's d effect sizes to measure the magnitude of the effect of the intervention on outcomes. Preliminary findings reveal small to large effects on executive functioning and social functioning (Refer to Table 1 & 2). Reports of tech skills and work skills revealed large gains. Employment rates increased from 20% to over 50% post intervention. Program satisfaction was very high with mean rating of 8.9 out of 10.
Conclusions:
This study demonstrates that an integrated program designed to develop technical skills and vocational soft skills positively impacts adults with ASD. These adults were substantially more prepared for the workforce and obtained employment at high rates. This job-training program revealed high satisfaction and promise towards vocational success for adults with ASD.

47 **124.047** Parent Preparatory Activities As Adolescents with ASD Transition to Adulthood

L. Graham Holmes[1,2] *and A. V. Kirby*[3], *(1)Department of Psychology, University of Utah, Salt Lake City, UT, (2)Child and Adolescent Psychiatry and Behavioral Sciences, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of Utah, Salt Lake City, UT*

Background:
Extant longitudinal research suggests parental expectations during adolescence are a significant predictor of outcomes in the areas of social participation, employment, and independenceÂ for adults with autism spectrum disorder (ASD). Parental expectations around sexuality in ASD populations have also been shown to predict parental actions (i.e., the provision of sex education).Â Thus, it is hypothesized that parents' selection of adulthood preparation activities during adolescence may serve as one mechanism through which parent expectations contribute to outcomes for adults with ASD.
Objectives:
1. Examine gender and cognitive level differences in the preparation activities endorsed by parents of youth with ASD.
2. Determine if gender, cognitive level, age, and parental expectations for the future predict parent-endorsed preparation activities.
Methods:
A national sample of 309 parents of 12–18 year-olds (M=14.4) with ASD (52% male; IQ estimates: 67% average or above, 13% borderline, 21% IQ <70) provided information about youth age, estimated IQ, autism severity (SRS-2), and parental expectations for the future regarding education, financial independence, community roles, and sex/romance (rated 1-5; very unlikely to very likely). Parents also endorsed actions taken to support development in the areas of sexuality/relationships and employment/independence. We grouped similar actions (e.g., enrolled child in a class to build skills, provided education, youth participated in paid or volunteer work) and created binary variables indicating whether any action in the category was endorsed. Chi-square tests and logistic regression were applied to address the objectives.
Results:
Parents of males were more likely to seek guidance from professionals about sex and relationships, talk to their child about jobs, and to have their child participating in paid or volunteer work. Parents of females were more likely to enroll their child in a class to build skills. Youth with IQ<70 were less likely to receive education related to sexuality/relationships and employment/independence.
Conclusions:
Because of the balanced inclusion of males and females, this study offers a unique look at gender differences in parent-endorsed preparation activities during adolescence. The finding that males are more likely to engage in activities in the community while females are more likely to participate in formal classes suggests there may be more concern about protection of daughters with ASD. It is noteworthy that parent actions were similar for youth in the two higher cognitive categories considering that prior studies report outcomes are similar across the range of adults with ASD without intellectual disability. Finally, this study provides evidence to support the hypothesis that the actions parents take to support their child's transition to adulthood are informed by their expectations and may serve as a mechanism through which expectations predict outcomes.

48 **124.048** Participation in Recreational Activities Buffers the Impact of Perceived Stress on Quality of Life in Adults with Autism Spectrum Disorder

***L. Bishop-Fitzpatrick**, L. E. Smith, J. S. Greenberg and M. R. Mailick, Waisman Center-University of Wisconsin, Madison, WI*

Background: As the number of adults with autism spectrum disorder (ASD) grows, the need to identify modifiable correlates of positive outcomes and quality of life (QoL) gains in importance. Research indicates that perceived stress is significantly correlated with QoL in adults with ASD. Studies in the general population of individuals without disabilities indicate that greater participation in social and recreational activities may lessen the negative impact of perceived stress on well-being, and this association may also hold among adults with ASD.
Objectives: Our objectives were to: (1) examine the association between perceived stress and QoL; and (2) explore the moderating effect of participation in social activities and recreational activities on the association between perceived stress and QoL.
Methods: Data to address our hypotheses were collected prospectively from 60 adults with ASD aged 24-55 and their mothers who were part of a large, longitudinal study of 406 adolescents and adults with ASD and their families. Measures assessed perceived stress (Perceived Stress Scale), QoL (brief version of the World Health Organization Quality of Life assessment), and self- and mother-reported social activities and recreational activities. Hierarchical multiple linear regression analyses first explored the buffering role of self-reported social activities and recreational activities on the association between perceived stress and QoL. Then, follow-up analyses used the same technique to investigate the impact of mother-reported social activities and recreational activities on the association between perceived stress and QoL.
Results: Overall, adults with ASD reported that they participated in slightly less than one social activity (*M=0.82, SD=0.90*) and about three recreational activities (*M=2.98, SD=.89*) per week, and mother-report data independently confirmed these patterns. Results of hierarchical multiple regression analyses revealed a significant, positive main effect of perceived stress on QoL, *B=-8.07, t(53)=-3.77, p<.01, sr^2=.18*, when controlling for age, sex, and ID status. Results revealed that recreational activities buffered the relationship between perceived stress and QoL, *B=5.88, t(51)=2.49, p=.02, sr^2=.07*, such that for individuals with higher levels of participation in recreational activities, the negative effect of perceived stress on QoL was lessened. Our findings related to mother-reported social activities and recreational activities mirrored our adult self-report findings.
Conclusions: Findings corroborate a growing body of literature that indicates that high perceived stress is a problem for a sub-group of adults with ASD that needs to be addressed through targeted treatment. Our findings also suggest that interventions and services that provide supports and opportunities for participation in recreational activities may help adults with ASD manage their stress and lead to better QoL. Of note, much of the ASD literature suggests that interventions should target core autism symptoms in order to help individuals with ASD to develop social networks. However, participation in social activities was not associated with QoL in our analysis. Thus, interventions that offer opportunities for participation in recreational activities, even if those activities do not provide explicit opportunities for socialization, may help adults with ASD manage their stress and, in turn, feel more satisfied with their QoL.

49 **124.049** Poor Initiation and Planning Abilities in Young People with Autistic Traits

***N. Albein-Urios**, M. Kirkovski and P. G. Enticott, Deakin University, Geelong, AUSTRALIA*

Background: The investigation of autistic traits in the "typically developing" population has shown that people with sub-threshold behavioural autistic traits perform poorer on some executive functions. However, little is known about how these traits relate to problems in executive functions using ecological measures.
Objectives: Â The present study examined whether young adults with autistic traits experience increased executive functions difficulties in their everyday life.
Methods: SeventyÂ young adults (18-30 years old) were administered the Autism Spectrum Quotient (AQ), and designated as high autistic traits (n=26) or low autistic traits (n=44). The Behavior Rating Inventory of Executive Function (BRIEF-A) was used to evaluate executive function.
Results: Individuals with higher autistic traits reported having more difficulties than the low autistic traits group in the BRIEF-A self-report in two scales: Initiate (p<0.05) and Planning (p<0.01).
Conclusions: Problems with initiation, the ability to begin an activity, and planning, the ability to anticipate future and implement goals, have been consistently reported in individuals with autism spectrum disorder. These results show that "typically developing" population with high autistic traits also experience difficulties in these two abilities.These findings call for further research on the relationship between autistic trait and executive functions, particularly with respect to underlying mechanisms that might mediate this association.

50 **124.050** Rates of Autism Spectrum Disorder in Adults with Prader-Willi Syndrome

C. Daniell[1], *E. Roof*[2], *H. M. Hunt-Hawkins*[2], *N. A. Dankner*[1], *E. B. Lee*[1], *C. Shivers*[3] *and E. Dykens*[2], *(1)Vanderbilt University, Nashville, TN, (2)Vanderbilt Kennedy Center, Nashville, TN, (3)Human Development, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Prader-Willi Syndrome (PWS) is a neurodevelopmental disorder caused by a lack of paternally derived imprinted genes on chromosome 15q11-q13. It is associated with mild to moderate intellectual disability, irritability, outbursts, rigid behavior, and hyperphagia which increases risk for obesity. Those with PWS have an increased risk for psychiatric issues such as anxiety, attention deficit disorders, psychosis and autism spectrum disorder (ASD). However, there are methodological concerns about the rates of ASD in PWS as most research in this area has relied upon autism screeners or checklists instead of direct assessments combined with clinical reviews to establish ASD diagnoses. Previous studies also typically include a wide age range, introducing potential age effects and observer memory bias. Finally, the nature of repetitive behaviors in PWS may inflate or complicate ASD diagnoses.
Objectives: This study addresses methodological concerns with ASD comorbidity in well-characterized adults with PWS.
Methods: Participants included 42 adults (19 male, 23 female) with PWS ranging in age from 22 to 55 years (M = 30.41 years, SD= 8.21). The Autism Diagnostic Observation Schedule (ADOS-2) Module 3 and Social Communication Questionnaire (SCQ) were used as two ASD assessments, with ASD diagnosis determined by clinician consensus and review of pertinent data. Each participant was also administered the Kaufman Brief Intelligence Test-2 (KBIT-2), the Vineland Adaptive Behavior Scales-II, and the Repetitive Behavior Scale-Revised (RBS-R).
Results: 20 adults (47.6%) were identified as meeting ASD criteria based upon the recommended SCQ cutoff score of >15. 13 adults (30.9%) were identified as meeting autism spectrum criteria using ADOS-2 calibrated severity scores. In contrast, only 4 adults (9.5%) received an autism diagnosis when ADOS-2 data, videos, and other behavioral data were subjected to a thorough clinical review. 3 out of these 4 were of the maternal uniparental disomy (mUPD) genetic subtype of PWS. For the group as a whole, no significant correlations were found between ADOS-2 scores and gender, age, RBS-R or KBIT-2 scores. Moderate negative correlations were found between Vineland's Communication, Daily Living Skills, and Socialization domain scores and ADOS-2 Overall Calibrated Severity Scores (r = -.49, -.63, -.44 respectively, p < .01) and Social Affect Severity Scores (r = -.44, -.57, -.35 respectively, p < .05).
Conclusions: Both the SCQ and ADOS-2 alone suggested more than twice of the sample met ASD criteria as compared to diagnoses made using a review of data and clinical consensus. Future studies should not rely on ASD screeners alone to establish probable ASD in PWS. Most adults with PWS and ASD had the mUPD genetic subtype of PWS.

51 **124.051** Ratings of Social Functioning and Participation in Employment and Postsecondary Education Among Adults with Autism and Schizophrenia

E. Jarzabek[1,2], *K. Ellison*[2], *Z. J. Williams*[1], *M. J. Rolison*[2], *K. A. McNaughton*[1], *T. C. Day*[2], *A. Ataybi*[3], *B. Lewis*[4], *J. Wolf*[1], *J. H. Foss-Feig*[5], *A. Anticevic*[6], *V. Srihari*[6] *and J. McPartland*[2], *(1)Yale Child Study Center, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT, (3)Pediatrics, University of Washington, Seattle, WA, (4)Yale School of Medicine, Darien, CT, (5)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (6)Yale University School of Medicine, New Haven, CT*

Background: Interpersonal skills are critical to success in meeting the demands of adulthood, including participation in continued education or employment. Social impairment is a core deficit of autism spectrum disorder (ASD) and an associated feature of schizophrenia (SZ) that may contribute to difficulties attaining successful adult outcomes. Adolescents with ASD tend to have more positively biased self-perception of their interpersonal self-efficacy than their typically developing peers, but little is known about the self-perception of adults with ASD. Findings regarding self-awareness among individuals with schizophrenia indicate that awareness of the illness along with minimal internalized stigma are related to improved social functioning. Thus, self-perception of one's skills may be an important factor in predicting adult outcomes.
Objectives: This study aims to investigate: 1) the relationship between subjective self-perception of social functioning and clinician-rated levels of social functioning and 2) the relationship between these indicators and participation in postsecondary education and/or employment in adults with ASD, SZ, and typical controls.
Methods: The sample for this study comprises 18 adults with ASD (15 males, 3 females; Mean age=24.6), 18 individuals with schizophrenia (14 males, 4 females; Mean age=28.0) and 6 neurotypical adults (4 males, 2 females; Mean age=25.8); data collection is ongoing. The ASD and the SZ groups were matched on age and IQ (*WASI-II* FSIQ), and all three groups were matched on age and nonverbal IQ (*WASI*-II PRI). Subjective self-perception of social functioning was assessed using the Social Communication Interaction (SCI) Total score of the *Social Responsiveness Scale- Second Edition – Adult Self-Report* form (SRS-2). Clinician-rated levels of social functioning were measured using the *ADOS-2, Module 4*Social Affect Algorithm Total score. Information regarding school and employment status was obtained during the ADOS-2 assessment.
Results: Both ASD [$F(1,22) = 7.05$, $p<.001$] and SZ [$F(1,22) = 6.08$, $p=.02$] groups reported greater deficits in social interaction than typical controls. A negative correlation between self and clinician rating of functioning was observed in the ASD group [$r = -.61$, $p=.007$] but not the SZ group. Additionally, a significant relationship between self-perceived severity of social impairment and participation in school/employment was found for the SZ group [$X^2(3, N = 18) = 9.36$, $p<.05$], such that decreased school/employment participation was associated with increased levels of self-reported social impairment. Self-reported social ability and school/employment outcomes were not associated for the ASD participants. No significant relationship between clinician ratings of social functioning and school/employment participation was observed in either group.
Conclusions: The present findings add to our understanding of self-perception and social functioning of adults with ASD and schizophrenia. While self-reported social impairment appears related to employment/school outcomes in individuals with SZ, no relationship was found for the ASD group suggesting that adults with ASD may have decreased insight into how their social impairment affects their employment/school outcomes.

52 **124.052** Relating ASD Symptoms to Well-Being: Moving Across Different Construct Levels

M. K. Deserno[1], *D. Borsboom*[2], *S. Begeer*[3] *and H. M. Geurts*[4], *(1)University of Amsterdam, Amsterdam, Netherlands, (2)Psychology, University of Amsterdam, Amsterdam, Netherlands, (3)VU University Amsterdam, Amsterdam, NETHERLANDS, (4)University of Amsterdam, Amsterdam, NETHERLANDS*

Background:
Little is known about the specific factors that contribute to well-being of individuals with autism spectrum disorder (ASD). A plausible hypothesis is that ASD symptomatology has a direct negative effect on well-being. Past studies investigating the interacting nature of ASD symptoms and well-being have often included higher order representations of ASD symptomatology in their analyses. In the current study, the emerging tools of network analysis allow to explore these functional interdependencies in a multivariate framework. We illustrate how studying both higher-order (total score) and lower-order (subscale) representations of ASD symptomatology can provide important insights into the interrelations of factors relevant to well-being.
Objectives:
We aim to study the interplay of ASD symptoms and domains of subjective well-being and daily functioning on three construct levels by applying network analysis techniques in an exploratory fashion.
Methods:
We estimated network structures for ASD symptomatology (item, subscale, total score), relating them to daily functioning and subjective well-being in 323 individuals with ASD (aged 17 to 70 years). For these networks, we calculated centrality indices to assess the importance of specific factors in the network structure.
Results:
First, results of our total score network reveal that ASD symptom severity has a direct influence on psychological well-being, which is, in turn, the most important factor for general life satisfaction of individuals with ASD. Second, the relation between depressed mood and ASD symptoms seems to be not a direct influence but funneled by many other domains of daily functioning. Third, the resulting networks do not feature a direct mutual influence between ASD symptom severity and comorbid problems.
Conclusions:
When focusing on the highest representation level of ASD symptomatology, we found a negative connection between ASD symptom severity and domains of well-being. However, focusing on lower representation levels of ASD symptomatology revealed that this connection was mainly funneled by ASD symptoms related to insistence on sameness and experiencing reduced contact and that those symptom scales, in turn, impact different domains of well-being. Zooming in across construct levels into subscales of ASD symptoms can provide us with important insights on how specific domains of ASD relate to specific domains of daily functioning and well-being.

53 **124.053** Relationship of Executive Functioning Deficits and Life Outcome in Intellectually Able Adults with ASD

K. B. Harrison *and K. A. Loveland, Psychiatry, University of Texas Health Science Center McGovern Medical School, Houston, TX*

Background: Â
Intellectually able persons with high-functioning autism spectrum disorders (ASD) often have difficulty with independent living and successful transition into adulthood. In addition to the social deficits of ASD, many experience deficits in executive functioning which may impede adaptive functioning, goal attainment, employment success, independent living, and achieving educational goals.
The Barkley Deficits in Executive Functioning Scale (BDEFS-LF) is a self-report assessment used to evaluate adults ages 18 to 81, and measures type and extent of EF deficits. Because it incorporates a long-term view of a person's executive functioning, the BDEFS-LF may be helpful for understanding where specific areas of difficulty correlate with life functioning.
Objectives: Â
This study is designed to investigate relationships between executive functioning deficits and life outcomes in intellectually-able adults who meet DSM-IV/DSM-5 criteria for ASD. A primary objective of this study is to provide evidence of BDEFS-LF score patterns linked to life outcome for intellectually able adults with ASD which can then be used for clinical application.
Methods: Â
Data were collected from archival records of intellectually able adults who qualify for a DSM-IV or DSM-5 diagnosis of Autism Spectrum Disorder (Asperger's Type) from an outpatient clinic which specializes in diagnosing ASD in adults. There were 43 participants with DSM-IV/DSM-5 ASD (40% F). Distribution of ages was 37% in the 18 -25 year-old category, 42% age 25-39, 20% over the age of 39. Specific records studied include scores from BDEFS-LF categories of self-management to time, organization and problem solving, self-restraint, self-motivation, and self-regulation. Independent variables were: Relationship Status, Education, Employment, and Residence.
Results:
Standard linear regression was conducted to determine the accuracy of the independent variables (BDEFS-LF scores for self-management to time, organization and problem solving, self-restraint, self-motivation, and self-regulation) in predicting the dependent variables of relationship status, education, employment, and place of residence.
Regression results indicate that the overall model significantly predicts current marital status and residence. Results for marital status are (R^2 = .144, $R2_{adj}$ = -.028, F(5, 37) = 1.244, p<.05), which accounts for 14.4% of variance. One of the four variables, self-management to time, significantly contributed to the model. The overall model also significantly predicts residence (R^2 = .209, $R2_{adj}$ = -.102, F(5, 37) = .1.957, p<.05). This model accounts for 20.9% of variance in the dependent variable of residence. As with the results for marital status, the variable of self-management to time significantly contributed to the model. However, regression results indicate the overall model does not significantly predict employment status or level of education.
Conclusions:
Results suggest the factor of self-management to time significantly impacts marital status and independent living for intellectually able adults with ASD. This preliminary investigation into specific executive functioning components which might benefit from clinical treatment suggests that focusing on time management skills might assist with growing skills for independence, particularly maintaining adult relationships and independent residence. Limitations include size of study and the preliminary nature of the investigation. Future directions are underway as data continues to be collected, and may include gender differentials.

54 **124.054** Sexual Orientation in High-Functioning Individuals with Autism Spectrum Disorder

R. M. George[1] *and M. A. Stokes*[2]*, (1)Victoria, Deakin University, Burwood, VIC, Australia, (2)School of Psychology, Deakin University, Melbourne, Australia*

Background:
Clinical impressions indicate a sexual profile within the Autism Spectrum Disorder (ASD) population unlike that seen in the general population that is suggestive of a wide range of sexual orientations. However, little is presently known about the demographics of sexual orientation in ASD.
Objectives:
We hypothesized that there would be an increased prevalence of non-heterosexual orientations within the ASD population.
Methods:
We surveyed sexual orientations with the Sell Scale of Sexual Orientation in an international sample of individuals with ASD (*N*= 309, *M*=90, *F*= 219), aged (*M*=32.30 years, *SD*=11.93) and compared these rates to those of typically-developing individuals (*N*=310, *M*= 84, *F*= 226), aged (*M*=29.82 years, *SD*=11.85). We also compared qualitative responses using thematic analysis, related to sexuality-related attitudes of 109 individuals with ASD (41 males, 68 females) with 70 TD individuals (36 males, 34 females).
Results:
When compared to TD individuals, individuals with ASD demonstrated significantly higher sexual diversity (χ^2= 45.85, p< 0.001, φ=0.39), and this diversity was greater among females than males with ASD. The ASD group reported higher rates of homosexuality (males OR= 2.53, p< .05; females OR= 1.87, p=.06), and asexuality (males OR= 4.18, p< .05; females OR= 2.58, p< .001), but lower rates of heterosexuality (males OR= 0.25, p< .001; females OR= 0.45, p< .01).Â Findings from the qualitative study demonstrated that relative to TD individuals, individuals with ASD reported the birth-sex of their romantic partner as being less important (χ^2= 52.48, p< 0.001, φ=0.56), more discontentment with their own sexual orientation, which was likely to fluctuate based on life-experiences (χ^2= 69.66, p< 0.001, φ=0.65), and were more approving of non-heterosexuality (χ^2= 15.34, p< 0.001, φ=0.30). The ASD group reported poorer mental health than controls and belonging to a non-heterosexual group worsened this effect.
Conclusions:
Results suggest that ASD presents unique challenges to the formation and consolidation of sexual identity. It is important that clinicians working with ASD are aware of the sexual diversity in this population, so that the necessary support for healthy socio-sexual functioning and mental well-being is provided.

55 **124.055** Social Cognition in Old Adults with Autism Spectrum Disorder (ASD): A Potential Age-Related Protective Effect

E. Yarar[1] *and F. Happé*[2]*, (1)King's College London, London, England, United Kingdom, (2)King's College London, London, UNITED KINGDOM*

Background: Although ASD is a life-long condition and most individuals with ASD are adults, there is little research about ageing in autism. Difficulties with social cognition have been repeatedly demonstrated in children, adolescents and young adults with ASD, but only a handful of studies have included individuals aged 50 years or over . It has been widely documented that social cognition gets worse with age in the neurotypical ageing population (perhaps secondary to changes in e.g., memory); however, we still do not know how age affects social cognition in older adults with autism.
Objectives: To gather more information about the pattern of social cognition in older versus younger adults with ASD compared to neurotypical (NT) adults, we investigated social cognition performance on a number of different tasks tapping Theory of mind and social cognition more generally. These included a novel cartoon sequencing task designed to be low in working memory load.
Methods: Performance on a set of social cognition tasks was examined in a group of adults with ASD (N=58; age-range: 19-71 years, M_{age} = 43.66 years, SD = 16.11) compared to an IQ-, gender-, and age-matched NT control group (N=49, age-range: 20-71 years, M_{age} = 44.95, SD = 17.54). Group comparisons between younger (N=49, aged 19 to 48, M_{age} = 29.45 years) and older adults (N=48, aged 50 to 71, M_{age} = 59.21 years) were made, for those individuals with and without ASD.
Results: In the NT group, older adults showed consistently poorer social cognition performance on than younger adults. No such age effect was seen in the ASD adults; although more impaired than NT controls in general, young and old adults in the ASD group did not differ significantly from one another in terms of their performance on the social cognition tasks.
Conclusions: This study represents an exploratory and preliminary step to fill the huge gap in the ASD literature concerning ageing. Results may suggest a protective effect on age-related decline in social cognition in ASD. Limitations, alternative explanations, and implications for future research will be discussed.

56 **124.056** State-Level Variation in Vocational Rehabilitation Services and Outcomes for Transition-Age Youth with Autism

A. Roux[1]*, J. Rast*[1]*, K. A. Anderson*[2] *and P. Shattuck*[1]*, (1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background:
Vocational Rehabilitation (VR) services might benefit many of the 50,000 youth with autism who turn 18 every year – only half of whom will hold a job for pay at any point between high school and their early 20s – most at part-time hours with low wages. The federal VR program provides grants to states to help individuals with disabilities find, maintain, or regain employment. Transition-age youth (TAY) with autism use VR services more than other age groups do, but they also have the worst employment outcomes.Â Individual-level factors are known to influence employment outcomes. Yet, we know less about the role of where you live in the U.S.
Objectives: Â To characterize variation in individual-level VR services and employment outcomes across states.
Methods: Â We analyzed VR service utilization and employment outcomes for 9,797 TAY with autism (ages 14-24) in the federal Rehabilitation Services Administration (RSA) database who received VR services and had a case that closed in FFY2014. Characteristics of these youth and their VR services use and outcomes were examined using bivariate analyses by state.
Results:
TAY with autism who used VR services were primarily male (84%), white (85%), and non-Hispanic (93%) with a mean age of 19 years at the time of VR entry. Approximately 55% were students when their VR case opened. Approximately one-third (29%) were receiving SSI benefits at VR application, and 68% were considered by VR to have a “most significant” disability. Over half (54%) received four or more VR services.
VR service use and related outcomes varied significantly by state. The percentage of TAY with autism who received VR services during secondary school varied by 70 percentage points across states (mean=68%, range 39-87%). TAY with autism who received VR services and exited with employment varied by 52 points across states (mean=58%, range 29-81%). The median hourly wage of those who exited with employment was $8 but ranged from $7.40 to $10/hour across states. The percentage of TAY with autism who received supported employment (SE) services varied by state. Nine states reported no SE services, while three reported rates of 100% (mean=23%). The amount of money states spent on services for VR service users with autism under age 25 averaged $6100 (range $1470-$9668).
Conclusions: Â Nearly every state has some type of policy, legislation, or activities focused on improving employment opportunities for persons with disabilities. Although individual-level factors contribute to a diverse profile of employment outcomes for TAY with autism, VR service utilization and employment outcomes also vary widely according to the state of residence. Future research should examine the influence of state-level factors on individual outcomes using multilevel modeling methods with a focus on modifiable state-level factors. This study provided contextual baseline data about TAY with autism ahead of the implementation of new federally mandated pre-employment transition services for students– the design of which will also vary by state.

57 **124.057** The Influence of Depression on Adaptive Behaviors and Quality of Life in ASD Compared to Typically Developing Adults

R. N. Crist *and K. Gotham, Vanderbilt University, Nashville, TN*

Background:
Co-occurring depression is prevalent among adults with ASD and is suggested to exacerbate deficits in adaptive behavior and quality of life (QoL) within this population. However, research is required to elucidate the individual and combined contributions of depression and ASD to domains of adaptive behavior and QoL.
Objectives:
1) To replicate findings indicating the association of comorbid depression with poorer adaptive behavior and QoL in adults with ASD.
2) To shed light on the unique influences of depression and ASD on adult outcomes by comparing adaptive behavior and QoL among typically developing adults with depression (TD-dep), adults with ASD with no current depression concerns (ASD-nd), and adults with ASD who score above clinical cut-off on a gold-standard survey of depression symptoms (ASD-dep).
Methods:
Participants included adults aged 18-34 with ASD (n=22) and TD adults with current depression (n=19). Diagnoses were confirmed with the ADOS-2 and the Structured Clinical Interview for DSM Disorders (SCID-5). All participants completed the SRS-2 for a dimensional measure of autism symptomology; the Adaptive Behavior Assessment System (ABAS-3) to assess adaptive behavior in Conceptual, Social, and Practical domains; the World Health Organization Quality of Life scale (WHOQOL-BREF); and the Beck Depression Inventory (BDI-II). Participants with ASD were divided into depression concern (n=10) and no-concern (n=12) groups based on the BDI-II clinical cut-off of 2. Groups were compared on variables of interest using ANOVA with Tukey's post-hoc tests. The effects of depression were assessed dimensionally within ASD using linear regression analyses.
Results:
The ASD-nd subsample was significantly younger than the ASD-dep group. SRS-2 total scores were significantly higher in the ASD-dep group, however TD-dep scores did not differ from ASD-nd. VIQ was not significantly different among the three groups (see Table 1 for all statistics). Adaptive behavior Composite scores were significantly lower for the ASD-dep group (indicating weaker skills) than the TD-dep group. As a group, ASD-nd tended to have poorer adaptive skills than TD-dep but stronger skills than ASD-dep, however no significant differences were found. This trend was preserved across Conceptual, Practical, and Social domains of adaptive behavior. Overall QoL was significantly higher in ASD-nd participants than both other groups, with no difference in QoL between TD-dep and ASD-dep. This trend persisted for all WHOQOL-BREF domains except Social Relationships, in which ASD-dep scores indicated the poorest QoL of all groups, and ASD-nd and TD-dep did not differ significantly. In dimensional analyses within ASD only, higher BDI-II scores predicted lower adaptive behavior Composites, even controlling for VIQ (B=-.398, p=.038), and lower QoL even controlling for autism symptomology (SRS-2) (B=-.764, p=.001).
Conclusions:
Results support findings that comorbid depression further compromises impairments in adaptive behavior and QoL for adults with ASD. Additionally, depression in TD adults appears to be associated with poorer adaptive behavior and QoL similar to those impairments in non-depressed adults with ASD. These data also suggest that depression may have a greater singular impact on QoL than does ASD, although co-occurring depression and ASD still account for the lowest QoL ratings.

58 **124.058** The Map Task: A New Assessment of Functional Capacity in Autism

S. Mahdavi[1], *J. McCauley*[2], *J. Farren*[3], *D. McLaughlin*[4], *T. A. Niendam*[5], *P. Harvey*[6], *B. Cornblatt*[7] *and M. Solomon*[3], *(1)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Department of Psychiatry & Behavioral Sciences, University of California-Davis, Sacramento, CA, (4)Northwell Health System, Glen Oaks, NY, (5)Department of Psychiatry & Behavioral Sciences, UC Davis, Sacramento, CA, (6)University of Miami, School of Medicine, Miami, FL, (7)Hofstra Northwell School of Medicine, Hempstead, NY*

Background: There is a need for meaningful predictors of adult functioning for individuals with autism spectrum disorder (ASD). In schizophrenia research, "functional capacity" measures have been developed to assess the underlying ability to carry-out real world functions. We use a new functional capacity measure—the Map Task—that has been validated in a large, cohort of individuals aged 12 to 35 with typical development (TD) or clinical risk for psychosis (McLaughlin et al., 2016). We implemented the task in a group of individuals with ASD aged 12-22.
Objectives: To investigate: (1) how ASD perform on the Map Task relative to TD, (2) whether this measure is related to cognitive functioning or age, and (3) if Map Task performance is associated with adaptive functioning.
Methods: Participants included 23 with ASD (Mean age=15.96), and 28 with TD (Mean age=15.75), matched on perceptual reasoning index (PRI; Wechler 2011). In the Map Task, participants were given a map of a fictional town and were instructed to complete errands quickly by drawing their route on the map. The instructions contained the order for errand completion and an errand list in the incorrect order. Independent variables included: number of errands completed, completion time, and frequency of 4 types of errors -- visiting extra stores, not entering/exiting stores correctly, going the wrong way on a one-way street, and errand order errors (e.g. completing tasks in an illogical order like mailing a card before purchasing the card). We assessed participant cognitive functioning with the NIH Toolbox – Cognition Battery and adaptive functioning with parent reports on the Adaptive Behavior Assessment System (ABAS-3; Harrison & Oakland, 2015). ANCOVAs (with verbal IQ as a covariate) were used to test mean differences on Map Task variables. Pearson correlations between error frequency, child cognition variables, age, and adaptive functioning scores were performed using SPSS 23.
Results: Total errands completed and completion time did not differ between groups. ASD made significantly more errand order errors ($F(1,48)=4.37$, $p=.04$). TD made more errors involving visiting extra stores ($F(1, 48)=4.00$, $p=.05$). The NIH Toolbox cognitive composite score was significantly correlated with errand order errors in both ASD ($r(21)=-.46$, $p<.05$) and TD ($r(26)=-.66$, $p<.001$). Age was negatively correlated with errand order errors in TD ($r(26)=-.60$, $p<.01$), but not in ASD. Finally, PRI was negatively correlated with errand order errors in both ASD ($r(22)=-.45$, $p<.05$) and TD ($r(26)=-.52$, $p<.01$). There were no associations between Maps Task variables and parent reports of adaptive functioning.
Conclusions: Findings indicated that individuals with ASD performed similarly to TD on the Map Task, although ASD made more errand order errors, while TYP visited extra stores. This suggests that ASD follow rules on a small scale (the order the of the list) rather than a large scale (completing all errands in the suggested order). Somewhat surprisingly, we did not observe differences in adaptive functioning in relation to performance on the Map Task. Data collection is ongoing—we will continue to investigate how inattention and cognitive inflexibility are associated with performance on this task.

59 **124.059** Theory of Mind, Early Social Experiences and the Judgment of Harmfulness and Wrongfulness

R. L. Young, *Flinders University of South Australia, Adelaide, SA, Australia*

Background:
Despite sensational portrayals of persons with ASD committing hideous crimes (e.g., Adam Lanza in the Sandy Hook massacre; Lysiak, Slattery, & Schapiro, 2012), there is no evidence to suggest that persons with ASD are more likely to engage in criminal behaviour (Freckelton, 2013).
Objectives:
The present study sought to identify if some persons with ASD may be vulnerable to involvement in criminal behaviour, not because they are bad people, but because they do not understand the wrongfulness of the situation or the wrongfulness of their actions due to features associated with the disorder, specifically limited early social experiences and poor Theory of Mind (ToM). It was hypothesised that individuals with ASD would have more difficulties making in the moment judgments of wrongfulness than typically developing (TD) individuals, and would base wrongfulness judgments on the actual harmfulness of consequences to a greater degree than TD individuals. Theory of mind (ToM) deficits and limited early social experiences in ASD participants were hypothesised to contribute to these difficulties.
Methods:
Thirty-three individuals with ASD and twenty-seven TD individuals completed an online questionnaire, rating wrongfulness of behaviour in a number of scenarios, both before and after the consequences of the behaviour were revealed; harmfulness was also rated.
Results:
Wrongfulness and harmfulness judgments did not differ significantly between ASD and TD participants, although a dichotomous view of wrongfulness was more prevalent among ASD than TD participants. Harmfulness and wrongfulness ratings were positively correlated for both groups. Both groups tended to change their judgment of wrongfulness if behaviour did not ultimately result in harm, however maintained wrongfulness judgments when harmful consequences occurred. For the ASD group, excluding individuals who viewed wrongfulness
dichotomously, more severe ToM deficits were associated with less differentiation of the severity of harmfulness. However, a relationship between ToM deficits and impaired wrongfulness judgment was not demonstrated nor any link found between judgments of wrongfulness and early social experiences.
Conclusions:
It appears that persons with ASD do not differ from their peers with regard to perceptions of wrongfulness. These findings have relevance in the legal system, particularly in the assessment of competence to commit a crime, when demonstrating the understanding of the wrongfulness of behaviour is a central criterion.

60 **124.060** Transition and Adulthood ASD Survey in Argentina

A. Rattazzi[1]*, N. Barrios*[2]*, S. H. Cukier*[1]*, R. Geloso*[3]*, M. Gotelli*[4]*, F. Satorra*[5]*, K. Solcoff*[6]*, D. Valdez*[6,7] *and C. Ysrraelit*[4]*, (1)PANAACEA, Programa Argentino para Niños, Adolescentes y Adultos con Condiciones del Espectro Autista, Buenos Aires, Argentina, (2)Fleni, Capital Federal, ARGENTINA, (3)Asociación Asperger Argentina, Buenos Aires, Argentina, (4)Fundación Brincar por un Autismo Feliz, Buenos Aires, Argentina, (5)TGD Padres TEA, Buenos Aires, Argentina, (6)FLACSO, Facultad Latinoamericana de Ciencias Sociales, Buenos Aires, Argentina, (7)Universidad de Buenos Aires, Buenos Aires, Argentina*

Background: Â In 2014, parent and professional organizations in Argentina created RedEA (Red Espectro Autista – Autism Spectrum Network) in order to increase ASD awareness and influence public policy related to ASD. The first project undertaken by RedEA was an ASD early detection awareness campaign called Mirame (Look at Me). In 2016, RedEA developed the Transition and Adulthood ASD Survey to assess the current situation of adolescents and adults with ASD in relation to diagnosis, level of functioning, services, education, employment, housing, money management, leisure and free time activities, social life, health checks, support networks and quality of life. The survey is intended for parents or primary caregivers of individuals with ASD over 13 years old and for individuals with ASD older than 18. After pilot testing of the survey, RedEA members reached a final version by consensus.
Objectives: Â To provide a comprehensive picture of needs, challenges and current situation of adolescents and adults with ASD in Argentina and other Latin American countries with the purpose of successfully enhancing awareness, improving services and developing long-term policy solutions related to ASD in the region.
Methods: The Transition and Adulthood ASD Survey will be broadly disseminated via social networks of RedEA organizations in Argentina during a period of 5 months (November 2016-March 2017) so that caregivers of individuals over 13 and/or adults with ASD older than 18 can complete it online. The survey solicits information about family demographics, individual characteristics, diagnosis, level of functioning, services, education, employment, housing, money management, leisure and free time activities, social life, health checks, support networks and quality of life. It is estimated that more than 400 surveys will be completed in total. After the collection of completed surveys, RedEA researchers will proceed to data cleaning and data analysis, and will draft a report.
Results: A summary of the results from the Transition and Adulthood ASD Survey will be presented, and regional similarities and differences will be analyzed.
Conclusions: The assessment of the current situation of adolescents and adults affected by ASD in Argentina and other Latin American countries is essential for the identification of knowledge gaps, service needs, inclusive education and employment, and quality of life of these individuals and their families. It is also important in the development of culturally relevant strategies for raising awareness about adulthood and ASD, promoting inclusive education, employment and housing, guiding the implementation of successful and improved ASD services and setting priorities for long term national and regional public policy solutions in this age group.

61 **124.061** Using Improv to Facilitate Social Inferencing Skills in Adults with Autism

S. Kashinath[1] *and C. Byward*[2]*, (1)California State University East Bay, Fremont, CA, (2)Communicative Sciences and Disorders, California State University East Bay, Hayward, CA*

Background:
Adults with autism in university and workplace settings continue to face many communication challenges, despite being relative successful in their academic and vocational abilities. Specifically, adults with autism have shown to demonstrate strengths in the structural and content aspects of language, but struggle to use language within the realm of social communication (Murza et al., 2014). A critical challenge in social communication for adults with autism is the inability to accurately read and integrate verbal and nonverbal cues of communication partners to make accurate inferences about feelings, intent, or general behaviors. Learning to make accurate social inferences is critical for adults with autism to integrate and succeed in higher education and develop the skills necessary for success in the 21st century workplace. However, there is a paucity of evidence-based strategies to address social inferencing skills in adults with autism.
Objectives:
The purpose of this research is to evaluate the effectiveness of a 10-week IMPROV based intervention protocol targeted towards improving the social inferencing skills of adults with autism.
Methods:
10 college age students with autism participated in a college based social skills group facilitated by the authors. The social skills group also included 5 typical peers (also college students) who participated in the intervention. Intervention targeted a set of 5 social inferencing rules and strategies identified collaboratively with the participants and adapted from various curricula, including Social Thinking (Crooke, Olswang, Winner, 2016), UCLA PEERS (Laugeson et al., 2015). Weekly sessions were focused on practice of these social inferencing rules/strategies. Each session was organized as follows: a)Warm up/Icebreaker activity, b) Focused Practice of target social inferencing rule/strategy using IMPROV activities (for e.g., utilizing the "Yes And.. IMPROV based strategy to facilitate students' ability to engage in small talk in social settings) which was video-taped, c) Video modeling where participants worked in small groups to create short skits around specific social situations related to the theme of the week (e.g., "you are at the movies and the people in front of you are laughing too loud"), d) Group reflection focused on reviewing the videos to discuss appropriateness and relevance of participant responses in the video. Further participants discussed the relationship of the day's activity to novel social situations.
Results:
Pre-post intervention measures of change in social cognition/inferencing as documented on the TASIT (The Awareness of Social Inference Test, McDonald et al., 2010) revealed variable results probably due to the variability in participant skills prior to intervention. Social validation data gathered from participants indicate that they found this approach to be engaging and useful in increasing awareness of appropriate social communication strategies. Video-coding and analysis of group reflections utilizing thematic analysis will be shared- offering important stakeholder perspectives on the utility of IMPROV based interventions for adults with autism.
Conclusions:
Young adults with autism present with unique skills and challenges. IMPROV based interventions may offer a unique opportunity to help adults with autism explore and practice use of appropriate social cues and strategies.

62 **124.062** What Is Important for Quality of Life in Adolescents and Adults with ASD? Results from a Nation-Wide Danish Follow-up Study.

A. Knuppel[1]*, G. K. Telléus*[2] *and M. B. Lauritsen*[1]*, (1)Research Unit for Child and Adolescent Psychiatry, Aalborg University Hospital, Aalborg, DENMARK, (2)Unit for Psychiatric Research, Aalborg University Hospital, Aalborg, Denmark*

Background: Â It is becoming increasingly common to measure Quality of life (QoL) among people with autism spectrum disorders (ASD). Most often, this is undertaken by using proxy reporting but letting people with ASD self-report on their QoL is possible and in some researchers' opinion the most correct method to apply. Furthermore, it is important to explore the factors of importance for having a higher level of QoL. However, usually only a few factors are included within a study, which makes it difficult to conduct a profound analysis of, what is important for QoL. Additionally, the ASD populations studied are often characterized by few females within each sample and a large age-span, including diversity in age at diagnosis.Â
Objectives: To investigate a range of diverse factors characterized as primarily within-person or between-person factors and their possible associations to different levels of QoL in a large population of adolescents and adults with ASD between 16 and 26 years.
Methods: Â In this nation-wide, follow-up study, 5642 adolescents and adults born in the period 1990-1999 and diagnosed with ASD before turning 14 years were invited to participate in an online survey together with their parents. The adolescents and adults with ASD were identified in the Danish Psychiatric Central Registry. Besides obtaining information about QoL, this survey includes scales and questions composing variables that can be characterized as primarily within-person factors; adaptive functioning, autistic symptomatology, psychiatric comorbidity and maladaptive functioning, and variables that can be characterized as primarily between-person factors; parent empowerment, type(s) of daytime occupation, and received support and intervention. QoL was measured applying three different scales to the ASD study population: The INICO-FEAPS Scale, Personal Wellbeing Index and a single-item visual analogue scale. Using regression models, the data analysis will examine these factors' contribution to different self-reported QoL levels in the study population. Furthermore, possible pathways between the factors will be explored.
Results: A total of 1731 parents corresponding to a response rate of 30,7% and 931 adolescents and adults with ASD corresponding to a response rate of 16,5% returned the questionnaire in the survey. This study is based on a subsample of the total sample (N=702). Mean age for the ASD population is 20,6 years (SD=2,77) with a male:female ratio of 1:0.25. The following ICD-10 diagnoses are represented (percentage of total sample): Infantile autism (28%), atypical autism (11%), Asperger's syndrome (43%) and pervasive developmental disorder, not otherwise specified (13%). For 5% of the sample it was not possible to classify the ASD diagnosis according to ICD-10. In the further analyses, factors contributing to different levels of QoL will be highlighted.Â
Conclusions: This nation-wide study which is among the largest performed to date will provide knowledge about factors associated with self-reported QoL among adolescents and adults with ASD including both within-person and between-person factors in the analysis to broaden the comprehension of how to understand and improve QoL in this population.

63 **124.063** What Skills Should Adaptive Functioning Interventions for Intellectually Able, Transition-Aged Youth Target? an Examination of Caregiver Responses on the Vineland-II

N. L. Matthews[1]*, A. Malligo*[2] *and C. J. Smith*[1]*, (1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)Southwest Autism Research and Resource Center, Phoenix, AZ*

Background: Research indicates the need for effective adaptive functioning (AF) interventions for intellectually able adolescents and adults with autism spectrum disorder (ASD). Specifically, adult outcomes are suboptimal (Eaves & Ho, 2008; Gary et al., 2014), and development of AF skills in intellectually able individuals appears to stagnate relative to cognitive development (Kanne et al., 2011). In order to develop effective interventions, targets must first be identified.
Objectives:
(1) To examine profiles of intellectual and adaptive functioning in intellectually able adolescents and adults and with ASD.
(2) To identify daily living skills (DLS) that the majority of intellectually able individuals and adults are unable to complete independently.
Methods: Participants were 29 adolescents (*M* age = 15.20, *SD* = 1.10), 37 young adults (*M* age = 21.22, *SD*= 2.95), and one caregiver of each participant. Participants had a DSM-IV or DSM-5 ASD diagnosis, met criteria for autism or autism spectrum on the ADOS or ADOS-2 administered by a research reliable rater, and had a composite IQ of 70 or above on the KBIT-2 (Kauffman & Kauffman, 2004). Each caregiver was administered the Vineland Adaptive Behavior Scales Survey Interview, Second Edition (Sparrow et al., 2005).
Results:
A 2 (age group) x 4 (IQ, Communication, DLS, Socialization) ANOVA was used to examine profiles of intellectual and adaptive functioning. The adolescent group had significantly higher scores than the adult group on all assessments ($F(1, 64) = 22.40$, $p < .001$; pairwise ps < .01). Across groups, intellectual functioning was significantly higher than all AF domains ($F(3, 192) = 140.01$, $p < .001$; pairwise ps < .001). The group by assessment interaction was not significant. Because the adolescent group had significantly higher IQs than the adult group, a 2 (age group) x 3 (AF domains) ANCOVA controlling for IQ was conducted. The adolescent group had higher (ps < .02) or marginally higher (socialization: $p = .09$) scores in all three domains ($F(1, 63) = 6.79$, $p = .01$). The main effect of AF domain and the interaction were not significant. Across groups, socialization scores were significantly lower than communication and DLS scores (pairwise ps < .001). DLS items were examined separately using percentages. DLS items were selected for analyses given their relevance to independent living and employment. Items for which more than one third of the sample were not functioning independently were identified as potential intervention targets (Table 1).
Conclusions: Findings replicate previous reports of a gap between intellectual and adaptive functioning in intellectually able individuals. Additionally, response percentages identified a number of skills that the majority of adolescents and adults in the current sample do not complete independently. These skills should be considered in the development of AF interventions for transition-aged youth. Reinforcing the need for this type of intervention, very few adult participants had held a part-time ($n = 7$) or full-time ($n = 1$) job for at least one year.

64 **124.064** Young Adults on the Autism Spectrum: College Experiences and Outcomes

C. M. Anderson *and C. L. Butt, Interprofessional Health Studies, Towson University, Towson, MD*

Background: There is limited information on outcomes for young adults with autism spectrum disorder (ASD) in many areas, including postsecondary education.
Objectives: To explore experiences of young adults with ASD and their families related to postsecondary education with an emphasis on common challenges and success factors.
Methods: Qualitative interviews addressing post high school experiences were conducted with 35 parents and 14 young adults with ASD. Interviews were transcribed; material relating to experiences at community or 4-year colleges was segregated, then coded using a grounded theory approach.
Results: Nineteen young adults, ages 19-31, reported a degree-seeking college experience. Several themes surrounding success or failure at college emerged. ***Student Preparedness:*** Most students with ASD were well prepared academically, but faced obstacles as a result of core social deficits, executive functioning challenges, rigidity, and mental health issues (e.g. anxiety). Academic achievement fed into what one mother called "a whole collective fantasy" that academics trumped all else on the part of high school, parents, and youth. As a result, deficits in navigating the social world, organization, self-advocacy, and daily living skills were minimally addressed. These deficits became glaring at college, sometimes resulting in catastrophic failure. A father of his son: "*He lasted 72 days… He never went to the dining hall once. He could not handle the dining hall, he could not handle the noise, he could not handle the whole thing.*" ***Student/College Fit:*** When student challenges were taken into account, success was more likely. Students who stayed closer to home and chose a smaller college with a culture accepting of difference did better. The ability to ease in by taking a reduced load was important, but not always accommodated by policies requiring full time attendance for financial aid or on-campus housing. A mother of her daughter: "*She fairly quickly found this kind of funky eccentric group and they hung out a lot together and she was the happiest I've ever seen her in her life.*" ***Student Challenges, Campus Supports, and Family Support:*** College students with ASD often struggled socially, sometimes becoming isolated or alienating peers. Issues with organization and planning could lead to falling behind and panic; a tendency not to tell anyone when they were in trouble made things worse. Academic accommodations typically offered were not designed to address social and executive functioning issues. Families often stepped in to bridge this gap, trying to monitor student performance, provide emotional support, and advocate when the student could not. Some paid for peer mentors, tutors, or formal student support programs. A mother of her son: "*They said they can give you a tutor… The problem is that he has to initiate this, he has to walk to the disability department to talk to them, but he didn't…*"
Conclusions: Many students with ASD face significant challenges at college. A better understanding of how both organizational practices and ASD-associated difficulties interfere with success may help high schools, parents, and colleges more effectively support youth with ASD as they plan for or attend institutions of postsecondary education.

65 **124.065** Self-Advocacy and Emerging Adults on the Autism Spectrum

V. Paradiz*, Valerie Paradiz LLC, Boulder, CO*

Background:
As young adults with autism leave the shelter of educational entitlements and the family home and transition into higher education and employment, self-advocacy is indispensable. Self-advocacy and transition planning programs are available for the general disability population, and there is a small body of literature regarding their effectiveness in positively impacting measures of self-determination, improved self-advocacy, and decision-making. However, a vital need for self-advocacy curricula remains, specifically for young people with autism in transition to adulthood. In addition, studies of such curricula to measure outcomes and to establish standards of practice in instruction are virtually non-existent. Illustrations from the panel participant's experience as a person with autism and as a parent of a young adult with autism will be shared.
Objectives:
For individuals with autism especially, learning skills to increase awareness of environmental triggers, cues, and situations that require self-advocacy decisions are essential. For example, an individual can work to understand how his or her own physiology and sensory experience interface with a given environment and then develop a strategy to improve his or her participation in that setting. Social awareness is another core component of self-advocacy development. For many individuals on the autism spectrum, addressing social challenges and differences, such as interpreting non-verbal cues, managing anxiety, and navigating workplace or college campus interactions, will be a high-frequency need that requires self-advocacy strategies. Supports and instruction aimed at improving ability should address self-regulation plans and strategies. Such plans should be developed out of the interplay between a person's self-awareness and social-environmental understanding.
Methods:
Strong self-advocacy programs for individuals with disabilities are built on several key components. An individual's development of self-determination is paramount, with an emphasis on communicating, acting, and decision-making. Illustrative examples from evidence-based, self-advocacy curricula and programs—specifically the Integrated Self Advocacy ISA programs—will be provided. Case studies will illustrate methods of increasing self-advocacy competencies for young adults in the workplace and in higher education settings.
Results:
Case data on the ISA Sensory and Social Scans put into practice in autism transition classrooms will be provided, with further summary discussion of the state of very limited research in self-advocacy measures, outcomes and effective programming. Additionally, ISA instruments for assessing self-advocacy competencies and measuring individualized progress on self-advocacy goals will be introduced.
Conclusions:
500,000 students with autism are expected to exit high school into young adult life in the next decade. Ensuring that young adults with autism not only understand their differences, but also have the liberty and power to act on their needs and rights both at work and in higher education settings, is one of the most essential lessons we can impart to them as they transition to adulthood. Greater efforts are needed in funding, establishing and researching self-advocacy curricula and programs in order to move the needle on real-world outcomes for young adults with autism who currently face unspeakably high rates of disengagement from employment and higher education in the years immediately following high school.

66 **124.066** Family Sex Communication for Young Adults with Autism Spectrum Disorder

T. Kozikowski[1] *and C. Warren*[2]*, (1)Eastern Virginia Medical School, Norfolk, VA, (2)Organizational Sciences and Communication, The George Washington University, Washington, DC*

Background: Previous research has suggested that many of the problems surrounding ASD and sexuality may be helped through family communication and education that are geared toward individuals with ASD. There has not been substantive research, however, as to what specific aspects of family communication about sexuality may need to be emphasized or altered for this population. Dr. Clay Warren developed the FSCQ along with Dr. Michael Neer in 1986. This measure evaluates child and parent communication about sexuality on three dimensions: comfort, information, and value. The current study represents the first time this measure was used to evaluate communication about sexuality between young adults with ASD and their parents.
Objectives: The purpose of this presentation is to address the first data on family communication about sex from young adults with autism spectrum disorder (ASD) and their parents collected via the Family Sex Communication Questionnaire (FSCQ). It will offer insights about family sex communication research collected over the thirty years since the development of the FSCQ from its author, Dr. Clay Warren. The presentation's primary focal points will be the differentiation of two regularly confused terms - sex education and sex communication - and the need for ASD young adults to have better sex communication with family members (with particular emphasis on the comfort dimension of the FSCQ).
Methods: 118 young adults with ASD (ages 18-30; 44% female) and their parents completed the FSCQ via an anonymous on-line survey. Young adults and parents from the same family were grouped together through a unique four digit code to ensure that data could be properly analyzed through paired samples t-tests.
Results: Â Paired samples t-tests were used to evaluate differences between parent and young adult reports on the FSCQ overall and its sub-scales. Results showed that young adults reported significantly lower comfort (t [115] = 13.56, $p < 0.001$), information (t [116] = 3.54, $p < 0.001$), and overall (t [117] = 6.28, $p < 0.001$) scores when compared to their parents. However, the two groups did not differ on the value sub-scale (t [116] = -0.17, $p = 0.87$). See Table 1 for the summarized descriptive statistics.
Conclusions: Â Young adults with ASD have lower levels of comfort and information but similar levels of value placed on family communication about sex when compared to the outcomes of their parents. Moreover, both parents and young adults reported lower than strong overall FSCQ scores (≤ 72). These results indicate that although parents and young adults are reporting different levels of comfort and information gained from communicating about sex, they both value communication about sex in general on the same level. In addition, the overall FSCQ scores of young adults are significantly lower than those of the parent group. Therefore, this study's outcome suggests it may be important to focus on aligning comfort and information facets, as well as boosting overall FSCQ levels (particularly those of young adults with ASD), in order to increase the overall effectiveness of family communication patterns about sex for this target group.

67 **124.067** Sexuality and the Autism Spectrum: Implications for Individuals with the Broad Autism Phenotype

L. R. Qualls[1] *and K. Hartmann*[2]*, (1)Virginia Consortium Program in Clinical Psychology, Norfolk, VA, (2)Eastern Virginia Medical School, Norfolk, VA*

Background: Differences in sexual behaviors exist between individuals with Autism Spectrum Disorder (ASD) and Typical Development (TD), with ASD individuals having fewer relationships and sexual experiences than their TD counterparts. Studies have also found differences in sexual orientation between people with ASD and TD, with women with ASD endorsing more lesbian or bisexual sexual identity and people of both genders with ASD endorsing a more asexual identity. Some people with TD have characteristics of autism but not the full disorder (Broad Autism Phenotype; BAP) and may have similar difficulties to people with autism. One area of difficulty may be expressing their sexuality, especially if they experience same-sex attraction. If the BAP is seen as being a part of the overall autism spectrum, then it is possible that any of the causes of increased incidence of non-heterosexuality and difficulty participating in sexual behavior in those with ASD could also affect those with the BAP.
Objectives: The purpose of this study is to measure the characteristics of the BAP, sexual experiences, and sexual orientation in a TD population to see if those who have more characteristics of the BAP show similar patterns of sexual behavior and sexual orientation to those of people with ASD, as reported in the literature.
Methods: Participants with typical development were recruited from a large mid-Atlantic University and from various online survey and social media sites. They were asked to complete a set of questionnaires that included the Autism Spectrum Quotient (AQ) and Broad Autism Phenotype Questionnaire (BAPQ) to measure traits of the BAP, the Klein Sexual Orientation Grid (KSOG) to measure sexual orientation, and a modified Brief Index of Sexual Functioning (BISF). The survey was completed anonymously online and student participants were compensated with course credit.
Results: Two sets of linear hierarchical multiple regressions will be calculated with the AQ and BAPQ serving as the predictor variables and sexual orientation and partnered sexual behaviors serving as the criterion variables. The same demographic predictors will be used for each regression equation. For Hypothesis 1, partnered sexual behavior as measured by the BISF will be predicted from the demographic variables entered at Step 1 and the AQ entered at Step 2. A similar analysis will then be run using the BAPQ instead of the AQ as the predictor in Step 2. For Hypothesis 2, sexual orientation as measured by the KSOG will be predicted from the demographic variables entered at Step 1 and the AQ entered at Step 2. A similar analysis will then be run predicting sexual orientation using the BAPQ instead of the AQ in Step 2.
Conclusions: Two hundred and fifty responses have been collected for this study and data analysis is underway. We hypothesize to find the following: BAP traits will negatively predict partnered sexual behaviors and positively predict greater homosexual sexuality, above and beyond the demographic variables.

68 **124.068** Autism, Sexuality, and the Law: A Case Study

***S. Carr**, Rehabilitation Research and Training Center, Virginia Commonwealth University, Richmond, VA*

Background: Most individuals with an autism diagnosis experience puberty and sexual development at the same rate as their peers (Lawson 2005; Murphy and Elias 2006). They however do not follow typical stages of development in social communication and social interaction (Atwood, 2014). These deficits become increasingly apparent in adolescence and young adulthood, when individuals are expected develop close friendships and romantic and relationships (Seltzer et al. 2003). The imbalance of development between physical and sexual and social- emotional coupled with deficits in Theory of Mind can lead to atypical interactions with peers leading to misunderstandings, inappropriate sexual activity, and potential legal consequences.
Objectives: To identify the social, emotional and communicative deficits that lead to incarceration of a young adult with autism.
Methods: This single-subject case study followed a young man with autism from arrest through trials and incarceration for sexual abuse spanning 5 years. In depth record review and analysis of psychological reports and assessments, court proceedings and evidence along with observation, interviews, and assessment were utilized to identify how a complex set of circumstances related to the core deficits of autism resulted in criminal charges.
Results: Results of this 5-year case-study resulted in identification of three specific deficits in psychosexual understanding including: lack of understanding of non-verbal cues (body language), misinterpretation of tone of voice, and lack of perspective taking.
Conclusions: The results from this longitudinal case study indicate the need for future research and interventions to address the intimate/social/sexual relationships and behaviors of individuals with autism. These interventions should target sexual education, social development, and sexual guidelines and consequences for aberrant sexual behavior.

69 **124.069** Problem Solving in Sexuality Education

***R. L. Loftin**[1], A. Burns[2] and E. T. Crehan[1], (1)AARTS Center, Rush University Medical Center, Chicago, IL, (2)AARTS Center, Rush University Medical Centre, Chicago, IL*

Background:
There is an urgent need to teach people with ASD about the social aspects, not simply the basic facts, of sexuality. Most people with ASD desire an intimate relationship (Healy et al, 2009; Koegel et al, 2014), but relatively few are able to form the partnership they desire (Hancock, Pecora, Mesibov, & Stokes, 2017). It appears that the social difficulties inherent in ASD are directly related to social isolation and loneliness (White & Roberson-Nay, 2009) experienced when relationships fail. An intervention was developed to address both sexuality education and social problem solving – the application of knowledge in real-world social situations,. The proposed presentation assessed use of a manual for sexuality education that was developed by ASD specialists and a consultant from Planned Parenthood and coupled sexuality education with social problem solving instruction.
Â
Objectives:
This presentation will outline the outcomes from a pilot investigation of sexuality education with social problem solving.
Â
Methods:
Ten young men with ASD (confirmed with ADOS2 administration and expert clinician diagnosis) completed a 14-week sexuality education course. The intervention was implemented by educators and/or master's level clinicians with training in ASD. The manual was based on a published curriculum (Davies & Dubie, 2012). Planned Parenthood's standards, adapted from the federal standards for sexuality education, were used as a framework for editing of the Davies and Dubie manual. Supplementary lessons were created for additional areas of need that were not fully addressed: legality/illegality of pornography and consent. In each session, instructors led participants through at least one example of problem solving following the standard 5-step model of social problem solving (D'Zurilla & Goldfried, 1971). Examples were tied to each week's content.
All participants participated in pre- and post-testing that included measures of social validity, knowledge questionnaires and vignettes of situations to assess social problem solving. Feedback from participants, course leaders and parents was collected to assess acceptability of the intervention.

Results:
Participants demonstrated knowledge acquisition in most areas; learning in some discrete topics was mixed. Surprisingly, knowledge of HIV went down, while knowledge of anatomy, male sexual function, and social-sexual boundaries increased. In response to the social problem solving vignettes, improvements in identifying the problem and offering realistic alternatives to solve the problem of were apparent in eight of ten participants, while two participants demonstrated no change. Acceptability among attendees was good, and feasibility of the intervention was high.

Conclusions:
There is a need for comprehensive sexuality instruction for people with ASD. Instruction in social problem solving is an important component to promote healthy outcomes and prevent problem behaviors. It appears that including a social problem-solving component in the regular instruction may improve problem solving, at least in testing situations. Additional study is needed to confirm that problem solving carries over to the natural setting. Given what we understand about autism, generalization deficits, and social problem solving challenges, however, it is likely that social problem solving instruction specific to sexual topics will be a valuable component of sexuality education curricula for this population.

Poster Session
125 - Brain Function (fMRI, fcMRI, MRS, EEG, ERP, MEG) I
5:30 PM - 7:00 PM - Golden Gate Ballroom

70 **125.070** A Functional MRI Meta-Analysis of Reward and Social Motivation Studies of ASD

A. Zoltowski[1], *C. C. Clements*[1], *L. D. Yankowitz*[2], *R. T. Schultz*[3] *and J. D. Herrington*[4], *(1)The Center for Autism Research/CHOP, Philadelphia, PA, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadlephia, PA, (3)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Â The Social Motivation Hypothesis posits that individuals with autism spectrum disorder (ASD) show diminished social motivation and responsiveness to social rewards (Chevallier et al., 2012). Two types of motivation typically distinguished are the "liking" of the reward that occurs during its consumption, and the preceding "wanting" of the reward (Berridge, Robinson, & Aldridge, 2009). Per the Social Motivation Hypothesis, people with ASD may 'like' and thus 'want' social interactions less, leading to fewer social learning opportunities and diminished social skills. Functional MRI studies can distinguish between 'wanting' and 'liking' a reward since the two processes are somewhat distinct in timing and neurobiological circuitry. However, it has been difficult to draw strong conclusions as the few studies on this topic have had limited sample sizes. For this reason, a meta-analysis synthesizing the current data may provide needed clarity.
Objectives: Â To use fMRI-specific meta-analytic techniques to 1) obtain information about the direction and magnitude of differences in reward processing in individuals with ASD relative to typically developing controls (TDCs), and 2) identify potential moderators of observed differences.
Methods: Â We systematically reviewed the fMRI literature on individuals with ASD and identified nine papers meeting inclusion criteria for meta-analysis. We leveraged novel fMRI meta-analytic methodology (Effect Size Signed Differential Mapping; Radua et al, 2012) to account for effect magnitude, effect direction, sample size, and covariates (age and IQ), since study samples showed a large range in mean ages (12-37 years) and IQs (103-127).
Results: Â Activation differences were observed in the ventral striatum and other regions (hypoactivation in the left nucleus accumbens (-6,6,-6), posterior cingulate gyrus (4,-6,30), right caudate nucleus (10,6,20), and right frontal pole (28,64,12), and hyperactivation in the hippocampus (26,-14,-34); all p's<.001) during 'wanting' of monetary but not social reward in individuals with ASD relative to TDCs, and no significant differences in 'liking' of reward. When we statistically controlled for the age of each sample in exploratory meta-regression, these results were no longer statistically significant, suggesting potentially important age effects in reward processing that have not been adequately accounted for to date. In analyses covarying mean IQ, the left nucleus accumbens and right anterior hippocampus results were preserved and the posterior cingulate gyrus result shifted dorsally (toward anterior cingulate gyrus).
Conclusions: Â These results suggest different processing of non-social reward during the 'wanting' but not the 'liking' phases of reward processing in individuals with ASD. The challenges of providing naturalistic social rewards in the lab, compared to providing actual monetary rewards, may contribute to the observed absence of differences in response to social reward. In addition, the effect for group differences in social reward conditions may be difficult to detect with the sample sizes traditionally used in this field. Exploratory meta-regression results highlight key differences between the ages and IQs of study samples that may explain contradictory results in the literature. Our results suggest that careful examination of current paradigms and systematic investigation of reward processing in ASD at different ages may be necessary to fully understand social motivation in autism.

71 **125.071** A Graph Theoretic Examination of Social Brain Networks at Rest in ASD

D. Moraczewski[1], *D. Levitas*[1] *and E. Redcay*[2], *(1)University of Maryland, College Park, MD, (2)Department of Psychology, University of Maryland, College Park, MD*

Background: Deficits in social interaction and social communication are core features of autism spectrum disorder (ASD). Dominant theories suggest that these deficits may be due to reduced or atypical social motivation (i.e., the motivation to seek out social interaction) and/or social cognition (i.e., inferring and reasoning about the mental states of others). Further, these social motivation and social cognitive systems may be linked such that reduced social motivation may affect social-cognitive development. While studies have demonstrated atypicalities of both social-cognitive and motivational networks in ASD, these typically are not examined together within the same individual. Further, key nodes within each of these networks such as the amygdala (social motivation) and temporo-parietal junction (TPJ) (social-cognition) may contribute to these atypicalities, as they play an integrative role both within and between functional networks.
Objectives:
We use resting state functional connectivity, which is an ideal method to examine baseline functional network organization, to examine within and between network organization with a focus on key nodes within networks associated with social motivation (amygdala) and social cognition (TPJ) using graph theoretic methods.
Methods:
Using the Autism Brain Imaging Database Exchange, we examined network organization in both ASD (N=79) and TD (N=104) groups. After strict motion control (mean frame displacement < 0.1mm), age, and gender matching, our final sample included N=76 individuals (ASD=30;TD=46; age range: 6.47-19.73, all male). Whole-brain networks were constructed from a freely available functional atlas (Yeo 17-networks), bilateral amygdala, and 12 ventral striatum regions for a total of 128 nodes. In order to examine within and between network organization, we assigned two community affiliations of interest. The social motivation community consisted of the amygdala, ventral striatum, and OFC and, since previous work has implicated the default mode network (DMN) in social-cognitive processing, we assigned the social-cognitive community as all DMN regions. All other regions preserved their community affiliation from the functional atlas. We used graph theory to calculate measures of within- and between-community connectivity for each key node (within-community connections and participation coefficient, respectively). Finally, controlling for head motion, we examined these metrics for group, age, and group*age effects.
Results:
For between-network connectivity, we found significant group ($F(1,71)=5.31, p<0.05$) and group*age ($F(1,71)=10.41, p<0.01$) effects in the left TPJ such that this region became less functionally connected with other communities with age in ASD and increased in connectivity in TD. Similar effects were seen in the right TPJ, but only reached trend level significance. No significant between-network effects were seen in the amygdala. For within-network connectivity, no significant effects were seen in either of the key nodes.
Conclusions:
Our results highlight a differential timecourse in the left TPJ's role in connecting the social-cognitive network with other large-scale networks. While we do not see differences within the amygdala, a key node within the social reward network, group difference may manifest earlier in development and/or be exacerbated in the presence of socially salient stimuli. Our results have implications for understanding functional brain development in ASD at the network level.

72 **125.072** A Novel Electrophysiological Marker of Autism Spectrum Disorder Based on Facial Expression Mental Imagery

M. Simoes[1,2], *R. Monteiro*[1], *J. Andrade*[1], *S. Mouga*[1,3], *P. Carvalho*[2], *G. Oliveira*[1,3,4] *and M. Castelo-Branco*[1], *(1)Institute for Biomedical Imaging and Life Science, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (2)Center for Informatics and Systems, University of Coimbra, Coimbra, Portugal, (3)Unidade de Neurodesenvolvimento e Autismo, Pediatric Hospital, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, (4)University Clinic of Pediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal*

Background:
The diagnosis of autism spectrum disorder (ASD) is based on behavioural assessment by multidisciplinary specialized teams. Therefore, it is not free of subjective bias and there is a need for specific 'biological markers' (or 'biomarkers'). Several biological characteristics of the disorder have been recently identified, especially in the field of functional genomics. However, they only cover a small percentage of the cases (between 15 to 20%). Some studies addressed neural coherence deficits to propose EEG-based classifiers. Here, we assessed the possibility of using face processing specific metrics to achieve neurophysiological discriminations.
Objectives:
To create a discriminant classifier between ASD andÂ typically development (TD) individuals capable to automatically identify if a new individual belongs to the ASD or TD group, using electroencephalography (EEG) data of mental imagery of facial expressions.
Methods:
Participants with ASD (n=17) and TD controls (n=17), matched by age and performance intelligence quotient, underwent a mental imagery task of happy vs. sad facial expressions in a virtual avatar while recording EEG from 58 scalp locations. The experimental design consisted of visualizing the avatar performing a dynamic facial expression (happy or sad) and then, after an auditory cue, imagining the avatar performing it again.
EEG data were preprocessed in order to remove bad channels and segments and to correct for artifacts. Thereafter, a group of features from time, frequency and non-linear domains were extracted for each electrode and for 7 frequency bands: theta, alpha, beta, 3 beta sub-bands and low-gama.
We conducted feature selection on the data in order to identify the clusters of electrodes and frequency bands that better discriminate the groups. Then, the best subset was used following a leave-one-out cross-validation approach. Training data were transformed through a Principal Component Analysis and the first four components were used to train the linear support vector machine. The same transformation was applied on the test set and then we measured the classifier accuracy. This analysis was paired with resting-state data in order to assess if results are task-specific or related to the ongoing EEG activity (in a baseline of neutral faces).
Results:
Feature selection showed that the best electrode clusters were located in right Fronto-Temporal, right Centro-Parietal, left Centro-Parietal, and right Parieto-Occipital regions. Best discriminating frequency bands were theta, high-beta and low-gama. Our classifier achieved 88.2% accuracy, 94.1% specificity and 82.4% sensitivity using just 4 principal components. Results with resting-state data (neutral face baseline) presented only 73.5% accuracy, 70.5% specificity and 76.5% sensitivity.
Conclusions:
Our results suggest that is possible to use EEG data from facial imagery to discriminate individuals with ASD and TD. The most discriminating cluster locations are coincident with the face perception network and the high accuracy achieved by the classifier suggests that the impairments of the ASD group in facial expressions processing and their mental imagery represent a robust biological phenotype. Results from resting-state data suggest some differences are present on ongoing activity, even when only a neutral face is present, but the accuracy increases significantly when subjects have to perform explicit imagery.

73 **125.073** A Simultaneous EEG, TMS and Eye-Tracking Study Investigating Mirror Neuron System Activity in Adults with Autism Spectrum Disorder When Inferring Intentions.

E. J. Cole[1], *N. E. Barraclough*[1] *and P. G. Enticott*[2], *(1)Psychology, The University of York, York, United Kingdom, (2)Deakin University, Geelong, AUSTRALIA*

Background: Autism spectrum disorder (ASD) is associated with difficulties inferring the internal states of others such as their intentions, beliefs or mental states. These are known as mentalizing tasks. Neuroimaging studies have found mirror neuron system (MNS) activity during these tasks and it has been hypothesised that MNS dysfunction may underlie mentalizing difficulties associated with ASD. However, MNS activation during mentalizing tasks may be simply due to the use of stimuli depicting biological motion and evidence regarding MNS dysfunction in adults with ASD is limited. This study investigated whether MNS activity was higher when mentalizing than in a control task when the same stimuli were used, and whether MNS functioning was atypical in adults with ASD.
Objectives: We used EEG and single-pulse TMS techniques to identify potential differences in MNS activity in high-functioning adults with ASD when inferring intentions from hand actions.
Methods: Thirteen adults with ASD and thirty control participants (15 low AQ, 15 high AQ) watched videos of actors performing hand actions. Participants were either asked to infer the actors' intentions (mentalizing task) or the success of the action (control task). TMS-induced motor evoked potentials (MEPs) and mu suppression measured by EEG were both used as indices of MNS activity. Eye-tracking data were also collected in order to identify any differences in fixation patterns associated with ASD.
Results: Â The EEG data showed lower levels of mu suppression during the mentalizing task across all groups. TMS-induced MEPs were largest when participants watched actions in which the intentions of the actors were not fulfilled (clumsy/accidental actions) even when participants were not directly asked to infer intentions. No differences in MNS activity associated with ASD were found. Eye-tracking data showed participants with low AQ scores looked at the head of actors more often and for longer during the mentalizing task but adults with high levels of autistic traits both with and without a diagnosis did not.
Conclusions: Â Our eye-tracking data imply that adults with high levels of autistic traits (with and without a diagnosis) do not alter their fixation patterns across mentalizing and non-mentalizing tasks in the same way as adults with low autistic traits. Despite this, no differences in abilities to infer the intentions of others or MNS activity were found associated with ASD. The TMS data suggest the MNS has a role in coding the consistency of a person's actions with their initial intentions, consistent with the predictive coding theory (Kilner, Friston & Frith, 2007). However, the EEG data provide evidence against MNS involvement in mentalizing tasks. Therefore TMS-induced MEPs and mu suppression appear to measure different aspects of MNS activity, consistent with previous studies (e.g. Lepage,Â Saint-Amour &Â Théoret, 2008).
Keywords: Transcranial magnetic stimulation (TMS), electroencephalography (EEG), mentalizing, eye-tracking

74 **125.074** Age-Related Changes in Auditory Event-Related Potentials Differ Between Typically Developing Toddlers and Those with Autism Spectrum Disorder.

R. De Meo[1,2], *S. K. Harootonian*[1], *S. Rivera*[1,2,3] *and C. Saron*[1,2], *(1)Center for Mind and Brain, University of California at Davis, Davis, CA, (2)MIND Institute, UC Davis Medical Center, Sacramento, CA, (3)Department of Psychology, University of California at Davis, Davis, CA*

Background: Unusual sensory-related behaviors, particularly in response to sound and touch, are associated with the phenotype of autism spectrum disorder (ASD) and such behaviors are now part of DSM-V criteria. However, little is known about the developmental trajectory of brain responses elicited by sensory stimuli in young children with ASD or how they differ from those in typically developing children.
Objectives: In this study, part of a larger, on-going project to identify autism subphenotypes (The Autism Phenome Project), we sought to identify the relation between chronological age and electrophysiological markers of auditory sensory processing in young typically developing children and those with ASD. Our approach was to examine the electrocortical response amplitude to stimuli of increasing loudness.
Methods: 61-channel event-related potentials (ERPs) were elicited by randomly presented 50, 60, 70, and 80 dB 50-ms complex tones via headphones from 31 typically developing (TD) and 52 children diagnosed with ASD. Diagnostic criteria were based on ADOS, ADI-R, DSM-IV and clinical observation. All children (26 - 63 mos.) had clinically normal hearing. A total of ~1200 stimuli with inter-stimulus intervals of 1-2 s were presented as children passively listened to the stimuli and watched a quiet video of their choice. Gross artifact-free average referenced concatenated epochs from -200 to +600 ms were submitted to Second Order Blind source Identification (SOBI) and signal sources identified as noise (e.g. emg, blinks) were removed. The remaining sources were combined, projected back into electrode space, and averaged by intensity per individual. The global field power (GFP) waveforms were analyzed time-point by time-point separately by intensity using Group (TD vs. ASD) as a between subjects factor and Age as a covariate. Significant time periods of Group by Age interactions were identified using a threshold of at least 15 contiguous time-points with $p<=0.05$. For each individual at each stimulus intensity level, we computed the average GFP across post-stimulus time windows defined by durations of significant interactions. Pearson correlations of these GFP values and age were performed.
Results: Significant Group by Age interaction time windows were found for 50 dB (70-100 ms), 60 dB (70-95 ms), and 70 dB (285-330ms) stimulus intensities. For all three of these conditions we observed significant correlations of increasing GFP amplitude with age for the TD children (50 dB TD $r = 0.49$, $p<.001$; 60 dB TD $r = 0.47$, $p<.001$; 70 dB TD $r = 0.36$, $p=.04$). No significant correlations with age were found in the ASD group.
Conclusions: These data extend the corpus of results demonstrating differences in auditory responses between TD children and those with ASD to investigation of ages 2-5 years—a period of development which includes marked changes in neuroanatomical maturation, cognitive development and typical acquisition of interpersonal skills. The data suggest that there are brain maturational-dependent processes present in TD children that may be delayed or disturbed in ASD. These results are in line with white matter tract differences that have been shown to differ in maturation between TD and ASD children of the same age range.

75 **125.075** Altered Neuromagnetic Evoked Responses and Neural Synchrony Related to Language in Autism Spectrum Disorder

A. M. Flores[1], *K. McFarlane*[1], *T. Andersen*[1], *C. Swick*[1], *R. Goodcase*[1], *K. Rusiniak*[1], *I. Kovelman*[2], *J. Brennan*[2], *S. M. Bowyer*[3] *and R. Lajiness-O'Neill*[1], *(1)Eastern Michigan University, Ypsilanti, MI, (2)University of Michigan, Ann Arbor, MI, (3)Henry Ford Health Systems, Detroit, MI*

Background:
Autism Spectrum Disorder (ASD) is characterized by atypical social and language functioning. Atypical electrophysiological signatures of auditory processing in ASD may provide evidence informing cascading impairment of higher-order social and language functioning (Brennan et al., 2016).
Objectives: Relationships between evoked response, synchrony, phonological processing (PP) and social communication were investigated.
Methods:
Eleven ASD (Age: M = 8.8; SD= 0.9) and 10 neurotypical (NT) children (Age: M = 9.4; SD = 1.4) underwent magnetoencephalography (MEG) at rest and during an oddball paradigm, which consisted of presentation of plausible (S1) and implausible syllables (S2). M100, M200, M250, and M300 amplitudes and latencies were quantified for evoked responses (ERP). An amplitude difference score (S1-S2) was calculated to reflect auditory sensitivity to novel language. It was hypothesized that decreased S2 sensitivity (smaller S1-S2 scores) would be associated with better PP and communication. Synchronization was quantified by calculating coherence between cortical sites. Kendall Tau correlations were computed to examine relationships between ERP, coherence, PP, and communication skills.
Results:
There were no group differences in amplitude, latency, sensitivity or PP (p>.05). NT had significantly higher communication skills, per parent report (p<.001). *ERP*: Higher communication skills were associated with longer S1 M300 latencies in ASD (p=.02) and shorter S1 M200 latencies in NT (p=.01). Significant associations between ERPs and PP were found at different latencies. In ASD, longer S2 M250 latencies (p=.02) and higher S1 M250 amps (p=.02) were associated with higher PP. Poorer M300 sensitivity was associated with higher PP (p=.04). In NT, longer S2 M100 latencies were associated with higher PP (p=.01). *Coherence*: In ASD, decreased interhemispheric angular to inferior temporal coherence was associated with larger S1 amplitudes at M250. In NT, higher intra- and interhemispheric cingulo-fronto-temporo-parietal coherence was associated with shorter S1 M200 latencies. Lower intra- and interhemispheric left angular to frontal region coherence was associated with longer S2 M100 latencies.
Conclusions:
There were no significant group differences in PP; however, there were significant group differences in parent reported communication skills. Despite a lack of significant PP group differences, differential electrophysiological profiles emerged. In NT, better PP was associated with longer M100 latencies (a latency associated with exogenous attributes of auditory stimuli) for implausible words and better communication was associated with shorter M200 latencies (latency associated with endogenous attributes of auditory stimuli) in response to plausible words. In ASD, a different profile emerged. *Longer* latencies and higher amplitudes at a latency associated with auditory processing of endogenous information was associated with *better* PP. Better PP was associated with poorer M300 gating, a latency associated with responding to deviant sounds in an oddball paradigm. Additionally, better communication was associated with longer M300 latencies. ERP data at latencies linked with endogenous auditory processing were associated with more global increased connectivity in NT and increased angulo-temporo connectivity in ASD. Finally, increased angulo-frontal connectivity was associated with longer latencies at exogoneous auditory processing latencies in NT only. Findings suggest differential electrophysiological profiles supported by cortical connectivity and ERPs in ASD and NT associated with PP and communication.

76 **125.076** An fMRI Investigation of Working Memory in Older Adults with Autism Spectrum Disorder: Fronto-Hippo-Striatal-Thalamic Network Differences

B. B. Braden[1], *C. J. Smith*[2], *T. K. Glaspy*[3], *E. Wood*[4], *D. Vatsa*[5] *and L. Baxter*[6], *(1)Speech and Hearing Science, Arizona State University, Tempe, AZ, (2)Southwest Autism Research & Resource Center, Phoenix, AZ, (3)Tufts University, Boston, MA, (4)Xavier Preparatory Academy, Phoenix, AZ, (5)BASIS Charter School, Scottsdale, AZ, (6)Barrow Neurological Institute, Phoenix, AZ*

Background: The effects of aging in adults with autism spectrum disorder (ASD) are understudied, but of increasing importance in order to anticipate unique needs of this growing group of individuals. Executive functioning is particularly vulnerable in both high-functioning ASD and in normal aging. Deficits are thought to arise from structural and functional connectivity disturbances between the frontal lobe and posterior brain regions. Recently, a cross-sectional study revealed sharper age-related declines of structural connectivity in adults with ASD, relative to typical adults (Koolschijn et al., 2016). However, differences in functional connectivity disturbances are still unknown; yet, emerging evidence suggests functional connectivity is the best neurobiological predictor of age-related cognitive decline.
Objectives: The current study investigated functional brain network recruitment during an fMRI executive function task in middle-aged men with ASD, compared to age- and IQ-matched typically developing (TD) men.
Methods: Â We evaluated 16 ASD and 17 matched TD men from ages 40 to 64 and of average to high intellectual functioning (IQ: 83-131), For participants with ASD, diagnosis was confirmed via the Autism Diagnostic Observation Schedule-2 and developmental history assessment. TD participants were screened for presence of ASD symptoms via the Social Responsiveness Scale-2. All participants were given the Kaufman Brief Intelligence Test-2. Participants performed the n-back fMRI task, a working memory task that is good indicator of executive function. Participants monitored a series of letters and identified targets that range from simply matching a target ("0-back") to identifying matches that are two letters apart ("2-back"). Functionally connected network activity was assessed via group independent component analysis. Working memory load comparisons were made by the 2 vs. 0 contrasts. Reaction time and accuracy were recorded. Participants performed the task twice.
Results: Â Both groups performed well on all conditions of the n-back task (over 85% accuracy). The ASD participants' reaction time was slower on the 2-back condition, but were similar for accuracy in all conditions. For the working memory load comparison (2 back vs. 0 back), both groups showed similar activation a classic cortical working memory network including the bilateral dorsolateral prefrontal cortex (dlPFC), parietal cortex, insula, and the anterior cingulate cortex, and deactivation the default mode network (DMN). However, only the TD group activated an additional network including the left inferior frontal lobe, and bilateral hippocampi, striatum, and thalamus (Fig. 1a). This working memory activation was significantly greater in TD older adults than older adults with ASD (Fig. 1b).
Conclusions: Â Results showed reduced engagement a fronto-hippo-striatal-thalamic neural network during working memory performance in older adults with ASD, compared to matched TD adults. Dysfunction within this network may underlie working memory and other executive function struggles in high functioning older adults with ASD, and could impact independence as aging ensues. Longitudinal evaluation of differences in age-related cognitive and brain trajectories between older adults with ASD and TD adults are in progress.

77 **125.077** Applying Regionalized Tessellation to Detect Diagnostic Markers of ASD in Resting EEG Data

A. Ataybi[1,2], *T. McAllister*[3], *S. Hasselmo*[4], *S. A. A. Chang*[5], *M. J. Rolison*[3], *T. A. Halligan*[4], *B. Lewis*[6], *T. C. Day*[7], *K. A. McNaughton*[3], *K. Ellison*[4], *J. Wolf*[8], *K. Stinson*[9], *S. M. Malak*[3], *J. A. Trapani*[3], *E. Jarzabek*[3], *J. McPartland*[3] *and A. Naples*[10], *(1)Pediatrics, University of Washington, Seattle, WA, (2)Seattle Children's Innovation & technology Lab, Seattle Children's Research Institute, Seattle, WA, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Child Study Center, Yale University, New Haven, CT, (5)Yale University, New Haven, CT, (6)Yale School of Medicine, Darien, CT, (7)Yale Child Study Center, Yale University, New Haven, CT, (8)Yale Child Study Center, New Haven, CT, (9)Yale University- Child Study Center, Milford, CT, (10)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Atypical functional connectivity in electrophysiological data is widely reported in individuals with ASD. Existing methods for connectivity analysis include investigating: 1) electrode-to-electrode functional differences and 2) electrode-groupwise differences (cluster based permutation and mass univariate analysis). The first approach results in dense connectivity networks, from which it is difficult to identify regional differences that reliably distinguish diagnostic groups. The second approach relies on finding subsets of electrodes that distinguish groups across empirically simulated distributions. However, this approach, primarily applied to frequency and time-frequency representations of EEG data, is not generalizable to arbitrary features of the EEG, such as variations of phase, complexity, entropy and so on.
Objectives: Our goal was to support identification of diagnostic markers of ASD by developing and applying a permutation-based connectivity approach that was both capable of incorporating arbitrary EEG features and robust to family-wise error.
Methods: Analyses were conducted on two minutes of resting state EEG from participants with ASD (N=73;age=14.2) and TD (N=32;age=12.4). Data were acquired at 1000Hz using a 128-channel Hydrocel Geodesic Sensor Net. Electrodes were assigned to regions based on scalp location, and summarized using any chosen EEG feature. For each investigated (red) region, pair-wise tests on these summaries identify a set of (green) regions that statistically differ from both said region and all non-significant (black) regions. The process is repeated with larger regions until no significant differences are identified.
Results: Our analyses focused on alpha power as the EEG feature of interest. Individuals with ASD showed reduced alpha correlation between right occipital and frontal electrodes, while TD individuals showed a pattern of reduced connectivity among frontal regions. This is shown by clusters of electrodes in individuals with ASD and TD that were significantly different from the region containing electrode E25 (marked as green cube in figures). In ASD, the trio of electrodes E90,E91, and E96 was found to be the main contributor to the observed regionalized significance, while in TD the trio of E62,E67, and E71 was the main source of the statistically significant difference. Two additional regions defined by single electrodes (E61 in ASD and E85 in TD) were also significantly different from the region containing electrode E25.
Conclusions: Our preliminary results support prior findings of reduced long-range but increased short-range connectivity in ASD, and show the utility of the regionalized tessellation methodology for automatically identifying scalp regions that distinguish between diagnostic groups. The strength of this approach lies in its ability to utilize a variety of arbitrary features of the EEG in our analyses. Our ongoing analyses focus on metrics of EEG complexity at the regional and electrode level. These analyses show that regionalized tessellation is capable of identifying established patterns of brain activity that vary between groups, and holds promise for novel investigations of large, high-dimensional data sets.

78 **125.078** Automatic Detection of Emotional Prosody in Children and Adults with Autism Spectrum Disorders

***M. Gomot**, J. Charpentier, J. Malvy, F. Bonnet-Brilhault, E. Houy-Durand and M. Latinus, UMR930, INSERM, Université François –Rabelais de Tours, Tours, France*

Background:
Although intolerance of change is a main feature of Autistic Spectrum Disorder (ASD), the brain processes underlying this aspect of the disorder remain poorly understood. This oversensitivity to changes may lead to an inability to adapt to new sensory inputs, and especially to the ever changing social environment. In this respect the processes involved in pre-attentional detection of changes in stimulus features have been investigated in ASD using the mismatch negativity (MMN), an event-related potential that reflects error detection caused by a deviation from a learned regularity. However, although ASD is also characterized by an inability to detect and adapt to changes in emotional states, only few MMN studies in this population have investigated automatic deviancy detection in an emotional context. These studies used different deviant emotions that where always compared to neutral standards, and showed that eMMN was smaller or less lateralized in ASD than in controls. Objectives:
In order to determine if particularities observed in previous studies are related to emotion processing or to change detection abnormalities, the present study addresses direct comparison of automatic change detection of neutral and emotional deviants with strictly controlled acoustic parameters, in children and adults with ASD.
Methods:
Thirty-two adults (16 typical; 16 ASD) and thirty 7-12 years old children (15 typical; 15 ASD) were presented with two voice deviants, neutral (p=.085) and angry (p=.085) (prosodic variation of the vowel 'aaa') embedded in a repetitive neutral stimuli sequence. Brain electrical activity was recorded using a 64-channels Biosemi EEG system, while participants were watching a silent movie. A genuine MMN was measured for each condition as the subtraction of the stimuli presented in an equiprobable sequence from the same deviant stimuli in the oddball sequence.
Results:
Comparisons of age groups and conditions during typical development indicate a late maturation of the brain processes associated with emotional prosody discrimination. Findings in both children and adults with ASD revealed an atypical processing of both emotional and neutral deviancy. In children with ASD, the amplitude of the responses to voice stimuli from the equiprobable sequence were significantly smaller than in controls for both the neutral and the emotional prosody, as where the responses to deviancy (nMMN and eMMN). In adults with ASD responses to voice stimuli were found normal, for both the neutral and the emotional prosody. However the MMN to neutral and emotional deviancy presented atypical brain distributions.
Conclusions:
The detection of prosody deviancy was found altered in children with ASD, together with atypical responses to voice, and this regardless of expression. In adults despite a normalization in voice processing, the detection of vocal deviancy remains affected.
Altogether these findings suggest that voice and prosody processing can improve with age in ASD, but that the lack of expertise in vocal encoding during childhood would lead to a long lasting inability to discriminate between different vocal emotions. This study points to specific difficulty in the online processing of emotional changes in ASD which potentially plays a crucial role in social interaction deficits regardless of age.

79 **125.079** Comparing fNIRS-Based Cortical Activation Patterns during Interpersonal Synchrony Tasks Between Children with and without Autism

***M. Hoffman**[1], S. Trost[1], M. Culotta[1] and A. N. Bhat[2], (1)Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE*

Background: The long-term goal of this research is to determine neurobiomarkers of imitation/interpersonal synchrony in children with and without Autism Spectrum Disorder (ASD) to explain the positive effects of imitation/synchrony-based interventions. Specifically, we will explain the neural basis for how socially embedded, synchronous, whole body movements may facilitate social communication skills in children with ASD.
Mirror Neuron Systems (MNS) in the frontal, parietal, and temporal cortices are active during action observation, production, and imitation (Iacoboni, 2005). The majority of the literature has described MNS dysfunction in children with ASD using fMRI techniques while performing hand motions (Dapretto et al., 2006). For the first time, we will be using functional near-infrared spectroscopy (fNIRS), a novel neuroimaging tool to assess changes in MNS activation across naturalistic interpersonal synchrony tasks.
Objectives: We aim to compare MNS activation across the frontal, parietal, and temporal cortices between children with and without ASD during naturalistic, interpersonal synchrony tasks.
Methods: 12 children with and without ASD between 6 and 12 years of age and 12 healthy adults were seated in front of an adult social partner while they were presented with a circle of blocks. The task involved cleaning up the blocks into a container in 3 ways (Egetemeir et al., 2011): a) *Watch (W)*: the child observed the adult complete the cleanup activity, b) *Do (D)*: the child cleaned up all blocks on their own, and c) *Together (T)*: the child cleaned up all the blocks near him/her along with the adult by matching the block location and color. The cleanup sequence was kept random by the adult to promote social monitoring. 24 trials were collected, 8 per condition using a rnadomized block design. The oxy hemoglobin response of the fNIRS signal was further analyzed to study differences in activation patterns between tasks, between hemispheres, and between the 3 regions of interest.
Results: Our preliminary data suggest more complex MNS activation during the Together (joint action) condition compared to the Do (solo action) or Watch (observation) tasks. Specifically, the temporal cortices showed greater activation during the watch and together conditions compared to the Do condition. In contrast, the fronto-parietal cortices were more active during the Do and Together conditions compared to the Watch condition.
Conclusions: Our results support the use of fNIRS technologies to study cortical activation patterns in children with and without ASD. In the long-term, we will examine the effects of imitation/synchrony-based interventions in children with ASD using MNS-based cortical activation as a neurobiomarker.

80 **125.080** Connectome-Wide Network Analysis of Male Youth with Autism Spectrum Disorder with and without Impaired Self-Regulation

H. Y. Lin[1], *H. C. Ni*[2], *W. Y. I. Tseng*[3] *and S. S. F. Gau*[1], *(1)National Taiwan University Hospital & College of Medicine, Taipei, TAIWAN, (2)Chang Gung Memorial Hospital- Linkou Medical Center, Taipei, Taiwan, (3)National Taiwan University Hospital, Taipei, Taiwan*

Background: Individuals with autism spectrum disorder (ASD) commonly present with impaired self-regulatory ability (dysregulation), in affect, cognition, and behavior domains, which would exacerbate social functional impairment in ASD and increase the burden on caregivers. The characterization of dysregulation and its neural correlates in ASD remains elusive and is a priority.
Objectives: Following our earlier structural MRI studies, we aimed to further characterize effects of dysregulation on intrinsic functional connectivity networks in youths with ASD
Methods: We conducted a multivariate connectome-wide association study (CWAS) examining dysconnectivity with resting state functional magnetic resonance imaging in a sample of 52 male youths with ASD, 49 neurotypical male comparators, age range 8-17 years. Dysregulation was defined by the sum of *T*-scores of the Attention, Aggression, and Anxiety/Depression subscales in the Child Behavior Checklist greater than 180. There were 36 and 16 boys with ASD in the ASD+Dysregulation and ASD-Dysregulation groups, respectively. ICA-based strategy for Automatic Removal of Motion Artifacts was applied to address in-scanner head motion. We investigated CWAS differences among the ASD+Dysregulation, ASD-Dysregulation and neurotypical groups. Significant CWAS findings were thresholded at $Z > 1.65$, and controlled for family-wise error rate using Gaussian Random Field (GRF) theory (cluster size threshold $p < 0.05$). Follow-up analyses used the clusters identified by CWAS as the basis for seed-based connectivity analyses.
Results: In CWAS, comparisons of ASD+Dysregulation and neurotypical youths revealed multiple regions where the multivariate pattern of connectivity differed between groups, implicating the dorsal anterior cingulate cortex (dACC) and left inferior frontal gyrus (L-IFG), bilateral precuneus, and right inferior parietal lobule (IPL). Comparisons of ASD-Dysregulation and neurotypical groups showed between-group dysconnectivity in the bilateral sensorimotor cortex. Comparisons of ASD youths with and without dysregulation identified group differences in the left posterior insula. Follow-up seed-based analyses identified increased dACC-bilateral superior temporal gyrus, decreased L-IFG-bilateral precuneus, increased bilateral precuneus-right IPL, increased bilateral precuneus-right IFG/anterior insula, alongside reduced bilateral precuneus-right sensorimotor connectivity in ASD+Dysregulation, relative to neurotypicals. ASD-Dysregulation youths had weaker connectivity between the bilateral sensorimotor cortex and bilateral precuneus/posterior cingulate cortex compared to neurotypical boys. The ASD+Dysregulation group had hyperconnectivity between the left posterior insula and bilateral precuneus/calcarine, between the left posterior insula and left insula, and between the left posterior insula and right supramarginal gyrus, as compared to the ASD-Dysregulation group.
Conclusions: The current findings of distinct intrinsic connectivity patterns in ASD with and without dysregulation suggest ASD with severe dysregulagtion may constitute a distinct subgroup on the spectrum, and the dysregulation level may be a potential yardstick to dissect heterogeneity of ASD. Dimensional neural correlates of dysregulation in ASD based on resting-state functional MRI warrant further investigation.

81 **125.081** Development of a Functional Connectivity Optical Imaging Protocol and Analysis Pipeline for Mouse Models of Autism Spectrum Disorder

R. Rahn[1], *M. Reisman*[2], *S. Maloney*[3], *G. Baxter*[2], *I. Orukari*[2], *K. B. McCullough*[4], *J. Dougherty*[4] *and J. Culver*[5], *(1)Program in Neuroscience, Washington University in St. Louis, St. Louis, MO, (2)Washington University in St. Louis, St. Louis, MO, (3)Washington University School of Medicine, St. Louis, MO, (4)Genetics, Washington University School of Medicine, St. Louis, MO, (5)Physics, Radiology, and Biomedical Engineering, Washington University in St. Louis, St. Louis, MO*

Background: Functional connectivity mapping is a method by which brain function can be non-invasively measured on a whole-brain level using fMRI. Studies of resting-state functional connectivity in autism spectrum disorder have focused on certain developmental stages or on individuals' level of functioning. However, genetic and environmental variation between individuals can introduce added noise to analysis of autism spectrum disorder in humans. Use of mouse models of autism can address this issue of heterogeneity by controlling for genetic and environmental differences. Optical intrinsic signal (OIS) imaging is a minimally invasive, low cost method for mouse neuroimaging, which can map resting-state functional connectivity and cortical activations in response to stimulation in mouse models of ASD and potentially offer insights into brain function in ASD.
Objectives: This study aims to develop functional connectivity optical imaging methods in mouse models of autism and to apply it to pilot groups of genetic or environmental mouse models of autism spectrum disorder (ASD).
Methods: Functional connectivity OIS imaging was performed on two cohorts of mice with autism-related behavioral phenotypes, an SSRI exposure model and a *Celf6* knockout model. In each pilot group, ASD model mice were compared to age-matched wildtype controls by imaging the cerebral cortex of the anesthetized mouse at adulthood, measuring changes in reflected light intensity to calculate relative changes in hemoglobin concentrations. Resting-state functional connectivity and left forepaw stimulation data were collected across multiple runs for each mouse and averaged to produce maps of functional connectivity and variation.
Results: Contralateral homotopic connectivity varied across cortical regions at rest and cortical activation in response to forepaw stimulation varied between mice. A similarity analysis evaluated how similar (spatially) the functional connectivity patterns of the ASD mice were to a control group. No consistent pattern of dissimilarity was found in the ASD groups of mice when measured at adulthood, but a common region of high variability was identified in the individuals of both the ASD groups and controls.
Conclusions: Functional connectivity OIS imaging is a minimally invasive optical imaging method that can be used to map functional connectivity in mouse models of autism. Mapping functional connectivity with these methods in mouse models of autism can control for genetic and environmental differences which may influence imaging research results in humans.

82 **125.082** Distinct Patterns of Auditory Evoked Potentials and Trial-By-Trial Neural Synchrony for Speech and Nonspeech Processing in Children with Autism

L. Yu[1,2], *Y. Fan*[3], *D. Huang*[3], *S. Wang*[4] *and Y. Zhang*[5], *(1)Speech-Language-Hearing Sciences, University of Minnesota, Minneapolis, MN, (2)Psychology, SOUTH CHINA NORMAL UNIVERSITY, GUANGZHOU, China, (3)Guangzhou Rehabilitation & Research Center for Children with ASD(Guangzhou Cana School), Guangzhou, CHINA, (4)School of Psychology, South China Normal University, Guangzhou, China, (5)Department of Speech-Language-Hearing Science, University of Minnesota, Minneapolis, MN*

Background: Individuals with autism often display atypical auditory evoked potentials (ERP) (Haesen et al., 2011), which could be due to pathological conditions affecting trial-by-trial neural synchrony (David et al., 2016). Such trial-by-trial neural synchrony to the onset of auditory stimulation can be computed as inter-trial coherence (ITC) for different frequency bands of interest. A smaller ITC could be interpreted as representing larger amounts of neural "jitter". It has been shown that reduced alpha (specifcally at 11.7 Hz) ITC in children with autism may be associated with poorer neuromodulatory control within the sensory cortex (Milne, 2011).
Objectives: This study aimed to verify whether atypical patterns of neural oscillatory activities mediate the auditory evoked responses to speech and non-speech sounds in children with autism.
Methods: EEG data were recorded from school-age Chinese-speaking children with autism and age-matched typically developing (TD) children with a passive listening paradigm. The stimuli were pure tones and Chinese words /bai2/ (Pure tone: ASD *N* = 15, TD *N* = 16; Word: ASD *N* = 14, TD *N* = 15). Amplitude and latency of P1 and N2 (also known as N250 or delayed N1 in children) components were calculated along with the ITC measures of delta, theta, alpha and beta frequency bands within the windows of interest.
Results: In the pure tone condition, there is a significant N2 reduction accompanied by smaller delta ITCs in the autism group. No group difference in the P1 response were observed. In the word condition, the autism group showed enhanced P1 amplitude accompanied by larger delta, theta, and alpha ITCs. There was a tendency (but not statistically significant) of diminished N2 response. In the pure tone condition, P1/N2 responses in both groups were correlated with ITCs, whereas in the word condition, only the autism group showed such relationship.
Conclusions: The comparison with age-matched controls in our study revealed distinct patterns of auditory P1/N2 responses and underlying cortical oscillatory activities for speech and nonspeech processing in children with autism. For the pure tone stimuli, we found evidence for weakened perceptual analysis of acoustic features in the N2 component with reduced inter-trial synchrony in the delta band (0~3 Hz) for the autism group. By contrast, we observed enhanced P1 responses to the speech stimuli accompanied by increased neural synchrony in frequency bands of 0 ~ 30 Hz in the autism group, suggesting a hypersensitive reaction to the word onset in children with autism. It remains unclear how these different patterns of neural activities for early sensory processing of speech and nonspeech sounds might correlate with higher-level behavioral perception. Further studies are needed to examine the potential impact of atypical auditory processing on speech and language development in children with autism.

83 **125.083** EEG Data Collection in Challenging Children: The Role of State in Data Quality and Spectral Power

C. DiStefano[1], *A. H. Dickinson*[2] *and S. S. Jeste*[3], *(1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)UCLA, Los Angeles, CA*

Background:
Resting-state EEG is commonly recorded during an eyes-closed condition, free of sensory stimuli. In studies of young children or children with limited cognitive ability, this pure "resting state" is challenging to consistently capture. These children may be unable to follow directions to keep their eyes closed, and require some stimulus in order to remain engaged and calm, thus introducing more variability in state. Child state during the EEG recording may influence both the success of data acquisition and EEG variables (Webb et al., 2015). In order for EEG to be related to clinical relevant traits, this distinction between state and trait must be elucidated. This is especially salient when comparing children with ASD to TD children, who may systematically differ in terms of their state during the EEG recording.
Objectives:
We quantified the "state" of participants (ASD and TD) during EEG recording. We examined how state related to: (1) child characteristics (age, IQ, diagnosis), (2) EEG data quality (percent of data retained), and (3) EEG power, particularly focusing on alpha due to its documented relationship with the resting state, attention and emotion regulation.
Methods:
Participants included a heterogeneous group of children with ASD (N=39) ages 5-10, and an age-matched TD group (N=16). Specific strategies were used to acclimate participants to the EEG testing environment, including modeling, incremental practice and positive reinforcement. Resting EEG was recorded while participants watched a video of bouncing soap bubbles. The state of the participant during the EEG recording was rated using a 5-point likert scale (Perceived State Rating; PSR), where higher scores correspond to higher levels of anxiety/agitation.
Results: EEG data was successfully collected 85% of participants with ASD. Participants with ASD were significantly more likely to have PSR above 1 than TD participants (p=0.002). Percent of EEG data retained was not related to chronological age, verbal IQ or non-verbal IQ. In the ASD group, significantly less data was retained in participants with PSR 2-5 compared with PSR 1 (t=3.22, p=0.003). Using linear regression, PSR significantly predicted percent of data retained (t=-2.69, p=.01), while VIQ, NVIQ and chronological age were not significant (p-values .17-.74). Children in the TD group had significantly higher alpha power compared with children in the ASD group (p-values 0.003-0.036). Within the ASD group, participants with high PSR had the lowest frontal alpha (t=2.49, p=0.02).
Conclusions: Given appropriate supportive strategies, EEG data can be successfully collected from children across cognitive and language levels. The child's state during the EEG recording was significantly related to both the amount of EEG data retained, and alpha spectral power. Alpha suppression has been consistently linked to attention and vigilance (Boiten et al., 1992; Klimesch, 1999), suggesting that reduced alpha power in children with an elevated state rating may reflect that these participants were less "at rest" during the EEG recording. These data highlight the importance of quantifying and addressing state when conducting EEG studies with challenging participants, both to increase data retention rates, and to reduce the influence of state on EEG variables of interest.

84 **125.084** EEG Markers of Learning from Joint Engagement in Toddlers at High Risk for Autism Spectrum Disorder

E. Pompan[1], *A. T. Marin*[2], *E. Baker*[3] *and S. S. Jeste*[4], *(1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)UCLA Center for Autism Research and Treatment, Anaheim, CA, (4)UCLA, Los Angeles, CA*

Background: Joint engagement (JE), defined as periods of joint attention shared between an adult and infant (Carpenter et al., 1998), emerges between 9-15 months of age (Adamson et al., 2009). JE promotes language, cognitive development and social skill acquisition (Mundy et al., 2007). Children with autism spectrum disorder (ASD) exhibit early social communication deficits including in joint attention (Mundy et al., 2007). Typically-developing toddlers have shown evidence of object discrimination based on JE using electroencephalographic (EEG) methods (Hutman et al., 2015); however, this has not been investigated in toddlers showing early signs of ASD. Examination of object discrimination based on JE in toddlers showing signs of ASD may improve understanding of social communication deficits, which can inform JE-based interventions.
Objectives: (1) To investigate if JE modulates object discrimination in toddlers (12-24 months) at high risk for ASD (HR, n=16) compared to typically-developing toddlers (TD, n=11) using a novel EEG paradigm that couples a live interaction exposure with an EEG test phase. (2) To identify if quality of JE between child and experimenter during the exposure phase relates to EEG markers of learning.
Methods: Toddlers were deemed HR if they scored within the mild-to-severe concern range on the Autism Diagnostic Observation Schedule-Toddler Module. During a 4-minute exposure, the experimenter presented two sets of toys in a social and non-social manner. Child behavior was coded to evaluate quality of JE with the experimenter. Participants then passively viewed images of toys presented during exposure while high-density EEG was recorded (128-electrode, EGI Inc.). The variable of interest was frontal mean Nc (400-800ms), thought to be a marker of attention.
Results: (1) A 3-way mixed-design ANOVA examined main and interaction effects of condition, region, and group. There was no effect of condition by group, $F(1,25)=.004$, $p=.95$. There was an interaction effect of condition by region, $F(2,24)=7.664$, $p=.003$. Post-hoc tests revealed significant differentiation of conditions in the middle region, $t(26)=-2.07$, $p=.049$. (2) Correlations were then conducted to evaluate associations between EEG markers and quality of JE. Time spent looking at the examiner during the social condition correlated with Nc absolute difference value in the middle region, $r(27)=.49$, $p=.01$.
Conclusions: Both HR and TD toddlers show increased familiarity to objects presented with JE. This suggests that toddlers showing early signs of ASD were able to learn via JE with an examiner in a comparable manner to TD children. Given that early intervention for ASD often relies on learning in a social context, these result are promising. The level of object discrimination based on JE, however, varied with regard to social behavior during the exposure phase. Specifically, toddlers who spent more time looking at the examiner during JE showed higher levels of discrimination, indicating salience of object learning may increase with eye contact. Further characterizing child behaviors that relate to learning based on JE may inform intervention treatment targets and predict response to treatment. Future research will aim to relate EEG markers of learning to gains in an intervention focused on improving JE, and to diagnostic outcome of HR toddlers.

85 **125.085** Early Visual Processing of Faces in Tuberous Sclerosis Complex (TSC) and in Children Showing Early Signs of ASD

M. A. Ware[1], *A. T. Marin*[2], *E. Baker*[3], *K. J. Varcin*[4] *and S. S. Jeste*[5], *(1)UCLA Center for Autism Research & Treatment, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)UCLA Center for Autism Research and Treatment, Anaheim, CA, (4)Telethon Kids Institute, Perth, WA, Australia, (5)UCLA, Los Angeles, CA*

Background:
Tuberous sclerosis complex (TSC) is a rare genetic disorder that confers a high risk for autism spectrum disorder (ASD), at a rate of 60% (Jeste, 2013). ASD is characterized by core deficits in social interaction and communication. EEG studies have revealed that children with ASD process faces differently when compared to children with typical development (Dawson, 2002; McCleery, 2009). Therefore, studying socially relevant stimuli, such as faces, may be an adequate way to measure atypical cognitive mechanisms in children with neurodevelopmental disorders, such as ASD and TSC. Not much is known about face processing in children with TSC, nor about how they process faces compared to ASD.
Objectives:
We asked whether EEG correlates of face and object processing differentiated four groups of 12-24 month-old toddlers at risk for ASD: 1. toddlers with TSC who had ASD outcomes (TSC/ASD), 2. toddlers with TSC without ASD outcomes (TSC/noASD), 3. toddlers showing early behavioral signs of ASD (HR) based on elevated scores on the Autism Diagnostic Schedule-Toddler Module (ADOS-T), and 4. low risk controls (LR).
Methods:
A cohort of 7 TSC/ASD toddlers, 11 TSC/noASD toddlers, 24 HR toddlers who scored in the moderate-to-severe risk range on the ADOS-T, and 28 LR toddlers were shown images of faces and objects in a randomized order while high-density EEG was recorded (128-electrodes, EGI Inc.). Event-related EEG components of interest were the N290 (peak amplitude and latency), P400 (peak amplitude and latency), and Nc (mean amplitude).
Results:
There were significant main effects of condition ($F(1,66)=3.86$, $p=.05$) and region ($F(2,65)=9.14$, $p<.001$) for the N290 peak amplitude, as well as significant condition by region ($F(2,65)=5.255$, $p=.008$) and condition by region by group ($F(6,132)=2.589$, $p=.008$) interactions. Post-hoc tests revealed regional differences, showing greater minimum N290 amplitude in the right ($M=5.10$) region than the left ($M=3.57$, $p=.036$). Post-hoc tests also showed differences in condition in the right region within the HR group only, suggesting greater responses to faces ($M=9.15$) than to objects ($M=9.00$, $p=.047$) in early visual processing. For P400 peak amplitude, there were significant main effects of condition ($F(1,66)=8.73$, $p=.004$) and region ($F(2,65)=3.79$, $p=.028$). There was a main effect of condition for Nc mean amplitude ($F(1,66)=24.35$, $p=.001$). There was a significant main effect of group in P400 latency to faces, with slowed processing in both TSC groups (TSC/ASD=446.17ms; TSC/noASD=440.28ms), compared to HR and LR (HR=396.77ms; LR=410.542ms; $p=.002$).
Conclusions:
Condition effects in the three components indicate that there was electrophysiological differentiation of faces and objects across all groups. The HR group showed differentiation in the early visual component N290, which may reflect visual processing mechanisms unique to ASD. The delayed face processing seen in P400 in the TSC group was not specific to ASD diagnosis and, therefore, may reflect a more fundamental delay in processing of social information that could have implications for social skills for all children with TSC. Further investigation of developmental outcomes and correlation of EEG patterns with social communication skills in TSC may shed light on the impact of delayed face processing in this high-risk cohort.

86 **125.086** Electroencephalographic Examination of Resting State Neural Oscillatory Activity in Young Children with Autism Spectrum Disorder

J. Rudoler[1], *L. A. Wang*[2], *J. Pandey*[1], *J. E. Maldarelli*[1], *T. Vanderwal*[3], *J. Miller*[1], *R. T. Schultz*[1] *and J. McCleery*[1], *(1)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Previous research has observed atypical neural oscillatory activity in 6-15 year-old children and adolescents with Autism Spectrum Disorder (ASD), using Magnetoencephalography (MEG; Cornew et al., 2012).Â In particular, participants with ASD exhibited regionally specific elevations in delta, theta, alpha, beta, and gamma band activity at rest, relative to controls. Furthermore, increased temporal and parietal alpha power was associated with greater symptom severity in ASD. These findings have been interpreted as evidence for an imbalance in neural excitation/inhibition in ASD.
Objectives: To investigate neural oscillatory activity in younger children with autism using a task-free “Resting State” procedure during continuous Electroencephalography (EEG) recording.
Methods: Participants are children with ASD aged 3- to 5-years ($n=28$) and control participants who were developing typically or experiencing non-ASD developmental delays (CON; $n=25$).Â ASD diagnostic status was assessed by research-reliable doctoral level clinicians using best clinical judgment based on several measures (ADOS-2, Mullen Scales of Early Learning, Vineland Adaptive Behavior Scales). Participants watched a movie (Inscapes) featuring moving abstract shapes without a narrative, designed to keep young participants still and awake (Vanderwal et al., 2015). Continuous 128-channel EEG (Electrical Geodesics, Inc.) was recorded for approximately 7 minutes per participant. Data were then processed offline, and only participants who produced 70 seconds or more of artifact-free data (ASD: $n=17$; CON: $n=19$) were included in further analysis. The final groups of ASD and CON participants were matched on chronological age and nonverbal mental age. Power Spectral Density data were calculated for theta (4 – 7 Hz) and alpha (7 – 11 Hz) activity, for electrodes located over the Orbitofrontal, Dorsolateral Frontal, Central, and Parietal Cortices. ANOVAs with Frequency Band (Theta, Alpha), Region (Orbitofrontal, Dorsolateral Frontal, Central, Parietal), and Hemisphere (Left, Right) as Within-Subjects Factors and Group (ASD, CON) as a Between-Subjects Factor were then conducted.
Results: Significant main effects were observed for Frequency Band ($F(1, 34)=191.957$, $p < .001$, $\eta_p^2=.850$) and Region ($F(2.215, 75.310)=153.733$, $p < .001$, $\eta_p^2=.819$), but not Group ($p=.350$). Significant main effects were moderated by a significant interaction between Frequency Band and Region, whereby power in the Theta and Alpha bands were less differentiated from one another in the Central and Parietal regions than in other cortical regions ($F(1.808, 61.467)=46.098$, $p < .001$, $\eta_p^2=.576$). No other significant main effects or interactions were observed. No significant correlations were observed between parietal alpha power and social functioning in either participant group.
Conclusions: The preliminary findings of this on-going EEG study of young children do not replicate previously observed MEG-based findings indicating atypical neural oscillatory activity in older children and adolescents with ASD. This may be related to differences in the studies, which include the age of the participants (younger versus older), the need to use video watching (versus eyes closed) with the young children in the current study, differences in EEG versus MEG measurement properties, and/or the currently smaller sample size ($n=36$ versus $n=50$) and associated differences in statistical power to detect effects to date in this on-going study.

87 **125.087** Electrophysiological Correlates of Word Segmentation in Three-Month-Old Infants at High and Low Risk for Autism Spectrum Disorder

A. T. Marin[1], *C. DiStefano*[2], *K. Visnagra*[1], *T. Toueg*[1], *T. Hutman*[2], *M. Dapretto*[1] *and S. S. Jeste*[3], *(1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA, Los Angeles, CA*

Background: Early Auditory Statistical Learning (ASL) – the ability to implicitly extract statistical regularities available in the input (Saffran et al., 1996) – is a precursor to later expressive language ability (Romberg & Saffran, 2010). ASL is crucial for language learning, as it allows infants to detect word boundaries by determining transitional probabilities between syllables in continuous speech (Kuhl, 2004). Successful word segmentation has been demonstrated in 6-month-old infants (Johnson & Tyler, 2010) but no studies to date have examined ASL in 3-month-old infants at high- and low-risk for autism.
Objectives: Here we examined whether EEG signatures of ASL can be quantified at 3-months-of-age, whether different patterns are observed in infants at high (HR: have an older sibling with ASD) and low-risk (LR) for autism, and whether ASL at 3-months predicts later language ability.
Methods: Three-month-old infants (HR:n=17, LR:n=22) were exposed to a continuous speech stream created by concatenating four tri-syllabic artificial "words", constructed from a set of 12 syllables. Infants were then presented with the same tri-syllabic combinations ("words"), as well asÂ tri-syllabic combinations not heard during the exposure phase ("non-words"). High-density electroencephalography (EEG) was recorded (128-electrode, EGI Inc.) and the event-related EEG components of interest included the frontal-auditory P100 and left-temporal Positive Slow Wave (PSW). A general linear model was used to examine within-subject effects of region and condition and between-subject effects of group with respect to P100 maximum amplitude and latency, and PSW mean amplitude. Evidence of word segmentation was operationalized as differences between conditions on PSW. Correlations between EEG markers of word segmentation and verbal ability (receptive and expressive language scales, Mullen Scales of Early Learning (MSEL), 1995), receptive vocabulary (MacArthur Bates Communication Inventory (MCDI), 2007) at 9- and 12-months were also examined.
Results: We observed a significant main effect of group ($F(1,37)=4.59$, $p=.03$) in the frontal P100 latency, with slower P100 peak in HR infants ($M=242.5$) compared to LR ($M=219.4$). With respect to PSW mean amplitude, we observed a significant region by condition interaction ($F(1,37)=3.84$, $p=.05$) and a significant main effect of region ($F(1,37)=4.66$, $p=.03$). Post-hoc tests revealed greater PSW mean amplitude within the left region ($M=2.9$) compared to the right ($M=1.47$, $p=.03$); however, a significant difference between conditions was only observed in the left temporal region only ($t(38)=2.29$, $p=.03$). No significant correlations emerged between P100 frontal latency and MSEL or MCDI measures but the difference in PSW mean amplitude between conditions significantly predicted MCDI words understood at 9-months ($r(25)=.46$, $p=.03$).
Conclusions: Our results indicate differential low-level auditory responses as a function of risk-group, with HR infants showing a delayed P100 compared to LR infants. Moreover, across risk groups, infants as young as 3-months show EEG evidence of ASL as evidenced by the left temporal PSW. ASL at 3-months of age predicted receptive vocabulary at 9-months. Further analyses will examine relations between low-level auditory processing, subsequent language development, and clinical outcomes in infants at high-risk for ASD as well as changes in ASL over the first year of life in both high- and low-risk infants.

88 **125.088** Electrophysiological Markers of ASD in Infants with Tuberous Sclerosis Complex: A Genetics-First Approach to the Search for Predictive Biomarkers

K. J. Varcin[1]*, A. Dickinson*[2]*, J. Frohlich*[2]*, D. Senturk*[3]*, S. Huberty*[3]*, L. M. Baczewski*[4]*, C. A. Nelson*[5] *and S. S. Jeste*[6]*, (1)Telethon Kids Institute, Perth, Australia, (2)University of California, Los Angeles, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)Boston Children's Hospital Labs of Cognitive Neuroscience, Cambridge, MA, (5)Boston Children's Hospital, Boston, MA, (6)UCLA, Los Angeles, CA*

Background: Tuberous sclerosis complex (TSC) is one of the most commonly-occurring single-gene disorders associated with ASD. Approximately 50% of children with TSC will meet criteria for ASD. Recent evidence has demonstrated striking phenotypic homology in the profile of social communication impairment amongst toddlers with TSC/ASD and toddlers with non-syndromic ASD (Jeste, 2016). In addition, infants with TSC/ASD can be distinguished from infants with TSC no-ASD as early as 12-months of age on the basis of non-verbal cognitive ability. However, there is currently limited understanding regarding the neurobiological mechanisms underlying the development of ASD in TSC. Conversely, animal and human model research has identified characteristic neurobiological aberrations in the context of a TSC mutation, namely in atypical white matter development (including hypomyelination). There is preliminary evidence from older children that these alterations may be most severe in children with TSC/ASD.
Objectives: We aimed to identify potential predictive biomarkers of ASD in TSC in order to inform our understanding of mechanistic pathways to ASD in TSC. Specifically, we examined whether developmental trajectories of electroencephalographic (EEG) power and peak alpha band frequency distinguish infants with TSC/ASD from infants with TSC no-ASD. We examined these specific electrophysiological markers as they have been linked to alterations in white matter development, and hence, may be sensitive to atypical development in TSC in early infancy.
Methods**:** Data reported here form part of a larger, multisite, prospective study of infants with TSC across the first three years of life. We collected high spatial density resting-state EEG recordings from infants with TSC ($n = 40$) and typically developing infants (TD; $n = 32$) at 12, 18, 24 and 36 months. ASD diagnosis at 24 and 36 months was determined using the Autism Diagnostic Observation Schedule and clinical best estimate. We calculated whole-brain relative power in delta (1-4Hz), theta (4-6Hz), low-alpha (6-8Hz), high-alpha (8-11Hz), beta (11-35Hz) and gamma (35-50Hz) bands, as well as peak alpha frequency (between 6-11Hz) for each infant at each age.
Results**:** Mixed-effects models revealed reduced low-alpha power across early development in infants with TSC/ASD compared to infants with TSC no-ASD at all ages ($p < .01$). As a group, infants with TSC exhibited lower relative low-alpha ($p < .001$) and gamma ($p < .001$) power from 12-36 months and reduced peak alpha frequency from 18-36 months compared to TD infants ($ps < .05$). Gamma power at 12 months was positively correlated with non-verbal abilities in infants with TSC ($r = 0.34$, $p = .01$).
Conclusions: Our results suggest that reduced whole-brain low-alpha power across early development may be a neurophysiological signature associated with ASD in TSC. Reductions in peak alpha frequency and relative whole-brain gamma power are associated with TSC as a whole, rather than ASD. Alterations in EEG power and alpha peak frequency are consistent with the characteristic disruptions to white matter development in TSC. Follow-up analyses will examine patterns of neural connectivity and brain-behavior associations to further inform our understanding of cortical alterations associated with ASD in the context of TSC.

89 **125.089** Enhanced Early Visual Responses to Emotional Faces in ASD

K. Kovarski[1]*, R. Mennella*[2]*, S. M. Wong*[3]*, B. T. Dunkley*[3]*, M. J. Taylor*[4] *and M. Batty*[5]*, (1)UMR 930 INSERM, University of Tours, Tours, France, (2)Department of General Psychology, University of Padova, Padova, Padova, Italy, (3)Hospital for Sick Children, Toronto, ON, Canada, (4)Hospital for Sick Children, Toronto, ON, CANADA, (5)UMR 930 Inserm-Universite Francois Rabelais Tours, Tours Cedex 09, FRANCE*

Background:
Sensory atypicalities in all the modalities in ASD have recently gained a crucial role in the description of the autistic symptomatology. In the visual domain, atypical neural responses have been reported in several low- and high- level tasks. Facial expressions, are essential for successful social interactions and represent a core problem for those with ASD. To better understand implicit and rapid processing of emotions in ASD, the visual cortex and emotional network should be considered in neuroimaging studies from its earliest stages.
Objectives:
The present study investigated the time course of brain activity in a large number of regions implicated in various stages of the processing of emotional faces, utilizing both the high spatial and temporal resolution of magnetoencephalography (MEG).
Methods:
Nineteen ASD adults and 19 typically developed adults (TD) took part in an implicit emotional task while MEG was recorded. Stimuli consisted of a face displaying a happy, an angry or a neutral expression and a scrambled pattern presented simultaneously just right and left of central fixation. The participants responded whether the pattern occurred on the left or right side of the screen. Emotions were thus implicit in the task. MEG responses in 23 bilateral regions of interest (ROI) were selected and seven time-windows of 30ms were visually identified to measure mean power. Statistical analyses were performed at each ROI when a deflection was present to investigate group emotion, hemisphere and interaction effects.
Results: Angry faces elicited a stronger response in both groups (110-140ms) in the fusiform gyri (FG), but only the TD presented similar emotional enhancement in the inferior temporal gyri. Hypo-activation in the postcentral gyrus was found in the ASD group to all facial expressions. In the occipital region and the middle temporal poles (125-155ms) the ASD group presented an enhanced activity and an emotion-specific response, while a hypo-activation in the right FG, the bilateral postcentral gyri and in the parietal cortex was found around 155-185ms. Happy faces elicited a greater parietal response in TD (220-250ms) while neutral faces elicited a stronger response than happy faces in the occipital gyri in the ASD (245-275ms). An emotion-specific responses were found (315-345ms) in the FG and in the parietal lobules for both groups. Differences between groups in hemisphere dominance were observed at several ROI and time-windows.
Conclusions:
These results demonstrate a distinct spatio-temporal organization during the processing of implicit emotional faces in adults with ASD. Consistent with perceptual and sensory theories of autism, an early enhancement in the visual cortices was found in the ASD group. Thus, the atypical implicit facial expression processing is not only due to hypo-activation of the FG, but to a broader atypical emotional face network, including atypical visual and emotion-specific responses. According to reports of enhanced visual functioning and to difficulties in configural face processing, a visual bias might be partly responsible for the impairment in the emotional face response in ASD. Thus, our data indicate that atypical early visual responses should be considered while investigating social cognition in autism.

90 **125.090** Enzyme Kinetics of N-Acetyl-Aspartylglutamate in the Cingulated Cortices in ASD: A 1H-MRS Model

C. D. Jimenez-Espinoza[1]*, F. Marcano*[2] *and J. L. González-Mora*[2]*, (1)San Cristobal de La Laguna, University of La Laguna, Santa Cruz de Tenerife, Spain,*

(2)Physiology, University of La Laguna, Santa Cruz de Tenerife, Spain

Background: The L-glutamate (Glu) and L-acetyl-aspartate (NAA) are products of N-acetyl-aspartyl-glutamate (NAAG) which require the participation of neurons, oligodendrocytes and atrocytes. On the one hand, NAAG is synthesized from NAA and Glu by an NAAG synthase, forming a dedicated pool of Glu that also cannot be further metabolized, and on the other hand, NAAG is then hydrolyzed by NAAG peptidase releasing Glu which activates the mGluR3 receptor. Enzymes stabilize transition states for reactions, and thus lower the activation energy required. A common measure for how much a reaction is sped up is called the rate enhancement, equal to the ratio of the catalyzed rate to the uncatalyzed rate. This ratio varies widely, ranging from one (which is technically no longer an enzyme - merely a protein) to 1.4×10^{17} for oritidine-monophosphate decarboxylase (an enzyme involved in DNA synthesis). At high concentrations, some substrates also inhibit the enzyme activity. Substrate inhibition occurs with about 20% of all known enzymes. It happens when two molecules of substrate can bind to the enzyme, and thus block activity. Altered NAAG metabolism has been described, in some neurological conditions but not in autism spectrum disorders (ASD). Our previous studies using proton-Magnetic Resonance Spectroscopy (^{1}H-MRS) in bilateral anterior (ACC) and posterior cingulate cortex (PCC) have described the altered neurometabolic patterns in adults with ASD.
Objectives: To study the enzyme kinetics of NAAG in vivo, using ^{1}H-MRS.
Methods: Single-voxel (^{1}H-MRS) in bilateral ACC and PCC, in 19 adults with a clinical diagnosis of ASD and 41 controls, matched for age, gender. Autism quotients (AQ) score were assessed. The affinity between enzymes and substrates associated with NAAG was measured. The Michaelis-Menten constant is calculated. One-way ANOVA and Bonferroni correction were applied.
Results: The ASD group had a significant increase of K*m* (NAA) = [5,79x10^6 (mM)]; R^2 = -27.05 compared with controls (TD) in ACC.
Conclusions: Altered enzyme kinetics N-acetylaspartylglutamate levels were found in cingulated cortices by ^{1}H-MRS in individuals with ASD, suggesting new therapeutic avenues.

91 **125.091** Evaluating the Neural Correlates of Intention Understanding in Autism Spectrum Disorder

N. I. Berger*, B. Ingersoll and M. Pontifex, Michigan State University, East Lansing, MI*

Background: Â Deficits in high level social cognitive skills such as joint attention and theory of mind are well documented in children with Autism Spectrum Disorder (ASD). However, the behavioral literature is equivocal to whether children with ASD have the ability to engage in lower level social cognitive skills such as recognizing others as acting intentionally. These equivocal findings may be partially explained by the varying methodology used to assess the construct termed 'intention' across studies. When children with ASD are simply required to attend to actions on an object to infer another's intention, studies reliably find intact intention understanding abilities. In contrast, when tested using paradigms that require children with ASD to attend to social-communicative cues (e.g., facial expressions, gaze, etc.) to draw conclusions regarding intention, impairment in intention understanding is identified. This study uses Event-Related Potentials (ERPs), a measurement of brain activity with millisecond resolution, to build upon the behavioral literature to better understand how different types of intention are processed at a neurological level in individuals with ASD.
Objectives: The purpose of this study was to use ERPs to assess, for the first time, the neural correlates of intention understanding in children with ASD and controls. Given behavioral research suggesting that ASD is associated with impaired intention understanding only when cued using social stimuli (e.g., facial expressions, gaze, etc.), this study compared differences in neural processing between groups across social and non-social stimuli.
Methods: We examined neural indices of social and non-social intention understanding in 22 school-age ASD children and 22 controls (age, gender, and IQ matched). Participants viewed picture sequences depicting either social or non-social intention. The final picture of the sequence varied such that an actor either completed the intended action (expected) or performed an unintended action (unexpected). We evaluated the P600 as it has been linked to expectancy violations in visual scene processing. Participants made button press responses to intended condition only.
Results: *Social stimuli:* Both groups demonstrated similar ERP responses, characterized by a greater (positive) P600 to unintended vs. intended condition. Response accuracy was significantly worse for the ASD group. *Non-social stimuli:* No group differences were identified in either response accuracy or ERP responses (greater P600 to unintended vs. intended condition).
Conclusions: Accuracy data concord with previous behavioral findings of a dissociation between social and non-social intention understanding, such that social intention alone is functionally impaired in ASD. However, no group differences were observed for either stimuli type at a neurological level. This is a particularly novel finding, as it demonstrates that observed behavioral impairments are independent from the neural processes supporting basic social intention understanding. Additional work is necessary to characterize this newly identified gap between neurological functioning and overt behavior.

92 **125.092** Event-Related Potentials Index Atypical Processing of Auditory Tones in Young Children with Autism Spectrum Disorder

J. L. Wood[1]*, L. A. Wang*[2]*, J. Pandey*[1]*, J. E. Maldarelli*[1]*, J. Rudoler*[1]*, R. F. Slomowitz*[1]*, R. T. Schultz*[1] *and J. McCleery*[1]*, (1)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Magnetoencephalography (MEG) studies have identified atypical processing of simple tones as a putative biomarker associated with Autism Spectrum Disorder (ASD). Specifically, participants with ASD exhibit temporal delays and hemispheric differences emanating from superior temporal gyrus between 50 and 100ms post-stimulus, and reduced activity at approximately 200ms post-stimulus, relative to controls. Furthermore, these differences are associated with language abilities in ASD. However, these findings have yet to be replicated using other measures, such as electroencephalography (EEG) based event-related potentials (ERPs). EEG and MEG are highly similar in their millisecond-level temporal resolution, yet different in that MEG has generally greater sensitivity to brain activity source locations with the limitation of being relatively insensitive to radially oriented brain activity.
Objectives: To investigate the neural correlates of simple auditory tone processing in children with ASD using EEG-based ERPs.
Methods: Participants are children with ASD aged 3- to 5-years (n=14) and chronological age and nonverbal mental age matched typically developing (TD) children (n=14). Auditory stimuli consist of 400ms long 200 Hz, 600 Hz, and 1000 Hz sine tones, presented at 70dB. The current analyses focus on the N200 and P200 components recorded over temporal and frontal cortex, respectively. ANOVAs with Frequency (200 Hz, 600 Hz, 1000 Hz) and Hemisphere (N200: Left, Right; P200: Left, Medial, Right) as within-subjects factors and Group (ASD, TD) as a between-subjects factor were conducted on the amplitudes and latencies of these components. Correlations between component latency and an index of language delay were also computed.
Results: P200 latencies exhibited a Frequency by Group interaction over frontal cortex ($F(2, 25) = 4.70$, $p < .05$, $\eta_p^2 = .273$), whereby latencies in the Medial region were shorter in ASD participants for 200 Hz (ASD: 174ms; TD: 187ms) and 600 Hz (ASD: 156ms; TD: 167ms) tones, but longer for ASD participants for the 1000 Hz tone (ASD: 163ms; TD: 153ms). No other significant Group effects were observed. P200 latencies were also negatively correlated with degree of language delay for the 200 Hz ($r = -0.575$, $p < .05$) and 600 Hz ($r = -0.601$, $p < .05$) tones in the ASD group.
Conclusions: The preliminary ERP findings of this on-going study replicate the general finding of atypical auditory perceptual processing for simple tones in ASD, albeit with a different pattern than that observed in previous MEG studies. Differences in the measurement properties and capabilities for MEG and EEG may explain the different patterns in the data. Alternatively or additionally, the age of the participants (younger in the current study) may help explain the differences. Regardless, the replication of an ASD versus TD group level difference in simple tone processing as well as correlation of more atypical tone processing with language delays in the ASD group, strongly suggest that the current EEG study findings reflect sensitivity to the biomarker previously identified using MEG. Together, EEG and MEG studies have potential to provide more detailed characteristics and explanations for atypical tone processing in infants, children, and adults with ASD.

93 **125.093** Frontal EEG Asymmetry As an Early Marker of Behavior Vulnerability in Infants with Congenital Visual Impairment Who Are at Risk of Autism Spectrum Disorder (ASD)

N. Dale[1]*, M. O'Reilly*[2]*, J. Bathelt*[3]*, E. Sakkalou*[4]*, A. Salt*[5] *and M. De Haan*[2]*, (1)Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom, (2)UCL Institute of Child Health, London, UNITED KINGDOM, (3)MRC Cognition and Brain Sciences Unit, University of Cambridge, Cambridge, United Kingdom, (4)Clinical Neurosciences, UCL Great Ormond Street Institute of Child Health, London, United Kingdom, (5)Great Ormond Street Hospital for Children, London, UNITED KINGDOM*

Background: Young children with congenital visual impairment (VI) are at increased risk of behavioral vulnerabilities. Previous literature on other clinical 'at risk' populations including young children with autism spectrum disorder (ASD) suggests that frontal electroencephalogram (EEG) asymmetry may be a marker of risk in temperament and behavior. *Objectives:* This study set out to investigate frontal EEG asymmetry at one year of age, behavior patterns at two years of age and their predictive associations. *Methods:* At Time 1, 22 infants (mean age 13 ± 2.5 months) with 'potentially simple' congenital disorders of the peripheral visual system underwent 128-channel EEG recording whilst being presented with happy, sad and neutral vocalizations. Frontal EEG asymmetry ratios were calculated from power spectral density values in the alpha frequency band (6-10 Hz), and a composite frontal EEG asymmetry score was derived. At Time 2, when the infants were approximately 2 years old, parent-rated behavior questionnaire (Achenbach Child Behavior Checklist) data was obtained. *Results:* The majority of the sample (63.6%) had greater left frontal asymmetry; 22.6% of the sample had clinical/subclinical range 'internalizing' behavior difficulties. Infants with the lowest vision levels (towards light perception at best or no vision) had significantly higher scores in the direction of behavior problems, specifically for Withdrawn problems. Longitudinal correlational analyses revealed a significant association between EEG frontal asymmetry and behavior, whereby greater left frontal asymmetry correlated with greater internalizing (emotionally reactive) problems. *Conclusions:* The finding of greater left frontal asymmetry in this sample of young children with VI is consistent with reports of greater left frontal asymmetry in other 'at risk' clinical populations including ASD (Gabard-Durnam *et al*., 2015). Our findings suggest the existence of a potential early electrophysiological marker of behavioral difficulties in young children with VI and later VI-ASD diagnosis, which is currently being explored.

94 **125.094** Impulse Control Is Differentially Modulated By Social Versus Non-Social Stimuli

D. J. Bos[1]*, E. L. Ajodan*[2]*, M. R. Silverman*[1] *and R. M. Jones*[3]*, (1)Dept. of Psychiatry, Sackler Institute for Developmental Psychobiology of Weill Cornell Medical College, New York, NY, (2)CADB, Great Neck, NY, (3)Weill Cornell Medical College, White Plains, NY*

Background: Extensive research has shown that typically developing individuals show a bias in impulse control towards faces. In autism, prior work has also shown increased impulsivity towards happy faces. However, it is unknown whether other types of salient cues, such as hobbies or interests, elicit a similar bias.
Objectives: The aim of this study was to investigate impulse control and underlying neural mechanisms towards different types of salient stimuli in typical development to provide a foundation for future studies in autism. We expected participants would show a similar bias towards interests as they do towards social stimuli.
Methods: Forty typically developing adults (17 females) aged 23.4 (± 3.3) years performed a novel go-nogo task during fMRI. For the social conditions, participants were presented with happy and calm faces. For the interest conditions, participants chose their favorite (interest) and least favorite hobby/activity (non-interest) from 23 options. There were 5 runs of go-nogo pairs (blue vs. yellow, happy vs. calm, calm vs. happy, interests vs. non-interests, non-interests vs. interests). Participants were instructed to press to the target cue (go) when it appeared on screen and not press to the distractor cue (nogo). False-alarm rates were calculated as the number of erroneous button presses to the nogo cue in each of the five conditions.â€¨D-prime was calculated as the normalized hit rate (go-accuracy) – normalized false alarm rate. We used ex-Gaussian distribution parameters to characterize fast (mu and sigma) and slow (tau) reaction times (RT's).
Results: Go-accuracy did not differ between conditions, showing participants attended to the different conditions equally well. Linear mixed-effects model analysis showed main effects for false-alarm rate (p = .006), d-prime (p = .006), reaction times to go-stimuliÂ (p < .001), and the ex-Gaussian parameters mu (p < .001), and sigma (p < .001). Participants showed highest d-prime, lowest false alarm rate, and fastest RT's to colors. There were no differences between calm and happy faces on any of the measures however; d-prime was significantly higher for interests compared to non-interests (p = .042), suggesting increased control towards interests. To assess an overall bias for social stimuli, comparing the collapsed social stimuli (faces) against the collapsed objects (interests/non-interests), showed d-prime was lower (p = .024) for social stimuli. Ex-Gaussian parameter mu also showed slower reaction times (p< .001) towards social stimuli. As expected, dorsolateral prefrontal cortex (dlPFC) showed heightened activation during inhibition. We will further investigate how cognitive control networks are modulated by distinct salient stimuli.
Conclusions: As expected, typically developing adults were more impulsive towards social stimuli. Interestingly, the difference in d-prime between social and non-social stimuli was driven by higher d-prime towards interests, suggesting that, in contrast to our hypothesis, one's interest facilitates inhibition. Together these findings show impulse control is differentially modulated by distinct salient stimuli, which may be important for individuals with autism, where stimuli associated with their interests may interfere during impulse control. Future work examining the neural underpinnings of impulsivity to salient cues will constrain interpretations of the behavioral data.

95 **125.095** Increased Connectivity of Voice Processing Brain Networks in Females with Autism: A Preliminary Study of Gender Differences in ASD

A. E. Baker[1]*, A. Padmanabhan*[1]*, D. A. Abrams*[1] *and V. Menon*[2]*, (1)Stanford University, Palo Alto, CA, (2)Stanford University School of Medicine, Stanford, CA*

Background:
Autism spectrum disorders (ASD) are poorly understood in females. The incidence of autism is greater in males, but it is unknown whether this disparity is due to actual occurrence rate or a bias in diagnosis; the criteria for diagnosing ASD has been developed using data almost exclusively from studies of males, and symptoms of ASD often manifest differently in females. Some believe that, due to genetics and environmental factors, females are more likely than males to have characteristics that help them compensate for and mask symptoms of ASD.
Autism is characterized by a lack of engagement with social cues, a primary of which is speech. We have developed a model of human voice processing composed of the core voice processing system, anchored in the superior temporal sulcus (STS), and an extended voice processing network, encompassing reward and affective areas. Previous research in our lab has shown that children with ASD show underconnectivity between core and extended voice processing networks; however, it is unknown whether connectivity of the voice processing system in ASD varies across genders.
Objectives:
The objective of this study is to examine gender differences in connectivity of voice processing brain systems in high-functioning ASD.
Methods:
15 females and 15 males with high-functioning ASD (8-16 y/o) were matched on age, IQ, ADOS Social Affect score, and head motion in the scanner. All participants underwent resting-state fMRI scans. In addition, participants were administered an extensive battery of questionnaires and clinical and cognitive assessments to determine IQ and ASD diagnosis. Functional connectivity analyses were used to examine between-group differences in connectivity for bilateral posterior and anterior STS (i.e., core voice processing network) seeds.
Results:
Compared to males with ASD, females with ASD demonstrated increased connectivity between nodes of the core voice processing network and a wide array of brain systems, including (1) reward and affect processing regions, including the nucleus accumbens, ventral tegmental area, orbitofrontal cortex, and amygdala, (2) canonical language processing regions, instantiated in middle and superior temporal cortex, inferior frontal gyrus, and angular gyrus, and (3) key nodes of the salience network, including dorsal anterior cingulate and anterior insula. No voxels were greater for males compared to females with ASD.
Conclusions:
Preliminary results suggest that compared to males with ASD, females with ASD demonstrate increased connectivity between the core voice processing network and an extended network of brain regions, including regions implicated in reward, affective, language, and salience processing, providing initial indication that females and males with ASD may in fact utilize different brain mechanisms for processing social cues. Further analyses and larger participant samples are needed to properly investigate the interaction between gender and diagnosis and the role this interaction plays in connectivity patterns of voice processing brain networks.

96 **125.096** Investigating Reward Processing in the Longitudinal European Autism Project (LEAP) Cohort with Fmri

S. Baumeister[1], *C. Moessnang*[2], *N. Muller*[1], *S. Hohmann*[1], *D. Goyard*[3], *S. Baron-Cohen*[4], *S. Durston*[5], *A. M. Persico*[6], *W. Spooren*[7], *D. G. Murphy*[8], *E. Loth*[9], *J. K. Buitelaar*[10], *H. Tost*[2], *D. Brandeis*[1,11,12,13], *A. Meyer-Lindenberg*[14] *and T. Banaschewski*[15], *(1)Department of Child and Adolescent Psychiatry and Psychotherapy, Central Institute of Mental Health, Mannheim, Germany, (2)Department of Psychiatry and Psychotherapy, Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany, (3)Neurospin, CEA, Université Paris-Saclay, Gif sur Yvette, France, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Rudolf Magnus Institute of Neuroscience, University Medical Center Utrecht, Utrecht, NETHERLANDS, (6)University of Messina, Rome, ITALY, (7)Roche Pharmaceutical Research and Early Development, NORD Discovery and Translational Area, Roche Innovation Center, Basel, Switzerland, (8)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (10)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (11)Department of Child and Adolescent Psychiatry and Psychotherapy, Psychiatric Hospital, University of Zurich, Zurich, Switzerland, (12)Zurich Center for Integrative Human Physiology, University of Zurich, Zurich, Switzerland, (13)Neuroscience Centre Zurich, University and ETH Zurich, Zurich, Switzerland, (14)Central Institute of Mental Health, Mannheim, Mannheim, Germany, (15)Central Institute of Mental Health, University of Heidelberg, Heidelberg, GERMANY*

Background:
Studying reward processing in autism spectrum disorder (ASD) has so far yielded inconsistent results. Some previous studies have proposed impaired reward processing in ASD specifically regarding social reward, while others proposed a general reward processing deficit across social and monetary reward types, possibly differentiating ASD from other disorders. However, current evidence does not clearly support either of these hypotheses. This likely reflects the heterogeneity of the disorder, which has been insufficiently addressed due to small sample size, along with the unknown reliability of the measures.
Objectives:
To address these issues, the Longitudinal European Autism Project (LEAP) is using functional magnetic resonance imaging (fMRI) during reward processing (for general aspects of multi-site fMRI assessment and effects of all applied tasks see abstract by Moessnang et al.) alongside an extensive cognitive and neuropsychological task battery in a large cohort of patients with ASD as well as typically developing (TD) subjects.
Methods:
A social and a monetary reward processing task were designed, as part of a comprehensive fMRI task battery which allows for the inclusion of participants across a broad age and ability range (including those with mild intellectual disabilities). FMRI was performed at six European centers following standard operations procedures. A total of 635 subjects completed the social and 565 subjects completed the monetary reward task, with an overlap of 562 subjects completing both reward processing tasks. Subjects were aged 6-30 years, with 53% ASD and 69% male participants. Baseline assessment was performed between April 2014 and September 2016. First pass analyses have been performed using standard processing routines implemented in SPM12 (http://www.fil.ion.ucl.ac.uk/spm/).
Results:
Preliminary statistical analyses based on the General Linear Model revealed robust activation of the network of interest, while simple case-control differences did not pass the significance threshold ($p<0.05$, family-wise error corrected across the whole brain). However, region of interest (ROI) analysis of the ventral striatum yielded hypoactivation of the right ventral striatum in ASD patients during monetary reward anticipation ($F(1,430)=5.447$, $p=.020$) but not during social reward anticipation ($F(1,501)=2.249$, $p=.134$).
Conclusions: The LEAP cohort represents the largest European task-based fMRI data set on autism. The employed tasks proved reliable and successfully engaged functional activation of the reward processing circuit both during monetary and social reward anticipation. In line with some previous smaller studies, ROI analysis of ventral striatal activation yielded a significant difference between ASD patients and TD subjects during monetary reward, while there were no effects on the whole brain level. However, further thorough investigation of different sources of variance, including direct social/monetary task comparisons, between-site differences, symptom profiles and developmental effects, is required. Further, the analysis of functional activation during reward receipt, as well as connectivity-based measures may aid in deeper understanding of the autism phenotype.

97 **125.097** Measurement of Autistic Children's Brain Responses with Emotiv EEG

J. Brock[1], *A. Woolgar*[2] *and N. A. Badcock*[3], *(1)Macquarie University, Sydney, NSW, Australia, (2)Macquarie University, Sydney, Australia, (3)Cognitive Science, Macquarie University, Sydney, Australia*

Background: The Emotiv EPOC is a cheap, portable, wireless electroencephalography (EEG) headset designed originally for the computer gaming market. Set-up time is quick (approximately 5 minutes) and simply involves adjusting the position of 16 saline-soaked cotton pads on the participant's scalp. Recently, we have adapted the Emotiv system to record event-related potentials (ERPs) to visual and auditory stimuli. In validation studies with typically developing children and adults, we have shown that ERP waveforms measured using the Emotiv system are comparable to those recorded simultaneously using a research-grade NeuroScan EEG system (Badcock et al., 2013, 2015).
Objectives: In this study, our aim was to determine the feasibility of the Emotiv system for use with children on the autism spectrum
Methods: We tested nine 8- to 12-year-old autistic children on an auditory oddball task in which they listened to sequences comprised of 85% standard tones (1000 Hz) and 15% deviant tones (1200 Hz). Brain responses recorded using the Emotiv EEG system were compared to those of age-matched typically developing children tested using identical procedures as part of our validation study (Badcock et al., 2015).
Results: All nine autistic children were able to tolerate the testing procedures. The prominent N1 and P3 responses to the standard tone were comparable to those of typically developing children. Autistic children also showed a clear mismatch negativity, calculated as the difference between responses to the standard and deviant tones.
Conclusions: Results provide preliminary validation of the Emotiv EEG system for autism research. The rapid set-up time and comfort of the headset make it especially suitable for studies of children whose sensory issues might mean they were unable to participate in EEG research. Given its low cost, portability, and ease of use, the Emotiv system could also be used in clinical settings and in large-scale, multi-centre studies looking for EEG markers of autism subtypes.

98 **125.098** Mu Rhythm Suppression Reflects Mother-Child Face-to-Face Interactions: A Hyperscanning MEG Study

T. Ikeda[1], *C. Hasegawa*[2], *Y. Yoshimura*[2], *H. Hiraishi*[2], *Y. Minabe*[2] *and M. Kikuchi*[2], *(1)Kanazawa University, Kanazawa, Japan, (2)Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan*

Background:
Spontaneous face-to-face interactions between mothers and their children play crucial roles in the development of social minds. However, these inter-brain dynamics are still unclear. To better understand the inter-brain dynamics that occur during human interactions, it is necessary to research not only a single brain in isolation but two brains during a real interaction. Simultaneous multiple brain functional measurements may reveal the brain dynamics underlying social interactions.
Objectives:
We measured the mu suppression during face-to-face spontaneous nonverbal interactions between mothers and their children with autism spectrum disorder (ASD) using the dual magnetoencephalography (MEG) system.
Methods:
Fourteen children with ASD and their mothers participated in this experiment. They were diagnosed by a clinical psychiatrist and a clinical psychologist with more than 5 years of experience in ASD using the Autism Diagnostic Observational Schedule–Generic (ADOS), the Diagnostic Interview for Social and Communication Disorders (DISCO), and the DSM-5 criteria at the time that they entered into this study. We used a 160 channel MEG (MEG vision NEO, Yokogawa Electric Corporation) and a 151 channel MEG (PQ1151R, Yokogawa Electric Corporation/KIT). These MEG systems were housed in a magnetically shielded room. To measure the mother-child interactions in a face-to-face situation, we set up a real-time dual video presentation to show the facial expressions of the mother and child. Short movies and the other's facial expression with a live movie or a still picture were alternately displayed for 10 or 15 sec, respectively, on the half-mirror screen, while simultaneous, neuromagnetic recordings of their brain activities were performed.
Results:
The results demonstrated significant correlations between the index of mu suppression (IMS) in the right precentral area and the traits of ASD in 13 mothers and 8 children (Data from some children and a mother could not be obtained due to artifacts). In addition, higher IMS values (i.e., strong mu suppression) in mothers were associated with higher IMS values in their children. To evaluate the behavioral contingency between mothers and their children, we calculated cross correlations between the magnitude of the mother and child head-motion during MEG recordings. As a result, in mothers whose head motions tended to follow her child's head motion, the magnitudes of mu suppression in the mother's precentral area were large.
Conclusions:
Our results from this study demonstrated that the mu suppression level of ASD children and their mothers reflects their social ability or autistic traits and demonstrated a correlation between the mu suppression in the mothers and their children. Further studies with larger sample sizes, including both typically developing children and children with ASD, are necessary to test the reliability of these findings and support their generalization to interactions between typically developed mothers and typically developing children.

99 **125.099** Neural Correlates of Affective Processing in Adults with Autism Spectrum Disorder

R. Leung[1,2]*, E. W. Pang*[1,2]*, E. Anagnostou*[2,3,4] *and M. J. Taylor*[1,2]*, (1)Hospital for Sick Children, Toronto, ON, CANADA, (2)University of Toronto, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Hospital for Sick Children, Toronto, ON, Canada*

Background: The ability to perceive and interpret emotional faces, integral to successful social functioning, has been found to be impaired in ASD. Magnetoencephalography (MEG) is a non-invasive neuroimaging modality that provides high spatio-temporal resolution of neural activity. Previous MEG studies have shown atypical neural activity during affective face processing in youth with ASD but no studies to date have examined the neural substrates of this ability in adults with ASD.
Objectives: The present study explored the temporal and spatial properties of MEG activation during implicit angry and happy face processing in young adults with and without ASD. We hypothesized that adults with ASD would show atypical activity, particularly in social brain areas.
Methods: We recruited 52 young adults (ASD group: N=26, 8 females, 26.3+4.2 years; Control group: N=26, 8 females, 26.3+4.1 years) to complete an emotional face processing task in the MEG. Participants were presented rapidly (80ms) with an emotional face (happy or angry) concurrently with a scrambled pattern (target) on either side of a central fixation cross. Using a response button box, participants indicated the location (right or left) of the target by pressing the appropriate button. A 3T structural MRI was obtained for each participant for co-registration with MEG data for accurate source localisation. SPM12 was used for MEG data pre-processing and analysis. Empirical Bayes Beamformer estimated activation sources related to happy and angry face processing.
Results: Happy and angry faces elicited greater activation in adults with ASD, relative to controls, in a number of areas including bilateral inferior temporal gyri, bilateral fusiform gyri, and left parahippocampal gyrus. Adults with ASD also showed greater activity in key social processing areas such as the right anterior insula and anterior cingulate cortex. Of particular interest was our finding that, to angry faces specifically, adults with ASD showed greater right amygdala and left superior orbital activity, relative to controls. In contrast, in controls, angry and happy faces elicited greater, relative to adults with ASD, activity in areas including sustained activity in the left cuneus/precuneus and the right post-central gyrus. Furthermore, within group analyses showed more scattered activation patterns to both happy and angry faces in adults with ASD, compared to controls.
Conclusions: This study is the first to provide evidence of distinct patterns of atypical activation to happy and angry faces in adults with ASD using MEG. Differences in neural activity between young adults with and without ASD indicate atypical processing in neural areas involved in face perception, affect processing, threat processing, and emotion processing and social reward may account for deficits in atypical emotional processing in adults with ASD. Within group results suggest adults with ASD show more disorganised processing of emotions. Thus, atypical recruitment of neural regions may contribute to deficits in affective processing early on in young adults with ASD.

100 **125.100** Neural Correlates of Hand Gesture Imitation in Children with Autism Spectrum Disorder

R. Nicholas[1]*, E. Sharer*[2]*, N. Wymbs*[1]*, M. B. Nebel*[3]*, D. Crocetti*[1] *and S. H. Mostofsky*[1]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)University of Minnesota, Minneapolis, MN, (3)Johns Hopkins School of Medicine, Baltimore, MD*

Background: Motor skill and motor planning impairments are frequently observed in children with ASD, which is associated with impaired acquisition of social communication skills linked to poor imitation learning. Learning an action requires integration of sensorimotor information and encoding models to replicate the action and understand those actions when performed by others. Learning skilled gestures is particularly reliant on integration of visual and proprioceptive input, and may provide critical developmental foundations for social communication. Exploring the diagnostic differences in imitation and motor planning may provide insight into mechanisms of social communication deficits.
Objectives: We used a gesture imitation task to examine the neural correlates of motor planning and to investigate whether differential neural patterns of motor planning during imitative learning exist between typically developing (TD) and high functioning children with autism (HFA).
Methods: fMRI data were collected on 22 subjects, HFA (*N=10*) (9M, 10.89+/-1.20 years) and TD children *(N=12)*(9M, 10.29+/-0.98 years). Participants were trained to imitate a series of 14 videos of novel meaningless-gestures performed by an actor using her left hand, establishing a similar level of performance crucial for investigating diagnostic differences. Participants were instructed to observe the gesture, plan how to copy, copy the gesture with their right hand (mirror image), and rest, according to trained colour cues.
Results: Behavioural analysis showed comparable gesture accuracy performance between groups (HFA: 77.8%±8.00; TD: 85.7%±7.14, p=.972). Preliminary analyses reflect significant effect of diagnosis at the p<0.001 level using a 10 voxel cluster-level threshold. In the observe condition greater activation in bilateral sensorimotor areas was observed in the HFA group than the TD, although the difference was more apparent in the right hemisphere. In the plan condition, it was the TD group that shows greater activation in the postcentral gyrus. In copy condition, there was greater activation for the HFA group localized to the left posterior cingulate gyrus, the right parahippocampus and anterior insula, whereas TD showed greater activation in V3.
Conclusions: While behavioural analyses demonstrated comparable gesture imitation, imaging analyses revealed significant group differences in the neural activation during observation, motor planning and execution. During observe, the HFA children recruited areas in the right somatosensory region relating to the left hand not seen in the TD group. The TD children showed recruitment of similar sensorimotor areas when required to plan the gesture, but in the left hemisphere, recruiting areas related to the right hand, used in copying the gesture. This differential recruitment in timing and hemispheres suggests that HFA children may have a delayed visuomotor transformation, initially encoding the anatomical hand (left) before transferring to the mirror hand (right). In copy, the posterior cingulate gyrus, involved in motor imagery tasks, is recruited in the HFA group, indicating mental imagery processing that is not apparent in TD children. These results suggest differential motor planning processing in imitative learning in children with autism, and may help to explain behavioural observations of autism-associated impairments in imitative skills. Further study needs to be done to explore possible differences in imitative encoding timecourses in autism.

101 **125.101** Neural Correlates of Olfactory Dysfunction in ASD: Preliminary Results

F. Velasquez[1]*, M. Reilly*[1]*, J. Sweigert*[1]*, G. Greco*[1]*, F. Reitz*[2]*, T. St. John*[2]*, G. E. Davis*[3]*, A. Estes*[2]*, S. Dager*[4] *and N. M. Kleinhans*[5]*, (1)Radiology, University of Washington, Seattle, WA, (2)University of Washington Autism Center, Seattle, WA, (3)Otolaryngology, University of Washington, Seattle, WA, (4)University of Washington School of Medicine, Seattle, WA, (5)University of Washington, Seattle, WA*

Background: Sensory abnormalities are prevalent in autism spectrum disorder (ASD) and may be an important predictor of ASD severity in various domains of dysfunction. Although olfaction is not the most commonly affected sense in ASD, atypical olfactory processing is the most predictive of ASD severity and is more prevalent in ASD than in other neurodevelopmental disabilities. Despite its shared neural substrates with primary emotion areas including the amygdala and orbital frontal cortex (OFC), the olfactory system is under-studied in fMRI research in relation to other sensory systems.
Objectives: To gain further understanding of the neural basis behind olfactory processing differences in ASD we hypothesized that school-aged children with ASD would exhibit increased activation of primary and secondary olfactory areas (OFC, amygdala, piriform cortex) compared to typically developing (TD) children and children with sensory processing challenges without ASD (SPC). Our second hypothesis was that greater Blood-Oxygen-Level Dependent (BOLD) responses in primary and secondary processing areas, independent of diagnosis, would be related to poorer olfactory function.
Methods: Â Eight children with ASD (Age M = 11.24, SD=1.6), ten typically developing (TD) (Age M = 9.61 SD=1.34) and eleven children with sensory processing challenges (SPC; Age M = 10.61 SD=1.5) were studied. Olfactory function was tested using the University of Pennsylvania Smell Identification Test (UPSIT). T1-weighted 3DMPRAGE and fMRI data were acquired on a 3T Philips Achieva scanner. During the fMRI, we exposed our participants to a rose-like odorant (phenyl ethyl alcohol), in four, 9 second blocks separated by at least 30 second intervals of air using a respiration-triggered odor paradigm. We tested for whole-brain group differences in activation in response to olfactory stimuli, and compared the relationship between brain activation and olfactory function using a fixed-effects model in FSL's FEAT Software.
Results: Â Participants with ASD yielded significantly greater OFC activation than TD participants (ASD>TD: Left OFC, *Z*-Max = 4.69, *p*=0.0085; Right OFC, *Z*-Max = 5.31, *p*<0.001; Figure 1A) as well as participants with SPC (ASD > SPC: Left OFC, *Z*-Max = 5.27, *p*<0.001; Right OFC, *Z*-Max = 5.34, *p*<0.001; Figure 1B). No significant group differences were observed in the amygdala or piriform cortex. We found a negative correlation between OFC activation and UPSIT score across the groups (Left OFC, *Z*-Max = 4.61, *p*=0.0017; Right OFC, *Z*-Max = 5.34, *p*=0.0014; Figure 2).
Conclusions: Children with ASD displayed greater bilateral OFC activation than children in both comparison groups, partially supporting our first hypothesis of ASD hyperactivation in olfactory areas. Additionally, we found a relationship between greater OFC activation and poorer olfactory function. Together, these results highlight the possibility that measures of olfactory functioning are sensitive to OFC dysfunction in ASD, which is consistent with the OFC's role in odor identification. Further, these results indicate that our method shows promise as an early diagnosis biomarker, as odor perception can be measured safely using fMRI with neonatal subjects. Data collection is ongoing and we aim to validate the current preliminary findings and further characterize the role of OFC dysfunction, as well as related neural circuitry, in ASD.

102 **125.102** Neural Mechanisms Underlying Visuospatial Expertise in ASD

V. D. Therien[1]*, D. Luck*[2] *and I. Soulières*[3]*, (1)University du Québec à Montréal (UQAM), Terrebonn, QC, CANADA, (2)University of Montreal, Montreal, QC, Canada, (3)University of Quebec in Montreal, Montréal, QC, Canada*

Background: Â Visuospatial strengths have been well documented in a large proportion of individuals with autism spectrum disorders (ASD). Brain mechanisms underlying visuospatial abilities have been investigated in previous studies, revealing higher activation in occipito-parietal regions and diminished activation in some frontal regions in ASD (Kana et al., 2013; McGrath et al., 2012; Silk et al., 2006). However, no such studies have investigated the brain correlates underlying superior visuospatial abilities in distinct subgrouping of ASD individuals based on their visuospatial abilities.
Objectives: Â The principal goal of this study was to uncover the neural network involved in visuospatial abilities and expertise in ASD in different subgrouping based on their Wechsler Block Design subtest's performance using functional magnetic resonance imaging (fMRI) technique.
Methods: Forty ASD male participants, 20 of them having enhanced visuospatial skills (defined as relative strength on Block Design subtest) (Wechsler, 2008), and 20 non-ASD male participants (age 18-37) matched on age and IQ will perform two visuospatial tasks in the fMRI scanner. The first task is an adaptation of the original Block Design subtest (BD) suitable for presentation in the MRI scanner. Perceptual cohesiveness of the target design is parametrically varied across the 90 trials. The second task is a classic mental rotation (MR) task with three-dimensional shapes. 104 pairs of images were presented with four different spatial orientations (0, 70, 140 and 180 degrees). Both tasks are presented in an event-related design, with percentage of correct responses and response time recorded. Preliminary results include 23 ASD participants, 10 of them having enhanced visuospatial skills, and 16 non-ASD subjects.
Results: Despite no differences in accuracy and response time across the three groups, ASD participants displayed greater activity in anterior prefrontal cortex (PFC) in both tasks compared to non-ASD participants. Furthermore, the MR task revealed higher activation in superior and inferior frontal gyri, superior parietal lobule and cerebellum in ASD participants compared to non-ASD participants, whereas the adapted BD subtest revealed higher activation in the right superior and middle temporal gyri and the left anterior cingulate gyrus in ASD participants. Non-ASD participants showed higher activation in supplementary motor area, and in primary motor and sensory areas in the MR task. Further analyses compared the brain correlates of ASD with and without superior visuospatial abilities. Higher activation in bilateral ventrolateral PFC was observed in the ASD group without superior visuospatial abilities while performing the adapted BD task, whereas higher activation in some occipital, parietal and temporal regions was observed for the ASD group with superior visuospatial abilities during the MR task.
Conclusions: Our preliminary results are inconsistent with previous results showing lesser activation in some frontal regions in ASD while processing visuospatial information (McGrath et al., 2012). Furthermore, despite equivalent performance, increased parietal and occipital activity in ASD individuals with superior visuospatial abilities compared to those without may suggest enhanced functional resource allocation in regions dedicated to visuospatial processing and expertise. Diminished prefrontal activity in ASD individuals with superior visuospatial abilities may suggest more efficient visuospatial processing requiring less cognitive control resources.

103 **125.103** Neural Mechanisms of Social Prediction Errors in Adolescents with ASD

J. K. Kinard[1], *M. Addicott*[2], *M. G. Mosner*[3] *and G. S. Dichter*[3], *(1)University of North Carolina - Chapel Hill, Cary, NC, (2)Duke University, Durham, NC, (3)University of North Carolina - Chapel Hill, Chapel Hill, NC*

Background: This study investigated the neural mechanisms of social prediction errors using functional magnetic resonance imaging (fMRI) in adolescents with and without autism spectrum disorder (ASD). Prediction errors occur when outcomes differ from expectations and are critical to reward learning. When expectations are violated, predictions are updated to maximize the potential for future rewards (Schultz, 2015). Prediction errors are reflected in neuronal activity in the mesolimbic dopaminergic system when better-than-expected and worse-than-expected rewards are received (Daniel & Pollmann, 2014; Schultz, 2015). Social prediction errors occur when expectations about social outcomes are violated, facilitating the updating of future predictions about social reward (Ruff & Fehr, 2014). It is possible that disruptions in neural mechanisms of social prediction errors contribute, in part, to social interaction deficits of individuals with ASD. Although there is growing functional neuroimaging literature addressing reward processing deficits in ASD (Chevallier, Kohls, Troiani, Brodkin, & Schultz, 2012), most studies have addressed reward anticipation or receipt, but almost none have addressed social prediction errors in ASD. It is critical to examine social prediction errors in ASD, since this neural system is critical for social learning.
Objectives: To compare blood oxygen level dependent (BOLD) signals among adolescents with and without ASD during a social prediction error task.
Methods: The sample included 41 12-to-17-year-olds: 21 with high-functioning ASD and 20 with typical development (TD). Prior to the scan, participants were taught to press a "check" every time they saw a symbol (i.e., "cue 1") that predicted a clear image and an "x" every time they saw a different symbol (i.e., "cue 2") that predicted a blurry image. In the scanner, participants saw images of smiling faces (i.e., social reward) or blurry faces (i.e., non-reward) across two 7-minute runs. In 20% of trials, the images violated expectations (i.e., "cue 1" predicted a blurry face, rather than a clear face as expected; "cue 2" predicted a clear rather than blurry face). Analyses focused on group differences with respect to the contrast between expected and unexpected reward outcomes, which are known to elicit prediction error signals in the midbrain, striatum, and prefrontal cortex (Ramnani, Elliott, Athwal, & Passingham, 2004),
Results: Data collection is complete and analysis is ongoing. Preliminary analyses found that the TD group demonstrated increased activation in the right inferior frontal gyrus compared to the ASD group when expectations were violated, whereas the ASD group demonstrated increased activation in the right frontal pole. When outcomes were as expected, the TD group demonstrated increased activation in the right frontal pole, whereas the ASD group exhibited increased activation in the left inferior frontal gyrus. Ongoing analyses will examine functional connectivity differences between groups, as well as relations between brain imaging metrics, task related behavior, and ASD symptom severity.
Conclusions: Preliminary results indicate differential activation in prefrontal cortical regions that are critical for eliciting prediction error signals in adolescents with ASD. These differences may provide a mechanistic account of disrupted social reward learning in ASD and contribute to the literature addressing reward processing deficits in ASD.

104 **125.104** Neural Theory-of-Mind Mechanisms and Their Relations to Children's Social Functioning

C. E. Mukerji[1,2], *S. H. Lincoln*[3], *A. V. Torricelli*[4], *S. Hasselmo*[5], *N. Kleeman*[1], *C. I. Hooker*[6] *and C. A. Nelson*[2], *(1)Harvard University, Cambridge, MA, (2)Boston Children's Hospital, Boston, MA, (3)McLean Hospital/Harvard Medical School, Boston, MA, (4)Rutgers University, New Brunswick, NJ, (5)Child Study Center, Yale University, New Haven, CT, (6)Rush University Medical Center, Chicago, IL*

Background: Theory of mind (ToM), the ability to reason about others' mental states, is a core facet of social cognition implicated in autism spectrum disorder (ASD). Neuroimaging evidence indicates that adolescents and adults with ASD show atypical activation in the neural ToM network during mental state reasoning. In addition, a recent study suggests that activation in the right temporoparietal junction (rTPJ), a key node of the ToM network, is linked to ASD symptom severity. Although influential developmental theories posit that ToM is central to social understanding and functioning, the relations between neural ToM mechanisms and the broad spectrum of empathy and social ability observed across typical (TD) and atypical child development remain unclear.
Objectives: This study aimed to (a) identify neural activation specifically elicited by ToM reasoning and to (b) elucidate relations between these neural ToM mechanisms and individual variation in children's socioemotional functioning. We predicted that TD children would demonstrate enhanced activation at key nodes of the ToM network (i.e., bilateral TPJ and precuneus) during mental state reasoning. Moreover, we hypothesized that the strength of this activation would be associated with individual variation in children's empathy and social functioning.
Methods: Participants were 32 TD children between 9 and 13 years old. Functional neuroimaging (fMRI) data were collected on a 3T scanner while participants completed a false belief task developed for children. In the experimental (ToM) condition, children listened to vignettes describing social scenarios and then evaluated characters' beliefs. In the control condition, they listened to non-social scenarios and then made inferences about physical causality. Children also completed a behavioral measure of empathy (Interpersonal Reactivity Index), and parents completed measures assessing multiple facets of their children's social abilities (Social Responsiveness Scale, 2nd edition) and competence (Child Behavior Checklist).
Results: Â Whole-brain analyses indicated enhanced activation to ToM reasoning versus the control task at key nodes of the ToM network, including the bilateral temporoparietal junction (rTPJ and lTPJ) and precuneus (p<.05, FWE-corrected). Controlling for age, greater activity in the bilateral TPJ correlated with reduced empathic concern for others (rTPJ: ρ=-0.46, p=0.01; lTPJ: ρ=-0.46, p=0.01) and poorer social competence (rTPJ: ρ=-0.56, p=0.03; lTPJ: ρ=-0.52; p=0.04). In addition, greater activity in the precuneus (ρ=0.48, p=0.02) and lTPJ (ρ=0.41, p=0.06) correlated with diminished social awareness.
Conclusions: During mental state reasoning, children engaged a distributed ToM network previously identified in adults. Moreover, greater activation in the TPJ and precuneus was associated with poorer socioemotional functioning, suggesting that reduced efficiency of ToM regions is linked to difficulties in empathy and social functioning among school-age children. These findings have important translational implications for understanding social deficits in children with ASD: dysregulation of ToM network activation may be a core neural mechanism underlying impaired social understanding and interaction. Our results also indicate that neural ToM mechanisms index individual variation in socioemotional behavior, demonstrating value as a biological metric of functional heterogeneity in social development. Ongoing connectivity analyses explore relations between functional integration of the ToM network during mental state reasoning and variation in children's social cognition and functioning.

105 **125.105** Neural and Attentional Indices of Joint Attention in ASD

A. Naples[1], *S. A. A. Chang*[2], *M. J. Rolison*[3], *S. Hasselmo*[4], *T. A. Halligan*[4], *B. Lewis*[5], *T. C. Day*[3], *K. A. McNaughton*[3], *K. Ellison*[3], *J. Wolf*[6], *K. Stinson*[7], *J. A. Trapani*[3], *J. H. Foss-Feig*[8], *E. Jarzabek*[3], *T. McAllister*[3] *and J. McPartland*[3], *(1)Yale School of Medicine, New Haven, CT, (2)Yale University, New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Child Study Center, Yale University, New Haven, CT, (5)Yale School of Medicine, Darien, CT, (6)Yale Child Study Center, New Haven, CT, (7)Yale University- Child Study Center, Milford, CT, (8)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Decreased joint attention is a symptom of autism spectrum disorder (ASD) commonly observed in clinical contexts. However, lab-based investigations have yielded inconsistent findings using both brain and behavioral measures. Prior research on gaze perception in ASD has focused on passive observation of social information, failing to address the interactive nature of joint attention. This research has identified atypicalities in event-related potential (ERP) and eye-tracking indices of gaze processing in individuals with ASD, but it is unclear how brain activity and attention unfold within interactive contexts.
Objectives: We developed an interactive neuroscience experiment to assess: (1) brain activity during simulated joint attention tasks in individuals with ASD; (2) visual attention and its relationship to brain activity during an interaction; and (3) the relationship of brain activity and attention to social function.
Methods: EEG was recorded from adolescents with ASD (N=33, mean age=14.15, mean IQ=112) and TD controls (N=31, mean age=14.4, mean IQ=110) using a 128 electrode net. ET was simultaneously recorded at 500hz and enabled the experiment to respond to the participants' gaze, simulating a social interaction. When participants looked at an onscreen face, it responded by returning gaze to the participant or looking to a treasure chest target in one of four corners of the screen. If the participant maintained eye contact with the onscreen face, they were rewarded with the face reciprocally smiling. If they followed gaze to the treasure chest, they were rewarded by the chest opening and showing a jewel. ERPs were time-locked to joint attention bids from the onscreen face (averted gaze or eye contact) and feedback (smiling faces, jewels).
Results: Preliminary analyses indicated that individuals with ASD displayed differential patterns of brain activity and attention during interactions. Individuals with ASD were slower to look to cued targets [t=-2.6, p=.008] and exhibited larger P100s to non-social feedback [F(41)=5.79, p=.021], suggesting differential patterns of anticipation. Temporally subsequent brain activity revealed that both groups displayed greater response to social feedback at the P200 [F(41)=8.58, p=.006] and P300 [F(41)=13.558, p=.001]. This activity was correlated with social function across groups such that reduced neural sensitivity to social reward predicted poorer social function on the Social Responsiveness Scale [r=.37, p=.033] and the Child Behavior Checklist [r=.44, p=.009]. Analyses in progress incorporate pupil dilation and oscillatory activity.
Conclusions: In an interactive social context, individuals with ASD exhibited atypical patterns of anticipation and response as measured by both brain activity and eye-tracking. Overall, both groups showed similar patterns of brain activity in response to social and non-social feedback, suggesting preserved basic mechanisms across groups. However, variability in phenotype predicted differential brain response, reflecting the importance of individual differences across groups. These findings demonstrate that interactive neuroscience approaches occupy a fruitful middle ground between passive experimental measures and unconstrained clinical contexts, and reveal meaningful relationships between clinical heterogeneity and well-specified markers of brain activity.

106 **125.106** Neural and Behavioral Responses in an Executive Functioning Task Predict Social Communication Symptoms in Children with Autism Spectrum Disorder

J. Buirkle[1], *T. Clarkson*[2], *A. Vaidyanathan*[3] *and S. Faja*[1], *(1)Boston Children's Hospital, Boston, MA, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Developmental Medicine, Boston Children's Hospital, Boston, MA*

Background: Underlying many of the social and cognitive symptoms exhibited in individuals on the autism spectrum is a deficit in executive functioning (Robinson, 2009). Executive functioning is defined as the ability to manage complex problems in the service of a goal. This skill involves the inhibition of conflicting information, decision-making, and shifting of attention. Impairments in these cognitive capacities are often observed in ASD, and can have direct implications for the ability to successfully navigate social situations. Little research has been done on whether specific neural components elicited during executive functioning tasks can predict the social deficits exhibited in ASD.
Objectives: To assess the correlation between inhibitory control, a core domain of executive functioning, and social communication symptoms in children on the autism spectrum, using behavioral and electrophysiological data.
Methods: 72 children with ASD were recruited from the University of Washington and Boston Children's Hospital for participation in this study. Children ranged from 7 to 11 years old (64 males; 8 females) with a minimum IQ of 80 measured using the WASI-2 (Wechsler, 2011), and diagnosis was confirmed through DSM-V criteria (American Psychiatric Association, 2013) after administration of the ADOS-2 (Gotham, Risi, Pickles, & Lord, 2007) and the ADI-R (Rutter, Le Couteur, & Lord, 2003). Parents completed the Social Responsiveness Scale (SRS), the Social Skills Improvement System (SSIS), and a Vineland-II interview on behalf of their child. To measure inhibitory control, both percent accuracy and reaction times were recorded during a flanker task called the Attentional Network Task (ANT). Electrophysiological recordings were also collected during this task to examine the N2 and P3 ERP components. Difference scores for both ERP amplitude and latency were computed for each of these components by taking ERP cluster averages for congruent trials, and subtracting from the incongruent trial average. Larger difference scores suggest more effortful processing for the more difficult incongruent trials of this task.
Results: Linear regression analyses were performed controlling for age, IQ, and gender. Severity scores on the ADOS Social Affect subdomain were predicted by percentage of correct incongruent trials (R^2_{change} =.0552, t(72)=-2.094, p=.040), and reaction time for correct congruent trials (R^2_{change}=.049, t(72)=2.029, p=.046), such that more severe social symptoms correlated with poorer performance. Percentage of incongruent trials also predicted scores on the SRS (R^2_{change} =.191, t(65)=-3.846, p=.000), The amplitude of the N2 component predicted scores on the Social Engagement domain of the SSIS (R^2_{change}=.106, t(54)=2.501; p=.016).
Conclusions: The severity of social symptoms in our population of children with ASD was predicted by both behavioral performance and specific ERP components in an executive functioning task measuring inhibition. Poorer performance and slower reaction times in this task, as well as larger differences for N2 amplitudes between congruent and incongruent trials, was associated with greater deficits in social communication. The ability to inhibit conflicting or interfering information is an aspect of executive functioning vital to communicating and interacting with others in one's environment, and our findings suggest a neurological source for these social deficits in children with ASD.

107 **125.107** Observation of Goal-Directed Social Actions in Individuals with Autism Spectrum Disorders

***M. A. Krol**, Psychological & Brain Sciences, Boston University, Boston, MA*

Background:
The mirror neuron system (MNS), which becomes active during both action execution and action observation, is assumed to be involved in processing social information. Social communicative symptoms related to autism spectrum disorders (ASD) have been proposed to result from impairments in the MNS, however mixed results were found by previous studies.
Objectives:
To the best of our knowledge, this is the first study to compare modulations of MNS activity by the social relevance of observed actions in typically-developed young adults and in young adults with ASD.
Methods:
Participants
In the present study 20 individuals with an official diagnosis of ASD (M = 19.8 years) and 25 typically-developed (TD) individuals (M = 21.8 years) were included. ASD diagnoses were confirmed by administrating the ADOS-2 module 4.
Stimuli and procedure
Electroencephalography (EEG) recordings were obtained during the observation of video clips depicting two actors playing a simple card game governed by a set of rules, which were explained to the participants prior to the experiment. Four conditions that differed in social relevance were presented: dyadic, social, individual, and no action (baseline). Mu suppression, power reduction in the 8-13 Hz frequency band at the sensorimotor areas, was taken as index for MNS activity.
Results:
The TD group demonstrated significant mu suppression during the observation of the three types of actions and not during the observation of a still image. The degree of mu suppression was similar for the different action conditions, though increased mu suppression was found in the dyadic action condition compared to the social action condition. In contrast to the TD group, the ASD group did not show significant mu suppression during the observation of the three different actions. Due to the absence of mu suppression in all action conditions, no modulation by social relevance was detected.
Conclusions:
Based on the current findings it can be concluded that individuals with ASD might have a dysfunctional MNS, which contributes to our understanding of neurological impairments related to ASD. The indication that the MNS is not activated during the observation of both simple individual actions and more complex dyadic actions, suggests a global, rather than a specific, deficit of the MNS in individuals with ASD. The proposed link between ASD and a dysfunctional MNS could lead to new approaches for diagnosing and treating ASD. For example, therapy using imitation techniques could be an effective form of treatment in infants and children with ASD to stimulate the MNS at an early age.

108 **125.108** Reduced Neural Activity in the Action Observation and Mentalizing Network in Children and Adolescents with Autism Spectrum Disorder during Execution, Imitation and Mentalization of Social and Motor Actions

***E. Kilroy**[1,2], L. A. Harrison[1,2,3], A. Concha[1], E. J. Goo[1], C. Butera[1], S. A. Cermak[1] and L. Aziz-Zadeh[1,2], (1)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Brain and Creativity Institute, Dornsife College of Letters, Arts and Sciences, University of Southern California, Los Angeles, CA, (3)California Institute of Technology, Pasadena, CA*

Background: A growing body of literature suggests that children with ASD often have motor deficits and that these deficits may be related to social skills in ASD (Dziuk, 2007). Previous imaging work has shown that motor system networks (e.g., Action Observation Network (AON)) play a role in supporting intention understanding as well as imitation (Iacoboni, 2005). It is thus possible that mechanisms underlying motor impairments contribute to social deficits in ASD. To our knowledge, no study to date has investigated social and motor neural processing in ASD across a spectrum of social-motor stimuli.
Objectives: (1) To assess neural differences in children with and without ASD while they observe, execute, imitate and mentalize social and motor actions. (2) To assess how these differences may be related to group differences in social and motor skills assessed with the Social Responsiveness Scale (SRS; Constantino, 2003) and the Sensory Integration and Praxis Test (SIPT; Ayres, 1988).
Methods: Six high-functioning children and adolescents with ASD (mean age [years] 11.26±1.09) and ten typically developing (TD) participants (mean age [years] 11.25±1.41) were recruited. Imaging data was collected on a 3-T Siemens MAGNETOM Prisma scanner. The imaging protocol included a T1-weighted structural and standard EPI scans. In the scanner, participants observed, executed, imitated and mentalized separately to three video stimuli conditions: (1) emotional expressions (i.e., Happy), (2) Non-Emotional expressions (i.e., wiggle nose) and (3) hand actions (i.e., cutting paper). Using a block design, each condition was randomly presented for 15-seconds followed by 15-seconds of rest. Standard preprocessing and motion scrubbing were performed. Direct comparisons between groups were made in regions of the AON (i.e., Inferior frontal gyrus; IFG). The degree of social and motor skills was analyzed to determine group differences in ability.
Results: TD and ASD groups showed no group differences in AON activation when observing social and motor actions. However, during the motor action tasks, the ASD group showed reduced activity in IFG compared to the TD group (bilateral during execution and left lateralized during imitation (p<.054)). During mentalizing, ASD participants showed decreased recruitment of action understanding regions; the left IFG (p<.039) and temporal parietal junction (TPJ; p<.078) when processing the most novel stimuli (non-emotional faces) and the most social stimuli (emotional faces), respectively. Groups differed behaviorally in motor (p<.002) and social skills (p<.001).
Conclusions: Our results support previous findings of behavioral and neural motor processing deficits in ASD. Specifically, these data suggest an impairment in the AON which may be related to sensory-motor mapping in the IFG. Differences observed in the hand conditions may be driven by the execution of hand actions since group differences were not seen during observation of the actions alone. Our mentalizing findings concord with the theory that left IFG activation during mentalizing may underlie communication disorders in ASD (Kleinhas, 2008) and TPJ activation with more social processing deficits. Ongoing analysis will continue to investigate these findings and make direct comparisons of brain function and behavioral characteristics associated with the AON.

109 **125.109** Representational Similarity Between Non-Symbolic and Symbolic Numerical Stimuli in High Level Visual Areas Is Uniquely Related to Individual Differences in Arithmetic Skills in Children with Autism

S. G. Mitsven[1], *T. Iuculano*[1] *and V. Menon*[2], *(1)Stanford University School of Medicine, Palo Alto, CA, (2)Stanford University School of Medicine, Stanford, CA*

Background: Recent findings have shown that while solving arithmetic problems, children with Autism Spectrum Disorders (ASD) display a unique pattern of brain organization that differs significantly from their Typically Developing (TD) peers (Iuculano et al., 2014). However, proficient arithmetic skills develop from more fundamental abilities. These include representing and manipulating different types of numerical information, such as arrays of dots (i.e., non-symbolic format) or pairs of Arabic digits (i.e., symbolic format) (Butterworth, 2003). Currently, nothing is known about how children with ASD process these basic numerical stimuli. Crucially, successful mapping between non-symbolic and symbolic stimuli has been proposed to be a strong predictor of arithmetic skills during typical development (Hiniker et al., 2015; Ansari, 2008).
Objectives: Here we investigate whether (i) children with ASD exhibit a unique pattern of neural mapping between non-symbolic and symbolic stimuli, compared to TD children; (ii) a higher degree of representational similarity between these two stimulus-types is related to individual differences in arithmetic skills in children with ASD.
Methods: Â We assessed a group of children with ASD (N =25; M_{age} = 10.55, SD = 1.36; 23 males; IQ = 109.96) and a matched group of TD children (N = 25; M_{age} = 10.07, SD= 1.35; 21 males; IQ = 112.12). ASD diagnosis was determined using the Autism Diagnostic Interview- Revised (ADI-R) and/or the Autism Diagnostic Observation Schedule (ADOS). A subtest of the Woodcock-Johnson III Tests of Achievement (Woodcock et al., 2001) battery was used to assess math proficiency in each participant. All children participated in a functional Magnetic Resonance Imaging (fMRI) session where they were asked to select the larger of two quantities, which were presented either in a non-symbolic or symbolic format. We used Representational Similarity Analysis (RSA; Kriegeskorte et al., 2008) to examine the degree of similarity between multivariate patterns of activity for non-symbolic and symbolic stimuli in both groups.
Results: At the behavioral level, performance did not differ between ASD and TD children during the non-symbolic or symbolic comparison tasks. At the neural level, children with ASD showed greater RS values between non-symbolic and symbolic stimuli than TD children in multiple brain regions that support successful numerical manipulations (Ansari, 2008). These included the dorsal and ventrolateral prefrontal cortices, the intraparietal sulcus, and the fusiform gyrus. TD children did not display any regions of greater RS values, compared to children with ASD. Importantly, higher representational similarity between non-symbolic and symbolic stimuli in the right fusiform gyrus significantly predicted better arithmetic skills in ASD (r = 0.48, p = 0.02). This was not evident in TD children.
Conclusions: These results suggest that children with ASD display a unique neural mapping between non-symbolic and symbolic stimuli, compared to TD peers. Critically, these findings support the idea that high level visual processing areas, particularly the fusiform gyrus, play a crucial role in the successful development of arithmetic skills in ASD.

110 **125.110** Resting Gamma Power Predicts Language Ability in Infants at Risk for ASD

X. A. Tran[1], *A. Miquelajauregui*[1], *J. Frohlich*[2] *and S. S. Jeste*[1], *(1)UCLA, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

Background: High frequency electrophysiological oscillations (gamma band: 30-50 Hz) are involved in binding local neural circuitry during language and cognitive processing (Basar 2013). During typical development, spontaneous gamma oscillations increase between 3-4 years of age and peak at 4-5 years (Takano 1998). While higher gamma power during toddlerhood has been shown to predict greater language and cognitive abilities (Gou 2011), the development and significance of gamma power in the first year of life, in the context of typical development and autism risk, is unknown. Infants are at high risk (HR) of developing ASD if they have an older sibling with ASD. Given the high rates of language difficulties in HR infants (Messinger 2013), early predictors of language development are important to establish.
Objectives: To examine whether baseline EEG power in the gamma frequency band measured at 6 months of age predicts language abilities at 12 and 18 months in infants who are at high risk (HR) and low risk (LR) of developing ASD. We hypothesized that higher gamma power will correlate positively with later language abilities, with a stronger positive correlation in LR infants compared to HR infants.
Methods: Â The sample included 28 HR infants and 17 LR infants. EEG was recorded at 6 months and behavioral testing was conducted at 12 and 18 months (m12, m18) using the Mullen Scales of Early Learning (Mullen) and MacArthur-Bates Communicative Development Inventory (MCDI). Baseline EEG was recorded using a high-density system for 2 minutes while infants watched a video of bouncing soap bubbles. EEG data were processed using Net Station 4.4.5 software (McEvoy 2015), and independent component analysis was done using EEGlab. Relative spectral power for gamma frequency band was calculated using Welch's method and averaged across 3 frontal regions.
Results: Â HR and LR infants did not differ in frontal gamma power. LR infants trended towards having higher language scores than HR infants, but the difference was not significant (Table 1). When HR and LR groups were combined together as one cohort, frontal gamma power did not correlate with language scores. Within the HR group, frontal gamma power positively correlated with m12 Mullen verbal developmental quotient (DQ), m18 Mullen verbal DQ, m18 Mullen receptive and expressive language, and m18 MCDI words understood. In the LR group, frontal gamma power did not correlate with language scores (Table 2).
Conclusions: Findings in the HR group support our hypothesis that higher gamma power positively relates to later language abilities. Our study is the first to examine the relationship between baseline gamma power and language ability in early infancy. In our HR infants, we replicated the positive correlation between baseline frontal gamma power and language ability as was shown previously by Gou *et al* in typically developing toddlers. Lack of differences in frontal gamma power between HR and LR groups suggest that at 6 months of age, differences in high frequency cortical activity between these two groups have not emerged. Lack of significant findings in the LR group may be due to inadequate statistical power due to sample size.

111 **125.111** Social Reward and Alpha Asymmetry in ASD

K. K. Stavropoulos[1] *and L. J. J. Carver*[2]*, (1)University of California - Riverside, Riverside, CA, (2)University of California San Diego, La Jolla, CA*

Background: The social motivation hypothesis posits that individuals with autism spectrum disorder (ASD) are less motivated to socially engage because they find interactions less rewarding than their typically developing (TD) peers. Our previous work corroborated this by measuring neural activity during reward anticipation (Stavropoulos & Carver, 2013; 2014). Our studies focused on event-related potentials (ERPs), which provided information about the timing of neural activity. Electrophysiology data also provides information about oscillatory patterns. Of particular relevance is activity in the alpha band (8-12Hz). Reduction in alpha is thought to reflect increased engagement, and left-hemisphere dominant alpha asymmetry (more left activation than right) is hypothesized to reflect approach motivation and reward.

Objectives: The current investigation measured alpha asymmetry during reward anticipation. We performed novel EEG analyses on brain activity in children with and without ASD (Stavropoulos & Carver, 2013). In this study, children were presented with reward indicators accompanied by face or non-face stimuli. Non-face stimuli were comprised of scrambled faces in the shape of arrows.

Methods: Participants were 6-8 year-old children with (n = 20) and without (n = 20) ASD. EEG data in the alpha band (8-12Hz) was extracted using EEGlab. Data were analyzed from four sets of left/right hemisphere (L/RH) electrodes in frontal, central, parietal, and temporal locations. To measure alpha asymmetry, log values from LH electrodes were subtracted from comparable RH electrodes for each location (frontal, central, parietal, temporal). ANOVAs were conducted on each location separately with Condition as a within-subjects variable, and Group as a between-subjects variable.
Results: A significant Condition x Group interaction was observed for temporal electrode locations (p = .053). Follow-up tests revealed (1) marginal effects of condition in the ASD group (p = .058); ASD children demonstrated greater LH activation for the arrow versus face condition, and (2) a marginally significant effect of the face condition between groups (p = .066); TD children evidenced greater LH activation when anticipating faces compared to children with ASD. Finally, we explored correlations between severity of ASD symptoms and alpha asymmetry in temporal electrodes. A significant correlation was observed between alpha asymmetry in the arrow condition and ADOS severity score (p= .01), Figure 1. Children who evidenced greater LH activation for the arrow condition had more severe symptoms of ASD.
Conclusions: We provide novel evidence that alpha activity during reward anticipation is different in children with and without ASD. Children with ASD evidenced more left-dominant activation when anticipating rewards accompanied by arrows compared to rewards accompanied by faces. Given that actual rewards were the same in both conditions, we suggest that children with ASD experience more approach-motivation prior to non-social versus social stimuli. Interestingly, this difference is correlated with symptom severity. Finally, TD children evidenced more left-dominant activation when anticipating social stimuli compared to children with ASD. Taken together, the findings support the social motivation hypothesis, and extend it by suggesting that children with ASD may have *too much* non-social motivation, which comes at the expense of social motivation.

112 **125.112** Spontaneous Alpha Oscillations Stratify Children Across the Autism Spectrum Based on Cognitive Ability

A. H. Dickinson[1,2]*, C. DiStefano*[3] *and S. S. Jeste*[2]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA*

Background:
Electroencephalography (EEG) measures of spontaneous brain oscillations hold particular promise for improving our understanding of the neurobiological bases of the clinical heterogeneity observed in autism spectrum disorders (ASD). Of particular relevance within the EEG signal are spontaneous alpha oscillations. The typical increase in peak alpha frequency seen during childhood is said to reflect the development of thalamo-cortical connections (Valdés-Hernández et al., 2010); disruptions to which are said to also manifest through atypical levels of alpha power (Doesburg et al., 2011). Therefore, measures of peak alpha frequency and alpha power may provide a sensitive marker of altered trajectories of neurodevelopment in ASD at an early age.
Previous studies have reported atypical alpha power (Wang et al., 2013) and peak frequency development in ASD (Edgar et al., 2015). However, there are no reports of spontaneous alpha oscillations in an ASD sample with variable cognitive abilities. It is currently unknown whether spontaneous alpha oscillations are altered consistently across a representative sample of children with ASD or whether they distinguish subgroups based on cognitive ability.
Objectives: We asked whether the power and frequency of spontaneous alpha oscillations distinguished children with ASD from age matched typical children and, moreover, whether alpha power and frequency differentiated children with ASD who had comorbid intellectual disability (ID).
Methods: Fifty-seven children with an ASD diagnosis (mean age=5.6 years, range= 2-12 years) were split into 'Low-IQ' (IQ = 11-69; N=30) and 'High-IQ' (IQ= 70-126; N=27) groups based on an IQ cut-off of 70. Forty age-matched typically developing (TD) children (IQ = 95-148) served as a control group. High-density EEG was recorded under task-free conditions while children watched bubbles on a computer screen. Relative alpha (8-12Hz) power and peak frequency were calculated.
Results: TD children showed the expected increase in peak alpha frequency with age (r=>.5, p=<.001), as did children in the high-IQ ASD group (r=0.35, p=0.05). However, this relationship was absent in the low-IQ ASD group (p=>.5). Low-IQ ASD participants showed lower alpha (p=<.01) power across the scalp and lower frontal peak alpha frequency (p=.02) compared to controls. Alpha power (p=>.52) and peak frequency (p=>.30) across the scalp did not differ between high-IQ ASD participants and controls.
Conclusions:
Our results suggest that while the typical development of peak alpha frequency with age is disrupted in ASD, this disruption seems to be driven by co-occurring ID. We also find reduced alpha band power differentiates children with comorbid ID and ASD. Together, these findings suggest that electrophysiological markers of atypical neural function may not be consistent across the spectrum in ASD. Whether these oscillations represent a biomarker of ID rather than ASD will require investigation in children with ID without ASD.
Furthermore, in the context of previous literature, the present study indicates that the level of disruption to the development of thalamo-cortical connections may contribute to the variability in EEG power measures previously reported in ASD. Our future research will utilize longitudinal data to determine how changes in peak alpha frequency are associated with the development of cognitive abilities across the autism spectrum.

113 **125.113** Structural and Functional Characteristics of XYY - Relationship to ASD

L. Bloy[1]*, J. Ross*[2,3]*, J. Rafalko*[3] *and T. P. Roberts*[1]*, (1)The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Thomas Jefferson University, Philadelphia, PA, (3)Nemours/duPont Hospital, Philadelphia, PA*

Background:
47,XYY syndrome (XYY) is a male sex chromosome disorder (two instead of one Y chromosome) associated with significantly increased risk (ranging from 19-50% in pre- and post-natally diagnosed cohorts) of autism spectrum disorder (ASD) diagnosis. While XYY occurs in ~0.1% of males in the general population it is reported in approximately 1% of males with ASD. This increased level of risk coupled with the 4:1 male preponderance in idiopathic ASD (ASD-I) and the recent interest in Y chromosome genes (i.e. NLGN4Y) makes XYY a potentially compelling genetic model of ASD.
Objectives: The focus of this study is to investigate, and potentially disambiguate, the effects of genotype (XYY vs. XY) and clinical phenotype (ASD vs. non-ASD) on neuroimaging measures of structure and function. ASD related neuroimaging measures were contrasted between four groups of boys (6-17 years old), ASD-I, typically developing (TD) and XYY boys meeting (XYY+ASD) and not meeting (XYY-ASD) diagnostic criteria for ASD.
Methods: Neuroimaging data was acquired from 10 XYY+ASD boys (12.8±4.1 years), 7 XYY-ASD (12.4±3.9 years), 16 TD (11.0±3.1 years) and 19 ASD-I (10.2±1.4 years) boys. The neuroimaging protocol consisted of a 3T structural MRI (1mm isotropic resolution), diffusion MRI (b1000s/mm^2 DTI) and whole cortex magnetoencephalography (MEG) recordings acquired during a passive auditory paradigm (500Hz sinusoidal tones). Statistical methods included an age-covaried 4x1 ANOVA to investigate Group differences and 2x2 age-covaried LMMs to investigate main effects of XYY and/or ASD status. Hemisphere was considered as an additional factor in omnibus LMMs; subsequently hemispheres were interrogated separately.
Results: There were no significant differences between groups, nor main effects of XYY or ASD status on structural MRI measures such as total grey matter volume. Fractional anisotropy values, derived from the white matter of Heschl's gyrus (as a surrogate for the thalamocortical auditory radiations) showed a strong tendency towards left hemisphere-only reduction of FA as a main effect of XYY status (XYY: FA=0.30+/-0.02; XY: FA=0.35+/-0.01, p=0.08). Commensurately, in the left hemisphere only, evoked responses from auditory cortex showed significantly delayed M100 latency values as a main effect of XYY status (XYY: M100=162+/-8ms; XY: M100=128+/-5ms, p<0.01). Effect of genotype (XYY status) dominated effects of clinical diagnosis (ASD status), but there was a tendency towards an additive interaction (M100 latency was most prolonged in the XYY+ASD group, although the interaction did not reach significance).
Conclusions: The XYY genotype appears to be associated with atypical maturation of auditory pathway white matter, with consequent significant delays in auditory cortex evoked responses. While these phenomena have previously been associated with idiopathic ASD cohorts, our observations implicates genotype as the dominant basis for these structural and functional sequelae.

114 **125.114** Superior Temporal Sulcus Response in Attributing Social Meaning to Actions in Autism Spectrum Disorder

C. Ammons *and R. K. Kana, University of Alabama at Birmingham, Birmingham, AL*

Background: Previous studies have shown that individuals with Autism Spectrum Disorder (ASD) often struggle to accurately attribute emotions and intentions to others. Such failures in ASD may result from a limited ability to attribute biological agency. In other words, a reduction in anthropomorphism - the attribution of human characteristics, intentions, or behaviors to non-human animals or objects (Chaminade et al., 2007). Due to its widespread and implicit nature, anthropomorphism is generally considered an innate human tendency (Hutson, 2012). However, children with ASD are less likely than their peers to use anthropomorphic language (Hieder & Simmel, 1944). Furthermore, neuroimaging studies have shown reduced activation in certain mentalizing regions (superior temporal sulcus, STS; medial prefrontal cortex, MPFC; and anterior cingulate cortex, ACC) during social attribution in ASD (Kana et al., 2009) and in response to biological motion (Pelphrey et al., 2005). Relatively less work has looked at the neural correlates of anthropomorphism combining social attribution and biological motion processing in ASD.
Objectives: Â To examine the neural correlates of attributing social meanings to human and non-human figures in dynamic anthropomorphic scenarios in ASD.
Methods: Â 34 age-and-IQ-matched participants (17 ASD, 17 TD) viewed short animations of either human-like stick figures or geometrical shapes (such as triangles) engaged in a series of random or socially meaningful movements (i.e. bullying, helping) during functional MRI scanning. In an event related design, participants were asked to determine via button press whether the character's movement was social or random. Structural and functional images were acquired in a 3T Siemens Allegra head-only scanner (17 oblique-axial slices; TR=1,000ms; TE=30ms) and processed in SPM12.
Results: Â ASD and TD groups were equally accurate at identifying social movement by human and non-human characters [Diagnosis x Movement x Character: F(1,28)=.103,NS]. Within-group analysis of functional activation revealed that observation of socially meaningful movement, regardless of character, activated bilateral posterior STS, bilateral MPFC, and the precuneus (Monte Carlo simulation corrected, p=.005, k=100) in the TD group. Activation in the ASD group was limited to the right pSTS and left MPFC. Furthermore, in the TD group attributing social vs non-social motives to shapes (anthropomorphism) was associated with greater activation of the left pSTS and bilateral MPFC compared to no activation differences in the ASD group. Direct comparison of brain activation between ASD and TD groups revealed a significant decrease in left pSTS activation in the ASD group associated with anthropomorphism (MC corrected, p=.01, k=200).
Conclusions: This study demonstrated that despite equal accuracy at identifying social movement of non-social objects, high functioning individuals with ASD may be using slightly different neural resources to accomplish the task compared to their TD peers. The findings of this study underscore the role of pSTS in biological and social information processing as it was recruited for human and non-human social movements alike. Greater bilateral recruitment of pSTS by the TD group when observing the social movement of shapes may reflect a stronger neural response toward anthropomorphism, whereas underactivity of this region in ASD may be a neural signature of their altered social functioning.

115 **125.115** The Development of Neural Correlates Associated with Visuo-Spatial Working Memory in Children with ASD: 2-Year Longitudinal fMRI Study

V. Vogan[1]*, B. Morgan*[2]*, M. L. Smith*[3] *and M. J. Taylor*[1]*, (1)Hospital for Sick Children, Toronto, ON, CANADA, (2)The Hospital for Sick Children, Toronto, CANADA, (3)Psycholoy, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Prior research has shown persistent impairments in visuo-spatial working memory (WM) in individuals with Autism Spectrum Disorder (ASD), compared to normative populations. Existing neuroimaging studies suggest reduced brain activation in fronto-parietal regions during WM tasks in both children and adults with ASD. However, our understanding of the neurodevelopmental patterns accompanying WM is limited. It is suggested that social deficits related to ASD could be explained in part by degraded memory ability. Social and environmental demands become increasingly complex as children mature to adolescents, and thus it is important to consider the development of associated underlying neuropsychological systems, such as WM processing, that are vulnerable in ASD.
Objectives: The purpose of the current study was to examine functional changes longitudinally, over 2 years, in neural correlates of WM in children and adolescents with and without ASD, and the impact of increasing cognitive load.
Methods: Measures of brain activity were acquired with functional magnetic resonance imaging (fMRI) during a visuo-spatial 1-back WM task with four levels of difficulty. A total of 14 children with ASD and 15 age- and sex-matched typically developing children (ages 7-13) were included at baseline and followed up approximately 2 years later. Diagnosis of ASD was confirmed using the Autism Diagnostic Observation Schedule (ADOS). Neural changes between the hardest and easiest difficulty level were analyzed, and the longitudinal change of this contrast was compared between children with and without ASD using a Group x Time interaction.
Results: Although similar task performance was seen at baseline and follow-up across groups, differences were evident in the developmental trajectories of neural responses. Typically developing children showed greater load-dependent activation which increased with age in frontal, parietal and occipital lobes and the right fusiform gyrus, compared to those with ASD. In these areas, children with ASD showed little load dependent increases. However, the ASD group showed greater longitudinal load-dependent *decreased* activation in default-mode related areas (parahippocampal gyrus and ventro-medial prefrontal cortex) compared to controls.
Conclusions: Our results suggest a lack of neural modulation with increasing cognitive demand in parietal-occipital cortical areas in children with ASD that showed no significant maturation into adolescence, in contrast to typically developing peers. Further, children with ASD demonstrated delayed, rather than arrested, maturation of DMN-related areas as observed by increased load-dependent suppression of brain activity across time, relative to typical children. Children with ASD may become quickly saturated and overwhelmed with incoming information, impacting their ability to balance multiple demands of their environment, which becomes increasingly more complex in adolescence. Thus, the period from childhood to adolescence is a critical time to support children with ASD by teaching them skills for facilitating WM (e.g., chunking strategies) and providing them with appropriate accommodations to compensate for WM deficits; this will allow them to benefit more from academic, social and/or behavioural interventions.

116 **125.116** The Impact of Stimulant Medication on EEG Alpha Power in Children with Autism Spectrum Disorder

A. Kresse[1]*, L. A. Edwards*[2]*, J. W. Keller*[2]*, C. A. Nelson*[2]*, K. A. Pelphrey*[3] *and S. J. Webb*[4]*, (1)Seattle Children's Research Institute, Seattle, WA, (2)Boston Children's Hospital, Boston, MA, (3)Yale University, New Haven, CT, (4)University of Washington, Seattle, WA*

Background: It has been estimated that 56% of children with autism spectrum disorder are taking at least one psychotropic medication (Mandell et al., 2008). These rates of medication use present a challenge for researchers studying brain activity in autism using EEG. For example, stimulants are one of the most commonly prescribed medications in autism, with approximately 22% of children taking some type of stimulant (Mandell et al., 2008). If children on medication are included in a study it may be impossible to differentiate brain responses due to medication from brain responses related to autism. However, if researchers choose to exclude individuals taking medications from their study, they could be eliminating a significant portion of children with autism, resulting in a limited and/or biased sample.
Objectives: This study will leverage the large sample size of the ACE GENDAAR Project to investigate the potential impact of psychotropic medication on EEG alpha power. To parse out the different effects of medications and the behaviors they're prescribed to treat, we will examine EEG alpha power and stimulant use in children with and without externalizing behaviors.
Methods: Â High density EEG was collected while children with autism between the ages of 8 and 17 completed a resting task that alternated passively viewing screensaver-like videos (Eyes Open condition) and sitting with eyes closed (Eyes Closed condition). Movement and blink artifacts were rejected, and FFT was performed over clean segments. Average power across 8 – 12 hz for mid-posterior electrodes was calculated for each subject. High externalizing behaviors were characterized as a Child Behavioral Check List domain of Externalizing Problems score in the borderline or clinical range (T score > 59). Of children with autism 22 were reported as taking a stimulant (High Externalizing, n = 10; Low Externalizing, n = 12) and 79 were not on a stimulant (High Externalizing, n = 28; Low Externalizing, n = 51); the samples did not differ on age (p = .35) or IQ (p = .53).
Two-way ANOVAs were calculated to look at the effects of both Externalizing (high, low) and Stimulant Medication (Stimulant, No Stimulant) on mid-posterior alpha power for both Eyes Open and Eyes Closed conditions.
Results: In the Eyes Open condition, there was a significant main effect of stimulant, $F(1,98) = 4.55$, $p = .04$; and on the Eyes Closed condition, there was a marginal main effect of stimulant, $F(1, 95) = 2.95$, $p = .089$). This suggests that regardless of externalizing levels, children who are currently taking stimulant medication have significantly higher mid-posterior alpha power compared to children who are not on stimulant medication.
Conclusions: These findings indicate increased mid-posterior alpha power in children with autism who are taking a stimulant medication, and provide evidence for the importance of taking medication status into account during EEG analyses. Findings will be extended by looking at alpha power spectra in other regions, including frontal alpha and hemispheric differences in alpha power.

117 **125.117** The "Speech-to-Song Illusion" in Children with Autism Spectrum Disorder

M. Sharda[1]*, N. E. Foster*[1]*, K. Jamey*[1]*, C. Tuerk*[1]*, R. Chowdhury*[1]*, E. Germain*[1]*, A. Nadig*[2] *and K. L. Hyde*[1,2]*, (1)University of Montreal, Montreal, QC, Canada, (2)Faculty of Medicine, McGill University, Montreal, QC, Canada*

Background: Children with Autism Spectrum Disorder (ASD) have been shown to demonstrate differences in behavioural and neural processing of speech, but they also show intact music and song processing (Lai et al., 2012). However, the degree to which music and speech share neural resources is currently unclear, limiting the use of music for neuro-rehabilitation. The "speech-to-song illusion" (Deutsch et al., 2011), in which acoustically identical stimuli may be perceived as speech or song through repetition of a spoken phrase, offers a novel approach to investigate the overlap between speech and music. This work can guide auditory-based interventions in ASD.
Objectives: The aims of the current study were to investigate 1) whether children with ASD and typically developing (TD) children perceive the "speech-to-song illusion" similar to TD adults, and 2) the neural correlates of this illusion in both ASD and TD.
Methods: Â Participants were 20 children with ASD aged 7-13 years and 21 TD children that were matched on age- and nonverbal IQ. ASD participants were diagnosed using the ADOS. All participants were tested on a speech-to-song illusion task that was previously validated in TD adults (Tierney et al., 2011). Stimuli were 40 spoken phrases, 20 that sounded like song when removed from context and repeated (Song), and 20 that did not (Speech). Additionally, 20 Scrambled phrases were used as an acoustic control. Participants performed a passive-listening task in a 3T MRI scanner. Stimuli were presented in eighty blocks of 16s each, where one phrase was repeated with a 0.5s interval. Speech, Song, Scrambled and Silence blocks were presented in random order. 480 whole-brain functional volumes (TR=2.57s) and a high-resolution anatomical T1, were acquired for all participants and analysed using SPM8. Following the scan, participants completed a behavioural task where they rated the same stimuli used in the functional task on a "songness" scale of 1 (Speech-like) to 5 (Song-like).
Results: A repeated measures ANOVA (Figure 1) showed a significant main effect of condition ($F_{(1,39)}=0.507$, $p<.001$). Post-hoc comparisons showed that both ASD and TD participants rated the Song stimuli as more song-like compared to the Speech stimuli ($p<.001$, Bonferroni-corrected). Both groups also rated the Scrambled stimuli as more song-like ($p<.001$). There was no main effect of group or group X condition. Preliminary analyses in TD revealed a left MFG activation for the Song-Scrambled contrast. Conversely, ASD activated the right MFG for the Speech-Scrambled contrast ($p<.05$, FWE-corrected, Figure 2).
Conclusions: These results show that both ASD and TD children perceive the "speech-to-song illusion", similar to TD adults. Interestingly, the neural correlates underlying the perception of stimuli as song or speech are distinct in both groups. Further investigation of brain activity underlying these stimuli as a function of perceptual ratings will provide insight into individual differences in speech and song processing in ASD. The behavioural validity of this task offers a novel, powerful tool to investigate the neural overlap between speech and music. This may provide a basis for the use of music-based therapies to improve speech and language in individuals with ASD.

118 **125.118** Using Complex Dynamic Video to Examine Neural Processing in ASD: A Semi-Naturalistic fMRI Study

J. Douglas, *L. Byrge, G. Lisandrelli and D. P. Kennedy, Psychological and Brain Sciences, Indiana University, Bloomington, IN*

Background: Traditional neuroimaging paradigms often do not fully reflect the richness and complexity of the natural world in which perceptual and cognitive processes are deployed. Recent interest in improving the ecological validity of neuroimaging research has prompted the creation of alternative naturalistic paradigms and stimuli. The use of multimodal, free-flowing stimuli with varying content can allow researchers to probe multiple constructs of interest, and interactions among them, concurrently. Naturalistic or semi-naturalistic approaches can prove especially beneficial to research on autism spectrum disorder (ASD), as these approaches most closely approximate the conditions under which impairments associated with the disorder manifest.
Objectives: To explore the use of unconstrained dynamic video stimuli within a free-viewing fMRI paradigm to examine neural responses to multiple perceptual and cognitive processes concurrently, and to extend this approach to the study of ASD.
Methods: 53 participants (24 individuals with ASD and 29 neurotypical individuals) passively viewed videos (each lasting approximately fifteen minutes) over four runs while lying in an fMRI scanner. The videos were composed of movie trailers spanning multiple genres. Using ELAN and MATLAB, we defined several events of interest, including instances of humans or human faces appearing onscreen, human speech, social interaction between two or more people, low-level changes in luminance, and inter-trailer intervals during which a stimulus was not presented. We conducted separate regression analyses using FSL with each such event type as a regressor in the model. Our primary analyses assessed both the neural specificity for each event type and the reliability of the response estimates obtained for each event type across the four functional runs. We also conducted group-level analyses for each of the event types, thereby quantifying similarities and differences between neurotypical individuals and individuals with ASD.
Results: Each event type produced a largely distinct pattern of activity in the canonical neural networks that have been identified in previous research using more conventional paradigms. Activation patterns showed a high degree of reliability across the four functional runs, suggesting that individuals reliably engaged in event-level processing that was independent of the idiosyncratic aspects of the videos. Finally, while we observed some small differences in the responses from participants with and without ASD, the groups displayed remarkable similarity overall across the different event types.
Conclusions: Our findings support the feasibility and efficiency of using complex, dynamic stimuli in neuroimaging studies of ASD. The video stimuli elicited robust activation in the brain regions purported to process the classes of events examined. Additionally, our approach allowed for simultaneous exploration of a number of event types and associated neural networks within a single experiment. The similar response profiles among participants with and without ASD suggest that the ability to spontaneously process specific inputs is largely preserved in ASD and that more pronounced differences might be revealed in paradigms with a social interaction component.

119 **125.119** Variance in Language Abilities in Autism As a Function of Hemispheric Lateralization and Functional Connectivity

A. J. Herringshaw[1] *and R. K. Kana*[2]*, (1)University of Alabama Birmingham, Birmingham, AL, (2)University of Alabama at Birmingham, Birmingham, AL*

Background: Â In autism spectrum disorders (ASD), the brain's language network (including Broca's and Wernicke's areas) has been found to be more right lateralized than in typically developing (TD) individuals, yet the consequences of this remain unclear. While some studies have correlated greater right hemisphere (RH) language lateralization with decreased language abilities, others argue that increased RH activity is an alternate but not inferior means of language processing. Previous literature shows that a weak hemispheric dominance in TD individuals predicts greater functional connectivity between LH and RH language areas (Tzourio-Mazoyer et al., 2015); this is important considering the disruptions in connectivity reported in individuals with ASD.
Objectives: Â To determine whether functional lateralization of Broca's and Wernicke's areas and functional connectivity between these RH and LH homologues during language processing accounts for variance in the language abilities of individuals with and without ASD.
Methods: Â High-functioning ASD (*N*=15) and TD (*N*=17) adults silently read literal and figurative sentences in a Siemens 3.0 Tesla fMRI scanner. Groups were matched on age (ASD=21.21 years, TD=21.87 years) and performance IQ (ASD=106.60, TD=107.94); however, verbal IQ (VIQ) differed significantly between groups (ASD= 102.33, TD= 114.65, $p<.05$). Based on neural activity during sentence processing, individual region-of-interest (ROI) lateralization indices (LI) and ROI-to-ROI functional connectivity were calculated in SPM12 and the LI and CONN toolboxes. Anatomical ROIs were defined using Brodmann areas BA 44 and 45 (Broca's area) and BA 22 (Wernicke's area). LI values and beta-weights of connectivity between RH and LH language homologues were treated as independent variables in two separate 3-way ANOVAs (group x LI x connectivity; one ANOVA for BA 44/45, one for BA 22) predicting variance in individual VIQ scores.
Results: Â 1) In BA 22, the three-way ANOVA yielded a significant group x LI x connectivity interaction, $F(1,24)= 7.407$, $p<.05$; 2). In BA 44/45 the same effect was not significant, $F(7,24)= 2.084$, $p= .085$. However, a two-way ANOVA testing group x LI significantly predicted VIQ, $F(3,28)= 4.319$, $p<.05$, such that in the TD group greater left lateralized activity predicted higher VIQ, while the opposite pattern was found in ASD. 3) An additional two-way ANOVA (group x BA 44/45 LI) significantly predicted interhemispheric BA44/45 connectivity $F(3,28)= 3.658$, $p<.05$, such that in the TD group connectivity increased as one's language network became less left lateralized, while no such relationship was found in the ASD group.
Conclusions: Â In BA 22, group x LI x connectivity interaction indicates that the VIQ varied extensively in the ASD group as a function of connectivity and lateralization. Most notably, in ASD a combination of weak inter-hemispheric connectivity and reduced LH dominance predicted some of the lowest VIQ's observed. In BA 44/45, the ASD group failed to show an increase in inter-hemispheric connectivity with weaker hemispheric lateralization. Overall, our findings suggest that the wide variance in VIQ seen in ASD is significantly related to interactions of functional lateralization and connectivity in this population in a manner that is distinct from what is seen in TD individuals.

120 **125.120** Word Processing of Child-Directed Speech in Young Preverbal Children with ASD

M. P. Sandbank[1]*, P. J. Yoder*[2] *and A. P. F. Key*[3]*, (1)Special Education, University of Texas at Austin, Austin, TX, (2)Vanderbilt University, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN*

Background: Previous investigations have shown that word processing, the cognitive retrieval of previously acquired words from mental storage, can be measured using event-related potentials (ERPs) and could be a useful predictor of language outcomes in young children with autism spectrum disorders (ASD). Other investigations have suggested that, in children with ASD, neural processing of linguistic stimuli may be aided by their tendency to attend to social stimuli, such as child-directed speech (CDS; also known as motherese).
Objectives: The current project examined processing of CDS word stimuli in young children with ASD in order to determine (a) whether they exhibited a typical neural response (at the location and time window documented in previous investigations of typically developing children), (b) the extent to which a brain measure of word processing derived from the response to CDS word stimuli was associated with a concurrent measure of receptive language, and (c) whether this association was conditional on the child's tendency to attend to CDS.
Methods: This study was a secondary analysis of data collected from a longitudinal study of preverbal children with ASD. Thirty-four children with ASD aged 2-5Â in preverbal or early verbal stages listened to a set of 10 words typically understood by infants aged 8-12 mo, and 10 nonsense words (Mills et al., 2004), while ERPs were collected using dense-array EEG technology. All stimuli were recorded by a young, female, native speaker, using speech features characteristic of CDS, and presented 3 times each in random order. Receptive language was evaluated using MacArthur-Bates Communicative Development Inventories (MCDI; Fenson et al., 2007). Participants' level of attention to CDS was measured twice across the course of the longitudinal study using a structured procedure in which child-friendly stimuli that featured CDS were presented from a puppet theater (Watson et al., 2010). Scores from each administration were aggregated to create a single score representing the child's generalized tendency to attend to CDS.
Results: ERP amplitudes at the left temporal electrode cluster (~T3) between 200-500 ms were more negative for CDS words vs. nonword stimuli, indicating a typical neural response associated with word processing. The word-nonword amplitude difference was not significantly correlated withÂ receptive language (r =-.17), though the association was in the expected direction. However, further analyses indicated that this measure statistically interacted with attention to CDS (β = -0.47, p = 0.04): the association between word processing and receptive language was stronger for children who displayed moderate or high levels of attention to CDS compared to those who did not.
Conclusions: Children with ASD as a group do exhibit the typical neural response to word stimuli delivered in CDS. However, the utility of this measure as a correlate of language outcomes is conditional upon the child's tendency to attend to CDS. Further work is needed to understand whether subgroups of children with ASD may benefit from language interventions that use other types of speech.

121 **125.121** Towards a Neurocomputational Model of Sensory Differences in ASD

J. Skewes[1]*, H. Thaler*[2] *and P. K. Mistry*[3]*, (1)Interacting Minds Centre, Aarhus University, Aarhus, Denmark, (2)Interacting Minds Center, Aarhus University, Aarhus, Denmark, (3)University of California Irvine, Irvine, CA*

Background:
ASD is associated with differences in sensory processing, including difficulties organizing sensory experiences (Dakin & Frith, 2005). Predictive processing theories of cognition explain these differences in terms of differences in statistical processing of sensory information in the brain. A core hypothesis of the predictive processing account is that people with ASD rely less on prior perceptual experience, and more on detailed sensory information, when making perceptual inferences about things in their environments (Pellicano & Burr, 2014). This account has been supported in recent experiments (Skewes et al, 2014; Skewes & Gebauer, 2016).
Objectives:
The purpose of the present research is to use computational modeling to pinpoint the specific mechanisms which underlie the tendency in ASD to rely less on prior sensory information.
Methods:
In the experiments cited above, participants are asked to make binary perceptual inferences given continuously distributed stimuli. For instance, in Skewes and Gebauer (2016), participants were presented with sounds which varied in the location of their spatial sources, and were asked to report whether each sound was produced by a "white" cricket, whose territory was distributed more towards the left auditory hemifield, or by a "black" cricket, whose territory was distributed more towards the right. Participants were given feedback at the end of each trial, and were rewarded for correct responses. Participants with ASD integrated prior information about the base-rates of each kind of cricket less optimally.
Drawing resources from Signal Detection Theory and Prospect Theory, we have developed a cognitive model of the processes underlying this integration. We model learning during the task as an interaction between 1) sensitivity to sensory error of judgements, and 2) sensitivity to feedback. This allows us to develop a deeper explanation of the functional differences identified for individuals with ASD.
To understand the neural mechanisms implementing these differences, we've adapted a neural network model designed to learn the same kind of perceptual inference required by the task (Helie, 2014). We used the experimental results to constrain simulations of the network. The results of these simulations allow us to make precise predictions about the neurobiological mechanisms underlying the functional differences observed in ASD.
Results:
In a novel pilot experiment designed to test our cognitive model, we found that autistic traits in the neurotypical population predicted sensitivity to feedback, but not sensitivity to sensory error. Based on this result, we adjusted the rate of learning in frontal GABAergic/dopaminergic synapses in the neural network, which represent the rate at which feedback drives learning in the model. Using simulations, we found that when the learning rate was set lower, the network performed in a way similar to participants in the cited studies.
Conclusions:
This research theoretically motivates the hypothesis that sensory differences in ASD result from differences in neurobiological mechanisms in frontal networks involved in learning about how to reduce continuous sensory information to informative perceptual categories.

122 **125.122** Interpersonal Predictive Coding Across the Autistic Spectrum

L. Schilbach*, Independent Max Planck Research Group for Social Neuroscience, Max Planck Institute of Psychiatry, Munich, Germany*

Background:
Action perception is not simply a reflection of what happens, but a projection of what will happen next. In this talk, the notion of interpersonal predictive coding will be introduced and reviewed in light of evidence from behavioral studies, which investigate the ability to use social information to learn from and predict others' actions by using point-light displays that depict communicative as compared to non-communicative actions between two agents. Furthermore, computational modeling was used in a second paradigm, which required individuals to learn about the probabilities of social and non-social cues and to integrate them in order to gain points in a card selection task. Objectives:
These studies aimed at investigating whether - in spite of intact performance on action recognition tasks - individuals with autism might show impairments of the ability to predict subsequent actions during an observed dyadic encounter. An additional aim was to characterize and quantify the processes that allow individuals to integrate social and non-social cues during decision-making.
Methods:
The first study used point-light displays that depict communicative as compared to individual actions between two agents and were taken from an established database. Agent A demonstrated either a communicative or an individual action while agent B either showed a communicative action or was not present. As part of this two-alternative forced choice paradigm, participants had to indicate whether they thought agent B had been present in one of two trials. Eyetracking measurements were also obtained.
In a second study the ability to integrate social and non-social information during decision-making was studied by making use of a probabilistic learning task in conjunction with Bayesian modeling to investigate autistic trait-related differences in basing one's decisions on social rather than non-social information. Using computational modeling a weighting parameter was calculated that indicated the extent to which participants were influenced by the social cues about which they had received no information during the instructions.
Results:
Using a two-alternative forced choice paradigm, it was shown that participants' sensitivity for detecting a second agent masked by noise signals was significantly higher when a first agent showed a communicative action. This measure of sensitivity also showed a negative and significant correlation with increasing autistic traits across the entire spectrum. Results from the second study show that autistic traits are negatively correlated with the extent to which decisions are based on social rather than non-social information. These autistic trait-related differences in cue integration also explained performance differences across different groups of participants.
Conclusions: Taken together, these findings highlight that autistic traits are related to differences in the integration, anticipation and automatic responding to social cues, rather than a general inability to register and learn from social cues. Importantly, such differences may only manifest themselves in sufficiently complex situations.

123 **125.123** Abnormal Functional Connectivity in the Social Brain Identified By a Generalized Classifier for Autism Spectrum Disorder

***R. Hashimoto**, Medical Institute of Developmental Disabilities Research, Showa University, Setagaya-ku, Japan; Department of Language Sciences, Graduate School of Humanities, Tokyo Metropolitan University, Tokyo, Japan*

Background: Autism spectrum disorder (ASD) has been increasingly conceptualized as a disease of functional brain networks. Among multiple nodes that constitute the brain's networks, several "social brain" regions have been proposed as key structures that particularly contribute to functional alterations in the ASD brain. However, because current standard analyses of functional connectivity (FC) are mainly driven by hypotheses related to deficits in interpersonal functions in ASD, highlight of abnormalities in the social brain may be an unsurprising consequence.
Objectives: In order to overcome potential biases of the present approaches, we adopted hypothesis-free data-driven analyses to a large cohort data of the resting-state FCs of adults with ASD collected at multiple sites and tested whether the importance of deficits in the social brain regions in ASD is supported without any hypotheses related to social functions.
Methods: Â We collected the resting-state FC data of 74 adult high-functioning ASDs and 114 typically-developed controls collected at three different MRI sites in Japan. From each participant, we generated a correlation matrix consisted of 9,730 FCs using a standard brain atlas. Using this set of the correlation matrices as input, we combined advanced statistical methods to develop a classifier consisted of a small number of FCs that distinguished between ASD and TD. We then examined the anatomical distribution of the regions included in the selected FCs of the classifier.
Results: We developed a classifier that incorporated as little as 0.16% of all the 9,730 FCs in the brain (16 FCs). This classifier turned out to distinguish between ASD and TD with high precision (85 %) for the data collected at the three Japanese sites. Furthermore, we observed the generalization of this classifier into the third cohort collected in the USA sites with 75% accuracy. Anatomical examination of the 16 FCs revealed a right-sided distribution (31% right intra-hemispheric FCs as opposed to absent left intra-hemispheric FC). Furthermore, the 32 brain regions comprising the 16 FCs contained most of the important nodes in the social brain network, including the right amygdala, superior temporal sulcus, cingulate cortex, orbitofrontal cortex, and inferior frontal cortex.
Conclusions: The results suggest that abnormalities of a small number of FCs underlie core ASD deficits. Our data-driven approaches highlight the importance of the social brain FCs in the ASD brain and provide complementary findings to standard hypothesis-driven approaches.

5:30 PM - 7:00 PM - Golden Gate Ballroom

124 **126.124** A Case for Including Adolescent Self Report of Sensory and Anxiety Symptoms in ASD: Evidence from Questionnaire and Autonomic Data

***J. M. Keith**[1], J. P. Jamieson[1], P. Allen[2] and L. Bennetto[1], (1)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY*

Background: Dysregulated sensory processing and anxiety are both highly prevalent clinical concerns for individuals with autism spectrum disorder (ASD). While it is clear that both sensory dysfunction and anxiety are present in individuals with ASD, accurately and fully measuring these symptoms is challenging, given that they are largely experienced internally. Furthermore, while past research has suggested that individuals with ASD have difficulty reporting on their internal states, parent report is also subject to limitations, such as reporter effects (e.g., bias, memory) and reliance on the ability to index internal emotions and sensory states based solely on observable behaviors.
Objectives: The current study used a multi-method approach to evaluate differences between child- and parent-report of sensory processing and anxiety symptoms in high-functioning adolescents with ASD and typically developing (TD) controls. To determine the relative validity of self- versus parent-report for identifying symptoms, we compared these questionnaires to objective, physiological measurements of the sympathetic and parasympathetic nervous systems during a laboratory sensory challenge.
Methods: Participants included 22 adolescents with ASD (mean age=14.5, range=12-17 yrs) and 18 TD controls (mean age=15.1, range=12-17 yrs). Diagnoses were confirmed using the ADOS and ADI-R in the ASD group and ruled out using the ADOS and SRS in the TD group. Groups were matched on age, gender, and Wechsler Verbal Comprehension Index. Each participant and their parent completed the Brain Body Center Sensory Scales and the Screen for Childhood Anxiety Related Disorders (SCARED). Electrocardiography, respiratory sinus arrhythmia, and electrodermal activity were collected at rest (baseline) and during a laboratory task presented in continuous, 75 dB gated broadband noise (sensory challenge).
Results: Group x Reporter ANOVAs were conducted for both sensory symptoms and trait anxiety. For both domains, the ASD group showed significantly higher symptoms than TD peers (sensory, F=41.27, p<.001; anxiety, F=30.15, p<.001). For both domains, there was also a significant effect of reporter. Children from both groups reported higher levels of sensory dysfunction than reported by parents, F=16.65, p<.001. An identical pattern emerged for the anxiety data, with children from both groups reporting higher levels of trait anxiety than their parents reported, F=18.27, p<.001. To better understand these reporter differences, we examined the relationship between questionnaire measures and autonomic arousal. Interestingly, in the ASD group, child-report of sensory (r=.55, p=.05) and anxiety (r=.49, p<.05) symptoms correlated with autonomic arousal levels, whereas parent-reports of these symptoms were not related to autonomic reactivity.
Conclusions: These results make a substantial contribution by demonstrating that high-functioning adolescents with ASD are able to accurately report on their internal experiences with sensory and anxiety symptoms, and that their report may reveal a greater degree of symptoms than reported by parents. The validity of child-reports in ASD was substantiated by demonstrating concordance between self-report of symptoms and autonomic arousal levels collected in the lab. Together, these results suggest that research and clinical evaluations of high-functioning adolescents with ASD should include the perspective of the individuals themselves as they are likely able to contribute a different and important perspective.

125 **126.125** A Network Perspective on the Relationship Between ASD and Depression Symptoms in Older Adults: The Role of Mastery & Worry

B. F. van Heijst[1], *M. K. Deserno*[1], *H. C. Comijs*[2] *and H. M. Geurts*[1], *(1)University of Amsterdam, Amsterdam, NETHERLANDS, (2)Psychiatry, GGZ inGeest, Amsterdam, Netherlands*

Background:
ASD and depression often co-occur: adults with ASD have a high incidence of depression (Croen et al., 2015; Lever & Geurts, 2016) and among depressed older adults, ASD characteristics are much higher than for non-depressed older adults (Geurts, Stek & Comijs, 2016). However, what remains unclear is how depression and ASD relate to each other. By using network analyses we aim to determine whether ASD and depression symptom clusters are strongly interconnected or whether this co-occurrence is due to a mutual relationship (i.e., bridge symptom-cluster) with another construct. We hypothesize that the latter is the case. As there is a strong connection of mastery (perceived control over life's stressors) and worry with depression, these are likely candidates to serve as bridge symptom-clusters.
Objectives:
To gain insight into the relationship between ASD and depression, and investigate the role of mastery and worry.
Methods:
We made use of an existing dataset from The Netherlands study of depression in older persons (NESDO; Comijs et al., 2011) that focused on depressed and non-depressed older persons (N=376, age M=69.9, 60-90 years) without an ASD diagnosis. Participants were assessed on ASD symptoms (AQ-28), depression severity (IDS-SR), worry (Worry Scale-R) and mastery (Pearlin Mastery Scale). The structure of the association network and centrality indices are the outcome measures. Further analysis (e.g. network reliability, concentration network) will be completed before the IMFAR conference.
Preliminary Results:
Visual inspection of the network shows some direct connections between ASD and depression, the strongest direct relation is between Motivation (IDS-SR) and Routine (AQ-28). ASD (AQ-28) relates to Worry. However, this is specific for Social Worry, which has the strongest connection to Social Skills (AQ-28). Social Worry further connects to depression (IDS-SR), and Mastery. Centrality analysis show that Mastery ranks among the most central nodes in the network.
Preliminary Conclusions:
Mastery so far seems to be a more likely candidate as a bridge symptom than worry per se, although social worries also play an important role. However, there is also a clear direct relationship between ASD and depression. Although speculative, the feeling of being in control of life's stressors, and worries about one's social life could both be important targets when treating people with depression and ASD. A future research avenue is to determine whether a similar network can be replicated in ASD sample. It is, however, likely that networks converge across different samples.

126 **126.126** ADHD Severity As It Relates to Comorbid Psychiatric Symptomatology in Children with ASD

R. Mansour[1], *A. T. Dovi*[2], *D. M. Lane*[3], *K. A. Loveland*[1] *and* ***D. A. Pearson***[1], *(1)Psychiatry & Behavioral Sciences, University of Texas McGovern Medical School, Houston, TX, (2)University of Houston, Houston, TX, (3)Psychology, Rice University, Houston, TX*

Background:
A growing body of research suggests that the prevalence rate of psychiatric comorbidity in individuals with ASD is much higher than it is in in the general population. Additional evidence suggests that ADHD contributes additional impairments in functioning. Not enough is known about the impact of ADHD on the development of comorbid psychiatric syndromes, or whether children with ASD who have more severe symptoms of ADHD are at higher risk for comorbid psychiatric symptomatology than are children with ASD who have milder ADHD symptoms.
Objectives:
The objectives of this study were to: 1) examine the rate of comorbid psychiatric disorders--including disruptive behavior disorders, mood disorders, anxiety disorders, elimination disorders, and eating disorders in children with ASD; and 2) determine if higher severity of ADHD symptomatology in children with ASD was associated with higher levels of psychiatric comorbidities and syndrome severity. It was hypothesized that children with ASD who have higher levels of ADHD symptom severity would be at higher risk for comorbid psychiatric diagnoses and symptomatology.
Methods:
Participants were 99 children (78 boys; mean age=9.4 yrs.; mean SB5 Full Scale IQ=84) who met DSM-IV criteria forÂ ASD on the ADI-R and the ADOS.Â Analysis ofÂ ADHD severity (as assessed by Conners' Rating Scale-Revised; Parent Version; global index) as a predictor of the number of comorbid diagnoses (using Diagnostic Interview for Children and Adolescents-Fourth Edition; DICA-IV) were examined using multiple regression analyses, with mental age (SB-5 FSIQ age equivalent) as a covariate. A regression model was then used to analyze the effect of ADHD severity on Child Behavior Check List (CBCL) symptom severity using eight subscale T scores as dependent variables (anxious/depressed, withdrawn, somatic complaints, social problems, thought problems, attention problems, rule breaking behavior, and aggressive behavior), with mental age as a control.
Results:
More severe ADHD symptomatology was associated with having more comorbid psychiatric diagnoses on the DICA-IV, $F(1,95)=9.04$, $p= 0.003$. More severe ADHD severity was also associated with higher levels of symptom severity on CBCL syndrome subscales, $F(8, 88) = 23.56$, $p<0.001$. Specific areas of concern included Disruptive Behavioral Disorders, Anxiety Disorders, Mood Disorders, Elimination Disorders, Eating Disorders, and Separation Anxiety Disorder. Interestingly, increasing severity of autistic symptomatology (as measured by ADI-R) was not associated with higher risk of comorbid psychiatric diagnoses or CBCL syndrome severity. These findings suggest that ADHD severity--but ASD severity--is associated with a higher risk for comorbid psychiatric symptomatology in children with ASD.
Conclusions:
These results suggest that children with ASD who also have severe ADHD symptoms are at high risk for a other psychiatric comorbidities. Not only did we find that a greater number of psychiatric diagnoses were associated with ADHD in children with ASD, but also that more severe ADHD symptoms led to more severe psychiatric symptoms in these children. It is interesting to note that ASD symptomatology was not associated with a higher risk for psychiatric comorbidity or severity. These results lend support to the notion that greater ADHD symptoms is a risk factor for greater comorbid psychiatric problems in children with ASD.

127 **126.127** ADHD Symptomatology in Preschoolers with Fragile X Contrasted to Idiopathic Autism

S. L. O'Connor[1]*, A. L. Hogan*[2]*, K. E. Caravella*[2]*, S. M. Matherly*[2] *and J. Roberts*[1]*, (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC*

Background:
Attention Deficit/Hyperactivity Disorder (ADHD) is the most commonly diagnosed behavioral disorder in children, with about 11% of the general population diagnosed with ADHD. Symptoms of ADHD, such as inattention, hyperactivity and impulsivity, are present at elevated rates in children with fragile X syndrome (FXS) and autism spectrum disorder (ASD). Estimates of ADHD in school-age children fall around 60% for youth with FXS and up to 53% in ASD. Screening for comorbid disorders in these high risk groups is important to aid in diagnostic determination along with accessing and directing treatment. To our knowledge, no study has examined ADHD symptom presence or severity in preschoolers with FXS or compared the severity of ADHD symptomatology between children with ASD and FXS despite the high prevalence and significant impact ADHD has on these populations.
Objectives:
In the present study we characterize ADHD symptom severity across three groups of preschool-aged children: FXS, ASD and typically developing (TD) controls. This study also investigates the effect of ASD severity on the impact of ADHD symptoms in the FXS group. The effect of sex was also investigated across all three groups.
Methods:
Participants included 22 children with FXS, 18 children with ASD and 18 TD children between the ages of 3-6 years old (boys' n = 46, girls' n = 12; Age M = 53.23, SD = 11.11). The Child Behavior Checklist 1½-5 ADHD-DSM subscale raw and t-scores (CBCL) were used to assess the presence and severity of ADHD symptoms. Cognitive functioning was measured by the Early learning composite (ELC) on the Mullen Scales of Early Learning (MSEL). Autism symptom severity was measured by the Autism Diagnostic Observation Schedule (ADOS-2).
Results:
Two ANCOVA's were run. Both sex and Mullen ELC were co-varied in the analyses. Results show no differences in mean scores across the three groups for both the ADHD DSM scale raw and T-scores on the CBCL (p > .05). No effect of sex was found. To investigate the effect of autism symptomology on CBCL ADHD DSM subscale scores, Pearson's correlations were calculated to look at the effect of autism severity on ADHD raw and t-scores for the FXS group. No significant relationship was found between autism severity and ADHD symptoms in the FXS group (p > .05).
Conclusions:
The present study findings suggest that group differences on ADHD symptomology are not evident at the preschool age for these clinical samples. This finding is striking as rates of ADHD in school age samples are much higher in both FXS and ASD compared to TD peers. These findings are important and indicate that early indicators of ADHD may be muted during the preschool years or that severity of ADHD symptoms may increase dramatically across early childhood. Thus, diagnostic surveillance for ADHD is important in ASD and FXS to detect symptom severity and impairment that may emerge at older ages than community samples. This work also suggests that treatment may be initiated in the absence of overt symptoms to minimize the severity of later-emerging symptomology.

128 **126.128** ASD and ID: Results from a National Study of ID of Genetic Origin

R. Srinivasan[1]*, J. Wolstencroft*[1]*, D. H. Skuse*[2] *and I. D. IMAGINE Consortium*[3]*, (1)UCL GOS Institute of Child Health, London, United Kingdom, (2)UCL GOS Institute of Child Health, London, UNITED KINGDOM, (3)UCL GOS Institute of Child Health, IMAGINE ID, London, United Kingdom*

Background: Intellectual disability (ID) is characterised by significant limitations in cognitive functioning and adaptive behaviour. Many people with ID experience significant behavioural difficulties or mental health problems. IMAGINE-ID, is a recently established national UK study of psychiatric risk in ID of known genetic origin, with up to 10,000 participants. Here, we investigate the association between ID and ASD in the general population, and the prevalence of comorbidities including Anxiety Disorders, Disruptive Behaviour Disorders (DBD), Attention-Deficit/Hyperactivity Disorder (ADHD) and Tic Disorders.
Objectives: In the initial phase of this program, our focus has been on children (4-18 years) with ID that is associated with pathogenic Copy Number Variants (CNV), ascertained by NHS Regional Genetics Centres. By means of online/in-person phenotyping, we aimed to assess the prevalence of ASD, and contrast psychiatric comorbidities in those with and without ASD.
Methods: Over 900 participants with ID of genetic cause confirmed by microarray have so far been recruited into IMAGINE-ID. 651 assessments have been completed and 330 completed assessments have been clinically rated to date (over 1000 by May 2017). A standardized psychiatric interview, the Development and Wellbeing Assessment (DAWBA), is administered to caregivers; this generates probability scores for DSM-5 rated psychiatric symptomatology, including ASD. The DAWBA has been used in the UK's national studies of child psychiatric adjustment. Genetic aetiology has been established: i) by microarray analyses (UK NHS accredited laboratories, with array resolutions typically 200kb); ii) aetiological SNV identified from the UK Deciphering Developmental Disorders survey.
Results: 31% of participants met criteria for a diagnosis of ASD. The male: female ratio in those with ASD was 3:1 but in the non-ASD group the sex ratio was equal. Mean age overall was 8.9 years (SD=3.8, range 4-18 years), with no significant differences in age, estimated mental age or language age between children with and without ASD. Participants with ASD were significantly more likely to meet DSM-5 criteria for an additional mental health disorder (36% vs 19%; p = 0.00) especially Anxiety Disorders (15% vs. 6%, p = 0.01), and Tic Disorders (4% vs. 1%, p=0.04). There were no significant group differences in the prevalence of ADHD or DBD. The Everyday Feelings Questionnaire (EFQ) measures impairment in caregiver emotional adjustment, and was completed by all participant parents. EFQ scores were higher for both ASD/non-ASD groups than the general population. Impairment was significantly greater in parents of children with ID+ASD (M=18.7 vs 15.9; p=0.00).
Conclusions: IMAGINE-ID is the first study to systematically evaluate the prevalence of ASD in a national cohort of children with ID of known genetic origin. A higher proportion of participants in IMAGINE ID display clinically significant ASD traits than identified in national UK studies (using the DAWBA) with children with ID of unknown aetiology. When associated with ASD, children with ID were more likely to have additional psychiatric comorbidities, especially Anxiety Disorders and Tic Disorders. The emotional impact of caring for a child with ID is increased in the presence of comorbid ASD.

129 **126.129** Adaptive Behavioral Dysfunction Is Associated with Increased Risk for ASD Symptoms in Toddlers with Tuberous Sclerosis Complex.

D. A. Pearson[1], *M. L. Kellems*[1], *S. S. Hashmi*[2], *H. Northrup*[2], *D. A. Krueger*[3], *A. W. Byars*[3], *D. S. Murray*[4] *and M. Sahin*[5], *(1)Psychiatry & Behavioral Sciences, University of Texas McGovern Medical School, Houston, TX, (2)Pediatrics, University of Texas McGovern Medical School, Houston, TX, (3)Neurology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Autism Speaks, Boston, MA, (5)Neurology, Boston Children's Hospital, Boston, MA*

Background:
Previous research has suggested that up to 50% of newborns with Tuberous Sclerosis Complex (TSC) will go on to develop autism spectrum disorder (ASD). Given that Tuberous Sclerosis Complex (TSC) can be diagnosed with 95% accuracy via prenatal ultrasonography, TSC offers a unique opportunity to study the early development of ASD. The goal of an ongoing multi-center study is ascertain possible biomarkers that could distinguish infants with TSC who will develop ASD from infants with TSC who do not develop ASD. Potential biomarkers being assessed in this project include imaging, EEG, genetic analysis, assorted clinical measures, and neurodevelopmental assessment measures (including adaptive behavior and behavioral/emotional function). Adaptive behavior deficits have long been associated with suboptimal developmental outcomes. Behavioral problems (e.g., inattention, social withdrawal), can significantly undermine adaptive functioning—which in turn undermines long-term educational, social, and occupational adjustment. At this point, little is known about the relationship between adaptive function and psychopathology in toddlers with TSC—especially with regard to symptoms, such as social withdrawal and emotional reactivity, that are closely associated with ASD.
Objectives:
The goal of this project was to determine if lower adaptive function is associated with higher levels of behavioral and emotional problems—especially symptoms closely associated with ASD-- in toddlers with TSC.
Methods:
Sample consisted of 66 toddlers (35 boys) participating in the TSC Autism Center of Excellence Research Network (TACERN). Mean age was 24.2 months, mean MSEL Composite was 79.6, and 14 had been diagnosed with ASD) by this point in the study. Adaptive function was assessed using the Vineland Adaptive Behavior Scale (VABS-II). Behavioral/emotional problems were assessed using the Child Behavior Checklist (CBCL, ages 1.5-5 years). Parents served as the informants for both instruments. Correlational analyses assessed the relationship between adaptive function and behavioral/emotional function.
Results:
Toddlers with TSC who had lower levels of adaptive function had significantly higher levels of behavioral and emotional concerns. Weaker adaptive function was associated with higher levels of internalizing problems (p<.001) and externalizing problems (p=.04). Of particular note were specific concerns in the areas of, pervasive developmental problems (p<.001), emotional reactivity (p=.022), and social withdrawal (p<.001). Other concerns associate with weak adaptive function included attention problems (p=.005) and affective problems (p=.002). When toddlers with ASD were removed from the sample and correlations re-run, weaker adaptive function was still associated with pervasive developmental problems (p=.001) and social withdrawal (p<.001), suggesting that these findings were not entirely driven by toddlers who had already been diagnosed as having ASD. However, it is possible that ASD had not yet been diagnosed in some of the 24-month old toddlers in this same—an empirical question to be addressed in subsequent neurodevelopmental evaluations.
Conclusions:
Even as early as 24 months old, toddlers with TSC who have weak practical living skills are at high risk for behavioral/emotional concerns that are associated with ASD, underscoring the need for early behavioral intervention for these toddlers in order to optimize developmental outcomes.

130 **126.130** Adaptive Functioning and Illness/Injury Coping in Children and Adolescents with Autism Spectrum Disorder

J. H. Filliter[1], *K. Aubrey*[2], *I. M. Smith*[3] *and S. A. Johnson*[4], *(1)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (2)Dr. Kate Aubrey, Psychologist, Kelowna, BC, Canada, (3)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (4)Dalhousie University, Halifax, NS, Canada*

Background: In children and adolescents (youth) with autism spectrum disorder (ASD), adaptive skills are often less well-developed than predicted by age and estimated IQ. Although social and communicative behaviours are the adaptive functioning domains typically most affected in ASD, daily living skills – including self-care, health, and safety behaviours – can also be compromised. Prior to this study, none had examined how the adaptive functioning of youth with ASD relates to illness/injury coping behaviours.
Objectives: We sought to better understand the relationship between adaptive functioning and illness/injury coping strategies in youth with ASD.
Methods: Participants were 24 youth with ASD (21 male), 24 age-, sex-, and IQ-matched typically developing (TD) youth (19 male), aged 10 to 17 years, and one parent for each ASD and TD participant (22 and 24 female, respectively). The Adaptive Behavior Assessment System – Second Edition (ABAS-II) was used to assess youth adaptive functioning. A semi-structured interview was administered to youth in order to assess illness/injury knowledge, both generally (e.g., illness/injury causality, symptom recognition, treatment, prevention) and in relation to specific ailments (e.g., cold, concussion, meningitis). Parent and self-reports of illness/injury coping were obtained using vignettes depicting characters with various ailments. The ailments consisted of illnesses, symptoms, and injuries that were balanced in terms of seriousness and frequency of occurrence, as determined by ratings from health care providers. Parents were asked to answer open- and closed-ended questions about how their children would cope with each condition.
Results: ABAS-II scaled scores were lower in the ASD group than in the TD group for all composite and subscales, including the Practical composite, which focuses on daily living skills and incorporates Health and Safety and Self-care subscales. There were no significant between-group differences in general or specific illness knowledge. Parents of youth with ASD described their children as displaying less active coping than their TD peers (60% vs. 93%, respectively), both with respect to general (e.g., information-, help-, and support-seeking) and specific (e.g., seeking out over-the-counter medications and ointments, requesting a physician visit) strategies. Youth with ASD were also reported to engage in more passive (e.g., emotionality, self-isolation) coping when ill/injured, compared to their TD peers (42% and 25%, respectively). Notably, use of specific active coping strategies was highly positively correlated with the Practical composite of the ABAS-II (r = .54). However, no relationship was found between use of general active coping strategies and the ABAS-II Practical composite (r = -.12).
Conclusions: Despite similarity in age, estimated IQ, and illness knowledge, youth with ASD and their TD peers demonstrated different illness coping patterns. Not surprisingly, youth with ASD who struggled more with daily living skills were reported to demonstrate fewer active coping strategies when ill/injured. However, this difference was restricted to specific and not general coping behaviours. Our results support the notion that personal care when ill falls within the broader construct of daily living skills, but suggest that actively seeking caregivers for assistance when ill/injured may be a particularly important behaviour to monitor in youth with ASD.

131 **126.131** Age-Based Patterns of Parent-Reported Medical and Behavioral Problems in Children and Adolescents with ASD

A. R. Marvin[1], *J. K. Law*[2], *D. J. Marvin*[3] *and P. H. Lipkin*[3,4], *(1)Painter Bldg 1st Fl, Kennedy Krieger Institute, Baltimore, MD, (2)Interactive Autism Network, Baltimore, MD, (3)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD, (4)Pediatrics, Johns Hopkins School of Medicine, Baltimore, MD*

Background:
Medical and behavioral problems are common in autism spectrum disorder (ASD); however, prevalence may vary by child's age and cognitive and verbal functioning.
Objectives:
To compare select medical and behavioral problems recently experienced by young children and adolescents with ASD, as reported by their parents
Methods:
Parent participants in the Interactive Autism Network (IAN)— a large, validated and verified, internet-mediated parent-report research registry—completed the Birth and Diagnosis Questionnaire (BDQ) on their child(ren) with ASD. The BDQ collects baseline data relating to each child's birth, ASD diagnosis, and development. In addition, the BDQ asks about the degree ("None", "Mild", "Moderate", or "Severe") to which the child has experienced 15 common medical/behavioral conditions associated with ASD during the past 30 days. See Table 1 for list of conditions. Parents were also asked to characterize their child's current level of functioning, including cognitive and verbal ability. A rating of "significantly below age level" on the cognitive functioning question was used as a proxy for intellectual disability (ID). A rating of "meaningful, fluent speech" was used to determine whether the child had normal verbal ability. Respondents were grouped into young children (6 to 10) and adolescents (ages 13 to 17). Children all had a professional diagnosis of ASD and a confirmatory score on the Social Communication Questionnaire >=12. Ordered Logistic Regression was performed on responses to the 15 condition questions by age group and degree of condition severity ("None", "Mild", "Moderate", or "Severe"). Control predictor variables included in the models were: Intellectual Disability; Normal Verbal Ability; Gender; Race; and Ethnicity.
Results:
Young Children (6-10 years): n=680; 80.4% male; 83.1% white; 10.3% Hispanic; mean (SD) age 8.6 (1.45) years; Adolescents (13-17 years): n=641; 81.6% male; 85.3% white; 11.2% Hispanic; mean (SD) age 15.1 (1.38) years. There was no statistical significant different in gender, race, or ethnicity.
See Table 1 for responses for each condition and the results of the Ordered Logistic Regression.
The areas of difficulty with the highest prevalence for both age-groups were: difficulty controlling emotions; irritability/aggression; hyperactively and impulsivity; anxiety; sensitivity to sounds; and sensitivity to textures/touch.
Young children experience more difficulties in: irritability/aggression; difficulty controlling emotions; self-injurious behavior; hyperactivity and impulsivity; movement/coordination; feeding; bowel movements; placing self in danger; placing others in danger; and elopement. Adolescents experienced a higher rate of depression. There was no age-related difference for: anxiety; sleep problems; sensitivity to sounds; and sensitivity to touch.
Intellectual Disability and/or abnormal verbal development were associated with 13 of the 15 factors. Gender in combination with cognitive and verbal functioning was associated with the following: depression (female + normal verbal development), anxiety (female + ID); and hyperactively and impulsivity (male + ID).
Conclusions:
Parents of young children report more challenges for their children than reported for adolescents in behavior, coordination, GI concerns, and safety, while adolescents had greater problems with depression. Professionals should provide age-based anticipatory guidance and health and behavior surveillance for early identification and treatment of these conditions.

132 **126.132** Altered T Cell Subsets in Children with Autism Spectrum Disorders and Co-Morbid Gastrointestinal Symptoms

D. Rose[1], *H. Yang*[2], *M. Careaga*[3], *K. Angkustsiri*[4], *M. Rose*[5], *I. Hertz-Picciotto*[6], *J. Van de Water*[7], *P. Ashwood*[8] *and R. Hansen*[9], *(1)UC Davis M.I.N.D. Institute, Sacramento, CA, (2)UCD MIND institute, Sacramento, CA, (3)UC Davis/MIND Institute, Sacramento, CA, (4)University of California at Davis, Sacramento, CA, (5)MIND Institute, University of California, Davis, Sacramento, CA, (6)University of California at Davis, Davis, CA, (7)University of California at Davis MIND Institute, Davis, CA, (8)UC Davis, Sacramento, CA, (9)UCD MIND Institute, Sacramento, CA*

Background: The existence of gastrointestinal (GI) symptoms in children with autism spectrum disorders (ASD) has been estimated to occur 6 to 8 times more often than in typically developing children. The most commonly reported symptoms include: diarrhea, constipation, alternating bowel habits, gassiness or bloating, vomiting, and abdominal pain. While intestinal inflammation, altered microbiome profiles, and impaired intestinal permeability have been observed in children with ASD who experience GI symptoms, mechanisms underlying GI symptoms in ASD and relationship with behavioral phenotypes or other comorbid symptoms is still poorly understood.
Objectives: To characterize and assess T cell populations in children with ASD with and without GI co-morbidities, and the association with behavioral symptoms.
Methods: Children were recruited from the CHildhood Autism Risk from Genetics and the Environment (CHARGE) study and placed into one of four study groups based on responses from the GI symptom survey (adapted from standardized Rome III Diagnostic Questionnaire for the Pediatric Functional GI Disorders): children with ASD who experience GI symptoms of irregular bowel habits (ASD^{GI}) and children with ASD who do not have a history of GI symptoms (ASD^{NoGI}) compared to typically developing children with GI symptoms (TD^{GI}) and typically developing children without a history of GI symptoms (TD^{NoGI}). Peripheral blood mononuclear cells (PBMC) were isolated from participant's blood, stimulated *in-vitro* for 4 hrs and stained for surface markers and intracellular cytokines for flow cytometry; including markers for T cell subsets and for β7, part of the α4β7 integrin that is upregulated on lymphocytes homing to the GI tissue. Behavioral assessments and diagnosis were performed by trained clinicians and included Autism Diagnostic Observation Schedule (ADOS), Autism Diagnostic Interview – Revised (ADI-R) and Aberrant Behaviors Checklist (ABC) scores.
Results: Flow cytometric analysis revealed several differences between groups. Children in the ASD^{GI} group had significantly decreased regulatory T cells (T_{regs}), identified as $CD25^{+}Foxp3^{+}$ T cells, compared to ASD^{NoGI}, furthermore, ASD^{GI} children were found to have a lower frequencyof gut homing T_{regs} ($B7^{+}CD25^{Hi}$ cells) compared to TD^{NoGI}, whereas both ASD groups were found to have reduced number of $IL\text{-}10^{+}$ T cells compared to TD^{NoGI}. However, ASD^{GI} children had the highest percentage of $IL\text{-}17^{+}$ CD4 T cells compared to all other groups, while ASD^{NoGI} displayed the highest percentage of $IL\text{-}13^{+}$ CD4 T cells. In addition to changes in T cell populations, children in the ASD^{GI} group displayed increased aberrant behaviors, as indicated by increased scores on the ABC subscales for: Irritability, Hyperactivity and Social Withdrawal.
Conclusions: Children with ASD displayed deficits in regulatory T cell populations compared to typically developing controls, regardless of the presence of GI symptoms, however, the ASD^{GI} group had the lowest T_{reg} population numbers. Interestingly, the two ASD groups differed in T helper subset populations with ASD^{GI} children displaying more of a T_H17 phenotype (elevated $IL\text{-}17^{+}$ T cells), whereas ASD^{NoGI} exhibited more of a T_H2 phenotype (elevated $IL\text{-}13^{+}$ T cells), suggesting that children with ASD may have deficits in immune regulation that may lead to elevated inflammatory T cell subsets.

133 **126.133** Anxiety Disorders in Adults with Autism: A Population-Based Study.

V. Nimmo-Smith[1,2]*, C. Magnusson*[3]*, H. Heuvelman*[1]*, C. Dalman*[3]*, M. Lundberg*[3]*, S. Idring Nordstrom*[4]*, P. Carpenter*[5] *and D. Rai*[1]*, (1)School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, (2)Avon & Wiltshire Partnership NHS Mental Health Trust, Bristol, United Kingdom, (3)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, (4)Department of Public Health Sciences, Stockholm, SWEDEN, (5)BASS Autism Services for Adults, Avon & Wiltshire Partnership NHS Trust, Bristol, United Kingdom*

Background: Anxiety is common in children with autism, but studies of the prevalence of specific anxiety disorders in adults with autism are limited. It has been suggested that anxiety disorders may be more prevalent in autistic individuals without intellectual disability, who may have more insights into their problems. Furthermore, autism may be genetically linked to anxiety disorders, but few studies have examined the rates of anxiety disorders in non-autistic full and half siblings of individuals with autism.
Objectives: 1) To assess the associations of autism with adult anxiety disorders compared with the general population. 2) To study whether the associations are different for people with autism with and without intellectual disability. 3) To examine the risk of anxiety disorders in non-autistic full and half siblings of probands with autism, compared to the general population.
Methods: The Stockholm Youth Cohort comprises persons aged 17 years or younger who had ever lived in Stockholm County, Sweden, from January 1, 2001, until December 31, 2011. We included cohort members aged 18 or older on December 31, 2011 who had ever received a diagnosis of autism (nâ€‰=â€‰3544) and their full and half-siblings never diagnosed as having autism. Of the 3544 individuals with autism we distinguished the 1046 with intellectual disability from those without intellectual disability (n= 2498). We calculated risk ratios (RRs) for all anxiety disorders ascertained using registers from outpatient and inpatient public service use, adjusted for parental age; highest parental education; household income; whether the child or either of their parents were born abroad; parental mental illness; sex and age at end of follow up.
Results: Â Around a fifth (20.8%) of people with autism had an anxiety disorder diagnosed in adulthood, compared to 8.6% of the general population (RR= 2.76, 95% CI 2.58-2.94). Individuals with autism without intellectual disability were much more frequently diagnosed with anxiety disorders in adulthood (24.38%), than those who had autism with intellectual disability (12.24%). The adjusted RRs for all anxiety disorders for people with autism without intellectual disability was 3.16 (95% CI, 2.95-3.38); whereas those for people with autism and intellectual disability were 1.72 (95% CI, 1.47- 2.02). Non-autistic full siblings of people with autism also had a greater risk of anxiety disorders than the general population [RR 1.35 (95% CI, 1.22- 1.48)] but there was no evidence for an increased risk of anxiety disorders for non-autistic half-siblings (RR = 1.03; 95% CI, 0.83-1.27) as compared to the general population.
Conclusions: People with autism without intellectual disability have notably higher rates of anxiety disorders diagnosed in adulthood than the general population, and than individuals with autism and intellectual disability. The associations with anxiety disorders were highest in individuals with autism, followed by non-autistic full siblings and lowest in non-autistic half siblings suggesting that greater genetic load for autism may increase the risk for anxiety disorders.

134 **126.134** Anxiety Disorders in Preschool Age at Risk Children: Autism Siblings and Fragile X Syndrome

K. E. Caravella[1] *and J. Roberts*[2]*, (1)University of South Carolina, Columbia, SC, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background: Anxiety is one of the most common co-morbid conditions presenting in individuals with autism spectrum disorder (ASD), with up to 66% meeting criteria for at least one disorder. In groups at high risk for ASD, such as infant siblings and individuals with fragile X syndrome (FXS), rates of anxiety have also been identified as elevated. In FXS, rates of anxiety disorders are reported to occur at a rate of 86% of individuals with FXS over the age of 5 meeting criteria for at least one anxiety disorder. In infant siblings without ASD, rates of anxiety are found to be greater than controls, however prevalence rates have not been reported in a preschool age sample.
Objectives: This study aimed to examine preliminary prevalence rates of anxiety disorders in a preschool age sample of two groups at high risk for developing ASD, ASIBs and individuals with FXS, compared to a chronologically age matched control sample.
Methods: The mothers of 58 children ages 3-6 (11 autism siblings (ASIB), 25 controls and 22 children with FXS) were administered the Preschool Age Psychiatric Assessment (PAPA) at one time point. The PAPA is a semi-structured diagnostic interview that measures symptoms consistent with DSM-IV childhood disorders and requires in-depth research training. The anxiety disorders domain was used in the analysis, which includes the following domains: Separation Anxiety Disorder, Specific Phobia, Generalized Anxiety Disorder and Social Phobia. PAPA algorithms provide a dichotomous output representing whether symptoms did or did not meet criteria for each disorder.
Results: Anxiety disorders occurred at a rate of 18% (n=2) in the ASIB group, 36% (n=9) in the control group, and 68% (n= 15) in the FXS group. Across all groups, Specific Phobia was the most commonly endorsed disorder, with all but one participant who met who an anxiety disorder (FXS), meeting criteria for Specific Phobia. Rates of the other anxiety disorders occurred at the following rates across the ASIB, control and FXS groups respectively; Generalized Anxiety Disorder: 18%, 9%, 23%, Separation Anxiety Disorder 9%, 8%, 5% and Social Phobia 9%, 16%, 32%.
Conclusions: This study is the first to examine rates of anxiety disorders in a preschool age sample of individuals with FXS and high risk autism infant siblings. Specific phobia had the highest prevalence across all groups, which inflated the summary level prevalence rates of anxiety disorders universally. The high rates of specific phobia may be due to its transient nature in childhood, which may represent a more developmentally appropriate fear response, rather than a stable anxiety disorder. Consistent with previous literature, rates of anxiety disorders were highest among the FXS group. In contrast with previous literature, ASIBs in the sample did not show elevated rates of anxiety compared to the control group, however interpretation is considered preliminary given the small sample size of ASIBs.

135 **126.135** Are Autistic Traits Associated with Suicidality in General Population Young Adults? a Test of the Interpersonal-Psychological Theory of Suicide.

M. Pelton *and S. A. Cassidy, Coventry University, Coventry, United Kingdom*

Background: Autism Spectrum Conditions (ASC) have recently been associated with increased risk of suicidality. However, no studies have explored how autistic traits may interact with current models of suicidal behaviour in the general population. This limits our understanding of possible risk and protective factors for suicide among those with ASC, and impedes development of appropriate risk assessments and suicide prevention strategies. The Interpersonal-Psychological Theory of Suicide (IPTS) is potentially a strong candidate for conceptualising the movement from suicidal thoughts to behaviours in relation to autistic traits, given its focus on difficulties which are commonly associated with ASC.
Objectives: To establish how self-reported autistic traits interact with perceived burdensomeness and thwarted belongingness in predicting suicidal behaviour, in the context of the Interpersonal-Psychological Theory of Suicide (IPTS).
Methods: The sample was comprised of 163 general population young adults (aged 18-30 years). Participants completed an online survey including self-report measures of thwarted belonging and perceived burdensomeness (Interpersonal Needs Questionnaire), autistic traits (Autism Spectrum Quotient), current depression (Centre for Epidemiological Studies Depression Scale), and lifetime suicidality (Suicide Behaviour Questionnaire-Revised).
Results: Results showed that burdensomeness and thwarted belonging significantly mediated the relationship between autistic traits and suicidal behaviour. Both depression and autistic traits significantly predicted thwarted belonging and perceived burdensomeness. Autistic traits did not significantly moderate the relationship between suicidal behaviour and thwarted belonging or perceived burdensomeness.
Conclusions: Results suggest that the IPTS provides a useful framework for understanding the influence of autistic traits on suicidal behaviour. Autistic traits present in the general population are associated with increased risk of suicidality. Feelings of not belonging in the world, being a burden on friends and family, and depression are all associated with autistic traits, and account for the association between autistic traits and suicidality. The psychometric properties of these measures need be explored in those with clinically confirmed diagnosis of ASC, in order to replicate and extend these findings. However, clinicians need to be aware of increased risk of suicidality in those with high autistic traits, and when present, screen for suicidal thoughts, behaviours, and feelings of belonging, burden and low mood.

136 **126.136** Arousal Dysregulation in Children with Autism Spectrum Disorder

S. Zavodny[1]*, C. M. Kerns*[2]*, L. Berry*[3]*, W. T. Eriksen*[4]*, A. Bennett*[5]*, S. K. Malone*[6]*, J. Pinto-Martin*[1]*, A. Hanlon*[7]*, J. D. Herrington*[8,9] *and M. C. Souders*[10]*, (1)University of Pennsylvania, Philadelphia, PA, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (3)Baylor College of Medicine, Houston, TX, (4)University of Pennsylvania School of Nursing, Philadelphia, PA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)Sleep Medicine, University of Pennsylvania, Philadelphia, PA, (7)School of Nursing, University of Pennsylvania, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Perelman School of Medicine, The University of Pennsylvania, Philadelphia, PA, (10)University of Pennsylvania/The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Substantial heterogeneity exists in the degree of impairment, the collection of behavioral symptoms and the medical conditions associated with Autism Spectrum Disorder (ASD). Identifying explicit ASD phenotypes based on a constellation of symptoms may lead to greater understanding of the causal mechanisms of ASD and precise treatments. Arousal dysregulation in children with ASD may produce symptoms including anxiety and insomnia.
Objectives: The purpose of this study was to investigate the relationship between anxiety, biomarkers of arousal dysregulation and sleep parameters in ASD versus typically-developing controls (TDC). We hypothesize that individuals with ASD and anxiety as compared to individuals with ASD without anxiety and TDC will have: (1) greater rate of insomnia, defined as difficulty falling and maintaining sleep with daytime impairment, and a sleep latency of greater than 30 minutes as measured by actigraphy; (2) greater sleep latency, decreased sleep efficiency; (3) higher levels of urine catecholamines; (4) lower Respiratory Sinus Arrhythmia score.
Methods: Setting: Home and center visit at the Center for Autism Research (CAR) at the CHOP. Anxiety diagnosis was made with Anxiety Disorders Interview Schedule. Sleep parameters included CSHQ and 7 nights of actigraphy. Biomarkers of arousal dysregulation included urine catecholamine diurnal samples. Respiratory Sinus Arrhythmia (RSA) was obtained using a BioHarness ECG system taking a clean 5-minute interval from a 30-minute session at the CAR lab.
Results: Sample = 57 ASD, 15 TDC, ages 6-18.
47% of ASD subjects had anxiety. 53% of ASD subjects had insomnia. Our sample had a significant relationship between anxiety and insomnia (X^2<.0001): 88.9% of children with ASD and anxiety also had insomnia, while insomnia was present in only 20% children with ASD without anxiety. In order to identify the relationship between a phenotype of arousal dysregulation and biomarkers, we separated the cohort into two groups: Group A including children with ASD without anxiety and no insomnia (n=24), and Group B including children with ASD, anxiety and insomnia (n=24).
ASD cohort had longer sleep latency than TDCs (30.5 min vs. 19.8 min, p=.025). Group A sleep latency was 19.7 min, and Group B sleep latency was 40.1 min (p=.001).
Group B had a higher CSHQ score than Group A (p=.082), specifically sleep anxiety (p=.072) and daytime sleepiness (p=.039). Group B sleep onset delay and sleep anxiety scores were greater than TDC (p=.065, p=.026).
Total sample mean evening urine epinephrine level was 9.39 µg/g creatinine, with Group A 7.57 µg/g creatinine, Group B 12.43 µg/g creatinine, and TDC 7.62 µg/g creatinine. Reference epinephrine level for children aged 10-15 years is 8 µg/g creatinine (Pussard). Urine epinephrine levels were greater in Group B than in TDCs and Group A (p=.1628).
Group B had lower RSA than Group A (6.1 vs. 6.9, p=.035).
Conclusions: Â A potential link between insomnia and anxiety in children with ASD was found. Sleep latency differed significantly between TDC and ASD, with Group B having the longest sleep latency. Increased epinephrine in evening urine and lower RSA support a hypothesis of an arousal dysregulation phenotype in children with ASD.

137 **126.137** Assessment of Suicidal Risk in Children and Adolescents with Autism Spectrum Disorder Presenting to a Pediatric Emergency Department

R. A. Vasa[1], *P. Nair*[2], *H. Wilcox*[2], *M. Goldstein*[2] *and S. Edwards*[3], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins Hospital, Baltimore, MD, (3)University of Maryland, Baltimore, MD*

Background: Assessment of suicidal risk in children and adolescents with autism spectrum disorders (ASD) is a challenge due to their limited verbal and communicational skills. The existing body of literature mainly focuses on youth with ASD in community and hospital settings. Results indicate a higher rate of suicidal ideation in youth with ASD compared to control subjects. Potential risk factors for suicidality in this population include the absence of intellectual disability, a history of trauma, and the presence of co-morbid psychiatric disorders. Research on assessment of suicidal risk among children and adolescents with ASD presenting to the emergency department (ED)is scarce. Given the high rates of ED use in youth with ASD and the challenges with eliciting suicidality, developing methods to assess suicidal ideation in ED settings is critical in order to determine the most safe disposition plan (Kalb et al., 2012).
Objectives:
1. To compare the efficacy of the Ask Suicide Screening Questionnaire (ASQ) versus general screening at triage when assessing suicidal risk in children and adolescents with ASD in the ED setting.
2. To analyze the primary concerns and associated characteristics of children and adolescents with ASD who reported suicidal ideation.
Methods: Participants included 104 children and adolescents with ASD who presented to the ED of a major academic medical center. Participants were screened for suicidal risk through general questioning at triage and using the ASQ questionnaire. The ASQ is a 4-item suicide screening instrument that can be administered to patients in the ED for psychiatric or non-psychiatric reasons by nurses regardless of psychiatric training (Horowitz, et al., 2012). Participants who presented with psychiatric or behavioral complaints were screened more consistently than those with medical chief complaints. A chart review was conducted for 21 among 31 ASD youth who screened positive for suicidality with the ASQ screen (data for 10 participants were unavailable).
Results: Twelve children with ASD were identified as experiencing suicidal ideation on general screening at triage where as 31 children screened positive for suicide by the ASQ questionnaire, indicating that the ASQ picked up 19 additional cases of suicidality among this group. Among the 21 children with ASD and suicidal ideation according to the ASQ who were studied in detail, 12 (57%) reported previous attempts to hurt themselves. Nine (42%) were identified as a suicidal risk only by the ASQ questionnaire and were missed during general risk assessment at triage. Among them, six (33%) patients presented to the ED with a chief concern of aggression and 3(14%) presented with psychosis. The most common psychiatric diagnosis in youth with ASD were anxiety (n=11, 52%), ADHD/ODD (n=9, 42%) and mood disorders (n=8, 38%). Precipitants for suicidal ideation included limit setting, bullying, and conflicts at school or with peers.
Conclusions: Brief suicide screening instruments such as the ASQ appear to be effective in assess suicide risk in children and adolescent with ASD who present to the ED. Further research is needed to identify specific risk factors and clinical determinants that characterize suicidal behaviors in children and adolescents with ASD.

138 **126.138** Associations Between Dietary Composition and Gastrointestinal Symptoms in Autism Spectrum Disorder

B. J. Ferguson[1], *D. M. Severns*[2], *S. Marler*[3], *E. B. Lee*[3], *M. O. Mazurek*[4], *M. L. Bauman*[5], *K. G. Margolis*[6], *J. Veenstra-Vander Weele*[7] *and D. Q. Beversdorf*[8], *(1)Radiology, University of Missouri, Columbia, MO, (2)University of Missouri, Columbia, MO, (3)Vanderbilt University, Nashville, TN, (4)Health Psychology, University of Missouri, Columbia, MO, (5)Dept of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA, (6)Pediatrics, Columbia University Medical Center, Morgan Stanley Children's Hospital, New York, NY, (7)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY, (8)University of Missouri, Columbia, Columbia, MO*

Background: Many individuals with autism spectrum disorder (ASD) have significant gastrointestinal (GI) symptoms, but the etiology is currently unknown. A previous study from our team found relationships between measures of autonomic nervous system (ANS) functioning and GI symptoms in ASD, especially for constipation. However, many individuals with ASD have altered diets which may affect GI functioning, and some may alter dietary composition in response to GI symptoms. Thus, it is important to examine dietary composition within the same sample of individuals from the aforementioned study to determine the possibility of diet interacting with the findings in this sample.
Objectives: In order to assess for an association between diet and GI functioning in ASD, we examined dietary composition and GI symptoms in a subset of individuals from a previous study in which our team had found relationships between measures of ANS functioning and GI symptoms, particularly for constipation.
Methods: A total of 80 individuals with ASD aged 6-18 who are enrolled in the Autism Speaks Autism Treatment Network (ATN) as well as general clinic patients at the University of Missouri Thompson Center for Autism and Neurodevelopmental Disorders participated in the study. A food frequency questionnaire assessing the child's dietary composition over the previous month was completed by the child's caregiver. The USDA Food Composition Database was utilized to provide comprehensive nutritional information for each food listed on the questionnaire, and the micronutrients and macronutrients contained in each food serving consumed over the past month were summed for each nutritional item (e.g., vitamins, minerals) for each participant. The child's upper and lower GI tract symptomatology over the past two months was assessed by administering the Questionnaire on Pediatric Gastrointestinal Symptoms, Rome III to this child's caregiver, and quantitative scores for upper and lower GI tract symptoms were created using a scoring rubric previously described by our research team.
Results: Although initial analysis found that upper GI tract symptoms were associated with total dietary fiber (p=0.042) and vitamin B6 intake (p=0.003), neither was statistically significantly associated with upper GI tract symptoms after adjusting for the 32 nutrients examined. There was no evidence for an association between lower GI tract symptoms and any nutrient.
Conclusions: These data suggest that nutritional composition is not associated with GI symptomatology in this sample of individuals with ASD. Therefore, variations in diet did not likely contribute to our previous findings of associations between GI symptomatology and ANS functioning as well as stress reactivity. Better understanding of other contributory factors will be needed to guide future research on the development of specialized treatments for those with ASD and co-occurring GI disorders.

139 **126.139** Associations of Sleep Disturbance and Autism Symptomatology in Children and Adolescents with ASD

T. Winkelman[1], *M. J. Rolison*[1], *S. L. Jackson*[1], *B. Lewis*[2], *S. Baddam*[3], *C. Canapari*[4] *and J. McPartland*[1], *(1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)Yale School of Medicine, Darien, CT, (3)Yale School of Medicine, New Haven, CT, (4)Pediatric Respiratory Medicine, Yale New-Haven Hospital, New Haven, CT*

Background: Between 50 and 80% of children and adolescents with Autism Spectrum Disorders (ASD) present with sleep disturbances, compared to just 9-50% of neurotypical and developmentally delayed (without ASD) children, suggesting a fundamental disruption of the sleep system in ASD. Clinicians and researchers often disregard these sleep abnormalities, despite their potential impact on the primary symptoms of ASD and on caregivers. The relationship between sleep difficulties and behavioral habits is likely bidirectional, as lack of sleep fuels daytime irritability, and behavioral problems interfere with a consistent sleep schedule. The resolution of sleep issues may allow for improved outcomes for the core symptoms of ASD.
Objectives: This study aims to retrospectively assess the association of sleep disturbance in children with autistic symptomatology.
Methods: Subjects were children and adolescents (N=52) seen in the Yale Developmental Disabilities Clinic. Children aged 3-14 years, with a confirmed diagnosis of autism (ADOS CSS≥4) were included. After excluding children outside the age range or without a confirmed autism diagnosis and those taking sleep medications other than melatonin, the final sample included 21 children; data collection and retrospective analyses of additional historical cases are ongoing. Parents completed a sleep history questionnaire which characterized sleep/wake time and sleep onset latency (SOL) as well as a 40-item Autism Screener Questionnaire, assessing symptoms of autism. T-tests were performed to evaluate the relationship of sleep disturbance and autism symptoms.
Results: Â Children aged 3-14 years (N=21) with a diagnosis of autism were stratified into those with (N=16, 76%) and without (N=5) disordered sleep as defined by SOL≥30 minutes. Children with disordered sleep were significantly more likely to have unusual sensory fixations (p<.001).
Conclusions: Â In this pilot study of sleep disturbance in a pediatric population with autism, disordered sleep as defined by a sleep onset latency of ≥30 minutes was observed in the majority of children with autism. Results are consistent with previously noted high rates of disordered sleep in autism. Our findings also suggest that disordered sleep is strongly associated with autistic symptomatology, specifically unusual sensory fixations. Future studies should assess sensory issues as a risk factor for sleep disturbance.

140 **126.140** Autism, Anxiety and the Role of Gene Expression in Female Children and Adolescents with Fragile X Syndrome

M. Chernenok[1], *J. L. Burris*[2] *and S. Rivera*[3], *(1)Department of Human Ecology, University of California, Davis, Davis, CA, (2)Department of Psychology, University of California, Davis, Davis, CA, (3)Department of Psychology, University of California at Davis, Davis, CA*

Background:
Fragile X syndrome (FXS) is a genetic disorder caused by a trinucleotide CGG expansion within the fragile X mental retardation 1 (*FMR1*) gene located on the X chromosome. In boys this typically leads to methylation and silencing of the gene. In girls, however, there is variability in gene expression due to compensation by the normally-functioning X chromosome. This variability provides an important opportunity to evaluate the differential role of FMR1 gene expression in the phenotypic presentation of the syndrome. FXS is highly comorbid (25-60%) with autism spectrum disorder (ASD) and with anxiety disorders (86%). Given the known increased prevalence of anxiety in females in general, the current study aims to not only elucidate the anxiety profile of adolescent females with FXS, but to also investigate the impact of ASD on anxiety in this population.
Objectives:
The current study evaluated the anxiety profiles of female children and adolescents with FXS, with and without comorbid ASD. Moreover, we included females with the full mutation and with mosaicism, as both groups allow us to explore the variable role of FMR1 gene expression on anxiety.
Methods:
Participants included 16 females with FXS, ages 9- 18, of which 8 had a comorbid ASD diagnosis. Allele status was confirmed by *FMR1* DNA testing. Activation ratio (AR) was calculated to measure the percentage of cells with the normal allele on the active X chromosome, and provided us with an estimate of *FMR1* of gene expression. Assessments included the Anxiety, Depression, and Mood Scale (ADAMS) used to evaluate anxiety, and the Autism Diagnostic Observation Schedule (ADOS) used to evaluate severity of autism symptomatology. An ANOVA was conducted to investigate the interaction between ADAMS, AR, and ASD diagnosis.
Results:
There was a significant main effect for autism diagnosis, F (1, 12) = 19.87, p = .001, such that girls with FXS who had an ASD diagnosis scored higher on the ADAMS (indicating increased severity) than those who did not. There was also a significant main effect for gene expression, F (1, 12) = 5.53, p = .037, and no diagnosis by gene expression interaction, indicating that individuals with decreased *FMR1* gene activation scored higher on the ADAMS independent of ASD diagnosis.
Conclusions:
These findings extend our knowledge about the role of autism and FMR1 gene expression in the severity of anxiety symptomatology present in adolescent girls with FXS. While prior work has focused on the prevalence of anxiety in the FXS phenotype, it has not, until now, examined the role of genetic variability in anxiety. Moreover, while ASD is also a clinically impactful component of the FXS phenotype, little to no work has linked ASD and anxiety directly to FXS. This study shows that not only do girls with FXS who have an ASD diagnosis have higher levels of anxiety, but that level of anxiety is directly impacted by the functioning of the *FMR1* gene.

141 **126.141** Behavioral Characteristics of Children with Comorbid Epilepsy and Autism Spectrum Disorder

H. N. Jackson[1], *J. Twachtman-Bassett*[2], *L. Derynioski*[3] *and L. Kalsner*[4], *(1)University of Connecticut School of Medicine, Farmington, CT, (2)Connecticut Children's Medical Center, Colchester, CT, (3)Connecticut Childrens Medical Center, Southington, CT, (4)Connecticut Children's Medical Center, Hartford, CT*

Background:
It is well recognized that epilepsy is more common among individuals with autism spectrum disorder (ASD) than in the general population, with prevalence estimates varying widely from 2.4 to 46 % compared to 1 to 2 % in the general population. While the co-occurrence of ASD and epilepsy is well established, it remains unclear if there is a causal relationship between the two disorders, or if shared neurobiological pathways are involved. The majority of research in to the relationship between comorbid epilepsy and ASD has focused on general variables including presence of intellectual disability and epilepsy type, yet little is known of the autism phenotype in this population, and how it differs from that of individuals with ASD alone. A few studies have investigated behavioral characteristics in those with ASD and epilepsy and have reported greater social impairment and maladaptive behaviors, yet results have been inconsistent and findings limited. Additional research is needed to fully characterize the autism-epilepsy phenotype as this may help to direct clinical care and assist in understanding the neurobiological basis of these co-existing disorders.
Objectives:
To compare clinical, genetic and neurobehavioral profiles of children with comorbid ASD and epilepsy to those with ASD alone in a clinic based, ethnically and racially diverse population.
Methods:
100 children with ASD (medical confirmation of diagnosis, completed DSM5 checklist or CARS-2 score verifying autism symptoms and ADOS-2 score in full autism range) were enrolled in the study (50 % Caucasian, 46 % racial or ethnic minority, 4% undisclosed). Eight subjects were diagnosed with epilepsy (history of two or more unprovoked seizures). Each subject underwent a detailed medical history and physical exam and chromosomal micro-array was sent. Participants were evaluated with the following assessments; Social Responsiveness Scale-2 (SRS-2), Vineland-II, PDDBI and either the Mullen Scales of Early Learning or the Stanford-Binet Intelligence Scales. Comparison was made between the ASD alone group (n=92) and those with comorbid ASD and epilepsy (n=8).
Results:
There was no significant difference in age, gender, race/ethnicity or presence of micro-array abnormality between groups. Children with ASD and epilepsy were reported to have higher rates of developmental regression, lower average IQ and were more likely to have speech delay. They were noted to have reduced responsiveness on the PDDBI along with decreased frequency of aggressive behaviors. In addition, the ASD/epilepsy group was noted to have greater deficits in social awareness on the SRS-2.
Conclusions:
We find that amongst children in a racially and ethnically diverse clinic setting, those with comorbid ASD and epilepsy have a greater degree of cognitive impairment and a specific pattern of behavioral deficits marked by reduced responsiveness and greater deficits in social awareness. Those with ASD and epilepsy have a decreased frequency of aggressive behaviors, possibly related to reduced awareness and responsiveness to their environment. These findings contribute to expanding literature describing the autism/ASD phenotype and the specific challenges faced by this subset of the ASD population.

142 **126.142** Behavioral Inhibition and Activation As a Modifier Process in Youth with ASD

H. K. Schiltz[1], *A. McVey*[1], *A. D. Haendel*[2], *B. Dolan*[1], *K. A. Willar*[3], *S. Stevens*[4], *A. M. Carson*[5], *F. Mata-Greve*[1], *E. Vogt*[1] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Interdisciplinary PhD program (Psychology and Biomed Science), Marquette University, Milwaukee, WI, (3)Children's Hospital Colorado, Aurora, CO, (4)University of Minnesota Medical School, Blaine, MN, (5)Baylor College of Medicine/Texas Children's Hospital, Houston, TX*

Background: The Modifier Model of ASD suggests that phenotypic variability in ASD may stem from non-syndrome specific psychological processes. One such process involves motivational biases, namely the Behavioral Inhibition System (BIS) and Behavioral Activation System (BAS). The BIS/BAS may not only contribute to core features of ASD, but these motivational systems have also been associated with vulnerability for emotional and behavioral difficulties in typically developing samples, which are also common co-occurring concerns among individuals with ASD. However, it remains unclear in what capacity BIS/BAS related motivation, as measured by a self-reported questionnaire, relates to ASD symptomology and co-occurring emotional and behavioral challenges in adolescents with ASD.
Objectives: This study aims to address the aforementioned gap in the literature by examining the relation between reports of behavioral inhibition and activtion, ASD Symptomology, and co-occurring emotional and behavioral symptoms in adolescents with ASD.
Methods: Forty-eight adolescents (Age: M=13.36, SD=1.37; IQ: 105.25, SD=18.21) with ASD participated in this study. One outlier was excluded from analyses. ASD was confirmed using the ADOS. Participants provided self-report on the BIS/BAS Scales and Youth Self-Report (YSR). Parents completed the Autism Spectrum Quotient (AQ) and the Child Behavior Checklist (CBCL) on their adolescent.
Results: Pearson's correlations revealed a significant negative association between the AQ total score and BAS Drive scale (r=-0.33, p=0.03). For the YSR, the BIS scale was positively related to the Anxious/Depressed (r= 0.45, p=0.001), Internalizing Problems (r=0.27, p=0.07), Anxiety Problems (r=0.40, p=0.005), Somatic Problems (r=0.31, p=0.03), Obsessive Compulsive Problems (r=0.38, p=0.008), and Post-Traumatic Stress Problems (r=0.45, p=0.002) subscales. The BAS Drive scale was positively related to the Withdrawn/Depressed YSR subscale (r=0.29, p=0.04). The BAS Fun-Seeking (r=0.36, p=0.02) and Reward Responding scales (r=0.37, p=0.01) were positively related to the Positive Qualities YSR subscale. For the CBCL, the BAS Fun-Seeking scale was negatively related to the Externalizing Problems (r=-.31, p=0.04), Withdrawn/Depressed (r=-0.29, p=0.05) and Somatic Problems (r=-0.30, p=0.04) subscales.
Conclusions: Overall, this study suggests that the BAS may be more salient for ASD-related symptoms, while the BIS appears to play a key role in co-occurring internalizing symptomology in adolescents with ASD. The BAS systems may modify the expression of ASD, such that less BAS Drive-related motivation was related to greater overall ASD symptom presentation. In regards to co-occurring symptoms, self-report on the YSR suggests that a greater tendency for BI may pose vulnerability for developing internalizing symptomology. The positive association between the BAS Drive and Withdrawn/Depressed might reflect that adolescents who have ASD and are more inclined to approach situations have more opportunities to experience social failure, which may trigger depressive symptoms. Parent-report revealed limited findings, potentially due the inherent imprecision of measuring internalizing symptomology as outside observers. Greater Fun-Seeking behavior was associated with a combination of less Withdrawn/Depressed and Externalizing problems. Perhaps, approach towards enjoyable experience (fun-seeking) is protective against displaying aggression and rule-breaking in youth with ASD.

143 **126.143** Behavioural Inhibition As a Predictor of Anxiety Problems Among Children at Risk for Autism Spectrum Disorders

M. Ersoy[1], *G. Pasco*[2], *C. H. Cheung*[3], *T. Gliga*[4], *E. Jones*[5], *T. Charman*[6], *M. H. Johnson*[4] *and T. B. Team*[7], *(1)King's College London, London, United Kingdom, (2)Institute of Psychiatry, London, UNITED KINGDOM, (3)Psychology, Institute of Psychiatry, Psychology and Neuroscience, London, UNITED KINGDOM, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (5)Birkbeck, University of London, London, UNITED KINGDOM, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Birkbeck College London, London, United Kingdom*

Background: Anxiety problems are highly prevalent among children and adolescents with autism spectrum disorder (ASD). However the constructs that lead to heightened levels of anxiety in ASD remain poorly understood. In typically developing children, behavioural inhibition (BI) in the early years, which refers to initial reactions of wariness, fearfulness and shyness in unfamiliar contexts, has been identified as a robust predictor of anxiety problems in later childhood. However, there has been no investigation of BI and its correlates with anxiety problems among children at risk for ASD.
Objectives: This prospective longitudinal study aims to explore whether elevated levels of anxiety are observed among infants at heightened familial risk of ASD (HR; due to having an older sibling with a diagnosis of ASD) compared to infants at low-risk (LR; having an older sibling without ASD). Parent-report measures of BI are obtained at 8, 14 and 24 months of age and used to investigate associations between BI and anxiety problems at 36 months.
Methods: The sample in this study includes 113 HR and 27 LR children. Of the 113 HR infants, 17 met DSM-5 criteria for ASD (HR-ASD), 32 participants did not meet clinical criteria for ASD but presented with other atypicalities (HR-Atypical), and 64 participants were typically-developing (HR-TD). BI was measured using the fearfulness subscale of the Infant Behaviour Questionnaire (IBQ) at 8 and 14 months and the fearfulness and shyness subscales of Early Childhood Behaviour Questionnaire (ECBQ) at 24 months. Anxiety problems were measured with the Child Behaviour Checklist (CBCL) at 36 months.
Results: There was a significant difference between outcome groups in anxiety scores F_w (3, 45) = 5.82, p<.001. Post-hoc comparisons showed that the HR-ASD group exhibited significantly higher anxiety scores than the LR group (d= 1.26, p= .001) and HR-TD group (d = 0.99, p= .001). There was a positive and significant association between BI scores at 8 (r=.30, p =.002), 14 (r=.35, p <.001) and, 24 (r=.48, p <.001) months and anxiety problems at 36 months. Conclusions: Children who met ASD diagnosis at age three years were reported to have elevated anxiety scores in infancy compared to LR and HR-TD groups. There was a significant association between BI and anxiety scores and the effect of this association increased from 8 months to 24 months. These findings are important for our understanding of BI as a predictor of the neurodevelopmental emergence of the co-occurring anxiety problems that are common in children with ASD.

144 **126.144** Characteristics of ASD in Adults with Williams Syndrome

E. Anderberg[1], *M. South*[2], *L. Dai*[3], *M. D. Prigge*[3], *M. Burback*[3], *J. S. Anderson*[3], *O. Abdullah*[3] *and J. R. Korenberg*[4], *(1)Brigham Young University, Provo, UT, (2)Psychology and Neuroscience, Brigham Young University, Provo, UT, (3)University of Utah, Salt Lake City, UT, (4)Pediatrics, University of Utah, Salt Lake City, UT*

Background: Â Williams syndrome (WS), a rare developmental disorder caused by deletion at 7q11.23, is generally characterized by excessive socialization and communication (over-friendliness and talkativeness). While this over-socialization is sometimes thought to be antithetical to the stereotypical under-socialization of autism spectrum disorder (ASD), prior research has shown that many young children with WS also show significant symptoms of ASD and may meet diagnostic criteria for ASD based on observational and parent reports. Little work has been done on the social functioning and repetitive behaviors in adults with WS and little is known about the overlap of WS and ASD in an adult population.
Objectives: Â This study aims to explore the prevalence of ASD in adults with WS and understand the characteristics of those who meet criteria for both disorders
Methods: Data for this study are taken from an ongoing genetics, neuroimaging, and behavioral study of adults with William's syndrome. Preliminary information is based on the first eight participants. 20 participants are expected by April 2017. The Autism Diagnostic Rating Scale, second edition (ADOS) was conducted by a research reliable clinician. Participants also completed a wide range of behavioral, emotional, and cognitive measures, including the Social Responsiveness Scale (SRS; parent report), the Wechsler Adult Intelligence Scale, 3rd edition (WAIS), the Peabody Picture Vocabulary Test (PPVT) and the Expressive Vocabulary test (EVT).
Results: In this sample, two participants (25%) received an ADOS classification of Autism, and one (13%) received a classification of Autism Spectrum. Five participants received non-spectrum classifications. Participants who showed significant ASD symptoms on the ADOS also had significantly higher SRS Social Communication scores, but did not show different SRS Repetitive and Restrictive Behavior scores from the non-spectrum participants. Verbal IQ and receptive and expressive vocabulary scores had an inverse relationship with ADOS scores and were the best predictor of autism spectrum classification.
Conclusions: Despite differences in social presentation, many adults with Williams syndrome also show significant symptoms of ASD. These symptoms seem to be mainly focused in the social communication domain of ASD, and observational measures and parent report measures line up well. The level of repetitive behaviors and interests in adults with WS does not seem to adequately discriminate those with ASD and those classified as non-spectrum. As has been shown in previous research, verbal IQ and vocabulary scores seem to be a relatively good predictor of social communication deficits in this population. Overall, a significant portion of adults with Williams syndrome may be experiencing social communication dysfunction that reaches a clinically significant level and likely requires attention and intervention.

145 **126.145** Characteristics of Children with ASD Who Improve with Fever: Insights from the Simons Simplex Collection

R. Grzadzinski[1], *C. Lord*[2], *S. J. Sanders*[3], *D. M. Werling*[4] *and V. Hus Bal*[5], *(1)Center for Autism and the Developing Brain, New York, NY, (2)Psychiatry, Weill Cornell Medical College, White Plains, NY, (3)UCSF, San Francisco, CA, (4)Psychiatry, UCSF, San Francisco, CA, (5)STAR Center for ASD & NDD; Dept of Psychiatry, University of California, San Francisco, San Francisco, CA*

Background: Anecdotal evidence suggests that a subset of children with ASD may show improvements during episodes of fever. The only prospective study on this topic (Curran et al, 2007) found that 83% of children with ASD showed significant improvements on at least one domain of the Aberrant Behavior Checklist (ABC) during an episode of fever. Overall, little is known about the broader behavioral profiles of children with ASD who are reported to improve with fever.
Objectives: The purpose of this work is to explore the behavioral characteristics of children whose parents report improvements during episodes of fever.
Methods: Using data from the Simons Simplex Collection (SSC), parents of 2,152 children between the ages of 4 and 18 (mean=8.9, SD=3.6) provided information about whether and in what areas their child improved during fever. Children who were reported to improve during fever (n=362; Improve Group) and those who reportedly do not improve during fever (n=1690; No Improve Group) were randomly assigned into discovery or replication samples (See Figure 1). The discovery sample consisted of 850 children (50%) from the No Improve group and 183 children (51%) from the Improve Group while the replication sample consisted of 840 children (50%) from the No Improve Group and 179 children (49%) from the Improve Group. Improve and No Improve groups in the discovery sample were compared on 1) demographic variables (age, sex, race), 2) NVIQ, 3) language level (per ADOS module), 4) parent report measures of medical history, ASD symptoms, repetitive behavior, adaptive skills, 5) clinical observation of ASD symptoms, and 6) presence of an ASD-associated de novo genetic mutation. Results from the discovery analyses that met the statistical threshold of $\alpha < .05$ were compared in the replication sample to confirm results.
Results: 362 children (17%) were reported to improve during fever across a range of domains (Temper/Behavior: 59%, Communication: 49%, Social Interaction: 41%, Repetitive Behaviors: 38%, and Cognition/Learning: 21%). Discovery analyses revealed that children in the Improve Group had significantly lower NVIQ [$t(1031) = 3.70$, $p < .001$] and language level [$\chi^2(2, N = 1033) = 6.79$, $p = .03$], as well as more restricted, repetitive behaviors across several domains on the Repetitive Behavior Scale-Revised and ABC. These results were consistent during replication analyses. In discovery analyses, children in the Improve Group were statistically more likely to have breathing problems during sleep [$\chi^2(1, N = 1024) = 7.94$, $p< .01$], but this result was not significant in the replication sample. Groups did not differ in age, race, sex, current parent-reported symptoms of ASD or in the proportion of children with de novo mutations.
Conclusions: Parents of a subset of children with ASD report improvements during episodes of fever. These children have lower language skills, lower NVIQ, and more restricted, repetitive behaviors. Understanding the behavioral profiles of these children may provide insights into the etiology of ASD and lead to innovative treatments.

146 **126.146** Chronobiology in Adulthood Autism Spectrum Disorder

P. Ballester[1,2], *M. J. Martínez*[3], *A. Javaloyes Sanchís*[4], *N. Fernández Cogollor*[5], *P. Gázquez Galera*[6] *and A. M. Peiró*[2,7], *(1)Hospital General Universitario de Alicante, Alicante, Spain, (2)Clinical Pharmacology, Organic Chemistry and Pediatrics, Universidad Miguel Hernández, Alicante, Spain, (3)Universidad de Murcia, Murcia, Spain, (4)EDUCATEA, Autism supporting living center, Alicante, Spain, (5)APNAV-ANGEL RIVIERE Autism supporting living center, Valencia, Spain, (6)Centro Infanta Leonor, Autism Support Living Center, Alicante, Spain, (7)Clinical Pharmacology, Hospital General Universitario de Alicante, Alicante, Spain*

Background:
Sleep disorders can occur in up to the 80% of people with Autism Spectrum Disorder (ASD). The evidence behind the contribution of sleep circadian rhythms and molecular mechanisms involving clock genes and melatonin route in ASD is very limited.
Objectives: Analyze the Circadian Rhythm sleep disorders (CRSD) in adults with ASD with Ambulatory Circadian Monitoring and their relationship with SNPs in *ASMT, Per1, Npas 2,* and *MTNR1A*genes.
Methods: A total of 92 subjects were enrolled on a prospective study to record sleep with Ambulatory Circadian Monitoring (24 hours for a week). Circadian rhythms (CR´s) were recorded and characterized by nonparametric indexes and sleep parameters were calculated. A subtotal of 51 subjects participated in a genetic substudy of SNPs from *ASMT, Per1, Npas 2,* and *MTNR1A*genes. Statistical analysis was performed using GraphPad Prism 5.0.
Results: ASD patients had significantly major total sleep time, sleep onset latency, num. awakenings, WASO and lower SE compared to controls with significant differences of Sleep CR´s along 24 h ACM determination. The genetic substudy found significant differences ($p< 0.05$) in the recessive genetic model from rs5989681 and overdominant genetic model of rs6416892 and rs885747 when compared the genotype and SOL.
Conclusions: This data suggest that ASD group sleep parameters and CR chronobiology could indicate the presence of CRSD in the ASD population. Apparently, there is a relationship between SOL and SNPs in genes Per1 and ASMT, but further genetic analysis increasing the study sample is required. Improving knowledge in this area is important for developing a model of sleep in ASD and targeting interventions.

147 **126.147** Chymotrypsin: Evidence of a Novel Pancreatic Insufficiency in Children with ASD?

D. A. Pearson[1], *L. E. Arnold*[2], *S. Bostrom*[3] *and M. G. Aman*[2], *(1)Psychiatry & Behavioral Sciences, University of Texas McGovern Medical School, Houston, TX, (2)Nisonger Center, Ohio State University, Columbus, OH, (3)Ericksen Research and Development, Centerville, UT*

Background:
Emerging research has suggested that some children with ASD appear to be at high risk for gastrointestinal concerns. It has also been noted that many children with ASD have diets that are highly self- selective, e.g., having a preference for carbohydrates. Although it remains unclear what the basis for GI disruption is, it may be the case that some children with ASD have insufficient levels of digestive enzymes needed to process some food types, e.g., protein. If a child has this deficiency, they cannot optimally digest a class of food (e.g., protein), their food avoidance may be related to unpleasant sequelae associated with its ingestion (e.g., under-digested meat feeling like "lead shot" in the stomach). The enzyme chymotrypsin digests protein into its component amino acids. Amino acids, especially essential amino acids, play a crucial role in the production of neurotransmitters (e.g., dopamine and serotonin), are regulators of gene expression, and form the building blocks for new proteins.
Objectives:
The objectives of this study were: 1) determine the prevalence of abnormal levels of the enzyme fecal chymotrypsin (FCT) in children with autism, and 2) to determine whether FCTÂ levels are associated with severity of autistic symptomatology.
Methods:
Participants were 323 children between the ages of 3 and 8 years (261 boys; mean age: 5.8 yrs.) who met DSM-IV criteria for Autistic Disorder, as screened by the Social Communication Questionnaire (SCQ) and confirmed by Autism Diagnostic Interview-Revised (ADI-R) and clinical interview.Â FCT levels were assessed using photometric assay of stool samples (performed by Quest Diagnostics); FCT levels ≤ 12.6 U/g are considered abnormally/pathologically low. Severity of autistic symptomatology was assessed using the total score of the Social Communication Questionnaire (SCQ) and the ADI-R subscale scores.
Results:
Of the 323 children, 198 (61.3%) had abnormally low/pathological levels of FCT activity (<12.6 U/g; mean FCT level=7.34), while 38.7% had normal levels (>12.6 U/g; mean FCT level=18.92). Comparison of FCT level and autism symptom level (i.e., ADI-R subscale scores, SCQ total score) in all participants revealed no statistically significant associations between FCT level and severity of autistic symptoms. This finding suggests that lower FCT levels in children with autism are not associated with more severe autistic symptomatology.
Conclusions:
The presence of low FCT levels in a large subset of children with autism suggests that chymotrypsin deficiency may be a key feature in some children with ASD. This enzymatic deficiency may place these at higher risk for a suboptimal supply of amino acids, which may in turn possibly undermine their ability to produce neurotransmitters, regulate gene expression, and synthesize new proteins. These findings may inspire further research into the role of the pancreas and amino acid deficiency in autism, and in a broader sense, into the physiology and biochemistry of a subset of children with autism. It also provides rationale for investigating chymotrypsin replacement therapy in children with autism who exhibit FCT deficiency.

148 **126.148** Diagnostic Billing Codes Vs. MINI PAS-ADD Clinical Interview: Big Data Accuracy for Identifying Psychiatric Comorbidities in Adults with ASD

K. J. Cottle[1], *M. Newman*[1], *A. V. Bakian*[2], *H. Coon*[1], *J. L. Davis*[1], *A. J. Fischer*[1] *and D. Bilder*[2], *(1)University of Utah, Salt Lake City, UT, (2)Psychiatry, University of Utah, Salt Lake City, UT*

Background: Researchers and clinicians report that 11-80% of individuals with ASD suffer from co-occurring psychiatric disorders. Researchers have begun taking advantage of the ease and availability of electronic medical records to study ASD and its comorbidities. Although this method of data collection is widely used to report prevalence estimates for medical conditions, the diagnostic accuracy of this data source for psychiatric conditions is unclear. Psychiatric conditions are more difficult to assess and could be biased by clinician preference, hospital setting, or documentation practices; therefore; it is possible that diagnostic billing code data are not a reliable source of case status identification. However, medical billing records still provide one of the only feasible opportunities to estimate co-occurring psychiatric disorders in large population-based samples.
Objectives: Evaluate the accuracy of using diagnostic billing codes to identify psychiatric comorbidities in adults with ASD.
Methods: Â This analysis is part of a larger study investigating medical, psychiatric, and social outcomes of 582 adults with ASD. The Mini PAS-ADD Clinical Interview was administered to assess co-occurring psychiatric disorders. The Utah Population Database provided diagnostic billing codes on psychiatric conditions from the two largest health care systems in the catchment area. All analyses were conducted between Mini PAS-ADD case status and diagnostic billing code case status for depression, expansive mood (bipolar disorder), anxiety, obsessive compulsive, psychosis, and an aggregated variable representing any co-occurring disorder. Chi-square tests were used to test for association. Spearman's rho was used to measure the strength of correlations. Lastly, sensitivity, specificity, positive predictive value, and negative predictive value estimates were calculated.
Results: Â The study sample consisted of 214 participants (84.6% male; mean age 35.4 years, SD=9.8) who had a completed Mini PAS-ADD interview. Fifty-four percent of participants had normal IQ. Significant differences were found in the proportion of ASD cases identified with co-occurring depression [$\chi^2(1)=22.5$, p <0.001], expansive mood [$\chi^2(1)=15.0$, p <0.001], obsessive compulsive [$\chi^2(1)=9.2$, p <0.005], psychosis [$\chi^2(1)=23.3$, p <.001], and any co-occurring disorder [$\chi^2(1)=4.0$, p <0.047] between the Mini PAS-ADD and diagnostic billing code approaches. In contrast, no difference was identified in the proportion of ASD cases with co-occurring anxiety [$\chi^2(1)=1.5$, p=0.22] between the two approaches.Â There were significant correlations for depression (r=0.32, p< 0.001), expansive mood (r=0.27, p<0.001), obsessive compulsive (r=0.21, p<0.002), psychosis (r=0.33, p<0.001), and any co-occurring disorder (r=0.14, p<0.05). Sensitivity estimates were relatively low, ranging from 24.1-58.2, and specificity estimates were relatively high, ranging from 67.9-92.7.
Conclusions: This preliminary analysis indicates that proportions of co-occurring disorders between data from diagnostic billing codes and diagnoses from the Mini PAS-ADD were discrepant. In addition, the sensitivity estimates were relatively low. Given that semi-structured clinical interviews are a preferred measure of co-occurring psychiatric conditions and the Mini-PAS ADD is empirically validated, the results suggest that diagnostic billing code data may not be a sensitive method of reporting co-occurring psychiatric diagnoses in adults with ASD for many co-occurring conditions. These associations will be explored further using an expanded data set.

149 **126.149** Differential Influences of ASD and ADHD Symptom Severity on Adaptive Functioning in Youth with and without ASD

Z. J. Williams[1], *S. L. Jackson*[2], *M. J. Rolison*[2], *T. C. Day*[2], *K. A. McNaughton*[1], *L. Morett*[1] *and J. McPartland*[2], *(1)Yale Child Study Center, New Haven, CT, (2)Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) are highly comorbid conditions, with population-based studies reporting that approximately 20% of children with ASD meet full criteria for an ADHD diagnosis (Surén et al., 2012). Children with comorbid ASD and ADHD tend to exhibit higher levels of autistic traits and lower levels of adaptive functioning than children with ASD alone, ADHD alone, or neither disorder. Only one study to date has investigated the ability of both ASD and ADHD symptom levels to predict adaptive functioning, finding that only ASD symptoms predicted adaptive behavior scores in a group of children with ASD, ADHD, or comorbid ASD/ADHD (Ashwood et al., 2015). It remains unknown whether that same relationship between dimensional trait measures and adaptive functioning exists in children with sub-clinical ASD/ADHD symptoms and higher levels of adaptive behavior.
Objectives: The current study aims to examine the relationship between dimensional measures of ASD and ADHD symptoms and adaptive functioning skills in youth with and without diagnosed ASD.
Methods: Parents of 45 (33 male, 12 female) intellectually able children and adolescents with ASD (age range 8-18, M = 14.13, SD = 2.62) completed the Child Behavior Checklist 6-18 (CBCL), Social Responsiveness Scale-Parent Report (SRS), and Vineland Adaptive Behavior Scales, Second Edition (VABS). These measures were also collected from the parents of 31 (17 male, 14 female) age- and IQ-matched typically developing (TD) controls (mean age = 14.13, SD = 2.24). The SRS total T-score served as a measure of autism symptoms, and the CBCL's Attention-Deficit Hyperactivity Problems (ADHP) T-score served as a measure of ADHD symptoms. Hierarchical regression analyses were performed separately for the two diagnostic groups, with the VABS subscales and Adaptive Behavior Composite (ABC) as dependent variables, Age, Sex, and FSIQ scores entered as independent variables during the first step (enter-method), and SRS and ADHP T-scores entered as independent variables during the second step of the analyses (stepwise-method).
Results: Regression analysis indicated that lower overall adaptive functioning (i.e. VABS ABC) was significantly predicted by higher SRS T-scores (β=-0.33) in the ASD group and higher ADHP T-scores (β=-0.41) in the TD group. Higher SRS T-scores significantly predicted reduced VABS Communication scores in both the ASD (β=-0.33) and TD (β=-0.49) groups. Like ABC scores, VABS Socialization scores were predicted by SRS T-scores (β=-0.42) in the ASD group and ADHP T-scores (β=-0.37) in the TD group. The regression model did not significantly predict VABS Daily Living Skills scores for either group (ASD: p=0.074; TD: p=0.194). The addition of ASD or ADHD symptom scores resulted in significant improvements in the predictive strength of all other models (ΔR^2=0.11–0.22, ps<0.05). In no model did both ASD and ADHD symptom levels independently predict adaptive behavior scores.
Conclusions: While ASD severity predicted overall adaptive functioning in those with ASD, sub-clinical ADHD symptoms more strongly predicted decreased adaptive functioning in children without either disorder. This finding implies that when present at sub-clinical levels, ADHD rather than ASD symptoms are more strongly related to functional impairment in the general population.

150 **126.150** Evaluation of Sleep Disruption in Adults with Neurodevelopmental Disorders

A. Galanopoulos[1,2], *J. Horder*[3], *V. Stoencheva*[4], *G. M. McAlonan*[5], *A. Nolan*[1], *D. G. Murphy*[5], *R. H. Wichers*[6], *K. Hughes*[1], *C. M. Murphy*[5], *K. L. Ashwood*[7], *S. Maltezos*[8], *D. Robertson*[1] *and E. L. Woodhouse*[9], *(1)Behavioural and Developmental Psychiatry, South London and Maudsley NHS Foundation Trust, London, United Kingdom, (2)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry,Psychology & Neuroscience, King's College, London, London, United Kingdom, (3)Institute of Psychiatry, King's College London, London, UNITED KINGDOM, (4)Sackler Institute for Translational Neurodevelopment and Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UNITED KINGDOM, (5)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Institute of Psychiatry, London, UNITED KINGDOM, (7)Forensic & Neurodevelopmental Disorders, King's College London, London, UNITED KINGDOM, (8)The Maudsley Hospital, London, UNITED KINGDOM, (9)Sackler Institute for Translational Neurodevelopment and Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom*

Background: Comorbidities commonly reported in children with Autism Spectrum Disorder (ASD) include sleep problems and attention-deficit/hyperactivity disorder (ADHD). ADHD itself is also often associated with sleep problems, however, there is limited understanding of the interplay between ASD, ADHD and sleep, especially in adults.
Objectives: This study aimed to identify the extent of sleep disturbances in a clinic sample of adults with ASD, ADHD, and both ASD and ADHD; and their relationship to symptom ratings. In addition, it examined the potential influence of symptoms of depression and anxiety on sleep patterns, as these symptoms are especially common in adults with ASD, and can also disrupt sleep.
Methods: The Pittsburgh Sleep Quality Index (PSQI) and Insomnia Severity Index (ISI) were used to assess sleep patterns in 164 (111 male, 53 female) adult patients attending ASD and ADHD specialist diagnostic services at the Maudsley Hospital, London, UK. Of these, 30 had a clinical diagnosis of ASD alone (ICD10), 98 had a clinical diagnosis of ADHD alone (DSM-V), and 34 had a dual clinical diagnosis of ASD and ADHD. Self-reported symptoms of ASD, ADHD, depression and anxiety were rated using the Autism-spectrum Quotient (AQ), Barkley's scale, and the Hospital Anxiety and Depression Scale (HADS), respectively.
Results: Overall, 91% of participants had "poor" sleep on the PSQI (total score 5+) and 44% had either "moderate" or "severe" insomnia on the ISI (score 15+). These high rates did not differ across the diagnostic groups (group comparison t-tests, all p>0.23). Insomnia scores across the entire cohort correlated with the HADS Anxiety score (r=0.477, p=0.001) but not the Depression rating (p=0.15). Insomnia scores also correlated with symptoms of hyperactivity (r=0.380, p=0.001), but not inattentive symptoms (p=0.15) and not with self-reported ASD symptoms (r=0.180, p=0.130). PSQI total score correlates were similar. Anxiety scores tended to be higher in those with ASD (p=0.055); whereas Barkley hyperactivity scores were significantly higher in those with ADHD (p=0.009).
Conclusions: This preliminary study indicates a high burden of sleep disturbances in adults with ASD, ADHD and comorbid ASD with ADHD. However the origins of these symptoms may be different in each condition, and this could have important implications for management. For example, it appears possible that anxiety is relatively more important in driving sleep problems in ASD, while hyperactivity is relatively more important in those with ADHD. Further work to characterize the causes of, and possible interventions for, sleep disorders in adults with neurodevelopmental conditions is therefore underway.

151 **126.151** Exploring Relationships Between Cognitive Rigidity, Alexithymia, Emotion Regulation, Intolerance of Uncertainty and Anxiety in Autism Spectrum Disorder

A. Ozsivadjian[1], *I. Magiati*[2], *M. Absoud*[1], *O. Malik*[1], *J. Oliver*[1] *and G. Baird*[3], *(1)Newcomen Children's Neurosciences Centre, Evelina London Children's Hospital at Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (2)National University of Singapore, Singapore, SINGAPORE, (3)Newcomen Children's Neurosciences Centre, Evelina London Children's Hospital at Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM*

Background: The increased prevalence of anxiety and autism spectrum disorder is now well documented (eg Simonoff et al 2008) and understanding of the atypical presentation of anxiety is also much advanced (Kerns et al 2014). However the aetiology of increased rates and atypical presentations is less well understood. Promising avenues of investigation include neurocognitive mechanisms such as cognitive rigidity and intolerance of uncertainty, and emotion processing pathways such as alexithymia and emotion regulation.
Objectives: In this study we investigate the inter-relationship between these variables and the relative impact of each on anxiety in a dataset of children diagnosed with autism spectrum disorder, using the ADI and ADOS, across a range of intellectual disability.
Methods: Questionnaires measuring intolerance of uncertainty, cognitive flexibility and alexithymia were administered to parent and child dyads as well as an emotional regulation questionnaire to parents only. Univariate statistics will be used to investigate significance of proposed predictors for anxiety. For the binary logistic regression, a model for anxiety will be developed using a backward elimination approach and then the performance of the proposed model will be assessed.
Results: Full results will be presented at IMFAR as we are currently still in the process of collecting data. The dataset will consist of approximately 150 children and parent dyads, with children aged between 6-18, and a gender ratio of approximately 3:1 males to females.
Conclusions: We propose a comprehensive model for mechanisms underpinning and/or leading to the increased prevalence of and frequently atypical presentation of anxiety and autism spectrum disorder.

152 **126.152** Exploring the Applicability of Models Explaining Development of Suicidal Thoughts and Behaviours in the General Population to the Case of Autism: A Systematic Review

K. S. Cook[1], *S. A. Cassidy*[1], *E. Bowen*[2] *and E. Knight*[1], *(1)Coventry University, Coventry, United Kingdom, (2)University of Worcester, Worcester, United Kingdom*

Background: Recent theoretical frameworks have been developed to explain why those who experience suicidal ideation may or may not go on to attempt suicide in the general population. However, despite growing evidence that suicidality is more prevalent in adults with Autism Spectrum Conditions (ASC) compared to the general population, these theoretical models have not been considered in relation to ASC.
Objectives: This systematic review aimed to identify models conceptualising the movement from suicidal thoughts to suicidal behaviours within the general population and consider their potential application to our understanding of suicide in ASC.
Methods: A systematic search of online databases (Psycinfo, PsycArticles, MEDline, EbscoAcademic Complete, CINAHL and Web of Science) was carried out to identify articles relating to models explaining the movement from suicidal thoughts to behaviours, in the general and ASC populations. In the general population, 385 articles were considered against the search strategy criteria and 7 studies were included in the final qualitative synthesis. The search was repeated to include ASC search terms and no relevant articles were returned.
Results: Three relevant models were identified through the general population search; the Interpersonal-psychological theory, the Integrated Motivational-Volitional model and the Three-Step theory. Characteristics of ASC were found to overlap with risk factors for both suicidal thoughts and behaviours in the general population. Reported difficulties in ASC including social cognition, and memory biases were represented as factors contributing to suicidal ideation in the general population, particularly within the integrated motivational-volitional model. All three models implicated some ASC symptoms including impulsivity and sensory sensitivities, as conferring increased capability for progressing from suicidal ideation to suicidal behaviours.
Conclusions: Although the search uncovered no current models of suicidality in people with ASC, findings from general population models generate hypotheses for future research to systematically explore suicidality within ASC populations. The general population models also provide an initial basis for developing ASC specific frameworks which take account of increased risk due to ASC symptomology. Findings of the systematic review and qualitative evidence synthesis provide a useful framework for future research exploring suicidality in ASC.

153 **126.153** Exploring the Relationship Between Autism Symptoms, Language Ability, and Externalizing Behaviors in Children with Autism

A. J. Schlink[1], *A. Sturm*[2], *C. Kasari*[3] *and M. Kuhfeld*[4], *(1)UCLA, Encino, CA, (2)Semel Institute for Neuroscience & Human Behavior, UCLA, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)University of Texas Austin, Austin, TX*

Background:
Individuals with autism spectrum disorders (ASD) often possess ADHD symptoms and problematic externalizing behaviors, which can exacerbate autism symptoms and reduce adaptive functioning skills (Sikora, Vora, Coury & Rosenberg, 2012). However, the relationship between these ADHD symptoms/externalizing behaviors and autism in children with minimal language has yet to be established.
Objectives:
The present study aimed to (1) evaluate the differences in presentation of externalizing behaviors between individuals with fewer than 5 words compared to those with more than 5 words and (2) to determine the relationship between autism characteristics and externalizing behaviors controlling for demographic characteristics.
Methods:
The present study included cross-sectional participant data from the Simons Simplex Collection and the National Database of Autism Research. Individuals who had received an ADOS Module 1 assessment were included in the presented analyses (Lord et al., 2012). Those who were rated as having fewer than 5 words on the ADOS item *Overall Level of Non-Echoed Spoken Language* were included in the “no words” group (*N*= 354) and individuals with more than 5 words were included in the “some words” group *(N*= 538). Externalizing behaviors were measured using the Child Behavior Checklist (CBCL) 1.5-5 or 6-18 *Aggressive Behavior* and *Attention Problems* and the Aberrant Behavior Checklist (ABC) *Hyperactivity* and *Irritability* subscales. First, magnitudes of mean differences between language groups on externalizing behaviors were computed using t-tests. Second, ADOS subdomains, gender, age, and language level ("no words", "some words"), were evaluated as predictors of externalizing behaviors in four separate regression models and insignificant predictors were excluded in the presented analyses. A Bonferroni correction (p<.0125) was applied to correct for multiple comparisons.
Results:
Language level did not significantly predict externalizing behaviors (*Attention Problems*: β=0.10, p=.99, *Aggressive Behavior*: β=0.33, p=.80, *Hyperactivity*: β=0.31, p=.09, *Irritability*: β=0.43, p=.17). None of the included variables were significant predictors of *Aggressive Behavior* $F(12,452)=1.51$, p=.12. ADOS RRB uniquely predicted both *Attention Problems* $F(1,466)=12.71$, p<.01 and *Irritability* $F(1,504)=7.92$, p<.01 such that more severe RRBs were associated with greater attention problems (β=0.16) and irritability (β=0.12). In contrast, *Hyperactivity* was predicted by ADOS SA Â (p<.01) and age ($F(2,695)=18.77$, (p <.01), such that more severe social affect was associated with higher levels of hyperactivity (β=0.14), and increasing age was associated with fewer symptoms of hyperactivity (β=-0.18).
Conclusions:
While presence of externalizing behaviors do not differ significantly for autistic individuals with no words compared to some language, externalizing behavior domains show varying association with social affect and RRBs. Individuals with more impaired social affect display more symptoms of hyperactivity, suggesting that treatment of hyperactivity symptoms may improve level of social engagement. It is noteworthy that the severity of RRBs is only associated with higher irritability and more attention problems. Determining the nature and directionality of the relationship between RRBs and attention and irritability is an important question for future research as well as exploration of additional predictors of externalizing behavior in minimally verbal individuals with autism to potentially facilitate intervention for core deficits.

154 **126.154** Exploring the Validity of the Social Anxiety Scale in Capturing Symptoms of Social Anxiety in Youths with Autism Spectrum Disorder

K. Ellison[1]*, K. Stinson*[2]*, K. Shulman*[3]*, M. J. Rolison*[1]*, T. C. Day*[1]*, K. A. McNaughton*[3]*, E. Jarzabek*[1]*, B. Lewis*[4]*, J. Wolf*[3]*, S. L. Jackson*[5]*, A. Naples*[6] *and J. McPartland*[1]*, (1)Child Study Center, Yale School of Medicine, New Haven, CT, (2)Yale University- Child Study Center, Milford, CT, (3)Yale Child Study Center, New Haven, CT, (4)Yale School of Medicine, Darien, CT, (5)School of Psychology and Neuroscience, University of St Andrews, St. Andrews, United Kingdom, (6)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Previous research indicates a high clinical prevalence of co-morbid anxiety in individuals with autism spectrum disorder (ASD). However, there has been less focus on the specific co-occurrence of social anxiety (SA) in ASD (Gillott et al., 2001). Limited research examines different aspects of SA or the relationship of SA to perceived social responsiveness in individuals with ASD (Bellini, 2004). Furthermore, while the Multidimensional Anxiety Scale for Children (MASC) has been found to be an appropriate measure of anxiety in ASD, there is a need for additional valid measures of SA specifically.
Objectives: The current study investigated SA in children with ASD and typically developing (TD) controls. We sought to evaluate the convergent validity of the Social Anxiety Scale for Adolescents/ Children, Revised (SAS-A/SASC-R) in capturing symptoms of SA in individuals with ASD through comparison to another established measure, the MASC. We also aimed to measure child-parent agreement in reports of the child's SA, as well as the relationship between SA and social behavior in ASD.
Methods: This study's sample was composed of 50 youth with ASD (37 males, 13 females) and 25 TD youth controls (18 males, 7 females), matched on gender, age and IQ (Table 1.). Data collection is ongoing. Social anxiety was measured using multiple standardized measures. Child self-report measures included the Multidimensional Anxiety Scale for Children (MASC-C) and Social Anxiety Scale for Adolescence/Children (SAS-A/SASC-R). Parent report of SA was also assessed by the MASC (MASC-P) and the child's social behavior was reported on the Social Responsiveness Scale, Parent Report (SRS-P).
Results: Children with ASD reported higher symptoms of SA [*M*=44.62, *SD*=11.76] than those with TD [*M*=38.44, *SD*=12.36] on the SAS-A/SASC-R [*F* (1,73) = 4.45 *p*=.04]. A multitude of significant correlates were found (Table 2.). SAS-A/SASC-R Total scores were highly correlated with the MASC-C SA [*r* =.70, *p*<.001] and MASC-P SA [*r*=.43, *p*<.001]. The subdomains of the SAS-A/SASC-R, Fear of Negative Evaluations (FNE) and Social Avoidance and Distress in New Situations and with New Peers (SAD-N) were also significantly correlated with the subdomains of the MASC-C, Humiliation and Rejection [*r*=.71, *p*<.001] and MASC-C Performance Fears [*r*=.59, *p*<.001], respectively. Child and parent scores on the MASC SA domain were significantly correlated (*r*=.39, *p*<.0.01), as were the MASC-P SA score and the child's SAS/SASC-R total [*r*=.44, *p*<.001]. The SAS-A/SASC-R, the MASC-C, and MASC-P SA domain did not correlate significantly with any domains of the SRS-P.
Conclusions: This study examined the validity of the SAS-A/SASC-R to measure symptoms of SA in individuals with ASD in comparison to the previously established use of the MASC. Results confirmed that the SAS-A/SASC-R can be used to measure symptoms of SA in ASD and can provide insight into the specific factors of SA that may be affecting the child. In this sample, social ability and symptoms of SA did not correlate. The SAS-A/SASC-R is likely capturing true symptoms of SA in children with ASD that are distinct from difficulties in social behavior as captured by the SRS-P.

155 **126.155** Eye Gaze Patterns of Adolescents with Social Anxiety Disorder: Associations Between ASD Features and Fixation Duration to Affective Stimuli

N. N. Capriola[1]*, A. T. Wieckowski*[1]*, S. W. White*[2]*, S. M. Roldan*[1] *and T. Ollendick*[1]*, (1)Virginia Tech, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Social Anxiety Disorder (SAD) is characterized by fears of potential evaluation by others. Autism Spectrum Disorder (ASD) is characterized by social communication impairments and restricted interests and repetitive behaviors (RRBs). SAD is a common co-occurring disorder for adolescents with ASD (White et al., 2014), however there is little agreement on how to disentangle features of SAD from ASD impairments. Although extant research has examined features of SAD within individuals with ASD (White et al., 2015), no research to date has examined how the features of ASD might manifest within youth with SAD. Previous eye-tracking research has shown that anxiety is associated with vigilance to angry faces (Mogg et al., 2000). However, the association between ASD features and fixation duration in teens with SAD has not been examined. It was predicted that features of ASD would be associated with heightened fixation duration to angry faces.
Objectives: The objective is to explore the influence of ASD features (i.e., social communication deficits, RRBs, and overall severity) on gaze in teens with SAD.
Methods: Data were drawn from a randomized controlled trial of a computerized treatment to reduce social anxiety in youth with SAD. The eye-tracking task used the NIMH Child Emotional Faces Picture Set (NIMH-ChEFS; Egger et al., 2011) consisting of teen faces. Each stimulus presentation contained a pair of photographs of the same person, one photo depicting an emotional expression and the other depicting a neutral emotional expression. All participants (*n*=49; *M*age=14.35) were between the ages of 12-16 and free of a co-occurring intellectual disability. SAD diagnoses were confirmed by semi-structured clinical interview (ADIS; Silverman & Albano, 1996) and youth with prior ASD diagnosis were excluded. Parents completed the Social Responsiveness Scale-2 (SRS-2; Constantino, 2012) as an index of ASD symptom severity and the youth self-reported on social anxiety via the Screen for Child Anxiety Related Disorders (SCARED; Birmaher et al., 1997).
Results: For the present analyses, social anxiety severity was controlled for in order to uniquely examine the role of ASD features on gaze duration to emotional faces. Partial correlation coefficients indicated that greater parent-reported ASD symptom severity was associated with longer gaze duration to happy faces (*r* = .34, *p* = .038). Contrary to our hypotheses, no significant association was present between ASD symptom impairments and gaze duration to angry faces. In addition, social communication difficulties (per the SRS-2 SC subscale) were also associated with longer gaze duration to happy faces (*r*=.44, *p*=.006). No significant association was found between RRBs and fixation duration, however.
Conclusions: The findings highlight that elevated ASD impairments are associated with greater fixation duration to happy faces, even after controlling for SAD severity. Socially anxious teens with heightened ASD severity and social communication difficulties might experience difficulties in peer relationships. Therefore, they might avoid looking at angry faces which could signal peer rejection. In turn, happy faces might serve as a security signal or protective factor from peer rejection. Findings highlight the importance of considering ASD features when conducting eye-tracking research with adolescents with SAD.

156 **126.156** Facing Puberty: Understanding the Onset and Experience of Menses for Females with Autism Spectrum Disorder

W. T. Eriksen[1]*, J. Pinto-Martin*[2]*, M. C. Souders*[3] *and R. Frasso*[2]*, (1)University of Pennsylvania School of Nursing, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania/The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Living with an Autism Spectrum Disorder (ASD) presents challenges across the lifespan. Puberty may pose unique difficulties for females with ASD with the onset of menses. Only a handful of studies have addressed onset and presentation of menses in females with ASD, yet the experience of puberty for these young women is currently absent from the literature. Findings suggest menarche may be incongruent to Neurotypical (NT) peers and menstrual symptoms may be more severe (Knickmeyer et al., 2006; Ingudomnukul et al., 2007, Burke et al., 2010, Whitehouse et al., 2011, Hamilton, Marshall & Murray, 2011, Pohl et al., 2014, Hergüner & Hergüner, 2016). As age at menarche (AAM) is associated with increased risk of serious health concerns across the lifespan, including obesity, adolescent depression and social anxiety (Freedman et al., 2003; Joinson et al., 2011; Blumenthal et al., 2009), these findings recommend further exploration into the timing and experience of puberty in females with ASD.
Objectives: (1) Describe the onset and symptoms of menses for females with ASD compared to NT, controlling for factors associated with menses, (2) compare reporting of menses between daughters and parents, and (3) explore the experience of puberty for females with ASD and their families.
Methods: Â Mixed-method study combining self- and parent-report on web-based questionnaires with semi-structured interviews of parent-daughter dyads. Participants were females under 18 years with (ASD Group) and without (NT Group) a diagnosis of ASD who had at least one menstrual cycle in the previous six months, and one parent.
Results: A multiple regression model was significant ($F(11, 54) = 2.19$, $p = 0.03$), with diagnoses of ASD in the daughter or a sibling representing significant predictors for early AAM ($\beta = -0.38$, $p > 0.01$; $\beta = -0.39$, $p > 0.01$). Parents of both ASD and NT participants reported similar AAM as their daughters. No differences were observed in characteristics of the menstrual cycle or symptoms across groups. Neurotypical parents underreported the severity and occurrence of their daughter's menstrual symptoms across all reported areas. ASD parents underreported level of menstrual pain, physical and behavioral symptoms, while reporting more pre-menstrual, emotional and dysmenorrhea symptoms. Participants discussed several themes, including (1) preparation for puberty, (2) the physical experience of menses, (3) speed bumps on the road through puberty, (4) managing the everyday, (5) looking to the future, and (6) reflective advice.
Conclusions: Controlling for known covariates, we observed a significant decrease in AAM for those reporting a diagnosis of ASD in the daughter or a sibling, suggesting the possibility of an underlying developmental mechanism common to both ASD and AAM. The participants underscored the unique and varied experiences of puberty for females with ASD, which highlights the importance of qualitative research for a holistic understanding of adolescence in females with ASD. These findings raise concerns for the health of women with ASD across the lifespan. It is critical that practitioners serving this population appropriately screen for associated health outcomes, as well as work towards establishing evidence-based education and resources for these families.

157 **126.157** Food Selectivity and Nutritional Deficits in Children with Autism Spectrum Disorder: Electronic Medical Record Review

V. Postorino[1,2], *K. Criado*[1,2], *L. Scahill*[1,2], *R. Berry*[1], *J. Yancey*[3] *and W. Sharp*[1,2], *(1)Marcus Autism Center, Atlanta, GA, (2)Department of pediatrics, Emory University School of medicine, Atlanta, GA, (3)Mercer University School of Medicine, Atlanta, GA*

Background: Children with Autism Spectrum Disorder (ASD) may exhibit a range of behavioral problems, including aggression, disruptive behavior, abnormal sleep patterns, toileting issues, and feeding problems. Food selectivity by type (i.e., eating only a narrow variety of foods) is a well-documented feeding concern in ASD, often involving strong preferences for starches and snack foods coinciding with a bias against fruits and vegetables. Children with food selectivity by type are at increased risk of nutritional deficiencies. Food selectivity by type falls under the diagnosis of Avoidant/Restrictive Food Intake Disorder (ARFID; APA, 2013), which requires failure to meet nutrition and/or energy needs. To date, however, research on food selectivity by type and associated health consequences is limited.
Objectives: This study describes food selectivity by type and nutritional deficiency in sample of patients with ASD referred for an interdisciplinary evaluation to the Pediatric Feeding Disorders Program at the Marcus Autism Center.
Methods: Electronic medical records of all patients referred for an interdisciplinary evaluation between January 2015 and January 2016 were reviewed. The electronic medical record review included: sex, age, diagnosis, chief complaint, anthropometric parameters, disruptive behaviors during meal time, and dietary status.
Results: A total of 163 children (age range 2.78 to 17.55 years) were referred for evaluation. Of these, 54 (33.1%) patients had a diagnosis of ASD and food selectivity by type and, thus, met inclusion criteria. All children exhibited disruptive behaviors during mealtime. 9.3% of children were underweight; 24.1% were overweight or obese. Detailed data on dietary intake were available for 33 patients; 24 of these children were deficient in 5 or more nutrients. Poor dietary intake of the following micronutrients was observed: vitamin A, vitamin B12, vitamin C, vitamin D, vitamin E, folic acid, calcium, iron, and zinc (Table 1).
Conclusions: These results suggest that in children with ASD and food selectivity by type are not consuming a diet adequate in vitamins and minerals. Children with ASD and food selectivity by type may require nutritional monitoring to prevent nutritional deficiencies. Further examination of the nutritional deficiencies in ASD associated with food selectivity by type, and associated health consequences, could contribute to the development of nutritional guidelines for clinicians and parents facing the challenges of food selectivity by type in children with ASD.

158 **126.158** Gastrointestinal Symptoms in Chinese Children with Autism Spectrum Disorder: Association with Emotional Symptoms?

P. W. Leung*, The Chinese University of Hong Kong, Shatin, NT, Hong Kong, China*

Background:
Autism spectrum disorder (ASD) is a complex neuro-developmental disorder with a wide range of physical and psychiatric co-morbidities. Identification of subgroups, e.g., in terms of comorbidities, has the potential to help clarify and disentangle the heterogenous aetiologies of the disorder. The comorbidity of gastrointestinal (GI) symptoms in a proportion of children with ASD has been put forward as a subgroup marker, and complex gut-brain interaction is thought to contribute to pathogenesis in this subgroup.
Objectives:
This study evaluated whether Chinese children with ASD did have an elevated rate of GI symptoms. Its design improved on previous studies by controlling a wide range of potential confounds which might in fact be the agents contributing to the increased rate of GI symptoms such as co-morbid emotional problems. The latter by themselves were well known to be associated with GI symptoms. Those previous studies could not be conclusive when failing to control such confounds.
Methods:
This study compared the rates of GI symptoms between Chinese children with ASD and typically developing community controls using the Questionnaire on Pediatric Gastrointestinal Symptoms – Rome III Version (QPGS-III). Confounding variables examined included the children's age, gender, co-morbid psychopathologies, diets, and parental anxiety and depression.
Results:
Our results were similar to western findings in that Chinese children with ASD were twice as likely to suffer from GI symptoms compared to typically developing children in the community. The types of increased GI symptoms most commonly reported were constipation, abdominal migraine and aerophagia. Of all the potential confounds examined, comorbid emotional problems exhibited a main effect in predicting increased GI symptoms, in addition to a main effect of ASD diagnosis in the regression analysis. More intriguingly, there was also an interaction effect between ASD and emotional symptoms to predict GI symptoms. In other words, while the presence of emotional symptoms was associated with an increased rate of GI symptoms in both the ASD and the community groups, the increase was significantly greater for children with ASD than for children without.
Conclusions:
Our findings indicate that ASD, emotional problems and GI symptoms form a multiplicative relationship. Despite that ASD and emotional problems are known to each contribute to an increased rate of GI symptoms, a multiplicative relationship is a new finding not reported previously. Such relationship warrants further investigation as a marker of an ASD subtype with potential distinctiveness in terms of etiologies, course of development, prognosis and treatment, etc.

159 **126.159** Gastrointestinal Symptoms, Behavioural Problems and Restricted Repetitive Behaviours in an Italian Sample of ASD Preschoolers

M. Prosperi[1], *E. Santocchi*[1], *A. Narzisi*[1], *F. Fulceri*[1], *F. Apicella*[2], *R. Igliozzi*[1], *A. Cosenza*[1], *R. Tancredi*[1], *S. Calderoni*[1] *and F. Muratori*[2,3], *(1)University of Pisa – Stella Maris Scientific Institute, Pisa, Italy, (2)IRCCS Stella Maris Scientific Institute, Pisa, Italy, (3)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background: Gastrointestinal (GI) symptoms in patients with ASD aged 1–18 years have been reported with prevalence higher than in typical development population, ranging from 9% to 91%, depending on the study's characteristics. Moreover, a greater severity of problem behaviours as irritability, emotional dysregulation, anxiety and affective disorders was found in children with ASD and concurrent GI symptoms. In addition, in children with ASD a correlation between GI symptoms and rigid/compulsive behaviours, increased sensory sensitivity, and sleep problems has been suggested. It is worth noting that behaviour problems, and possible self-damaging acts could increase in ASD patients who are not able to communicate their GI discomfort.
Objectives: This study aims to explore if and how the presence of GI symptoms could influence the clinical features of ASD preschoolers and whether it is possible to define a particular clinical phenotype characterized by the presence of GI symptoms and ASD.
Methods: A total of 163 preschoolers with ASD were included in the study, comprising 137 males and 26 females (mean [SD] age = 43.16 [13.85] months; range 20-71 months). ASD patients were assessed through the ADOS, psychometric test, language assessment, Child Behavior Checklist (CBCL 1½-5), and Repetitive Behavior Scale-Revised. CBCL 1½-5 has been used to explore GI symptoms and to identify two groups on the basis of the presence or absence of GI symptoms ("ASD GI+" versus "ASD GI−").
Results: The percentage of ASD GI+ patients was 40.5%; the more frequently reported symptoms were constipation, feeding problems and abdominal pain. Greater severity of behavioural problems in ASD GI+ children compared to ASD GI- peers was found, whereas differences in ADOS calibrated severity mean scores, in language level and in performance IQ between the two groups were not significant. In ASD GI+ versus ASD GI- patients were detected: (a) more frequent and severe stereotyped behaviours and restricted interests; (b) a more severe dysregulation profile (sum of the scores of the "Anxious/Depressed", the "Attention Problems" and the "Aggressive Problems" scales of the CBCL); (c) significant higher scores in "Externalized Problems" and "Total Problems" scales of the CBCL (and in lesser proportion also in "Internalized Problems" scale). Moreover, more self-injurious behaviours were observed in subjects with constipation.
Conclusions: We confirm a high prevalence of GI problems in ASD pre-schoolers; in particular, the most common types of GI symptoms in children with ASD were constipation, abdominal pain and significant food problems expressed as resistance to feeding. More frequent behavioural problems were observed in ASD individuals GI+ that could be interpreted as manifestations of a distress difficult to communicate. Crucially, ASD GI+ individuals were not different in language level, cognitive development and autism severity than ASD GI- children. It is therefore useful to investigate the possible presence of GI symptoms in all patients with ASD, even more in children with repetitive and behavioural problems.

160 **126.160** Hedonic Capacity Influences Motivated Behavior in Autism Spectrum Disorder

J. Shah[1], *M. G. Mosner*[2], *J. K. Kinard*[3], *S. McWeeny*[1], *C. Damiano*[4], *M. R. Burchinal*[5], *H. J. V. Rutherford*[6], *R. K. Greene*[2], *M. T. Treadway*[7] *and G. S. Dichter*[2], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)Carolina Institute for Developmental Disabilities, University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)University of North Carolina, Durham, NC, (5)Data Management and Analysis Center, Frank Porter Graham Child Development Institute, Chapel Hill, NC, (6)Child Study Center, Yale School of Medicine, New Haven, CT, (7)Department of Psychology, Emory University, Atlanta, GA*

Background: Major depression (Treadway, Bossaller, Shelton, & Zald, 2012) and anhedonia (Treadway, Buckholtz, Schwartzman, Lambert, & Zald, 2009) influence effort expenditure for rewards and major depression is one of the most common comorbid psychiatric disorder in autism spectrum disorder (ASD) (Ghaziuddin, Ghaziuddin, & Greden, 2002).
Objectives: Our research group recently reported different profiles of effort expenditure for rewards in adolescents with ASD (Mosner, Kinard, Mcweeny, Shah, Damiano, Burchinal…& Dichter, 2016). Specifically, adolescents with ASD were characterized by decreased motivated behavior in response to medium and small reward magnitudes and high reward probabilities on the Effort-Expenditure for Rewards Task (EEfRT).Â The goal of the current study was to explore whether depressive symptoms or hedonic capacity were related to patterns of motivated behavior in adolescents with ASD in this same sample.
Methods: Twenty-six typically developing controls (TDCs; age *M*= 15.81, *SD*=3.06; IQ *M*= 109, *SD*=10.82) and 49 high-functioning adolescents with ASD (age *M*=15.98, *SD*=2.59; IQ *M*=103, *SD*=17.00) completed the EEfRT. On each trial, participants choose between selecting an "easy task" for the chance to win a small, constant monetary reward, or a "hard task" for the chance to win a variable, but consistently larger monetary reward. Each choice was presented with a low, medium, or high probability of winning the reward if the task was successfully completed (Treadway, Buckholtz, Schwartzman, Lambert, & Zald, 2009). Depressive symptoms were measured using the Child Depression Inventory (CDI; ages 12-17; Helsel & Matson, 1984) and the Beck Depression Inventory (BDI; ages 18-20; Beck, Steer, Ball, & Ranieri, 1996).Â Because younger participants received the CDI and older participants received the BDI, CDI and BDI scores were standardized within groups and then combined to create a continuous measure of depressive symptoms examined across all participants. Hedonic capacity was measured using the anticipatory and consummatory subscales of the Temporal Experience of Pleasure Scale (TEPS; Gard, Gard, Kring, & John, 2006).
Results: Correlations between the CDI /BDI composite score and the anticipatory subscale of the TEPS and all EEfRT metrics were non-significant. There were significant correlations between the consummatory subscale of the TEPS and EEfRT choices on the high reward probability (r=0.37, p<0.05), medium reward magnitude (r=0.31, p<0.05), and low reward magnitude (r=0.34, p<0.05) conditions. These correlations remained significant when controlling for severity of ASD symptoms as measured by the Social Responsiveness Scale (SRS; Constantino et al., 2003).
Conclusions: These results extend prior findings on relations between hedonic capacity and effort expenditure for rewards in a nonclinical sample (Geaney, Treadway, & Smillie, 2015) to an ASD sample, although the prior nonclinical finding identified linkages with anticipatory pleasure (Geaney, Treadway, & Smillie, 2015) and the current ASD study found linkages with consummatory pleasure. These results suggest hedonic capacity is related to motivated behaviors in adolescents with ASD and that future studies addressing reward processing in ASD should consider hedonic capacity as an important explanatory variable.

161 **126.161** IMPACT of Multiple Comorbid Emotional and Behavioral Conditions on Youth with Autism and Their Families

K. N. Medeiros[1,2] *and M. O. Mazurek*[1]*, (1)Health Psychology, University of Missouri, Columbia, MO, (2)Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO*

Background:
Comorbid emotional and behavioral problems are very common in children and adults with autism (Levy et al., 2010), and several studies have highlighted the effects of comorbid conditions on school performance, adaptive skills, and peer relationships (Storch et al., 2012). These additional complications also place strain on the entire family as well as the individual with autism (Kerns et al., 2015). The literature in this area includes a wide variety of methods and assessment tools and sample characteristics. Prior research has been limited by narrow samples, limited outcome constructs, and a lack of attention toward child- or family-level variables that may influence the impact of comorbid conditions.
Objectives:
The purpose of this project was to determine whether comorbid emotional and behavioral problems significantly impact children with autism over and above child and family characteristics. Our primary hypothesis was that emotional and behavioral comorbidities in youth with autism would be associated with greater functional impact for the child, more difficulty accessing services, greater family impact, and greater transitional needs.
Methods:
Using the 2009-2010 National Survey of Children with Special Health Care Needs (NSCSHCD), we examined 3,055 cases of children and adolescents with autism (ages 2 to 17) who had varying numbers of comorbid conditions (i.e., ADHD, depression, anxiety, or behavior problems). For continuous dependent variables, hierarchical linear regressions were executed, with child-level variables entered in the first block (age, intellectual disability, and developmental delay), family-level variables entered in the second block (income, education, and respondent relationship), and number of comorbidities entered in the third block. For dichotomous dependent variables, the same three block method was used in hierarchical logistic regression analyses. We reported effects sizes for significant predictors with an odds ratio greater than 1.
Results:
Multiple comorbid conditions did have a significant impact on elements of child functioning (i.e., daily activities and school attendance), difficulties and frustrations accessing services for multiple reasons, and family impact (mental health need, more hours of care) in youth with autism. These effects were observed over and above the effects of child age, intellectual disability, developmental delay, family income, family education, and respondent relationship. Child and family characteristics were also important predictors for outcomes in child functioning, family impact, and transitional needs.
Conclusions:
These findings are important for families, practitioners, paraprofessionals, and educators of youth with autism. Addressing the compounding effects of comorbid emotional and behavioral conditions may improve services and supports for youth with autism and their families.

162 **126.162** Implementing Reliable Screening of Co-Occurring Medical Conditions in Children with Autism Spectrum Disorders Across the Autism Treatment Network

D. S. Murray[1,2]*, K. H. Klatka*[3]*, K. Sohl*[4]*, L. Cole*[5]*, P. Manning-Courtney*[6] *and D. L. Coury*[7]*, (1)Autism Speaks, Boston, MA, (2)Division of Developmental & Behavioral Pediatrics, Cincinnati Children's Hospital, Cincinnati, OH, (3)Division of General and Academic Pediatrics, Mass General Hospital for Children, Boston, MA, (4)University of Missouri - Thompson Center, Columbia, MO, (5)University of Rochester, Rochester, NY, (6)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (7)Nationwide Children's Hospital, Columbus, OH*

Background: Children with an Autism Spectrum Disorder (ASD) frequently present with co-occurring medical conditions such as sleep problems and constipation. These disorders, when left untreated, may compromise not only general health, but also behavioral, developmental, and educational outcomes of individuals with ASD. Clinical care recommendations exist for sleep problems and constipation in ASD, but these guidelines are underutilized. Screening for these conditions by clinicians is inconsistent, resulting in delays in, or lack of treatment. Children with ASD require regular screening for chronic co-morbid health conditions during the course of regular health supervision visits.
Objectives: Our primary goals were to a) increase reliable screening for these medical co-occurring conditions in children with ASD by subspecialists, b) for patients with a positive screen, develop appropriate care plan(s) in partnership with families to address the problem(s).
Methods: This effort used quality improvement (QI) methodology to promote reliable screening for sleep problems and constipation in a network of 15 medical centers. The Model for Improvement, developed by Associates in Process Improvement (API), was used to frame the work. Specific Measureable Actionable Realistic Time (SMART) aims were developed focusing on increasing screening, and documentation of constipation and sleep problems. Interventions were tested to improve the reliability of screenings and development and documentation of care plans. These included education sessions for providers and clinic staff, modifications to medical records procedures, and personalized interventions for low performing providers. The sites randomly selected 20 charts per month for review to measure documentation of screening and care plans. Results: Over a one year period, the majority of the 15 Network sites (13 of 15) reached at least 85% reliability in screening for sleep problems and constipation in children with ASD; and development and documentation of care plans for those with a positive screen. Preliminary outcome data suggests a majority of children showed improvement in these co-occurring conditions with early identification and first line intervention (75% constipation, 61% sleep).
Conclusions: This work describes a multi-institutional QI collaborative using a modified Institute for Health Improvement (IHI) Breakthrough Series to improve the identification and treatment of medical conditions seen frequently in individuals with ASD. Improvement was documented at all sites, with several meeting the pre-determined goals and most reaching high levels (85%) if not reaching the goal of 95%. Preliminary data indicated that the improvement in the clinical process was having an impact on the symptoms of those patients with identified conditions. QI methodology is an effective framework to impact change across a network of providers in unique healthcare settings. This effort can provide networks a framework to systematically implement standards of care across multiple medical settings.

163 **126.163** Increased Presence of Familial Psychiatric and Neurodevelopmental Disorders in Groups with Unclear or Negative Autism Spectrum Disorder Diagnosis in a State-Wide Autism Registry

D. Morriss[1,2], *H. Tokadjian*[1,3], *C. McCormick*[1,3], *L. Oberman*[1,4], *T. F. Anders*[1,4], *E. M. Morrow*[1,4,5] *and S. J. Sheinkopf*[1,2,3], *(1)Rhode Island Consortium for Autism Research and Treatment (RI-CART), Bradley Hospital, East Providence, RI, (2)Department of Psychiatry & Human Behavior, Brown University, Providence, RI, (3)Brown Center for the Study of Children at Risk, Women and Infants Hospital, Providence, RI, (4)E. P. Bradley Hospital, East Providence, RI, (5)Department of Molecular Biology, Cell Biology and Biochemistry and Institute for Brain Science, Brown University, Providence, RI*

Background: Family history is important to consider in patients with Autism Spectrum Disorder (ASD) as literature has shown increased presence of familial psychiatric disorders compared to the general population. Psychiatric comorbidity is also high in ASD and associated with functional impairment and increased diagnostic challenges (Leyfner et al. 2006; Molloy et al. 2011). Disorders that are especially prevalent in these families include depression, bipolar, and anxiety disorders (Cohen & Tsiouris, 2006; Micali et al., 2004).
Objectives: To investigate differences in family psychiatric and neurodevelopmental history in individuals referred to an ASD research registry grouped by level of diagnostic confirmation and confidence.
Methods: Participants were the first 1,000 individuals enrolled in a state-wide autism registry (Male = 780; M_{age} = 13.6 years, SD = 9.6). Referrals were based on existing diagnosis or concern for ASD. Participants were categorized into three groups: (1) ASD (N = 533): having a community diagnosis of ASD confirmed by the ADOS-2; (2) ASD-unclear (N = 318): having an inconsistency between community diagnosis and ADOS-2 result; and (3) non-ASD (N = 101): having a negative ADOS and no community diagnosis. Family history was obtained by interview. Analyses examined group differences of individual disorders as well as composite scores of total number of neurodevelopmental and psychiatric disorders.
Results: Using one-way ANOVA and Tukey post-hoc tests, controlling for false-discovery rate, there was increased presence of multiple psychiatric and neurodevelopmental disorders in non-ASD and ASD-unclear groups as compared to ASD group. The overall number of psychiatric disorders in first-degree relatives was significantly higher in ASD-unclear (M = 2.15, SD = 2.05, F ((2, 862) = 14.0, $p < .001$) and non-ASD (M = 2.42, SD = 2.35, $p < .001$) as compared to ASD (M = 1.56, SD = 1.66). The non-ASD group reported more neurodevelopmental disorders in first-degree relatives (M = 1.62, SD = 1.70, p = .013) than the ASD group (M = 1.11, SD = 1.48). Follow-up analysis showed that probands in ASD-unclear (M= 2.3, SD = 1.7) and non-ASD groups (M= 2.5, SD = 1.7) had increased psychiatric comorbidities as compared to ASD group (mean = 1.58, SD = 1.5, F (3,546) = 16.1, p < .001). There was a significant positive correlation between number of psychiatric diagnoses in the proband and number of psychiatric disorders in first-degree relatives (r = .28, N = 550, p <.001). A linear regression was performed controlling for biologic sex and age (R^2 = 0.13, F (3, 546) = 25.92, β = .27, t = 6.8, $p < .001$), that confirmed a statistically significant association between number of first-degree family diagnoses and number of proband comorbidities.
Conclusions: Individuals in the ASD group had less family members affected with neurodevelopmental or psychiatric disorders and less psychiatric comorbidities as compared to ASD-unclear and non-ASD groups. This finding supports that registry referrals of ASD-unclear and non-ASD individuals are in part due to more complicated psychiatric presentation, and demonstrates the need for clinical tools that can aid in differentiating these groups.

164 **126.164** Increased Psychiatric Complexity of Autism Spectrum Disorder: Explaining Diagnostic Inconsistencies

H. Tokadjian[1,2], *D. Morriss*[1,3], *C. McCormick*[1,2], *K. A. Perkins*[1,4], *L. Oberman*[1,3,5], *T. F. Anders*[1,5], *E. M. Morrow*[1,3,6] *and S. J. Sheinkopf*[1,2,3], *(1)Rhode Island Consortium for Autism Research and Treatment (RI-CART), Bradley Hospital, East Providence, RI, (2)Brown Center for the Study of Children at Risk, Women and Infants Hospital, Providence, RI, (3)Department of Psychiatry & Human Behavior, Brown University, Providence, RI, (4)E. P . Bradley Hospital, East Providence, RI, (5)E. P. Bradley Hospital, East Providence, RI, (6)Department of Molecular Biology, Cell Biology and Biochemistry and Institute for Brain Science, Brown University, Providence, RI*

Background: Recent studies have indicated that the Autism Diagnostic Observation Schedule (ADOS) has reduced specificity in samples with a broad range of developmental and behavioral disorders (Molloy et al. 2011), and a pilot study found that “false-positive” ADOS results may be attributable to symptoms of co-morbid psychiatric conditions (Stadnick et al. 2015). However, literature has yet to appropriately quantify phenotypic characteristics of individuals with diagnostic inconsistencies in ADOS and community diagnosis.
Objectives: To identify whether clinical characteristics differ in individuals with discordance between community diagnosis and ADOS as compared to individuals with concordance in these same measures.
Methods: Â The sample was comprised of 762 individuals (ages 3 – 18; M_{age} = 13.27 years, SD = 9.45, 78.3% male) selected from a state-wide ASD registry. Participants entered the registry either with an existing diagnosis or due to a concern of an ASD. All participants were administered the ADOS-2 upon enrollment. Participants were grouped into four diagnostic categories depending on status of community diagnosis and ADOS-2 result: (1) Community ASD diagnosis and a positive ADOS-2 (N=533); (2) Community diagnosis and a negative ADOS-2 (N=54); (3) No community diagnosis and a positive ADOS-2 (N=109); and (4) No community diagnosis and a negative ADOS-2 (N=66). The presence of psychiatric diagnoses and the reports of current medications were obtained through caregiver-completed questionnaires. The number of different psychotropic medications were summed to create four dichotomous variables representing antidepressants, Attention-deficit/hyperactivity disorder (ADHD) medications, antipsychotics and mood stabilizers. Autism severity was measured by standardized scores available through a caregiver-completed Social Responsiveness Scale, Second Edition (SRS-2).
Results: A series of logistic regressions of co-morbid diagnoses with age and gender as covariates revealed that the discordant subgroups were more likely to have depression (χ^2 = 61.47, p < .001), anxiety (χ^2 = 51.93, p < .001), ADHD (χ^2 = 18.70, p = .002) and oppositional defiant disorder (χ^2 = 13.97, p = .016). Chi-square analyses revealed a significant difference between diagnostic groups and the likelihood of taking antipsychotic (p = .031) and ADHD (p = .020) medication. However, these effects did not survive follow-up logistic regression analyses controlling for age and gender. Further, there was a significant difference between diagnostic groups on SRS-2 severity (F(3,659) = 5.34; p = .001). Participants with a positive ADOS-2 result and community diagnosis scored higher on the SRS-2 compared to those with no ASD diagnosis (p= .003). Results support the sensitivity of the SRS-2 to measure ASD symptom severity in a subgroup more likely to have a true positive diagnosis.
Conclusions: Children presenting to an ASD registry with inconsistencies between community diagnosis and ADOS-2 findings had increased rates of caregiver-reported psychiatric diagnoses and psychotropic medications as compared to those whose ADOS-2 result was concordant with community diagnosis of ASD. The results concur with prior reports of reduced specificity of the ADOS-2 in the presence of co-occurring psychiatric symptoms. These findings are both empirically and clinically relevant, confirming the need for cautious interpretation of positive ADOS-2 results in the presence of psychiatric complexity.

165 **126.165** Interoceptive Sensibility Predicts Anxiety in Children on the Autism Spectrum

E. R. Palser[1], *A. Fotopoulou*[1], *E. Pellicano*[2] *and J. M. Kilner*[3], *(1)UCL, London, United Kingdom, (2)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (3)UCL Institute of Neurology, London, United Kingdom*

Background: Anxiety is a major co-occurring feature of autism spectrum disorders (ASD). Interoception refers to the sensation of the internal state of the body including afferent information from the viscera, respiratory and genitourinary systems (Cameron, 2001). The incidence of anxiety symptoms in this population has been associated with problems with interoceptive processing (Garfinkel et al., 2016). Despite the developmental nature of autism, and findings of declining interoceptive accuracy with age (Khalsa et al., 2009), this relationship has only previously been investigated in adults.
Objectives: Here, we assessed the relative contribution of interoceptive dimensions to anxiety symptoms in autistic and typical children. Mirroring Garfinkel et al.’s previous research our hypotheses were that 1) a diagnosis of ASD will be associated with impaired interoceptive accuracy (reduced performance on an objective test of interoception); 2) individuals with ASD will display enhanced interoceptive sensibility (their subjective belief about their interoceptive aptitude); 3) the discrepancy between interoceptive accuracy and interoceptive sensibility, operationalised as interoceptive trait prediction error (ITPE), will be predictive of anxiety symptoms. In addition to this, extrapolating from Khalsa et al., (2009) we expect 4) interoceptive accuracy to decline with age, peaking in late childhood or early adolescence.
Methods: We assessed the interoceptive accuracy (using heartbeat detection tasks), interoceptive sensibility (subjective sensitivity to internal sensations on a self-report questionnaire), and state and trait anxiety of 20 children diagnosed with an ASD and 30 age-matched typically developing children, aged between 6 and 18 years.
Results: We found higher levels of anxiety in autistic children and adolescents than typically developing children on parent-report, but not self-report measures, and poorer interoceptive accuracy in autistic than typical children, replicating previous findings (Garfinkel et al., 2016). Intriguingly, we identified a significant negative relationship between age and interoceptive accuracy, whereby younger children had better interoceptive awareness in comparison with older adolescents, extending previous findings of a negative relationship (Khalsa, Rudrauf, & Tranel, 2009) into a younger sample. In contrast to findings in adults, we observed a negative relationship between ITPE and self-report anxiety, across the entire sample. In typical and autistic individuals, the best predictor of anxiety symptoms was interoceptive sensibility, the subjective report of interoceptive symptoms. The more interoceptive symptoms an individual reported, the higher their anxiety score.
Conclusions: The findings presented here support the notion that emotional processing difficulties in autism arise in part through a compromised interoceptive channel (Quattrocki & Friston, 2014). Reduced accuracy in the detection and prediction of interoceptive signals could disrupt their use in forming emotional inferences, causing uncertainty and anxiety about the external and internal world. Finally, these data underscore the need for research examining the characteristics of anxiety and interoception in autism within a developmental framework.

166 **126.166** Is There Sexual Dimorphism of Hyperserotonemia in Autism Spectrum Disorder?

L. C. Shuffrey[1,2,3], *A. Montgomery*[1,3], *S. J. Guter*[4], *S. Delaney*[5], *S. Jacob*[6], *G. M. Anderson*[7], *J. S. Sutcliffe*[8], *E. H. Cook*[9] *and J. Veenstra-Vander Weele*[3,10], *(1)New York State Psychiatric Institute / Columbia University, New York, NY, (2)Biobehavioral Sciences, Teachers College, Columbia University, New York, NY, (3)Center for Autism and the Developing Brain, White Plains, NY, (4)University of Illinois at Chicago, Chicago, IL, (5)Columbia University Medical Center, New York, NY, (6)University of Minnesota, Minneapolis, MN, (7)Yale University School of Medicine, New Haven, CT, (8)Vanderbilt University, Nashville, TN, (9)Psychiatry, University of Illinos at Chicago, Chicago, IL, (10)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY*

Background: Â Approximately 30% of individuals with autism spectrum disorder (ASD) have elevated whole blood serotonin (5-HT) levels (Gabriele et al. 2014). Genetic linkage and association studies of ASD and of whole blood 5-HT levels as a quantitative trait have revealed sexual dimorphism.
Objectives: Few studies have examined the effect of sex differences on hyperserotonemia within ASD. Based upon previous work suggesting that hyperserotonemia is more common prior to puberty, we focused our analysis on pre-pubertal children with ASD.
Methods: 292 participants with a diagnosis of Autistic Disorder, Asperger's Disorder, or Pervasive Developmental Disorder Not Otherwise Specified (PDD-NOS) were recruited based on the DSM-IV-TR criteria. ASD classification was confirmed using the Autism Diagnostic Observation Schedule (Lord et al. 2000) and the ADI-R (Lord et al. 1994). Participants who were taking medications that could affect 5-HT, such as serotonin reuptake inhibitors, stimulants, and atypical antipsychotic medications were excluded from analysis. Whole blood 5-HT was measured by high-performance liquid chromatography.
Results: We relied upon published norms to define the hyperserotonemia range as whole blood 5-HT levels above 270 mg/mL (Anderson, Freedman, et al., 1987; Anderson, Hertzig, & McBride, 2012). In the current study, 41% of pre-pubertal participants were in the hyperserotonemia range. Among 182 pre-pubertal children with ASD, the overall distribution of whole blood 5-HT levels showed a rightward shift from a normal distribution. Kolmogorov-Smirnov tests of normality indicated that whole blood 5-HT levels for pre- and post-pubertal females did not deviate significantly from normal (D(23)=0.15, p=.16; D(14)=0.13, p=.20); whereas distributions for pre- and post-pubertal males were abnormally distributed (D(157)=0.08, p=.005; D(70)=0.14, p=.001, respectively). The mean whole blood 5-HT levels were not significantly different for the male and female pre-pubertal populations (t(180) = 1.29, p = 0.19); however males were significantly more likely to have hyperserotonemia compared to females (x2 = 4.338, p = 0.03).
Conclusions: This represents the largest sample of subjects with ASD for whom whole blood 5-HT levels have been reported. Similar to previous studies, we found that a substantial subset of children with ASD had whole blood 5-HT levels in the hyperserotonemia range (Gabriele et al. 2014). In the pre-pubertal sample, we found that males with ASD are more likely to have hyperserotonemia than females. This may be consistent with the genetic literature identifying linkage to the 17q11 and 17q21 gene regions, containing SLC6A4 and ITGB3, respectively, in families with multiple affected males with ASD but not in families with affected females (Stone et al. 2004; Cantor et al. 2005; Sutcliffe et al. 2005), along with data showing association between these two genes and 5-HT levels in males within a large founder population (Weiss et al., 2005). More work will be needed to replicate this intriguing finding and to understand whether it relates to differences in patterns of ASD risk between males and females.

167 **126.167** Is the Latent Structure of Psychopathology the Same in ASD and Non-ASD Youths? Evidence from Multi-Group Invariance Testing

***T. Rosen**, C. Rodriguez-Seijas, K. Gadow, H. Kim, M. D. Lerner and N. Eaton, Stony Brook University, Stony Brook, NY*

Background: Psychiatric comorbidity within autism spectrum disorder (ASD) is highly prevalent, with rates surpassing those of the general population (Simonoff et al., 2008). Indeed, these comorbid conditions, rather than ASD itself, are often the presenting complaint for psychiatric evaluations in youths (Gadow et al., 2004). Currently, there is considerable interest in whether these comorbidities represent true co-occurring disorders, or whether they are a unique manifestation of ASD-specific symptoms (i.e., ASD epiphenomenon; Wood & Gadow, 2010). Research suggests that common psychiatric disorders co-occur at high rates by virtue of their associations with core transdiagnostic internalizing (mood and anxiety disorders) and externalizing (e.g., ADHD, ODD, and conduct disorder) factors (e.g., Eaton et al., 2015). However, no research has examined this transdiagnostic comorbidity framework in ASD youths or characterized the degree to which it differs between psychiatric referrals with and without an ASD diagnosis.
Objectives: Â The primary purpose of this study was to examine the extent to which differences in symptoms of common mood, anxiety, and behavioral disorders among youths with ASD—when compared to psychiatric controls without ASD—might be explained by differences in latent transdiagnostic comorbidity factors.
Methods: Â Participants were 6-18 year olds (N=1,223), either referred for evaluation in a developmental disabilities clinic and diagnosed with ASD (N=280; M_{age} =10.7, SD_{age}=3.4) or referred to a psychiatry outpatient clinic with no ASD diagnosis (N=943; M_{age} = 12.1, SD_{age}=3.4).Â Comorbid symptoms were measured using the CASI-4R (Gadow & Sprafkin, 2005) parent-report. Using confirmatory factor analysis (Figure 1), we investigated the measurement invariance of transdiagnostic factors across ASD and non-ASD groups.
Results: Â Measurement invariance analyses suggested that latent transdiagnostic factors were comparable, such that the same symptoms related to each factor and had the same meaning (e.g., symptoms showed similar factor loadings) across groups. However, important group-specific differences in mean parent-rated social anxiety and ADHD symptomatology were observed (Table 1).
Conclusions: Â These findings suggest that elevated symptomatology of common mood, anxiety, and behavioral disorders in ASD youths—when compared with their non-ASD counterparts—can be largely explained by differences at the latent transdiagnostic comorbidity level, and are not necessarily as a result of epiphenomena of the ASD diathesis. Exceptions to this rule, however, apply. A diagnosis of ASD was associated with elevated symptomatology for social anxiety and ADHD regardless of transdiagnostic factors levels. These findings may be explained in part by 1) the strong genetic overlap of ASD and ADHD (e.g., Rommelse et al., 2010), 2) social deficits of ASD that may make youths more vulnerable to social stressors and subsequent anxiety (e.g., Bellini, 2004) and 3) symptom overlap which leads parents to perceive greater social anxiety and ADHD symptoms in ASD youths. Therefore, while differences in internalizing and externalizing levels can explain the heightened comorbidity of psychiatric conditions seen in ASD youths, it appears that elevated symptomatology of social anxiety and ADHD specifically may also be partially understood as specific to the ASD diagnosis.

168 **126.168** Item-Level Analysis of the Intolerance of Uncertainty Scale in Youth with ASD

***R. A. Vasa**[1,2], A. Keefer[1,2], V. Singh[1] and S. H. Mostofsky[1,2], (1)Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins School of Medicine, Baltimore, MD*

Background:
Intolerance of uncertainty (IU) is a transdiagnostic construct in which individuals experience negative emotional, behavioral, and cognitive reactions to uncertain situations. In typically developing (TD) individuals, IU has been associated with anxiety, obsessive-compulsive disorder, and depression. Multiple studies have reported higher rates of IU in youth with ASD compared to TD peers (Chamberlain et al., 2013; Kreiser et al., 2016). IU has also been increasingly identified as a key variable in the relationship between ASD and anxiety. It has been found to mediate the relationship between ASD and anxiety (Boulter et al., 2014), to predict outcomes of CBT for anxiety (Keefer et al., 2016), and to be associated with ASD symptoms when controlling for anxiety (Neil et al., 2016; Kreiser et al., 2016). Thus far, the main tool to assess IU has been the Intolerance of Uncertainty Scale (IUS). Studies that have used this instrument have examined total IUS scores, and no studies have examined whether specific IU traits may be particularly heightened in youth with ASD.
Objectives:
To examine differences in the 27 questions on the IUS between youth with ASD and TD controls using parent and child report.
Methods:
One hundred and sixteen youth, 8 through 16 years, and 97 parents were enrolled for this study from ongoing research studies. Two groups of children were examined: children with ASD and TD children without psychopathology. All participants in the ASD group were well-characterized using the ADOS/ADOS-2, ADI-R and WISC-IV (VCI greater than 70). IU was assessed using the Intolerance of Uncertainty Scale for Children, Parent and Child Report (IUS-P, IUS-C; Comer et al., 2009), a 27 item rating scale which has demonstrated good internal consistency in the ASD population (Kreiser et al., 2016) and in TD youth (Comer et al., 2009).
Results:
Results of the logistic regression analysis indicated that children with ASD reported significantly higher scores on ten IUS-C items compared to TD controls (See Table 1). Seven of these ten items have themes of negative emotions ("I can't relax," "I get frustrated") and cognitions ("It makes life hard," "It's not fair," "It's hard for me to have fun," "I am not great.") when experiencing uncertainty. Additional items contained themes related to "behavioral paralysis," which refers to avoidant-oriented responses to uncertainty. The highest odd ratio was associated with the item, "Being unsure of things means I am not great," indicating a connection between high IU and negative self-appraisal. Parents, however, reported broad based differences in IU with 20 items that were significantly greater in the ASD group compared to the control group. These items overlapped with most child report items, and similarly contained themes of negative emotions and cognitions, as well as "behavioral paralysis".
Conclusions:
Children with ASD report dysphoric emotions and cognitions when experiencing IU. This suggests that IU may be associated with different types of psychopathology including depression, irritability, and behavioral dysregulation. Clinicians may consider incorporating questions about IU in their mental health assessment and in the development of psychosocial interventions for youth with ASD.

169 **126.169** Language and Social Communication in Children with ASD: Longitudinal Impact on Anxiety and Externalizing Behaviors

N. V. Rodas[1]*, A. Eisenhower*[2] *and J. Blacher*[3]*, (1)Psychology, University of California, Los Angeles, Los Angeles, CA, (2)University of Massachusetts Boston, Boston, MA, (3)University of California - Riverside, Riverside, CA*

Background: Anxiety disorders are prevalent in about 40% of youth with an Autism Spectrum Disorder (ASD) (Jennett et al., 2013). It is still unclear whether or not anxiety functions in the same manner in children with ASD and those who are typically developing (TD). Children with ASD also present with higher levels of externalizing behaviors when compared to their TD peers (Kanne & Mazurek, 2011). Research has demonstrated that anxious children with ASD who present with co-occurring externalizing behaviors, are at greater risk for heightened anxiety symptomotology as well as to have an attenuated response to treatment (Stoch et al., 2012).
The influence of language abilities on the development of anxiety disorders has been understudied in children with ASD. In typically developing children, communication difficulties such as a stuttering, have been associated with higher levels of anxiety symptoms (Beitchman et al., 2001). However, in children with ASD, anxiety is actually more prevalent in those who are higher functioning and more verbal (Davis et al., 2011). Research findings examining the relationship between language and externalizing behavior problems in children with ASD have been mixed (Sipes et al., 2011; Matson et al., 2009). It is likely that different language domains are driving the differential findings among the research base. Thus, it is essential to determine the impact of specific language domains on anxiety and disruptive externalizing behaviors in order to help clarify conflicting findings in the literature.
Objectives: The primary aim of this study was to examine effects of language production and social communication on anxiety and co-occurring externalizing behaviors in young children with ASD. We examined the following research questions: 1a) To what extent does language production relate to child anxiety in young children with ASD over time? 1b) To what extent does social communication relate to child anxiety in young children with ASD over time? 2a) To what extent does language production relate to child externalizing behaviors in young children with ASD over time? 2b) To what extent does social communication relate to child externalizing behaviors in young children with ASD over time?
Methods: Participants were 126 children with ASD, ages 4 to 7 years and their mothers, who were recruited for a larger study examining the transition to early schooling for children with ASD and their families. Children were included in this study if their Full Scale IQ was above 70 (mean= 93.6, SD= 12.8), and English was their primary spoken language. Utilizing structural equation modeling we examined relationships among language production, social communication, anxiety symptoms, and externalizing behaviors.
Results *:* Social communication, but not language production, was inversely related to child anxiety (*ß*= -.64, $p<.05$) and co-occurring externalizing behaviors (*ß*= -.62, $p<.05$).
Conclusion*s:* These findings suggest that children with ASD may be at heightened risk for anxiety and externalizing disorders due to their social communication deficits rather than to their language production deficits at large.

170 **126.170** Measurement of Multiple Radical Scavenging Activity As a Diagnostic Method for Autism Spectrum Disorder in Children

H. Matsuzaki[1] *and A. Hirayama*[2]*, (1)Research Center for Child Ment, University of Fukui, Eiheiji-cho, Fukui, Japan, (2)Center for Integrative Medicine, Tsukuba University of Technology, Tsukuba City, Ibaraki, Japan*

Background: Oxidative stress plays a central role in the pathogenesis of autism spectrum disorders (ASD). Though early interventions are important, ASDs are rarely diagnosed in toddlers, because diagnosis is based deeply on psychological assessment and observation.
Objectives: We investigated the availability of the measurements of multiple free radical scavenging activity (MULTIS) as a novel diagnostic tool for ASD children.
Methods: Serum samples from ASD children and neurotypical children (NT) were analyzed under informed consents. This study enrolled 23 children (3.9±0.8 y.o.) with ASD recruited at the Miyagi children's hospital (Sendai, Japan) and 34 age-matched NT recruited by advertisement. DSM-IV-TR diagnosis of autistic disorder was made for all subjects. Fasting human blood samples were collected by venipuncture in a sitting position with a tourniquet from all participants for both groups who are Japanese and drug-naïve. In MULTIS method, serum scavenging-activity profile against 5 reactive oxygen species, namely .OH, O2.-, RO., ROO. and 1O2 were measured using spin traps CYPMPO and TMPO (Oowada S et al., J Clin Biochem Nutr. 2012;51:117-21.).
Results: Scavenging activity against was significantly decreased in ASD group (approximately 55% of NT group mean value). Contrary to .OH, scavenging activities against O2.- and RO. were significantly increased in ASD group (approximately 120% and 157% of NT group mean values, respectively). No differences were observed in ROO. and 1O2 among the two groups. When diagnostic criteria for ASD was made using .OH, O2.- and RO. scavenging activities, the calculated sensitivity, specificity and positive likelihood ratio were 65%, 93% and 9.78, respectively. Moreover, when the data of ROO. and 1O2 were added, the positive likelihood ratio increased to 22.17.
Conclusions: Measurements of serum multiple free radical scavenging activity by MULTIS method could be a very powerful non-behavioral tool for diagnosis of ASD children.

171 **126.171** Need for Valid, Reliable Gastrointestinal Symptoms Measurement Tool for Autism Spectrum Disorder, a Review of the Literature

C. Holingue[1], *C. A. Newill*[1], *L. C. Lee*[1,2], *P. Pasricha*[3] *and M. D. Fallin*[1,2], *(1)Wendy Klag Center for Autism and Developmental Disabilities, Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Center for Neurogastroenterology, Department of Gastroenterology and Hepatology, Johns Hopkins School of Medicine, Baltimore, MD*

Background:
Gastrointestinal symptoms (GI) have been implicated in Autism Spectrum Disorder (ASD), and the purported association between GI symptoms and ASD has fueled the development of dietary interventions that claim to repair a damaged gut, and to improve GI and core ASD symptoms. However, there is no validated tool for measuring GI symptoms in this population and therefore no valid estimate of GI symptoms.
Objectives:
The purposes of this review were to 1) describe approaches used to measure GI symptoms, 2) summarize GI prevalence estimates across studies, and 3) discuss how the measurement variation affects GI symptom estimates.
Methods:
PubMed was used to find ASD studies published between 1980-2016 that measured GI symptoms/diagnoses. For inclusion, studies were required to have 10 or more individuals with ASD; review articles, meta-analyses, hypotheses papers, narratives or editorials, and animal studies were excluded. From these studies, we extracted study characteristics as well as information on how GI symptoms/diagnoses were measured. To ascertain a range of estimates of GI symptom prevalence, we further refined this set of studies by excluding those in which sampling was based on GI symptoms/diagnoses, that included or excluded participants based on diet, or that were experimental.
Results:
Of the 357 studies returned from PubMed, 132 met our inclusion criteria for description of GI measurement. The publication dates ranged from 1986 to 2016. Fifty-five studies were clinic-based, 18 were population-based, 2 were enriched-risk, and 57 studies did not have enough information to assess the type of sample. There were 55 case-control studies, 32 cross-sectional studies, 15 cross-sectional studies with a comparison group (such as history of regression), 24 experimental studies, 1 study with both a case-control and experimental sample, and 5 cohort studies. Studies used the following methods to assess GI symptoms/diagnoses: parents/caregivers questionnaires (n=73), medical records (n=15), parents/caregivers as well as medical records, physician, teacher, or self-report (n=27). Seventeen studies did not specify who reported GI symptoms/diagnoses. Of the 110 studies that used a questionnaire for assessment, 61 used their own tool, while 49 studies used or modified an existing tool. Popular questionnaire options included the Rome III criteria (n=11), the GI severity index (n=5), and the Autism Treatment Network GI Symptom Inventory (n=3). Of the 78 studies that were kept for the prevalence estimates, the range of estimates for variables including an aggregate of GI symptoms or counting any GI symptom was 4.2-96.8% (median 47.1%). The range for estimates for diarrhea specifically was 2.3-75.6% (median 14.6%), and constipation 4.3-45.5% (median 21.4%). GI symptom estimates were significantly associated with the type of study sample and the method for reporting symptoms/diagnoses ($p<0.05$).
Conclusions:
This study reviewed the breadth of approaches to measuring GI symptoms in studies of ASD. The type of study sample and approaches used to measure GI symptoms were significantly associated with the estimated GI symptom prevalence. The range of GI symptom estimates was wide, highlighting the need for a reliable, valid tool to be used consistently across studies measuring GI symptoms in ASD studies.

172 **126.172** Needs Assessment for the Development of an Evidence Based Practice to Support Teens with Co-Occurring ASD and Gender Dysphoria

J. F. Strang*, M. Knauss, L. Kenworthy, L. Russell, M. D. Powers and L. G. Anthony, Children's National Health System, Washington, DC*

Background: ASD and gender dysphoria (GD) often co-occur (de Vries et al., 2010; Strang et al., 2014), and the co-occurrence presents diagnostic/treatment challenges (Strang et al., 2016). Models for pediatric GD care programs exist (e.g., Menvielle et al., 2012), but there are no studies of clinical service models to address the needs of GD youth with ASD.
Objectives: Address two primary questions: What are the concerns/needs of youth with ASD and GD? How can a therapeutic group program best support youth with this co-occurrence and their families?
Methods: As part of a gender discernment/support group program for youth with GD and ASD, we conducted in-depth needs assessments with twenty-one participants (13 parents and 8 youth with ASD and GD) through written feedback following group sessions, and interviews (transcribed verbatim) at the completion of one year in the program. Framework Analyses (Ritchie et al., 2003) were conducted using *Dedoose* (SocioCultural Research Consultants, 2016) to identify and organize themes, with separate schema for youth and parents due to contrasts in themes between the groups. A consensus approach was employed to avoid relying on a single researcher's perspective. As a final validity check, the frameworks were presented to the participants to ensure they reflected their experiences.
Results: Youth data organized into primary themes: the significance of finding connection with others who have GD and ASD; a wish to increase social connections with group members, though awareness that ASD interferes with social connections; and the importance of role models of gender outcomes (i.e., community adult visitors to group who reflect a range of gender outcomes). Youth data revealed little concern with real-world challenges of ASD or GD, excepting specific focus on gender-related medical treatments. The parent framework included: a strong parent need for education and resources (e.g., legal and medical aspects of gender transition); the centrality of challenges related to ASD (i.e., GD may be the most noticeable issue at first, but it is less impactful than the ASD); and a significant parent concern regarding real-world gender and ASD challenges (school, transition to adulthood, college, informing extended family regarding gender transition). A comparison between youth and parent data identified one common theme: the unique/meaningful quality of acceptance/community provided by a group specifically for GD and ASD. Contrasts between youth and parents included: youth tended to focus on the social nature of the group, whereas parents focused on the practical needs of their children; the overall tone of the youth was less worried and more hopeful than that of their parents; and the youth focused primarily on gender, whereas their parents focused initially on gender, and increasingly on the challenges/demands of ASD over time.
Conclusions: This is the first study to directly capture the voices, experiences and needs of individuals with ASD and GD and their families. Primary themes for developing an evidence-based group program include the importance of concrete exemplars of a range of gender outcomes, as well as blending of support group and ASD intervention group models for group treatment.

173 **126.173** Parent-Child Informant Discrepancies of Social Anxiety in ASD Relate to ASD Symptoms and Adaptive Functioning

C. A. Burrows[1], *L. Usher*[2], *E. M. Becker-Haimes*[3], *C. M. McMahon*[4], *P. C. Mundy*[5], *A. Jensen-Doss*[1] *and H. A. Henderson*[6], *(1)University of Miami, Coral Gables, FL, (2)University of Miami, Madison, WI, (3)Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, (4)Department of Social & Behavioral Sciences, Miami University, Hamilton, OH, (5)University of California at Davis, Sacramento, CA, (6)University of Waterloo, Waterloo, ON, CANADA*

Background: Social anxiety is highly comorbid with autism spectrum disorder (ASD), and impairs individuals' adaptive responses in daily life. Parents and youth often endorse discrepant levels of youth anxiety, which may be exacerbated by the socio-communicative impairments inherent to ASD. However, despite best-practices calling for gathering information from multiple informants, little research has comprehensively evaluated correlates of parent-child informant discrepancies (PCIDs) for social anxiety in youth with and without autism spectrum disorder (ASD).
Objectives: This study examined PCIDs for social anxiety symptoms in youth with ASD and an age-matched typically-developing comparison sample (COM), and factors that moderate the extent of disagreement.
Methods: Participants included 223 verbally-fluent (i.e., verbal IQ>70) children and adolescents (8 to 16 years old, 110 ASD, 113 COM) and their parents, who completed the Social Anxiety Scale for Children, Revised (SASC-R; La Greca & Stone, 1993). Parents also completed the Social Communication Questionnaire (SCQ; Berument et al. 1999) assessing the child's autism symptoms and the Behavior Assessment System for Children (BASC-2; Reynolds, 2010) to measure adaptive functioning.
Results: A two (informant: parent, youth) by two (group: ASD, COM) repeated-measures ANCOVA on SASC scores revealed that participants with ASD (M_{adj}=49.90, *SE*=1.00) were rated as having higher social anxiety than COM participants [M_{adj}=35.57, *SE*=0.99; *F*(1, 219)=98.06, *p*<.001]. Informant discrepancies were lower, but more variable in the ASD group, relative to COM participants, *F*(1, 219)=7.67, *p*=.006, Levene's Test of Error Variances: F(1, 221)=12.06, *p*=.001 (Figure 1). We then assessed whether the PCIDs of social anxiety were related to demographic and diagnostic characteristics using polynomial regression analyses (Laird & Weems, 2013). In this model, patterns of agreement or discrepancy are characterized using an interaction between parent and youth informants' reports, controlling for main effects (linear and quadratic) of each informant. Informant agreement was not related to demographic factors of age, or verbal IQ for either group (Table 1). In the ASD group, youth autism symptoms (SCQ) and adaptive functioning (BASC) were related to PCIDs, such that profiles that agreed on youth anxiety symptoms had lower lifetime autism symptoms and better adaptive skills. A different pattern emerged in the COM group, where youth that agreed with their parents on high anxiety symptoms had the lowest adaptive skills.
Conclusions: This was the first study to assess PCIDs of social anxiety using polynomial regression analyses, which allow examination of different profiles of agreement and discrepancy. Given the group differences in the degree and variability of PCIDs, it appears that youth with ASD do not reliably differ from their parents on reports of social anxiety, highlighting the importance of characterizing correlates of PCIDs in this group. PCIDs of social anxiety were not related to verbal IQ or age for either group, indicating that demographic factors likely do not influence the accuracy of informant reports of anxiety. Associations between PCIDs and outcomes indicate that for individuals with ASD, parent-child agreement on level of youth anxiety, be it high or low, was related to better outcomes. Implications for clinical and research practices are discussed.

174 **126.174** Parent-Reported Sleep Problems in Children with Comorbid Autism Spectrum Disorder and Attention-Deficit/Hyperactivity Disorder

K. C. Reynolds[1], *M. A. Patriquin*[2], *C. A. Alfano*[1], *K. A. Loveland*[3] *and* ***D. A. Pearson***[3], *(1)Psychology, University of Houston, Houston, TX, (2)Psychiatry & Behavioral Sciences, Baylor College of Medicine, Houston, TX, (3)Psychiatry & Behavioral Sciences, University of Texas McGovern Medical School, Houston, TX*

Background:
Sleep problems are frequent and well documented in children with Autism Spectrum Disorder (ASD), children with Attention Deficit/Hyperactivity Disorder (ADHD) and children with anxiety. Anxiety is also highly prevalent in children with ASD and ADHD: Up to 84% of children with ASD report anxiety symptoms, and 25% of children with ADHD meet criteria for co-occurring anxiety disorders. Although the prevalence of sleep problems has been well documented within each pure diagnosis, limited work has examined sleep problems and anxiety levels in children presenting with comorbid ASD/ADHD.
Objectives:
The objectives of the current study were to: 1) determine which diagnostic factors are related to problematic sleep behaviors in children with comorbid ASD/ADHD; and 2) to assess the association between problematic sleep behaviors and functional impairment in this sample specific to academic performance, intellectual functioning, and executive functioning. We expected that 1) increased ASD, ADHD, and anxiety symptom severity would predict elevated levels of problematic sleep behaviors, and 2) that more severe problematic sleep behaviors would predict increased academic, cognitive, and executive functioning difficulties over and above ASD and ADHD diagnostic severity and anxiety symptom severity.
Methods:
Participants were 85 children (*M* age = 9.29, *SD* = 1.79; range = 6.66 – 12.91; 64 boys) who met DSM-IV criteria for both autism and ADHD. Sleep, anxiety, intellectual functioning, academic achievement and executive functioning were assessed. Hierarchical linear regression analyses were completed to determine the relationship between anxiety symptom severity, ASD symptom severity, ADHD severity, and total problematic sleep behavior. Multivariate regressions examining the link between problematic sleep behaviors and functional outcomes (i.e., academic performance, intellectual functioning, executive functioning), using anxiety symptoms severity, ASD symptom severity and ADHD symptom severity as predictor variables were also completed.
Results:
Parent-reported child anxiety significantly predicted parent-report of their child having nightmares (R^2_{change} = 0.078, F_{change} = 7.036, β = 0.253, p = .010), being overtired for no reason (R^2_{change} = 0.132, F_{change} = 12.448, β = 0.347, p < .001), and their total problematic sleep behaviors score (R^2_{change} = 0.091, F_{change} = 8.221, β = 0.226, p = .005). ASD and ADHD severity did not significantly predict any sleep behaviors. Parent report of sleeping more than other children significantly predicted increased verbal IQ (F = 5.345, p = .023), and better sentence comprehension (F = 5.708, p = .019) and math computation (F = 5.296, p = .052), with a trend towards significance for spelling (F = 3.732, p = .057) over and above ASD, ADHD, or anxiety symptomology.
Conclusions:
Results suggest that anxiety is the most consistent predictor of problematic sleep behaviors in children with comorbid ASD/ADHD, and that increased sleep may be beneficial for children with comorbid ASD and ADHD. Further, our results indicate that anxiety symptoms play a significant role in problematic sleep behavior in children with ASD and ADHD. Clinically, these results imply children with ASD who present with problematic sleep behaviors should receive a comprehensive evaluation to identify specific problematic sleep behaviors and their potential relationship with anxiety.

175 **126.175** Prevalence and Clinical Features of Suicidal Ideation in Cognitively Able Children and Adolescents with Autism Spectrum Disorder

***S. L. Jackson**, K. Ellison, E. Jarzabek, K. A. McNaughton, T. C. Day, M. J. Rolison and J. McPartland, Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Some of the most prevalent risk factors associated with suicidal behavior include impulsive/aggressive tendencies, social isolation, bullying, anxiety, and depression; all of which are well-documented areas of difficulty for individuals with autism spectrum disorder (ASD). The limited research on this topic in adults with ASD has reported abnormally high rates of suicidal ideation (66%) and suicidal plans/attempts (35%; Cassidy et al., 2014; Paquette-Smith, Weiss, & Lunsky, 2014). In the two studies that have examined this topic in children/adolescents with ASD, elevated rates of suicidal ideation (11-14%) were observed, even at these young ages (Dickerson-Mayes et al., 2013; Storch et al., 2013). As a history of previous suicidal behavior is one of the greatest predictors of suicide attempts, it is of critical importance that additional research investigates the prevalence, predictors, and indicators of suicidal ideation in youth with ASD, so focused efforts can be made to identify those at risk and provide pre-emptive intervention.
Objectives: Â The current study investigates prevalence rates and clinical features representing risk factors and/or warning signs for suicidal ideation in youths with ASD.
Methods: Collected as part a larger program of research, the sample for this study was comprised of 34 youth with ASD (28 male, 6 female; *M*=13.8 years-old) and 30 typical developing (TD) youth controls (15 male, 15 female; *M*=13.0 years-old). Groups were matched on IQ (DAS-II GCA) and age (Table 1). Suicidal ideation was assessed by parent-report of whether their child "talks about killing self" over the past 6-months, as reported on the CBCL. Clinical features examined as risk factors were assessed by both parent-report (CBCL, MASC-P, SRS-2) and child-report (MASC-C). Data collection is ongoing.
Results: Suicidal ideation was endorsed by parents of six (17.65%) children with ASD, as compared to one (3.33%) child with TD [$X^2(1)=3.73$, $p=0.05$]. Examining solely the ASD sample, none of the demographic variables (age, gender, ethnicity) were significantly associated with suicidal ideation ($0.28<ps<0.53$). Stronger cognitive abilities (IQ) were marginally associated with suicidal ideation ($r=0.33$, $p=0.06$). Although degree of ASD symptomology severity (SRS-2) was not significantly associated with suicidal ideation ($p=0.51$), multiple clinical features (assessed by the CBCL and MASC-C/P), associated with aggressive behaviors, internalizing problems, oppositional-defiant problems, feelings of humiliation/rejection, and parent-reports of overall anxiety, were significantly correlated with suicidal ideation (detailed in Table 2).
Conclusions: In line with previous findings, children/adolescents with ASD presented with elevated rates of suicidal ideation as compared to a matched TD sample. The observed relationships between suicidal ideation and clinical features provide information about potential risk factors (keeping problems internalized, increased concerns over being teased and/or viewed negatively by others) and warning signs (aggressive or defiant behaviors, elevated presence of observable symptoms of anxiety) of suicidal ideation in youth with ASD. Such information can provide guidance for future interventions (e.g. developing skills around sharing and communicating problems), and insight for preventative efforts [e.g. encouraging caregivers/teachers/practitioners to recognize the manifestations of problematic behaviors (such as aggression, defiance, anxiety), as potential indicators of underlying emotional issues that may eventually result in suicidal thoughts/behaviors].

176 **126.176** Relation of Social Anhedonia with Social Anxiety, Depression and Schizophrenia Symptoms in ASD and Psychiatry Referrals.

*H. Garman[1], A. Mulhall[2], B. Velia[1], R. J. Weber[1], E. Kang[1], **T. Rosen**[1] and K. Gadow[1], (1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: Social anhedonia (SA), a preference for being alone, is an accepted symptom phenotype in autism spectrum disorder (ASD), depression (MDE), and schizophrenia spectrum disorder (SSD); nevertheless, it remains under-investigated. It is unknown what drives SA in ASD: lack of pleasure from social interaction, social anxiety or fear of social humiliation (Asendorpf, 1990), or lack of skills to engage in social interaction.
Objectives: We sought to characterize the clinical correlates of SA and social anxiety in youth with ASD and non-ASD psychiatry referrals. To distinguish between fear of, versus desire for, social interaction, we investigated co-occurring social anxiety and SA. First, we characterized the prevalence and severity of SA and social anxiety between clinical groups. Next, within the ASD sample, we explored whether youth with SA evidenced more severe social deficits, social anxiety versus other forms of anxiety, and co-occurring commonly studied clinical correlates such as MDE, SSD and intellectual disability (ID).
Methods: Â Participants were youth with ASD (*N*=283) and non-ASD psychiatry referrals (*N*=653) between 6-18 years. Parents completed assessment batteries including the *Child and Adolescent Symptom Inventory–4R* (CASI-4R; Gadow & Sprafkin, 2005), *Parent Questionnaire* (Gadow et al., 2008), and *Social Communication Questionnaire Lifetime Version* (SCQ; Berument et al., 1999). Based on CASI-4R, youth were considered: socially anhedonic (**SA**), diminished social interaction (**DS**), or none (**NONE**).
Results: Â Rates of SA were higher in ASD (33%) than non-ASD clinic referrals (10%; $X^2(2) = 138.64$, $p < .001$). Similarly, rates of social anxiety disorder were higher in ASD (28%) than non-ASD youth (13%; $X^2(2) = 19.38$, $p < .001$). Among ASD youth, social anxiety disorder rates were significantly greater for SA (49%) compared to DS (30%) and NONE (7%; $X^2(2) = 39.88$, $p < .001$). There was a significant main effect for SCQ social deficits ($F = 19.4$, $p < .001$) in ASD; Tukey's post-hoc showed SA and DS youth were comparable but more severe than NONE ($p < .001$). There was a significant main effect for social anxiety disorder symptoms ($F = 24.2$, $p < .001$) in ASD; Tukey's post hoc showed SA youth evidenced more symptoms (but not other anxiety disorder symptoms) than both DS and NONE ($p < .001$). In contrast, non-ASD SA youth evinced greater symptoms of social *and* non-social anxiety disorders compared to DS and NONE (all $p < .05$). A main effect was found for MDE and SSD ($F > 12.3$, $p < .001$) in ASD; Tukey's post hoc showed that SA youth evinced more symptoms than DS and NONE for both disorders ($p < .001$). SA was not associated with ID in ASD youth ($X^2(2) = 3.15$, $p > .05$).
Conclusions: Â SA was found to be more common in ASD than non-ASD psychiatry referrals, yet it is not a defining characteristic of ASD. More importantly, only within ASD, SA youth evinced more social anxiety disorder symptoms but *not* other anxiety disorder symptoms compared to DS youth, suggesting that social anxiety may be driving SA. Interventions targeting social anxiety may therefore benefit SA youth.

177 **126.177** Relationship Between ASD Symptomology, Intellectual Functioning, and Seizure History in Children with ASD

J. L. Peterson[1]*, M. Kelly*[2]*, A. Cole*[2]*, H. Panjwani*[2]*, K. Steinman*[3] *and R. Bernier*[4]*, (1)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA, (3)University of Washington and Seattle Children's Hospital, Seattle, WA, (4)University of Washington Autism Center, Seattle, WA*

Background: Â Autism Spectrum Disorder (ASD) and epilepsy frequently co-occur, and despite similarly identified genetic contributors, it is unclear how shared etiologies are driving the association and how seizures impact ASD symptomology (Gilby & O'brien, 2013). ASD-epilepsy comorbidity has been associated with greater impairment in adaptive functioning, motor skills, and severity of autism, with severity often defined as level of intellectual functioning (Robinson, 2012; Turk, 2009; Viscindi et al., 2014). Additionally, increased rates of restricted and repetitive behaviors have been reported in individuals with comorbid ASD-epilepsy distinguishing them from individuals with ASD alone even when accounting for intellectual disability (Cuccaro et al., 2012).
Objectives: Â First, to explore the ASD symptomology profile associated with ASD and history of seizures or ASD alone in a sample of children ascertained for ASD. Second, to further examine the relation between seizure history, autism symptoms, and cognitive functioning
Methods: Our preliminary analyses included data from 110 children and young adults with ASD between ages of 4 years and 21 years with no reported history of seizures (n = 81, Male = 81%) and a history of non-febrile seizures (n = 30, Male = 73%). Seizure history was defined by parent interview. ASD symptomology was characterized using the ADOS-2 subdomain totals and ADI-R domain totals. Full Scale IQ Standard Score was derived from the Differential Ability Scale for Children (DAS-II; Elliot, 1990) with subjects stratified into IQ equal or higher than 70 (58%) and IQ lower than 70 (47%). Two MANCOVAs examined the effects of IQ status and seizure history (ASD+No Seizure History vs. ASD + History of Seizures) on parent derived ASD symptom scores (ADI-R subdomain totals) and clinician derived ASD symptom scores (ADOS-2 subdomain totals), controlling for current anti-seizure medication use.
Results: There were no significant multivariate effects or interactions for parent derived ASD symptoms. Significant main effects were found on the clinician derived ASD symptoms for IQ status, $F(3,97) = 14.73$, $p < .001$, Wilk's Lambda = .687 and seizure history, $F(3, 97) = 4.94$, $p = .003$, Wilk's Lambda = .876. A trend for the interaction between groups was observed, $F(3, 97) = 2.67$, $p = .052$, Wilk's Lambda = .924 (see Figure 1). Post hoc testing indicated this interaction was significant for only the behavioral subdomain, $F(1, 98) = 6.43$, $p = .013$, such that children with higher IQ and with a positive seizure history showed significantly lower restricted and repetitive behaviors compared to children without a history of seizures or children with a seizure history and IQ below 70.
Conclusions: Â Results suggest patterns of autism symptoms are associated with seizure history and intellectual functioning with greater ASD impairment associated with intellectual disability.Â Findings also reveal independent and interactive effects of intellectual functioning and seizure history on ASD symptomology particularly in the area of restricted and repetitive behaviors. Specifically, children with ASD, seizure history, and without intellectual disability demonstrated significantly less behavioral symptoms, suggesting a protective contribution of cognitive functioning in this group.

178 **126.178** Relationship Between Medical Comorbidity and Problem Behavior in Children with Autism Spectrum Disorder

A. Stedman[1]*, K. A. Smith*[2] *and M. Siegel*[3]*, (1)Spring Harbor Hospital, Westbrook, ME, (2)Maine Medical Center, Portland, ME, (3)Maine Medical Center - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME*

Background: Medical comorbidities, such as gastrointestinal and neurological disorders, in children with autism spectrum disorder (ASD) are relatively common and may have a negative impact on existing behavior problems related to an ASD diagnosis. The prevalence and type of medical comorbidities within the severely affected ASD patient population remains unclear. An improved understanding of medical comorbidities and their relationship to problem behavior has significant implications for treatment.
Objectives: To examine the prevalence of medical comorbidities within the Autism Inpatient Collection (AIC) sample, and to examine the relationship between common medical comorbidities and behavioral problems among severely affected children with ASD.
Methods: Data for this analysis were collected as part of a prospective study (AIC) examining phenotype, behavioral, and genetic data of children with ASD recruited from six specialized inpatient psychiatric units. Three-hundred and fifty children with ADOS-2-confirmed ASD enrolled in the AIC between February 2014 and October 2015 were included in this analysis. Medical comorbidities for each participant were collected from Axis III discharge diagnoses and categorized by ICD-10 code. To quantify severity of behavioral problems, the Aberrant Behavior Checklist-Irritability subscale (ABC-I) was completed at admission by a primary caregiver. Data analysis consisted of frequency and proportion calculations for ICD-10 categories, as well as t-tests to examine the relationship of medical comorbidities and ABC-I scores.
Results: The average age of the total sample was 12.9 years (*SD*=3.3, range 4-21), 79% were male, 79% Caucasian, and 93% non-Hispanic/non-Latino, with an average length of hospital stay of 25.6 days (*SD*=23.8, range 3-163). Sixty-percent of the sample (n=211) was diagnosed with at least one Axis III medical condition. Of those, 23.7% (n=83) had one diagnosis, 17.1% (n=60) had two, 10.0% (n=35) had three, 6.6% (n=23) had four, and 2.6% (n=9) with five diagnoses. Medical comorbidities were categorized by ICD-10 diagnostic groups. Of the 446 total diagnoses, the following categories were most prevalent: endocrine/nutritional/metabolic diseases (20.4%, n=91), diseases of the digestive system (14.8%, n=66), diseases of the respiratory system (11.7%, n=52), and diseases of the nervous system (11.4%, n=51) (see Figure 1). There were no significant differences in mean admission ABC-I scores between patients with any Axis III diagnosis (mean=27.96, SD=9.24) compared to those without (mean=26.47, SD=9.49), *p*=0.182. Further investigation by type of comorbidity (using ICD-10 categories with greater than 50 diagnoses in the sample as a cut-off) indicated subjects with at least one nervous system comorbidity (such as epilepsy, sleep disorder, or migraines) had significantly higher ABC-I scores (mean=29.98, SD=9.97) than those with no medical comorbidities (mean=26.47, SD=2.49), *p*=0.04.
Conclusions: Endocrine, gastrointestinal, respiratory, and nervous system disorders were found to be the most prevalent medical comorbidities in this inpatient sample. Behavioral severity for subjects with at least one nervous system problem was significantly higher on average than those with no medical problems, and merits further investigation. Targeting treatment of seizure and sleep disorders and other neurologic problems may play a role in decreasing the severity of problem behaviors.

179 **126.179** Relationships Between Social Anhedonia, Capacity for Social Pleasure, Loneliness, and Depressive Symptoms in Adults with Autism Spectrum Disorder and Typically Developing Never-Depressed and Depressed Comparisons

G. Han *and K. Gotham, Vanderbilt University, Nashville, TN*

Background: The social motivation hypothesis posits that individuals with Autism Spectrum Disorder (ASD) experience reduced levels of social pleasure and hedonic capacity for interpersonal and social rewards. In typically developing (TD) adults, especially among those with depression, such deficits have also been associated with increased loneliness. Exploring the relationships between measures of social motivation and loneliness with depressive and autism symptoms allows for a deeper understanding of the social experience of adults with ASD, including those with the common comorbidity of depression.
Objectives: The present study investigated the relationship between social pleasure, social anhedonia, and loneliness, as well as measures of depressive symptoms and ASD traits, in adults with ASD, TD currently depressed adults, and TD non-depressed controls.
Methods: A total of n=57 adults aged 18-35 with verbal IQ>80 were recruited from three cohorts: ASD (n=23); TD with current depressive disorders (DEP, n=19); and TD comparison participants with no depression or anxiety history (TDC, n=15). All participants completed diagnostic screening and testing (including the Autism Diagnostic Observation Schedule [ADOS-2] and the Structured Clinical Interview for DSM-5 Disorders [SCID-5]), as well as self-report measures of capacity to experience social pleasure (Anticipatory and Consummatory Interpersonal Pleasure Scale; ACIPS), social anhedonia (Revised Social Anhedonia Scale; RSAS), and loneliness (Loneliness in Context Questionnaire; LiCQ). Participants also provided self-reported measures of autism spectrum traits (Autism Spectrum Quotient; AQ) and depressive symptoms (Beck Depression Inventory-II; BDI).
Results: The ASD and DEP groups were not statistically different from each other on social interest/anhedonia measures (ACIPS and RSAS), though they showed less social interest and increased anhedonia compared to the TDC group. As a group, ASD reported greater loneliness than TDC but less loneliness than DEP. Within ASD, increased social anhedonia and decreased social pleasure were significantly associated with greater levels of loneliness (LiCQ), depression (BDI-II), and ASD symptoms (AQ). In DEP, increased social anhedonia was significantly associated with increased loneliness and depressive symptoms, and marginally significantly associated with increased ASD symptoms.
The integrity of the associations between social interest/anhedonia and loneliness was further explored when controlling for AQ and BDI-II scores in a multiple linear regression framework that is statistically equivalent to the assessment of partial correlations, where either AQ or BDI-II was added as a covariate. The TDC and DEP groups were collapsed into one TD group with greater variability in social motivation measures and depressive symptoms. When controlling for AQ across groups, increased RSAS and decreased ACIPS remained significant predictors of loneliness, except for the nonsignificant association between ACIPS and loneliness in ASD. When controlling for BDI-II scores, RSAS and ACIPS no longer significantly predicted loneliness, except for a marginally significant association between ACIPS and loneliness in the TD group (Figure 1).
Conclusions: Results indicate that decreased social interest and increased anhedonia are both associated with loneliness in TD and ASD adults. However, preliminary findings suggest that depressive symptoms, not ASD traits, in ASD and TD account for self-reported loneliness over and above measures of social interest/anhedonia.

180 **126.180** Repetitive Cognition Mediates the Relationship Between Autism Symptoms and Depression

E. G. Keenan*, C. M. Esposito, A. Labozzetta and M. D. Lerner, Stony Brook University, Stony Brook, NY*

Background:
In typically-developing (TD) populations, repetitive cognition (e.g., rumination) often correlates with internalizing psychopathologies (Nolen-Hoeksema, 2000). In individuals with autism spectrum disorder (ASD), depression is similarly associated with rumination (Gotham et al., 2014), and there is an increased prevalence of depression in ASD (Buck et al., 2014).
Rumination has likewise shown correlations with some types of repetitive behavior seen in ASD, specifically those related to rigidity/insistence on sameness factor (Carcani-Rathwell et al., 2006; Gotham et al., 2014). Individuals with ASD exhibit a higher prevalence of rumination than TD peers (Crane et al., 2013).
It is unknown whether other forms of repetitive cognition seen in ASD (rigidity, fixation on interests, etc) are associated with increased depression risk or risk for other internalizing constructs, such as rejection sensitivity (an anxious preoccupation with expected rejection; Downey & Feldman, 1996); while these repetitive cognitions may be developmentally distinct from rumination as seen in TD peers, they may function similarly to predispose an individual to depression.
Objectives:
The present study aims to investigate whether increased levels of repetitive cognition may explain increased levels of a) depression and b) rejection sensitivity seen in individuals with more ASD symptoms.
Methods:
200 typically-developing adults were recruited through an online subject pool of university undergraduates. The following measures were used to assess our hypotheses: The Autism Quotient (AQ; Baron-Cohen et al., 2001), the Perseverative Thinking Questionnaire (PTQ; Ehring et al., 2011) and Rumination Response Scale (RRS; Treynor et al., 2003), the Patient Health Questionnaire – 9 item version (PHQ-9; Kroenke et al., 2001), and the Rejection Sensitivity Questionnaire (RSQ; Downey & Feldman, 1996).
Results:
There was a positive association between AQ and PHQ-9 (b = .26, p < .001) as well as AQ and PTQ (b = .32, p < .001) and RSQ (b = .39, p < .001). A model assessing PTQ as a mediator between AQ and PHQ-9 had a significant indirect effect (b = .18, 95% CI [.09, .28]). The direct effect of AQ on PHQ-9 after taking the mediator into account was nonsignificant (b = .07, p = .18), consistent with full mediation. Effect size was medium (κ^2 = .13, 95% CI [.03, .23]). Another model assessing PTQ as a mediator between AQ and RSQ was similarly supported with a significant indirect effect (b = .14, 95% CI [.07, .24]).
Conclusions:
A positive association was found between ASD symptoms and depression, which was at least partially explained by increased perseveration. Similarly, perseveration partially explained the relationship between ASD symptoms and rejection sensitivity. These findings support the use of cognitive approaches, such as cognitive-behavioral and mindfulness therapies, for treating depression in ASD, given their explicit focus on addressing repetitive thinking and other maladaptive cognitions (Anderson & Morris, 2006; Spek et al., 2012). Relatedly, these findings may indicate that repetitive cognition is a cognitive factor underpinning increased depression risk in ASD. Further research should clarify the role of increased perseveration in the development of internalizing psychopathologies in individuals with ASD.

181 **126.181** Risk and Protection Factors of Comorbidities in Pediatric Cohort with ASD: Elena Cohort

A. Baghdadli[1] *and C. Rattaz*[2]*, (1)CHU MONTPELLIER, Montpellier, France, (2)Centre de Ressources Autisme, Montpellier, FRANCE*

Background: Medical conditions are more prevalent in youth with ASD than in the general population. These conditions are often related to the occurrence of aberrant behaviors, under-diagnosed and not taken into account for prevention.
Objectives: This study aimed to better estimate the prevalence and risk factors of comorbidities in ASD among children and adolescents.
Methods: ELENA cohort is a French prospective and multicenter study. Participants aged between 2 and 16 years, have a diagnosis of ASD formally established by multidisciplinary assessment according to ADOS, ADI and international criteria (ICD10/DSMV). Medical conditions are collected using an exhaustive and standardized parental questionnaire adapted from NIMH* and psychiatric symptoms using the CBCL.
Results: Our data focused on a subset of 400 participants. The most frequent prenatal medical conditions during are: maternal infection treated by antibiotics (17.6%), high maternal blood pressure (8%) and drug exposure (40%). The most frequent post-natal medical conditions are: gastrointestinal diseases (31.8 %), dermatological diseases (29.9%) and neurological disorders (29.5%). About 38% of children are under medical treatment. According to the CBCL6-18 years, 66% of participants exhibit psychiatric internalizing symptoms and 42% of externalizing problems: 51% of anxiety problems, 49% of affective problems, 19% of oppositional defiant problems, 14% of hyperactivity and attention deficit problems, 7% of conduct problems and 5% of somatic problems. The links between the occurrence of these conditions and several clinical or psychosocial variables are examined in order to find risk or protection factors.
Conclusions: These results confirmed the high frequency of medical conditions and comorbid symptoms in pediatric population with an ASD. These comorbidities are linked with clinical and psychosocial and they have to be better identified and early treated to prevent their negative impact on outcome trajectories. This will contribute to improve the quality of life of the whole family.

182 **126.182** Schizotypal Personality Traits in Autism Spectrum Disorders: What Are the Roles of Alexithymia and Anxiety?

N. C. Russell[1]*, K. Stephenson*[1]*, C. Haenschel*[2]*, M. South*[3] *and S. B. Gaigg*[2]*, (1)Brigham Young University, Provo, UT, (2)Psychology, City, University of London, London, United Kingdom, (3)Psychology and Neuroscience, Brigham Young University, Provo, UT*

Background: There is a large diagnostic overlap between autism spectrum disorders (ASD) and schizotypal personality disorder (SPD). In particular, characteristics associated with increased ASD traits have been linked with increased negative symptoms, social skills deficits, and disorganized behavior in SPD. In addition, the presence of anxiety can be identified in both ASD and SPD at high rates of prevalence. Alexithymia (a difficulty identifying internal emotional states) is often found among those suffering from anxiety in the general population and is associated with ASD and SPD traits. Furthermore, it is an influential moderator of the relationship between ASD traits and anxiety and is associated with anxiety in schizophrenia. Despite these suggested associations, the nature of this overlap is unknown but a better understanding of it could aid discrimination in differential diagnosis and inform intervention selection and design. While it has been shown that the overlap between ASD and SPD traits is not due to anxiety, it is possible that this overlap is explained not by anxiety per se but by alexithymia.
Objectives: We examined the relationship between ASD and SPD traits in adults with ASD, and the roles of alexithymia and anxiety in this relationship, using structural equation modeling (SEM).
Methods: A combined UK-US sample of 75 adults with a confirmed diagnosis of ASD completed self-report questionnaires. ASD traits were identified using the Autism Spectrum Quotient (AQ), SPD traits were identified using the Schizotypal Personality Questionnaire (SPQ), and alexithymia was assessed by means of the Toronto Alexithymia Scale—20 (TAS-20). Anxiety was a latent variable constructed using the Penn State Worry Questionnaire (PSWQ), the Trait form of the State Trait Anxiety Inventory—Form Y (STAI-T Form-Y), and the Fear of Negative Evaluation Scale—Brief (FNE Brief).
Results: The SEM analysis supported the hypothesis that alexithymia plays an important role in the relationship between ASD traits and SPD traits. All factor loadings were in the expected direction and there was converging evidence for excellent model fit. Simple relationships (ASD traits to SPD traits and ASD traits to anxiety) were significant when modeled individually but these were eliminated by adding alexithymia as a mediator (ASD traits to SPD traits; 89.4% of the influence) and reduced by adding SPD traits as a mediator (ASD traits to anxiety; 38.9% of the influence). In the combined model, ASD traits did not directly predict anxiety when controlling for alexithymia and SPD traits nor did they directly predict SPD traits. However, increased ASD traits did predict increased alexithymia and alexithymia predicted SPD traits. Increased SPD traits predicted increased anxiety but increased alexithymia did not.
Conclusions: Alexithymia and SPD traits both served as mediators for their respective relationships, albeit to differing degrees. These results suggest that the presence of SPD traits in individuals with ASD is largely explained by alexithymia symptoms and not the ASD traits themselves.

183 **126.183** Self-Reported Suicidal Ideation, Depression and Loneliness in Adults with Autism Spectrum Disorder (ASD)

D. Hedley[1]*, M. Uljarevic*[2,3]*, M. Wilmot*[1]*, J. Spoor*[4]*, A. L. Richdale*[2] *and C. Dissanayake*[1]*, (1)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia, (4)Department of Management & Marketing, La Trobe Business School, La Trobe University, Melbourne, Australia*

Background: Previous studies report an exceptionally high rate of suicidal ideation (30 - 66%), plans or attempts at suicide (15 - 35%), and depression (31 - 70%), in adults with ASD, when compared to the general population (Balfe & Tantam, 2010; Cassidy et al., 2014; Raja, Azzoni, & Frustaci, 2011; Takara & Kondo, 2014). Depression is a significant risk factor for suicide, with symptoms present in at least 90% of individuals who die by suicide (Barraclough, Bunch, Nelson, & Sainsbury, 1974). However, studies on depression in ASD, and suicidal ideation in particular, are sparse and often anecdotal (Cassidy et al., 2014). Furthermore, adults with ASD may experience high rates of isolation and loneliness, both of which are associated with increased rates of depression (Mazurek, 2013), which may add to suicide risk.
Objectives: Our aim was to report and examine the relationship between self-reported depressive symptoms, suicidal ideation and loneliness in adults with ASD.
Methods: Participants were 76 adults (88% male) with ASD aged 17 to 56 years (M = 25.15, SD = 7.74 years) who were participating in a longitudinal employment study. Participants completed the Patient Health Questionnaire-9 (PHQ-9; Kroenke, Spitzer, & Williams, 2001), which includes a question concerning suicidal ideation, and the University of California Los Angeles Loneliness Scale (Russell, 1996; Russell, Peplau, & Cutrona, 1980; Russell, Peplau, & Ferguson, 1978). We report frequency of depressive symptoms (excluding ideation), ideation, and loneliness, and utilized correlation and mediation analysis (Hayes, 2013) to examine the relationship between these variables.
Results: Overall, 19.7% of the sample reported that they had experienced recent (last 2 weeks) thoughts that they would be better off dead, or of hurting themselves on several days (15.8%), more than half the days (1.3%), and nearly every day (2.6%). In terms of depressive symptoms, 25% of the sample were in the moderate to moderate-severe range, and 1.3% were in the severe range. Loneliness was significantly correlated with depressive symptoms (excluding ideation), r_s = .44, p < .001, but bore only a weak relationship with suicidal ideation, r_s = .29, p = .012. There was a significant indirect effect of loneliness on suicidal ideation through depression, b = .01; BCa CI [.004, .02], standardized effect size = .21; BCa CI [.10, .34].
Conclusions: Both the rates of suicidal ideation (19.7%) and at least moderate rates of depression (26.3%) were lower than those reported previously in adults with ASD. This difference may be accounted for by differences in methodology and sampling compared to previous studies which have, for example, used clinical interviews to ascertain ideation and history of suicide attempts in clinical groups (e.g., Cassidy et al., 2014). Nonetheless, these rates remain substantially higher than that for the general population, which are 3.7% and 6.2% for suicidal ideation and depression respectively (Crosby, Han, Ortega, Parks, & Gfroerer, 2011; Tiller, 2012). Importantly, we characterised the relationship between depression, loneliness and suicidal ideation, showing that depression mediated the relationship between loneliness and suicidal ideation.

184 **126.184** Simons Simplex Collection at the Interactive Autism Network: An Online Follow-up Study

E. Brooks[1]*, J. S. Toroney*[2]*, P. Feliciano*[1]*, L. Snyder*[1]*, J. K. Law*[2]*, C. W. Lehman*[1]*, P. H. Lipkin*[3] *and W. Chung*[1]*, (1)Simons Foundation, New York, NY, (2)Interactive Autism Network, Baltimore, MD, (3)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD*

Background: The Simons Simplex Collection at the Interactive Autism Network (SSC@IAN) is an online cohort of families from the original SSC study who have agreed to be contacted about additional research opportunities. Participants in the SSC@IAN are members of simplex families, each of which has one child affected with an autism spectrum disorder, and unaffected parents and siblings. The online research environment at the SSC@IAN affords a unique, centralized platform to follow up with SSC families from all over the United States and Canada.
Objectives: The SSC@IAN follow-up study was an online study to gather medical, educational, diagnostic, and psychosocial updates on SSC probands and their families 5 to 8 years following their participation in the original SSC study. The original SSC cohort is a clinically and genetically well-characterized cohort that has proven valuable for research, and the follow-up study aimed to provide researchers with updated data on as many families as possible.
Methods: SSC@IAN families were provided the opportunity to complete 3 modules, accessible via their online research dashboard. Each module included a selection of update surveys (e.g. medical, pharmacological/treatment, educational, and diagnostic history) and standardized measures such as the Social Responsiveness Scale – Second Edition, Adult Behavior Checklist or Child Behavior Checklist, Aberrant Behavior Checklist, and Repetitive Behavior Scale-Revised.
Results: Four hundred (400) families with probands under age 18 completed some portion of the follow-up study. Ratios of males to females and IQ, are comparable between the original SSC cohort and the follow up participants. Mean full scale IQ for the original SSC cohort was 81, verbal IQ was 78 and nonverbal IQ was 84; for the follow-up study, the full scale IQ was 83, verbal IQ was 80, and non-verbal IQ was 86.Â Age ranged from 4 to 17 for the complete original SSC cohort (mean 9.0 years), and 8 to 17 years of age for the follow-up study cohort (mean 12.9 years).Â The age at baseline assessment in the present follow-up cohort was 4 to 11 years. Compared to the baseline SSC cohort data, probands showed lower scores in some specific areas, including RBS-R repetitive and sensory behaviors (total mean 27.0, 21.7), and CBCL6-18 externalizing behaviors (T mean 56.2, 52.7).Â Internalizing behavior and ADHD scores were similar between the follow-up study and baseline SSC cohort data (Internalizing T mean 60.0, 60.1; ADHD T mean 61.9, 60.6).Â In terms of comorbid diagnoses, parents reported high frequencies of diagnosis or treatment for ADHD (42%) and anxiety (26%) in probands at follow-up, with lower frequencies of seizure (6%), depression (4%), and bipolar disorders (2.5%).
Conclusions: The SSC@IAN follow-up study provides additional longitudinal data for researchers to investigate outcomes in this well-characterized ASD cohort.Â In general, the current sample shows a trend towards lower scores on some ASD and related behavioral measures compared with the SSC cohort's original data, suggesting milder symptoms. However, consistent with other studies, anxiety disorders and ADHD are common comorbid conditions now reported in these older children and teens with ASD.

185 **126.185** Specific Medical Conditions Are Associated with Unique Behavioral Profiles in Autism Spectrum Disorders

D. A. Zachor[1] *and E. Ben Itzchak*[2]*, (1)Tel Aviv University / Assaf Harofeh Medical Center, Zerifin, Israel, (2)Communication Disorder, Ariel University, Ariel, ISRAEL*

Background:
Autism spectrum disorder (ASD) is a heterogeneous group of disorders which occurs with numerous medical conditions. In previous research, subtyping in ASD has been based mostly on cognitive ability and ASD symptom severity. Several medical conditions have frequently been described as co-occurring with ASD. Research so far has not addressed the question of whether unique medical conditions occur in specific ASD subtypes. Medical phenotypes can potentially be used as biological variables to define specific endophenotypes in ASD.
Objectives:
The aim of the current study was to investigate whether specific medical conditions in ASD, including macrocephaly, microcephaly, developmental regression, food selectivity, and sleep problems are associated with unique behavioral profiles.
Methods:
The study population included 1,224 participants, 1043 males and 181 females (M:F ratio=5.8:1) with a mean age of 49.9m (SD=29.4) diagnosed with ASD. All the participants underwent comprehensive assessments, including medical history and neurological examination, cognitive and adaptive behavior evaluations, and ASD diagnostic tests. The behavioral profile was composed of cognitive ability, adaptive skills, and autism severity using the relevant standardized scores and was examined in each of the aforementioned medical conditions.
Results:
Groups with and without the defined medical conditions were compared on the behavioral measures. Developmental regression was present in 19% of the population and showed a more severe clinical presentation, with lower cognitive abilities, more severe ASD symptoms, and more impaired adaptive functioning. Microcephaly was observed in 6.3% of the population and was characterized by a lower cognitive ability and more impaired adaptive functioning in comparison to the normative head circumference (HC) group. Severe food selectivity was found in 9.8% and severe sleep problems in 5.1% of the ASD population. The food selectivity and sleep problem subgroups both showed more impaired adaptive skills, and more severe autism symptoms as described by the parents, but not per the professional assessment. Macrocephaly was observed in 7.9% of the ASD population and did not differ from the normative HC group in any of the examined behavioral measures.
Conclusions:
Based on these findings, two unique medical-behavioral subtypes in ASD that affect inherited traits of cognition and/or autism severity were suggested. The developmental regression phenotype occurred with widespread, more severe impairments in cognition, autism severity and adaptive skills, while the microcephaly phenotype occurred with more impaired cognition and adaptive skills. In contrast, severe food selectivity and sleep problems represent only comorbidities to ASD that affect functioning as manifested by lower adaptive skills. Defining specific subgroups in ASD with a unique biological signature and specific behavioral phenotypes may help future genetic and neuroscience research.

186 **126.186** Sustained Pupil Dilation to Sad Faces Is Associated with Self-Reported Rumination in Adults with Autism Spectrum Disorder and Adults with Current Depression

K. Gotham[1]*, G. Han*[1]*, R. N. Crist*[1] *and J. W. Bodfish*[2]*, (1)Vanderbilt University, Nashville, TN, (2)Vanderbilt University School of Medicine, Nashville, TN*

Background: Rumination, or repetitive negative thinking, is associated with the onset and maintenance of depressive disorders in the typically developing (TD) population. Autism spectrum disorder (ASD) is marked by repetitive thinking and behaviors as one of the core symptom domains that characterize this disorder. Rates of depression are also notably high in adolescents and adults with ASD. Our long-term goal is to explore repetitive thinking as a pathway to depressed mood in ASD. However, we first must lay groundwork in understanding the measurement of and mechanisms associated with depressive rumination in this special population. Pupillometry offers a neural measure of *sustained*cognitive-affective processing, which may converge with repetitive thinking.
Objectives: The current work aims to advance understanding of how people with ASD, a population marked by repetitive thinking and high rates of depression, compare to typically developing depressed (DEP) and never-depressed controls (TDC) on measures of repetitive negative thinking and sustained neural response to social-emotional material. We assessed group differences among these three diagnostic cohorts on both self-reported rumination and on pupil indices of reflexive cognitive-affective response over time, and assessed whether rumination is related to affective response in general, and within ASD specifically.
Methods: A total of n=53 adults aged 18-35 with verbal IQ>80 were recruited from three cohorts: ASD (n=21); TD with current depressive disorders (DEP, n=13); and TD comparison participants with no depression or anxiety history (TDC, n=19). All participants completed diagnostic screening and testing (including the Autism Diagnostic Observation Schedule [ADOS-2] and the Structured Clinical Interview for DSM-5 Disorders [SCID-5]), self-reported on depressive rumination with the Ruminative Response Scale (RRS), and provided pupillary response data within a passive-viewing task in which emotionally-valenced faces were displayed for 400 ms, followed by an 8 second mask.
Results: Participants with ASD were significantly higher than TDC and significantly lower than DEP on depressive rumination (RRS). For pupil analyses, patterns of significant cohort differences preserved across stimulus condition (Happy, Sad, Angry, Neutral) suggest a more dynamic trajectory in ASD pupil response, in which ASD resembles TDC at second 2 and grows in magnitude of pupil dilation over the trial duration to more resemble DEP by second 8 -- whereas the two TD cohorts show an immediate response (either low or high) and sustain that level on average throughout trial duration (Figure 1). Individuals who ruminate more (here, they tended to belong to the ASD or DEP cohorts) generally had greater pupil dilation to Sad faces across 8 second trials (Figure 2). When TDC and DEP were collapsed into one TD group with greater variability on rumination, the interaction was also significant for Happy and marginally significant for Angry conditions.
Conclusions: These data suggest that both ASD and TD individuals who endorse ruminating also are likely to exhibit sustained neural activity following emotionally-salient information. This work helps to locate ASD on a continuum of rumination scores, and to evaluate the convergence between self-reported rumination and sustained neural response to emotional stimuli within and across these diagnostic cohorts.

187 **126.187** Testing the Psychometric Properties of the Spence Children's Anxiety Scale (SCAS) and the Screen for Child Anxiety Related Emotional Disorders (SCARED) in Autism Spectrum Disorder.

***S. Carruthers**, R. Kent, M. J. Hollocks and E. A. Simonoff, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
There is a need to screen for anxiety in individuals with autism spectrum disorders (ASD) as it is one of the most prevalent co-occurring conditions (Simonoff et al., 2008) and individuals have reported these additional symptoms to be more impairing than their ASD symptoms. Questionnaires are most often used for screening for anxiety but have usually only been validated in typically developing populations. Study of the psychometric properties of such measures for use with ASD populations is limited.
Objectives:
To explore the psychometric properties of two commonly used questionnaires, the SCAS and the SCARED, with an ASD sample, in comparison to DSM-IV anxiety diagnoses according to the Child and Adolescent Psychiatric Assessment (CAPA).
Methods:
The study included 49 males (aged 10-16 years) with a clinical diagnosis of ASD. The SCAS (Spence, 1998) and SCARED (Birmaher et al., 1999) were completed by parents and children. Trained researchers also conducted the parent-version of the CAPA (Angold and Costello, 2000), a semi-structured psychiatric interview schedule.
Results:
Rate of comorbidities
Using the DSM-IV CAPA algorithms, 63% of participants with ASD met criteria for one or more anxiety diagnosis: the most common were generalised anxiety (39%) and panic disorder (27%).
Internal consistency
The internal consistency for the total scores on both measures was high for both parent-report (both; αÂ =0.95) and self-report (SCAS; αÂ =.92, SCARED; αÂ =.94). The internal consistency of the sub-scales was higher in the SCAS (parent αÂ =.65–.84; self-report αÂ =.69-.81) than the SCARED (parent αÂ =.47–.75; self-report αÂ =.46-.66) and in the parent report compared to the self-report.
Parent-child agreement
Parent and child scores were significantly correlated for both the SCAS (r =0.59, p <0.001) and the SCARED (r =0.46, p <0.001).
Comparison of the SCAS and the SCARED
The difference in the power of the two parent-report questionnaire measures in predicting an anxiety disorder was not significant when measured using ROC analyses ($X^2(1)$ =2.18, p =0.14) or between the two self-report measures ($X^2(1)$ =0.16, p =0.69).
Cut-points with parent data
In the ASD sample, using the recommended cut-off on the SCARED (25) gives 77.4% sensitivity and 50% specificity (67.4% correctly classified). ROC analyses in the ASD sample suggest an alternate cut-off of 28.5 to maximise both the sensitivity (74.2%) and specificity (72.2%), which would correctly classify 73.5% of the sample. The suggested cut-off for the parent SCAS (24) gives 87.1% sensitivity and 66.7% specificity (79.6% correctly classified). In this ASD sample, ROC analyses suggest a higher cut-off of 27.5 maximises both the sensitivity (77.4%) and specificity (77.8%), which would correctly classify 77.6% of the sample.
Conclusions:
There was no significant difference between the predictive power of the SCAS and the SCARED in an ASD sample; both questionnaires had good levels of sensitivity and specificity using cut-points validated in the typically developing population. Analyses indicate higher cut-points in ASD may be more accurate. This may reflect the symptom overlap in ASD and anxiety.

188 **126.188** The Children's Sleep Habits Questionnaire: Evaluating Subscales for Sleep Problems in Children with Autism Spectrum Disorder

***E. Abel**[1] and A. J. Schwichtenberg[2], (1)Purdue University, West Lafayette, IN, IN, (2)Purdue University, West Lafayette, IN*

Background: Â Children with Autism Spectrum Disorder (ASD) face many developmental obstacles, including elevated sleep problems. To accurately identify these problems, psychometrically sound measures are important. The Children's Sleep Habits Questionnaire (CSHQ; Owens et al., 2000) is the most common measure of sleep problems in early childhood—including children with ASD. However, despite its common use, few studies have assessed the accuracy of the CSHQ in screening sleep problems in this population.
Objectives: Â We aimed to explore the basic psychometric properties of CSHQ subscales in a sample of children with ASD. We further aimed to determine whether these subscales were useful in screening pediatric sleep problems.
Methods: This study included 41 children with ASD between the ages of 2-10 (*M*= 5.5). Caregivers completed the CSHQ as part of a larger study of sleep and behavior in the context of early intervention. The CSHQ includes 33 parent-report items with eight empirically derived subscales (Owens et al. 2000). This measure was recently validated in children ages 2-5, resulting in five subscales for use in toddlers and pre-school aged children (CSHQ-T; Sneddon et al., 2013). Children were first grouped into 'sleep problem' and 'non-problem' categories via parent reports at time of enrollment (Does your child have a sleep problem?). Using data from published validation studies (Owens et al., 2000; Sneddon et al., 2013), mean subscale scores for the 'sleep problem' group were compared to a clinical sample, and mean subscale scores from the 'non-problem' group were compared to a community sample. Differences between samples were evaluated using Welch's *t* tests.
Results: Â Cronbach's alpha ranged from .64 to 1.00 for Owens' subscales, and .78 to 1.00 for the CSHQ-T. When comparing Owens' community sample with the 'non-problem' group, two subscales were significantly different ($p < .05$): Parasomnias and Daytime Sleepiness (Table 1). In this comparison, mean subscale scores were higher in the 'non-problem' group than the community sample. When comparing Owens' clinical sample with the 'sleep problem' group, only sleep duration was significantly different ($p < .01$). Duration difficulties (mean scores) were higher in our 'sleep problem' group than the clinical sample (Table 1). Finally, two subscales differed significantly when comparing the CSHQ-T community sample and the 'non-problem' group, with higher mean scores in the 'non-problem' group. However, there were no significant differences between our 'sleep problem' group and the clinical sample (Table 2).
Conclusions: This work contributes to a growing body of literature on sleep problems in children with ASD.Â Specifically, this is the first known study to explore basic psychometric properties of the CSHQ-T in a sample of children with ASD, including statistical comparisons with published clinical and community samples. Overall, both sets of subscales had acceptable psychometric properties and accurately distinguished between problem and non-problem sleepers in our sample. Significantly higher scores for children in the 'non-problem' group compared to community samples may reflect under-reporting of ASD sleep problems at time of enrollment. Future directions include validating the CSHQ-T with a larger, representative sample of children with ASD.

189 **126.189** The Gender Development Scale: Screening for Gender Dysphoria or Incongruence in Youth with ASD

S. Goldstein[1], *G. L. Wallace*[2], *L. G. Anthony*[3], *L. Kenworthy*[3], *A. C. Armour*[4], *M. Knauss*[3] *and J. F. Strang*[3], *(1)National Institute of Child Health and Human Development, Washington, DC, (2)Department of Speech and Hearing, George Washington University, Washington, DC, (3)Children's National Health System, Washington, DC, (4)Children's National Medical Center, Washington, DC*

Background: An overrepresentation of ASD among individuals with gender dysphoria (GD) has been reported, with rates of almost 1 in 10 youth diagnosed with GD meeting full diagnostic criteria for ASD, and many others presenting with the broader ASD phenotype (de Vries et al., 2010). There is also evidence that gender-related concerns are more common among youth with ASD (Strang et al., 2014; Janssen et al., 2016). Initial clinical guidelines for supporting individuals with co-occurring ASD and GD have been developed (Strang et al., 2016), but there are no established screening methods for assessing GD in individuals with ASD. The Gender Development Scale (GDS; Strang et al., 2016) includes not only a self- and parent-report measure assessing current presentation of gender identity and gender dysphoria, but also retrospective parent-report of children's gender presentation prior to puberty (age 4-8) to assess pre-pubertal (historical) signs of GD.
Objectives: Evaluate critical items from the self-report and parent-report versions of the GDS in cis-gender neurotypical (NT) youth, cis-gender youth with ASD without intellectual disability (ID), and gender dysphoric youth with ASD without ID. In youth with GD and ASD, evaluate pre-pubertal history, as reported by the parent, for signs of GD or gender variance.
Methods: Fifty-two youth (age 7-19) and their parents completed items from the GDS (26 cis-gender NT, 16 cis-gender with ASD, 10 gender dysphoric with ASD). Parents completed additional GDS items assessing gender characteristics prior to puberty (age 4-8).
Results: Three critical items assessing gender congruence/dysphoria showed 96.4% accuracy in categorizing youth according to GD vs. cis-gender status, with 99.14% accuracy for the self-report version alone. Among individuals with ASD and GD, there were no endorsements of gender non-binary identity (i.e., being both male and female) or agender identity (i.e., being neither male nor female), though one GD individual wished for a body that was neither male nor female. Parent-report from pre-puberty among individuals with GD and ASD indicated few signs of GD or gender nonconformity prior to puberty. Nineteen percent of youth in this study endorsed a strong wish for their body to stay a child's body and not become a grown-up body, with no differences in rates of endorsement between cis-gender NT, cis-gender ASD, and gender dysphoric ASD groups ($\chi^2(2)=0.77$, $p=.69$).
Conclusions: This study found that critical items from both the self- and parent-report of a gender questionnaire (The Gender Development Scale) accurately classified GD vs. cis-gender status in youth with ASD without ID, as well as among cis-gender NT. This establishes preliminary validity for this assessment method. Gender presentation as reported by parents prior to puberty was negative for signs of GD or gender nonconformity, adding support to clinical observations that GD youth with ASD tend to present gender concerns later in development. Future studies should explore why GD presents later in development in ASD.

190 **126.190** The Relationship Between Group Belonging, Subclinical Autistic Traits and Mental Health

A. E. Robertson, *K. Mitchell and S. Sankalaite, Psychology, School of Social Sciences, University of Dundee, Dundee, United Kingdom*

Background:
There is evidence that depression and anxiety is elevated in young adults with high levels of subclinical autistic traits (Kanne et al., 2009). Furthermore, identifying with multiple groups (e.g. family, local community and social groups) predicts lower levels of anxiety and depression in adults in the general population (Sani et al., 2015). Individuals with ASD experience difficulties with communication and social interaction, which may impact on forming relationships with other people. They also experience elevated levels of mental ill health (Simonoff et al., 2009). Therefore, it is anticipated that subclinical autistic traits and group belonging are predictive of symptoms of generalised anxiety and depression.
Objectives:
It was hypothesised that:

- People who report identifying with fewer groups (either zero or one) will have more autistic traits than people who report identifying with more groups (either two or three).
- Group identification and autistic traits will significantly predict generalised anxiety symptoms and depression symptoms.Â Gender and age were also included as predictor variables for both multiple regressions.

Methods:
The Autistic Spectrum Quotient (AQ; Baron-Cohen et al., 2001), Group Identification Scale (GIS: Sani et al., 2014), Generalised Anxiety Scale–7 (GAD-7; Spitzer et al., 2006) and Major Depression Inventory (MDI; Bech et al., 2001) were administered to 171 individuals. Data from 149 participants (Female: 69.8%; Male: 30.2%) were analysed after exclusion criteria (i.e. missing more than one item per measure) were applied.Â AQ scores ranged from 3 to 45 (M = 17.16; SD = 8.37) and number of groups identified with ranged from 0 to 3 (M = 1.85; SD = 0.898).
Results:
The autistic traits of people with high group identification (2 or 3 groups) were compared to individuals with low group identification (0 or 1 group). The low group-belonging group had significantly higher autistic traits (M: 23.64; SD: 10.19) than those in the high group (M: 14.54; 5.76), t(147) = 6.891, p<.001.
GAD-7: The overall model demonstrated that age, gender, autistic traits and group identification statistically significantly predicted generalised anxiety symptoms, $F(4,144) = 15.741$, $p < .001$, R^2Adj. = .285.
MDI: The overall model demonstrated that age, gender, autistic traits and group identification statistically significantly predicted depression symptoms, $F(4,144) = 13.970$, $p < .001$, R^2Adj. = .260.
Conclusions:
Autistic traits and group belonging significantly predict generalised anxiety scores and depression scores in adults in the general population. Furthermore, individuals with low levels of group belonging had significantly more autistic traits than those with high group belonging. Higher levels of group belonging are related to both better physical health (Sani et al., 2014) and mental health (Sani et al., 2012) outcomes. Based on the results from this study, we suggest it would be beneficial to explore group belonging in individuals with diagnosed ASD, in order to determine whether it is predictive of mental health outcomes. If found to be the case, there are important clinical implications (e.g. for interventions to manage depression and anxiety) that should be explored.

191 **126.191** Traditional and Distinct Symptoms of Anxiety in Youth with ASD and a Broad Range of Intellectual Functioning

C. M. Kerns[1]*, B. Winder-Patel*[2]*, M. Solomon*[3]*, B. Heath*[4] *and D. G. Amaral*[3]*, (1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)MIND Institute, University of California, Davis, Sacramento, CA, (3)Department of Psychiatry & Behavioral Sciences, University of California-Davis, Sacramento, CA, (4)Mind Institute, UC Davis, Palo Alto, CA*

Background:
Research suggests that youth with ASD present with both DSM-defined –hereon called "traditional"– anxiety disorders (e.g. specific phobia, generalized, separation, and social anxiety) and also more idiosyncratic –hereon called "distinct"– manifestations of anxiety, such as fears of change, anxiety around social rules/unpredictability and unusual phobias (e.g. fears of men with beards, toilets, sounds). Distinct symptoms share many qualities with traditionally-defined anxiety disorders (e.g. anticipatory worry, avoidance, physiological arousal), but do not fit DSM-defined anxiety categories and have historically been viewed as associated symptoms of ASD. The lack of clarity about where autism stops and anxiety begins contributes to variability in measurement and impedes progress in research. Furthermore, distinct anxiety may be particularly prone to being overshadowed by ASD, potentially reducing access to appropriate behavioral and cognitive-behavioral treatments.
Objectives:
The present study aimed to examine the rate and quality of traditional and distinct anxiety in a cohort of children with ASD and highly varied IQ. We also explored concordance between brief questionnaires and a gold-standard clinical interview for traditional and distinct anxiety.
Methods:
A preliminary sample of 24 youth (*N*=35 anticipated by 05/2017) with ASD (ages 9–15 years: *M*=11.96,SD=1.12; 70% male; 33% with IQ<70 (range: 31 - 170) were recruited as part of a longitudinal study of biological and behavioral correlates of ASD. Participants were enrolled at age 2-3.5 with follow-up assessment at 9-13 years (ongoing). Anxiety symptoms were assessed at follow-up via the Anxiety Disorders Interview Schedule–Parent/Autism Spectrum Addendum (ADIS/ASA), a gold standard clinical interview validated to assess traditional and distinct anxiety in ASD, the Child Behavior Checklist (CBCL), the Manifest Anxiety Scale for Children (MASC), and the Screen for Anxiety and Related Disorders (SCARED). ADIS/ASA Clinician Severity Ratings (CSRs; Range 0-8; CSR≥ 4 clinical cut-off for diagnosis/significant impairment) reflect anxiety-related impairment for traditional and distinct anxiety. The highest traditional and distinct CSRs were used to categorize each child's anxiety presentation and assess concordance with brief measures.
Results:
Per the ADIS/ASA, 71% of children presented with clinical anxiety (CSR ≥ 4), including: 21% traditional anxiety, 21% distinct anxiety, 29% both. Clinical anxiety was as common in youth with and without ID, but there was a trend for youth with ID to have less traditional anxiety (X^2 = 3.00, *p*=.08). Whereas the highest traditional anxiety CSR was correlated with SCARED (*r*=.57, *p*=.01), MASC (*r*=.67, p<.01), and CBCL Anxious/Depressed totals (*r*=.57, *p*=.01), distinct CSRs were not (*r*=-.14, .04 and .02 respectively). Exploratory analyses revealed that brief measures appeared more sensitive to DSM-anxiety in youth, but did flag anxiety in some youth with only distinct presentations (Table 1).
Conclusions:
This study illustrates the presentation of traditional and distinct anxiety in youth with ASD and a broad range of intellectual functioning. It suggests that brief measures detect traditional anxiety better than distinct symptoms and may fall particularly short for youth with ID. Anxiety may be particularly likely to be missed in youth with ASD when the content of their worries/fears varies from traditional conceptualizations or when their cognitive abilities are impaired.

192 **126.192** Predicting Parent-Reported Sleep Problems Using Longitudinal Data and Machine Learning Methods in the Autism Speaks-Autism Treatment Network Registry

A. M. Shui[1], *T. Katz*[2], *B. A. Malow*[3] *and M. O. Mazurek*[4], *(1)Massachusetts General Hospital, Boston, MA, (2)University of Colorado, Aurora, CO, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Health Psychology, University of Missouri, Columbia, MO*

Background: Sleep difficulties in children with Autism Spectrum Disorder (ASD) have been well established, and studies indicate that 50 to 80% of children with ASD have sleep problems (Richdale, 1999; Polimeni, et al, 2005; Courturier, et al, 2005; Krakowiak, et al, 2008). Of the children in the Autism Speaks-Autism Treatment Network (ATN) registry who do not have any parent-reported sleep problems at baseline (58%), a substantial subset have sleep problems reported at first follow-up (20.5%). Developing a predictive model for parent-reported sleep problems using longitudinal data and machine learning could help with treatment and prevention of these problems.
Objectives: To develop a model to predict sleep problems at first follow-up from baseline characteristics among children with no sleep problems at baseline.
Methods: A sample of children in the ATN registry without parent-reported sleep problems at baseline and with complete sleep data at first follow-up was randomly split into training and test samples, stratified by ATN site and age group. Children taking medications indicated for sleep at baseline or follow-up were excluded. Training sample baseline characteristics, including demographics, IQ, psychiatric diagnoses, health problems, and autism severity, behavior, and sensory scores, were tested for associations with subsequent sleep problems. Predictors were chosen based on statistical significance and clinical importance, correlation and multicollinearity considerations, and comparison of c-statistics from alternative logistic regression models. Given probabilities of sleep problems from the final model, a threshold for classifying children as at risk was selected that yielded at least 85% sensitivity and maintained maximum associated specificity. Each child in the test sample was then scored and assigned a predicted sleep problem status based on the model threshold. Comparison of the predicted and true sleep problem status of the test sample yielded sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy.
Results: In the training sample (n=527), children with less educated parents (28.0% vs. 15.9%, p=0.007), ear, nose, and throat (ENT) problems (27.4% vs. 14.6%, p=0.028), asthma (37.5% vs. 16.5%, p=0.023), higher Child Behavior Checklist (CBCL) Anxious/Depressed and Aggressive Behavior z-scores (0.0 vs. -0.3 for each, p=0.031 and p=0.029, respectively) have more sleep problems. In the final model using these predictors, aggressive behavior remains independently associated with higher odds of having sleep problems at first follow-up (OR 1.66, 95% CI 1.07-2.58, p=0.024), and having asthma is associated with higher odds but with borderline significance (OR 2.71, 95% CI 1.00-7.33, p=0.050). This model performed in the test sample (n=518) with sensitivity 80.3%, specificity 33.4%, PPV 18.5%, NPV 90.0%, and accuracy 40.9%.
Conclusions: Among children with ASD, those with more aggressive behavior, asthma, ENT problems, anxious/depressed behavior, and less educated parents at baseline may present with more sleep problems at first follow-up. In a multivariable model aggressive behavior independently predicts sleep problems. The multivariable model, with high sensitivity for identifying children at risk for sleep problems as well as accurate prediction of low risk of sleep problems, can help with treatment and prevention of sleep problems. Further data collection may provide better prediction through methods requiring larger samples.

193 **126.193** Predicting Insomnia in Young Adults: The Role of Autism Symptom Severity, Sensory Atypicality and Intolerance of Uncertainty.

A. L. Richdale[1,2], *M. Uljarevic*[1,2] *and R. Y. Cai*[1,2], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia*

Background: Poor sleep, primarily insomnia symptoms, is highly prevalent in autism across the lifespan and has a significant negative impact on all aspects of functioning, often over and above core autism symptoms. Therefore, insomnia constitutes an important treatment target, however, factors underlying insomnia problems in autism are currently poorly understood. Both autism symptom severity and atypical sensory behaviour are related to poor sleep. Intolerance of uncertainty is a trans-diagnostic risk factor predisposing individuals with and without autism to experience higher levels of stress and anxiety, and might therefore be related to insomnia problems. However, its role in ASD has not been previously explored.
Objectives: To examine the role of autism symptom severity (ASS), sensory seeking behaviour (SSB) and intolerance of uncertainty (IU) in predicting insomnia symptoms in young adults with and without autism.
Methods: Participants enrolled in the Autism CRC School Leavers longitudinal study completed online questionnaires on ASS (Autism Quotient [AQ]-28), SSB (Repetitive Behaviour Questionnaire [RBQ]-2A-SSB), depression (Patient Health Questionnaire-9), anxiety (DSM-5- Dimensional Anxiety Scales: Generalized Anxiety), IU (Intolerance of Uncertainty Scale [IUS]-12) and sleep (Pittsburgh Sleep Quality Questionnaire [PSQI]). There were 53 young adults (M_{age}=18.39 years, SD=2.44; 56.6% male) with 65.4% (N=52) reporting an autism spectrum diagnosis; those with a diagnosis (M_{AQ-28} = 76.79, SD=10.92; 73.5% male) had a significantly higher AQ-28 score (P<.001) than the non-autism group (M_{AQ-28}= 58.83, SD=14.15).
Results: 56.6% (N=53) of individuals had a sleep problem (PSQI>5), including 55.9% of those with, and 61.1% of those without autism (χ^2 (1, N=52) = .005, P=.946). Neither age nor gender were significantly associated with SSB (P=.707; P=.788), IU (P=.785, P=.743), PSQI (P=.721, P=.205), anxiety (P=.396, P=.127) or depression (P=.855, P=.633), respectively. Consistent with more males with autism, the AQ-28 score was significantly associated with gender (P=.039), but not age (P=.673). Depression and anxiety scores were all moderately or strongly and significantly associated with ASS, SSB and IU. A hierarchical regression predicting insomnia (PSQI score) was conducted, with scores for AQ-28 entered at Step 1, RBQ-2A-SSB entered at Step 2, and IUS-12 entered at Step 3. The final model was significant F (3,49) = 7.059, P<.001, R^2=30.2 % of variance in sleep accounted for (adjusted R^2=25.9%). At Step 1 (AQ-28) ΔR^2=12.8% (P=.009), at Step 2 (RBQ2A-SSB) ΔR^2=9.1% (P=.019), and at Step 3 (IU-12) ΔR^2=8.3% (P=.020); IU was a significant unique predictor of insomnia (β=.349; P=.020) in the final model.
Conclusions: Autism symptom severity, sensory atypicality and intolerance of uncertainty together accounted for 30% of variance in insomnia scores, with intolerance of uncertainty being an independent predictor. This supports increased autism symptoms and intolerance of uncertainty as risk factors for insomnia. Our study thus provides the first evidence pointing to the trans-diagnostic factor, intolerance of uncertainty, which underlies susceptibility to anxiety and depression, as a potential key factor in the development of insomnia in autism. Further exploration, including models with anxiety and depression, is indicated to understand how insomnia develops in autism, thus informing the development of both prevention and treatment approaches for insomnia across the lifespan.

194 **126.194** Employment Status Is Related to Sleep Problems in Adults with Autism Spectrum Disorder

E. Baker *and A. L. Richdale, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Sleep problems are commonly reported for individuals with Autism Spectrum Disorder (ASD). While insomnia symptoms are the most frequently reported problems, there is emerging evidence that the timing of sleep is also atypical, with circadian rhythm sleep-wake disorders (CRSWDs) also reported for some individuals with ASD. Research also demonstrates a distinct sub-group of individuals who do not have sleep problems. However, there is very little research that has investigated factors that may be associated with the presence or absence of sleep problems in those with ASD. Comorbid diagnoses of psychopathology disorders (anxiety and depression) as well as employment outcomes may be associated with the presence of sleep problems in adults with ASD. Gaining an understanding of factors that are associated with and without sleep problems, will assist in the development of appropriate prevention and treatment techniques.
Objectives: The aim of this study was to explore factors that may be associated with the presence and absence of an ICSD-3 defined sleep problem in adults with ASD and no comorbid intellectual impairment.
Methods: 36 adults with ASD (47.2% male; M_{age} = 34.41 years, *SD*= 6.52) completed a 14-day sleep-wake diary and 14 day actigraphy assessment. All participants had an IQ > 80. Fifteen participants were medicated for a comorbid diagnosis of anxiety and/or depression. Participants also completed a questionnaire battery including the Pittsburgh Sleep Quality Index (PSQI), the State-Trait Anxiety Inventory (STAI), the Patient Health Questionnaire (PHQ-8; depression scale) and a demographic questionnaire.
Results: Based on 14-day sleep-wake diary and actigraphy assessment four adults with ASD met criteria for insomnia, 10 for a CRSWD and six met criteria for both. Demographic variables including FSIQ, age and gender did not differentiate the two groups of adults (Table 1). Consistent with the presence of sleep problems, PSQI scores were higher in the Sleep Problem group. The groups did not differ on their scores on the STAI (t = -0.998, p = .325) and PHQ-8 (t = .019, p = .985). Likewise, there were no differences in the proportion of individuals in each group who were medicated for comorbid diagnoses of anxiety and depression (χ^2 = .630, p = .427). The Sleep Problem group were more likely to be unemployed compared to adults with no sleep problem (χ^2 = 12.963, p < .001). In particular, all nine adults who were unemployed met criteria for a sleep problem.
Conclusions: Employment outcomes are frequently reported to be poor in adults with ASD. These poor outcomes have typically been associated with the social deficits those with ASD experience. The findings of this study demonstrate for the first time that sleep problems are associated with unemployment, however the direction of this relationship is unclear. It is possible that sleep problems, particularly CRSWDs that have developed during adolescence make attainment and maintenance of employment for those with ASD difficult, or that a lack of employment results in less restrictions required for optimal and appropriate sleep timing. Longitudinal studies would be beneficial to further explore this relationship.

195 **126.195** Parent-Based Sleep Education in Autism: A Community-Academic Research Partnership

B. Drury*, L. L. MacDonald, W. A. Loring, M. Alder, M. Matthews, D. Wofford, J. Lutz and B. A. Malow, Vanderbilt University Medical Center, Nashville, TN*

Background: Sleep disturbance affects 50-80% of children with autism spectrum disorder (ASD). Behavioral sleep education for children with sleep disturbance is currently provided largely within academic medical centers, which often include long waiting lists for this service.
Objectives: Our study aims to determine the feasibility of providing sleep education training to parents of children with ASD in diverse community settings in relation to more traditional university-based settings.
Methods: We included three Middle Tennessee pediatric practices in this study—Mercy Community Healthcare, Rivergate Pediatrics, and Goodlettsville Pediatrics, along with community therapists. The following elements comprised our study: (1) Recruitment and consent of participating families, as well as instruction in study procedures such as actigraphy; (2) Collection of baseline data; (3) Therapist training and fidelity; (4) Delivery of sleep education to families; and (5) Collection of intervention data.
Our sleep education curriculum was delivered in one 60-90 minute session with 2 follow-up sessions and covered appropriate sleep habits, including construction of an individualized bedtime routine and optimization of parent-child interactions. Paired t-tests were used to compare data pre and post intervention. We used on-line surveys through Research Electronic Data Capture (REDCap) to reduce family burden.
Results: Â Recruitment for our study is on target, with families expressing support for having study procedures done at their pediatricians' office, rather than driving to the medical center. All of our therapists reached fidelity on mock sessions and actual parent education sessions. To date, 21 families have participated with 16 completing baseline and intervention data. Children with ASD had a mean (standard deviation) age of 7.0 (2.9) years. Improvements were noted in the following Children's Sleep Habits Questionnaire (CSHQ) subscales: sleep onset delay (p=0.000), bedtime resistance (p=0.001), sleep duration (p=0.000), night wakings (p=0.048), and parasomnias (p=0.030). CSHQ subscales in sleep anxiety (p=0.226), sleep disordered breathing (p=0.382), and daytime sleepiness (p=0.257) did not show improvement. The Family Inventory of Sleep Habits (FISH) also improved (p=0.002). Actigraphy measures showed improvement in sleep onset delay with a mean of 38.6 (18.4) minutes pre- intervention and 33.3 (21.4) post- intervention, but did not reach significance (p = 0.313).
Conclusions: This study shows that sleep education typically housed within specialized medical settings can be extended to community practitioners with minimal to no background in sleep, allowing families to receive behavioral sleep education in familiar locations as part of their ongoing care and with potentially shorter wait times. Partnering with community practitioners to deliver such education to families provides an opportunity to broaden access to sleep therapeutics in the community, while forging collaborations between sleep medicine physicians, primary care providers, and community therapists.

196 **126.196** Effects of Social Skills on Anxiety and Parasympathetic Activity Among Youth with Autism Across the PEERS® Intervention

A. McVey[1], *K. A. Willar*[2], *H. K. Schiltz*[1], *A. D. Haendel*[3,4], *B. Dolan*[1], *S. Stevens*[5], *A. M. Carson*[6], *F. Mata-Greve*[1], *E. Vogt*[1], *K. M. Rivera*[1], *E. Habisohn*[1], *J. Hilger*[7], *N. Fritz*[1] *and A. V. Van Hecke*[1], *(1)Marquette University, Milwaukee, WI, (2)Children's Hospital Colorado, Aurora, CO, (3)Interdisciplinary PhD program (Psychology and Biomed Science), Marquette University, Milwaukee, WI, (4)Concordia University Wisconsin, Mequon, WI, (5)University of Minnesota Medical School, Blaine, MN, (6)Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (7)Illinois State University, Normal, IL*

Background: Improving social skills is likely to lead to decreases in anxiety symptoms, especially social anxiety, for adolescents with ASD (Bellini, 2006). In particular, the PEERS®intervention demonstrates such an effect, via self- and parent-report (Schohl et al., 2014). Neither longer-term outcomes for anxiety nor changes in arousal as a marker of anxiety have been previously examined.
Objectives: To determine if adolescents with ASD showed significant declines in self- and parent-report of anxiety and improvements in respiratory sinus arrhythmia (RSA) across three time points.
Methods: Thirty-nine adolescents with ASD (*N*=39) aged 11 to 16, IQ≥70 participated in this study. ASD was confirmed using the ADOS. Adolescents comprised the experimental group of a randomized controlled trial and received the Program for the Education and Enrichment of Relational Skills (PEERS®), which focuses on improving friendship quality and social skills among adolescents with ASD. Adolescents completed the Social Anxiety Scale for Adolescents (SAS-A), Youth Self-Report (YSR), and an eyes-open resting-state RSA paradigm (Porges & Bohrer, 1990). Parents/caregivers completed the Social Anxiety Scale for Adolescents, Parent (SAS-P) and the Child Behavior Checklist (CBCL). All data was collected pre-, post-, and six months following PEERS®.
Results: Pearson's correlations showed some evidence of a relationship between anxiety and RSA, but no consistent pattern across time points. Repeated Measures ANOVAs showed significant declines in self-report of social anxiety, SAS-A ($F(2, 76)=9.174$, $p<.001$), parent-report of social anxiety, SAS-P ($F(2, 64.34)=11.34$, $p<.001$), and parent-report of general anxiety, CBCL ($F(2, 32)=4.476$, $p=.019$), but not self-report of general anxiety, YSR ($p>.05$). Paradoxically, RSA significantly declined across the three time points ($F(2, 55.04)=8.875$, $p<.001$).
The sample was subsequently split into socially anxious (SA) and not (NSA) using the clinical cutoff for the SAS-P at pre-, and the ANOVAs were rerun. Results showed significant differences across time for the SA subgroup (SAS-A, ($F(2, 68)=8.35$, $p=.001$); SAS-P, ($F(2, 44)=13.92$, $p<.001$); CBCL, ($F(2, 24)=5.85$, $p=.009$); YSR, $p>.05$), but not for the NSA subgroup (all p's >.05). RSA data continued to show declines across time for the SA subgroup ($F(2, 50)=7.35$, $p=.002$), NSA ($p>.05$).
Conclusions: Results suggest the PEERS® intervention has a lasting positive impact on co-occurring symptoms of general and social anxiety, especially for adolescents who begin with high levels of social anxiety. Likely, as adolescents with ASD utilize social skills, their symptoms of anxiety decline. Interestingly, measures of arousal were not strongly related to anxiety, and implied that employment of social skills leads to heightened dysregulation, contrary to previous findings among neurotypicals (Porges, 2003). Perhaps, for adolescents with ASD in a social skills intervention, outcomes may be better explained by an Information Processing Model of RSA rather than the Social Engagement Model. That is, social interaction may require greater attention and more effort, associated with greater dysregulation and heightened arousal as these skills are employed. Further research is needed to better understand which of these competing models best explains social interaction in ASD across intervention. Longer-term follow up is also necessary to understand how these processes evolve over time.

197 **126.197** Hemispheric Asymmetry As an Electrophysiological Marker of Anxiety in Youth with Autism Spectrum Disorder

E. Kang*, C. M. Keifer, T. Rosen, T. Clarkson and M. D. Lerner, Stony Brook University, Stony Brook, NY*

Background: Research suggests that a left-dominant pattern of hemispheric asymmetry (HA) in frontal cortical EEG activity is associated with generalized approach motivation, whereas a right-dominant pattern is related to withdrawal (Coan & Allen, 2004). Converging evidence suggests that right-dominant HA is evident in youth with autism spectrum disorder (ASD; Shamay-Tsoory et al., 2010). While resting frontal HA is also linked to emotion-related disturbances, such as anxiety (Tibodeau et al., 2006), it is not clear whether HA is related to anxiety in ASD, which are frequently comorbid (Simonoff et al., 2008). Recent findings indicate that frontal HA may predict internalizing symptom treatment response in typically-developing individuals (Baskaran et al., 2012) and may be malleable to a common ASD social skills intervention (SSI; Van Hecke et al., 2015); yet, it is not clear whether HA is a potential predictor of anxiety-related treatment response to SSIs.
Objectives: This study examined whether frontal HA in ASD is a correlate of co-occurring anxiety and a predictor of anxiety-related improvements in response to a SSI.
Methods: Thirty-nine youth (M_{age}=12.23, SD_{age}=2.99; 30 male) with IQ≥70 (M_{IQ}=105.74, SD_{IQ}=15.35) and ADOS-2-confirmed ASD diagnosis participated in a 10-week SSI. Pre- and post-test measures included self- and parent-report of psychopathology symptoms (BASC-2; Reynold & Kamphaus, 2004), self-report of social anxiety (SAS; La Greca & Lopez, 1998), and parent-report of psychiatric symptomatology, impairment (CASI-5; Gadow & Sprafkin, 2013), and anxiety symptomatology (MASC-2; March et al., 1997).
At baseline, resting EEG data were collected for 6 minutes alternating between 1-min blocks of eyes open or closed. Frontal alpha-band (8-12Hz) power was computed using a Fast Fourier transform with an 80-ms Hanning window and 50% overlap across segments, resulting in a 0.5Hz frequency resolution. Differences of natural log-transformed scores [Ln(Right) – Ln(Left)] were calculated for mean alpha power across F3(L)/F4(R) and F7(L)/F8(R) pairs, such that positive scores indicate greater relative left frontal brain activity (as alpha is inversely related to brain activity).
Results: Bivariate correlations revealed associations between greater left frontal brain activity and lower parent-reported anxiety symptomatology, including CASI-5 social anxiety symptom severity and impairment, multiple domains on the MASC-2 (including GAD, separation anxiety, social anxiety, and physical symptoms), and BASC-2 anxiety (see Table 1).Â Moreover, ANCOVA-of-change models revealed that greater left brain activity predicted greater reduction on self-reported BASC-2 anxiety marginally (β=-.299, p=.069) and SAS social anxiety (β=-.314, p=.014), particularly in social avoidance and distress in new situations (β=-.398, p=.003), over the course of the SSI.
Conclusions: Overall, our findings suggest that frontal HA is a useful marker of anxiety in youth with ASD, as evidenced across multiple measures of anxiety symptomatology. Importantly, individual differences in frontal HA predicted improvements in anxiety symptomatology following the SSI; this pattern was especially pronounced for social anxiety in new situations, which is consistent with the social approach model of HA (Lopez-Duran et al., 2012). These results suggest that frontal HA could be important for parsing the heterogeneity in comorbid anxiety in individuals with ASD, and predicting who may show the greatest anxiety-related response to treatment.

198 **126.198** Common and Distinct Patterns of Functional and Structural Activity in Resting State Brain Networks in Autism and Social Anxiety

M. Coffman[1], *L. Antezana*[1], *S. W. White*[2] *and J. A. Richey*[3], *(1)Virginia Tech, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Virginia Tech, Blackbsurg, VA*

Background:
Individuals with Autism Spectrum Disorder (ASD) also commonly have Social Anxiety Disorder (SAD), with up to 42-84% of those with ASD also meeting diagnostic criteria for SAD in their lifetime (de Bruin et al., 2007; Muris et al., 1998; Simonoff et al., 2008). Examination of possible disruption in the default mode network (DMN), which is active in the absence of task demands and involved in normative aspects of social cognition, may offer an opportunity to identify basic mechanisms responsible for heightened risk for social anxiety. Disruptions in the function of DMN would be expected in disorders characterized by alterations in social function. Consistent with this notion, both ASD and SAD are associated with altered activation of several core regions of the DMN. Despite emergent evidence for alterations within the same brain systems in SAD and ASD, as well as a behavioral continuum of social impairments, no study to date has examined the unique and common underlying brain systems within these disorders.
Objectives:
The primary aim of the current study is to characterize brain connectivity using a multimodal approach (e.g., functional and structural analyses) within the DMN in SAD, ASD, and controls.
Methods:
Forty-five individuals (15 per group; mean age = 23.92) participated in this study. Functional connectivity analyses were conducted by using resting-state fMRI data to identify intrinsic connectivity via independent components analysis (ICA). The ICA approach is based on FSL's MELODIC (Beckmann et al., 2005).
To evaluate the structural connectivity of the DMN, we examined diffusion tensors via AFNI's FATCAT (Taylor & Saad, 2013). We selected regions of interest (ROIs) based on the DMN (Left and Right Parietal Region, Posterior Cingulate Cortex (PCC), Anterior Cingulate Cortex (ACC)) to examine the structural integrity between these regions.
Results:
Functional analyses revealed increased coactivation of the dorsomedial prefrontal cortex in ASD and SAD compared to controls, $p < .05$.
Structural analyses revealed both over and under white matter fiber connectivity in ASD compared to both controls and the SAD group. Specifically, there were significant differences between the ASD and control group for the Right Parietal Region <--> ACC connectivity contrast, $p = 0.0387$, and the ASD and SAD groups, $p = 0.039$. This difference was not found between the SAD and control groups, $p = 1$. In the Left Parietal Region <--> PCC connectivity contrast, we found a significant difference between the ASD group and control group, $p = 0.20$, and ASD and SAD group, $p = 0.019$, but not between the SAD and control, $p = 0.667$.
Conclusions:
These results may hold significance for clinical treatment of ASD with comorbid SAD. Treatment of ASD often targets specific symptoms and ranges from speech to social and cognitive skills without insight into the neural structures subserving the mechanisms of social deficits (Reichow & Wolery, 2009; Dawson & Bernier, 2013). Knowledge of potentially common neural and physiological processes subserving social deficits could aid identification of treatment informed by the underlying mechanisms.

199 **126.199** Experiential, Behavioral, and Physiological Correlates of Mixed Emotions in Individuals with Autism Spectrum Disorder

A. C. Samson[1], *S. D. Kreibig*[2], *J. J. Gross*[2], *Y. Enav*[2], *J. M. Phillips*[3], *A. Zaharia*[1] *and A. Y. Hardan*[3], *(1)Swiss Center for Affective Sciences, University of Geneva, Geneva, Switzerland, (2)Psychology, Stanford University, Stanford, CA, (3)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*

Background: Mixed emotions are the co-occurrence of two or more differing emotional feelings (Larsen & McGraw, 2011) and their understanding can be seen as a sign of emotional maturation (Harris, 1989).
Objectives: The goal of this study was to examine experiential, behavioral, and physiological correlates of positive, negative, and mixed emotions in individuals with Autism Spectrum Disorder (ASD) compared to typically developing (TD) individuals. Social cognitive processing was required to process the film clips, since they required either the ability to understand humor (positive film clips), to understand other people's pain (negative film clips), or both simultaneously (mixed film clips).
Methods: Twenty-seven participants with ASD (4 female; FSIQ: *M*=101.74, *SD*=18.34) and 32 TD participants (9 female; FSIQ: *M*=112.75, *SD*=11.43) between 8 and 20 years (*M*=12.85, *SD*=2.96) were asked to rate amusement and repulsion on a scale from 1 (not at all) to 5 (very strongly) after each of 18 film clips eliciting either pure positive (i.e., amusement in the face of humorous lapses), pure negative (i.e., repulsion in the face of painful accidents), or mixed emotions (i.e., amusement and repulsion in the face of ambiguous bloopers) while facial electromyographic (zygomatic and corrugator activity), cardiac (heart rate), and electrodermal (skin conductance) activity was measured during presentation of films. Since groups differed in FSIQ, all analyses included FSIQ as covariate.
Results: Preliminary analyses revealed that the three film clip categories induced as expected positive, negative, and mixed (as assessed with the minimal shared feeling of amusement and repulsion, Schimmack, 2001) emotional states, as revealed by self-report and facial expressions. However, the three conditions did not reveal differences in cardiac and electrodermal activity. Main analyses revealed that individuals with ASD did not differ from TD participants in their self-reported amusement and smiling behavior (zygomaticus activity). However, individuals with ASD experienced more repulsion towards positive film clips and less repulsion towards mixed and negative film clips, while expressing less frowning behavior (corrugator activity) in all three conditions. Individuals with ASD experienced more mixed feelings in response to positive film clips, and showed a tendency to experience less mixed feelings in mixed film clips. Finally, no differences were observed between the two groups in cardiac or electrodermal activity.
Conclusions: Individuals with ASD have similar positive emotional responses to positive, mixed, and negative film clips suggesting no differences in humor processing, but showed mainly differences in their self-report and expressive behavior when it comes to negative emotional responses. Decreased repulsion experience and expression towards mixed and negative film clips might be linked to lower sensitivity towards pain of others. Interestingly, mixed emotions are higher in individuals with ASD towards positive film clips, also related to higher negative emotional experience in this condition. Group differences in mixed feelings may be due to an altered repulsion experience in individuals with ASD. Since there were no group differences in cardiac and electrodermal activity, future studies should examine synchronization of emotional response components in individuals with ASD compared to TD participants.

200 **126.200** The Role of Alexithymia in Emotional Reactivity and Emotion Regulation in Children with Autism Spectrum Disorder

A. P. Costa[1], *G. Steffgen*[2] *and A. C. Samson*[3], *(1)University of Luxembourg, Esch sur Alzette, LUXEMBOURG, (2)Institute for Health and Behavior, University of Luxembourg, Esch sur Alzette, Luxembourg, (3)Swiss Center for Affective Sciences, University of Geneva, Geneva, Switzerland*

Background: Emotional disturbances, including emotional reactivity and regulation difficulties, are common among children with autism spectrum disorder (ASD) and pose risk factors to other problematic behaviors. In addition, alexithymia has a high prevalence among individuals with ASD and has been considered to be more relevant in the development of emotional problems than ASD symptoms themselves.
Objectives: Â The present study aimed to examine the effect of alexithymia on emotional reactivity and regulation difficulties in children with ASD compared to typically developing (TD) children.
Methods: Â Thirty-seven children previously diagnosed with ASD (5 female) and 41 TD children (9 female) and their parents participated in the study. Children were aged 3 to 13 years old. A multi-method assessment of children's emotional reactivity and emotion regulation measures including parent-reports (Emotion Regulation Checklist; Shields & Cicchetti, 1997), behavioral observations (frequency of facial expressions' valence; use of emotion regulation strategies), and physiological measures (percentage of change in heart rate; respiratory sinus arrhythmia) were used together with a parent-report of children's alexithymia (adaptation of the Alexithymia Questionnaire for Children; Rieffe et al., 2006). The study took place in one visit during which parents were requested to fill out questionnaires and then an electrocardiogram measurement of the child took place at rest and during a frustration eliciting situation (Attractive Toy Removal; Goldsmith & Rothbart, 1999). The study was reviewed and approved by an ethics review panel.
Results: Â Children with ASD had a significantly higher alexithymia score than TD children [$t(76)=4.98$, $p<.001$, $d=1.13$]. Compared to TD children, children with ASD had more difficulties in all indicators of emotional reactivity even after controlling for alexithymia: parents of children with ASD reported higher lability/negativity in their children compared to parents of TD children [$F(1,75)=11.93$, $p<.01$, =.14], children with ASD expressed more negative emotions than TD children [$F(1,75)=15.66$, $p<.001$, =.17], and the absolute percentage of HR change in children with ASD was higher than in TD children [$F(1,70)=6.26$, $p<.05$, =.08]. Similarly, children with ASD had more difficulties in all indicators of emotion regulation even after controlling for alexithymia: parents of children with ASD reported lower emotion regulation ability than parents of TD children [$F(1,75)=5.49$, $p<.05$, =.07], children with ASD used less adaptive emotion regulation strategies than TD children [$F(1,75)=16.13$, $p<.001$, =.18], and resting respiratory sinus arrhythmia was lower in children with ASD than in TD children [$F(1,72)=4.39$, $p<.05$, =.06]. Hierarchical regression models indicated that alexithymia contributed significantly to the explanation of certain aspects of emotional reactivity, but did not contribute further to explain emotion regulation difficulties.
Conclusions: Our results show that children with ASD, compared to TD children, have more negative emotional reactivity, more difficulties in emotion regulation, and increased levels of alexithymia. Moreover, alexithymia plays an important role in the explanation of emotional reactivity but does not seem to contribute to difficulties regulating emotions. Therefore, these findings suggest that interventions targeting emotional reactivity would benefit from integrating alexithymia, and that interventions specifically targeting emotion regulation could help alleviate emotional disturbances in ASD.

201 **126.201** Emotion Regulation Strategies in Preschoolers with Autism Spectrum Disorder: Associations with Wellbeing, Sleep and Temperament

H. J. Nuske[1], *D. Hedley*[2,3], *A. Woollacott*[4], *P. Thomson*[5] *and C. Dissanayake*[2], *(1)University of Pennsylvania, Philadelphia, PA, (2)School of Psychology & Public Health, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, Melbourne, AUSTRALIA, (4)Seattle University, Seattle, WA, (5)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Emotional dysregulation has been shown to be strongly associated with challenging behaviours and mental health problems in children. Recent studies have highlighted that children with Autism Spectrum Disorder (ASD) use less adaptive strategies for regulating their emotion and tend to have a limited repertoire of regulatory behaviours compared to their typically developing (TD) peers, however it is unknown how these strategies map on to wellbeing, mental health and associated factors in children with ASD.
Objectives: To explore differences in emotion regulation strategies between children with ASD and matched controls and to examine relationships between emotion regulation strategies, mental health, quality of life, sleep quality and temperament.
Methods: 44 children with ASD and 29 matched controls (2- 4 years) were administered tasks from the Laboratory Temperament Assessment Battery. Tasks were designed to mimic everyday life experiences in which children would need to regulate low-level stress (e.g. waiting for a snack). Coders blind to diagnostic group coded twelve emotion regulation strategies (see Figure 1), ranging from adaptive (e.g. social strategies) to maladaptive (e.g. avoidance) strategies. Parents reported on their child's mental health, quality of life, sleep quality and temperament.
Results: Â As can be seen in Figure 1, children with ASD used significantly fewer social strategies mediated through unfamiliar people (researchers), $t(71) = 4.87$,Â pÂ < .001, more avoidance, $t(71) = -3.68$,Â pÂ < .001, and marginally more physical comfort from their parents, $t(71) = -1.90$,Â $p = .06$, compared to controls. For children with ASD, greater wellbeing was related to less perceptual disengagement, $r(41) = -.30$,Â $p = .05$, and self-soothing, $r(41) = -.28$,Â $p = .07$. For children with ASD only, longer sleep time was related to social strategies, mediated through unfamiliar people $r(43) = .42$,Â $p < .01$. Social strategies mediated through family members was negatively associated with effortful control in the TD group, $r(27) = -.36$, $p = .06$, but positively associated in the in the ASD group $r(42) = .33$, $p = .03$.
Conclusions: These findings suggest that children with ASD use less adaptive and more frequent physical comfort strategies than children without ASD. Unique relationships of emotion regulation strategies in ASD were identified, highlighting the link of sleep with social strategies and wellbeing with less use of maladaptive strategies. TD children who have higher effortful control skills appear to rely less on family members to mediate low-level stress, whereas for the children with ASD this relationship is reversed.

202 **126.202** The Efficacy of a Novel Emotion Regulation Group Intervention in Parents of Children with ASD

Y. Enav[1], *J. J. Gross*[1], *D. Weiss*[1], *K. Mirit*[1], *A. C. Samson*[2], *D. Pestagourakis*[3] *and A. Y. Hardan*[4], *(1)Psychology, Stanford University, Stanford, CA, (2)Swiss Center for Affective Sciences, University of Geneva, Geneva, Switzerland, (3)Department of Psychology, Stanford University, Stanford, CA, (4)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*

Background:
Children with Autism Spectrum Disorder (ASD) have impairment in reading socio-emotional information such as affect, social cues, and facial expressions and often experience less reward in social interaction. These characteristics limits children's capacity to understand their own mental state, that is, to mentalize. From the parent's perspective the child's "mindblindedness" makes him a most challenging social partner who brings only few rewards into the relationship. A child with ASD needs a supportive relationship to survive, but even more than most children he needs his parents to be stable regulators of his experiences and emotions. Thus, parents need to make sense of what seems incomprehensible and unrewarding to their child with ASD.
Objectives:
The goal of this pilot study was to examine the effectiveness of a novel Regulative Parenting Workshop in teaching mentalization, reflective functioning, and emotion regulation skills in parents of children with ASD.
Methods:
The study involved a non-randomized controlled 4-week trial. Parents were assigned to treatment or control groups. Measures included Parental Developmental Interview (PDI) that assesses the parent's mentalization level. Children's internalizing and externalizing behavior, and total problems were assessed with the Child Behavior Checklist. Measures from the treatment group were taken at baseline before the workshop and at 4 weeks after completing the workshop. Measures from the control group were taken twice with an interval of 3-4 weeks between the two assessments.
Twenty-three parents in the treatment group and 24 parents in the control group completed assessments at all time points and were included in the analysis. There were no differences at baseline between the groups on any demographic variable. Parents age ranged from 31-64 years. Eighty percent were female, and 19.6% were male. A large majority of participants were married (95.6%), 2.2% were single, and 2.2% were in a committed relationship. The majority of participants had completed masters degree or graduate degree (51.2%), 18.6% had a bachelors degree, and 20.9% completed college.
Results: Preliminary analyses from this pilot investigation revealed that parents receiving the intervention showed significant increase in total mentalization level based on the PDI ($F(1,45)=4.5$, $p=.04$). Moreover, parents in the intervention group increased in mentalization on all PDI subscales except of one. Children's total problems ($F(1,41)= 11.18$, $p=.002$), internalizing behavior ($F(1,41)=6.62$, $p=.014$), and externalizing behavior ($F(1,41)=2.85$, $p=0.05$) decreased in the treatment group, but not in the control group.
Conclusions: Parents of children with ASD were able to improve their mentalization capacity towards their children after four group sessions focused on constructive strategies to regulate emotions. It seems that the parent's capacity to mentalize the child by itself has a strong regulative effect. Parents reported after the workshop that the children's symptoms decreased. It may be possible that the parents' perception about the child's symptoms changed and not necessarily the symptoms. However, changing the perception about the children's symptoms may be an important goal by itself. Future studies are needed to replicate these observations in a randomized controlled investigation of a larger sample of participants.

203 **126.203** Inter-Relationship Between Insistence on Sameness, Effortful Control and Anxiety in Adolescents and Young Adults with Autism Spectrum Disorder

M. Uljarevic[1,2], *A. L. Richdale*[1,2] *and R. Y. Cai*[1,2], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia*

Background:
Insistence on Sameness (IS) behaviours include complex patterns of rigid, routinized and ritualistic patterns of behaviour. In addition to being a diagnostic feature of autism spectrum disorder (ASD), these behaviours also form part of typical development. Whilst IS behaviours in ASD tend to be relatively stable over time and negatively impact the functioning of individuals and their families, in early typical development, these behaviours are transitory and often serve an adaptive role. More specifically, these behaviours appear to be related to normative fears and anxieties, serving as an early form of self-regulation, and eventually reducing as more advanced forms of self-regulation develop. In ASD, it is possible that IS behaviours continue to serve a regulatory function beyond the period when they should have been replaced by more developmentally appropriate forms of self-regulation. Thus IS behaviours may negatively affect development including sustaining anxiety. However, this proposal has not been previously tested.
Objectives:
The aim of the present study was to characterise the IS-self-regulation-anxiety inter-relationship by investigating the potential contribution made by self-regulation, measured via effortful control, to the IS-anxiety relation in a cross-sectional sample of adolescents and young adults with ASD.
Methods:
Participants were 58 adolescents and young adults with ASD (40 males, 18 females; M_{age}= 19.14 years, SD_{age}= 2.53, range: 15.71-24.91) who participated in the Autism CRC School leavers study. As a part of the study, participants completed the Adult Repetitive Behaviours Questionnaire-2 (RBQ-2A), Effortful Control Domain of the Adolescent/Adult Temperament Questionnaire and DSM-5 Dimensional Anxiety Scales (DSM-5 DAS) as measures of IS behaviours, Effortful Control and anxiety respectively.
Results:
The cut-off score (≥ 14) for elevated anxiety was met by 44.8% of participants. Preliminary analysis showed no statistically significant association between chronological age and gender and IS behaviours, anxiety, or effortful control scores. IS behaviour score was associated with both effortful control (r = -.42, p = .001) and anxiety (r = .47, p < .001), and anxiety was in turn associated with effortful control (r = -.51, p < .001). In order to characterise the nature of this interrelationship, two mediation analyses were performed using the serial mediation model in PROCESS with 5000 resamples in bootstrapping. There was a significant indirect effect of effortful control on anxiety through IS (Model 1a; b = -.06; BCa CI [-.13, -.02], standardized effect size = .13; BCa CI [-.27, -.04]) and there was a significant indirect effect of effortful control on IS through anxiety (Model 1b; b = -.006; BCa CI [-.01, -.002], standardized effect size = -.17; BCa CI [-.34, -.06]).
Conclusions:
Our study provides first exploration of the IS-anxiety-self-regulation inter-relationship in ASD. However, findings are limited by a cross-sectional nature of our data, as cross-sectional designs are unable to capture these dynamic processes as they unfold over time. Despite this limitation, our study has potential implications for interventions targeting IS behaviours and also anxiety in ASD. Our finding that lower levels of self-regulation are related to both anxiety and IS behaviours, suggest self-regulation as a viable intervention target.

204 **126.204** Effects of Emotion Regulation and Intolerance of Uncertainty on Anxiety and Depression in Adolescents and Young Adults with Autism

R. Y. Cai[1,2]*, A. L. Richdale*[1,2]* and M. Uljarevic*[1,2]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia*

Background:
Anxiety and depression are very frequent and disabling comorbid psychiatric conditions in individuals with autism, however, the reasons for such high prevalence are currently poorly understood. Emotion regulation (ER) and intolerance of uncertainty (IU) are factors most commonly implicated in the development and maintenance of anxiety and depression in non-ASD population. Recent research has started to explore the role of IU and ER in autism and some patterns are emerging e.g., maladaptive ER strategy use predicts internalizing symptoms and IU is a predictor of anxiety. However, previous research has not addressed relationship between IU and ER and depression, nor assessed the inter-relationship between ER and IU in predicting anxiety and depression.
Objectives:
To assess the inter-relationship between ER, IU, anxiety, and depression. It is hypothesized that both IU and ER strategy use would have direct and indirect effects on anxiety and depression, over and above autism symptoms, gender, and age. These effects will be tested using four mediation models: IU as a predictor of anxiety and depression (separately), mediated by ER, and ER as a predictor of anxiety and depression (also separately), mediated by IU.
Methods:
Forty-eight individuals with autism (13 females; M_{age}= 18.20 years, SD_{age}= 2.41) completed the online questionnaires Autism Spectrum Quotient-28 (AQ-28), Patient Health Questionnaire-9 (PHQ-9), Dimensional Anxiety Scale for DSM-5 (CROSS-D), Emotion Regulation Questionnaire (ERQ), and Intolerance of Uncertainty Scale-12 (IUS-12). For analyses, instead of using the suppression and reappraisal sub-scale scores, an ERQ ratio was calculated by diving the suppression score by the reappraisal score.
Results:
Pearson's correlation analyses with bootstrapping showed ERQ ratio was moderately associated with IUS-12 (r=.37), CROSS-D (r =.40) and PHQ-9 (r =.47). IUS-12 was strongly associate with CROSS-D (r =.60) and PHQ-9 (r =.62). Age, gender, and AQ-28 were not associated with any of these four variables. Following the mediation model analyses, these results were found: 1) ER mediated the effect of IU on depression (b = 0.72, BCa CI [0.06, 1.79]), 2) ER did not mediate the effect IU had on anxiety (b = 0.68, BCa CI [-0.06, 1.81]), 3) IU mediated the effect of ER on anxiety (b = 3.89, BCa CI [0.67, 8.42]), and 4) IU mediated the effect of ER on depression (b = 2.98, BCa CI [0.41, 6.07]).
Conclusions:
Consistent with previous research, individuals with autism who reported greater levels of IU and greater use of suppression reported higher symptoms of anxiety and depression. This study also builds on previous research by characterizing the nature inter-relationships between IU, ER, anxiety and depression for the first time. These findings have significant implications for designing intervention programmes for anxiety and depression in ASD; treatments combining both Cognitive Behavioural Therapy with the goal of increasing tolerance of uncertainty and Acceptance Commitment Therapy to accept painful emotions and thoughts in order to modify behaviour may be most effective for individuals.

205 **126.205** Addressing Intolerance of Uncertainty in Anxious Young People with Autism Spectrum Disorder

J. Rodgers[1]*, M. Freeston*[2]*, E. Honey*[3]*, A. Hodgson*[4]*, K. Shields*[4] *and C. Wright*[5]*, (1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Psychology, Newcastle University, Newcastle, United Kingdom, (3)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle Upon Tyne, UNITED KINGDOM, (4)Newcastle University, Newcastle, United Kingdom, (5)Northumbria Healthcare, Newcastle, United Kingdom*

Background:
Anxiety is a significant problem for many children with autism spectrum disorder (ASD), who frequently present with multiple anxiety disorders concurrently. Treatments targeting underlying anxiety mechanisms may therefore be most efficacious. Over the last five years our group has worked towards providing a theoretically informed formulation of anxiety in ASD. This work has focused on a consideration of a well-established model of anxiety: the Intolerance of Uncertainty Model. *Intolerance of uncertainty* (IU) is a 'broad dispositional risk factor for the development and maintenance of clinically significant anxiety' in neurotypical populations. The concept of IU has utility not only to theoretically inform understanding of the factors underlying the development and maintenance of anxiety, but has also been shown to be a beneficial target for treatment. Intervention studies with neurotypical individuals with high IU provide evidence that reduction of IU is associated with reduction in anxiety. Cognitive behavioural treatments for clinically anxious patients have been developed which emphasise treating the cognitive *process* rather than the cognitive *content* of anxiety, specifically by aiming to increase patients' tolerance for uncertainty and thereby achieving more sustainable change. Over the past five years research has investigated the relevance of IU to anxiety in ASD. This work indicates that IU is a key construct in anxiety in children and adolescents with ASD, which may account for the increased vulnerability to a range of anxiety disorders in this population.
Objectives:
Our objective was to develop and evaluate the feasibility and acceptability of a parent mediated, group intervention targeting IU for young people with ASD.
Methods:
Phase One: Parent focus groups informed the development of the materials and trainers' manual. An eight week manualised intervention programme was developed; *CUES, Coping with Uncertainty in Everyday Situations©*. The treatment provides parents of children with ASD, with effective strategies to reduce their child's IU in everyday situations.
Phase Two: The programme was delivered to 11 parents of children with ASD, aged between 8 and 15 years across three treatment groups, two recruited via a research data base and one via clinical services. The intervention included in-session activities and homework tasks, which focus on increasing tolerance of uncertain situations. Baseline and outcome measures assessing child and parent anxiety and IU were completed. Individual follow-up interviews were undertaken with parents to ascertain acceptability and feasibility.
Results: Â Data regarding retention, acceptability and feasibility indicate that the parents who participated valued the programme. Preliminary data relating to effect size analyses of outcome measures indicate that the programme has promise as a treatment option of young people with ASD and IU. Parents reported a reduction in their own and their child's intolerance of uncertainty and anxiety subsequent to participation on the programme.
Conclusions:
The findings indicate that parents of young people with ASD view an intervention which focuses on intolerance of uncertainty to be valid and meaningful. The data available indicate that CUES may have promise as a targeted package to assist young people with ASD and their families to manage their responses to uncertainty.

206 **126.206** A Randomized Controlled Trial Comparing Online Mindfulness and CBT Programs to Alleviate Anxiety in Adults with ASD.

S. B. Gaigg[1], *R. Shah*[1], *G. Mclaven*[1], *P. Flaxman*[1], *D. M. Bowler*[1], *B. Meyer*[2], *A. Roestorf*[1], *C. Haenschel*[1], *J. Rodgers*[3] *and M. South*[4], *(1)Psychology, City, University of London, London, United Kingdom, (2)Psychology, University of Southampton, Southampton, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Psychology and Neuroscience, Brigham Young University, Provo, UT*

Background: Anxiety Disorders are around five times more common in ASD than in the general population and are widely recognised as an important treatment target due to the consequences for an individual's quality of life and broader wellbeing. The choice and effective delivery of treatments, however, is complicated because the mechanisms that mediate anxiety in ASD remain poorly understood and the frequent necessity to interact with therapists is costly and also problematic because of the high demands on social-communication skills. Maisel et al., (2016) have recently shown that Intolerance of Uncertainty (IoU), Alexithymia (Alx) and Non-reactive thinking (NR) play a critical role in mediating anxiety in ASD, suggesting that Cognitive Behavioural Therapies (CBT) and Mindfulness-Based Therapies (MBT) may be differentially effective by targeting IoU and Alx/NR respectively.
Objectives: 1) To examine the effectiveness of online CBT and MBT programs to alleviate anxiety in ASD, 2) to establish whether treatment effects are mediated by changes in IoU and Alx/NR, 3) to determine whether reductions in anxiety translate into wider benefits for the wellbeing of individuals with ASD.
Methods: Thus far, thirty-three adults with ASD have been randomly allocated to either a CBT (n = 10), MBT (n = 10) or Waitlist (WL) group (n = 13), matched at baseline for age, ASD symptoms and IQ. Participants in the CBT and MBT groups received instructions on how to pursue respectively the existing online programs *Serenity* (*http://serene.me.uk/)* or *BeMindful* (http://bemindful.co.uk/) for between 4 – 6 weeks. Participants learned different stress and anxiety management strategies each week, and a reflective diary served to monitor how frequently and feasibly these were practiced in daily life. Participants in all groups completed measures of Anxiety (BAI, STAI-T, LSAS, GAD-7), broader wellbeing (HADS, CORE-OM), intolerance of uncertainty (IoU-12), Alexithymia (BVAQ) and Mindfulness (FFMQ) at enrolment and again at completion of the 6-week period.
Results: At baseline, results confirmed that IoU and NR are significant and independent predictors of trait (STAI; R^2=.37) and generalised (GAD; R^2=.22) anxiety, which in turn are highly correlated with the CORE-OM index of general wellbeing (STAI: r = 0.81; GAD: r = 0.75). Across the 21 participants (5 MBCT, 7 CBT & 9 WL) tested so far at time 2, reductions are evident particularly in generalised anxiety ($F(1,19) = 7.01$, $p < .05$) with large effects in both the CBT (Cohen's d = .85) and MBT (Cohen's d = .74) but not the WL group (Cohen's d = .13). Improvements in more general wellbeing (CORE-OM)Â were also evident ($F(1,19) = 5.90$, $p < .05$) and the preliminary data suggest that IoU and NR do indeed play a role in mediating treatment benefits. Contrary to predictions no effects were observed in relation to Alexithymia.
Conclusions: Online CBT and MBT programs provide viable treatment options for anxiety in ASD that translate into wider benefits for general wellbeing. The discussion will focus on feedback from participants that provides useful pointers on how to tailor existing programs more specifically to the needs of those with ASD.

Poster Session
127 - Service Delivery/Systems of Care
5:30 PM - 7:00 PM - Golden Gate Ballroom

207 **127.207** A Pragmatic Comparative Trial of Educational Service Delivery Models for Children with ASD
